The plasterer's putty or lime putty referred to here is prepared from pure chalk lime broken up and placed in a tub with water, and left to slake. The slaked lime is sifted through a very fine sieve into another tub, covered with water, and usually left to mellow for some weeks. The longer it is left, the better it becomes. Fine stuff is composed of lime-putty and fine, washed sand, in the proportion of 1 of putty to 2 of sand. The expression gauged stuff is applied to compounds composed of either coarse or fine grain stuff, mixed with plaster of Paris or some similar material which hastens the setting.

The plaster may be applied to rough brick walls or to a stud partition, built up in timber and lathed over with wooden laths or metal lathing, or even on a backing of coarse canvas strips, cut and nailed to a framework of wood for temporary structures.

Plaster. Fig. 1. Preparing the lime plaster in the centre of a crater of sand.

Tools for the Amateur. The chief tools used in plastering are illustrated in Fig. 2. The hawk consists of a square piece of board measuring about 14 in. across, with a small round handle underneath. Stuff that is being applied to the wall or ceiling is conveyed from the mortar board to the hawk and laid on with a trowel. The latter is an oblong tool made of steel, having a handle attached, and is used for applying the first coat of material, known as the coarse stuff. The hand float, similar in shape, but made of wood, is employed for applying the final or setting coats.

Plaster. Fig. 2. Tools which are necessary to the plasterer.

Left to right, top: traversing rule, hawk, derby float; bottom: hand floats, lath hammer, angle float, laying-on trowel, gauging trowel, corner tool.

Fig. 3. Jointing rule, used for floating or levelling the surface of plaster in the angle of a room.

The scratch consists of 3 or 4 laths nailed together in the form of a fan, the ends being pointed. It is used for scratching over the surface of the second coat, so as to form a

key for the succeeding coat.

The gauging trowel resembles the ordinary trowel used by bricklayers, except that it is tapered, and does not terminate with a sharp point, but is slightly rounded off. Its use is for mixing small quantities of material, such as putty and plaster. The margin trowel is for work where it would not be possible to use a float. In shape it resembles a small shovel with the sides turned up about $\frac{1}{2}$ in., and is made of steel. The stock brush is for sprinkling small quantities of water on to the work to keep it to working consistency.

There are other tools used by the plasterer which require professional skill and much practice to handle; they are used principally in the formation of mouldings and cornices. For example, the running horse is a tool cut to a particular shape to form a certain section moulding. These tools are generally specially made for the particular job, in conjunction with small moulding tools of different shapes. Another tool is the joint rule (Fig. 3) for working in the angles on cornice work. All these implements may be obtained from any good tool store.

Plastering a Brick Wall. Supposing that a rough brick wall is to be plastered, then the work will be carried out in the following manner: First, with a garden syringe or a bucket and brush, thoroughly wet the bricks. Having placed several buckets full of the coarse stuff on a mortar board in a convenient position, as, for example, on a box adjacent to the wall to be plastered, take a hawk in the left hand and the laying-on trowel in the right hand, and, with a swinging, circular movement apply the plaster to the brickwork, pressing it firmly into contact and making it about $\frac{1}{2}$ in. thick. Fig. 4 illustrates the method of application. Only sufficient of the wall should be covered at a time to permit of convenient working.

The next stage is to take a derby float, and work over the whole surface to flatten and even it. If, however, the wall surface is to be got up in any style, a screed will be necessary. This, in the case of a room having a picture rail and skirting board, may be wooden strips about 2 in. wide and $\frac{1}{2}$ in. thick, securely nailed to the wall, and backed up when necessary with rough grounds, so that their surfaces are in line and represent a level surface. A traversing rule or long batten is worked up and down, levelling off the plaster and making its surface uniform with the level of the grounds.

When the plaster begins to set, a wide, flat, rough wood float, having a nail driven through it, the point of which projects through the face, is applied to the surface of the plaster, producing a series of scratches; this provides a key or hold for the second coat. For all ordinary partitions a second coat may be applied the next day; it may be composed of fine stuff, gauged with a proportion of Keene's cement, or some similar hard, quicksetting material. It is applied with a wooden float, this coat not being so thick as the former.

Fig. 4. Using the laying-on trowel to apply first coat of plaster. Fig. 5. Applying the finishing coat. Fig. 6. Hand float finishing the coat. Fig. 7. Rounding off a corner with a wooden float which is triangular in section with one of its angles suitably curved.

Fig. 5 shows the mortar board in position in the centre of the room and the second coat in course of application. It is brought to a true and flat surface by the aid of a traversing rule, with a metal float and a liberal application of water. The great point is to prevent the plaster from setting too quickly, and this can generally be accomplished by moistening the work, and keeping it damp as the job proceeds, both with the first and second coats. All small blemishes are carefully worked out with a laying-on trowel, or hand float, as illustrated in Fig. 6, and the corners finished off. They may be finished square with the aid of a special trowel virtually having two faces, which work simultaneously at the juncture. A different treatment, and one that is very effective and hygienic, is to cove the corners, that is, round them off, using a wooden float more or less triangular in section, with one of the angles rounded off to the desired curvature. The appearance of such a corner, in course of completion, is illustrated in Fig. 7.

Great care must be taken in reducing the finishing coats to a smooth and level surface in every part. It is important in this connexion to work the first layer as evenly as possible. Equal care should be taken in finishing the arrises, or edges, of projecting corners, particularly the edges of chimney breasts.

Ceilings. Similar methods are employed in the case of ceilings. These are often decorated with applied fibrous plaster ornamentations, which take the form in general of cast plaster enrichments, the plaster of which they are composed being reinforced with fibrous material, such as hair, coconut fibre, and the like. In many cases canvas is used as a backing, and thin strips of wood are employed as a reinforcement. These are simply cemented in place with plaster of Paris.

If the cornice is large and consequently too heavy to be made solid, it is usually cast in pieces and then fixed into position. An alternative method is to fix blocks of wood, either triangular in form or of a shape approaching more nearly to the outline of the cornice, so that strips of wood or laths may be nailed on and thus provide a strong foundation for the first layer of coarse work. Full instructions for repairing a damaged ceiling are given in the article on Ceilings (q.v.). Plaster work on walls is liable to sustain damage, in which case any dents or bruises can be filled in with neat plaster or a mixture of lime-putty and plaster of Paris. The general procedure is to hack out the plaster over the damaged area, thoroughly wet it and work in the new plaster with a small trowel, trowelling it flat, true and level with the surface. To ensure a good joint the edges of the old work must be kept saturated with water. On all angles or corners liable to sustain extra wear, the first coating of plaster should be composed of Portland cement and sand in equal proportions. Sometimes in a lath and plaster partition or ceiling the laths are broken, or they fail through age or some defect, in which case all the affected laths should be cut out and replaced by new. The process is described and illustrated under the heading Ceilings.

PLASTER: In Medicine. The value of plasters applied to the skin may depend on the support and protection they give, or on the drugs they contain.

A plaster should not be used indiscriminately for closing skin cuts and slight wounds, as there is always a risk of microbes thus being enclosed in the wound. The wound should first be protected by a thin layer or pad of antiseptic gauze. Strips of plaster should be used with spaces between to allow of the escape of discharges. Plasters are usually so made that the heat of the body melts them sufficiently to allow of them clinging to the skin. *See* Adhesive Plaster; Corn; Mustard.

PLASTER OF PARIS. Calcium sulphate, known as plaster of Paris, is used for the production of casts of many varieties of small statues and ornaments, for mouldings and interior decorations. It is employed in making casts of parts of the human body, and has numerous applications in surgery. It is finely ground and is obtainable in several grades, and should invariably be kept in a dry place.

Plaster of Paris has the property of setting into a hard white substance when it is mixed with water. The best proportion to use is water 1 pint to plaster 2 lb. When the plaster sets, it expands slightly. Plaster figures are made by pouring mixed plaster into moulds. The figures are generally hollow, the residue of plaster from the centre being poured out before it has had time to set. If a small proportion of Portland cement is added to the plaster the time of setting is delayed. The hardness of the plaster is increased by using alum solution instead of water in the mixing process. Plaster of Paris is useful in the household for mending broken tiles and for filling up crevices in walls.

If only a small quantity is wanted, a good plan is to fill a bowl about $\frac{2}{3}$ with cold water and pour in the plaster with a circular motion, distributing it evenly over the water and at the same time stirring with a circular motion, using a wooden spoon or smooth stick. The surface of the water will exhibit air bubbles, and the plaster should be stirred until these bubbles no longer appear. The stirring should be steady, and the water should on no account be violently disturbed, as the air bubbles will be imprisoned and the work will be imperfect. The mixture speedily gets thicker, and if required to be poured into a mould to make a cast, this should be done just as the plaster is in the thickening stage, approaching the consistency of thick cream. If required for moulded work, pour the plaster in steadily so that the air in the mould can escape. *See Casting; Modelling.*

PLASTIC WOOD. This is the name given to a preparation of wood in paste form. It is used as a filler in woodwork and for a variety of other purposes. It can be moulded by hand or modelled, dries and hardens in a short time, and takes stain or polish readily. When using plastic wood to fill nail holes, knot holes, or shakes, the stopping should be left a little above the surface level and the surplus chiselled off when dry. Any moisture or grease on the surface to be treated will prevent the filler from adhering properly, and if a considerable area is to be dealt with it is as well first to apply a little of a special softening preparation, which can be had from the maker of the plastic wood.

PLATE: The Utensil. As used in the household a plate is a flat, shallow dish used for holding food at the table and elsewhere. Plates are made in every possible kind of china and earthenware, in enamel ware, aluminium and pewter. In dozens or half-dozens they form an essential part of breakfast, dinner, dessert and tea services. Plates of four sizes are usually part of a dinner service, those for the soup having deeper bowls than the others. With breakfast and tea services there are larger plates for bread and butter, cakes, etc. Plates are also sold singly or in odd numbers, and plates of metal are used for cooking and other purposes.

Plate Rack. Usually of wood in the larger sizes, smaller plate racks are often in metal. Teak wood plate racks with accommodation also for cups and saucers are convenient fittings for the scullery or kitchen sink when there is a good deal of washing up to be done for the household.

When fixing a wooden plate rack, stout ear plates (or mirror plates) are screwed to the back, and plugs are fixed in the wall at suitable places to coincide. If fibre plugs are used (*see Plug*), screws must be employed which are threaded close up to the head, so that the screw can be driven right home into the plug and properly grip the countersunk portion of the ear plate. When attaching the plates see that the countersunk side of the hole in projecting top portion faces the proper way (i.e. outwards into the room).

Plate Warmer. Any apparatus that is used for heating plates or dishes may be described as a plate warmer. A type used mainly in large establishments somewhat resembles a miniature oven, and has separate shelves for plates, vegetable and meat dishes.

In the home, the iron rack above the stove is often used as a substitute for a warming plate, the dishes being left there while the meal is being prepared. A small metal standard plate rack is useful for this purpose, and it accommodates a number of plates. Electric warming plates can be obtained in various sizes, fitted with flexible cable and wall plug.

A less modern kind of plate warmer still used consists of a deep dish which contains a trough for holding hot water. The plate is placed on top of this trough, and the water as it becomes cold is poured away, fresh hot water being put in to replace it. *See China; Dinner; Sink; Tea; Washing Up.*

PLATE: In Photography. A plate is a piece of thin glass of standard size coated with light-sensitive emulsion for exposure to light in a camera. After exposure and development plates are called negatives. When the sensitive emulsion is coated on a celluloid support the combination is known as a film.

There is a somewhat greater variety of glass plates than of films, both in the matter of speed or degree of sensitivity to light, and of the kinds of emulsion used. For this reason many amateur and professional photographers prefer glass plates to films, in spite of their greater weight and bulk. Nevertheless the use of flat films in addition to roll films has so increased that one company, the Kodak Co., has abandoned the manufacture of glass plates.

Varieties of Plates. The varieties of plates which are of use to the amateur are stated in the following paragraphs.

Ordinary plates made under this title by most plate manufacturers are coated with plain emulsion and moderate in speed, and are very suitable for all-round amateur work if sufficient exposure can be given. They have a finer grain than faster plates, and therefore give good contrast and make excellent enlargements and lantern slides. They are not fast enough for snapshot work. Orthochromatic or panchromatic emulsions include dyes that give more accurate response to colour values than the plain emulsions.

The plate sold as ordinary has generally a speed of about 70 H. and D. (Hunter and Drifffield system). Other ordinary plates, i.e. with plain emulsion, but of higher speeds, are sold under such names as Special Rapid, Rapid Chromatic; Self-screen and Super-speed Ortho.; Soft, Special Rapid and Hyper. Panchromatic, etc., and have H. and D. speeds of 270-300, 400-550, 700, 1200, up to 2500. Unfortunately there are different systems of calculating plate speeds, and great difficulty in obtaining results which are scientifically consistent. Thus a batch of plates marked 200 H. and D. by one maker is not necessarily of the same speed as another maker's plates also marked 200 H. and D. This is the principal reason why the amateur is always advised to keep to the brand of plate whose qualities in working he knows by experience.

A speed number is not a reliable indication of the quality of a plate. As a general rule medium speed plates are more likely to be of high quality than very fast ones, although some of the most rapid plates give very good results. Experience can be the only guide in the choice of a plate, but for general use an extremely fast plate should be avoided. The slower plates have thicker emulsions than the faster, and are therefore freer from liability to fog, give better contrasts, and a wider range of tones. The faster plates have much thinner emulsions, and there is consequently greater difficulty in manufacture to ensure freedom from fog, and to avoid halation owing to the surface of the glass support being nearer the surface of the film. Fog is due to scattering of light over the sensitive surface of the plate with the result that a general greyness is observed in the negative which consequently gives a somewhat flat, grey print.

STANDARD SIZES OF PLATES

Name	Size		Diagonal
—	2- 5/16 in.	x 1 3/4 in.	3 in.
—	3 1/2 in.	x 2 1/2 in.	4 1/2 in.
Lantern plate	3 1/4 in.	x 3 1/4 in.	4 5/8 in.
1/4 -plate	4 1/4 in.	x 3 1/4 in.	5 3/8 in.
Continental equivalent of 1/4 plate	9 cm.	x 12 cm.	
	(= 3·54 in.	x 4·7 in.)	5·9 in.
—	5 in.	x 4 in.	6 3/8 in.
Postcard	5 1/2 in.	x 3 1/2 in.	6 1/2 in.
—	6 1/2 in.	x 4 1/4 in.	7 3/4 in.
1/2 -plate	6 1/2 in.	x 4 3/4 in.	8-1/16 in.
Stereoscopic	6 3/4 in.	x 4 1/4 in.	7 1/2 in.
Whole plate	8 1/2 in.	x 6 1/2 in.	10-11/16 in.
—	10 in.	x 8 in.	—
—	12 in.	x 10 in.	—
—	15 in.	x 12 in.	—
—	18 in.	x 12 in.	—

Many plates are now available designed to overcome halation troubles. One method is to coat the back of a plate with a black non-reflecting substance, such as caramel. These plates are sold as backed plates. Another is to coat the plate with a matt emulsion. When developed, the negative has the appearance of being coated upon finely ground glass. For interiors with window-lighting, light coming through tree foliage, polished metal articles, and similar subjects which cannot be satisfactorily reproduced on ordinary plates on account of halation, these plates are very useful. Other anti-halation plates are available in which a special light-absorbing coating is placed between the emulsion and the glass plate.

For amateur purposes the sizes of plates best suited are the 3 1/2 in. by 2 1/2 in., the 1/4 plate, and the 1/2 plate, the favourite being the 1/4 plate. A better-shaped plate for general use, particularly for landscape work, is the standard continental plate, 9 cm. by 12 cm., or about 3 1/2 in. by 4 3/4 in. The following are standard British and continental sizes.

The diagonals given in the above table serve as a guide to the size of condenser required if the plates are to be used in an enlarging lantern. All the sizes given are also standard sizes for bromide and gaslight papers and the sizes up to whole plate for P.O.P. *See* Developing; Film; Negative; Panchromatic.

PLATE GLASS. In the processes of its manufacture plate glass is finished with a flat and true surface, and, being transparent and free from irregularities or surface markings, it is used for good-class windows. In the home plate glass is also used as a protective covering for washstands and the tops of tables. The surface is easily kept clean, and decorative material can be placed beneath the glass to add colour to the room. In the same way a well-polished piece of furniture or tray can be protected, and the grain and colour of the wood revealed.

Another application of plate glass in the home is as shelves in the bathroom, or for pastry making in the kitchen. Shelves should have rounded and polished edges, and they are generally supported by electro-plated wall brackets.

Plate glass can be purchased from builders' merchants or first-class ironmongers, and has to be cut to size by the manufacturers. In ordering it is well to give the exact dimensions, or a full-size pattern of the piece required. The thinnest plate glass measures $\frac{3}{16}$ in. thick. A useful thickness is $\frac{1}{4}$ in., and this will generally be supplied if no thickness is mentioned at the time of ordering. *See* Glass.

PLATE MARK. Articles of gold and silver plate are marked with a set of symbols by certain recognized guilds or assay offices in the United Kingdom, as a guarantee that the metal is of standard purity, and also to indicate the date. These hall-marks on plate are a greater safeguard than potters' marks on china, and are always taken into account by collectors. They have no relation to the artistic merits of the plate.

From 1784 to 1890 in Great Britain, and from 1807 to 1890 in Ireland, the sovereign's head was punched on all plate to denote that duty had been paid. The duty marks of the three kings faced to the right, Queen Victoria's to the left. Duty-free pieces, intended for export, were identified by a figure of Britannia to prevent their being sent out of the country duty free and then immediately brought back again. In 1876 all imported plate marked at an English office was required to bear the letter F, to indicate its foreign origin. In 1906 distinctive symbols for imported plate were prescribed, such as the constellation Leo for London, of Libra for Sheffield, and a triangle for Birmingham. *See* Silver.

PLATINUM: The Metal. Of whitish-grey colour, platinum is generally to be found in the native state, although it may be alloyed with other platinum minerals. It is used extensively for the manufacture of jewelry and objects of art, for various dental and medical appliances, and for several forms of chemical crucibles. Owing to the fact that platinum has nearly the same expansion rate as glass, it is employed in making many forms of electrical contact points and connexions for lamps and other fittings, especially where the conductor has to pass through the glass.

Platinum is used in jewelry chiefly as a setting for diamonds. On account of the high cost of this metal, such a setting is usually backed with gold. Platinum needles, or points, as they are called, form a part of every pokerwork outfit, and their uses in this connexion are described under the heading Pokerwork.

PLATYCERIUM. This plant, which is commonly known as the elk's-horn fern, is epiphytal in form and practically provides its own nourishment. Its horn-shaped fronds are fertile, but in addition to these it throws up flat, broad, barren fronds, which spread upon the surface; these decay, and provide substance upon which the plant survives.

Plants are best arranged upon blocks of wood, covering their roots with peat and moss, and binding the whole firmly with copper wire. Thus prepared they may be suspended from the roof or other parts of a warm-shaded greenhouse, keeping them moist at all times, and top-dressing every year with peat and fresh moss. Propagation is by offsets, with rootlets, thrown off at the base of the plant, and planted during March.

Platycerium, or elk's-horn fern, a greenhouse fern with curiously shaped leaves.

PLATYSTEMON. The common name of Californian poppy (q.v.) is applied to the hardy annual, *Platystemon californicus*, and to various other flowers. The platystemon, which is raised from seeds sown out of doors in April where the plants are to bloom in summer, grows from 10 to 12 in. high, has grey-green leaves and bears pale yellow poppy-like flowers.

PLAY and GAMES. Play is as important to a child as school-work, for it is an essential part of his physical and mental growth. The child becomes what he is as a result of what he does. No child can refuse to play and still develop a well-balanced character. Playing games is an instinct, having been handed down through unnumbered ages. The play instinct is fostered by the establishment of school playgrounds and recreation centres, under the supervision of trained instructors, who teach what games to play and how to play them. But all alert children quickly invent games of their own on far more individualistic and realistic lines; and these games are most valuable of all to the young mind, since they are so highly imaginative. The intensity of the child imagination is often not fully realized. The child who imagines that his scooter is a high-powered express locomotive, and "plays trains" accordingly, is actually living temporarily in the world of his imagination. Many parents make the mistake of thinking that a child is "lying," when he is merely acting a part in some imaginative game of his own devising.

Nevertheless, organized games have a more disciplinary value for both mind and body. No brain can work properly without the nourishment of strong blood. No virile thoughts can come from a brain fed by organs neglected throughout life. It is a child's right to have ambition to be a leader, and we do not accord him his privilege if we withhold the opportunity to build a body that will make his brain active. The following games are of value in bringing out that desirable idea of leadership and self-reliance in the child, and in developing the qualities of fair play, mental alertness and physical strength. Other such games will be found throughout this Encyclopedia.

For Younger Children. "Follow my leader" is for any number of players. One player, who is specially resourceful or skilful, is chosen as leader. The others all form in a single file behind him, and imitate anything that he does. The leader aims at making these tasks as difficult and unexpected

as possible. Anyone failing to perform the required feat drops out of the game, or goes to the foot of the line, or pays a forfeit (q.v.).

“Cat and Rat” is a game for 10 to 30 or more players. One player is chosen for the cat and another for the rat. The others form a circle by clasping hands. The cat is outside the circle, the rat inside. The cat says, “I am the cat.” The rat says, “I am the rat.” The cat says, “I will catch you!” The rat says, “You can’t!” This remark of defiance starts the chase. The rat is assisted by the players, who raise their hands to let him through, but the cat is prevented by the players, who try to keep him on the opposite side of the circle. When the rat is caught, he joins the circle. The cat becomes the rat, and a new cat is chosen.

For Older Children. “Twos and Threes” is simply an elaboration of our old-fashioned Touch (q.v.). The players, grouped in couples (one player behind another), form a large circle, facing in. One player is selected as a runner, and another is “he,” or the chaser. The chaser attempts to touch the runner, who tries to escape by dodging in and out of the circle. The runner being chased eventually stands in front of any couple, making “three deep.” This crowds off the rear player of the original couple. He immediately becomes the runner and is chased until caught, or until he saves himself by standing in front of another couple, making it “three-deep” and crowding off another player. When the chaser catches a runner, the positions are reversed. This is a game that gives every player a chance, whether fleet of foot or not. The uncertainty and rapid changes keep everyone alert.

“Puss in the Corner,” “Turn the Trencher” (q.v.), and “Frog in the Middle,” are other well-known games of this class. They will also be found useful as indoor games for rainy days or for children’s parties. Most of the oldest and most popular games did not originate as mere games, but have come down to us as survivals of tragic or comic or exciting events in history and folklore. They spread from country to country, with changes of name. Politics, religion, mythology, folk-tales, folk customs, common occupations, have all given rise to games which have spread abroad.

PLAYER PIANO. The terms player piano and piano player are often used as if they were synonymous, which is not the case. When the idea of playing the piano by means of a mechanical adjunct first became practicable, it took the form of a cabinet containing the mechanism, which was moved to and from the piano as required. This was the piano player. It had drawbacks in the way of adjustment, which inventors overcame by finding room for the mechanism in the body of the piano, thus making the adjustment invariable. This is the player piano. Apart from certain differences connected with the altered positions, the principles of construction and management are the same.

The Mechanism. The principle of the player is pneumatic. The motive power is supplied by a pair of treadles like those of the harmonium, which fill the bellows, the action being made to operate on the keys of the pianoforte. The notation for the player piano consists of a roll of paper having perforations in it. This roll is attached to the spool, and when the treadles are worked it unwinds and passes over a tracker bar pierced with 85 or 88 holes, corresponding to the notes of the ordinary or the extra compass pianoforte. When a hole in the roll coincides with a hole in the tracker bar, the note on the piano corresponding to it is made to sound.

Below the keys are 6 or more levers, or sometimes buttons, for various purposes—rolling and re-rolling the music; controlling the tempo; lessening the tone on either or both halves of the compass; and working the pedals of the piano; to which may be added one for controlling the melody.

The player piano is an ingenious device for rendering pianoforte music without the aid of fingers (in a pianistic sense), but there is, however, not only ample scope, but an absolute necessity, for individuality on the part of the operator if the effect is to be musically satisfactory. The player piano

has to be studied just the same as any other instrument, and the first thing to be learned is how to use the treadles, for on this depends the various degrees of tone from pianissimo to fortissimo. The possessor of a player piano should always buy good rolls, not only as to the music cut on them, but also as to the quality of paper, for if this be poor and soft it will take up moisture from the air, swelling to such an extent that exact tracking and accurate playing will be out of the question. The roll can be dried, but it is better to buy the best only. It is cheapest in the long run, as with careful use a roll should last a long time. In buying a second-hand instrument it is best to get someone who understands players to test it thoroughly before clinching the bargain. *See Piano.*

Play Pen. Fig. 1. Folding play pen with two long and two short sides. Fig. 2. Shape of top with uprights in Fig. 3. Section showing bead rods and method of securing uprights and rail. Fig. 4. Alternative method of fastening uprights and rail. Fig. 5. Top view of hinge at corners. Fig. 6. Front view of hinge at ends. Figs. 7, 8 and 9. Method of making and fitting locking plate. Fig. 10. Wing nut with wire chain fastening.

PLAYPEN: How to Construct. Suitable either for in or out of doors, a play pen is useful for assisting a baby to walk. For convenience in carrying it about, the pen should fold up in a small space, and, although it should be strong and rigid, the method of construction must allow of the use of comparatively thin material.

The play pen illustrated in Fig. 1 has 2 long and 2 shorter sides, the latter being hinged together in the centre and also hinged at each end to the long sides, so that they fold inwards and allow the sides to close up. First prepare four 48 in. lengths of birch or white-wood to $1\frac{7}{8}$ in. by $1\frac{1}{8}$ in., and, if the material is purchased especially for the purpose from a timber yard, order some 2 in. by $1\frac{1}{8}$ in. material to be machine-planed on all sides, which will bring it to the approximate size. In addition, about 53 lengths of $\frac{5}{8}$ in. birch dowels, 24 in. long, and another 12 ft. of the $1\frac{7}{8}$ in. by $1\frac{1}{8}$ in. wood will be sufficient.

Place 2 of the 48 in. lengths together, and, beginning at the centre, set off $1\frac{1}{2}$ in. each side, and follow with 3 in. marks across the edges, making 16 marks in all and leaving a $1\frac{1}{2}$ in. space at each end. Draw a line along the centre of the whole length and bore centre or twist bit holes to a depth of $\frac{3}{4}$ in., but first make sure, by testing, that the hole is a tight fit for the dowels. The total height of the pen is to be 24 in. over all, so that the depth of holes and length of rods must be carefully gauged throughout the job. On the remaining 2 lengths draw a line along the centre. Place them together, and this time commence marking 3 in. spaces $7\frac{1}{2}$ in. from the centre, which will give 12 centre marks for the holes. In one length, which will be the bottom one, set out 2 marks 4 in. from the centre; the corresponding space in the top piece is left plain. Bore holes as before. Then plane off the corners of top lengths and at top of bottom lengths, round the ends and finish quite smooth.

The 2 lengths with the 16 holes are now glued up, the dowels being cut off to $21\frac{3}{4}$ inches.

The section at Fig. 2 shows the shape of the top pieces with the dowels in position. When the round rods of the other long side are in position, there will be a space of 15 in. between the 2 inner ones, this is to allow for the bead frame. The method of making this part is to trim the ends of a $15\frac{3}{4}$ in. length of dowel for the horizontal piece. A, as in the section at Fig. 3, and three $11\frac{3}{4}$ in. lengths for the vertical rods at B. Holes of $\frac{1}{4}$ in. diameter and $\frac{3}{8}$ in. deep are bored in the 2 uprights $11\frac{1}{4}$ in. up, and others corresponding to those at the bottom in the horizontal length, and the trimmed ends of rods fitted in.

Three $15\frac{3}{4}$ in. lengths of $\frac{3}{16}$ in. brass rod are next fitted in the upper part of the inner uprights as at C, Fig. 3, and 18 coloured glass or wooden beads threaded on, 8 on the top, 6 on the centre, and 4 on the lower rod. The side can now be glued up, provided all corners have been rounded and smoothed with glass paper.

An alternative method of securing the short lengths of dowel is to file a hollow on the ends and screw them together as in Fig. 4. Instead of using round wood for the uprights and centre bar, $1\frac{1}{8}$ in. square wood can be mortised and tenoned together.

For the ends, cut off 8 lengths of $16\frac{7}{8}$ in. by $1\frac{7}{8}$ in. by $1\frac{1}{8}$ in. wood, place them together, and set off 3 in. marks from one end; these will fit next the side. Draw centre lines and bore the holes for the dowels as before, each length having five holes. Round the top lengths to match those of the sides, as shown in the section at Fig. 2, and take the corners off the underside and on top of the bottom lengths. Dowels can then be fitted and glued to give a total height of 24 in., as with the sides: Before the corners are hinged together, as at Fig. 5, with $1\frac{1}{2}$ in. by 1 in. back flap hinges, the 2 halves of the ends are hinged with similar hinges on the outside, as shown in Fig. 6. In addition to the hinges, it is necessary to fit locking plates on the top bars; these are made from sheet iron or brass 5 in. by 1 in. by $\frac{1}{8}$ or $\frac{3}{16}$ in.

The screw holes are drilled at one end, and a $\frac{1}{4}$ in. bolt soldered to the other through a hole drilled $\frac{1}{2}$ in. from the end, the end of the plate being rounded as in Fig. 7. The plate is screwed to one half of the rail, and the bolt fits in a hole in the opposite half, being held by a wing nut as in Fig. 8. The

centre for the hole should be accurately marked from the plate and bored right through the top rail; but to allow the bolt to enter, the wood is cut away with a chisel at a slant on the inner edge of the hole, as shown in Fig. 9.

In order to prevent the loss of the wing bolts, a groove should be filed round each, and a length of brass wire with an attached loop fitted on, the ends being soldered, so that it will move but not slip off. A length of chain is attached to the loop, as in Fig. 10, and fastened to the top rail. The woodwork if quite smooth should be sized and varnished, or it may be enamelled white. The metal fittings, with the exception of the rods in the bead frame, should be coated with black enamel, but care must be taken that the rough edges of the hinges and locking plates are taken off with a file and smoothed up with emery cloth. *See Baby; Nursery.*

PLEATING. One or more folds of material pressed flat and held in usually at the upper end only, allowing the lower one to open and give extra fullness when required, is called pleating. The arrangement of folds to form pleating is used extensively in dressmaking.

Different kinds of pleating are suited to heavy or light materials. Kilting and box-pleating are generally employed for the former, while a finely woven material should be chosen for accordion pleating, as otherwise it is difficult to keep the pleats in place.

Inverted pleats or box pleats are made as shown in Fig 1, quite close together. In the case of pleating for a skirt a piece of binding or tape is usually placed at intervals of about 6 in. across the inner side of the pleats, and tacked to each one to prevent them opening and coming out of shape. Crêpe-de-Chine, georgette, or any light woollen fabric can be accordion or knife pleated with success. Accordion pleats are rather difficult to keep in place. Knife pleats (Fig. 2) may be tacked into position and pressed flat.

Pressing the Pleats. When pleats become creased or lose their shape, the garment should be spread on a table, the folds adjusted, tacked into place, and the whole covered with a clean, damp cloth. Press this heavily and evenly with a hot iron until it is dry and the steam ceases to rise, and the pleats will then be found neatly pressed. If the pleats are many, the process should be done in stages, two or three pleats being pressed at a time. The iron should not be too hot, otherwise the covering cloth may be dried before the pressing is finished, or the garment beneath may be badly singed. If the result is not satisfactory, the cloth may be damped again and the process repeated. Box pleats are the easiest to press, but the finer kinds and sunray pleating, in which the pleating widens towards the base of the garment, need to be arranged skilfully, and in a great number of cases are best sent away for professional treatment.

Pleated frilling in net, ninon, and voile becomes limp and shapeless when washed, and requires special skill in ironing to restore the original pleats. Some of the laundries specialize in dealing with pleated and frilled garments and return them in an almost new condition. *See Box Pleat.*

Pleating Fig. 1. Inverted and box pleating. Fig. 2. Knife pleating.

PLEIONE. To-day classified as *Coelogyne* by botanists, this genus of orchids includes some very pretty species. One of the best for cultivation in a cool greenhouse is *maculata*; its flowers are fairly large, with attractive markings of yellow and crimson upon white, and these are borne in autumn, appearing while the plants are leafless. *See* Orchid.

PLEURISY. Pleurisy, or inflammation of the pleurae, the membranes which line the chest cavity and cover the lungs, often follows a chill, but this is only a predisposing cause. The active agent is the germ of such diseases as diphtheria, typhoid fever, pneumonia, and especially tuberculosis. The attack may be of the dry type, or fluid may accumulate in the pleural cavity.

In dry pleurisy a severe cutting, stabbing stitch is felt under the armpit or around the nipple, but it may be above the collar bone or on the abdomen. Any movement of the chest greatly increases the pain. Vibration may be felt when the hand is laid on the chest. The patient lies on his back, or very often on the healthy side, because pressure on the affected side causes pain; when the pleura becomes filled with fluid he usually lies on the affected side so as to have full use of the healthy side.

Pleurisy with effusion, being commonly caused by the tubercle bacillus, is often followed by consumption of the lungs. If much fluid fills the pleural sac, it may cause bulging of the spaces between the ribs, and the heart and the abdominal organs may be displaced.

In the dry stage the chief aim of treatment is to relieve pain. For this purpose apply linseed meal poultices, hot fomentations, turpentine stupes, or a mustard poultice. In the effusion stage the affected side is often painted with a mixture of equal parts of the tincture and the liquor of iodine. Drugs such as potassium iodide, the salicylates, etc., are usually given. Aspiration, or removal of fluid through a hollow needle inserted by the physician into the pleural sac, is a common remedy in this disease, notably in the chronic form. Exercises to expand the lungs should be practised. Iron tonics and cod liver oil are useful, and a few months' residence at a mountain resort is very beneficial in most cases. *See* Lung.

PLEURO-NEUMONIA. This term means, with reference to human beings, a combination of pneumonia and pleurisy. The term is more properly applied to a disease which is very fatal to cattle but does affect human beings. *See* Pneumonia.

PLIERS. Of the many patterns of this tool there are 3 that should be found in every amateur's tool kit, and these are: side cutting, gas and round-nosed pliers. The first, generally made with flat jaws and with cutting edges at the sides, are used for snipping off wire. Gas pliers, made with serrated, circular, internal jaws, are for gripping pipes and rods. Round-nosed pliers with tapered jaws are indispensable for forming eyes at the end of wire and for other purposes, such as bending wire and thin sheet metal.

Electricians' pliers are made with heavily insulated handles to protect the worker from electric shock. Small flat-nosed pliers are handy for bending thin metal. Cone pliers, which resemble gas pliers, are used for tightening cones on a bicycle. *See* Leather Work.

Plimsolls. This word is sometimes used for the rubber-soled shoes worn by children and known also as sandshoes.

PLINTH. As employed in architecture a plinth is the base or slab on which a column rests. The term is also applied to the same part of the construction of a base for a statue or pedestal. In another application the word is used to describe the upper projecting course, or cornice, of a wall. The word is also used in a similar sense by the woodworker. *See* Chest of Drawers: Cupboard.

PLOUGH: The Plane. A plough is a woodworking plane designed to make a groove on the face of a board parallel to an edge. The hardwood body of the plane is furnished with a steel sheet, or blade, projecting downward, which is divided so that the cutter, or iron, can pass through; the blade is thinner than the width of the narrowest iron to be used. Two bars pass transversely through the body of the plane, and carry a hardwood block, or fence adapted to bear against the edge of the board.

Plough Plane. Simple type used for making a groove to take 3/16 in. plywood. Inset, right, sectional view of the plane. (Courtesy of Handicrafts, Ltd.)

Below. Plough Plane. Regular type in use on a board, showing how the tool cuts a groove.

In use the bars are pushed through the plane body and locked by wedges, so that the distance from the centre of the iron to the face of the fence is equal to the required distance from the centre of the groove to the edge of the board. The width of groove depends on the size of the iron chosen. The amount cut at each stroke is regulated by the amount that the edge of the cutter projects below the bottom of the blade; the iron is locked by a wedge after being adjusted as required. The total

depth to which the groove is ploughed out is regulated by an adjustable stop below the plane body. The tool is pushed along the work repeatedly till it reaches the required depth, when it ceases to cut owing to the operation of the stop. While cutting is in progress the fence is kept up against the edge of the work so that the groove comes in the right place. The tool must be so held during the cutting process that it is kept level laterally. Two useful types are illustrated. *See Plane.*

PLOVER. Plovers are almost invariably roasted, the directions being the same as those given for roasting game. While cooking, they must be kept well basted, otherwise they will be found too dry. They may be drawn or left undrawn, but whatever the method adopted, the livers must be left inside. The time required for cooking is about 20 min., and the bird should be served on small rounds of fried bread. Garnish with watercress and cut lemon.

Plovers' Eggs. The eggs are of a rich flavour, and are regarded as a delicacy. Though sometimes eaten hot, they are better cold, and, after being hard boiled, should be left in cold water until they are to be served. They may be served on small ovals of bread and butter, and garnished with cress or salad and maître d'hôtel butter. If the eggs are preferred hot, they should be re-heated in some suitable sauce and served in it. *See Game.*

PLUG: In the Wall. Before any fitment can be attached to a brick, breeze block, or plaster wall, holes must be made to take plugs in which the nails or screws can be driven home. For many of the jobs about the home the patent fibrous plugs offer the most convenient means of doing this. The plug consists of a short piece of specially prepared fibrous material, through the centre of which is a small hole. In the material in which the screw is to be inserted a suitably sized hole is made with a drill or jumper, the plug pushed into it, and the screw driven into the plug. The effect is to cause the fibre to open and expand, thereby firmly gripping the walls of the hole in the walls, etc. The plug can be applied to brickwork, stone, or plaster, and is a practical means of fixing a great number of articles in the home.

Some care is needed in making the hole. A jumper of the proper size for the plug should be employed, and the latter must be the one intended to be used for the particular gauge of screw employed. Do not attempt to drive the tool straight into the wall, or the outside edges of the wall will probably be cracked and break off, leaving an unsightly mark. Hold the jumper lightly in the left hand and strike the tool a series of sharp, light taps, slightly turning the tool in the hole after each tap. In this way a perfectly round hole can be formed in the wall without damage. The tool should not be forced, and it should be held straight out from the wall, or perpendicular to it, as in Fig. 1.

Fig. 1. Plug. Fig. 1. Making hole for fibre plug with borer.

Fig. 2. Inserting fibre plug in hole made in plastered wall. Fig. 3. Showing how screw enters the hollow centre of the plug.

Having prepared the hole to a depth suited to the screw, a plug of the required length is inserted in the hole, so that the end is flush with the wall surface. The length of the hole, and consequently the plug, will vary with the article to be fixed. Suppose, for instance, the fitting is $\frac{1}{4}$ in. thick. If the article were not very heavy, a $1\frac{1}{4}$ in.

screw would probably be sufficient, leaving 1 in. of the screw to fit into the hole in the wall. In this case a plug 1 in. long, fitted into a hole about the same depth, or slightly more, would be needed. The next step is to insert the screw through a suitable hole drilled through the article, and into the hollow centre of the plug fitted into the hole in the wall. The screw should then be screwed up tightly with the aid of a suitable screwdriver.

The holes for a rail or other like article should be bored in the wood and the positions of the holes carefully marked on the wall. The plug holes must coincide exactly with these, and the screws must enter the plugs accurately, centre to centre, or the plug may split. The screw must be of such a

length that it can be driven home, and thus hold the fitment tightly to the wall, without the unthreaded portion reaching the plug. If the screw is too long for the plug, so that the unthreaded portion reaches the latter, further attempts to screw it home will result in the plug being loosened.

For such hard materials as marble, concrete, slate, and the like, it is better to use a plug slightly shorter in length than the screw, and to drive the plug in so that it is below the surface of the wall. This prevents the unthreaded portion of the screw from entering the hollow of the plug, and thus facilitates the screwing-up operation. An alternative is to use screws which are threaded right up to the head, when the plug can be fitted flush to the surface of the wall as usual. This type of screw is required in fixing thin metal fittings, such as brackets, mirror plates, and hangers.

It is often necessary to plug a brick wall to provide a fixing for rough grounds, heavy shelves, etc. Where the joints between the bricks are visible it is generally possible to cut out the mortar. Prepare a hardwood plug equal in width to that of the hole and about 3 in. long, and drive it into the joint along the way of the grain, so that the end grain is facing out of the hole. The wood should be tapered, and is driven in tightly with a hammer. The joint may then be made with neat cement.

If it is necessary to place the plug in the brick itself, or in a plastered brick wall when the joints of the bricks are not visible, the hole must first be chipped out with a cold chisel, or brick borer, as illustrated in Fig. 4. The rough hole thus formed is drilled out smooth, and a softwood plug driven into the brickwork, as in Fig. 5. If the plug is made to proper length, which is slightly less than the depth of the hole, it will only have to be driven in flush with the wall, otherwise the protruding end may be sawn off with a hand saw, interposing a piece of zinc between the side of the saw and the wall to prevent scratching the latter.

Fig. 4. Rough hole chipped out with cold chisel. Fig. 5. Driving wooden plug into hole.

In plugging a concrete wall it is necessary to chip out a hole in the concrete, making the hole wider at the bottom than at the mouth. The plug should be split at the top and provided with a wooden wedge, which is first placed in the hole; the plug is then introduced so that the wedge goes into the slit, and the whole is driven into place. The wedge will expand the wood plug at the back and cause it to grip the concrete. As an extra precaution, the hole may be loaded with plaster, or, preferably, cement, before driving the plug in, so that every crevice is filled with cement.

When making holes in walls for plugs, care must be taken to avoid gas and water pipes, or the casings of electric light cables that may be embedded in the plaster work. When plugging into brickwork, especially near the fireplace, the hole must not go too near a flue, or the plug may take fire. *See Gas.*

PLUMS: THE GARDEN VARIETIES

The Growing and Cooking of a Delicious and Serviceable Fruit

This article deals firstly with the growing of plums and with keeping the trees free from insect pests. This is followed by entries that describe the making of various plum dishes. See further Fruit; Grafting; Pruning; the articles on other popular fruits, e.g. Apple; Cherry; Pear; also Bottling; Bullace; Cordon; Espalier; Greengage; Jam; Silver Leaf; Spraying, etc.

The plum is one of the most useful of late summer and early autumn fruits, and if correctly managed will yield satisfactory crops unless climatic conditions are very unfavourable when the trees are in blossom in spring. Many of the dessert plums are self-sterile, and unless other varieties are planted near them they will not bear fruits freely. A mixed plantation is indispensable to success. Plum trees may be grown in the open garden in the form of bushes or standards, or as trained trees on walls; they are also grown as cordons, but are not so suitable for this method of training as apples and pears.

During the first few years after planting plum trees usually grow very vigorously but bear little fruit. Orchard standards, which eventually form large trees, must be allowed to grow freely and much fruit cannot be expected from them for several years. But by correct management bush and trained trees can be made to yield in their early years.

Plum trees thrive best in well-drained loamy soil, especially that which overlies chalk. In preparing sites on clayey land the sub soil should be broken up to provide drainage, mortar rubble should be added very freely, and lime should be applied. Manure ought not to be mixed in and the trees must be planted with their uppermost roots 2 or 3 in. below the surface. Every autumn for the first three or four years it is a good plan to lift young plum trees, shorten the thick roots, and replant at once. On light land, loamy (turfy) soil should be placed about the roots at planting time.

The following are some of the best cooking plums. Although all are self-fertile varieties it is, nevertheless, safer to have a mixed plantation than to rely on one or two varieties only. Czar, blue-black, August; Gisborne's, greenish yellow, August; Monarch, large, dark purple, Sept.-Oct.; Pershore (yellow egg plum), yellow, August; Victoria, rose-red, September. Other cooking plums to be recommended for a mixed plantation are Pond's Seedling, a large reddish fruit ripe in September, and River's Early Prolific, small purple, late July.

There are some delicious fruits among the dessert plums, but as a rule they do not bear so freely as the cooking varieties and ought always to be interplanted with the latter. Some of the most reliable are Coe's Golden Drop, yellow, September, which does best on a wall facing west; Comte d'Althan's Gage, reddish, September; Denniston's Superb Gage, greenish, August; Early Transparent, Gage, yellow and crimson, August; Jefferson, yellow and red, September; Oudin's Golden Gage, yellow, August; and Stint, small, yellow and red, August.

Plum. The variety Victoria, as a trained tree, bearing large pink fruit.

Pruning the Trees. Plum trees need very little pruning; indeed, they are usually worse for much cutting. One reason is that they are addicted to gumming, and nothing is more likely to bring a bad attack of this, particularly in a mature trained tree, than severe pruning. The pruning necessary for the training of the tree should therefore be done at a very early stage, and after they have become established they should be pruned as little as possible. Repeated hard shortening should never be practised with open-headed trees, whether dwarfs or standards, as such pruning is apt to result in the production of a large number of soft, whippy shoots, none of which will be found suitable for an extension branch.

Summer pruning may be applied to the new lateral shoots of plums. Matured trees need little pruning, save the occasional removal of a branch here and there if the head threatens to become too thick. Trained trees, whether cordons, fans, or horizontals, will produce a certain amount of breastwood from the main branches, and the course of pruning in this case is the same as with similar trees of apples and pears, namely, summer pruning and winter spurring.

Plums. 1. Planting: a, very firm soil; b, heavy loam and grit. 2. Pruning a young tree. 3. Type of shoot to be discarded. 4. Pruning a fruiting shoot to form spurs. 5. Type of shoot to encourage. 6, 7 and 8. How to bud plums. 9. Potted plant during winter, showing layers of cinders, fine ashes, and straw. 10. Leaf sawfly grubs at work. 11. Plum leaf sawfly. 12. Plum fruit sawfly. 13. Fruit sawfly maggot at work. (By special arrangement with Amateur Gardening.)

Pests and Diseases. The plum, in common with other fruits, has numerous enemies. It escapes the canker which is often so deadly in apples, but falls a victim to the equally destructive silver leaf, which attacks trees at all ages, but is most dangerous in old trees. There is no reliable remedy. The trees should be grown in well-drained, substantial soil containing lime, pruned little, and maintained

in as healthy a state as possible, according to the circumstances and the means at disposal. Beyond that, prompt removal of badly affected branches is desirable. In July, every bit of dead wood should be burned, as it carries the spores which spread the disease.

Caterpillars are sometimes injurious, and in the presence of an attack the trees should be promptly sprayed—but not while the trees are in bloom in case of injury to the trees—with a solution of arsenate of lead, 1 lb. in 25 gallons of water.

Plum. Two specimens of Orpington Prolific, a purple dessert plum of delicious flavour.

Gumming is liable to cause trouble in plums, as in other stone fruits, especially if the soil is undrained and very loose and rich, or if much winter pruning is done. But trees grown in well-drained, fertile soil, and pruned by summer pruning or branch thinning in summer, instead of winter pruning when there is very little sap moving, seldom gum. Green and blue flies (aphides) sometimes check plums severely, especially in dry spells, and curl the leaves. One of the general winter sprays, such as lime, lime-salt, and lime-sulphur, tends to keep down aphides; but if an attack has to be fought directly, a paraffin and soft soap emulsion is excellent, and the best remedy of all is 1¼ oz. of commercial nicotine and 1 lb. of soft soap in 20 gallons of water. To be efficacious this mixture must be used very hot.

How to Cook. To stew plums, remove the stalks and wipe the fruit; then put them in a stewpan with 6-8 oz sugar and ½ pint water to 1 lb. plums. The amount of sugar varies with the kind of plum employed and the degree of ripeness. Let them simmer until soft.

Another way of preparing plums is to bake them in a jar. First skin the plums. If they are ripe, the skin will peel off; if not, they will first require scalding. A fruit knife should be used to draw off the skin. Put them in a stone jam jar or crock, with the sugar on the top and just a little water, and bake until tender.

Except that plums are used instead of apples, the method of making plum charlotte is exactly the same as for apple charlotte (q.v.). For pie, flan or tart plums should be ripe or partly stewed first with sugar and allowed to get cold. Otherwise the procedure is the same as for other fruits when making these dishes.

Plum Jam. To every lb. of plums used in jam-making, ¾ lb. sugar is required. Wipe and stalk the fruit, put it into a preserving pan with the sugar, and cook slowly until the latter has dissolved. Keep the jam well stirred so that it will not burn, and when the sugar has melted bring it to the boil, boiling it for ¾ hour or more. In the course of cooking most of the stones will leave the plums; these should be taken out as soon as they appear, and if they are cracked, the kernels blanched and then put back, the jam will be improved.

To make plum and apple jam peel and core 4 lb. apples, cut them into rough pieces, add 7½ lb. sugar, and bring them to the boil in a preserving pan. Put in 6 lb. plums. Boil fast, removing the scum, until the syrup jellies when cooled on a plate. This should take about an hour. Pour the jam into jars and tie down the jars when the contents are cold.

Plum Solid. This sweet can be made with any kind of ripe plum. For it take 4 oz. granulated sugar, a lemon. 1 oz. gelatine, and $\frac{3}{4}$ pint water to each lb. plums. A glass of claret and a stick of cinnamon an inch long may be added, or instead of the claret almond essence may be used for flavouring.

Having washed and stalked the plums, put them into a pan with the water, the sugar, the cinnamon, and the rind of the lemon thinly peeled. Simmer them until tender, strain off the liquid and rub them through a sieve. Melt the gelatine in the plum liquor, strain this into the purée, add the claret or essence, and reheat the mixture. It should then be poured into a basin and stirred frequently until cool.

When cold turn the mixture into a mould that has been rinsed out in cold water, and leave it until it is set. Then turn it out into a dish and decorate it with chopped almonds or pistachio nuts and some Devonshire cream.

PLUMBAGO. This group of climbing half-hardy shrubs is suitable for cultivation under glass and of herbaceous perennials for the garden. For the former purpose the chief favourite is the Cape leadwort. *Plumbago capensis*, a leaf-losing climbing shrub for the slightly heated greenhouse; it bears bunches of lovely pale blue flowers in summer. It is usually planted in a border of loamy soil, but may be grown in a tub or large flower pot; it should be pruned in February. Cuttings can be made from the fresh shoots in spring. *Plumbago rosea*, which bears rose-coloured flowers in winter, needs the temperature of a hothouse.

Of the herbaceous perennials the best is *Plumbago larpentae*, a beautiful plant 12 in. or more high, suitable for a sunny spot in the rock garden or at the foot of a low wall: it needs sandy, loamy soil. The rich blue flowers open in August-September, and the leaves colour well. It is increased by division in spring.

Plumbago larpentae, a charming blue-flowered plant for a sunny place in the rock garden.

PLUMBAGO: The Mineral. This is another name for graphite, a form of carbon. It has many applications as a lubricant. Plumbago is a conductor of electricity, and in electro-plating work it is used as a preliminary coating on non-conducting materials, such as india-rubber, which have subsequently to be electroplated. Crucibles are made of plumbago, as they stand the heat of the furnace, and are extensively used for the melting of metals.

PLUMB BOB AND LINE. The plumb line is piece of string or cord, fairly thin and of even texture, to the lower end of which is attached a plumb bob. It is used by suspending it and allowing it to hang down freely. It will then naturally assume a perfectly vertical position as soon as it has come to rest.

It is used for comparing upright parts of a structure, adjusting them to the line so that they themselves will be upright or plumb. All such operations as setting up doorposts, corner posts of buildings, and so forth, should be checked by the plumb line to make sure the vertical members are perfectly upright. When not in use, the line should be coiled up on a reel, wound on to a spool, or wound around a stick, and preserved in the tool chest or other convenient place.

There are various patterns of the bob, ranging from simple ones which are merely plain lead castings to instruments made of brass and filled with lead, accurately machined and finished. The illustration shows a typical pattern in use and indicates the method of handling it.

A plumb line is easily extemporised from a piece of smooth string to the lower end of which is attached any weighty object of symmetrical form. A heavy lead sinker, as used by anglers, could be employed, or a large hexagonal nut with the string passed through the hole in its centre.

A plumb level comprises a combined plumb rule and spirit level. It has a vertical bubble tube for plumbing upright work, in addition to the usual tube in horizontal position. Another type can be used with a plumb bob for vertical work. *See Brick; Plumb Rule.*

Plumb Bob and Line in use.

PLUMBING: FOR THE AMATEUR

Practical Hints that will Save Time and Money

Other articles that bear upon the subject of Plumbing are those dealing with Bath; Gas; Gutter; Hot Water Supply; Lead; Pipe; Roof; Soldering; Tap; Water Supply, etc.

So far as the amateur is concerned, plumbing consists chiefly in making joints in lead pipes and sheets, generally in connexion with the water supply to the house, or the guttering and roof coverings. There are many difficulties that must be overcome for successful plumbing, which is a craft that is neither easily nor quickly acquired; but some of the repair work of a house, however, can be carried out by the skilful and careful amateur with no small degree of success.

A collection of the principal tools required is illustrated in Fig. 1. The hammer, saw, screwdriver, snips, pliers, and blow lamp are the ordinary tools to be found in any amateur's kit, but there are also some others used especially by plumbers.

The bossing stick and dresser, made from boxwood or other hardwood, are used for working the sheet lead into various forms. A drift and chase wedge are employed for working the lead into corners and angles. The bossing mallet is for driving the other tools, and the tan pin is for opening the end of the lead pipes. A rough chipping knife is used in conjunction with a hammer for cutting the lead, and a draw knife, not unlike a linoleum knife, for cutting the thin sheets of lead by hand. A small hand saw is employed for sawing the pipes asunder. The snips or shears are for cutting the metal. A soldering iron of good size is necessary, as is also some flux, such as "killed" spirits of salts, or soldering paste. A ladle and solder pot are required, as well as a plumber's stove or other means of heating the solder. The shave hook and other hooks are intended for shaving the edges to a level surface before soldering.

Rasps are used for preparing the ends of the pipes before they are jointed. Fixing points or blunt-ended punches are driven into the joints of brickwork or into other surfaces to obtain a temporary fixing by wiring or tying the pipes to them while the joints are being made. A rule, compasses, bevel, and chalk line are used for measuring and setting out the work. A wrench hammer and gas pliers are required for dealing with nuts and collars, especially those found on brass or iron pipes.

Typical Jobs. Before attempting any work the amateur should obtain a few lengths of lead pipe about 1 in. in diameter, and should then practise on them. Probably the repairs most commonly needed are those to water pipes and gutters. First of all, a suitable length of pipe is cut off with a

saw or by means of a rasp, and the end of the pipe is opened out with the aid of a tan pin, as in Fig. 2. An assistant holds the pipe while the plumber takes the tan pin in his left hand and drives it home with the mallet in the right, thus belling out the mouth of the pipe. The pipe is then held on the bench by a hook-headed nail or lightly grasped in the vice.

Should it be desired to fit a union to the end of the lead pipe, this can be accomplished by the following method, which also applies to effecting the joint with another piece of pipe. In Fig. 3, the union end, previously bent, is shown in position for soldering. Note particularly the wood screw jammed in between the union and nut to prevent the latter falling, and the wood chips inside to ensure alinement of pipe and union. The scraped pipe end may also be seen, as well as the size and lamp-black deposit to prevent the solder adhering where not wanted. This mixture is applied to the pipe while in a moist state.

Plumbing. Fig. 1. Plumber's tools. A, dresser. B, gas tongs. C, wood blocks. D, snips. E, wrench. F, gas pliers. G, screwdriver. H, tan pin. J, shave hook. K, back saw. L, chisels. M, blow lamp. N, paste. O, stake. P, lead. Q, wiping cloths. R, combination wrench. S, compasses. T, pliers. U, shears. V, rasps. W, cold chisel. X, fixing points. Y, knife. Z, hammer; aa, opening rasp, bb, mallet.

Fig. 4 shows the first step in building up the joint, the lead solder being applied to the pipe and union. The rough, ultimate shape of the joint may be seen, and nearly sufficient solder has been applied to form the joint. The solder is built up in this way by melting it with the blow lamp, after which the joint has to be wiped. In Fig. 5 the joint is seen nearly finished and being wiped. The wiper is made of moleskin from which all the hair has been removed, and is boiled in tallow. The metal blobs running down to the blackened portion of the pipe have not actually adhered to it, and they will be found quite easy to remove with the fingers after the metal has cooled.

Fitting a Branch Pipe. To make a T or saddle joint, as in fitting a branch to a running pipe, the first step is to make a hole in the main pipe, as in Fig 6. A half-round rasp is used, and the result of filing

at right angles to the pipe is to form a round hole in the pipe wall. After filing, the hole is scraped into a funnel shape. Fig. 7 shows the branch pipe fitted into the main pipe. The meeting and joint faces of the pipes are scraped clean with the shave hook, and subsequently the solder is melted around them, as in Fig. 8, and allowed to run on the joint. About 1 lb. of solder is required, and when it is being applied the final shape of the joint is borne in mind.

Plumbing. Fig. 2. Opening out end of pipe with tan pin. Fig. 3. How the union is fitted. Fig. 4. Melting solder to joint. Fig. 5. Wiping joint. Fig. 6. Use of rasp for cutting hole in main pipe. Fig. 7. Fitting branch pipe to main pipe. Fig. 8. Building up solder around joint. Fig. 9. Finished wiped joint.

The main pipe is secured by a nail and a piece of string to a temporary block of wood, so as to raise the pipe from the wall or other backing. The main pipe should be bent or closed up so as to grip the branch pipe. Fig. 9 illustrates the saddle joint complete. The main pipe has been straightened; but at least 20 min. must be allowed before straightening to permit of the joint cooling sufficiently. The pipe is straightened by careful bending with the hands and lightly striking it with a wooden mallet.

This class of joint is employed when it is required to run an additional branch, as for example for the supply of water to a tap over a copper, or some other position. Where it is necessary to make several bends in the branch pipe these should be worked before it is attached to the main pipe. Fig. 10 shows the pipe being bent at right angles over the plumber's dresser, which is resting on top of a trestle to allow free movement and space in any direction. Care must be exercised not to distort the section of the pipe to any extent. This is avoided by careful manipulation of the pipe, gently hammering the sides wherever it exhibits any tendency to flatten. The hammering is done in order to drive the pipe back from an oval section to the proper circular shape.

When a sharp bend is to be made, the amateur may get good results by the method illustrated in Fig. 11, where a sharp bend in a pipe is made for a square corner of a rough piece of wood, in which a groove has been cut to the width of the pipe. The walls of the groove should be upright and exactly the diameter of the pipe, so that the latter is gripped firmly in the groove, and this tends to prevent the pipe closing up at the bend. The same idea of providing a groove or chase for the pipe to be laid in should be followed in the corners of walls, or in places where the pipe has to be bent round, so as to reduce the sharpness of the bend and provide a secure fixing for the pipe.

Plumbing. Fig. 10. Bending a pipe over the dresser. Fig. 11. Showing how a sharp bend is made in a pipe.

Fixing on the Tap. Having worked the pipe to the desired location, the next step is to fix a tap on to the end of it. This is accomplished in substantially the same way as that in which the union end was fitted to the end of the pipe. In this case, however, there are short brass sockets or fittings usually supplied with the tap and

fitted at right angles to the pipe as if the brass socket were the branch to be fitted to the main pipe. The solder is built around it and the joint subsequently wiped. Brass fittings have first to be tinned on the joint surface. This process consists in cleaning the brass, coating it with the soldering flux, heating it, and then working the solder all over the surface with the soldering iron.

When the brass fitting has been soldered into the pipe, the tap is screwed into it with a washer interposed between the joint surfaces to ensure a watertight connexion. The end of the lead pipe beyond the tap is closed by melting in some solder and then smoothing off the end with a soldering iron, or wiping as previously described. The same principles are applied to the repair of all kinds of lead pipe joints. In the case of iron pipes, the joints are almost always effected by means of screwed fittings, the end of the pipe simply having to be cut with the requisite length of screw thread on the outside of the pipe, to suit the sockets or other fittings used. When connecting pipes the threads are coated with red lead and gold size, or any good thick paint, a few strands of hemp being twisted into the groove before screwing home the pipe.

Plumbing: repairing a gutter. Fig. 12. Cracked gutter before repair. Fig. 13. Gutter cut across and raised, and groove cut in gutter board. Fig. 14. Melting lead solder into groove and joint. Fig. 15. Surface of molten metal being levelled flush with the lead.

Repairing Gutters. Figs. 12 to 15 show various stages in the repair of gutters. In Fig. 12 the crack is shown in the gutter, but before attempting to close it, it must be made larger, as in Fig. 13, where the crack has been extended by cutting with shears. The gutter board underneath has a rough groove cut in it, about $1\frac{1}{2}$ in wide and $\frac{1}{2}$ in. deep in its deepest part. In Figs 14 and 15 the gutter side is shown cut through and bent back to enable the process to be seen clearly. The lead on each side of the crack, which was cut and turned up to allow the groove to be made in the gutter board, is now hammered down into that groove. All surfaces to which solder is to be applied are cleaned, and their immediate surroundings coated with the lamp black and size mixture. Fig. 14 shows the solder being melted and run into the groove. Rather more solder is required than would be sufficient to bring the surface flush with the existing gutter bottom. Fig. 15 shows the repair nearly completed. The solder is wiped flush with the lead as the work proceeds, rendering a further heating of the joint unnecessary.

There are one or two points that the amateur plumber should bear in mind. The water supply companies have stringent regulations governing piping and fittings connected to their mains, and

only materials and fitting of an approved specification may be employed. Local authorities also have regulations which must be complied with, especially as regard any work connected with the sanitation system. Some require that the work shall be done by a registered plumber. The advice or assistance of a competent person should be obtained before undertaking any task other than that dictated by conditions of emergency.

Plumb Level. *See* Plumb Bob.

PLUMB RULE. The plumb rule is employed for testing the uprightness of a structure. It comprises a piece of board with a pear-shaped hole at the bottom of it. A line is scribed down the centre of the board, and near the top a nail or peg is fixed, to which is attached a strong, smooth, and fine string, the lower end of which is weighted with a pear-shaped piece of lead, which swings clear in the pear-shaped hole cut in the board. To prevent the string of the plumb from dangling about, a strap of leather or some other material is fixed across the board just above the opening, and is so arranged that the string can swing clear, but not to too great an extent.

Plumb Rule in use to test uprightness of door lining.

The illustration shows the method of use, which is to hold the board against the object to be tested, and to judge its uprightness, or otherwise, by the line of the string in relation to the line scribed on the board. If the structure is out of plumb, that is, not vertical, the upper end of the board will lean outward, or inward, and the bob will tend to swing over, and the string will not coincide with the scribed line. In testing a corner of brickwork, or when erecting a corner post, a timber-structure, or a door post, it is necessary to test in two directions, applying the plumb rule to both faces of the work, as it may be upright in one direction but not in another. Adjustments are made to the work until the string hangs exactly in register with the scribed line on the board.

A plumb rule can be made up by any amateur from a piece of board about 4 ft. long, 6 in. wide and $\frac{1}{2}$ in. thick. The line must be scribed in the centre of the board, exactly parallel to both the outside edges. The hole is cut out with a pad saw or keyhole saw, and the edges smoothed off with a gouge or sandpaper. The line is twisted into three saw cuts made in the top end of the rule, one central and the others at convergent angles, as shown. *See* Plumb Bob.

Plum Cake. Cakes containing raisins are often spoken of as Plum Cakes. *See* Cake.

PLUM DUFF. To make this plain boiled pudding, which is also known as spotted dog, chop up very finely $\frac{1}{4}$ lb. suet and mix it thoroughly with $\frac{1}{2}$ lb. flour to which $\frac{1}{2}$ teaspoonful baking-powder has been added. Add also 4-6 oz. well-cleaned currants, 1 oz. sugar, and a pinch of salt. Mix together with a well-beaten egg, adding a little milk if necessary. Scald and flour a pudding cloth, put the mixture into the centre of it, and either roll it and tie it at either end, or tie it on top. In either case leave plenty of room for the pudding to swell.

Drop the pudding into boiling water and boil for 2-3 hours.

PLUME POPPY. This is the popular name of *bocconia*, a group of vigorous hardy herbaceous perennials, 6 ft. or more high, with decorative grey-green leaves and plumes of small pale flowers

in late summer. They thrive in ordinary soil in a sunny place and are increased by division in autumn. The favourite kind is *Bocconia cordata*.

Plum Pudding. *See* Christmas Pudding.

PLUSH. A longer pile distinguishes plush from velvet. Mohair plush is cheaper than silk plush and is sometimes used for covering large pieces of furniture. Teddy-bear plush is obtainable about 50 in. wide.

Linen plushes can be had for making curtains, but their pile is more easily flattened down than that of silk or hair plushes. Hatter's plush, made with a laid pile instead of an erect pile, and intended for covering silk hats, is a distinct variety. *See* Upholstery.

PLYMOUTH CHINA. The interest of Plymouth china for the collector lies in the fact that it was the earliest true or hard-paste porcelain to be produced in England of English materials. As it was being made for a few years only before 1770, when its inventor, W. Cookworthy, transferred his activities to Bristol, it is not easy to come by, and is also sometimes difficult to distinguish from Bristol ware. The sides of the vessels from both factories frequently show a spiral ridge, due to a defect in the throwing. But Plymouth ware can often be identified by a characteristic smoky stain in the glaze, as well as by its high polish, and also by the cold, grey tint of the underglaze blue.

Plymouth China coffee pot, dating from 1768-70. (British Museum)

The pieces to look for are cups with foliage reliefs, statuettes, shell-shaped salt-cellars, and oyster and pickle stands. These are either plain white or with blue decoration, which was also done on mugs, saucers, sauceboats, and full services. Enamelled designs were painted on plates, teapots, vases, and figures, those comprising birds and flowers having been done sometimes by a French artist from Sèvres. The usual mark, in underglaze blue or enamel colours, resembles a combination of 2 and 4, being the alchemists' symbol for tin. This appears in gold on some of the finest pieces, which perhaps belong to the Bristol period of Cookworthy's work. *See* China.

PLYMOUTH ROCK. One of the most popular breeds of poultry is the Plymouth Rock, which is generally spoken of as the farmer's fowl. This bird has a large frame which carries plenty of meat. It is a good, especially a good winter, layer. The hens are most excellent mothers, and the chicks are hardy and quick in maturing.

The Plymouth Rock is bred in 6 colours—barred, white, black, blue, buff, and golden barred, the latter being the latest to appear. The barred has a greyish, bluish-white ground colour with glossy steel-blue bars running across. These bars must be distinct, even, and narrow. The chicks are greenish grey with pale cream under parts, or very dark, almost black, top colour, with a small spot of a light colour on the head.

Whites are pure white right through, the chicks creamy white. Blacks are a rich lustrous beetle-green black, the chicks black and white. Buffs are a sound even shade of soft lemon buff, the chicks buff. Blues are of an even slaty blue throughout, the chicks blue and blue and white. The golden

barred are as the barred, except that the ground colour is two shades of golden buff, the chicks buff. *See Fowl; Poultry.*

PLYWOOD. Made of thin layers of wood glued together at right angles or diagonally and then placed under considerable pressure, plywood can be obtained in large sheets or panels, and in thicknesses from $\frac{1}{8}$ in., increasing by $\frac{1}{16}$ in. to $\frac{3}{8}$ in. These thicknesses are generally of 3 ply, but additional layers of wood are commonly used up to 5 ply to a thickness of $\frac{5}{8}$ in.

Various kinds of wood are used. Birch, white-wood, satin walnut, and pine are softwoods and suitable for backing or staining. Of the commonly used hardwoods, oak, mahogany, teak, black walnut, and bird's-eye maple are obtainable in plywood. The more expensive woods are made with a core of cheaper wood.

The main feature of plywood is the strength it affords in a thin board.

It is estimated that a piece of plywood is four times stronger than solid wood of similar thickness.

The method of manufacture, which places the grain of the layers at right angles to one another, prevents splitting and renders the material comparatively free from risk of warping and shrinkage. The amateur will find many uses for plywood, especially for the backs of cabinets and for linings and bottoms of drawers and small boxes. It may be employed for panelling, and owing to the large size of the sheets it is useful for either temporary or permanent partitions in rooms. A simple plough plane for grooving rails, legs, etc., to take $\frac{3}{16}$ in. plywood can be purchased quite cheaply (*see Plough*), and such furniture parts are obtainable also with the grooves ready worked on.

For all kinds of small articles plywood is very handy. Owing to its stiffness it is convenient in making small cabinet doors. The stiles and rails can be of thin wood, glued and screwed to the plywood back.

The best way of obtaining a good top surface on plywood is to size it first, rub it down with fine glass paper, give it another coat of size on top, and lightly rub over to remove grit. The material will now take a good polish, or it can be previously stained. If the edges of the plywood are in a prominent position, it is advisable to use a wood filler, and whiting mixed to a paste with glue answers very well. This should be rubbed well into the grain and cleaned off with glass paper before the wood is polished or painted. *See Door: Ingle Nook.*

PNEUMONIA. Any inflammation of the substance of the lung constitutes pneumonia. It is one of the most fatal of the acute diseases to elderly persons, habitual drinkers, people who are under-fed, and weakly children. There are three varieties of the disease. Acute croupous or lobar pneumonia attacks one or more lobes of the lung. Acute catarrhal or lobular pneumonia, also called bronchopneumonia, is distributed over numerous small areas throughout the lung, and is a frequent consequence of bronchitis. In chronic or interstitial pneumonia the tissue forming the framework of the lung is inflamed.

The essential cause of pneumonia is a germ, usually the pneumococcus. Numbers of these organisms are very commonly present in the mouth and nose cavities of healthy persons, doing no harm until a chill or some other cause lowers the vitality and enables the germs to multiply. One of the most powerful predisposing causes is intemperance. No other factor assists recovery so much as plenty of fresh air. The patient should have a large well-ventilated room.

High temperature is one of the greatest dangers, as it may lead to failure of the heart. If necessary, sponge the patient with cold or tepid water, uncovering only a small part of the body at one time, and drying it before sponging another part.

Pneumonia in Dogs. Pneumonia is a common sequel to distemper, or it may follow bronchitis or a severe chill. There is a high temperature, breathing is quick and difficult, and a characteristic

symptom is blowing at the lips. The patient should be kept in a temperature of about 60°, with plenty of fresh air.

Envelop the chest in gamgee wool with a flannel coat over it. Apply compresses to the side as hot as can be tolerated. Place a piece of flannel in a length of linen and insert it in boiling water containing a little methylated spirit. It can then be wrung dry without hurting the hands. Place it well at the sides, at the back of the elbows, and under the chest. Cover with flannel, and then the gamgee wool. Do this several times a day. Feed little and often with strengthening foods. *See Dog.*

POCKET BOOK. A pocket book, in one meaning of the term, is not, strictly speaking, a book at all, but a wallet, usually of leather, provided with compartments for holding letters, papers, notes, stamps, etc. It usually folds down the middle and is of a convenient size to carry in a man's pocket. In another sense a pocket book is an ordinary printed book made in a small size. Pocket editions are obtainable of most of the classics and a great number of other well known works.

A third meaning of the term is almost synonymous with note book, except that the latter has a wider significance, embracing books of almost any size, while the size of a pocket book usually varies between about that of a postcard and that of a playing card.

POCKET KNIFE. Strictly speaking, the blades of a pocket knife are placed side by side at one end of the case while those of a pen-knife are at opposite ends, but for practical purposes the distinction is no longer made, and the term pocket knife is applied to both.

The ordinary pocket knife is usually about 3 in. to 4 in. long. Blades are mounted between two plates, usually of brass, a brass rivet fitting a hole in the shank of the blade holding them in place. The rivets embrace the covering of horn, bone or other material, as well as the brass plates. A steel spring riveted in the centre presses against the shank ends of the blades, causing them to open and shut with a snap. A shoulder on the back of the knife blade fits the top of the spring and takes the strain of the blade when in use. Each blade is provided with a thumb-nail groove in order to facilitate its extraction from the case.

A well-made pocket knife is a long-wearing tool, and it is only rarely that it needs attention. The most easily worn parts are the brass rivets. Constant opening and shutting the blades in time wears away these parts until the rivet either snaps or wears so thin that the spring loses its effect. While the parts are separated to put in new rivets the knife can be thoroughly cleaned and reconditioned.

The method is as follows:

The blades, or blade if the knife has only one, are opened and clamped between two pieces of wood held in a vice. Using a very small drill about the size of a rivet head and a hand brace the burrs of the rivets on one side only are drilled away. This process is shown in Fig. 1. The knife is then removed from the vice, into which is tightly clamped a small hexagon nut. A small rivet punch is improvised from a piece of steel knitting needle of rather smaller diameter than the rivet itself. The knife is placed on the nut so that the rivet comes over the hole in the nut, and the rivet is then punched out. (Fig. 2.)

The parts should be cleaned by dipping them in petrol and rubbing them with a rag. A short length of stout brass wire is obtained of a diameter to fit the rivet holes, and the blades and spring are reassembled as shown in Fig. 3. The coverings are also fitted and the brass wire cut off to within 1/16 in. of the covering plates. A flat hammer head is fastened in the vice to form an anvil for riveting. The rivet is held against the hammer head while a series of gentle taps are given to the other end in order to spread it.

Fig. 4 shows the burring over of the new rivet, which should be struck on its edge in order to create as large a burr as possible. When a substantial burr has been obtained on one side, the knife is turned over and a rounded burr knocked on the other side. All the rivets are treated in this way. The

next step is to file off the rivet ends flush with the covering plates, taking care not to remove too much of the rivet head in the process or the rivet will not hold.

It occasionally happens that one side of the scale or covering of a knife cracks across. A suitable material is chosen, and a new scale cut and filed to shape to replace the broken one. Rivet holes are drilled to correspond, and reassembly is proceeded with as above. The life of the rivets is considerably lengthened by a drop of oil on the moving parts from time to time.

POD. The botanical definition of a pod is a dry fruit (possessing several seeds) which is dehiscent, i.e. which when ripe opens to let the seeds fall. It is popularly used in reference chiefly to peas, beans and other members of the Leguminosae family.

PODOPHYLLUM. This hardy herbaceous perennial possesses large, deeply lobed leaves and bears chiefly white flowers in summer. They should be planted in damp leafy soil. Propagation is by division in spring. Two of the chief kinds are *peltatum* 12 in. high, with pale flowers and small green fruits (hence its popular name May apple), and *emodi*, 12 in. high, with bronze-green leaves and white flowers followed by red fruits.

The dried root of the May apple is used in medicine as a purgative and stimulant for the liver, preparations in common use being podophyllin, dose $\frac{1}{4}$ to 1 gr.; tincture of podophyllin, 5 to 15 minims. It is usually taken in the form of a pill, which may be made up from 3 gr. of podophyllin resin and 21 gr. of extract of hyoscyamus. This is divided into 12 pills.

POET'S NARCISSUS. This is the common name of *Narcissus poeticus*, of which there are many beautiful varieties. The perianth is white and the crown or centre is of various rich colours. See *Narcissus*.

POINSETTIA. This hothouse plant is grown for the sake of its scarlet bracts, which are in full beauty in winter, the true flowers being small and inconspicuous. When the plants have finished flowering they should be pruned and kept rather dry at the root for a few weeks. Then if kept moist and warm they will start into fresh growth, and the young shoots are taken off and inserted as cuttings in pots of sandy soil in a propagating case. Subsequently they must be potted in small pots and finally in those 5 or 6 in. wide, in a compost of loam two thirds, leaf-mould and decayed manure one third, with a free addition of sand. During the summer months a cool, airy greenhouse or frame suits them, but in September they must again be placed in warmth.

Poinsettia (Euphorbia) pulcherrima, an evergreen hothouse plant with brilliant scarlet flower bracts.

POINTER: The Dog. Besides having a good nose to find the game, a pointer must have endurance and pace, and he should be built on lines which indicate the two latter. His forelegs should be straight and strong, the thighs long and muscular, the shoulders long and sloping, chest deep and not too wide, body well developed and powerful, loin slightly arched, broad and muscular. In fact, he should be symmetrical all through, giving the impression of being able to gallop and stay. White usually predominates in the colour, and the markings may be lemon, orange, or liver. Whole-coloured black or liver are occasionally seen. See Dog.

Pointer. The sporting dog at work, trained to point out game. (Photo. Thos. Fall)

POINTING: In Building. Pointing is the process of finishing the face of joints in brickwork or stonework, giving it a better appearance and offering resistance to rain at the joints. It may be done as the building work proceeds, which is the strongest form of pointing, or it may be done at the completion, working from the top downward and striking the scaffold as the work is finished. The latter method gives the better and cleaner appearance, but it is not as strong as the other and it is more costly, because the joints have to be raked out to at least $\frac{1}{2}$ in. deep so as to receive the material that is used for pointing.

The struck joint is the best and strongest kind of pointing. It consists in pressing the mortar tightly into the joint with the trowel, forming a smooth face splayed back at the top edge so as to weather the joint, or in other words so as not to hold the rain that might drive on to the wall.

Flat pointing or flush pointing is carried out on the interior of walls that are not to be finished in any way other than limewashed; it consists in flushing the wet mortar off with the trowel, so as not to encourage the lodgment of dust. Flat pointing is sometimes used on external work, but it is then what is termed jointed, that is, while the pointing material is still wet a grooving tool is pressed into it and, when set, there is a recess to receive more jointing material, usually of a contrasting colour.

In repointing an old building the joints have to be raked out to about 1 in. in depth and in the process the edges of the bricks often become very damaged. They are first flush pointed so as to make sound the damaged edges, then a grooving iron or jointer is drawn along the wet pointing, forming a recess, into which is put usually a white pointing. The flush pointing is first coloured, however, to match the brickwork.

Fig. 1

Fig. 2

Pointing: four types.
Fig. 1. Struck joint, the top edge being splayed back to weather the joint.
Fig. 2. Keyed pointing, in which the mortar is grooved.

Fig. 3. Flat or flush pointing. Fig. 4. Tuck pointing, a more ornamental form, but less easy for the amateur.

FIG. 3

Fig. 4

In keyed pointing the pointing material is pressed into the joints with the trowel in the usual way, then a grooving iron is placed into the joint and drawn along, thus forming a semicircular recess. The grooving tool is made generally from a piece of $\frac{3}{8}$ in. round iron, set up so as to form the handle at one end. There are other forms of keyed pointing, but these need professional skill and are used principally where rendering of the walls is to follow.

The tools required for pointing consist of a pointing trowel—i.e. one having a blade about 4 in. long and a straight-edge—a piece of wood about 3 ft. long, 2½ in. wide, and $\frac{3}{4}$ in. thick. An old table-knife ground off to a point is used for trimming the edge of the joint that has been pointed, so as to cut off any surplus material there may be.

The material used is, as a rule, cement mortar, made up of equal proportions of Portland cement and clean, sharp pit sand. The materials are mixed together dry, then sufficient clean water is added to make them plastic. Only as much of the material is mixed as can be used. The mortar is pressed into the joints, and brought to a smooth face by drawing the trowel along it, cutting the edges straight with the knife and straight-edge.

If old brickwork is being pointed, or new work at the completion of the ordinary bricklaying, then, in addition to raking and cleaning out the joints, water must be copiously employed. On no account should pointing be done during very frosty weather, because the material will ultimately fall out of the joints.

POISON. Certain substances are statutory poisons. They are enumerated in a list to be prepared by the Poisons Board. Any preparation which contains a statutory poison must be labelled as “poison.” A medicine prescribed for internal use may be thus labelled, but this fact need not alarm the patient; care must be taken, however, to adhere to the instructions.

When an Act passed in 1933 is brought fully into force, poisons will be divided into two classes. The first can be sold only by authorized sellers, e.g. registered pharmacists; the second may also be sold by persons registered by local authorities. The container must be labelled with the name of the poison, the word “poison” or other prescribed wording, and name and address of the seller. Poisons in the second class are mostly those in common use for purposes other than the treatment of human ailments.

POISONING. In few emergencies can sagacious first aid be of such service as in that of poisoning. The need may arise in a variety of circumstances. It may be definitely known that poison has been swallowed or otherwise may have got into the body, and the nature of the poison may even be known. Without this knowledge, however, the probability of poisoning would be recognized when a person becomes ill shortly after taking food, drink or a dose of medicine.

Some poisons destroy tissues with which they come into contact, and are known as corrosives. There is evidence of destruction of the lining of the mouth, and possibly marks on the face and clothing. Such poisons cause an immediate burning pain in the mouth, throat and stomach, also vomiting, and perhaps purging. There may be difficulty in breathing. The patient is collapsed.

Amongst the corrosive poisons are the strong mineral acids, such as oil of vitriol; the caustic alkalies, such as strong ammonia. corrosive sublimate, formalin oxalic acid, certain metallic salts, etc. Carbolic acid and creosote also cause a burning pain, but vomiting is uncommon, and there is a sense of giddiness and intoxication, followed by unconsciousness.

Irritant poisons may or may not occasion a hot feeling during swallowing, but they cause nausea, vomiting, abdominal pain, purging, and more or less collapse. Some cause difficulty in breathing, and some cramps in the legs. They include antimony, arsenic, copper, lead, mercury, zinc, croton oil and other strong purgatives, arum, cantharides, etc.

Narcotic poisons may, like opium, cause immediate somnolence, deepening into sleep and coma; or, like belladonna, there may be pronounced delirium and then coma; or, like alcohol and nitrobenzene, they may cause signs of intoxication, followed by coma.

Some poisons, including aconite, diluted oxalic acid, prussic acid, etc., cause great depression of the heart, while others, such as hemlock, calabar bean and curare, cause muscular paralysis. Nuxvomica and its alkaloids strychnine and brucine, cause convulsions without impairing consciousness or producing signs of irritation of the alimentary tract.

In the event of poisoning a doctor should be sent for at once, and should be told what poison has been taken, if this fact be known. In the meantime, first aid should be rendered promptly. If the nature of the poison is known, instructions as to its treatment will be found under the appropriate heading in this book, but, if not, treatment should be along the lines to be now laid down:

If the poison be a corrosive, on no account should an emetic be given, as vomiting might cause perforation of the stomach, but in all other cases, if the patient can swallow, an effort should be made to empty the stomach.

To this end a tablespoonful of mustard or two tablespoonfuls of common salt may be given in a tumbler of warm water. Vomiting may be hastened by tickling the back of the throat with a feather or a paper spill, and when it begins the patient should drink large draughts of tepid water in order to wash out the stomach.

In the next place, or in the first, when dealing with a corrosive poison, something should be given to neutralise the activities of any drug remaining in the stomach; a list of the appropriate antidotes to use for each poison is given here. A strong infusion, or decoction, of tea is usually a good thing to give, as not only does it stimulate, but the tannic acid which it contains is an antidote for alkaloids, the active principle of most vegetable poisons, and for some metals.

The irritation caused by a corrosive or irritant poison may be lessened by giving demulcent drinks, such as milk, thin gruel, thin cornflour or arrowroot, olive oil, or white of egg in water. Oil should not be given, however, in poisoning by cantharides or phosphorus and as little water as possible in poisoning by oxalic acid or lysol. When poison has been in the stomach for some time some of it may have passed into the bowel, in which case one or two tablespoonfuls of castor oil, or a tablespoonful of Epsom salts in a tumbler of warm water, should be given. For difficulty of breathing caused by corrosive poisons, hot cloths should be put on the neck, and the air may be moistened with steam by means of a bronchitis kettle (q.v.), which can be improvised, if necessary. Pieces of ice should be given to the patient to suck.

Faintness and collapse are treated by keeping the patient lying down in bed and promoting warmth by blankets and by putting hot-water bottles, covered with flannel, at the feet and by the sides. Stimulants should be given in the shape of sal volatile, a teaspoonful in a wineglass of water, whisky or brandy, a teaspoonful or more, according to age, etc., well diluted, or strong tea or coffee. No alcohol should be given in poisoning by aniline, nitro-benzene, or related poisons. Pain or cramps are treated by placing large hot fomentations over the affected parts.

Any bottles found near the patient, or any vomited matter, should always be kept for the doctor's inspection. *See* Artificial Respiration; Emetic; Fainting; Food, Poisoning by; Ptomaine Poisoning; Shock; and under the headings of all the principal poisons.

TABLE OF COMMON POISONS GROUPED ACCORDING TO THEIR ANTIDOTES

Poison	Antidote
Oxalic acid (salt of sorrel or lemon; Castor oil.	Lime water or tablespoonful doses of chalk, whiting, magnesia, or plaster taken from the walls and powdered, mixed with water.
Sulphuric acid (oil of vitriol); Hydrochloric acid (spirit of salt); Nitric acid (aqua fortis); Strong acetic acid	Lime plaster, magnesia, chalk, whiting, washing soda, or bicarbonate of soda, in water. Weak solution of ammonia, sal volatile in water. Olive oil.
Washing soda, caustic soda; caustic potash; strong ammonia (spirit of hartshorn)	Two or three tablespoonfuls of lemon or lime juice, or vinegar, in water. Weak solution of citric or tartaric acid crystals. Olive oil.
Carbolic acid; creosote	Epsom salts, $\frac{1}{2}$ oz. in warm water, $\frac{1}{2}$ pint or more.
Corrosive sublimate (perchloride of mercury)	White of an egg in water.
Arsenic (white arsenic, rat poison, weed killer)	Tablespoonful doses of dialysed iron; magnesia freely, in water.

Antimony (tartar emetic, antimonial wine)	Strong warm tea freely.
Phosphorus (match heads, rat poison)	Weak solution of permanganate of potash. Old oil of turpentine, tablespoonful, if doctor advises.
Iodine (tincture of iodine)	Weak solution of washing soda. Starch in water.
Sugar of lead (lead lotion, white lead)	Epsom salts, $\frac{1}{2}$ oz. in water.
Copper (bluestone, verdigris); silver nitrate (lunar caustic)	White of egg.
Cantharides (Spanish fly, blistering fluid)	White of egg. No fat.
Poisonous fungi	Weak solution of permanganate of potash, brandy, sal volatile. Atropine, to be administered by doctor.
Zinc salts (zinc sulphate, zinc lotion)	White of egg, milk, olive oil.
Oil of turpentine	Epsom salts, $\frac{1}{2}$ oz. in water.
Digitalis (foxglove)	Strong warm tea.
Opium (laudanum, morphia, morphine, warm paregoric, chlorodyne, Battley's solution, pint of Dover's powder, soothing syrups)	Weak solution of permanganate of potash, strong tea, strong coffee; if patient unconscious, a warm strong coffee by the bowel.
Belladonna (deadly nightshade, atropine, liniment of belladonna, A.B.C. liniment, eye drops to dilate the pupil), hyoscyamus (henbane), black nightshade, woody nightshade (bittersweet)	Strong warm tea.
Alcohol (spirits, liqueurs, wines, beer, rectified spirit, methylated spirits)	Strong warm coffee, sal volatile. Ammonium chloride, large doses, given by a doctor.
Cocaine	Alcoholic stimulants, strong warm tea.
Chloroform, ether, chloral, chloralamide	Warm strong coffee, sal volatile. For chloroform, large doses of bicarbonate of soda also.
Nitrobenzene (nitro-benzol, oil of mirbane), Prussic acid (hydrocyanic acid, cherry-laurel—leaves and water—bitter almonds, cyanides)	Fresh air, inhalation of ammonia, sal volatile.

Strychnine (nux vomica, Easton's syrup, tonic tablets)	Strong warm tea.
Aconite (monk's hood), wolfsbane, tobacco (nicotine, fruit-tree spray)	Strong warm tea, spirits, sal volatile, strong warm coffee.
Antipyrine (phenazone), phenacetin, exalgin, antifebrin (acetanilide), camphor (camphorated oil)	Sal volatile, strong warm coffee, whisky or brandy.
Sulphonal, veronal, trional	Strong warm coffee.
Laburnum	Sal volatile, spirits, strong coffee, freely.

POKER. Pokers are made of iron, steel, brass, copper, oxidized silver, and other metals. The cheapest are little more than iron bars, but more expensive ones are made with a certain amount of ornament, and are usually part of a set of fire irons. Ornamentation is confined to the handle and upper part.

Poker Gas Burner. This is a burner used for igniting a coke or coal fire. It is connected to a plug point at the fireplace, the gas lighted, and the burner thrust into the fire amongst the coke or coal. When the fire is well alight the burner is withdrawn and disconnected. *See* Fire Irons; Gas.

POKER: The Card Game. Poker is a card game for any number of players less than seven. There are several varieties of the game, the commonest being draw poker, and the rules differ greatly in minor details. This game is played with an ordinary pack of 52 cards, and the cards rank as at whist; the ace can count high or low as required, but not both at once.

One player usually acts as banker, and sells counters to the others, redeeming them as required. A limit usually is set to the amount that any player may raise a bet. In one general variation each player begins with the same number of counters, and when he loses all or is frozen out, he drops out of the game. Any player may quit the game when he wishes, receiving from the banker their value for any counters he may still hold. No hand may be shown until betting has ceased. The players cut for deal, the lowest dealing, and aces count low. In some forms of deciding the opening, player cards are dealt round, and the first to receive a jack deals.

The Hands. Five cards are dealt to each player, one at a time, and these five cards constitute a hand. There are 10 varieties of hands, as follows: The hands are given in the order of their importance, beginning with the highest possible hand that can be held. A flush is 5 cards of a suit. Royal flush consists of the ace to the 10 of any suit. Straight flush is any 5 cards of a suit in sequence, excluding royal flushes. Four of a kind consists of 4 aces, 4 kings, etc., and one ordinary card. A full house consists of 3 cards of a kind, as 3 tens, and a pair. Three of a kind is 3 cards of the same denomination, as 3 tens, 3 fours, etc., and 2 ordinary cards. Two pairs are self-explanatory. One pair and 3 ordinary cards is the lowest hand but one. The lowest hand contains none of the above, and consists of all ordinary cards.

The royal flushes tie, since the suits do not rank at poker. Some players, however, rank the suits as at bridge, so that a royal flush in hearts beats one in diamonds, etc. If 2 players hold hands of the same class the highest denomination wins, e.g. 3 kings beat 3 fours. If 2 hands tie, except royal flushes, the highest card wins. In a sequence a top card, for example, decides, as does the top card

in a flush, though in some forms of poker flushes are always equal. If each player has equal pairs the highest ordinary card settles the winner. If a hand has no scoring cards the highest card wins. If the highest cards tie, the second highest wins and so on. If hands tie throughout, the pot is divided. The player to the dealer's left is known as the age, and before the deal he places a counter or counters in the pool. This stake is known as the blind or ante, but must not exceed one-half the limit. Since this stake is a compulsory one on an unknown hand, it is invariably made as low as possible, usually a single counter.

How to Play. Each player is dealt 5 cards each in turn, and after looking at his hand he may do one of three things. He may pass, in which case he throws his cards face downward on the table, and takes no further part in that particular hand. He may go in, that is, decide to play, in which case he puts in the pool double the amount of the ante. He may put in the pool double the ante and then raise the stake to the limit, or any less he chooses.

Any player who wishes to go on then must put in the amount of the raise. One player may raise the contributions one counter, the next by 2 or 3 counters, and so on; but every player who decides to play must contribute the full amount of the highest raise plus double the ante. Any player who has already contributed before a player who raises, may decide to throw in his hand and lose the counters he already has in the pool rather than risk losing more on a bad opening hand.

When all players have decided to go in or pass, each player may discard any number of cards from his hand up to 5, and receive an equal number from the dealer. The discarded cards are thrown face downward on the table, and must not be looked at by any player. This drawing of cards is known as filling the hands, and the object of each player is to improve any hand he may have. A player may have a pair, for example, and he discards 3 cards and draws a fresh 3 in the hope he may get another card to pair, or otherwise increase the value of his hand. A player who draws no cards is said to stand pat.

The drawing is all important, for by it each player tries to deceive the others as to the cards in his hand. A player may hold 4 fours and an ordinary card, for example, when the pot is opened. If he stands pat the other players may suspect the cards he holds, or assume he has in any case a flush or full hand. If he discards one card, however, and draws another, though the latter in any case cannot help him, his opponents are not sure whether he is drawing to 2 pairs, trying to complete a flush or a sequence, or even trying to make a full house when holding 3 of a kind and 2 odd cards. In the same way a player may hold 3 of a kind, and throw out only one card.

A player on the other hand may hold 4 cards of a suit and draw one card to try and get the fifth for a flush. If he fails, it does not necessarily follow that he throws his hand down at once. For all his opponents know he may have obtained his flush, or he may have been drawing to 2 pairs to try to get a full house, and so on. He may decide to bluff and boldly raise the stakes, frightening other players into the belief that he has a good hand, and inducing them to throw their hands in. If players throw in their hands the winner is not bound to show his cards, and it is therefore not known whether he was bluffing or not. It is this fact which is important in the game, for if a player is a good one, it is never a certainty whether he is bluffing or not.

The players having filled their hands bet in turn or pass out. Any player may raise the bet of the last player or decide to see him, and all cards are exposed in the last case, unless a player still to bet decides to raise. But when the players decide to see the highest bet, the cards are exposed, and the best hand takes the pool.

Other Games of Poker. In straight poker the hands are not filled as in draw poker already described, each player retaining the 5 cards originally dealt him. Each puts in the pool the same amount as ante or blind, and players pass or come in as at draw poker. If all pass the pool is added

to afresh, as for a new deal, the deal passing to the left. In stud poker one card only of each hand is dealt face downward, the remaining four being dealt face upward. The betting is as in draw poker. Jack pots is a well-known variation of poker. In this form of the game each player puts an agreed stake into the pool, which cannot be opened, that is, played for, unless some player holds either a pair of jacks in his original 5 cards, or some combination which is better than a pair of jacks. Such a player may or may not open the jack pot as he pleases. If he does so he may open it for any stake he pleases up to the limit, and each player must stake a similar amount or throw in his cards. The stake may be raised up to the limit by any players. If no player comes in except the opener of the pot, the latter takes the pool, and shows the necessary cards which are equivalent to or will beat the pair of jacks required for opening. If no player opens there is a fresh deal, each player once more contributing to the pot, and so on until the pot is opened.

POKERWORK IN VARIOUS FORMS

Appliances, Tools, and Methods for this Decorative Handicraft

This contribution explains the methods for decorating suitable materials by means of pokerwork.

Other artistic crafts treated on similar lines include Enamelling; Gesso; Lacquer; Leather; Mocassins; Papier Mâché; Stencilling; Woodcarving.

The ornamentation of wood, leather, and velvet by tracing the pattern with a hot platinum point or needle is known as pokerwork or pyrography. There are various appliances for this purpose. One of these, an electrical apparatus contained in a box, is illustrated in Figs. 1 (left) and 3. A small plate screwed on to the front panel merely needs reversing to change the voltage. The machine can be fitted with either an adapter or plug-piece, and used on any ordinary fitting.

A simple appliance is shown in Figs. 1 (right) and 2. Instead of an ordinary union, a pyro top is fitted into the neck of a bottle which is charged to two-thirds of its capacity with benzoline. It is advisable to leave the benzoline in the bottle for half an hour, if possible, before putting in the top. There is a small tap on the pyro top. When first heating the point, this should be vertical. Press the bellows slightly and light the little jet at the top of the union. Hold the platinum point in this until red hot. Then turn the tap horizontally and continue pumping to force the gas generated from the benzoline through the tube on to the point. Care must be taken never to touch any metal with the point when hot, as this will greatly damage it.

When burning wood, the point should be kept hot, so that as it burns along the outline it produces a tiny flame which will consume the smoke. There is a small attachment sold which can be fitted to the cork handle. This is called a smoke diffuser. When working on leather or velvet, the point must only be a dull red, as the method is to scorch a line and not actually to burn it. In velvet the pile only should be touched, and it is advisable to use a small, light point. For general use where only one point is available, an ordinary flat point is best, as the outlining can be done by holding the point almost upright and sideways. For the broader work, the point may be used as a modelling tool. A horn point is useful for outlining, and burns a good clear line, cutting deeper than the flat point. Shading is done by means of a shading point, or the flat point held over the wood to scorch it.

Pokerwork on Wood. The surface of the wood should be carefully prepared by rubbing over with a piece of sandpaper, and then the design is traced on it or transferred by placing the pencil side of the tracing next to the wood and going over the back with a hard pencil. Pokerwork transfers are obtainable in variety, but an original design is to be preferred where possible or one that is adapted to the shape of the particular piece to be decorated. The worker next pokers the outlines. He must use the point as a pencil and draw with it, avoiding any uneven pressure, which means a bad line. As soon as the point touches the surface, the work must be continued or a hole will be burnt. It is

wise to practise on a piece of wood, making lines, curves, etc., and in this way to determine the correct heat for the point. When the end of a line is reached, take up the point. Avoid pressing too heavily on the wood, as a line can always be deepened if necessary. The point of the needle must not be too hot if the wood is soft. If it is intended to colour the work, the outline and main shading only should be poked.

Pokerwork. Fig. 1. Two forms of apparatus used. In that shown on the left the point is heated by electricity. The right-hand one consists of a bottle of benzoline surmounted by a pyro top. Fig. 2. Showing the platinum point being heated in the benzoline flame.

*Left.
Fig. 3. The electrically heated point in use.*

Fig. 4. Tools used in some forms of this handicraft. Reading downward: small gouge, fluter, and bent-knife point for relief work.

The cabinet illustrated in Fig. 5 is an example of surface work. The design is first traced on the wood, previously prepared, then the whole of the outline is poked, using a horn point. For the fine lines a small horn point is used. The work is then lightly rubbed over with an old piece of sandpaper to remove any charred wood or grease, and stained with water stains. The dogs and the clothes of the figures are coloured in liquid enamels. (See Enamel: Flower Designs on Wood.) Antique gold bronze colour is employed for the arches of the cabinet.

A round box decorated with pokerwork and coloured with oil colours makes an excellent workbox, powder or cigarette box, according to size selected. A suitable design is shown in Fig. 7.

Make a design of conventional flowers to fit the top, and transfer it. Then poker the outline, making the larger flowers rather more pronounced than the rest of the design. Paint it in oil colours, using megilp as a medium. Make all the colours as bright as possible and outline some of the flowers in gold. Stain the edge and the rest of the box walnut colour, using two coats of stain, and wax polish.

Pokerwork. Fig. 5. Cabinet in surface poker, the finer lines of the design being worked with a horn point, and the whole finished in stains, gold bronze colour and enamels. Fig. 6. "Silvel" work on black velvet coloured with spirit stains.

Pokerwork. Fig. 7. Lid of box with simple flower design in colours. Fig. 8. Panel in relief burning, which gives the effect of carving. A, traced design outlined. B, background sunk by means of a gouge. C, modelling of the leaf begun. D, the finished leaf before colouring.

Velvet and Leather. "Silvel" pokerwork on velvet, Fig. 6, produces a good effect. The silver sheen is obtained by means of a sheath which is fixed over the point. Heat the point in the ordinary way and then try the sheath on a piece of the velvet. Most velvet pokers best going with the pile; but

there are exceptions. The whole of the outline should first be worked and the design then coloured in with spirit stains or pastels. Spray with "Silvel" fixative to make the work brighter.

Pokerwork may be used on heavy cloth to outline stencilling, and forms a decoration for the tops of floor cushions. The stencilling should be done with a strong brush to ensure a clear outline.

To use pokerwork on leather the worker should select a suitable design, and when working, the point should be kept a dull heat, as only surface burning is required. The whole of the design should be poked and the necessary colouring then done. To make important parts of the design stand out use lacquer and bronze colours. The rest of the leather should be stained a dark colour to tone, and the whole should be wax polished.

Relief Poker Work. Relief-burning, which is an advanced form of pyrography, has the appearance of carving when finished and can be used to decorate furniture. A different point is needed, called a bent-knife (Fig. 4). The work should be cramped to a table.

The point must be made very hot, and after the design has been traced it should be outlined as at A, Fig. 8. The line should be burnt to about $\frac{1}{8}$ in. deep, holding the bent-knife almost parallel to the surface of the wood. It should not be allowed to lean to either side, and is held more upright in going round a curve. It is essential to have a clean outline, and it is best to cut the outline outside the design. A little methylated spirit rubbed lightly over the surface to be burnt will prevent the wood from charring too much. Should there be an angle in the design, begin each line from the corner.

The next thing is to sink the background. This can be burnt out with the point, but it uses the points a great deal and causes excessive smoking. It is much quicker and easier to use a small gouge, as in Fig. 4. For large spaces a larger gouge can be employed. Carve out the wood across the grain as far as possible to prevent tearing it, and do not cut too deeply at first. Be careful not to damage the design. It is most important to keep the tool well sharpened. Fig. 8, B shows the background carved out.

Before attempting the modelling study a similar subject, and determine which portions of the design require to be sunk. The edges are left and the portions of a leaf on either side of the centre vein. It is a good plan to start from the centre of the leaf, using the flat side of the bent-knife, and gradually to work almost to the edge, pressing a little heavier to make a depression. This is often done by means of the gouge in order to save the point (Fig. 8, C).

A fluter, another carving tool, shown in Fig. 4, is used to make a groove for the centre vein. The point is used to smooth away any irregularities and put in the finishing touches. The veins must be put in, using the edge of the point, and the background burnt even. It is necessary from time to time to brush over the work with a wire brush to remove the charred wood; and if the work is not sharp enough after this operation, touch it up again with the point. An uncoloured leaf is shown at D, Fig. 8. The colouring should be as soft as possible, merely to enhance the value of the carving, not to supersede it. The background should be stained to match the other furniture. Marquetry stains are best.

When polishing a large surface or an elaborate piece of work, coat it all over with liquid wax polish, using a soft brush. Allow this to become dry. Then smear a little wax polish on a piece of wood. Take a soft brush and brush this over the wood, up and down, until the polish is spread evenly over the surface of the brush. Then brush over the work, following the direction of the grain of the wood. Do this several times, leaving the work a few hours between each rubbing.

POKERWORK: ON VARIOUS MATERIALS

1. Leather box worked with poker needle and coloured with leather stains. 2. Chair back in fustanella, first stencilled in oil colours and then outlined with poker needle. 3. Box with simple flower design in colours. 4. Silvel work on black velvet coloured with spirit stains. 5. Table cover in velveteen coloured with pastels. 6. Velvet table centre with chrysanthemum design. 7. Workbox with poker work design finished in oil colours.

POKE WEED. The hardy perennial poke-weed (*Phytolacca decandra*), sometimes called the red ink plant, is suitable chiefly for the shrubbery or wild garden. It forms a large bush 5 ft. or more high, with white flowers, succeeded by purple berries during autumn. The plant will grow in any ordinary soil, but can only be recommended for the effect which is produced by its berries. The roots of the plant are poisonous.

Pole: The Measure. *See* Rod.

Polemonium. *See* Jacob's Ladder.

POLENTA. Served with liver and bacon, polenta makes a good supper, luncheon, or breakfast dish. To prepare it, boil up 4 teacupfuls milk and water mixed in any proportions, adding salt to taste: sprinkle in 1¼ teacupfuls maize meal, and stir the whole over the fire for about 10 min. Then draw the pan to the side of the fire and cook its contents slowly for about 1 hour, stirring them occasionally.

When cooked, spread the mixture on a plate, allow it to get cold, and then cut it into squares. Fry the latter in a pan of fat or bake them in the oven until they are crisp. Serve the cakes with a slice of liver and bacon on each, and some good gravy.

POLISH. Any preparation that is used to produce a glossy surface on wood, leather, plate, linoleum, etc., is known as a polish. It is sold in liquid and paste form, and is usually applied on a rag or brush. Various kinds of polishes, such as those used for cleaning boots, brass, and furniture, are employed regularly in the home. *See* Boot Polish; Floor Polish; Furniture Cream and Polish; Metal Polish.

POLISHING: FINISHES FOR VARIOUS SURFACES

Effective Methods of Treating Wood and Metal

Reference may be made to the article on Furniture and to those on the various pieces of furniture that can be treated in this way, e.g. Table. *See* also French Polishing; Labour Saving; Stain.

The process of french polishing is described in a separate article under that heading. As a substitute for french polishing the process known as glazing will be found useful. Glaze can be purchased ready made, but is easily prepared by dissolving 3 oz. of gum benzoin in ½ pint of methylated spirit. The mixture should be allowed to stand for several days before use, as it improves by keeping. The surface of the wood should first be filled and rendered perfectly smooth with fine glass paper. A body of ordinary polish is then applied, as described in the article on french polishing.

The glaze can be applied with a brush, but it is customary to use a rubber and paint it on, applying it in the direction of the grain. The method is to dip the rubber in the glaze, which should be placed in a saucer, and wipe it over the work quickly, lightly, and evenly, taking care not to go over the surface twice until the first application is dry. With wide surfaces some experience is necessary, and unless great care is used the surface will be left in ridges. This may be avoided by using a wide camel-hair brush, but practice will enable the largest surfaces to be successfully treated with the rubber, which is by far the better method.

Eggshell finish can be obtained with a glaze finish by adding about one-third of sandarac to the mixture of benzoin and spirits; the finest finish is obtained by rubbing down the finished polished surface with pumice powder, applied with a piece of felt slightly lubricated with raw linseed oil. Dip the felt into the oil, place on it some pumice powder, and rub well over the work with an even,

circular motion. The pressure applied although not light must not be heavy; the rubber must be kept supplied with powder and enough, but not too much, oil. When the surface has been dulled evenly all over it should be rubbed down with a clean rag and wiped over with benzoin. Small mouldings or carvings can be rubbed with a brush.

Oil Polish. Oil polishing has several advantages over other forms of surface finishing, and is particularly effective on oak. It does not crack or blister, neither does it show marks made with water, but it requires time and a considerable amount of friction. Prepare linseed oil by placing a quantity into a vessel, surround it with water, and allow it to simmer on a gas stove for about $\frac{1}{4}$ hour. Pour it into a bottle, and add one-eighth the quantity of turpentine. Apply the oil with a felt or flannel rubber and rub it thoroughly into the wood. It is possible to apply too much oil, but the amount of rubbing cannot be overdone. The work should be carried on over a period of 2 or 3 weeks at least; a little oil and plenty of rubbing every day or every-other day. When a suitable polish has been obtained and the work shows signs of sweating, a little methylated spirits can be rubbed over the surface, as this will dry it without spoiling the polish. Further applications of oil can be applied if required, and the spirit finishing will not affect it in any way.

Floors can be polished with oil polish applied with a pad made by wrapping some flannel round an old brush; by applying the oil polish to a stained floor and thoroughly rubbing it in, a lasting polish will result.

Polishing. Fig. 1. Rubber for wax or oil polishing. Fig. 2. Pounce bag of muslin for holding pumice. Fig. 3. Rubber made of rag for use in surface filling. Fig. 4. Method of using rubber by making continuous strokes with circular movement. Fig. 5. How the rubber is held.

Wax Polish. Wax polishing may be used on any kind of wood and gives an eggshell gloss which is most effective on oak, mahogany and walnut. Either white or yellow wax should be shredded, placed in turpentine, and left to dissolve. The consistency of the mixture should be that of cream. It is applied with brush or rubber, and must be evenly distributed and thoroughly well rubbed in. A dry rag should be used for finishing, but a good body of polish must be applied if the finish is to last. The finest effects of wax polishing are obtained by giving the surface a body of french polish, rubbing the surface down with pumice powder, and then applying the wax polish; but if ordinary wood is properly filled and thoroughly cleaned down with fine glass paper a satisfactory polish can as a general rule be quite easily obtained.

Carved and Pierced Work. The treatment of carved work depends mainly on its surroundings, and generally a high polish is not desirable. The most suitable method is to cover the work with raw linseed oil, allow it to stand for a few hours, and wipe it off with a soft rag. After 2 or 3 applications, followed by vigorous rubbing, the groundwork will remain dull, but a soft polish will appear on the raised parts. Although a body of french polish can be applied to carved work, and some portions brought to a high polish, the better medium for woods like oak, walnut and mahogany is a creamy mixture of beeswax, turpentine, and boiled linseed oil applied with a rag, or brushed and rubbed down.

Fretwork and pierced woodwork are more difficult to polish owing to the broken surface. With wax or oil, it is mainly a matter of working into the crevices, but with french polish, a particularly light touch is required. The edges of large pierced surfaces, especially the end grain, should be filled with size or a prepared filler, and well smoothed down. The polish can then be applied on a small pad made by wrapping a little cotton wool round a thin stick and covering it with soft rag.

Treatment of Stains and Cracks. The repolishing of surfaces which have become stained usually means the removal of the old polish, in many cases right down to the surface of the wood. If the surface is dented, it may mean planing, or, at least, filling the surface to bring it up smooth and level. Special preparations for removing old polish can be obtained, but the usual method is to soak the surface with methylated spirit to soften the shellac, and rub it with a coarse rag. Glass paper will then be sufficient to take the top surface off. Unless the work is dented or cracked, or the stains go too far down, it is better to leave the original body so that a fresh surface of polish can be applied. With veneered surfaces, the greatest care must be taken. If the veneer is damaged, repairs can often be effected by the application of a hard filler, or by the use of wax.

Defects in polished surfaces do not always show at once, but when they do, they should be remedied as soon as possible. The commonest defect in french polishing is known as sweating, and is caused by the excessive use of oil, which breaks through the hardened surface. It is difficult to treat, as any further hardening of the surface will be affected in the same way. Continual application of furniture cream will keep the surface bright, but until the surplus oil embodied in the polish has worked out, further french polishing will do no good. Cracks which may have occurred on a french-polished surface can only be removed by rubbing the whole of the surface down with pumice powder, and then repolishing in the ordinary way.

White marks on a french-polished surface may be caused by defective materials, or by water or spirit stains on a glazed or poorly finished surface. The best way to remove them is to take off the top surface and repolish; to put a new coat of polish on the old one, without removing the stains, is not advisable. Light stains can be taken out by wiping the surface with linseed oil and then rubbing it lightly with a rag dipped in methylated spirit. If the stains are caused by hot plates, the only thing to do is to rub the surface down and repolish.

Polishing Metal. The polishing of metal surfaces can be done in many cases by purely mechanical means or alternatively by hand. Polishing wheels of various kinds can be fitted to the lathe or arranged separately on a special bench fitted with a polishing head and a fly-wheel. A useful polishing head with a drill chuck, etc., can be bought for a few shillings. Hand polishing, essential for some work, is done with rifflers, emery cloth and buffing sticks.

In machine-polishing, turned work is first rubbed down with emery cloth, finishing with the finest grade. The surface should be left free from scratches, for all subsequent work depends on the quality of the emery finish. As a rule, the emery cloth is used in conjunction with a piece of wood.

The next process is to apply pumice powder by means of a buffing stick, made by glueing strips of basil leather to wood strips of convenient size. For iron and steel it will generally be sufficient to complete the polishing with pumice powder, but a high finish can be obtained by using flour of emery and oil. To obtain a good surface on turned brass in the lathe, first use emery cloth, then pumice powder, and finish with powdered rotten-stone and oil.

By the use of a polishing head, with wire scratch brushes and polishing mops—and these can also be attached to a lathe—much more rapid results are obtained. The scratch brush is made of hard brass wire and used with vinegar and water or stale beer to produce a lather so that a scouring effect results.

For further finishing, brushes made of bristles, leather, calico and swansdown are suitable for applying pumice, rotten-stone and other polishing powders. As a rule the brush is revolved towards the article and the worker, and the highest speed is used for the final polish. The highest possible finish for brass and copper articles is obtained by the use of crocus powder applied with a calico mop. Silver can be scoured with a scratch brush, then treated with rotten-stone and oil and finished with rouge and water, the highest gloss being obtained by burnishing.

POLKA. The polka is danced to 2-4 time, and consists of light, springing, semicircular movements of three steps each. The original movement was to start off with a little spring, so that counting in teaching is spring 1, 2, 3, and not 1, 2, 3, spring. *See* Dance; Dancing.

POLLACK. Known in Scotland as lythe, the pollack is a large fish of the cod tribe with protruding jaws, and is rich in oil. It is cooked by the same methods employed for cod. Plain boiled or steamed is perhaps the best way to cook it, but it requires a well-flavoured sauce. Large fish of this description can be baked with advantage. They should be cut into slices or steaks, laid in a deep dish well lined with butter, sprinkled with seasoning and lemon-juice, covered with buttered or greased paper, and baked until cooked through to the bone. Pollack should be served accompanied by piquant or shrimp sauce.

Occasionally the name of pollack is applied to the coal fish, also to some descriptions of fresh-water fish; but these are of a different species. A small fish of delicate flavour found in some of the Scottish lakes is called a pollack, but has, however, no relation to the other varieties of fresh-water pollack. *See* Cod; Fish; Sauce.

POLLINATION. In gardening pollination is the process of self or cross fertilization. It means the placing of pollen on the stigma of the same or a different flower whence it was taken. There are three natural methods and one artificial, the first being effected by insects, self-agency, or wind; the latter by the hybridist, with the object of securing fresh varieties of flowers, fruit, or vegetables.

When the pollen is placed on the same flower, or another upon the same plant, it is termed self-pollination; but if transferred by insects, wind, or hybridizer to the flower of another variety, it is called cross-fertilization.

POLONY. A description of dry sausage known as polony, and first made at Bologna. is a sausage which has been either boiled or smoked, and is fit for consumption without further cooking. The polony is a mixture of finely minced meat, highly seasoned and spiced. In the best varieties lean beef, ham or pork is used as a foundation, with portions of fat bacon interspersing the lean. The sausage is flavoured with chives or onions, spiced with mace or nutmeg and seasoned with salt and black pepper. A large clean sausage skin is then filled with the mixture, and it is boiled for 2 or 3 hours, or smoked for several weeks. If boiled the skin must be frequently pricked with a needle to keep it from bursting. In some parts of the country the skins are dyed a bright red. This skin is not edible. Sometimes strings of dried or smoked sausages are called polonies.

POLYANTHA ROSE. The dwarf polyantha, or baby rambler roses, as they are popularly called, vary in height from 12 to 36 in. and bear bunches of single, semi-double or double flowers in summer and autumn. They are useful for planting in flower beds or as an edging to large borders and for cultivation in pots under glass. They need the same treatment as other low growing roses. Pruning, done in early April, is severe or light according to whether small or large bushes are wanted.

The older type of dwarf polyantha rose is of low growth, 12-18 in., with bunches of small flowers. Some of the newer varieties are taller and more vigorous and bear larger blooms. A few of the best are Karen Poulsen, crimson-scarlet, Eblouissant, bright crimson, Ellen Poulsen, rose, Else Poulsen, light pink, Gloria Mundi, orange salmon, Katherine Zeimet, white, Kersbergen, dark red and Mrs. Cutbush, pink.

POLYANTHUS. The bunch-flowered primrose called polyanthus is one of the loveliest of spring flowers. The modern strains are distinguished by vigorous growth and large clusters of bloom of rich and varied colouring—crimson, orange, yellow, and cream. They are invaluable for spring bedding. Seeds are sown in boxes of fine soil or on a prepared seed bed out of doors in May. The seedlings are grown on a reserve border during the summer and in October are planted where they are to bloom in April-May. Another method of propagation is to lift the plants after they have finished flowering, separate them into pieces each with a few roots attached and replant them on a reserve border for the summer. A slightly shady place suits them best at that season. The old gold-laced polyanthus is now little grown except for exhibition purposes.

Polyanthus. Blossom heads of this many-coloured spring flowering primula.

POLYANTHUS NARCISSUS. The bunch-flowered or polyanthus narcissus (tazetta) is valuable for cultivation in pots under glass, in bowls of fibre indoors and in beds and borders out of doors. They need the same treatment as other forms of narcissus. The old small-flowered varieties have been superseded by others raised by cross-breeding between them and the poets' narcissus (poeticus); they are called poetae narcissi. These are more vigorous and altogether finer plants with large bunches of fragrant showy flowers: they are also hardier than the old type.

Some of the best of them are *Aspasia*, *Elvira*, *Jaune à Merveille*, *Klondyke*, and *Orange Cup*: they have white, cream-white, or yellow perianth, with cup or centre of yellow, orange, or orange-red. *See Narcissus*.

POLYGONUM. Knotweed is the common name of this group of hardy plants, some of which are valuable for the rock garden or border. Others spread very rapidly and may soon prove a nuisance in gardens of moderate size. The most familiar is a rampant climbing plant, *Polygonum baldschuanicum*, which is useful for covering a trellis or arbour, while it looks well if allowed to clamber over an evergreen. It bears bunches of small white flowers in early and late summer. Two pretty little plants for the rock garden front of the border are *affine*, 6 in., and *Bistorta*, 24 in., both bear rose-coloured flowers in late summer. *Cuspidatum* and *sacchalinese*, which grow 8 or 10 ft. high and bear white flowers in late summer, spread quickly, and it is difficult to get rid of them. They look well in the wild garden or shrubbery. A half hardy silvery-leaved plant. *Polygonum lanigerum*, is often used for summer bedding.

POLYPODY. This is the popular name of a genus of ferns, called botanically *polypodium*. The common polypody (vulgar) is a hardy evergreen fern, 12 in. or more high, which likes a shady place and soil with which leaf-mould or peat and sand have been mixed. There are many attractive named varieties of this fern. The beech fern (*Polypodium phegopteris*) and the oak fern (*Polypodium dryopteris*) are other popular kinds. Many polypodiums need to be grown in a warm, moist atmosphere under glass and must be shaded from sunshine. A suitable compost is made by mixing loam, leaf-mould and peat in equal proportions, and adding sand freely. Some of them are *Knightae*, *nigrescens*, *Smithianum*, *Mayi* and *schneiderianum*.

POLYSTICHUM. The greenhouse and hardy evergreen fern *polystichum* is known as shield fern from the curious shape of its leaves. Culture is not difficult if protection from the rays of the sun is afforded, whether in the heated house or open garden. *See Fern*.

POMEGRANATE. This is a flowering and fruiting shrub (*Punica Granatum*) which is suitable only for planting in a well-drained border of loamy soil at the foot of a sunny wall in comparatively mild districts. Only in exceptionally favourable seasons are fruits likely to develop. The pomegranate bears scarlet flowers, but not, as a rule, very freely in Great Britain. Little pruning is needed.

The fruit consists of seeds ripened in a tough, yellowish-red, leathery case. The seeds only should be eaten, the bitter yellow skin that surrounds them being pulled away after the fruit has been peeled. Pomegranates should not be cut open unless they are to be eaten at once, for the seeds quickly become discoloured. The juice of the pomegranate stains badly, and is difficult to remove from light materials; but the general methods recommended for taking out fruit stains may be tried. *See Fruit*.

Pomegranate. Two specimens of the ripe warm-coloured fruit.

POMERANIAN DOG. A splendid house guard and a devoted companion, the Pomeranian in his original stature adds a handsome appearance to his other good qualities. Formerly weighing from 10 lb. to 20 lb., he has now been bred more from the toy point of view, and present-day examples are mostly under the 7 lb. limit of the miniature class. The head is much like that of the fox, with a sharp muzzle, dark eyes, and small, erect ears. The neck and body are short and compact, the body rounded and deep chested; legs straight, fine boned, and well feathered; feet small. There are two coats, the under soft and fluffy, the upper long and rather harsh, standing out straight like a frill around the neck, shoulders, and chest. The tail, too, which is carried flat over the back, is profusely covered with long stiff hair. All colours are admissible, either selfs or parti-coloured in patches; but the selfs are preferable. Except white selfs, no pom should have white feet. Most poms were pure white until pure blacks became fashionable. *See Dog; Kennel; Mange; Rabies, etc.*

Pomeranian. Prizewinner of a breed of toy dog which makes a good house guard.

POMPON: In Dress. This soft, fluffy ball is used for fancy dress, especially for pierrot costumes, and also for finishing the ends of a girdle for a dressing-gown.

To make pompons of wool or knitting silk, cut two rounds of cardboard a little larger than the required pompon. In the centre of each cut a round hole, about a third of the diameter of the whole round. Place the two cardboard rings together, and wind the wool, which can be all one colour or many different ones, round them, passing it through the hole in the centre. If the pompon is to be a small one, the

wool must be threaded through a needle; and even if it is to be large, a needle will be required when the hole is nearly filled.

Only when the hole is completely full has enough wool been used. Then thread a bodkin with several strands of wool, and slip it all round the circumference, under the edge of the wool, so that the two ends of wool come out in the same place. Pull them carefully but tightly, so that the strands passing round the circumference slip between the two cardboard circles. Then put the point of a pair of scissors just between the cards, and cut the wool all round. Draw the strands as tightly as possible and tie them firmly, leaving the two long ends for attaching the pompon. Then cut the cardboard away, and the pompon is finished. A woolly ball for a child can be made in the same way.

POMPON: In the Garden. This name is given to certain varieties of chrysanthemum and dahlia which bear small, round blooms. *See Chrysanthemum; Flower Garden.*

POND. A pond is a pool of standing water. Ornamental ponds are found in a number of gardens, in which they form a picturesque feature. The pond should always be made in the open clear away from trees. Board fences close to the pond are also objectionable, because they hinder the continuous circulation of warm and cold air. The exact top of a hill is always chosen in preference to other sites, as it affords ideal conditions for the downward flow of constantly fresh supplies of air. The pond should be quite shallow; in shape it should resemble a saucer rather than a bowl.

The Soil. If the soil is well drained and of a dry nature, such as the Sussex chalk or the Surrey gravel, all that is needed is to select a site on level ground to preclude the possibility of disaster being caused by small surface rivulets in time of heavy rain. Given such a site the pond can be dug

out, thickly lined with straw or reeds, covered with a good crust of carefully puddled clay, extending well out over the margin of the straw to keep it dry, and the clay protected by a thick layer of stones or pebbles.

If the soil is lowland clay or loam, a pond sunk below ground level is doomed to fail, and it is better to have the whole of the pond above ground. This may be arranged by building a low skirting wall with drainage holes through it at intervals round the base, forming the surface of the ground inside to a slight rise in the centre, paving the bottom with concrete or otherwise to prevent interference by earthworms, and then putting in the lagging, puddle, and stones. Dew ponds do not require artificial flooding when constructed, as they commence work from the dry of their own accord.

A Dew Pond. This is an artificial basin with a layer of material that is a good nonconductor of heat below. It has the remarkable property that dew forms on it in greater quantity than on surrounding objects, and that it will also collect dew on nights when the country in general gets none. The supply of dew at night during a dry summer is adequate not only to compensate for evaporation by day, but also to afford a valuable supply of water; for instance, in the otherwise waterless parts of the down country of the south of England, all stock are watered at dew ponds.

The reason why a dew pond supplies itself with water is really very simple when it is properly understood. On a calm and cloudless night the air which has been warmed during the day tends to cool rapidly by radiation of heat out into space, while at the same time the warm earth radiates heat up into the air; the result is that the air, which is losing heat above, but receiving some compensation from below, cools slowly, so that dew is likely to be deposited on the ground in small quantity towards the end of the night when the air temperature has dropped low enough to cause condensation of the water vapour in it.

Now a dew pond, with such water as it contains already, may be considered as a patch of land over which a shallow surface layer is cut off from all heat communication with the deeper-seated levels of the soil; hence the dew pond gets quite cold by radiation quite early in the night, after which it ceases to keep the air above it warm by further supplies of radiant heat. The consequence is that the air above the pond becomes so cold, by itself radiating its heat upward, especially at the bottom where it is in contact with the cold pond, that it deposits dew in the pond basin. Again, the coldness of the column of air above the water causes it to descend on to the pond surface, deposit its dew, and flow away horizontally. *See Dutch Garden; Lily Pool.*

PONGEE. Unbleached, brownish, handmade silk from N. China is the original pongee. It is plain, but has irregularities in the thickness of its threads. The material has a crispness which softens a little after repeated washings.

PONY: How to Keep. In many country houses a pony is kept either for the children to ride, for pulling a lawn mower, or for light road work in a governess cart. Being smaller than a horse, it costs less to feed; it is also much hardier, and can therefore be run at grass in a small paddock during the greater part of the year. There are several distinct breeds in Great Britain, the main varieties being the Shetland, Welsh, New Forest, Dartmoor, Exmoor, and the Hackney. Next to the Hackney the Welsh is probably the best, but for real hardiness the Shetland cannot be surpassed.

A good pony should have short legs and sound feet. Too many have narrow feet, contracted at the heels. It must be surefooted and free from tricks. If required for saddle work it must have an oblique, not up-right, shoulder.

As for colour, the best ponies are light and dark bay, blue roan, red roan, brown, and grey. There are good chestnuts, but chestnut is not a hard colour, nor is black. A pony may be kept in a shed if left unclipped, but a stable is preferable. A pony stable may be built cheaply out of wood, with a

galvanized iron roof, but whatever the material it is essential the floor should be sound and well drained.

Feeding the Animals. As a rule, ponies are less dainty than horses, and therefore less difficult to feed. A pony at regular work will require 6 to 8 lb. of oats or similar food daily, but if not required for work may be run out at grass. It is well to bring the animal in at night and give it a small amount of hay. If turned to pasture for some considerable time, it is a good practice to remove the shoes, but tips should be fixed to the forefeet in order to prevent the horn from becoming broken. A good supply of fresh water must be arranged for. In summer a pony will require some 5 gallons a day.

In the matter of feeding, a mixed diet is best. It can consist of oats, beans, maize, bran, and chaff. In buying oats it is necessary to avoid those which are broken or dusty. Good oats should be plump, not too dark coloured, and quite free from any musty smell. Some horses and ponies do better on crushed or braised than on whole oats. Maize is useful for a pony in poor condition, because of its fattening qualities. Beans form a strong and stimulating food, but should be at least a year old before being used. Barley is inferior to oats as a food for horses or ponies. If a ration of lentils is given it should not exceed $\frac{1}{2}$ lb. daily. A little bran is useful for an animal that is not getting green food.

As a rule, a mixture of oats with chopped hay is the staple food for all ponies kept in stables. Condiments may be given at times, but any excess of treacly or sugary matter is not good. A little linseed is beneficial to the animal's coat, and a bran mash should be given 2 or 3 times a week. The best hay is that from upland pastures. Hay that is burned or mow-heated is always a poor investment. Good hay can be told by its unmistakable fragrance. All ponies are fond of carrots, a few of which should be given at intervals. Swedes form a good substitute if carrots are unobtainable. Under no circumstances should a pony be fed while hot from exercise. A good driver, however, does not bring in his animal in a state of perspiration, but allows it to go quietly for the last mile of the journey, and so to come in cool.

Grooming and Bedding. In the matter of grooming it is essential to remove mud as soon as possible from a pony's feet and legs. The feet of an animal standing in the stable must be cleaned with a hoof pick at least twice a day. Shoeing must be done with care. Many smiths are prone to cut away too much of the horn in shoeing, with the result that the animal soon goes lame. A pony that is kept clipped will require to be covered by a blanket while standing in the stable.

Good bedding is essential, but for a pony it is not necessary to go to the expense of straw. In most country districts bracken is obtainable, and forms a useful substitute; it is cut usually in September, and can be dried easily and stacked. Bracken is distinctly preferable to sawdust or pine needles. The bedding must be forked over daily, and, if possible, turned out in the air to dry. If a pony is allowed to stand on wet and fermenting bedding its health and feet alike are certain to suffer. *See Horse; Stables.*

POODLE. This dog is not so well fitted to be a home companion as most other domestic breeds, as he is neither so affectionate nor so reliable in temper. Moreover, to keep him in good companionable condition may involve considerable work. His coat is the chief trouble; though the very long hairs are hard, they are much disposed to tangle, and the daily use of the comb and brush is a necessity. This is the reason why most poodles have a great part of the coat clipped closely or even shaved, leaving tufts at certain points, which give the animal a grotesque appearance.

Without constant grooming the hair twines up into long cords which trail along the ground and require oiling, which soon renders the dog unpleasant company indoors.

Regular combing, by getting rid of the shed hairs, reduces the length of the coat, and this curls instead of cording. Even so, the Poodle Club recommends that a third of the body should be clipped or shaved.

The colour of a good poodle should be unmixed, that is to say, all black, all white, all red, or all blue. See Bog; Kennel; Mange, etc.

Poodle. A dog which owes its grotesque appearance to the manner of clipping its coat.

POOL. This ball game is played on a billiard table by a number of persons. For it special balls are provided, each of these being a different colour, white, red, yellow, green, brown, blue, pink, and then, if necessary, the same colours in the same order, spotted. Each player has his own ball, and they play in turn, the sequence of the colours being set out on the scoring board in the order mentioned above. The game is for each player to play at the ball of the previous player in order to pocket it.

Method of Play. The players must first determine by lot, or by some other convenient method, the choice of the balls. Each player starts with three lives. The owner of the white ball places it on the spot, the owner of the red ball plays at it, and at the end of his break the next in order follows. The striker's ball must hit the one at which he is playing. If the latter ball is lawfully pocketed its owner pays a forfeit, loses a life, and his ball remains in hand until his turn arrives again. The one who pockets a ball continues to play, aiming at the ball nearest to where his own rests. If he can continue to play until all the balls on the table are pocketed, he places his ball on the spot, and the next player plays from hand. If the striker fails to score or makes a foul, the next in turn plays.

In pools of less than four players, the game continues until all the players but one have lost their lives. The surviving player then takes the whole pool. In pools of four or more players, when only two players are left in with an equal number of lives, they divide the pool. If they have an unequal number of lives, the game is continued until the number becomes equal, when they divide, or until one loses all his lives, when the survivor takes the whole pool. It is provided, however, in all cases that a striker who has lawfully pocketed a ball has the option of either continuing his break or dividing.

Starring. The first player who loses his three lives is entitled to purchase a star by paying into the pool the value of three lives, for which he receives as many lives as there remain to the player or players with the lowest number. The player, however, must decide whether he will star or not before the next stroke is played. If the first player who is out refuses to star, the second may do so; if the second refuses, the third may do so, and so on until two only are left in the pool, in which case the privilege ceases.

If before a star two or more balls are pocketed by the same stroke, including the ball played at, each having one life, the owner of the ball first struck has the option of starring. If he refuses, and more than one remains, the persons to whom they belong must draw lots for the star. If the balls pocketed do not include the ball played at, their owners must draw lots for the star.

Only one star is allowed in a pool of six players, but two stars are allowed in a pool of seven or more players. The player taking a second star pays double the amount of the first star. The same player may take both stars.

No convenient method of handicapping at pool has been devised. The handicap of starting with two lives instead of three is a very severe one. The best player, however, may arrange to divide, in the proportion of their remaining lives, at the request of the player who survives with him to the end of the pool. The best player may also agree not to star. This information is taken from the rules of the Billiards Association. *See* Billiards; Russian Pool; Snooker Pool.

P.O.P.: In Photography. Printing-out paper, or P.O.P., is used for the printing of pictures from photographic negatives. It is so called from the fact that when the paper is exposed to daylight behind a negative, the picture gradually prints out until it attains its full depth. It is one of the easiest photographic papers, but is less popular since a still simpler variety, namely self-toning paper, has largely taken its place. P.O.P. prints require to be toned in order to give them a pleasing colour; prints on self-toning paper, however, have only to be fixed, since gold contained in the coating produces the toning action when the prints are placed in the fixing bath.

P.O.P. is made by almost every manufacturer of photographic papers in several varieties, differing chiefly in surface. There are three descriptions of the paper, matt, semi-matt, and glossy, the last-named being chiefly used, as it gives the utmost detail in the pictures. Sensitive P.O.P. postcards are made for the production of photographs of this size. P.O.P. is used almost exclusively for printing from small negatives on account of its rendering of detail. It cannot be used for enlargements or for printing by artificial light, since the low sensitiveness of the paper makes it necessary to use daylight in printing.

When exposing the paper behind the negative, it is necessary to allow the light to act until the picture is very much darker than it is required to be when finished. The print is, therefore, examined from time to time by turning back one half of the printing frame. The correct degree of printing is reached when the shadows of the picture have a choked-up appearance, and when the highlights (the sky) are perceptibly of deeper tone than a pure white. In ordinary good daylight, printing will be completed in from 5 to 15 min., according to the density of the negative. Some practice is needed in hitting the exact degree of over-printing correctly; more over-printing is needed when a negative prints quickly, say, in 5 min., than when printing occupies a longer time.

A number of prints having been made, they require to be toned and fixed in order to change the reddish colour of the prints to an agreeable purple or purplish brown. The most satisfactory method for the beginner is to tone and fix at the same time, in a single solution which contains gold chloride for the toning and hypo for the fixing, with other chemicals necessary for the process. This combined bath, as it is called, is best purchased in liquid form, or as a powder requiring to be dissolved in the requisite quantity of water.

The prints, without any previous washing, are placed one by one face down in the combined bath, and kept on the move. When the prints have taken on an agreeable purplish tone, transfer them to a dish of water and give them a thorough washing by allowing the water from a tap to run into the dish for about one hour. During this time the prints must not be allowed to clot together, otherwise the water does not obtain free access and the chemicals are not removed.

As a safeguard, and particularly if prints tone quickly, e.g. in less than 5 min., it is advisable to use an additional solution for extra fixing. This is made by dissolving 3 oz. of hypo in 20 oz. of water. Prints are transferred direct to it from the combined toning bath, and kept moving in it for about 10 min. After the washing process the prints are laid face up on blotting paper, or clipped up on a line to dry. On no account must they be put face down on anything, or heated, as the sticky gelatine surface will be spoilt. *See* Printing; Self-Toning Paper.

POPCORN. This is an American dish made with maize or Indian corn. The unripe grains are parched over the fire until the heat bursts them open and the centre of the grain is exposed. In this

condition it is eaten and considered a great delicacy. The best maize to use for popcorn is that with a smallish grain.

Popcorn is also sold as a sweetmeat. The grains are popped, and coated with either pink or white sugar very much in the same manner as is a sugar plum.

POPE JOAN. This card game is played with a special board, which consists of a circular tray or board revolving on a central post or stand. The tray is divided by lines running from the centre to the circumference into 8 compartments, each of which will hold 100 or 150 counters. Each division has a name, these being pope, king, matrimony, queen, intrigue, knave, ace, and game. Pope is the nine of diamonds, matrimony is king and queen in the same hand; intrigue is queen and knave. The ace counts the lowest.

The game is played with a full pack, save that the eight of diamonds is withdrawn. This card, and also the four kings, are stops, i.e. a sequence stops when one of them is reached. The cards are dealt round to the players, and the last is turned up for trumps. An extra hand is dealt to the centre of the table, and the cards therein are stops, as are those just before the ones that have been already led in play. Each player contributes an agreed number of counters for the stake, and these are distributed among the several compartments of the tray.

The elder hand, i.e. the player on the dealer's left, leads any card he likes, at the same time naming it. The next to play is the person who holds the next highest card in that suit, who also names it. This continues until no one can play a higher card, when the one who played last leads again, and the process is repeated. When the sequence is thus stopped, the cards previously played are turned face downward.

During the game a player who plays king, queen, ace, or knave of the trump suit or pope takes the counter or counters in the corresponding compartment of the board. If he plays both king and queen of trumps, he takes those from the matrimony compartment; if he takes queen and knave of trumps, those in intrigue. If the card turned up for trumps is ace, king, queen, knave, or pope, the dealer takes the counters in the compartment concerned. The aim of each player is to get rid of all his cards, and the one who does this is the winner. He is entitled to the counters from the game compartment, and also to one counter from each of the other players. The holder of the pope, if the card is still in his hand, does not pay this counter. If, however, he has played it, he does.

If, as is usually the case, counters remain in some of the compartments when the game is over, the cards are dealt round face upward in order to see who shall take the spoil. Those who obtain ace, king, queen, and knave of diamonds take the counters in those divisions, if there are any; pope entitles its receiver to the counters in that division. The counters in matrimony, if any, are divided between the holders of the king and queen of diamonds, and those in intrigue between the holders of queen and knave.

POPLAR: The Tree. Few trees grow more quickly than the poplar and it will flourish in damp low-lying land unsuitable for many other kinds. The best known is the Lombardy poplar (*Populus nigra pyramidalis*), a tall tree of columnar form; it makes a good windbreak or screen if pollarded to make it spread when the desired height is reached. The white poplar (*Populus alba*) and the aspen (*Populus tremula*), which is distinguished by the possession of leaves which quiver in the slightest breeze, are other kinds. Most of the poplars are easily increased by cuttings set out of doors in autumn. The aspen is usually propagated by suckers.

Uses of the Wood. Poplar, although not a wood of much commercial value, nor always obtainable from timber dealers, is useful for numerous purposes. It is used for sugar and herring barrels, packing cases, matches, clothes pegs, chums, pails, clogs, and wood wool or shavings for packing;

also for brake blocks, the bottoms and sides of carts, wagons and barrows, and sometimes for field hurdles. It is soft, light and porous, easily dented, but does not splinter so easily as most woods and does not bum readily. It shrinks a great deal and is not very strong or durable, but is easy to work and seldom split by nails, though it holds nails well. In colour it is light grey or pale yellowish brown. *See Wood.*

POPLIN. Irish poplin is a combination of silk and wool, slightly ribbed, firm and warm without being stiff and heavy.

Cotton poplins, plain-coloured or striped, are the chief poplins in use for curtains and light upholstery fabrics. They are obtainable in a wide range of colours and guaranteed fadeless.

POPPY: The Flower. Three kinds of poppy are invaluable hardy garden flowers: the oriental, which is perennial, the Iceland, which is biennial, and various types of annual poppies. The oriental poppy (*Papaver orientale*) thrives in ordinary well-tilled soil and bears large handsome blooms in crimson, scarlet, rose, salmon and other colours in May and June. It dislikes being disturbed and should not be transplanted unnecessarily: it is increased by sowing seeds in May or by taking root cuttings in autumn. There are many named varieties.

The Iceland poppy (*Papaver nudicaule*) is grown in gardens as a biennial, seeds being sown in boxes of fine soil or out of doors on a prepared seed bed in May to produce flowering plants the following year. The seedlings must be transplanted before they become crowded and put out in autumn or spring where they are to bloom. The Coonara is an improved type of Iceland poppy. The chief favourite among the annual poppies is the Shirley; but the large double varieties of the grey-leaved opium poppy are very handsome. All these are raised from seeds sown out of doors in March-April where they are to bloom in summer. The flowers of poppies are very fleeting, but if cut before the buds have expanded they last well in water indoors. *See Iceland Poppy; Nepaul Poppy; Opium Poppy.*

Poppy. Flowers and buds of the Ryeburgh poppy a dainty variety with a crinkled edge.

POPPY ANEMONE. This is one of the most brilliant of garden flowers: its botanical name is *anemone coronaria*. There are many strains or types, the St. Brigid being the favourite: the flowers are large and of brilliant and varied colour—scarlet, crimson, purple, rose, etc. The roots should be planted on a sunny sheltered border in September to provide blossoms in spring: they are set 3 inches deep and 4 or 5 inches apart in well drained friable soil of loam, leaf-mould and sand. Planting in February will ensure a later display of bloom.

POPPIES: SPECIMENS OF ANNUAL AND PERENNIAL VARIETIES

Individual types, such as Iceland and Shirley poppies, are dealt with under their own headings.

PORCELAIN:

WONDERFUL PRODUCTIONS OF CHINESE POTTERS

1. Famille verte dish of Kang Hsi period (1662-1722). 2. Bottle of Kang Hsi period. 3. Enamelled teapot of Kang Hsi period. 4. 16th century vase. 5. Famille rose plate of Yung Cheng period (1725-35). 6. Statue of a Judge of Hell, early 17th century. 7. Ewer of Wan Li period (1573-1619). 8. Famille verte vase of Kang Hsi period. 9. Water-pot of Kang Hsi period. 10. Beaker of Wan Li period. 11 and 15. 15th century vases. 12. Bottle of Kang Hsi period. 13. Famille noir jar of Kang Hsi period. 14. Vase of Kang Hsi period. 16. Bowl of Chia Ching period (1522-66). 17. 15th century wine jar. 18. 16th century enamelled bowl. See also under heading China.

PORCELAIN. Porcelain is a fine, thin, transparent ware, practically the same as china. *See* Chelsea; China; Dresden Plymouth Sèvres, etc.

PORCH. A porch is a covered entrance to a house, either built on to it in front of the door or part of the house itself. Whether it is a successful adjunct or not depends on its harmony with the architectural style of the house. Porches are sometimes added to existing dwellings with bad results because they completely spoil the frontages designed by architects in planning the main buildings. A porch must be an important feature; it is therefore essential that it should be an attractive one. For our first illustration a quaint brick porch with a tiled and pointed roof is selected. Both brickwork and tiling accord with the style of the little house, the walls of which have been partially whitewashed with so thin a coating that the outlines and colour of the bricks show through it. The porch is ceiled and has an electric light fitting which illuminates the entrance and the name on the door.

Very different in character is the other small porch illustrated in Fig. 2. This somewhat formal entrance belongs to a house in a town street. The classical character is suggested by the pilaster effect at each side and by the projecting roof. The paintwork of porch and doorway gives distinction to the front of the house. Glazed bricks are used for the step, and there is an electric light fitting.

Porch. Fig. 1. Quaint brick porch with pointed tiled roof which suits this modern type of country cottage.

Fig. 2. This formal porch for a small town house is painted to harmonize with the door. (Humphrey & Vera Joel)

Half-timbered houses and country cottages are often designed with picturesque porches. A combination of herringboned brickwork and oak for the timbers and side balustrades is employed to construct the porches of some modern houses with excellent old-world effect. For a whitewashed cottage the simple roomy porch illustrated in Fig. 3 is a charming architectural feature. The door and timbers are of old oak, and the tiles of the porch roof match those of the house. The side windows are glazed to afford better protection from the weather. The rafters are exposed, as a ceiling would be out of place in such an entrance.

A dignified porch is illustrated in Fig. 4, with its semicircular formation, domed roof and pillars. It is an attractive feature for the “angle house” designed with two wings to catch as much sun as possible. In such a porch there is room for a white painted seat at either side of the door, or for green tubs containing hydrangeas or other suitable flowering plants. The roof is ceiled and finished off as a part of the interior of the house. It has a central enclosed electric light fitting.

An attractive porch for a bungalow can be constructed entirely from light timber. The uprights, 3 in. square, are connected by short cross-pieces of timber, 2 in. deep and 1 in. thick, mortised or dowelled into place. At the top the uprights are framed into place with timber 4 in. in breadth and 3 in. in thickness, finishing flush with the tops of the posts. The roof rafters are brought down on to

this plate and the roof tiled. The eaves are finished with soffit and fascia board, faced with O.G. cast-iron guttering, the down pipe for the rain water being provided in the most convenient position adjacent to the rainwater drainage system. Such a porch should be made in prepared timber, and looks well if oak stained to contrast with whitewash or rough cast and brick. *See Loggia; Lych Gate; Name Plate; Path.*

Porch. Fig. 3. An attractive porch made from old oak beams roofed with tiles, set outside a whitewashed cottage.

Fig. 4. Domed and pillared entrance in the angle of two walls of a brick-built house. (No. 4 by courtesy of Our Homes and Gardens)

PORK. The season for pork should be confined to the winter months, or from the end of September to the beginning of April. When salted, especially in the form of bacon, pork is more wholesome than the fresh meat. This is the only salted meat which is superior in point of digestibility.

Particular attention should be paid to the condition of the meat, and to see that not only is it free from taint, but that the fat is devoid of kernels. The best joints for roasting are the leg, loin, and fore-loin; the spare rib, also, may be roasted, but it is not so thrifty. Roasted joints should be stuffed with sage and onion stuffing, served with thickened brown gravy and accompanied by either onion or apple sauce. If it is not desired to stuff the joint the stuffing may be formed into balls and cooked in the tin along with the meat.

Pork. Showing how the carcass is divided to form joints.

To prepare the leg for roasting, saw off the shank bone and make an incision between the rind and the flesh just below the knuckle. Fill the cavity with the stuffing and sew it in securely, or it will ooze out and be partially lost in the pan. Then, with a sharp-pointed knife, score the surface on the rind in even lines about $\frac{1}{4}$ in. apart. Cut well into the rind but not deeper than the outer skin. Pork should always be well basted

with plenty of good dripping, and be exposed to a good solid heat, especially at first; but on no account must the crackling be scorched. Allow 20 min. to the lb. for roasting the leg, and 20 min. over.

All solid joints require longer to cook than thinner pieces, and the time for cooking meat should be measured rather by the compactness of the flesh than the actual weight, after considering the average. The crackling of pork is improved if, when nearly cooked, it is rubbed over the surface with butter, dredged slightly with flour, and then basted before being returned to finish. The directions given apply to all joints of pork, but for loin and fore-loin saw off the chine. For loins or spare rib make the incision where convenient well under the skin. Before roasting these, and after the chine bone is removed, just separate the rib bones, but be sure that the joint is left whole.

The gravy should be served in a gravy-boat. Any trimmings should be added to the stock from which the gravy is made: also the dregs remaining in the pan in which the joint has been roasted should be added, after the dripping has been poured off. Pork dripping should never be mixed with that from other meats. It is always rather highly flavoured and will have absorbed the taste of the stuffing. Pork dripping can be used for basting poultry or game.

To boil a leg or hand of pork, saw off the shank bone and put the leg into a saucepan with a large onion stuck with 3 cloves, 1 lb. carrots, and the same of parsnips. Cover it with cold water, boil up, skim, and continue boiling very gently for about 3 hours, or a little over or under according to the size of the leg; 20 min. to the lb. is usually allowed for thick joints, but pork must invariably be cooked right through to the bone. For pork and beans add $\frac{1}{2}$ lb. soaked haricot beans 30 min. before the pork is cooked. Drain the beans and serve separately with parsley sauce. The spring or belly of pork is usually salted and boiled, but if not too thin it can be roasted. Care must be taken not to overcook it. Make up some sage and onion stuffing into balls, fry these, and dish with the pork.

The ears and feet can be cooked together. Purchase them ready cleaned, and soak them for 12 hours, then rinse and boil them till tender. Let them get cold, and then soak again for 1 hour in a little vinegar, 2 cloves, 1 bay-leaf (bruised), and seasoning. When ready to cook, dry them and cut the ears in slices and bone the feet, cutting the flesh in neat pieces. Fry the slices and pieces in butter after egging and crumbing them; or they may be dipped in batter before they are fried.

Pork chops should not be cut more than $\frac{1}{2}$ in. thick. They should be neatly trimmed, beaten with a cutlet bat, and fried in hot butter. To dish, sprinkle with a little chopped onion and powdered sage. Pork cutlets are cut from the neck bones, and should not be more than $\frac{1}{3}$ in. thick. They should be egged and crumbed, and a little minced shallot and powdered sage may be mixed with the egg. The cutlets are fried on both sides in hot butter until thoroughly cooked.

Pickled Pork. To pickle pork, cut the meat into joints of a convenient size and, after wiping it and removing all kernels and pipes, rub it well with common salt. Let it stand for 12 hours, then drain off the brine, and the following day steep it in a pickle prepared from $1\frac{1}{2}$ lb. common salt, $\frac{1}{2}$ lb. brown sugar, 1 oz. saltpetre, and a gallon of water. Boil these ingredients together for about $\frac{1}{4}$ hour, remove the scum from the top, and then strain them. The pickle should be allowed to cool before being poured over the meat, and the latter should remain completely immersed in it for about 12 days.

Pork Pie. To make a raised pork pie, weigh out 1 lb. neck of pork, freed from skin and bone, cut it up finely, season it to taste, and then add $\frac{3}{4}$ tablespoonful chopped onion and $\frac{3}{4}$ teaspoonful powdered sage. Make 6 oz. hot water crust (*see* Pastry), turn it out hot on to a floured board, and knead it until it is perfectly smooth. Cut off three-quarters of it and roll it out to a circle about $\frac{1}{4}$ in. thick, keeping the edges even and the strip itself of uniform thickness. The remaining piece of pastry should be wrapped in paper and kept hot over steam. A raised pie mould like the one

illustrated should be used for baking a pork pie. Line the mould evenly with the large piece of pastry. If no mould is available the pastry may be shaped over the bottom of a round cake-tin. Stand the tin in the centre of the circle of pastry, and press pastry evenly up the sides, keeping the top edge level. Remove tin and tie a band of greaseproof paper round pastry case.

Pork Pie. Raised pie mould with hinged side to facilitate the removal of the pie when cooked. On the left of the illustration the mould is shown open.

Put in the pork mixture, moistening it with a little stock or water, and press it well in, leaving a narrow rim of pastry standing above it all round. Roll out thinly the smaller piece of pastry, cut from it a round for the top, brush the edges of it with cold water and then lay it on top of the pie, pressing the edges together. A ridge of pastry standing about $\frac{1}{2}$ in. higher than the pie should be

left all round, and this should be trimmed and decorated with a pair of scissors. A hole must be left for steam to escape. Any scraps of pastry may be used to decorate top of pie.

Brush some beaten egg over the whole pie, and bake it in a moderately hot oven for $1\frac{1}{2}$ -2 hours, or until the pastry is lightly browned and the meat tender. When the pie is cooked, pour through the hole in the top a little warm stock in which a sheet of gelatine has been dissolved, and then allow it to get cold. *See Apple Sauce; Bacon; Pastry; Sage.*

PORRIDGE. The preparation known as porridge is made by stirring oatmeal, wheat-meal, Quaker Oats, or some similar patent food into boiling water or milk, or a mixture of both. It is eaten for breakfast either with sugar and hot milk, with cream, or with salt, and is both heating and nourishing.

To make oatmeal porridge boil up 1 pint water, then sprinkle in 3 oz. oatmeal, stirring all the time to prevent burning. Continue stirring until the mixture is smooth and creamy, then add salt to taste and let the porridge cook slowly at the side of the fire for about 45 min. Stir occasionally to prevent sticking, and add more boiling water if necessary. Serve in porridge plates or soup plates.

Porridge made with wheaten meal requires about $1\frac{1}{2}$ handfuls to each cup of water. The meal is sprinkled into boiling water, salt being added to taste. Stir till smooth, then allow to cook gently 40 to 50 min. Porridge is also made with barley meal and oatmeal. The method is similar, the oatmeal being sprinkled into boiling water, allowed to boil for 10 min., then the barley is sprinkled in finely through the fingers and table salt added. This form of porridge is best taken with cream. As it helps to purify the blood, it is said to be good for the complexion.

PORRINGER. A porringer was originally a vessel used for holding porridge. Though it is sometimes known as a caudle cup, strictly speaking a caudle cup has a lid and is bellied, or rather squat, in shape. A porringer proper is lidless, with fairly straight sides. Porringers were made in silver, pewter, and Sheffield plate, and good examples are much sought by collectors. They are known to have existed in the 16th century, and the lion and unicorn pattern appeared after the Restoration.

Porringer. Silver porringers, dating, left to right, from 1694 and 1713. (Courtesy of Chapple & Mantell)

The best porringers were made from 1660 to the time of Anne. Examples are freely decorated with acanthus and roses. Repoussé is used for decoration with, in some cases, a little chasing by way of relief. 17th century specimens are found with fanciful devices of animals, birds, and flowers thereon; but with the accession of William III, Dutch influence was exercised in the direction of simplicity, and the flute and the gadroon appeared. *See Pewter; Silver.*

PORTABLE WIRELESS SET. This is a completely self-contained receiver which can be carried about and operated without the necessity of external batteries or aerial and earth connexions. A frame aerial is used, and this is generally wound round the chassis of the instrument or fitted to the back of the cabinet. In some instances, sockets are provided for an additional and external aerial and an earth connexion so that it is possible to increase the range of reception if desired.

A frame aerial (q.v.) is directional in its qualities and it is, therefore, desirable for a portable set to be fitted with a turntable in its base so that it can easily be swung round into the best position for receiving any particular station.

Portable Wireless Set. Modern "Ever Ready" transportable, capable of receiving a number of programmes without the aid of an external aerial or earth.

A large proportion of the weight of a set of this kind will be due to the high tension battery and the L.T. accumulator. Special H.T. batteries are made for portables providing the greatest current capacity for a given weight, and the circuits are designed and valves chosen for a minimum consumption of H.T. compatible with an adequate performance.

When a portable set is not in use it is advisable to remove the batteries, as the sulphuric acid and other chemicals employed in them are liable to cause corrosion of the internal metal parts of the set. During such periods of rest the accumulator must be kept charged. If this is not done sulphation may set in.

Unspillable accumulators of two kinds are made for portable wireless sets. The one is known as the "free acid" type and is designed on the principle of the unspillable ink-well. This is to be preferred to the type containing a "jelly acid." Most portables can be laid down on their sides or even stood upside down without any harm resulting to them while they are kept stationary. When they are being carried by road or railway they should be kept upright or the valves may fall out and be damaged, although in some cases protective packing is provided to guard against this happening. Even so, it should be remembered that the most carefully designed portable can possess only a limited degree of robustness. Constant rough handling is bound to result in damage occurring.

When choosing a portable radio set these are the points which should be borne in mind:

1. **Quality of Reproduction.** With the special valves, loudspeakers and circuits available to designers, it is possible to achieve a quality almost equal to that of a good table set. There must, however, be some loss of quality consequent upon the reduction of the weight and size of loudspeaker and its restricted cabinet accommodation. A further restriction is the limiting of the

H.T. current consumption to a practical value. The higher musical notes and speech should, however, be clear: the loss will largely be in the bass.

2. **Range of Reception.** A portable set using four valves should be capable of providing a number of programmes without the aid of any external aerial.

3. **Selectivity.** It should not be necessary to rely to any great extent on the directional qualities of the frame aerial in the set (by twisting the set round) in order to separate most of the more powerful broadcasting stations.

4. **Effect of Vibration.** Owing to the closeness of the valves and tuning (components to the loudspeaker in most portable sets, "microphony" is sometimes encountered. This is evinced by a howl when the set is working at great volume, or at least considerable distortion. The set may also be sensitive to external mechanical vibration. Careful choice of valves and skilful general design are necessary to avoid this bad effect. The assembly of a portable must be carried out on sound engineering lines or the vibration to which it is subjected when being transported, and the sound vibrations from its loudspeaker concentrated in its compact construction will inevitably result in loose connexions and other such faults.

PORTER: The Drink. This name is given to the dark-coloured malt liquor similar to but thinner than stout, and not so frequently used. *See* Stout.

PORTLAND CEMENT. Portland cement is so named because of its resemblance in colour to Portland stone. It is made by the intimate mixing of calcareous and argillaceous materials such as limestone and clay, in certain definite proportions. Portland cement should always be of the British standard specification. *See* Brick; Cement; Concrete; Rendering.

PORTRAIT ATTACHMENT. A small lens known as a portrait attachment, or magnifier, is attached by screwing to the lens mount of a Kodak or other folding camera to increase the focal length, for taking portraits.

With the ordinary lens alone nothing nearer than about 15 ft. to 20 ft. is in focus, so that portraits of sufficient size on the film or plate cannot be obtained. The portrait attachment, by lengthening the focus of the lens, allows the camera to be brought within 8 ft. or 10 ft (not nearer) of the person to be photographed.

Another use for the portrait attachment is to get photographs of buildings and objects in confined spaces where it is impossible to get the whole of a building within the limits of the focussing screen without tilting the camera, and so producing distortion. *See* Lens; Swing back.

PORTRAITURE: IN PHOTOGRAPHY

Simple Rules for Good Results in Amateur Work

Continuing the sequence of our photographic articles, our contributor deals here with the taking of portraits. Other entries that bear upon this subject include Orthochromatic; Panchromatic. *See* also Camera; Enlarging; Lens; Photography; Spot-light.

Of all branches of amateur photography portraiture is probably the most difficult. Much can be done with the ordinary snapshot camera, particularly if it be clearly recognized that it is not designed for portrait work, and its use is mainly confined to out-of-doors portraits taken with the subject some distance from the camera. For indoor work a stand camera is essential. To get

satisfactory results with a fixed-focus camera an extra lens, called a portrait attachment (q.v.) or magnifier, should be used.

With the ordinary lens the figure will be too small on the plate or film, even for enlargement, since if the sitter is brought near to the camera he will be out of focus and the perspective will be distorted. Even with a portrait attachment the sitter should not be less than 8 ft. or 12 ft. from the camera. This will give a somewhat small image on the plate, which, however, can be enlarged satisfactorily.

Portraiture. Fig. 1. Result obtained with lighting from one window. Fig. 2. Reflecting screen added, with improved lighting of head and face modelling. Fig. 3. Picturesque lighting effects obtained with background screen and arrangement of reflector and camera. Fig. 4. Good effect with lighting from two windows and reflector. The diagram above each photograph shows the arrangement of camera (c), sitter (s), reflector (R) and window lighting used. (Specially photographed by E. O. Hoppé)

To obtain a large image on the plate, such as is seen in professional portraits, a lens with a long focus is necessary. For a $\frac{1}{4}$ plate camera an 8 in. or 10 in. lens will give good results. Its definition may not be perfectly sharp, and its depth of focus will be small if, as should be the case, it is of fairly large aperture. These qualities, however, are advantages in portrait work, giving soft, rounded pictures. Thus an old single landscape lens will serve excellently. If the lens of the camera in use is what is known as a doublet, consisting of two separate lenses, one of which can be screwed out, it will be found that using the back lens only will give the extra focal length required, i.e. enlargement of the image, although it will have the effect of reducing the aperture, and therefore increasing the exposure.

The next consideration is shortness of exposure. Naturalistic portraits cannot be obtained if the sitter has to keep a rigid position for more than a fraction of a second. This is one of the reasons why the amateur snapshot portrait is often more pleasing than some professional portraits. Short exposure is obtained by using a fast lens, i.e. working at an aperture of $f/6$ or less, fast plates or films (such films as the Kodak 'Verichrome' used with a pale filter can be made to give good results), and

strong light. Outdoor light is the strongest, and therefore best for amateur portraits, although it has the disadvantage that it cannot be controlled.

For outdoor work avoid full front lighting, and place the sitter so that the light is stronger on one side than the other. With the sitter facing the strongest light squarely, all modelling in the face will be lost and the portrait consequently untrue and uninteresting. For similar reasons full sunlight is usually unsatisfactory, apart from the fact that it makes the subject screw up his eyes and wrinkle the forehead. A tree, wall, fence, or other object on one side of the sitter will help to give the necessary side lighting and greatly improve the modelling. Lighting from above also needs consideration, for if it is too strong the eyes will be shadowed by the forehead and hair and give a scowling effect.

If the top lighting is too harsh a screen can be rigged up with an old sheet stretched horizontally 2 or 3 ft. above the subject's head. A camera with a focussing screen enables all these effects to be studied. Much can be learned if a good-sized sculptured bust or plaster cast is used for experiments and for trial exposures.

Great care is necessary in the choice of a background. It must not be full of detail sharply rendered, or the interest will be divided. A neutral background should be chosen if possible. If it is in deep shadow without high lights, the portrait will be thrown up well. A simple and effective background is provided by a sheet stretched on a clothes horse. Whatever its nature it should be well out of focus.

Another point is to see that there is no incongruous object, such as a bush or tree trunk, immediately behind the sitter.

Whenever possible use orthochromatic or panchromatic plates or films. Apart from questions of colour in the dress, freckles or slight rednesses or other blemishes in the skin, hardly noticed by the eye, are greatly exaggerated by ordinary plates on account of their insensitiveness to red. With colour sensitive plates these characteristics are reduced to their proper proportion, and retouching, a matter hardly within the capacity of the average amateur, is avoided.

The pose of the sitter should be attended to carefully, but without making him adopt unnatural or uneasy positions which will give the effect of strain. Do not let him sit in a slovenly attitude, but reasonably upright, with the chin held up a little and the eyes looking very slightly to one side for a full-face portrait. The camera should be so arranged that the lens is about level with the chin. The face should be studied to ascertain whether full face, side face, or profile gives the most characteristic and pleasing likeness.

Indoor portraiture is somewhat more difficult than outdoor work. Much more careful control of the lighting is both necessary and possible, and effects can be obtained which are impossible outdoors. Longer exposures are required, but this difficulty can be partly overcome by the use of very fast plates, or of panchromatic plates without light filters.

The tendency with indoor amateur portraits is towards harshness of lighting. This is avoided by using a room with a good-sized north window, or, better, with two windows, the lower part or the whole lightly screened with lace or muslin curtains, or other white translucent material, to soften and diffuse the light. The subject should be placed near, but not too close, to the window, and a reflector on the other side (Figs. 2 and 3). This lights up the portions of the face and figure otherwise in shadow. A reflector can be contrived with a large sheet or white paper hung on a clothes horse or a line that can be moved about. The positions of screen and camera are best found by experiment. Suggestions are given in Fig. 1-3, which show three possible arrangements in a room with one window, and in Fig. 4 for a room with two windows. Very interesting effects can be obtained with the reflector placed in front of the sitter, the camera lens pointing through a hole cut in the reflector.

If the top light is too strong, it can be regulated by short curtains on rods hung at the top of the window.

The background in an ordinary room should be carefully considered. It is usually best to contrive a simple background out of some unpatterned material not too light in colour hung on a line stretched across the corner of the room and kept out of focus. If the ordinary room furniture constitutes the background take care that no prominent lines of furniture, picture frames, etc., pass directly behind the sitter's head, and also that the glass of pictures, or other bright objects, do not catch the light, thereby making a glaring white blob in the photograph.

The head should not be central in the plate unless a full-face front-figure portrait is being made. With side face, or profile, much more pleasing results are obtained with the head on either side of the middle line of the plate.

Exposure should always be checked with an exposure meter, except when artificial light is used, when actual experiment alone can decide, according to light, lens, and plate used. Development should be deliberately on the thin side, either using the ordinary developer diluted with one-third the amount of water extra to the ordinary amount, or by shortening the time of development. Over-development will entail loss of modelling and harshness without any gain in detail. For most portraits rather broad effects are best, and these are given by thin negatives, which are printed or enlarged on matt or rough papers.

PORTUGAL LAUREL. This vigorous evergreen (*Prunus lusitanica*) forms an attractive tree if allowed to grow naturally and bears white flowers in summer. The best time to plant is in September or early May, and it is wise to put in small trees as large ones can rarely be transplanted successfully.

Portugal Laurel. Evergreen flowering tree attractive for the garden shrubbery.

PORTULACA. The dwarf-growing portulaca is a S. American annual flowering plant of low growth. It is raised from seed sown in pans in a cold frame in early spring and planted out in June. Sowing may be made in the open ground in May. The flowers are crimson, pink, white, and yellow. They need light soil and a sunny place.

PORT WINE. There are three classifications of port: vintage, ruby, and tawny, of which particulars are here given.

Vintage Port. Vintage port is wine of a particular year, shipped, as a rule, from 2 to 4 years after it is made, bottled in Great Britain, and allowed to mature in cellars. It matures slowly and improves with age. Only those years in which conditions have been favourable to the perfect ripening of the grapes are known as vintage years.

The purchaser of vintage port should take care that the wine has been shipped by a reliable shipper in the first instance, and bottled by a good wine merchant. The purchaser should always assure himself of the bottling date before taking delivery. The most economical plan is to buy vintage port early, as soon as the wine merchant has bottled it. The wine should then be laid down in the cellar for keeping purposes. Ten years in bottle is a fair age, although the wine may improve up to 20 years or more.

Vintage port is known by its character, full, fruity flavour, colour, and fine bouquet. In the process of maturing in bottle a crust is formed, and the wine should be carefully decanted, the white splash on the end of the bottle being kept uppermost. The decanter should be perfectly dry and clean. The bottle must not be shaken, nor the sediment allowed to pass into the decanter. If the cork breaks, the wine should be poured into the decanter through a strainer or piece of muslin.

Port bought for immediate use from wine merchants should be stood upright for 24 hours in the dining room to enable the crust to settle, and so that the wine acquires the temperature of the room. Port should be decanted at least 2 or 3 hours before drinking, as the wine develops in bouquet and flavour.

Other Ports. Tawny port is not a wine made from any one special year's grapes, but a blend of wines of a number of years. It is matured at Oporto in wood instead of in bottle, and consequently loses its deep red colour. It is a lighter wine, both in colour and body, than vintage port.

Ruby port is a compromise between vintage and tawny. It may be a wine of a particular vintage kept in wood for some time before being bottled so that it has lost some of its depth of colour and strength; or it may be a blend of wines of different years blended at Oporto or in Great Britain by wine merchants. The percentage of alcohol in port wine is from 15 to 20 per cent. When more than 15 or 16 per cent, of alcohol is present, the wine has been fortified, that is to say, spirit has been added to it. Much cheap wine sold under this name may be nothing but a mixture of potato or grain spirit coloured and flavoured with dyes and essences. Natural port is a wholesome beverage, but the artificial compounds may be extremely injurious. Port wine is combined with malt or malt extract in some tonic preparations. *See Alcohol; Wine.*

Port Wine Mark. *See Birthmark.*

POSITIVE. In photography a positive is the reverse of a negative, and may be made, as is most usual, on paper or on glass, when it is seen by transmitted light instead of by reflected light, as in the case of a print. A glass positive is generally known as a transparency. It may be for use as a lantern slide or a colour transparency.

Ordinary transparencies are made for the purpose of copying negatives by contact. A slow plate is best. *See Colour Photography; Negative.*

POST. A post is a piece of timber, metal, or other material usually fixed in a vertical position and used as a means of support or attachment.

The majority of fences are constructed of posts made in wood, cast or wrought iron, or concrete, set at a distance apart, the intervening space being filled with rails, palings of wood, chains, stout galvanized iron wire, or barbed wire. In the latter two cases a stouter post, called a straining post, is often placed at certain distances, incorporating a drum with a ratchet device for tightening the wire.

A gate post has to carry a heavy weight, and often needs a support on the opposite side to the gate. Since a gate sinks if the post falls even slightly out of the vertical, it is advisable when erecting the post to ensure a perfectly sound foundation. Where the gate post is of wood, it should be well creosoted or treated with some other form of wood preservative, to prevent rotting. *See Clothes Line; Fence; Gate.*

Post. How a corner post is erected in the course of constructing any small building.

POSTAGE: RULES AND REGULATIONS

A Concise Guide to Matters of Everyday Concern

This article contains information about the dispatch of letters and postal packets of all kinds. Branches of the subject are dealt with under the headings Money Order; Parcel Post; Postcard. See also Letter; Parcel; Telegram.

The cost of sending letters, papers, cards, newspapers, etc. through the post is met by purchasing stamps and fastening them to the letter, card, or wrapper. Parcels, not exceeding a certain weight, can be sent in the same way.

The communications that are sent through the post may be divided into four classes: letters proper, this including letter cards and letter packets; postcards; newspapers; printed papers of other kinds.

Letter Rates. A letter may be sent to any part of the British Isles, including Eire, for 1½ d. provided it does not exceed 2 oz. in weight. If it does exceed 2 oz. in weight, it will cost an extra ½ d. for every 2 oz. or portion of 2 oz. Thus a letter weighing 3 oz. will cost 2d., and one weighing 5 oz. will cost 2½ d.

The prepaid rate of postage on letters and letter-packets from the United Kingdom to Empire countries served by the England—South Africa and England—India—Burma—Malaya—Australia air routes and to Egypt is 1½ d. for each ½ oz.; letters and letter-packets for these countries are despatched by air as the normal means of transmission. To other parts of the British Empire, and to H.M. ships abroad, the U.S.A. and the British Postal Agencies in Morocco, the rate is 1½ d. for the first oz. And 1 d. for each additional oz., and to all other places 2½d. for the first oz. and 1½ d. for each additional oz. Letters and letter-packets for most European countries, prepaid at the ordinary international postage rate, are forwarded by air or surface transport, whichever offers the quicker delivery.

To most countries to which correspondence is not despatched by air in ordinary course, air mail services are available at varying rates of postage. Full particulars of these services will be found in the Air Mail Leaflet.

A letter if posted unpaid is charged on delivery with double postage; if posted underpaid, with double the amount of the deficiency.

Postage stamps can be bought from any post office. They are sold in the following values: ½ d., 1 d., 1½ d., 2 d., 2½ d., 3 d., 4 d., 5 d., 6 d., 9 d., 10 d., 1 s., 2 s. 6 d., 5 s., and 10 s.

An assortment of ½ d., 1d. and 1½ d. stamps is provided in the form of books priced 2 s. 0 d., 3 s. 0 d. and 5 s. 0 d. Various items of stamped postal stationery are also sold.

Redirecting Letters. Any kind of postal packet can be redirected to the same person at another address under certain conditions. This privilege is necessary when persons remove from one house to another. It is also very useful when families go away for the summer holidays, and during other absences from home. It can be done either by someone authorized by the person to whom the letter is addressed, such as a relative or caretaker, or by an official of the Post Office. The redirection of letters for the first year after removal is done without charge. For redirection during the second and third years a fee of 1 s. a year is charged. After that 5 s. a year is charged.

The postal authorities only undertake to redirect letters, postcards, etc., when such cannot be redirected at the place of address. They do not, for instance, redirect postal packets addressed to a person who has temporarily left his house, unless the house is left uninhabited; or those addressed to clubs, hotels, boarding houses, or lodgings.

Notices of removal and applications for redirection must be signed by all the persons to whom any packets to be redirected are to be addressed. Thus, in case of a removal, all the members of a family who have any reason to expect letters must sign, not the head of the house only. Printed forms for this purpose can be obtained from the local post office or from a postman, and when filled up and signed should be sent to the postmaster or handed to the postman.

Registered Letters. Letters which contain money or articles of value should be registered, and if this is done compensation will be paid by the Post Office, subject to certain conditions, in the event of loss or damage. Any letter, parcel or other postal packet can be registered. Anything intended for registration must be handed to an official of the Post Office, and a certificate of registration, bearing an acknowledgment that the necessary fee has been paid, must be obtained. Nothing intended for registration should be dropped into a letter box.

The fee for registration is 3d. exclusive of postage. This insures an inland packet up to £5, so if it is worth more than that sum a higher registration fee should be paid. The fees and limits of compensation are as follows, this applying obviously to inland packets only. No compensation in excess of £400 is paid.

Fee d.	Comp'nstn £	Fee d.	Comp'nstn £
3	5	1/2	220
4	20	1/3	240
5	40	1/4	260
6	60	1/5	280
7	80	1/6	300
8	100	1/7	320
9	120	1/8	340
10	140	1/9	360
11	160	1/10	380
1/-	180	1/11	400
1/1	200		

A packet intended for registration must be made up in a reasonably strong cover appropriate to its contents. Letters and parcels must be fastened with wax, gum, or other adhesive matter. It is not sufficient merely to tie a packet with string, but if it is tied with string in addition to the fastening, the string need not be sealed.

If it is desired to secure compensation in the event of damage to a fragile article sent in a letter or parcel, the packet should bear the words "fragile, with care." These words should appear on the face of the cover, above the address. Any official to whom a packet is tendered for registration is instructed to refuse to register it if the packing is, in his opinion, obviously inadequate. Compensation will nevertheless be refused if, though accepted, the packet is afterwards found to have been imperfectly packed. When several packets are sent for registration by the same person it is desirable for a list of the addresses in duplicate to be sent with them; one copy is kept by the post office and the other is signed and returned to the sender. The sender of any registered postal packet may arrange at the office of posting, either at the time of posting or subsequently, for an advice of its delivery to be sent to him. The fee is 3d., payable by means of stamps affixed by the sender to a form provided for that purpose.

Packets that contain coin or jewelry, and also all packets for inland postage bearing the word Registered or any other word, phrase, or mark to the like effect are, if posted otherwise than in accordance with the regulations, subject to compulsory registration and are charged on delivery with a registration fee of 6d. less any amount prepaid in excess of the postage. Any packet which is found open in the post or cannot be delivered, and which is found to contain an uncrossed postal order in which the name of the payee has not been inserted, a cheque or dividend warrant not crossed or made payable to order, a banknote, postage stamps, or any article, other than coin or jewelry of a value in each case of 10s. or over, will be subject to registration and be charged with a registration fee of 3d. No compensation will be given for any postal packet that has been compulsorily registered.

Compensation in respect of money of any kind, coin, banknotes, postal orders, cheques, stamps, etc., will be paid only in those cases in which the money is enclosed in one of the registered letter envelopes sold by the Post Office, and the packet is tendered for transmission by registered letter post. The compensation paid in respect of coin, which must be packed so that it cannot move about, will in no case exceed £5.

Printed Papers. For printed papers the prepaid rate of postage is $\frac{1}{2}$ d. for every 2 oz. or fraction thereof up to a maximum of 2 lb. (Inland Service). Printed paper includes all documents that fall into the following six classes. Such documents must consist of a printed form and any writing on it must refer solely to its subject matter or must consist of formulas of courtesy or of a conventional character, not exceeding five words or initials.

(1) Commercial or business papers of a formal character, namely, invoices, orders for goods or for work, confirmations of orders, advice notes of the dispatch or receipt of letters, documents, goods, or money, waybills, bills of lading, receipt for goods or money, statements of account, price lists, prices current, market reports, delivery and shipping notes, tenders for goods or for advertisements, quotations for goods, estimates for work, inquiries for quotations, contract notes, confirmations of contracts, share transfer notices and applications for employment. Notices of assessments and applications for payment of rates, notices relating to the registration of voters, notices, certificates, reports, and returns given or made to or by public bodies, lists and tabular statements.

(2) Proposals and policies of insurance, powers of attorney, proxy papers, licences, voting papers, testimonials, and certificates.

(3) Circulars, that is, printed notices and letters.

(4) Printed Christmas, New Year, Easter, birthday picture, greeting and visiting cards.

(5) Manuscript for press and printed proofs (including information for insertion in directories and similar publications) with corrections and instructions.

(6) Educational exercises and examination papers with comments, corrections and instructions.

As every printed paper is subject to examination, it must be posted in a cover that can be easily removed for the purpose of examination without breaking any seal, tearing any paper, separating any adhering substance, or cutting any string. No printed paper may contain or bear any communication in the nature of a letter.

No paper money may be posted or conveyed or delivered by post in a printed paper. A stamped proxy paper or a stamped and addressed card, wrapper, label, or envelope forwarded in order that

such card, wrapper, label, or envelope may be returned through the post is, however, permitted. A packet prepaid as printed paper, but which contains an enclosure of any kind, is not admissible at printed paper rate.

Newspapers. Newspapers can be sent through the post at special rates provided such newspapers have been registered at the General Post Office. If this has been done, the words Registered for transmission through the post will usually be found thereon. The rate of postage on publications registered in this way is 1d. for every copy not exceeding 6 oz., with a further charge of $\frac{1}{2}$ d. for every additional 6 oz. or fraction of 6 oz.

The rate is per copy; so if two or more copies are sent in a single packet each is liable to the same postage as if posted separately. But in no case will a copy or a packet of such copies be chargeable with a higher rate than that chargeable on a printed paper of the same weight. A copy or a packet of copies posted unpaid or underpaid is chargeable on delivery with double the deficiency at the newspaper rate or printed paper rate, whichever involves the lower charge. No copy or packet of copies may weigh more than 2 lb.

Every newspaper sent through the post should be so folded and covered, if a cover is used, as to admit of the ready inspection of the title. Every copy or packet of copies must be posted either without a cover or in a cover open at both ends, which can be easily removed for the purpose of examination. No copy of a newspaper sent by post at newspaper rate may bear on the paper itself or on the wrapper any writing except the name, address, and description of the person to whom it is sent, the name of the sender, the words "With compliments," and a request for its return in case of non-delivery.

No unregistered publication and no article that is not part of a publication registered as a newspaper or a supplement thereto may be enclosed in any packet sent at newspaper rate. No supplement to a publication registered as a newspaper is admissible at the newspaper rate unless it is sent through the post with the publication to which it is a supplement. If any of these regulations are infringed, the packet will be charged, either as an underpaid printed paper or an underpaid letter, or is transferred to the parcel post and charged with a fee of 1d. in addition to any deficient parcel postage, whichever involves the lower charge.

Other Points. If a postal packet which is chargeable with a postage exceeding 1d., whether a letter, newspaper, printed paper or parcel, cannot for some reason be delivered at the place to which it is addressed, it is returned direct and unopened to the sender, provided it bears on the outside his or her name and address. If this is not thereon, the packet is opened by an official of the Post Office, and if it contains the sender's address it is returned thereto. An undelivered postal packet which cannot be returned to the sender and contains no enclosure of importance is destroyed.

Any person who desires proof that a letter, letter card, postcard, printed paper, or newspaper has been posted to a particular person, should hand in the letter or card at a post office and ask for a certificate of posting. The fee for this is $\frac{1}{2}$ d., payable by means of a stamp, which must be affixed by the sender to the certificate. A letter which contains anything of a fragile nature should be labelled Fragile.

In towns, where post offices or pillar boxes are found in almost every street, the postmen are not allowed to accept anything for the post, but in country districts it is different. There, subject to certain conditions as to weight, etc., a postman must accept any letter, parcel, or other postal packet handed to him on his round, whether intended for registration or not.

Railway Letters. In Great Britain the railway companies will accept and convey letters both on weekdays and Sundays by the next available train or ship, either to be called for at the station of

address or to be transferred to the nearest letter box. These are called railway letters and must not exceed 1 lb. in weight and must be taken to a passenger station of the railway company over whose line it is to be sent, and tendered, during such hours as the station is open to the public, to a servant of the company. Postage at the inland rate must be prepaid by putting stamps on the cover in the ordinary way. In addition, a railway fee, which must be paid in cash to the railway company's servant, is chargeable upon each railway letter as follows:

Weight not exceeding 2 oz.	3d.
Over 2 oz. and not exceeding 4 oz.	6d.
Over 4 oz. and not exceeding 1 lb. (maximum)	9d.

Nothing further is payable on delivery. For the Railex Service, *see* Express Delivery.

Mails by Air. Any kind of letter packet may be sent by air mail, that is, letters, postcards, printed papers and commercial papers, and samples. The limits of size and weight are the same as for similar correspondence sent by ordinary post. Air mail letters can be accepted for registration, for insurance is limited to letters and boxes for Holland and Switzerland. A special blue air mail label must be affixed to the top left-hand corner of every air mail packet. These labels may be obtained free of charge at any post office.

Stamps to the full value of the combined postage and air fee must be affixed at the top right-hand corner of the address side of the envelope. If the proper fees are not prepaid, the packet cannot be sent by air mail. The combined postage and air fees for correspondence for countries outside Europe are for a weight of half an ounce.

POSTAL ORDER. Those who wish to send small sums of money through the post may do so by purchasing one or more postal orders from any post office where this kind of business is transacted. Postal orders are issued for various amounts between 6d. and £1 1s. The charge is 1d. each for those of 2s. 6d. and less, 1½ d. for those between 3s. and 15s., and 2d. for those above that amount. If odd sums of money are required stamps can be fastened on to the order, if they do not exceed 5d. in value.

To obtain the money for one of these orders the recipient must take it to a post office and sign his name thereon, or pay it into a bank where he has an account. If, however, it is crossed, it can only be paid through a bank. Persons wishing to send larger sums of money through the post can do so by means of money orders. *See* Money Order.

POSTCARD. A postcard is a card on which a message is written and which is sent through the post. Postcards are sold ready stamped at all post offices for a little more than the cost of the stamps, while unstamped cards suitable for postcards can be bought and stamped by the sender. The inland rate of postage is a penny for every card. A postcard, if posted unpaid, is charged double postage on delivery; if posted underpaid it is charged double the amount of the deficiency. The prepaid rate of postage on every reply postcard is 2d. As regards size, a postcard may not exceed 5½ in. in length by 3½ in. in width, or be less than 4 in. in length by 2¾ in. in width. If private cards are used as postcards, their material must be ordinary cardboard or paper not thinner than that sold at the post offices for use as postcards. Picture postcards, if containing not more than five words, will go for ½d. as printed papers. (*See* Postage.)

Nothing may be attached to a postcard except the stamps; a completely adherent gummed label or slip that folds back, bearing the name and address of the person to whom the card is sent; a similar label, not exceeding 2 in. long and ¾ in. in width, bearing the name and address of the sender of the card; and engravings, drawings, photographs, and printed matter on very thin paper and completely

adherent to the card. These additions may be fixed either to the back of the card or to the left-hand half of the front. The right-hand half of the front must be reserved exclusively for the address and the postage stamps. If these rules, which are intended mainly to allow picture postcards to go through the post, are not observed, the postal authorities may refuse to deliver the card, as they are officially entitled to do. A postcard may not be folded, nor may it be bent or altered in such a way as to reduce its size below 4 in. by 2¾ in. It must not be fastened against inspection in any way, nor enclosed in a cover of any kind. If these rules are broken the card will be treated as a letter and will be charged accordingly.

Postcards can also be sent to destinations outside Great Britain. Generally speaking the rules are the same for these as they are for inland postcards. The rate of postage for postcards sent to any part of the British Empire, Egypt, H.M. Ships abroad, U.S.A. and the British Postal Agencies in Morocco is 1d. (reply paid 2d.). To all other places the rate is 1½ d. (reply paid 3d.)

Postcards are afforded the same means of transmission as letters, and consequently to many countries they are forwarded by air in ordinary course (*see* under "Postage, Letter Rates"). They may be sent by air to most other countries on payment of the special air postage rates set out in the Air Mail Leaflet. An unpaid or underpaid postcard from abroad is charged on delivery with double the amount of the deficient postage, the minimum surcharge being ½ d. Any card can be stamped and used as a postcard for the foreign and colonial post provided it is of cardboard similar to, but not thinner than, that used for the cards sold at the post offices for use as postcards. They may not exceed 5⅞ in. in length by 4⅞ in. in width, or be less than 4 in. in length by 2¾ in. in width.

Postcards for abroad must bear on the face the heading *Carte postale*, or the equivalent of the heading in another language. This heading however, is not obligatory for single postcards that have been manufactured privately. Reply paid postcards must bear on the face in French, as a heading on the first half, the word *Carte postale avec réponse payée*; on the second half, *Carte postale réponse*.

Each of the two halves must, moreover, comply with the other conditions laid down for single postcards. One half should be folded over the other, and they must not be closed in any way.

Official postcards sold for inland postage may be used for destinations outside the United Kingdom if they bear a postage stamp for the additional postage required. This concession does not apply to reply paid cards. A postcard must be sent unenclosed, that is to say, without wrapper or envelope.

Although it is forbidden to join or attach to postcards samples of merchandise or similar articles, yet illustrations, photographs, stamps of any kind, address labels, and cuttings of any kind may be affixed to them, provided that these articles are not of such a nature as to alter the character of the postcard; that they consist of paper or other very thin substance, and that they adhere completely to the card. With the exception of address labels or slips, these articles may only be affixed to the back, or to the left-hand half of the address side. These details are sufficient for ordinary purposes, but fuller ones will be found in the Post Office Guide.

POSTE RESTANTE. This name is given to a post office where postal packets of all kinds may be addressed and left until called for.

When letters, etc., are addressed to a person at a poste restante, the words, *To be called for*, or *Poste restante*, should appear in the address. The poste restante is intended solely for the accommodation of strangers and travellers, who, however, must not use it for more than three months consecutively. Postal packets addressed to initials or to fictitious names, or to a Christian name, without a surname, are not taken in at a poste restante.

Postal packets may not be re-directed from one poste restante to another in the same town, or from a private address to a poste restante in the same town. For the purpose of this rule the various postal districts of London are considered as different towns. All persons applying for letters at a poste

restante must furnish sufficient particulars to prevent mistakes and to ensure delivery to the proper person.

Postal packets from abroad will be kept at a poste restante for a period of two months, and those from within the United Kingdom for a fortnight. Letters addressed to a post office at a seaport town for a person on board ship expected to arrive at that port are kept for two months. At the expiration of these periods postal packets will be treated as undelivered. If, however, one bears a request for its return within a specified time, not exceeding the official period of retention, it will, if not delivered, be dealt with in accordance with such request. *See* Postage.

POT. A pot is a general term for a vessel for holding food, both when cooking and at other times. The word, however, has been superseded largely by the special names given to the various utensils, although it remains in mustard pot, pepper pot, and stock pot, and in the words pot-hook, potherb, and pottery. Another pot is the flower pot, and potting is a familiar term among gardeners. (*See* Flower Pot; Mustard; Pepper; Potting Stock Pot.)

Pot Plants. Plants grown in flower pots are chiefly relied on for the decoration of the conservatory and greenhouse, and by making a selection of suitable kinds a succession of bloom can be assured all the year round.

Those of chief value for summer and autumn flowering in the amateur's greenhouse are tuberous begonia, yellow arum lily, fuchsia, zonal geranium, begonia semperflorens, campanula isophylla, herbaceous calceolaria, petunia, chrysanthemum, hydrangea, marguerite, heliotrope, lilies, nerine, Scarborough lily or vallota and various annuals.

For winter and spring flowers reliance must be placed on daffodil, hyacinth, paper white narcissus, tulip, Chinese and other primulas, Persian cyclamen, stocks, azalea, arum lily, cineraria and perpetual flowering carnation, together with various shrubs which may be forced into bloom. Suitable foliage plants are ferns, palms, indiarubber plant (*ficus elastica*), *aralia sieboldii*, *araucaria excelsa*, blue gum (*eucalyptus*), *grevillea robusta*, *isolepis gracilis* (a grass-like plant for edging), *ophiopogon variegata*, *panicum* (also suitable for edging) *tradescantia*, *asparagus Sprengeri*, and *smilax*.

Seeds of hardy and half-hardy annuals should be sown in pots in September for spring and early summer bloom and in March to provide a succession. Several seeds are sown in 5 in. or 6 in. pots and the seedlings are thinned out, not transplanted. The butterfly flower (*schizanthus*) is one of the best for sowing in September, but many annuals can be grown in pots.

Watering is one of the most important details in the management of pot plants: most failures are due to incorrect watering. The secret of success is not to moisten the soil until it is moderately dry, and then to fill the pot to the rim. Water should not be given again until the soil is fairly dry.

POTASH: In Medicine. Applied externally in concentrated form, potash acts as an irritant and caustic. In medicinal doses internally the action of potassium salts resembles practically that of the corresponding salts of sodium. The sulphate, tartrate, and acid tartrate of potassium are all commonly used as saline purgatives or "salts," and may be employed in habitual costiveness. The best way to take these salts in this ailment is dissolved in half a glass or more of warm water, slowly sipped, before breakfast. The acid tartrate is one of the ingredients of Imperial drink (q.v.), often prescribed as a cooling beverage in slight feverish states.

Potassium chlorate is commonly used as a mouth-wash or gargle, the drug exhibiting an antiseptic, curative action in all kinds of sore throats, tonsillitis, and similar conditions. It should be discontinued, however, after a few days' use. An aerated water containing bicarbonate of potash makes a palatable diluent of other drinks, and is feebly antacid.

As a Fertilizer. Potash is an essential element of plant food, producing quality and flavour in fruit, tubers, and roots. The form used is kainit, an easily soluble salt containing about 15 per cent potash, but embodying impurities that sometimes harm active roots if placed in immediate contact with them. It should be applied to the soil in late winter, if possible.

Muriate of potash is a highly concentrated form, and needs discrimination in its use. Sulphate of potash is a purified form of kainit containing about four times as much pure potash, and may be substituted in proportionately smaller quantity. Wood ashes, the ash of burnt prunings of trees, shrubs, and plants, are rich in both potash and phosphates, and should be carefully preserved and kept dry for use as lawn dressing, or for dusting along drills before sowing such vegetables as onions, carrots, peas, beans, beetroot, etc. *See Manure.*

POTATOES: CULTIVATION AND COOKING

Successive Steps in Preparing this Vegetable for the Table

Other articles that contain something useful about potatoes include Black Scab; Cutworm; Digging; Division; Forcing; Kitchen Garden; Manure; Trenching. See also Burgundy Mixture; and for the cooking, Chips; Frying; Hot Pot; Irish Stew; Salad; Shepherd's Pie, etc.

For garden purposes the most suitable soil in which to grow potatoes is a rich loam, a trifle on the sandy or chalky side, well drained, and in a sunny situation. If the soil is heavy it should be thoroughly dug over during the autumn and winter. Couch grass, docks, nettles, and other perennial weeds should be forked out; if there is any reason to suspect that leather jackets, wire worms, or millipedes are present, the soil should be turned over.

When the soil is sandy or open in texture it can be improved, as far as potato growing is concerned, by adding dead leaves of decaying vegetable matter. Impoverished land should be enriched with stable manure, which may be dug in during the autumn or winter or before planting in spring. Lime, say 7 lb. to the rod, is beneficial to rich garden soils.

The selection of the best varieties of potatoes for planting purposes is a matter of great importance. Some which do well in one district prove disappointing in others, and an actual trial is often the only means of proving whether a new variety is worth planting.

Potato. Method of preparation for planting. 1. Large tuber divided. 2 and 3. Divisions ready for liming. 4. Well-sprouted tuber with superfluous eyes removed. 5. An ill-sprouted tuber with weak useless shoots. 6. How the tubers are arranged in a box for sprouting.

Planting. Early potatoes can be planted early in March. After the surface of the ground has been levelled, the sets should be put in about 9 in. apart, at a depth of 6 in. There should be a span of 18 in. between the rows. If the soil is heavy, the potatoes should not be buried so deeply.

The end of March or the beginning of April is the best time for planting the ordinary kinds. A space of 12 to 15 in. should be left between the sets, and the rows should be from 2 ft. to 2 ft. 6 in. apart.

If plenty of ground is available, the potatoes may be inserted at 3 ft., and catch crops grown in between the rows. They may be planted either whole or in pieces, according to the number and quality of the eyes or shoots.

When the potatoes are about 9 in. high they should be earthed up. Sufficient soil is banked up to cover any young tubers that may be growing near the surface.

Growing Under Glass. Potatoes may be grown under glass where bottom heat is available. A frame or pit should be prepared early in January, with a good bed of manure or leaves. This is covered with about 1 ft. of soil, and the potatoes planted about 6 in. deep. Plenty of fresh air should be given in mild weather, and tepid water. No earthing up is required. The potatoes will be ready early in May. A few radishes may be forced in between the rows, if desired, in which case the turnip-rooted sorts are the best to employ.

Digging. As regards the digging or lifting of potatoes, growers are prone to lift early ones too early and late ones too late. The bulk of the earlies ought not to be lifted until the tubers have got at least to the size of a hen's egg and the tops have changed colour. If they are lifted too early the crop will suffer from loss of weight or of starch, the substance which gives the tuber its nourishing value. Exposure on the ground for a few hours is desirable, as it allows for setting the skins. There are few cases in which potatoes lose by being lifted before Michaelmas, and there are many in which they gain. It is well, if possible, to lift them when the soil is comparatively dry, as they will then come up fairly clean. Late potatoes lifted in September may, as a rule, lie on the ground for 20 hours, provided the weather is not too wet.

Potatoes for Seed. For seed, potatoes of a suitable size can be bought, or they can be saved from a previous crop, provided it is a good one. It is not desirable to plant the very small potatoes known as chats, or the largest tubers, except in the case of first early varieties, when cutting should be avoided. As potatoes lose their vitality if grown continuously in the same locality, frequent change of seed is recommended; experience has shown that it is desirable to obtain seed tubers from a district farther north than that in which they are to be planted. Some growers obtain new seed tubers every second year from Scotland. In the warmest and driest districts of the country a change of seed is advisable every year.

Growers who wish to provide their own seed tubers should set aside a portion of the crop for this purpose, lifting it before the tubers are fully ripe, as immature tubers make the best seed. They should then be selected. Clean tubers, having been selected, should be allowed to lie on sacking or on the ground for a few days, and should be turned occasionally so that they become greened. This will improve their keeping quality. In winter they should be placed with the crown uppermost in shallow trays or boxes, or on shelves one layer deep. These should be laid in a cool, frostproof place where they will get as much light and air as possible. Tubers boxed in this fashion develop 2 or 3 strong green sprouts instead of a large number of weakly shoots, which they produce if they are pitted or kept in the dark.

Manuring. A good system of manuring consists in the application just before the time of planting of a mixture of superphosphate of lime, 5 parts, and sulphate of ammonia, 3 parts, at the rate 3-4 oz. to the sq. yd. If sulphate of ammonia is applied after the shoots have come above the ground, it should be mixed with soil so that the growing plant does not come in contact with it. The addition of a small quantity, 1 oz. to the yd. run, of wood ashes as a dressing to the soil before the sets are planted is also to be recommended. If potatoes are cut into sections before being planted, the wounded parts should be dipped into slaked lime. Storing. For potatoes stored on a large scale, a

clamp or pit is almost a necessity, but other methods are possible with small quantities. A dry, frost-proof shed makes an excellent store. In this the potatoes should be spread in layers on the floor, either directly or on straw, bracken, or sacking. The depth of the layer must not be more than 2½ ft. or the tubers may become heated and begin to sprout. They should be covered with straw, litter, or sacking to keep out the light, unless they are intended for seed.

Potatoes in various stages of growth, illustrating how the tuberization is effected. (Courtesy of Amateur Gardening)

Potato. Double row dug up showing number of tubers produced. (Courtesy of Amateur Gardening)

They should be inspected 10 days after they have been put in store, and diseased potatoes removed. The shed should be ventilated whenever possible or desirable. A watch must be kept for rats and mice, and every care taken against frost. One effective method of doing this is to scatter litter lightly but thickly over the heap.

Where there is no shed suitable for storing, and the quantity is not too great, the tubers may be placed in thick bags and left in a larder. Quicklime or lime and flower of sulphur sprinkled lightly among them will help to keep down the disease. During the late autumn season they should, if possible, be looked over once a fortnight, and diseased tubers removed. In winter old sacking thrown over the sacks will protect the potatoes from frost. In very severe weather extra covering should be put on at night and removed in the morning.

If no suitable place is available, potatoes may be stored in a cellar, careful attention being paid to ventilation, particularly during the first months of storage.

For growers who are in a position to store their potatoes in a clamp or pit, the following hints maybe helpful. The condition of the potatoes at the time of clamping is most important. They should be put away in a dry state, and as free from soil as possible.

Large clamps are liable to develop more heat than small ones. As a general rule it is unsafe and inadvisable for the base to exceed 7 ft., while smaller clamps are often seen. The site should be dry and well drained, and the base, if anything, should be slightly above the general level of the soil.

Having been placed in a heap, shaped like a pyramid, the potatoes must next be covered. First cover them with a layer of straw about 6 in. thick. A plank about 1 ft. broad and from 8 to 10 ft. long should be placed along the top or ridge of the heap, and the sides, to the edge of the plank, covered with an inch or two of soil. The plank is then moved along, and another length covered with soil. In this way the top of the clamp is kept free from soil, thus providing for the necessary ventilation.

The covering soil should not be put on at once. If the weather is fine and severe frost is not threatened, a full fortnight should elapse between putting on the straw and closing in with the first covering of soil, as this allows much of the heat that is produced by respiration to escape. In very

wet weather the soil may be put on sooner, as it is inadvisable to close in when the straw is sodden. It may be necessary to add more soil to the sides later in the year.

Adequate top ventilation must be given. The straw should be left exposed along the ridge and not closed in completely.

Potato Diseases. Potatoes are subject to a number of diseases. The chief one is known sometimes as potato blight and sometimes as potato disease. The first sign of the disease visible to the naked eye is the appearance on the leaves of dark brown or blackish spots of irregular size and shape, on the under surface of which a delicate white mould may be seen, especially round the margin of the diseased areas. If weather conditions favour the fungus the dark-coloured patches spread rapidly, and the whole of the foliage, and sometimes the stems also, soon become blackened. Potato plants badly attacked by blight give off a very distinct and disagreeable smell.

How to grow Potatoes. 1. Planting on the flat: a, well-dug bottom soil; b, pulverized top soil. 2. Planting in ridges. 3 and 4. Good and bad planting: a, bad; b, its results; c, equally bad; d, good, and its results. 5. Why earthing is necessary: a, exposed tubers greening. 6. Earthing up in stages. 7. Very early potatoes in frames: a, fine soil; b, soil and leafy mould; c, hotbed of leaves and manure.

If the weather is wet after the haulm has been attacked, the tubers soon begin to be affected. Infection of the tubers is brought about by spores which, liberated from the surface of the leaf, are washed into the soil.

By the use of Bordeaux or Burgundy mixture in June and July the spores of the fungus are prevented from germinating and producing threads which grow into the tissues of the leaf, and hence the haulm, instead of withering, as it does when attacked by blight, remains healthy and green. Spraying must be done in good time, and if heavy rains have washed the spraying material from the leaves, the operation of spraying must be repeated.

Potatoes in store are liable to diseases. One of these is dry rot, which usually develops from December onward, becoming more severe as the spring advances.

Potato Leaf Curl. Probably no disease is more directly responsible for weakly potato plant and light crops than that termed potato leaf curl. In the lighter soils in the southern and drier part of Great Britain it is very prevalent and is particularly abundant where the practice of using locally grown seed is followed. A marked symptom is curling of the leaves.

As the disease is perpetuated by means of the seed tubers it is of the utmost importance that they should not be saved from affected plants. Not only should tubers from dwarfed or distinctly curled plants be rejected for seed purposes, but also those from all plants showing curling of the lower leaves and, at all events in the south, those in immediate proximity to diseased plants.

Potato Scab. Common potato scab or brown scab is one of the most widespread diseases affecting the potato. It is particularly prevalent on light gravelly soils poor in humus, and on other soils where ashes, lime, and other alkaline substances have been used freely. The disease is also caused by a minute fungus which attacks the surfaces of the tubers and gives rise to the production of dark scattered scabs, or large eroded patches. The scabs increase in size with the growth of the tubers, and they may in bad cases cover almost the entire surface of them. For eating, the sound part of a scabbed tuber is not injured.

The most important preventive, according to Leaflet 5 of the Ministry of Agriculture, is suitable treatment of the soil. To sandy or gravelly soil organic matter of a vegetable nature should be applied. In gardens and small holdings, decayed leaves, spent hops and grass mowings may be used. The application of lime, ashes and soot should be temporarily suspended on alkaline soils, and their alkalinity counteracted by the use of superphosphate of lime and sulphate of ammonia in spring. Black scab or wart disease, a serious trouble, only attacks certain varieties. Where it is prevalent, immune varieties must be grown. If it is suspected, notify the Ministry of Agriculture.

Sclerotinia and Sprain. Potatoes are also subject to a number of other diseases, although these are neither so widespread nor so frequent as those already mentioned. The sclerotinia disease is most destructive in the northern and damper parts of the country, and is especially virulent in the west of Ireland. To eradicate it the most important step is promptly and systematically to collect and burn all diseased portions of the plant in order to prevent the disease from spreading and the sclerotia from reaching the soil. The sterilization of the soil by steam is also recommended. Unless this has been done, potatoes and other plants liable to this disease should not be grown in infected soil until at least three years have passed.

The disease known as sprain is not generally distributed, but it is troublesome in certain localities where the soil conditions appear to favour its development. It may be recognized by the appearance of dark brown blotches or streaks on the flesh of the tubers. The disease known as pink rot is common in parts of Ireland, especially in the west, and has also appeared in Great Britain. The fungus causes a wet rot of the tubers, and the disease owes its name to the fact that the cut surfaces of infected tubers turn pink when exposed to the air. It commences when the potatoes are still in the ground.

Cooking Potatoes. The potato is almost entirely a starchy food. It contains useful salts, but these are mostly lost unless it is cooked in its jacket. To support life it must be combined with fats, gravy, for example, improving its food value; and proteins, meat, fish, milk, or cheese. New potatoes are less starchy than old ones.

To boil potatoes in their skins, wash and scrub the required number of potatoes, put them into a pan containing enough boiling water to cover them, adding a dessertspoonful of salt to every quart. Bring them to the boil, then simmer them gently until they are soft but not broken. Drain off the water, peel the potatoes, and then put them back into the pan, covering them with a clean cloth and placing the lid so that it half covers the top. Put the pan over gentle heat for a few minutes, shake it occasionally, and then turn the potatoes into a hot vegetable dish. If preferred, the potatoes may be served in their skins, water being drained off and the potatoes left to dry thoroughly in the covered pan. The time required for cooking is 20 to 30 min.

To boil potatoes without the skins, they are washed and peeled thinly, the eyes and any damaged or discoloured portions being removed. Potatoes of large size are cut into halves or quarters of uniform proportions. They are then put into a pan of salted boiling water and cooked in the same way as potatoes boiled in their skins. Some varieties of potatoes cook better if placed in cold water, so should results not be successful by the method given try this. Potatoes need careful watching to prevent them boiling into the water. Some do this quicker than others, therefore it is impossible to give a definite time for cooking.

Steamed potatoes cooked in their skins should first be washed and then placed in a covered steamer over a saucepan of boiling water. Cook them until the skins begin to crack and the potatoes themselves feel soft when tested with a fork; then take the lid off the steamer, move the pan to the side of the fire and let its contents dry. Peeled potatoes may be steamed in the same way. This method of cooking takes about ½ hour.

Potatoes baked or roasted with a joint should first be parboiled, drained and sprinkled with salt. Lay them in the pan under the meat, basting them frequently, and when they are brown on one side turn them and brown the other. They may be served on the dish with the joint or placed in a hot vegetable dish. These require about 1 hour's cooking.

Gloves for scraping new potatoes are a useful invention. Those illustrated have a metal attachment for removing eyes. The potato skins are rubbed off by means of the wired surface on the fronts of the gloves.

Potato. Gloves for scraping new potatoes. The fronts are made of fine wire and the potatoes are rubbed between them. Note the attachment on the right-hand glove for removing eyes, etc.

New potatoes, after being washed and scraped, are put into a pan of boiling salted water with a sprig of mint, and simmered gently until they are tender. The water is poured off, the pan returned to the side of the fire, the top half covered with the lid, and the potatoes left to dry. A small lump of butter or margarine is placed in a hot vegetable dish, and the potatoes served in it, with the mint removed and a little chopped parsley sprinkled on top; 20-30 min. is the time required.

Fried Potatoes. Fried or chip potatoes are served with grilled chops and steaks, fish, etc. Old potatoes are more successful than new ones. The starch cells in new potatoes are undeveloped, so they do not fry a good brown. They can be used, but care must be taken not to over-cook them in the effort to get them as brown as old ones. Slice some washed and peeled potatoes into finger-shaped pieces with a knife or potato cutter, or cut them into straws, cubes or thin oval-shaped slices. Put them into a bowl of cold water until they are required, and in the meantime heat some fat in a saucepan until a faint blue smoke rises from it. Drain the potatoes in a clean cloth, and put them into a frying basket, placing the latter in the fat. Shake the basket occasionally so that the potatoes may cook on both sides, and when they are brown and crisp lift out the basket, let the fat drain from it into the pan, and then empty them into a dish lined with crushed tissue paper. Stand in a warm place until potatoes are drained thoroughly, then serve in a hot vegetable dish with salt sprinkled over them.

Fried potatoes that can be eaten hot or cold, known as potato crisps, are prepared by slicing the potatoes as finely as possible with the special cutter illustrated in this page or with a very sharp knife. Put the pieces in cold water and let them stand as long as possible. Heat a pan of deep fat until it is past the blue-smoke stage; it must be perfectly still and no sign of smoke arising. Dry the potatoes well, and put them into a fine-meshed frying basket. Reduce the heat under the frying fat, and lower the basket in carefully. The fat will bubble up in the pan, and must be withdrawn from the heat if it shows signs of boiling over. Allow the potatoes to cook for about two minutes—until they are transparent looking but not browned at all.

Then take them up, and let them drain in the basket in a warm place while the fat is reheated to the same degree as before. Then put in the basket of potatoes again. They will become crisp and brown almost immediately, and must then be taken up and drained well on tissue paper. Sprinkle with salt and serve, or if required cold they should be stored in an airtight package. The two fryings take every scrap of moisture from the potato slices so they remain crisp indefinitely.

Other Methods. For sauté potatoes, cold boiled potatoes are required. Cut $\frac{1}{2}$ lb. of these into slices $\frac{1}{2}$ in. thick, and fry them in a pan containing 1 oz. smoking hot fat. When they are pale brown on one side turn them over and cook them on the other. Serve them hot, sprinkled with salt and finely chopped parsley.

Boiled potatoes may also be served au gratin. To do this, cut 6 large cooked potatoes into slices, place these in layers in a fireproof dish with a little grated cheese and salt and pepper sprinkled between each layer. About 3 oz. cheese will be required for this. Pour $\frac{1}{2}$ pint white sauce over the whole, sprinkle a little more cheese on top, and heat the mixture in a moderate oven or under a griller. Serve the potatoes in the dish in which they were cooked.

Potatoes that are to be mashed should first be boiled or steamed, and then put through a sieve, beaten up with a fork, or pounded with a potato masher. The potatoes are placed in this and are forced through a wire mesh by pressing down a handle. Add $\frac{1}{2}$ oz. butter or margarine and a tablespoonful of milk to each lb. of potatoes, season to taste, and then put them into a hot vegetable dish. Mark the top with a fork and then place the dish under a griller or in the oven so that the potatoes may become lightly browned on top.

For potatoes à la Duchesse, melt 2 oz. butter in a saucepan, and when hot add 2 oz. grated cheese, and the yolk of one egg. Mix all well together over gentle heat, and season to taste with salt and pepper and a dust of nutmeg. Turn out on to a floured board, and spread out until $\frac{1}{4}$ in. thick. If the mixture seems too soft, add a little flour. Cut out into rounds with a pastry cutter or make into 3 in. squares. Mark the tops in a lattice pattern with the back of a knife. Brush over with beaten egg, put the pieces on a greased baking sheet, and bake in a moderate oven until a delicate brown. The same

mixture as the foregoing may be shaped into potato balls, egg and bread-crumbed, and fried in deep smoking fat.

Potato scallops are also made with this mixture put into buttered scallop shells, the tops sprinkled with grated cheese and baked in a hot oven till slightly brown.

Cold cooked potatoes may be used to make potato fritters. Melt a lump of butter a little less than twice the size of a hen's egg in a saucepan, stir in $\frac{3}{4}$ lb. cooked potatoes rubbed through a sieve, the yolks of 1 or 2 eggs, a dust of nutmeg and seasoning to taste. Mix in also 2 stiffly whisked whites of egg, and in the meantime heat up a deep panful of fat. When the latter boils, drop in the mixture a teaspoonful at a time, and cook the fritters until they are a golden brown. Then drain them and serve them garnished with parsley.

Potato Cake. Cold boiled potatoes may be employed to make these cakes. Prepare them by rubbing 2 oz. butter into $\frac{1}{2}$ lb. flour, adding 2 oz. castor sugar, $\frac{1}{2}$ lb. mashed cold potatoes, and 2 oz. sultanas, and mixing the whole with a beaten egg. Roll the mixture out to a thickness of about $\frac{1}{2}$ in., cut it into round cakes, and bake these in a hot oven for about 20 min. When they are cooked, slice them through the middle butter them and serve them hot. If sweet potato cakes are not liked the sultanas and castor sugar may be omitted.

Potato Croustade. Savoury croustades can be made from 2 lb. cooked potatoes, 1 egg and 3 extra yolks, some breadcrumbs and seasoning. Rub the potatoes through a sieve, then mix them with the 3 yolks and salt and pepper to taste, and shape the mixture into flat round cakes, about $1\frac{1}{2}$ in. high and the same in diameter.

Brush these over carefully with beaten egg and coat them with fine breadcrumbs; repeat the operation, and then with a small cutter mark a small circle in the centre of each cake. Fry the croustades in hot fat, drain them on kitchen paper, and with a sharp-pointed knife take out the centre pieces. Scoop out as much as possible of the potato without damaging the sides and fill the hollow with minced poultry, game, or fish, seasoned and mixed with thick sauce.

Potato Dumpling. Potato dumplings for serving in soup can be made in the following way: Boil 6 dry mealy potatoes in their skins and, after removing the latter, rub them through a fine sieve. Beat 1 oz. butter to a cream, add to it the yolks of 2 or 3 eggs, and then mix in the sieved potato, $\frac{1}{2}$ oz. flour, and seasoning to taste. When the mixture is firm, divide it into small, even-sized pieces, shape these into dumplings and cook them for about 5 min. in a pan of boiling stock.

Potato Rolls. Steam two good sized potatoes, and while still hot pass them through a wire sieve into a basin and mix with them $1\frac{1}{2}$ lb. sifted fine flour and 1 teaspoonful salt. Cream $\frac{3}{4}$ oz. yeast with sugar and add to it $2\frac{1}{2}$ gills of warm water. Make a well in the centre of the flour and potatoes and pour in the yeast and water. Sprinkle a little flour from the sides over the top, cover it over with a thick cloth, and set it to rise in a warm place.

When it is quite light knead in 2 oz. butter and the well-beaten yolks of 2 eggs, and work up into a dough as for bread (q.v.), adding with the eggs $\frac{1}{4}$ teaspoonful carbonate of soda dissolved in 1 tablespoonful warm water. Divide the dough into equal parts and make each into long-shaped rolls. Place these on a floured baking sheet to prove. Bake them in a hot oven. They should be eaten hot after being pulled apart with two forks and buttered.

POTATO CUTTER. There are various kinds of potato cutter on the market, one of them being a cylinder-shaped tin with a perforated top. The potato is forced through these holes with the hand and comes out in long finger-shaped pieces. This cutter is specially designed for chip making. The

cutter illustrated on the left is used for slicing potatoes finely for crisps. The other is for cutting fancy shapes.

*Potato Cutter which cuts fancy shapes, mainly for purposes of garnishing.
Left, device for slicing potatoes finely and quickly for potato crisps.*

POTATO PEELER. There are various kinds of patent potato peelers, differing both in size and design. The most effective type consists of a straight piece of wood about 4 in. long, into which is fitted a convexshaped projection of cast iron. The latter, in turn, is fitted with a blade which reaches just below the edge of the iron.

The blade is drawn sharply over the potato, with the result that the peel is drawn upward and outward through a slit in the iron. This peeler can also be used for peeling other vegetables as well as fruits. Its chief recommendations are that it can be used without danger of cutting the hands and it peels the skin off without waste.

POTATO RING. In silver and Sheffield plate the potato ring is now chiefly a curiosity valued by collectors. It was first made in Ireland early in the 18th century, and Irish specimens fetch high prices. The rings were used as stands for the wooden bowls in which the potatoes were brought to the table.

The conventional shape is a band of metal about 2½ in. deep, bent to form a circle something like a large napkin ring. This was swaged to present a concave surface, and was decorated by piercing or embossing; sometimes by chasing or engraving. Most rings were larger on one side than on the other, the reason being that they could be used for bowls of different sizes.

Potato rings are occasionally found fitted with glass bowls. Several beautiful examples are in existence. One in Sheffield plate is ornamented with foliage, and has flat chasing with ogee mounts round base and rim. *See Sheffield Plate; Silver.*

POTENTIAL DIVIDER: In Wireless. This is a tapped resistance, which, when connected across a source of potential, enables voltages to be obtained which are a known fraction of the total voltage across the ends of the resistance. Thus a potential divider joined across a 6-volt battery might have tapplings at one third, one half and two thirds of the total resistance. The voltages between each tapping and the negative end of the resistance would be four, three and two volts respectively.

Potential dividers are widely used in mains driven radio receivers for adjusting the voltages for the different valves. This is particularly the case in sets designed for operation on direct current supplies. The device is wound on heat-resisting material, and there must be a free circulation of air round it so that heat can be readily dissipated.

In practice there should not be more than a slight "warmness" from the component itself, so long as it is wound with a generous gauge of wire. Nevertheless, this heat will be supplemented by that from the valves and, therefore, ventilation by means of apertures in the back or base of the set is usually provided.

These should be left free, e.g., not impeded by standing the set flat against a wall. However, that a set should feel warm when touched, especially after it has been in operation, is quite normal.

Potentiometers, i.e. potential dividers having continuously variableappings, are used in wireless receivers for controlling volume.

Volume control potentiometers, when incorporated on the low frequency side of a set, should have a value of not less than 500,000 ohms, and may take the place of the grid leak in a resistance capacity coupled stage or be connected across the secondary winding of a low frequency transformer.

POTENTILLA. The cinquefoil or potentilla is an old hardy herbaceous perennial of which there are several improved varieties with large showy flowers. The plants reach a height of 18-36 in. and bear single or semidouble strawberry-like flowers in summer. They can be increased by division in autumn or by sowing seeds out of doors in May. The varieties Gibson's Scarlet, Yellow Queen and William Rollinson, red and orange yellow, are a few of the best. *Potentilla nitida* is a beautiful little rock garden plant with grey leaves and pink flowers: it needs gritty soil and should be protected by a raised piece of glass in winter.

POTHERB. This name is used for any plant the leaves and stalk of which are used for food, more especially for such herbs as thyme, marjoram, etc., used for flavouring. Vegetables that are served in stews, such as carrots, turnips, parsnips, onions, etc., are often known as potherbs. *See* Asparagus; Balm; Basil; Cabbage; Spinach, etc.

POTLID. Owners of picture potlids, which were sold in such large numbers between 1848 and 1859, and are now valuable, often complain of there being no really satisfactory method of displaying them. The pictures require no covering of glass, being upon earthenware, glazed, and absolutely permanent. The illustrations show the system of framing.

Potlid. Sectional view of framing.

To make the rim, it should be turned about 1 in. in width all round, and of an inside measurement about $\frac{1}{4}$ in. less than the potlid in diameter. The front may be moulded, but the outside circular edge and the back are kept flat. No rebate to take the lid, as an ordinary frame takes glass, is necessary, but one may be turned out of the back if desired. Any convenient wood may be used, one of the hardwoods being desirable; that illustrated is from walnut, 1 in. thick. The rim is shown in section at A.

The backing consists of a ring of common wood—soft white deal is suitable. The ring is turned of an outside diameter like that of the frame ring, or, if preferred, a trifle smaller, but in any case, not larger, than the frame. The inner circular aperture in

the backing ring is of a size to fit tightly over the outside rim of the potlid. This backing ring is shown at B.

The potlid, C, is adjusted in the frame, A, the convex or picture side of the lid being outward, and thus visible through the frame. The ring, B, is then slipped over the rim at the back, and the ring screwed, with not less than 2 and not more than 3 screws, to the frame. One screw is shown at D. The potlid is thus held most securely in the circular frame, and both the front with its picture, and the inner portion of the lid with perhaps its maker's marks, are visible as desired. A picture ring, E,

permits of the framed lid being exhibited upon a wall. The best plan is to arrange them along the top of a set of shelves, or an oak dresser.

Potlid. Front and back view of the lid with frame completed.

POT POURRI. There are various recipes for making pot pourri from mixtures of sweet-scented flowers, herbs and leaves, preserved with salt and

spices. It is necessary to gather the flowers or leaves to be used on a dry day as any dampness on them causes mould. The stalks should be removed and the flowers, etc., dried for at least two days in the sun. The old-fashioned roses with strong perfume are the best to use.

A simple recipe is made from rose petals and a powder composed of equal quantities of musk, storax, cloves, orris root, Jamaica pepper and dried lemon peel. A layer of rose leaves is put into the jar, then bay salt and next a layer of the pounded and powdered spices. Repeat these layers till the jar is full. Cover closely and leave for a month. After that the contents may be mixed and stirred and placed in ornamental jars or muslin bags. Jars are better for preserving the scent of pot pourri. They should be provided with well fitting lids, which may be removed to allow the fragrance to escape into the room as required.

Another recipe requires a handful each of lavender flowers, rose petals, sweet briar leaves, jasmine, rosemary and half a handful each of sweet geranium leaves, mint, thyme and lemon verbena. Put layers of these in a wide-mouthed glass jar with bay or rock salt between each layer. Cover for a month and after turning out the mixture add 1 oz. powdered orris root, a few drops each oil of neroli, oil of musk, oil of cloves and oil of cinnamon. The bay salt which is obtainable in lumps is roughly pounded. It may be mixed with an equal quantity of common salt.

POTTED FISH. Almost every kind of fish may be potted, but those usually preserved in this way are salmon, shrimp, and lobster. They may be bought in small glass jars or tins, but can also be prepared at home according to the following directions.

Potted salmon is best made from cold boiled fish. Remove all skin and bone from the latter and pound it well in a mortar with enough butter to make a smooth paste. Add seasoning to taste, then turn the mixture into clean, dry jars, and cover it with melted butter before tying it down.

To make potted shrimp, remove the heads and tails from a pint of shrimps, and then pound the latter in a mortar with a little butter. The shells also should be pounded with butter and then pressed through a fine hair sieve before they are added to the fish. Season to taste.

Melt a lump of butter about the size of a hen's egg in a pan, and stir the shrimp mixture into it. When the butter has been absorbed, move the pan to the side of the fire and add a little powdered mace. Let the mixture cool before potting it as described in the previous recipe. Prawns may be potted in the same way, and so may the remains of any cooked white fish. The latter, however, should be flavoured with anchovy and well seasoned.

POTTED MEAT. Almost any cold cooked meat may be potted. First free the meat from skin and gristle, then mince it finely and put it into a mortar with seasoning to taste. To every $\frac{1}{2}$ lb. meat allow a little more than 3 oz. melted butter, adding it gradually and reserving a little to cover the meat when it is potted. A little tomato sauce or Worcester sauce added to cold mutton or beef is an improvement. Pound the mixture well, then rub it through a wire sieve and put it into pots, pouring the remainder of the butter over it to keep out the air.

Two different kinds of meat, such as veal and ham or chicken and tongue, may be used together. Ham, from its salt nature, makes a good addition to most fresh meats, but should not be used in too large a proportion.

Potted chicken is especially tasty when mixed with ham or tongue. To prepare it, take $\frac{1}{2}$ lb. cooked chicken and $\frac{1}{4}$ lb. cooked ham or tongue, mince these thoroughly by putting them through a machine 2 or 3 times, and then pound them in a mortar with a little more than 3 oz. butter, previously melted. Season the mixture to taste, rub it through a fine wire sieve, and then put it into small glass pots, putting a little more melted butter on the top of each.

Raw meat may also be potted, but should be as lean as possible. Bake 1 lb. of this in a jar to which is added a tablespoonful of butter, the same quantity of water, a few cloves, a pinch of allspice, and some salt and pepper. Cover the jar well with buttered paper and a close-fitting lid, and place it in a tin of boiling water in the oven, or in a saucepan of boiling water on the stove. Cook the whole gently for 2 or 3 hours, then take the meat out of the jar and make into a paste by pounding it in a mortar. Finally, rub it through a sieve and put into jars covered with clarified fat.

POTTERY AND POTTERY COLLECTING

How to Recognize Typical Pieces of Many Periods

This contribution is concerned with decorative earthenware pieces, and the reader is especially referred to the article on China. Other branches of ceramics are dealt with under Faience; Terra Cotta; Tiles. See also the separate entries on kinds of Pottery, e.g. Satsuma Ware; Wedgwood; Whieldon Ware.

Although the term pottery is sometimes used in a general way for all pieces of the potter's art, including china, porcelain, earthenware, faience and stoneware, certain authorities make the distinction between china and pottery that the former ware is manufactured from the finer clay fabrics, while the latter includes the pieces made from the coarser kinds. This distinction has been accepted for the purposes of this Encyclopedia.

As far as English pottery is concerned, existing pieces range from the 4th century, but very few which authentically belong to a date earlier than the 18th and 19th centuries are to be found in ordinary collections. The 18th century English earthenware was, however, of great beauty, interest and diversity, and single pieces are still to be picked up at reasonable prices. Owing to the immense output of pottery of all types it is best to confine a small collection if not to one particular kind, at least to one class, country or period.

Early Pottery. The most valuable pieces of pottery, however, are not the English wares, but those made by the ancient Egyptians, Greeks, Romans, Chinese and Persians. In the main these are beyond the means of the ordinary collector, although specimens are found in the great public and private collections. The Egyptians were highly skilled potters, and passed on their art to the Greeks. Roman pottery showed refined taste in glazing and decoration. The most interesting Chinese periods for pottery are the T'ang (618-906) and Sung (960-1279) dynasties. The glazes of the pieces are rich and are sometimes dark brown or palish green. White T'ang wares have a crackled glaze and a creamy glaze. Specimens of Sung ware show incised designs under a green celadon glaze.

The Chinese have been acknowledged the world's masters in ceramic technique, certain of their periods and styles produced articles that have probably never been excelled for beauty of workmanship. Persian pottery was influenced to some extent by the Chinese. Fig. 1 shows a Persian example of Ray pottery dating from the 12th century. In the 13th century the royal city of Rhages was the producing centre of Persian pottery, and beautiful lustre painting was revived to decorate many of the pieces. The Persians extended their art into the island of Rhodes, and early Rhodian ware followed very closely the inspiration of Persian ceramics, being fabricated of a sandy, highly vitrified clay, covered with a hard glossy paste and decorated with floral, bird and animal designs. Other sources from which the potter's art was introduced into Europe were by the Moors in Spain. Fig. 2 illustrates an example of Valencia ware dating from about 1470, which shows the Moorish influence.

Pottery. Left. Fig. 1. Rare Persian example of Ray pottery dating from the 12th century. (Parish-Watson Collection. New York)

Right. Fig. 2. Specimen of Valencia ware, a vessel with shield of arms and bryony scrolls, c. 1470. (British Museum)

Fig. 3. Example of Palissy Ware, a 16th century dish with cupids set between the sunk portions. (British Museum)

Apart from Majolica and other faience ware, Palissy ware made in France by the French potter of that name was one of the most important steps towards perfecting the potter's art in Europe during the 16th century. An example of Palissy ware is illustrated in Fig. 3.

English 18th-Century Pottery. English earthenware of the 18th century rivals in interest and importance that of later times, including as it does the supreme achievements of the prince of English potters, Josiah Wedgwood. He and his contemporaries, Turner, Adams, Palmer, and others, produced work of which scattered examples may still be met with. Modern reproductions are made at Etruria, and in the Adams works at Tunstall, from the old formulas and models. That epoch-making age was preceded by the hard Staffordshire salt-glaze which, for a century after 1690, was the glory of native ceramic art. A typical example is illustrated in Fig. 4. In the earlier part of the 18th century, before English porcelain was yet in being, there were produced the Elers red teapots, the variegated ware of Astbury and Whieldon, the Fulham stoneware of John Dwight, and the delft, which was wrought at Lambeth, Bristol and Liverpool. Astbury ware also included pottery statuettes an example of which, dated 1740, is shown in Fig. 5.

For about eighty years of the 18th century the Frank family were producing pottery of a refined delft type at Bristol. This earthenware had a clear greenish-blue glaze, and many of the designs were transferred by printing. Some of the pieces had grounds of blue or purple dots surrounding a printed or painted panel. Characteristic also of Bristol ware was white ornament over the enamel glaze. The initials of the painter, sometimes the word Bristol, the date or occasionally two strokes crossed diagonally with two others were marks used on Bristol 18th century ware. While Chinese, Persian and Indian styles of decoration were copied in the Staffordshire potteries, several firms specialised in views of cathedrals, castles and country houses. These were mostly on dishes and plates; figures also received much attention from the designers.

Pottery. Fig. 4. Quaint salt glaze group, dating from about 1730. (British Museum)

Fig. 5. Grenadier in Astbury ware, c. 1740.

In cottage homes, apart from lusted ware, the taste for chimney-piece ornaments was catered for by the Staffordshire factories, with the so-called china toys. These earthenware figures were in part based upon the Chelsea tradition, in part upon the uninstructed

work of local modellers. Their figures were artless, but they carried on the 18th century work of the Wood family. Fig. 6 illustrates a statuette of a girl modelled by Ralph Wood about 1760.

Fig. 6. Statuette of a girl, modelled by Ralph Wood, c. 1760.

The productions of John Walton, nearly all in enamel colours, such as his shepherdesses with a foliage background, and his scriptural groups, mark a degeneration of type which ultimately led to the spotted dogs and woolly sheep of Ralph Salt. The figures of these and a score of other potters, who turned out farmyard incidents and portraits of celebrities, are to be found, genuine or forged, on many a farmhouse mantel. Most of this class of image-work is unmarked, and indeed a marked piece should be suspected. With these may be ranked the jugs and mugs portraying historical events, with other memorial ware.

Leeds ware includes Egyptian basalt (matt black), glossy black, white ware which is blue printed, and lustre printed pottery.

Like the willow pattern at Caughley, lustre ware was introduced, at Spode's, in the later years of the 18th century. The large output of Newcastle and Sunderland lustre ware of a less interesting and artistic character covered with scenes, rhymes and texts in black transfer work and enlivened by patches of pink or purple lustre fell within the earlier years of the 19th century. When the design itself was lustred the effect was less crude, but this north-country ware at its best seldom reached the level of that made in Leeds, Swansea and Staffordshire. As it was mostly unmarked, its origin is usually determined on

the dubious evidence of the potting.

Some of the best Staffordshire lustre was made by Wedgwood's, whose founder himself did some good work in this method. After 1831, a silver lustre made with platinum was introduced at Longton by Charles Allerton, and for 40 years his products attained such distinction that they were in constant demand by collectors. In contradistinction to the Sunderland lustred mugs are the salt-glazed brown wares produced at Bampton and Chesterfield, inaccurately called Nottingham ware. This includes complimentary tankards, jugs with hunting scenes, and animal figures for the mantelpiece.

Victorian Pottery. With the Great Exhibition of 1851 there was inaugurated a revival, which profoundly influenced the pottery crafts. Many of these pieces have an old-fashioned rather than an antique air. Victorian pottery should be chosen for its decorative merit, whether it seeks to simulate ancient styles or is the outcome of the creative thought of its own age.

The task of emulating the gleaming hues of the medieval majolica was approached in the mid-century at Minton's, and afterwards at Wedgwood's. The two methods of reproduction were quite distinctive, the former using dark clays with opaque enamels, the latter white bodies with coloured glazes. Later on the accomplished Work of William de Morgan, who successfully rivalled the glories of the old Gubbio as well as the Persian lustre, remains quite unsurpassed.

A profound influence has been exerted upon the ceramic industry by the faience and other art fabrics for which the Boulton works at Lambeth are famed. Dating from the Great Exhibition, they present distinct qualities of make and design, and as moulds are but sparingly if ever used each piece possesses its own individuality. Even when the work is deliberately reminiscent of early pottery, as in the case of Miss Crawley's studies in the old Persian and Rhodian manner, the same observation applies.

Another great development of this period was the invention of Parian ware (q.v.), whose ivory-white body, unglazed or slightly glazed, enabled statuettes to be moulded which resembled marble. Besides Copeland's, Minton's, and Wedgwood's, there are other works, such as Bootes' in Burslem, and the Irish factory at Belleek, which did admirable Parian figures. A polychrome effect was also secured by majolica pigments at Stoke, especially by Poole, Stanway and Wood. The smaller examples are often desirable and, like other Victorian products, will assuredly attract in due time the attention of collectors. The larger figures and groups are often of poor design and pretentious.

Demanding at their best no less care in modelling, are the terra-cotta figures and groups of the same period. Notable among these are the classical statuettes turned out at the Dale Hall pottery. This was founded by a potter of another name in 1790, and a mark embodying this date was adopted late in the 19th century. It is one of several instances of a mark with an early date actually attesting not the antiquity but the modernity of the ware.

Modern Pottery. Much rustic pottery is turned out to-day in Sussex, Devonshire and other districts. Some of it is made of common brick clays with blended glazes, others have a fireclay body. Specimens of the best work of the Ashted Potteries are most desirable acquisitions. Their table ware is excellent in shape and design. In the productions of the Wedgwood, Minton, Copeland, Cauldon and other Staffordshire potteries, besides the Doulton in London, there is great variety. Individuality is a vital characteristic and the pottery of to-day has attained a standard of popularity on its own merits. In some of the designs there is a note of the bizarre in brilliant colour and geometrical forms. In others rich soft tones are finely blended, as in the modern versions of pebble ware (q.v.) and of "Peach bloom." White ware is perhaps the most beautiful, and two examples of fine design and glaze are illustrated in Figs. 7 and 8. This white ware is sometimes faintly tinged with colour where the pottery shows through the paste surface. Very beautiful book-ends are modelled in it, while candlesticks made of white Poole pottery show fine designs. A lovely branched pair for the mantelpiece or for the dining table have a conventionalised bunch of grapes on each stand. Book-ends in creamy crackle, which serves to mellow the appearance of the pottery, show geometrical designs, and are a change from the animal and cherub figures so often seen. Other decorative book-ends are made in polychrome pottery, in a great variety of shapes, designs and colours.

Modern Pottery. Fig. 7. Duck and drake in highly glazed white ware, characterized by beautiful modelling.

Fig. 8. Statuette of Victorian lovers.

Pottery. Fig. 9. Brown earthenware amphora, a graceful and useful pottery vase for tall flowers or foliage. Fig. 10. Example of modern lustre ware shading from rose pink to wine red.

The modern vases shown in Figs. 9 and 10 rely on shape for their simple beauty and for their usefulness, as they are both entirely charming and adequate for flower arrangement. Fig. 9 is in brown earthenware of the classical amphora shape, while Fig. 10 is of rose-pink lustre shading to deep wine red. Ashted and Poole pottery vases showing multi-coloured designs on white grounds provide many examples of decorative modern English ware, while French pottery is well represented by pieces which have

excellent designs of sporting character, the development of sport having greatly increased of late years in France. Modern designs, whether English or French, are characterized by suggestion: the amount which is left out being as important as that which is detailed. There are most certainly outstanding potters to-day whose collected work will increase in value. Holiday makers often bring home as souvenirs of continental travel individual pieces of local pottery which have attracted their attention. Favourite objects of this kind are imitations of Cologne stoneware tankards, Dutch delft—often not delft at all in the sense of being tin-enamelled—Italian majolica, and Spanish lustre. The homely wares of North Africa with their brilliant and strikingly oriental designs are gay in certain rooms. Modern Italian pottery also is much favoured on account of its wealth of colour and pleasing shapes.

The most popular rival of British pottery that is procurable without foreign travel comes from Japan. Of its earthenware fabrics, not to be confused with the true porcelains, the most famous are those of Satsuma. The tawdry platters and vases which are turned out mechanically in Japanese factories for the purposes of export trade should be avoided.

POTTERY: MAKING SIMPLE PIECES

An Outline of a Pleasing and Useful Handicraft

This contribution explains how simple articles can be modelled, fired and glazed, at home, and concludes with a brief description of methods for decorating pottery.

There are two methods of forming the shapes in pottery; one is by building up the clay by hand on a potter's wheel, the other by casting and pressing. Apart from the potter's wheel and a muffle furnace, the tools are simple and inexpensive. The clay used for making bricks or flower pots can be used if properly sieved and evaporated down, but for good work it is advisable to employ common C.C., or cane-coloured earthenware. China clay forms the main body of porcelain; blue clay, known also as ball clay and black clay, is very strong and plastic. Felspar, flint which has been calcined and ground, and bone ash are mixed with clay to bind the material together and render it translucent.

How to Mix the Clay. Ordinary clay can be refined by mixing it with water to form a thin cream, passing it through a No. 40 sieve. The mixture is placed in a shallow pan and slowly evaporated. The dried clay is mixed with fine sand and powdered flint—8 parts of clay, 2 of flint, and 1 of sand. This body, although not so safe in use as the properly prepared C.C. body, is quite suitable for such

objects as candlesticks, small trays, or thick bowls for bulbs, but it would not do for circular forms on the wheel, or for casting.

The clay being hard at first is moistened with water; the lumps should be reduced to powder by pounding, water being then added until the clay is soft enough. It is of the right consistency when the fingers easily make an impression in it without picking any of it up. It can be kept in this condition for a long time if placed in a tin or zinc-lined box; small quantities will remain plastic if kept in a tin biscuit box and covered with a damp cloth.

Pottery. Useful articles which can be modelled in clay, and fired and glazed at home. The photograph shows, amongst other pieces, a candlestick, an ash tray, and a vase ornamented with a conventional flower pattern.

Before being used, the clay must be worked so as to exclude all air

bubbles and render it perfectly smooth and even in texture. For simple work it can be placed on a board, kneaded with the hands, and rolled out flat 2 or 3 times with a rolling pin. An oblong piece is worked to a brick shape, as shown in Fig. 1, by banging it down on the table several times until the sides are fairly smooth.

A wedge is then cut from the corner as in Fig 2, using a piece of string to cut the piece off. The wedge is placed in the centre of the block of clay and driven in with a mallet or flat board (Fig. 3). The result is seen in the cut edge, small holes being formed by the air previously imprisoned in the clay. It will be necessary to repeat this operation at least a dozen times before the clay is ready for use. Improperly worked clay is sure to break in the kiln, so it is important that every trace of air should be removed.

Simple Modelling. The first stages in modelling are illustrated in making a simple tray as in Fig 4. A lump of clay should be taken from the box, a piece a little larger than an orange being sufficient. Place it on a board and work it into a brick shape with the hand. Next roll it out flat with a rolling pin to a thickness of about $\frac{1}{4}$ in. Break the piece up and work it into a brick shape again, then roll it to about $\frac{1}{8}$ in. thick. Repeat the process, finally leaving a flat piece about $\frac{3}{16}$ in. thick. Then cut the edges off to form a square of 4 in. or so.

The next step is to mark off lines $\frac{3}{4}$ in. from the edges, using the sharp edge of the modelling tool lightly. The edges of the clay are gradually bent upward, working with the finger and thumb and shaping the corners round one finger. The surface of the clay should be finished smooth, and the work placed on one side to dry. A similar tray can form a base for a candlestick, the standard being made on the wheel if possible, although it may be square in section.

Good practice for the wheel will be found in shaping small circular trays or bowls as shown in section in Figs. 5 and 6. The method of working, called throwing, is to place a ball of clay on the centre of the wheel, which should then be revolved from right to left. Finger and thumb are used to press the clay down to the revolving board, and when sufficiently flattened out the edge should be

raised. To form a bowl shape, as in Fig. 6, start with a well-worked ball of clay, wet the thumbs and work the lump of clay into a mound. The clay is worked into a cone shape to indicate the centre, and then the thumbs, pressing downward, will throw out the material sideways. By pressure here and there any required shape can be formed, but considerable practice is necessary before a shape of even form and thickness is produced. The candlestick shown in Fig. 7 is a suitable shape for a piece of wheel-made pottery; the section in Fig. 8 indicates the proportions of the various parts.

Pottery-Making. Fig. 1. Preliminary working of clay into a brick shape. Fig. 2. Wedge cut from corner with a piece of string. Fig. 3. Wedge placed in centre and driven in.

Fig. 4. Easily made tray.

Figs. 5 and 6. Small curved trays and bowls in section.

Fig. 7. Candlestick suitable for a piece of wheel-made pottery.

Fig. 8. Section showing proportion of parts.

Fig. 9. Form for a vase which can be cast in a 3 piece mould.

Duplication of Pieces. Casting and pressing is the method to be followed if several objects of the same shape are required, or if it is desired to make a duplicate of an existing piece of pottery. The vase form in Fig. 9 is suitable for the wheel and equally so for casting in a 3 piece mould; if the top were not curved inward, the shape could be cast in a 1 piece mould. Taking a small bowl as a pattern for a 1 piece mould, prepare some plaster by sprinkling plaster of Paris from the hands rapidly into a basin half full of water until the surface is reached. Pour off the surplus water, and stir very carefully to avoid bubbles, and then use. The bowl should be lengthened with clay and placed upside down in a circular cardboard box or a clay-made receptacle. Pour the plaster over the bowl, and when set remove the bowl with a twisting motion. If it sticks, wet the plaster and try again. A 1 piece mould can only be used for forms that can be removed in this way.

A large number of shapes can be cast in a 3 piece mould, but they must not have sharp contrasts in form. To make one, first set out on the pattern a line that will divide it into 2 equal parts. Place it on the board and build up a bed of clay to the halfway line, extending $\frac{1}{2}$ in. at the top and $\frac{1}{4}$ in. at the bottom. Shape the sides of the clay and attach a border of cardboard, as in Fig. 10 then fill up the space with plaster, allowing at least $1\frac{1}{2}$ in. of plaster above the pattern. When set, carefully remove the walls and the clay and work out semicircular depressions at each corner of the half mould, as shown in Fig. 11. These recesses, which should be quite-smooth, are necessary in order that the two halves of the mould may be accurately keyed together.

Figs. 10 and 11. How to cast the vase. Fig. 12. Recesses cut in each mould at right angles to the join.

Fig. 13. Mould tied together with string tightened with wedges.

Coat the surface of the plaster with olive oil, replace the walls, the half mould being at the bottom, as in Fig. 11, and fill up with plaster again. When set, the walls should be removed. Then smooth the bottom of the mould and cut the recesses in each half at right angles to the join, as shown in Fig. 12. Oil this surface, place walls round the mould and fill up with plaster to give a thickness of about 14 in., thus casting the third member or bottom piece of the

mould. When set, the two halves of the mould should be prized apart, the pattern removed and the mould placed together again to dry, the final drying taking place with the parts separated.

Casting a Vase. The method of casting allows considerably thinner pottery to be made. First prepare a large bowl or small pail, which should be perfectly clean. Place a few lumps of clay in it, and pour water in to more than cover the clay. Next squeeze the clay between the fingers, and thoroughly mix the clay with the water until it forms a creamy liquid. The liquid, termed "slip," is passed through a No. 40 phosphor-bronze sieve, a stiff bristle brush being used to assist it. The mould is sponged lightly with water and tied together with string, one or two wooden wedges being used to tighten up the parts, as in Fig. 13.

The mould is now tilted, and the slip should be very carefully poured into it so that no bubbles are formed, as these mean holes on the surface of the finished casting. The liquid or slip should be watched, and it will be seen that the level gradually falls. Keep refilling it, and give the mould a revolving movement from time to time to prevent the clay settling at the bottom. As the sides absorb the water from the slip, the clay becomes deposited on the mould; and when sufficiently thick, the slip should be poured out and the mould left in a warm place for about $\frac{1}{2}$ hour. The mould should now be taken apart, using every possible care; there should be no difficulty in removing the vase, as the clay shrinks on drying. The lines and the waste at the top should be trimmed off with a sharp knife; then leave the shape to become quite hard.

To complete the work, rub the base on glass paper to level it, rub the sides down with fine glass paper, round off the edges at the top, and finish by wiping over the whole of the shape with a damp sponge. Throughout these finishing operations the clay shape must be handled very carefully, as it is very fragile, and will continue to be until it is fired. The 1 piece mould is done in the same way, but as only those objects that can slide out of the mould, after the casting has set, are suitable, all that is necessary to take the casting from the mould is to place it upside down. The same methods of cleaning up apply.

Pressed Shapes. These are easier, but it is not so easy to make the ware thin. Proceed by flattening a lump of clay, using if desired a batter as in Fig. 14, this being a thick disk of plaster with a stout handle. The clay is placed on a piece of linen or calico and pressed out flat with a rolling pin to a thickness of $\frac{1}{4}$ in. or so. Sponge the surface of the mould, place the thin slab of clay on it, and press carefully to the shape.

Pottery-Making. Fig. 14. Disk of plaster with handle attached, used for flattening a lump of clay.

When both sides of the mould have been done in this way, smooth the edges, coat the joins with slip, place a thin layer of clay along the join, and then place the parts together. The joins are pressed to the sides of the mould from the inside and wiped over with a damp sponge fitted to the end of a piece of stick. If the mould is placed in a warm room for an hour the shape inside will have shrunk sufficiently for the mould to be taken apart, when it can be treated like a casting.

Much pottery can be made without moulds by building the shape or throwing on the wheel, but in making spouts and handles, either pressing or casting should be followed. Any additions can be made to a piece of pottery while in the clay stage by scratching the parts to be joined, coating them with slip, and holding in position until set. Handles or projections applied in this way should not be touched before firing, and must be carefully fixed, or they will come apart. When making pottery, it must not be allowed to dry out, and if the piece cannot be finished at one sitting it must be kept covered with moistened cloths.

There are many ways of decorating pottery. Line incision is the earliest and the easiest; it is done with a modelling tool, and for small work there is considerable opportunity for artistic treatment. Another method suitable for the pre-fired stage is to use slip formed from different coloured clays: a number of pleasing effects can be worked in this way by applying the slip with suitable brushes.

Firing the Clay. Before pottery can be glazed or painted it is necessary to subject it to great heat and to transform it into what is known as biscuit. This is the most critical part of the work. If a small furnace is used, the work must be placed in a muffle, supported on slabs of fireclay or sand. The shapes are conveniently arranged, the air inlet almost closed and the dampers $\frac{1}{4}$ open. Light up gradually if using a gas muffle furnace, close the lower door, and after the muffle has got sufficiently hot—in about half hour—the lower door should be pushed in close and the interstices covered over with clay.

Fig. 15. Muffle furnace for firing pottery. (Fletcher, Russell & Co., Ltd., Warrington)

When the work has finished steaming turn on more gas, leave for about an hour, plaster up the top door, and give full heat until the interior, judged from the spy hole, is white hot; this will take about an hour. The work can now be allowed to cool. To make quite sure, the placing of suitable trial pieces so that they can be removed during firing will help; if the trial piece can be scratched on the surface it is a proof that the firing is not complete. Small pieces of clay, known as Seger cones, can be placed inside; these will bend over when the correct temperature is reached. Common C.C. requires a temperature of $1,100^{\circ}\text{C}$. and about four hours in the furnace.

We illustrate a special gas muffle furnace for pottery. It is made in a number of sizes, but the amateur potter will need a muffle size of at least 14 in. wide, 8 in. high and 18 in deep, if vases and similar objects are to be fired. A still larger muffle has a height of 14 in., the other dimensions being as last mentioned. A furnace of either type needs a $1\frac{1}{4}$ in. gas service. The makers, Fletcher, Russell & Co. Ltd. of Warrington, issue a useful booklet with information about the use of gas fired muffles.

Pottery Making. Fig. 16. Painting on unglazed pottery with cloisonné enamels after the design has been incised, as shown on the plate. The vase has been gilded but not coloured, while the jar is half completed.

Colouring and Glazing. The biscuit ware is now ready for glazing or underglaze painting. The glaze is obtainable in various colours, and may be applied with a diffuser or a brush. A glaze firing at about 800°C . will be found most convenient, and if the article is to hold water it will be necessary to glaze the interior as well. Colours can be added to a plain glaze by mixing them with boiling water, passing through a 200 sieve, and mixing with the glaze; only a small amount of colour is required. Before the underglaze paint is applied, the surface of the pot must be stopped by coating it with a solution composed of gum arabic and water. The paints employed for the work are metallic oxides or oxy-salts, and give their true colours when combined with the glaze.

Shapes that are not quite perfect need not generally be thrown away, for small defects on the biscuit pottery can be removed with glass paper, and small holes, cracks or chips in the article can be filled

up with a cement made of 3 parts fired clay, 1 part damp clay, and $\frac{1}{4}$ part of No. 8 flux, ground to a powder, sieved, and mixed with gum. Biscuit pottery can be coloured without firing by applying colour diluted with gum arabic, dextrine, and water to the moist surface of the clay. A fine surface can be applied to unglazed pottery by using ordinary wax polish.

Cloisonné Decoration. Another method is to apply cloisonné enamels. A simple outfit of these contains 6 enamels, gold and silver powder, medium, varnish, 1 flat brush and 4 camel-hair brushes. The design is incised on the plastic surface of the pottery with a modelling tool before the clay is fired. Fig. 17 shows the pleasing and simple type of design which lends itself admirably to this kind of decoration. Pieces of pottery can be painted in sets to harmonize with any colour scheme. This style of decoration is particularly suited to pottery book-ends of simple or geometrical shapes. For those who are unable to make their own pieces, a variety of articles can be obtained with designs already incised. The procedure is very simple. First coat the whole of the article with the special varnish, which dries in about half an hour. Then a coat of gold or silver enamel is applied, taking care that this flows into the incised lines of the design; this, again, is allowed to dry for about an hour and the decoration in colours is proceeded with. Fig. 16 shows articles in three stages of decoration. The plate is merely incised with the design, the vase has been gilded, and the small jar has been half coloured. The design is picked out in various tints, using a separate fine brush for each tint employed on the piece. Figs. 17 and 18 show the pieces finished.

Fig. 17. The finished pieces.

Fig. 18. Jar with lid decorated in colours.

Care should be taken not to let the colours run into the incised lines, or the effect will be spoilt. There is no need for subsequent varnishing, as the enamels are durable and have a brilliant finish. They can be thinned if desired with a special thinning medium.

The larger brush used for the varnish should be cleaned with methylated spirit, while the brushes for the gold, silver and coloured enamels should be cleaned with turpentine.

POTTING: In the Garden. Success in the potting of plants is acquired only by practice and experience; ignorance of its elementary principles is the cause of nine-tenths of the sickly anaemic-looking plants seen in many greenhouses and in rooms. For successful potting attention must be paid to the cleanliness of the crocks and pots, the drainage, the ingredients for composts and correct planting.

Pots and crocks should be well soaked and cleansed with water, even if quite new. Proper drainage is essential. Take a fairly large piece of curved crock, and place this, hollow side downward, over the pot hole. Incidentally, an oyster shell is admirable for the purpose. The next layer of crocks must be determined by the class of plant being potted. If this is a hard-wooded subject, crocks should be

broken up quite small, but if the plant is softwooded, as, for example, the geranium, then larger pieces will be required.

The larger the pots the larger the crocks, allowing deeper drainage to plants remaining in pots for a considerable time, and less to those having a shorter stay. Indeed, for forcing stuff, such as spireas, one large curved crock is often sufficient. On top of the drainage place a little rough of leaves, moss, or fibre, to prevent loose compost dropping amongst the crocks and choking drainage.

The chief ingredient in potting composts is loam with plenty of fibre, such as is obtained from old pastures, where the roots of grass are several inches deep. Cut turves in autumn, stacking them grass downward, and placing light facings of well-rotted manure and a sprinkling of lime between layers. In twelve months this will become a stack of loam in suitable condition to form a base for most potting composts.

Other indispensable materials for the potting shed are leaf-soil, peat, silver sand, charcoal, wood ashes, mortar rubble, and bonemeal. These are not all required at one time; but with supplies to draw upon, practically any combination for many different kinds of plants may be made up at will. Whatever combination is in preparation, this should be well mixed and turned with the spade, damping it when necessary, until a gripped handful will hang together, yet separate at slight touch.

Potting. 1. How to crock: a, potsherds; b, chopped turf or rough soil. 2. Crocks seen from above. 3. Potting stick. 4. Example of good potting. 5. Bad method of potting. 6. Design of a useful potting bench. 7. Diagram showing proportions of various ingredients which are necessary to make an ideal compost.

A good general compost is formed of 3 parts loam, 2 parts leaf-soil, and 1 part sand. For seeds and cuttings only use equal parts of loam, leaf-soil, and sand, finely sieved and mixed.

The placing of the plant is no less important than the contents of its pot. Do not drag, or lift by the stem, any young plant from its early receptacle, but spread it upside down upon the fingers of one hand and gently rap the rim of the pot on the potting bench, so that the pot itself may be lifted clear. Carefully remove any old crocks with as little root disturbance as possible.

A few inches of soil, made firm with a potting stick, should be placed in the larger pot, and the new plant arranged upright in its centre. Suitable compost should be worked round and rammed firm, but not hard, until the pot is filled within $\frac{1}{2}$ in. of its rim, a necessary space for watering.

When ramming, be careful not to touch the old ball of soil, but only the filling of new compost. Various plants and bulbs require potting at different depths.

A potting bench or table is desirable for the amateur gardener, the construction of which may be on the lines suggested in the sketch.

Labels, too, should not be ignored if choice plants are to be duly identified. A potting stick is easily constructed from an old broom handle, rounded at one end and cut chisel-shaped at the other. Different sizes of pots should be stocked and boxes of graded crocks kept ready to hand. A mistake is to use pots that are too large. A safe rule is to take a size which allows 1 in. between its sides and the old root ball. *See* Aspidistra; Chrysanthemum; Flower Pot; Hydrangea; Palm.

Pottle. A pottle, originally a little pot, has come to mean a measure of liquid, one consisting of 4 pints.

Pott's Disease. *See* Curvature; Tuberculosis.

POTT'S FRACTURE. Fracture of the fibula, the smaller bone of the leg, about 3 in. from its lower end, is called Pott's fracture. It is produced by twisting the foot outward, as for example, in slipping off the kerb or into a hole in the ground.

The slighter cases may be mistaken by the patient for a sprain of the ankle. It is therefore desirable to consult a doctor when a sprain is at all severe. First-aid treatment consists in the application of well-padded splints from the knee to below the ankle.

POUFFE OTTOMANS OR HUMPTIES

Materials and Methods for Making Attractive Floor Cushions

The reader of this article should turn for further information to the entries on Box Ottoman; Cushion; Leather Work; Patchwork; Upholstery

A pouffe or humpty is the name given to a variety of floor cushions varying considerably in size and shape, from small circular pouffes to large square or oblong box humpties which possess well sprung and upholstered lids.

Pouffes are suitable for use in small rooms as they take up little floor space, and when not required as seats they can be placed out of the way in a corner or under a table. The box type is a useful addition to bedroom or sitting room, as it can be used either as a slipper, hat or work box. The softer type of solid pouffe floor cushion is a cosy accessory for the nursery, while invalids and elderly people find them more comfortable than the old-fashioned footstool.

Solid Pouffes. The solid pouffe is the simplest kind to make. It can either be circular or square in shape, and is made by stuffing a calico cover with some suitable filling. Decide approximately the size required, then cut out a pattern in strong paper. This can be pinned up, and gives a good idea of

what the size will be when the floor cushion is completed: 16 in. diameter each for top and bottom, as in Fig. 1, makes a mediumsized circular one with a band of 16 in. deep between, as in Fig. 2. It is important to get a true circle, or the finished shape will not be good. A circular tray can be used; or if this is not available, take a piece of fine string, tie a small loop in one end, and fasten the other end to the centre of the piece of paper with a drawing-pin. Place a pencil in the loop, stretch it tautly, moving it in a circle; the length of the string gives the radius, or half the diameter.

To make the case, cut a strip of unbleached calico, preferably selvedge way, equal in length to the circumference of the circle, and allowing 1½ in. for turnings. Tack the top of the band to one circle and the bottom of the band to the other circle; the case then resembles a short bolster, as in Fig. 3. Machine on the wrong side, leaving about 6 in. open on one side.

Pouffe. Fig. 1. Top and bottom pieces for circular pouffe. Fig. 2. Band to go between circular pieces. Fig. 3. Band sewn together and joined to top and bottom pieces. Fig. 4. Cording the waist of the stuffed pouffe.

As a quantity of filling material is required when making large floor cushions, the centre can be filled with cuttings of woollen or cotton materials. For the new filling necessary, imitation hair, fibre, flocks or brown rugging wool, with wood wool right in the centre, is the most suitable. For a medium size pouffe about 10 lb. of wool is necessary.

As the filling is a dusty process, it should be done in a room with little furniture, and preferably in one with a linoleum floor covering. Each handful of filling should be fluffed out before it is put into the case. Use a wooden spoon or stick for forcing the wool into the edges. When as much as possible has been forced into the case, take a piece of flat wood and beat it evenly all over.

Fig. 5. Pattern for square-shaped pouffe. Figs. 6-9. How to fold pattern and to cut shape. Fig. 10. Shaped corners sewn together. Fig. 11. Top and bottom joined, leaving 6 in. through which pouffe will be filled.

Unless the cushion is well stuffed, after it has been in use a short time it becomes flat and loses its shape. When it is impossible to add any more wool, the seam can be sewn up securely. Take some strong string and, using a slip-knot, cord the waist as tightly as possible, Fig. 4. Place a piece of flat wadding cut to size over the top of the case before covering with the upholstery fabric.

For a pattern of a square-shape pouffe cut two pieces of paper about 30 in. by 30 in., as in Fig. 5, for a medium-sized pouffe. Fold each piece in half lengthways, and then width-ways—this gives a

small square of 4 thicknesses, as in Fig. 6; curve off the top left-hand corner (Fig. 7) and the shape will resemble Fig. 8. These two pieces form the top and bottom of the pouffe.

Having cut out the unbleached calico for the case, sew the curves at each corner together as in Fig. 9, and when all the curves are joined the cap-shaped pieces are formed which make the top and bottom of the pouffe. Place one above the other and join them together, leaving one of the four seams open for filling (Figs. 10 and 11).

There are two ways of making the outer covering for pouffes: either by making the material into a bag-shaped case, leaving one side open into which the cushion is dropped, or by stretching the material and sewing it securely along each waist-line. The former is less trouble, but the latter allows the covering material to be stretched more tightly. Place the weft edge, with a 1 in. turn, along one side of the waist, and stitch securely with strong thread. Then pull the fabric tightly round the cushion, stitch it firmly along the opposite waist-line, again along the first side, and attach the material to the two remaining sides of the waist, cutting off any surplus. Gather the corners of the material to form ears, and neaten the waist with cord to match the cover; if the cord is thick the ears can be secured by being slipped through the twisted cord. A pouffe of the above description is illustrated in Fig. 12.

Pouffe. Fig. 12. Solid pouffe upholstered in small patterned brocade. Fig. 13. Pouffe ottoman, which can be made from a wooden box, with sprung and upholstered top.

Attractive round pouffe floor cushions can be made by using velveteen for the sides and bottom and introducing patchwork of leather and velvet for the top. Such a pouffe can be finished without the corded waist if made 20 in. in diameter, the outer covering being cut in the shapes shown in Figs. 1-3, and the top and bottom finished with a piping or fancy cord. The side strip (Fig. 2) may be cut 10 in. deep (less turnings). Fancy striped material may be used for the top and bottom of such pouffes with a plain fabric for the sides; or terry cloth with an appliqué design in a contrasting colour will make a good cover for a nursery floor cushion.

A two-colour scheme may be devised for a square floor cushion by mounting a square piece of brocade or damask cornerwise on upholstery satin which matches the groundwork of the figured material, and finishing off the edges with narrow gold braid or coloured gimp.

Pouffe Ottoman. The pouffe ottoman, shown in Fig. 13, makes an attractive piece of furniture, as well as a convenient receptacle for music, needlework, or newspapers. A strong wooden box should be procured, if possible with dovetailed sides. No lid is necessary. A box 18 in. long, 12 in. wide, and 12 in. deep is a convenient size: one of smaller dimensions, when upholstered, would not have a very roomy interior. Divide the box in two pieces, cutting off a section 4 in. deep; but if the box is too shallow to allow of this, a narrow box having the same length and width can be utilized by knocking out the bottom, or a wooden frame can be made by using four 4 in. battens; this should be strengthened at the corners. The bottom part of the box will form the container or ottoman, and the 4 in. frame, when fitted with springs, will make the lid and seat of the pouffe.

The two parts must be upholstered separately, the fixing of the hinges being the last step. First upholster the bottom part; if necessary, scrub and dry the box, preferably out of doors. When dry,

rub the inside first with coarse and then fine glass paper. Cover the sides with any suitable fabric, such as casement cloth or hessian. Measure the distance round the box and the depth; allow 2 in. for turnings. Tack the hessian firmly along the top edge and the bottom, keeping it as taut as possible. The reason for covering the wooden sides is that it is impossible to fix hair or wool filling on to wood.

Stitch 3 or 4 rows of strong twine loops into the hessian, using a sacking needle and leaving about 2 in. between each row. Each loop should measure about $2\frac{1}{2}$ in., and a back stitch is necessary between the loops, otherwise the filling, when forced under, causes them to slip. Fig. 14 shows the lower part of the box covered with hessian, and the rows of twine loops ready for the stuffing.

Wood wool is a very cheap first stuffing and rugging wool, fibre, or imitation hair are all suitable for the top layer. Arrange the stuffing as evenly as possible under the string loops, giving the corners extra padding, so that when finished they will be well rounded, as in Fig. 13. Cut off a length of unbleached calico, allowing for the padding and for mitred corners, and tack it in position along the bottom of the box; standing over it, pull the cover up tightly over the padded sides, as in Fig. 15, rearranging and adding more stuffing if needed. Tack the cover just inside the box. Line the inside first with layers of cotton wool and then with casement cloth. A straight piece of material about 2 in. deeper than the sides of the box and long enough to go round it is necessary. Use small brass tacks to fix the lining along the inside of the top edge. Cut a piece of stiff cardboard to fit the bottom of the inside tightly; cover it with the same material, and place it in position. A piece of plain American cloth to match the upholstery fabric in colours should be tacked over the bottom of the box that comes next to the floor, to prevent the edges of the material fraying and to neaten. The bottom of the pouffe should be fitted with castors or glides. If the latter are used, 4 small stained blocks of wood should be screwed in position at each corner, in which the prongs of the glides should be fixed; this raises the pouffe off the ground and improves its general appearance.

Pouffe. Fig. 14. Lower part of ottoman covered with hessian, also four rows of string loops and some of the wool in position. The last piece of webbing is being strained and tacked on the lid. Fig. 15. Springs placed on webbing of lid.

To upholster the lid, first stretch the frame with good quality webbing bands lengthways as in Fig. 13, and then interlace them at right angles in basket fashion. A webbing-strainer or small piece of wood used as shown enables the bands to be stretched very tightly. Procure five or six 8 in copper springs, arrange them in position on the webbing, and stitch them firmly, using twine and a packing needle. When all the springs are fixed at the bottom, tack the outside ones tightly to the frame, and tie each one to the adjacent springs. When all are lashed down, cover the springs and sides of the frame with hessian, make twine loops and pad in exactly the same way as the lower part. Extra padding must be piled on to the top of the springs or the seat will become flat after being in use a short time. Keep the stuffing in position with a cover of unbleached calico, tacked to the lower edge of the frame.

Tapestry, rep, velveteen or plush may be used to cover the humpty; with a patterned material a more professional appearance is given if an oblong panel 10 in. by 14 in. is piped on to a length of fabric. The panel must be arranged so that it comes in the centre of the lid, and the piping should be of one of the colours incorporated in the pattern. Mitre the corners neatly, making any surplus material into small rosettes. Make a small tab of covering material about 2 in. long, and tack it to the middle of the front edge of lid, to facilitate opening. Line the inside of the lid with casement cloth over cotton wool, tacking it on to the wooden rim. Attach the bottom of the pouffe to the lid by two small brass hinges. Two chains screwed inside to the sides of the box and to the rim of the lid may be added to keep the lid from falling back.

POULTICE: How to Make. As a means of applying moist heat to any part of the body one may make use of a poultice. Poultices increase the flow of blood to the part which they cover, withdrawing it from deeper, congested areas; hence they are useful in deep-seated pain, as in chest affections, inflammatory pain in the abdomen, or in the painful swelling of joints. In the case of boils, poultices relieve the tension and bring the boils to a head more quickly. The materials used are crushed linseed, bread, oatmeal, starch, etc. Crushed linseed is better than linseed meal, because it contains more oil, and therefore does not so readily stick to the skin. Mustard and various antiseptics can be combined in the poultice. Bread, linseed and mustard poultices are described under their own headings, while directions for making one of starch are given in the article on Eczema.

Poultices large enough to cover both the back and chest of the patient are sometimes ordered. For children, these can usually be made in one piece, the poultice being wrapped right round the body and secured with safety pins; but for adults it is generally necessary to make two separate poultices, large enough to meet at the sides. These cannot be pinned satisfactory, and are therefore held in place with a special binder or a wide strip of material that will serve the same purpose. A warm, close-fitting jacket, such as that sometimes worn by pneumonia patients, is also useful for confining these poultices.

Linseed and other poultices, to be effective, must be smooth, soft, and as moist as possible, without being sloppy. They should be thick enough to retain heat and moisture for some time, but not so thick as to be uncomfortably heavy. As their value lies principally in the warmth they supply, it is necessary to make them quickly, and to apply them at once before they have time to cool. For this reason everything that is required should be got ready before commencing to make the poultice, and the patient should also be prepared. Poultices on any part should be removed before they become cold. The skin should then be dried with a soft cloth, smeared with vaseline, and covered with a piece of flannel. See Bread Poultice; Eczema; Fomentation; Linseed; Mustard, etc.

POULTRY AND POULTRY HOUSES

How to Rear the Birds Successfully in Town and Country

The poultry keeper will find further practical information under the headings Chicken; Incubator.

The entry Fowl and those on the various breeds, e.g. Leghorn; Minorca, may also be consulted.

Attention is also drawn to the colour plate.

The facilities for those who wish to keep a few fowls are much greater than they were a few years since, as stock is so much more easily obtained. Many now buy pullets of various ages from three to six months. This means that the small poultry keeper avoids the trouble and time spent in breeding and rearing and therefore needs less accommodation.

These young pullets may be bought, kept until they have completed their first season of laying and then sold to a dealer, or else fatted and killed for the table. It pays better to buy what is known as

guaranteed stock, that is birds bred from stock which has been trap-nested, and whose production is known. To-day poultry farmers are catering for such buyers as they never did before. Many are breeding cross-bred birds, known as sex-linked, that is the union of two pure breeds which have progeny of such colour and marking that the sexes are dissimilar as soon as the chicks are hatched. This method of breeding reduces the breeder's costs, as he is saved the expense of rearing his cockerels.

POULTRY: A SELECTION OF THE MOST POPULAR AND PROFITABLE BREEDS

1. Silver-spangled Hamburg. 2. Black Leghorn. 3. Ancona. 4 and 5. Spangled Old English Game Bantams. 6. Buft Plymouth Rock. 7. Single-comb Rhode Island Red. 8. Silver Sebright Bantam. 9. Silver Campine. 10. Houdans. 11 and 12. Black Red Modern Game Bantams 13. Black Sumatra Game. 14 and 18. Brown Leghorns. 15. Black Minorcas. 16. Australorp 17. Light Brahma. 19. Croad Langshan.

The Poultry House. For suburban or town poultry keeping, a house with a covered run is best. The space given in the house to each bird should be three to four square feet, and the run should be about from 20 to 24 feet long and as wide as the house. If the house can be placed on grass the larger portion of the run should be open, and the house and run should be moved from one spot to another each year. If grass is not possible, the run should be well brushed and scraped each week, also dug over about once a month, and given a good covering of lime.

The floor of all poultry houses should be boarded and covered with peat moss or chaff. Such a floor is more sanitary and there is less trouble from rats and mice. As soon as the litter on the floor shows signs of becoming damp, or there is a musty smell, it should be swept out and a fresh lot put in. The perches should be fixed from 18 in. to 2 ft. from the floor so as to avoid injury to the legs and feet when the birds fly down from the perches, and so as to miss the draughts which are a frequent cause of colds when the perches are fixed too high.

If the houses are kept clean, the perches and their holders brushed over with paraffin or turpentine every fortnight (except in the height of summer), when once a week is to be preferred, there will be little trouble from red mites, or lice. The best aspect for a house is south-east. The birds then get the early morning sun, and avoid its heat during the latter part of the day in the summer months.

Poultry House. Fig. 1. Combination house and scratching shed, which will accommodate six or eight birds. (Courtesy of Boulton & Paul, Ltd.)

The manufacture of poultry houses has now become a great business, and the poultry appliance builders can supply any sized house that may be required from one suitable for 5 or 6 birds to one for several hundred. Strongly built, well lighted, efficiently ventilated, yet draught proof, are the points of a good

serviceable house. The ready-made houses are sent out in sections and are quickly and easily bolted together. They are fitted with all the necessary locks and bolts, and windows.

Three common types of poultry house are illustrated. Fig. 1 shows a combination house and scratching shed for six or eight birds. The simplest type of house consists of four walls of timber covered with a timber or felt roof and possibly provided with a boarded floor. Half of the front is usually devoted to a door, of which the one part may be boarded up or the upper part can be made with wire netting. The other half of the front may take the form of a window covered with wire netting and provided with some kind of adjustable screen or shutter, as shown in Fig. 2.

A development of the same type of building is illustrated in Fig. 3, and comprises a small house with a span roof. The building is mounted on strong cast-iron wheels. In addition, perches, dropping board, and outside nest boxes are provided, and so arranged that the birds can enter them from within and the attendant can remove the eggs from the exterior. This type of house is suitable for birds that are kept on open range, as the building can be moved about from one place to another and the birds enabled to run on fresh pasture.

Larger and more pretentious buildings used for roosting and scratching sheds are often used. By another method, an extension of the main building consisting of a long run with a back and side

wall and open front is enclosed with wire netting, and is used for scratching purposes, the main building being reserved for roosting and laying. One portion may be utilized for breeding and incubation purposes. Another plan is to use the main building for egg production and to have separate buildings for incubators, rearing, and the storage of foodstuffs. Provision should be made for keeping the grain and other foodstuffs in a dry location and free from attack by rats and sparrows.

For the benefit of the poultry keeper who wishes to build his houses and runs we give at the end of this article constructional details of two or three useful types.

Poultry House. Fig. 2. Strongly built house, small enough and light enough in weight to be easily portable. (Courtesy of T. Bath & Co., Ltd.)

Below. Fig. 3. Useful poultry house, with outside nest boxes, the whole set on wheels for easy transport.

Feeding the Birds. In feeding a small flock the table scraps mixed with equal parts of bran and middlings will give them good feeding, in fact all they need, except for grain and green food. The latter may be the refuse of the vegetables used in the house, such as the outer leaves of lettuce, cabbage and broccoli, the tops of carrots, parsnips, beetroot, and turnips. The rinds of vegetable marrows and melons may be boiled and mixed with the household scraps. The grain feed, wheat and oats, should be given at night, a good big handful for each hen. It is advisable that the house scraps and meal mash should be given warm in the early morning.

By way of a change barley meal, or Sussex ground oats, may be used occasionally instead of the middlings. Fresh clean water should be provided every morning, and in the summer time at midday as well. Flint grit and oyster shell is also needed. If

the run is not very large the birds may be exercised by hanging the green food in a net bag and suspending it just out of their reach, thus compelling them to jump for it.

Keep the nest boxes very clean, supply them with fresh hay, and dust them once a week with a good insect powder. The houses should be whitewashed inside twice or thrice a year. This not only keeps the house sweet, but also makes it lighter than when it is creosoted. A few drops of carbolic may be added to the whitewash when it is mixed. The outside may be painted, tarred, or creosoted as desired.

The Breeds. The best breeds for a small household flock are the non-broody or light breeds such as Leghorns, Anconas, Andalusians, Minorcas, and Campines. The Leghorns and Anconas lay eggs about 2 oz. to 2¼ oz. in weight. The Andalusian and Minorca eggs are generally from 2¼ oz. to 2¾ oz., and sometimes a bit more. The Campines eggs are from 1⅞ oz. to 2 oz. The Hamburg family are also non-sitters and prolific layers, whilst they are among the most beautiful of all fowls, but their eggs are small. All these mentioned lay white eggs.

For town and suburban lovers of poultry, whose accommodation is limited in character and who only need the birds as a hobby, Bantams are useful. The breeds to be recommended are the Sebrights (gold and silver). Black Rosecombs, Minorcas, Leghorns, Old English Game, and all the Wyandottes, except the whites and Columbians which are not suitable for town runs. The featherlegged breeds like Pekins and Brahmas are suited for the show man only, and the same may be said of modern game bantams.

Those who have a field, or paddock, in which to keep their birds, may indulge in breeding with consequent pleasure and profit. They have a much larger field from which to select their birds. Among the birds they may choose from are all the sitting breeds such as Wyandottes (Whites, Blacks, Blues, Buffs, Columbians, Gold and Silver laced. Partridge, and Silver-pencilled); Australorps; Orpingtons, Dorkings; Plymouth Rocks (Barred Buff, White, Columbian, and Partridge); Barn welders, Sussex (Light, Red, Speckled, Buff, Brown, and White); Croad Langshans; Rhode Island Reds; Indian Game; Old English Game (Black-reds, spangles. Brown-reds, Birchens and Piles); Houdans; Faverolles; also any of the light non-sitting breeds. The non-sitting breeds lay white-shelled eggs; the sitting breeds tinted or brown, except the Dorking, which is white. Breeds like the English modern game, modern, Langshans, each very long in leg. Brahmas and Cochins with their heavy body and leg feathers are not to be recommended to the ordinary amateur. They are fancy breeds entirely and require special care and treatment.

One breed which is most useful and at the same time handsome is the latest comer from Holland—the Welsummer. It is the only light breed which lays a brown egg, but it is not safe to style it a non-sitter because many of the hens do go broody.

Of the heavy breeds the best layers are the White Wyandottes; Rhode Island Reds, Australorps; Barred and Buff Plymouth Rocks and Light Sussex. None of the light breeds are good table birds. The best breeds for table poultry are Dorkings, Sussex, Orpingtons, Croad Langshans, Houdans, Faverolles, Indian and Old English Game. The best of the general purposes breeds, that is fairly good egg producers and table poultry, are the Wyandottes, Plymouth Rocks, Rhode Island Reds, Barnwelders and Croad Langshans.

Crossing is not advisable when egg production is the chief thing to be considered because it induces broodiness and loss of production, but for table purposes crosses between Indian Game on the one side and Dorking, Sussex, Buff or White Orpington, or Faverolles, on the other are to be recommended, especially Indian Game and Faverolles, the progeny of which are very quick growing. Crosses between the Old English Game and any of the birds mentioned as suitable to the Indian Game, are good, but generally not quite so large when matured as those from the Indian Game.

Fattening for the Table. In fattening poultry the following procedure is adopted. The birds that are to be fatted for the table should be penned in a small place for about a fortnight before being killed. During this period they are fed upon mash made of Sussex ground oats and barley meal in which about two ounces of mutton fat is mixed per bird daily.

This fat may be chopped fine, or it may be melted and mixed with the meal before the water, or milk, is added. Milk can be used the flesh will be whiter and more succulent. No grain or grit should be given during the fattening period. When the time for killing comes the birds should be starved for 24 hours, as the flesh keeps better.

Killing the Birds. The most simple and humane method of killing is to hold the bird with the shanks closely gripped together in the left hand, place the bird across the knee, head down wards, grasp the head with your right hand, and give the neck a swift jerk and twist at the same moment. Death follows quickly. The bird should then be hung head downwards to allow the blood to drain down into the neck. If this is not done the blood will remain in the body and cause the flesh to be discoloured. The feathers should be removed whilst the body is still warm, they will then come away quickly and easily. Always draw the feathers in the direction they lie with a downward movement and so avoid breaking the skin.

Final Hints. The chief things needed to ensure success in the keeping of poultry is to purchase sound healthy stock, house it in buildings which are waterproof, light, and well ventilated. Everything about the house and run should be kept scrupulously clean so as to avoid disease and attacks from vermin, such as red mites and lice. The food should be sound and fresh and given regularly. Regularity in feeding has much to do with good health and egg production. A bird that is unhealthy is not a good layer. Crushed oyster shell and sharp flint grit are as necessary to the birds' welfare as is food. Water pots should be of earthenware and kept scrupulously clean. Never let the water which the birds are to drink stand in the sun. Sun-warmed water is a frequent cause of diarrhoea.

Making a Poultry House. A portable run and roosting house suitable for 8 or 9 birds is shown in Fig. 4. The whole of the timber consists of white deal framing, weather boarding, and tongued and grooved flooring boards. A method of framing is shown in Fig. 5. Here the cross-rails are halved and nailed to the uprights, and by using corrugated fasteners mortise and tenon and bridle joints are avoided. The centre upright rails of the run (F, Fig. 4) may be nailed on the inside of the top and bottom rails, as shown. The small feeding-door (G) is made by nailing tongued and grooved flooring boards on two battens, and hinging it with a pair of stamped steel butt hinges costing a few pence.

The top part (E) is boarded so as to provide a shelter to the stock at times when it may not be desirable to allow them access to the interior of the pen. The shelter, on account of expense, may be omitted if desired, and it is left to the discretion of the builder as to covering it with tarred roofing felt. The outside and the top of the run is covered with wire netting, which is secured to the framing by small galvanized wire staples.

The pen is made by constructing two end frames, the joints of which are constructed similarly to Fig. 5. These frames are connected together by nailing weatherboarding (C and D) on the back and front; and $\frac{3}{4}$ in. matchboarding (lettered H) on the end. For the opposite end (B) a battened door is made and hinged to the upright rail (R). This door will allow easy access to the interior of the pen and permit the removal of the eggs. An arrangement such as this is essential to a good poultry run.

erecting 2 in. by 2 in. deal posts, 7 ft. 6 in. long and 10 ft. apart, the corner posts strutted with similar material.

They are preferably coated with creosote or some other preservative prior to their erection. Some galvanized iron wire, 16 gauge, is then strained through holes drilled at the top and near the ground-level of the uprights, and drawn up tight with an eyebolt or strainer, as in the method adopted when erecting a wire fence.

For this run 10 lb. of the wire will be required. The object is to provide support for the poles, which it does in an economical and effective manner. The run is completed by fastening galvanized iron wire netting to the poles, using staples for this purpose and further securing the netting by wiring it to the straining wires. This netting must be at least 6 ft. high, and may be all 3 in. mesh. If young birds are to be allowed to run, the better plan is to begin at the bottom with a length of 1 in. mesh wire 2 ft. high, and complete the work with 3 in. mesh wire. The wire netting is fixed to the ground with wooden pegs cut as shown in detail in Figs. 8 and 9. A panel of the run is shown in Fig. 10.

Alternatively the bottom can be boarded up to a height of 2 ft. with rough wooden planks. This latter method is necessary if the run is used as a breeding-pen.

Poultry. Figs 6 and 7. Interior and exterior views of a hygienic poultry house, showing the covered run, with food hoppers, nest boxes, perches, etc.

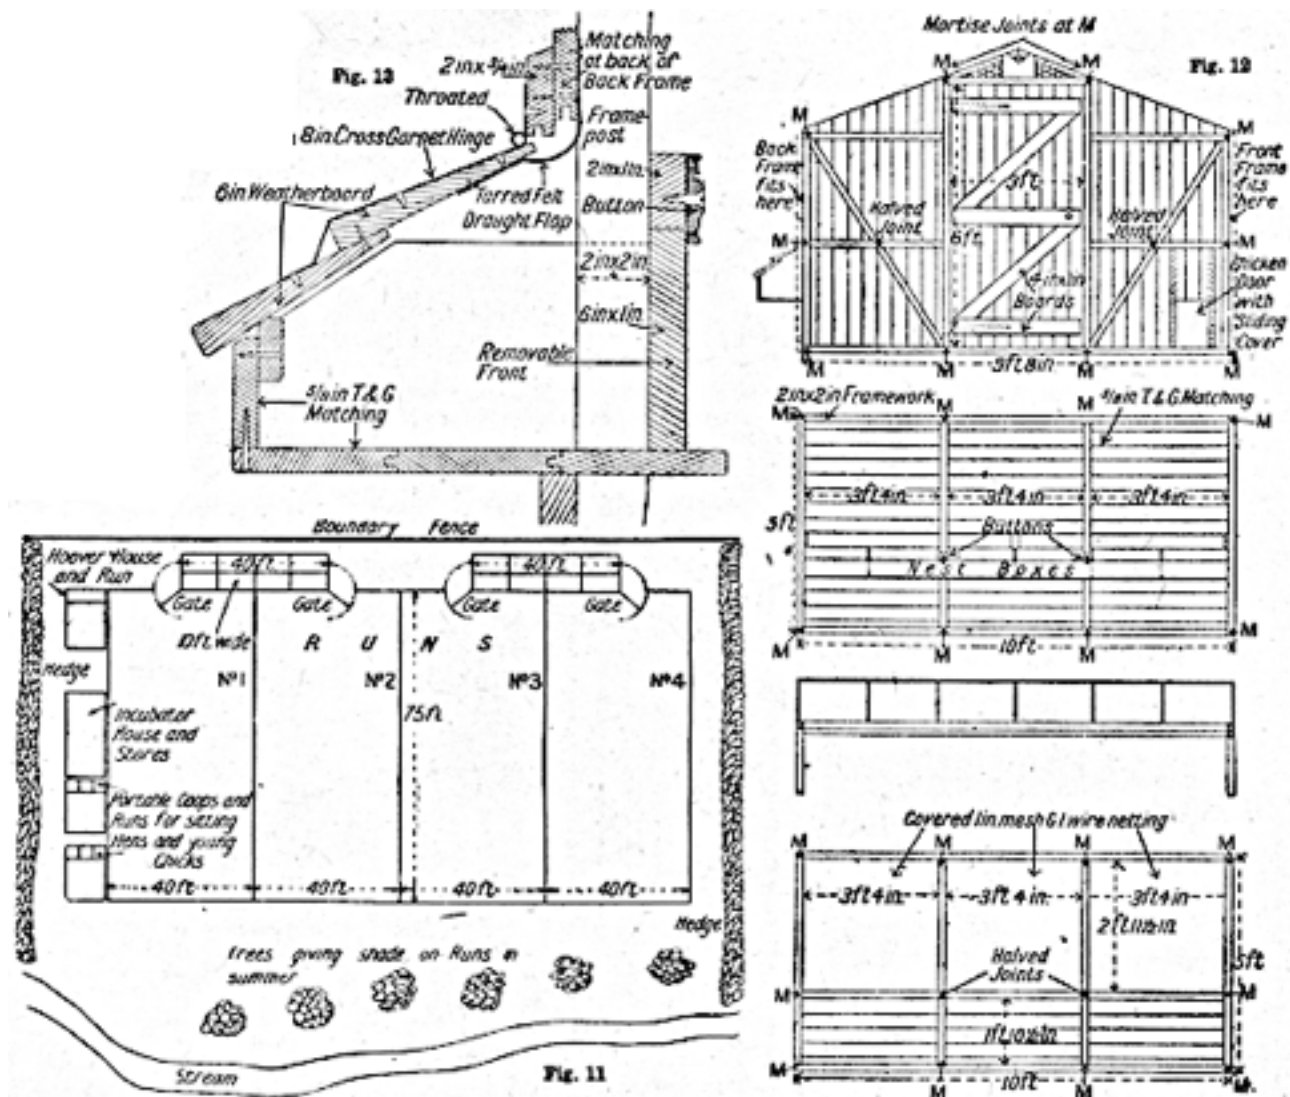

Above. Figs. 8-10. Constructional details of the large wire run shown in Fig. 7.

The Semi-intensive System. Fig. 11 is a block plan showing the lay-out for a poultry farm handling 200 laying birds on the semi-intensive system. The houses have been designed with a view to economy in material, ease of construction and erection, combined with greater comfort and durability than is generally the case in the housing of poultry. The houses are made in sections, each of which is 10 ft. in length and provides accommodation for 25 laying hens, and includes nest boxes and a covered scratching-shed or run all under one roof. Any number of birds in multiples of 25 can

be accommodated by constructing the requisite number of back, front, and end sections. Each two sections have a separate outdoor run 75 ft. long and 40 ft. wide.

The following is the method adopted in constructing the houses. The necessary details are given in the diagrams at Fig. 12. In the first place the ground was inspected, and the best position for the house determined, having regard to the contour of the land, which falls away from the house on the south. The house faces due south-west, receiving the full benefit of the sun, morning and evening. The ground was then marked out and trenches 9 in. wide and 2 ft. deep dug out and filled in with concrete and brickbats as a protection against rats.

The top surface of the concrete was then levelled to receive the building. The building consists of a framework of 2 in. square deal, covered with $\frac{3}{4}$ in. tongued and grooved matchboards, those with a damaged bead being set aside for use as dropping boards or elsewhere than on the external walls, as the latter must be weatherproof. The joints at corners are mortised and tenoned, and the door parts are similarly jointed, all the others being halved and screwed or nailed. The accompanying working drawings give all dimensions and details. All material was first cut to length, then the joints prepared, the matchboarding nailed on, and the whole creosoted inside and out. As soon as this is dry, the work of erection proceeds.

Poultry. Fig. 11. Block plan of the lay-out of a chicken run on a poultry farm, suitable for two hundred laying birds. Fig. 12. Diagrams giving dimensions and details for making a sectional house to accommodate 25 laying hens. Fig. 13. Sectional diagram of a nest box.

A start is made at one corner, setting up the end section, and holding it in place with battens fixed to the top and secured at the bottom to pegs driven into the ground. The front section is then put up in place and similarly supported. Every care must be taken to get this corner square and perfectly upright, otherwise the house will always be lopsided and insecure. A plumb rule proves the latter, while a stout cord, 10 ft. long, attached to hooks fixed exactly 6 ft. from the corner in the end section, and 8 ft. from the corner on the front section, ensures the squareness of these two sections. The corner is bolted together with 5 in. by $\frac{3}{8}$ in. coach bolts and nuts, with a washer beneath the nut. Then the back section is erected and bolted in place. The remaining front, back, and end sections are then erected and bolted together, temporary cross pieces being nailed from side to side, while the internal stretcher section and the ridge pole and struts are nailed in place.

The roof is covered with 3 in. mesh galvanized iron wire netting stretched very tightly, and a covering of tarred felt securely nailed to the top of the section with clout nails. The roof is completed by laying the 6 ft. lengths of galvanized corrugated iron, completing the work with a standard galvanized iron ridge capping securely nailed into the ridge pole. This roof costs very little more than an ordinary boarded and felted roof, and is much more durable. The tarred felt lining is essential, as otherwise the condensation would make the interior of the house very damp and uncomfortable. The fronts are enclosed with 2 in. mesh galvanized wire netting, and portable screens made of waterproofed canvas in a wooden framework are provided for use in very wet and cold weather.

Nest Boxes. The nest boxes (Fig. 13) are made to project on the back of the house, and constructed with a weatherboarded hinged top providing easy access for egg collecting. Perches made from 2 in. by $1\frac{1}{2}$ in. deal with rounded edges are carried in bearers, and can be lifted out for cleaning. Dropping boards, supported on bearers and legs, are provided with cross battens and lift-out for cleaning. A sliding hen door is fitted at each outside end of the section, and the intermediate section has double folding doors normally closed and bolted. Exterior doors are ledged and braced, hung on 18 in. cross-garnet hinges and fitted with a lock and key, and also a turn-button on the inside to enable the attendant to close the door while working inside the house. The floor is left in its natural state and covered with a deep bed of litter wherein the hens can scratch for grain. This is good for the birds and keeps them healthy and contented.

A large water vessel, feeding trough and hopper, and a dust bath built in one corner complete the house. Access to the runs is obtained by framed doors covered with 2 in. mesh galvanized iron wire netting, hung on simple hinges and provided with a hook and eye fastener. The combination of run, scratching-shed, and roosting house has always proved satisfactory. In fine weather the birds can be outdoors in the run; in wet weather they are confined in the scratching-shed. On extremely cold and wet days the screens are put up, and the birds are warm and comfortable, and able to seek their food in daylight and also in the dry, with satisfactory results in egg production.

POUNCE POT. Also inown as a sand bottle, the pounce pot in silver and Sheffield plate is sought by collectors. It was made for holding sand, which was used before the general employment of blotting paper to sprinkle over writing in order to dry the ink.

POUNCING. Patterns may be pounced on to metal, glass, or pottery by means of a linen bag containing blue chalk. By pouncing is meant that the bag will be dabbed all over the surface of a stencil and will thereby transfer to the surface of the article itself the outline of the design cut in the stencil paper. *See Stencilling.*

POUND. This standard English measure of weight is divided into 16 ounces, and consists, strictly speaking, of 7,000 grains; 14 pounds go to the stone, 28 to the quarter, and 112 to the hundredweight. There are 2,240 pounds to a ton. The usual abbreviation for pound is lb., which is used throughout this work. *See* Avoirdupois Weight.

Pound Cake. This is a rich sultana cake usually baked in a square or oblong, fairly shallow, cake tin. *See* Cake.

POUT: The Fish. The pout possesses a membrane covering the head and eyes, and which it has the power of inflating. The best known is the whiting pout, a member of the haddock tribe. It makes excellent eating, but must be consumed very shortly after being caught to be in good condition. Large specimens attain the weight of 5 lb., but the smaller fish have the best flavour. They can be cooked by the same methods as are used for haddock.

POWDER. A powder may be described as any substance reduced to fine particles. Powders used in the home may be divided into those used for the toilet, e.g. face and tooth powders, those used for various cleansing purposes, and those taken as medicines.

For the complexion, powders can be had in white, cream, pink, and flesh tints, variously perfumed, and either in solid or loose form. They should be carefully selected both for texture and colour. Many women blend their own by mixing two or three shades until the desired tint is obtained. Other kinds of toilet powders include rice, pearl, violet, and talcum powders.

Cleansing powders include those for cleaning silverware and cutlery; there are also sanitary powders and vermin destroying powders. Powdered soaps are used in washing clothes, while another powder used in the household is baking powder.

The powders used in medicine are reduced to very small particles by a mill, or with pestle and mortar. To give bulk where a small quantity of the drug is to be taken, sugar of milk is frequently included. Powders may be taken by sprinkling on the tongue or in jam or syrup.

Powder Puff. Puffs for applying powder to the skin are made chiefly of swansdown, lambs' wool, and beaver fur; for hygienic reasons no puff should be used too long.

To make a powder puff, cut out a circular piece of swansdown or fur, turn in the edges to the wrong side, and then cover the back with a circular piece of white or coloured silk. If a bone button and ring, or some other type of handle, are attached to the centre back, the puff will be found easier to use. Large puffs intended for powdering the neck, shoulders, and back are fitted with long handles of wood, bone, or tortoiseshell, and are backed with ruched satin narrow ribbon, or floral trimming.

A usual kind of powder puff is a handkerchief puff. Small pieces of coloured swansdown can be purchased and neatly sewn on to the middle of a crêpe-de-Chine or georgette handkerchief. This may be decorated by painting or pattern printing (q.v.).

On large powder puffs the usual bone button and ring may be substituted by a handle made from a bow of satin ribbon or a small bunch of padded silk-covered flowers and fruit. *See* Baby; Baking Powder; Beauty; Emery Powder; Make-up; Scent; Talcum; Teeth, etc.

Power Grid Detection. *See* Detector.

PRAIRIE SUNFLOWER. The fine species of perennial sunflower, *Helianthus rigidus*, is a good plant for the garden or for yielding cut flowers. Improved varieties of this prairie sunflower, as it is called, include Miss Mellish, Miss Willmott, Daniel Dewar, and Rev. Wolley Dod. All are in varying shades of yellow, the flowers being borne on slender erect stems, 6 ft. or more high.

Prairie Sunflower, a favourite species, with flowers ranging through all shades of yellow.

PRATIA. Being a dwarf plant of trailing habit, pratia is suitable as a creeper for a slightly shady place in the rockery. It belongs to the harebell family. The chief kind is *Pratia angulata*, which grows up only 3 in. high, and during summer bears white flowers; repens has white flowers followed by red berries. It is best planted in March, and may be increased by division during, the same month. See Rock Garden.

PRAWN. In appearance resembling the shrimp, the prawn is larger and more delicate in flavour. Like the shrimp, it is bought ready boiled, and if fresh it should be firm and a good pink in colour. Prawns can also be obtained preserved in tins, in which case they are not only cooked but also shelled.

Preparing Prawns. To shell prawns, take the head and tail in the two hands and pull the prawn straight, giving it a little twist at the same time. In this way practically all the shell will come off with the head and tail; the piece that remains can quite easily be removed.

Cut some large tomatoes in slices, and on each slice place a thin slice of cucumber and then 2 prawns. Prepare some thin bread and butter, spread it over with anchovy paste, mixed if liked with tomato sauce. Cut the bread and butter into strips, roll them up, and place them on the dish between the tomato slices. Another way is to place the prawns on a thin slice of lemon, and garnish them with parsley or sprigs of watercress.

To prepare prawns in aspic, line some small dariole moulds with aspic jelly, and leave them until the jelly is nearly set, when some finely chopped olives, or pickled gherkins, and some chopped lobster coral is sprinkled over it. Then put 2 large prawns or 3 small ones into each mould, fill them up with more aspic, and put in a cool place or on ice to set. Meanwhile make as many croûtes of fried bread as there are dariole moulds, and spread them with green butter. This is made by placing 1½ oz. mixed and washed herbs, comprising parsley, tarragon, chervil, and chives in a saucepan of cold water and boiling them ; dry thoroughly with a clean cloth and pound in a mortar with 3 oz. butter, a little anchovy essence and seasoning, afterwards rubbing the mixture through a sieve.

When the prawns are to be served, a mould is turned out upon each prepared croûte, and one is served to each person.

Prawns in aspic served on croûtes of fried bread spread with green butter.

To preserve prawns whole in butter, shell 1 pint of prawns and pack them closely in shallow china pots. Crush the shells roughly, and put them, with ¼ lb. fresh butter, into a stone jam-jar in a pot of boiling water. When the butter is thoroughly melted strain it free of shell, flavour it with cayenne, nutmeg, and a little salt, and pour it over the prawns. More melted butter should be added when this is cold, if the pots are not full. Tie them down, and store them in a cool, dry place.

Prawn Patties, consisting of puff pastry cases, with a filling made from white sauce, small pieces of prawn and some grated cheese.

Prawn Patties. While the puff pastry for these patties is cooking, the filling may be prepared. Make a plain white sauce, and add to it $\frac{1}{2}$ gill shelled prawns cut into small pieces. Make the mixture thoroughly hot in a pan over the fire, then stir in 4 tablespoonfuls grated cheese and salt and pepper to taste. When the cheese has melted, fill the pastry cases with the mixture, and garnish the top of each patty with a prawn's head.

Prawn Sauce. This sauce can be served with any white fish. To make it, prepare 1 pint melted butter sauce, season it to taste, and add $\frac{1}{2}$ a teaspoonful lemon juice and a few drops anchovy essence. Then drop in $\frac{1}{4}$ pint shelled prawns, and the sauce is ready. *See* Aspic; Curry; Hors d'Oeuvres; Patty; Salad.

PRECEDENCE. Precedence is the order in which individuals follow one another at state and other public ceremonies. There is also an order of precedence for private gatherings, although this is not so rigid. There precedence is usually given to the guests in order of their rank and social standing. For state ceremonies there is a regular order of precedence for peers and officials. The king comes first, then the prince of Wales, and the other male members of the royal family. Next come the archbishop of Canterbury, the lord Chancellor, the archbishop of York, and the prime minister, in the order named. Other high officials follow and then come the peers, rank after rank. After the peers come a number of other persons, sons of peers, baronets, knights, and other members of the various orders.

Women take the same rank as their husbands or as their eldest brothers. Daughters of peers rank immediately after the wives of their elder brothers and before their younger brothers' wives. Daughters of peers marrying peers of lower degree take the same order of precedence as their husbands; thus the daughter of a duke marrying a baron degrades to the rank of baroness, while her sisters married to commoners retain their rank. Mere official rank on the husband's part does not give similar precedence to the wife. *See* Dinner Party; Etiquette.

PREGNANCY. The fact of conception may be shown, or at any rate suggested, almost at once by nausea, sickness, or an ill-defined sensation of some sort, but much more commonly it is not suspected till the failure of a menstrual period. Morning sickness may appear very early in pregnancy, but as a general rule it appears towards the end of the first month, lasts two or three months, and disappears.

As soon as a woman finds herself pregnant she can generally, by consulting a doctor, find out within a week or two the probable date of her confinement. She is thus able to engage a doctor and a nurse. The duration of pregnancy is about 40 weeks, that is to say, 10 lunar months or 9 calendar months. There are various methods of calculating the date of a confinement. One is count back 3 months from the beginning of the last period, and to add 10 days.

Pregnancy does not, and as a rule need not, interfere with the ordinary routine of a woman's life and duties. She should be careful to avoid physical strain or shock, such as is involved in lifting weights, in journeying in jolting vehicles or in occupations in which there is prolonged standing.

She should take open-air exercise every day, and should live in well-ventilated rooms. She should have a sufficiency of rest at night, and as her pregnancy advances she will, as a rule, find it desirable to lie down for a little several times during the day. It may be a comfort to her and make exercise more easy if she wears a properly fitted obstetric belt. Her dress should be loose. She should have plenty of plain food. In most cases she is better without alcohol.

It may be well to supplement the ordinary diet with a free allowance of milk.

Constipation is apt to be troublesome, and an attempt should be made to obviate it by including porridge, brown bread, vegetables, and fruit in the diet. Should an aperient be required a teaspoonful or more of castor oil at bedtime may be sufficient, and may be taken every night if necessary; or liquorice powder or cascara may equally serve the purpose.

The use of strong purgatives is dangerous.

The drawbacks of morning sickness may be avoided by having a light breakfast in bed and an hour's rest before getting up. A woman should keep in touch with her doctor throughout her pregnancy. *See* Baby; Childbirth.

PRESERVATIVE: In Food. The use of chemical preservatives for food can hardly be dispensed with, as so much food is imported and both this and home-produced food require to be stored, sometimes for considerable periods. Some chemicals used for preserving are harmful if taken in the amounts which might well be ingested in the course of ordinary diets containing a fair proportion of preserved food. Boracic acid, once used extensively, is an example.

In Great Britain the Public Health (Preservatives, etc., in Food) Regulations prescribe the articles which may contain chemical preservatives, the appropriate preservative and amount in each. The only preservatives allowed are sulphurous acid and benzoic acid. *See* Adulteration; Food.

PRESERVING: Of Food. Fruit, vegetables, meat or fish may be preserved and sterilized by a simple method and the use of the outfit illustrated. This is an economy to the housewife, as foods may be purchased when prices are low, or home-grown vegetables and fruits may be preserved during the plentiful season. The shelves of the larder may be stocked with jars of chicken, fish, game, soups, fruit or vegetables which have been preserved, and will keep for years owing to efficient sterilization without the use of chemicals.

The Process Described. The process is simple and fuel saving. The jars are first filled, placed on the combined holder and stand as shown in the illustration, and then put into the sterilizer. When the water at the bottom of the sterilizer reaches the correct temperature the jars are hermetically sealed. No screwing covers are needed, the glass covers are self-sealing and the contents can be preserved for years. The natural juices and vitamins are retained, and the food kept pure and wholesome. With the combined holder and stand all the jars can be placed into the sterilizer or taken out with one operation. The stand is supplied with six clips for holding jars securely in position. Shallow jars can be placed one on top of the other. The thermometer is protected by a steel sheath and is clearly charted to show the correct temperature for sterilizing various foods, milk, etc. The special jars can be obtained in several sizes and are guaranteed against breakage by heat.

Preserving Pan. This shallow pan for making jam or marmalade is usually made of brass, copper, or aluminium, but cheaper kinds can be obtained in tin, iron, and enamelled ware. The iron ones are not to be recommended, as they often discolour their contents, while the tin and enamel pans quickly become overheated and so cause the jam to burn unless the latter is kept well stirred. Enamel pans are also liable to chip.

Preserving and sterilizing outfit, comprising of sterilizer, thermometer, combined holder and stand, and glass jars.

PRESSED BEEF. To prepare this procure a piece of brisket of beef weighing from 5 to 6 lb.; see that it is well covered with fat and neat-looking, also perfectly free from the slightest taint. Wipe it and lay it on one side while preparing the brine. Mix well in an earthenware pan 2 lb, common salt, 1 oz. saltpetre, 3½ oz. raw sugar, 1 bay-leaf bruised, 1 small teaspoonful mixed sweet herbs, which have been sifted, 1 blade mace, and 4 cloves.

Bone the meat, immerse it in the pickle in the pan, and rub it well with this mixture all over, doing this for about 5 min. Keep it in a cool place, and every day for 5 days turn the meat and rub it as on the first day, taking care that it is left on the side which has been turned over. The joint must remain in the salt for from 12 to 15 days, but after the first five days it need not be rubbed, only turned each day. The saltpetre gives the red tint.

To cook the meat, wash it free from salt in cold water, then lay it in a saucepan large enough to give it plenty of room. Cover it with cold water and boil it up, skimming it very carefully. Add 20 peppercorns, 3 carrots, 2 onions, each stuck with 2 cloves, 1 head of celery, and 2 turnips. All the vegetables should be prepared and cut into pieces of convenient size. Simmer the whole gently for 4 or 5 hours, or until it is very tender, skimming occasionally. When cooked, take up the meat, drain it and lay it on a deep dish, quite flat. Cover it over with a second dish and arrange on the top sufficient weight to press the brisket into an oblong shape.

When cold, remove the weight and covering dish, and trim the meat; then glaze it and dish it, garnished with parsley. The bones removed from the brisket can be added to the contents of the stock-pot, or boiled down separately with a little vegetable and converted into glaze. The stock left over from cooking the meat may either be served as a broth, with the addition of suet dumplings, or it may be used as the foundation of a brown soup. Brisket is too fat for some tastes, and a piece of silver-side or round of beef may be substituted.

Brisket can be bought ready salted and cooked in the same way. *See Beef.*

PRESSING: Of Clothes. Pressing is one of the most important items in the care of clothes, as prevents them from losing their shape. When pressing is done systematically by means of a clothes press, it is seldom necessary to resort to other treatment; but with garments where this method is not practicable, steam pressing is usually effective.

Pressing. Sword iron, heated by electricity for pressing men's ties.

Steam pressing can be done at home with the aid of a hot iron and a damp cloth. The latter should be of linen or calico or some similarly thin material.

Press heavily on the iron so as to remove any creases, and continue pressing until the cloth is dry, taking care that it does not become singed. If the garment itself is wet when pressed, the cloth that covers it should not be damped. The iron must not touch the garment itself, otherwise a shiny appearance may quite likely develop.

Any cleaning that is required should be done before pressing. A special iron for pressing men's ties is shown in the illustration. The "sword" is heated by

electricity in the ordinary way and the tie is stretched on to it after the silk has been slightly damped. *See Clothes; Ironing.*

PRESSURE COOKER. Food cooked by steam pressure in a pressure cooker requires only a very short time owing to the high concentration of the steam inside the cooker.

There are several makes of pressure cookers on the market, but the principle is identical in all cases. The cooker is really a strongly made casserole with food containers and a lid which fits internally

into the cooker. This is held in position with a locking bar. When the lid is in position no steam can escape; the greater the steam pressure the more securely the lid is held in position, and the lid cannot be removed while the steam pressure remains. The lid is fitted with a whistle device, the function of which is to regulate the cooking of the food, and when sufficient pressure has been generated this whistle blows and warns the user to remove the cooker from the gas or other heat. The whistle is marked with numbers on the movable top half and with a red line at the base, and one of these numbers is set to the red line according to the kind of food which is being cooked. There is also a safety valve on the lid.

Pressure Cooker consisting of a casserole with food containers. The food is cooked by steam pressure, which is regulated by a special device. (Courtesy of Harrods, Ltd.)

Inside the cooker are basket containers for vegetables, also a combined lifter grid and strainer. It is possible to cook a complete meal in a pressure cooker, as each food keeps its own flavour, and does not affect that of others. Greens retain their colour, and dried vegetables can be cooked in a few minutes without soaking. There is very little shrinkage or loss in cooking, and all the natural juices and valuable salts are retained. For stewing or boiling, cold water is put into the cooker to the depth of 1 in. to 1½ in.; for roasting, boiling fat is put in.

Below are a few examples of the time taken for various foods to cook in a pressure cooker. Roast chicken, 6-10 minutes instead of 40-60 minutes. Roast joint, 12-15 minutes instead of 2 hours or longer. Stewed meats, 12 minutes instead of 2-3 hours. Potatoes, 8 minutes instead of 20-25 minutes. Green vegetables, 7-10 minutes instead of 25 minutes. Dried vegetables, 20 minutes instead of 2-3 hours. *See Digester.*

PRICKING-OUT: Of Plants. The process of transplanting the seedlings as soon as possible after they have made their first true leaf in addition to the seed leaves is termed pricking-out. It requires care, and where the seedlings are very small a thin, flat stick, notched V-shape at one end, should be used to lift them from the seed-pan or box.

Tender seedlings raised under glass should be pricked out into pots or pans, at distances apart according to their habit of growth; they will require careful shading and watering for some time after pricking-out, and must be kept under glass until established. Outdoor plants raised in heat must be hardened off before permanent planting.

Seedlings raised directly in the open may be thinned out instead of pricked out, and, where necessary, transplanted when 3 or 4 true leaves have formed.

PRICKLY HEAT. In the tropics Europeans frequently suffer from the skin disorder known as prickly heat. It produces intolerable tingling, pricking, and itching, and is due to obstruction of the sweat ducts. Small red pimples, no larger than a pin's head, cover the arms, breast, neck, shoulders, and thighs.

Rest in a cool, shady place, if practicable, is one of the best measures. Iced and hot drinks, spirits and wine, are to be avoided. So are hot baths, especially with the use of soap. Many remedies are recommended, of which the best appears to be a mixture of 8 parts of olive oil and 1 part of lanolin rubbed into the skin night and morning.

A tepid alkaline bath has sometimes a very soothing effect. It is made by adding 1 oz. of bicarbonate of soda to each gallon of water. Or a tepid bath of plain water may be taken, the skin being afterwards rubbed with lemon-juice, or carbolic lotion (1 part carbolic to 60 parts water), or calamine ointment; or dusted with a powder made of equal parts of oxide of zinc, boric acid, and starch.

PRICKLY PEAR. This is the common name of opuntia, one of the cacti. It is usually cultivated in pots under glass in a collection of cacti, but a few, notably monacantha and vulgaris, can be grown on a sunny, well-drained rockery at the foot of a wall.

PRICKLY THRIFT. This is the popular name of a rock garden plant, acantholimon, which forms a low evergreen tuft of spiny leaves and bears rose-coloured flowers in summer. It needs well-drained sandy loam and a sunny position, and is increased by cuttings in a frame in August. Acantholimon glumaceum and venustum are the chief kinds: both have rose-coloured flowers.

Prickly Thrift. Rose-coloured flowers of a rockery plant which requires a sunny position.

PRIMING: For Painting. As applied to house painting and similar work, priming is an undercoating or groundwork for subsequent coats of paint or enamel. Proprietary brands are made

up specially for woodwork, metal, or stone. The amateur can make his own by mixing red lead in paste or powder form with white lead and linseed oil thinned with turpentine, and a little driers added. This is brushed well into the woodwork immediately it has been prepared. The advantage of a priming coat is that it works well into the wood and acts as a durable base for the paint that follows, which would otherwise peel off after exposure to wind and weather. *See Paint.*

Priming paint applied as a groundwork to raw timber.

PRIMROSE. This is the popular name of the spring-flowering Primula vulgaris and its varieties. Primroses are natives of hedgerows, banks, woods, and the sides of streams, and when found wild they may be dug up and brought into cultivation. They are increased by division after flowering or by seeds sown in spring in a frame.

The blue primroses are great favourites and the double varieties are charming flowers. Primroses like slight shade in moist, loamy soil. See Auricula; Evening Primrose; Himalayan Primrose.

PRIMULA. This group of hardy and greenhouse plants is of the utmost importance to the gardener, for many of the species and varieties are invaluable for spring and summer blooming out of doors or for providing a show of flowers under glass in winter and spring.

Primula. 1. How to sow; a, corks; b, chopped old turf; c, drainage soil; d, seed sown on top; e, glass. 2. Seedlings ready for pricking out. 3. Seedlings pricked out in box. 4. First potting. 5. Second potting. 6. Plants placed in cold frame. 7. Position in greenhouse; a, moist shingle. 8. Method of propagation by shoots slit at base, as shown by unshaded portions. 9. Shoots heaped with moss to make roots firm. 10. Rooted shoot potted separately. (By special arrangement with Amateur Gardening)

There are two chief types of hardy primula, those which flourish best in partial shade in deep, moist soil, and others which thrive when planted in crevices of the rock garden. Among those which need deep, moist soil there are some remarkable plants. These are some of the best: *beesiana*, 2ft., reddish-purple and yellow; *cockburniana*, 10 in., orange scarlet; *denticulata*, 12 in., lilac; *frondosa*, 6 in., lilac-rose; *japonica*, 24-30 in., various colours; *Florindae*, two feet, primrose-yellow; *pulverulenta*, 24—30 in., of rich and varied colouring; *rosea*, 6 in., carmine rose; *sikkimensis*, 2 ft., pale yellow. In addition to these, numerous hybrid or cross-bred forms have been raised.

Some of them are doubtful perennials in many gardens, and it is wise to raise them from seeds every year to ensure vigorous free-blooming plants. The seeds ought to be sown as soon as possible

after they are ripe in late summer or early autumn. If they do not germinate before winter the pots of seeds should be kept out of doors exposed to all weathers until March; then if they are placed in a frame or greenhouse the seedlings will soon appear. If when large enough the seedlings are transplanted into boxes of soil and later on planted out of doors they will bloom the following year. Deep loamy and leafy soil which does not dry out in hot weather suits them best, and slight shade is beneficial. Planting may be done in autumn or spring.

Primula. Left, tuft-like flower heads of the species *denticulata*, which needs a moist situation. Right, *P. variabilis*, a rock-garden flower.

Most of the rock-loving primulas will thrive in crevices in the rock garden if planted in a compost of loam and leaf-mould with grit added freely. Among them are *glutinosa*, violet; *nivalis*, white; and *viscosa*, rosy purple. Others which need a similar compost with lime or mortar rubble added are *auricula*, yellow; *clusiana*, reddish purple; *marginata*, lavender; and *spectabilis*, rosy-lilac. All are low growing and benefit by slight shade.

As regards planting, this should be carried out in early autumn or in spring.

Several of the primulas are charming winter and spring-flowering greenhouse plants which can be grown to perfection in a minimum temperature of 50 degrees. The Chinese primulas (*sinensis* and *stellata*), of which there are numerous varieties in rose, crimson, salmon and other colours, are the most valuable. The yellow-flowered *Kewensis* and *floribunda*, the pale yellow *verticillata* and the fairy primrose (*malacoides*) in lilac, mauve and rose are others to be recommended. *Primula obconica* is a showy kind with blush, rose or crimson flowers. Gloves should be worn when handling the plants or the hairs on the leaves may cause irritation of the skin.

Seeds of primulas *sinensis* and *stellata* should be sown in pans of fine soil in a frame in May. During summer the plants must be grown in a cool, shady frame, and in September they should be placed in the greenhouse. A suitable potting compost consists of loam two-thirds and leaf-mould one-third, with sand added freely. Pots 5 to 6 in. wide are large enough for the final potting.

Seeds of primulas *floribunda*, *Kewensis* and *verticillata* should be sown in April; those of *malacoides* in April and June to maintain a succession of bloom. *Primula obconica* should be sown in March in order to provide plants in bloom in winter. These need the same treatment as the Chinese primulas. *See* Flower Garden; Potting; Pricking Out; Rock Garden.

PRINCE'S FEATHER. This is the common name of a half-hardy annual (*Amarantus hypochondriacus*), which bears spikes of crimson flowers on stems 3 ft. or more high in summer. It is raised from seeds sown in a heated glasshouse in March, the seedlings being planted out in May. Other favourite allied plants are love-lies-bleeding (*Amarantus caudatus*), and Joseph's Coat (*Amarantus tricolor*).

PRINT: The Material. Many kinds of cloth are printed with designs, but the name print is most often given to simple cottons, useful for aprons, working overalls and dresses, or for dust sheets. Print can be pasted down as a lining to wooden boxes or cupboards, and it can be employed as a backing to curtains made of washing material. Old print dresses can be cut up to make capital dusters, and when these are worn out they are still useful for wiping grease from machinery or for polishers for floors, furniture, or boots.

PRINTS: THE JAPANESE ARTIST AT HIS BEST

PRINT: How to Choose. Print collecting is still a hobby open to people of moderate means. Most old print shops have hundreds of prints put away in portfolios through which the would-be collector may look and find treasures, ranging from a few pence to a few shillings apiece.

The collector's first business is to learn to identify the different processes of engraving and cutting by which the print is evolved. The broad distinction between an etching and a mezzotint or a lithograph is fairly evident at sight. But it is not so easy to tell the difference between an engraving on steel and one on copper, or to know at a glance the mixed processes employed to produce a certain kind of etching. Only by watching an operator at work on a plate through all its stages can absolute certainty be gained as to the way it is done.

Londoners have access to some of the finest prints in the world at the British Museum, at South Kensington, and the Guildhall; but all over the country there are plenty of good prints to be seen. Yet the most valuable experience is that gained in the shop. For prints of all descriptions the inexperienced collector's safest guide is an intelligent and honest printseller.

It should be remembered that prints of views, topical events and sports, if good in themselves, are bound to increase in value. Anyone who specialises in prints of one town or district, of naval and military subjects, yachting, motoring, or aviation, may probably form an interesting and valuable collection.

While etchings by great masters, such as Rembrandt, Albrecht Dürer, and Whistler, and colour prints after Morland, Wheatley, and other artists are beyond the reach of the ordinary collector, there are many decorative prints in colour or monochrome which can be picked up for comparatively small sums.

The collector's Japanese prints form a class in themselves and are nearly always pleasing, and those by the less known names may often be bought cheap. One should, however, remember that the Japanese produce a large class of prints solely for export, and they are not of the best quality.

Plate Marks. Every collector is warned against the purchase of prints lacking the slight indentation that shows where the plate has been pressed on the paper; yet a print without a plate mark is not necessarily a fake. Absence of the mark may simply be the result of printing from a plate larger than the paper. The illustrations, for instance, to Scott's novels and Rogers' poems were printed from plates larger than the pages of the book, and there are hundreds of similar cases where the plate mark has disappeared for this reason.

False margins can generally be detected by holding the print up to the light, just as the most cleverly executed repair of a hole or tear in the specimen betrays itself if the light is strong enough. Touch can often determine the age of a print by revealing the texture of the paper. Modern paper is hard and harsh compared with 18th century and older paper. This test, however, is not infallible.

A finger passed lightly over the surface of a print should show whether it is genuine or a clever photographic reproduction.

Baxter Prints. Genuine Baxter prints, the work of George Baxter, are valued by collectors. Baxter illustrated a large number of books, producing frontispieces and vignettes in addition to separate pictures. Many of these were used to illustrate pieces of music, and valuable Baxter prints have been discovered in this way, especially portraits about 4½ in. long, into which he put some of his best work. Some printing firms were afterwards licensed to use the Baxter process, which consisted in building up beautifully coloured prints by the use of many blocks; but the work of these licensees never equalled the originals either in colour or finish. Some of them bear the name of Baxter, and collectors are very liable to be misled by these. Genuine examples bear the name of the artist and one or other of his various addresses in London; they have good mounts and are generally clean and

unfaded, Baxter's brilliant and lasting colours being one of the principal secrets of his remarkable success.

There was no 3 colour process in Baxter's day: each colour in a picture had to be applied separately, and in this Baxter excelled. He started with an engraving, originally on wood, later copper, and then steel, printing in black, brown, or purple. This was the foundation. After that he applied his colours with a series of wood blocks, letting one impression dry and then adding another.

The variety of colours is always a striking feature of his work, from 8 to 20 different colours or tints being found in a single print. The register is always perfect; that is to say, each colour is fitted exactly into its place. This is one of the characteristics of a Baxter print; another is the beauty of the colouring. Baxter ground and mixed his own colours, and was very particular in his choice of paper. He engraved the plates himself, and personally superintended every stage in the production of his prints. *See Picture.*

PRINTING AND PRINTING FRAMES

The Best Methods for the Amateur Photographic Worker

For the photographer who carries out the technical processes of his hobby clear instructions are given under this and the relative headings, Developing; Enlarging; Fixing; Negative; Washing. See also Gaslight Paper; P.O.P.; Self-toning Paper.

Photographic printing processes are divided into two classes. The first and oldest, and apparently simplest, is the printing-out method in which daylight is allowed to act on sensitive paper behind a negative, the action continuing until all details of the image are visible. The paper which is used in this process is called printing-out paper or P.O.P. (q.v.).

In the second method, called the development method, artificial light is used, and the exposure of the sensitive paper is very much shorter, no visible image being produced until the paper is treated with a chemical developer.

In both P.O.P. and development papers the negative is held in a printing frame for exposure, since it is essential that the sensitive paper should be closely and evenly in contact with negative and also that light should not leak in through the edges of a glass negative. Printing frames can be bought cheaply; if a number are required, they can be made as described later.

When printing films, it is necessary to place a piece of clean glass in the frame first, then the film, followed by the paper, the sensitive side of the film being in contact with the paper, or the image will not be quite so sharp and will also be reversed. A waste negative glass of the right size for the frame, carefully cleaned, will serve best for the film support, keeping it flat and in close contact with the printing paper. If glass negatives are being printed see that the glass side is thoroughly cleaned and without smears or finger marks, for any marks will appear in the print, particularly if it is on gaslight paper. Care must also be taken to see that the negative is thoroughly dry, or it will adhere to the sensitive paper, spoiling the negative and causing silver stains on it, which are extremely difficult to remove. Take great care to see that the paper itself is not handled with moist or dirty fingers.

When printing in daylight on P.O.P. the frame should be filled in dull light or shadow, and the printing should be carried out in diffused light, never in direct sunlight, except perhaps in weak sunlight from November to February. Too strong a light reduces the contrasts even in a good negative, and gives flat, dull prints. Weaker light, well diffused, increases contrasts and brightens the prints. Place the frame, on the window-sill out of the sun, but with an uninterrupted view of the sky. After a short time the print is examined in a dull light by opening one half of the hinged back of the frame.

See that the paper is not pulled or disturbed in any way, or a double and blurred image will appear on the finished print. Depth of printing varies somewhat according to the paper and toning bath used, but as a general rule it should be carried on until the whites of the picture are well coloured and the shadows begin to appear solid. Fixing and toning should be carried out as soon as possible after printing, as P.O.P. tends to discolour if kept after printing and will not tone so well.

All prints, whether on P.O.P., gaslight, or bromide paper, are much more effective if a white margin appears round the photograph proper. This is obtained by the use of a mask, best cut to fit the particular photograph from opaque paper, flat and uncrumpled, such as the black paper used for wrapping sensitive plates. A sharp knife or a mounted razor blade must be used to cut the mask, since clean, straight edges are essential. Sets of masks may be bought, but those of oval shape or with rounded comers should not be used, for their effect is most inartistic.

To get clouds visible in a negative to print properly on P.O.P. paper it is necessary to shield the ground portion of the negative for part of the time during printing by placing a card over the frame, and so allowing the sky portion extra time for printing. The card should not touch the glass, but should be about $\frac{1}{2}$ in. to 1 in. away from it, and moved occasionally, or a sharp line will appear in the print. In a similar way, when there are no clouds in the negative, the sky portion being opaque, the print will be improved if, instead of appearing a blank white, it shows some tone of varying density.

To do this, expose the paper first in the frame through plain glass, covering all but the topmost (sky) portion of the negative with a card as before, gradually moving the card downward so that the top of the print has the longest exposure and shows a decided tint. The finished picture will show a graduated sky of much more natural appearance than if left blank. This process is called sunning-down. When printed P.O.P. papers are toned and fixed together with self-toning papers the two operations of toning and fixing are combined in one.

Printing Frame. Fig. 1. Frame with mortise and tenon corners. Fig. 2. View showing joint and rebate. Fig. 3. Section of side. Fig. 4. Detail of joint. Fig. 5. Alternative joint. Fig. 6. Spring. Fig. 7. Another method of making frame. Fig. 8. Section showing spring and staple. Fig. 9. Hinged back.

Printing Frame. Several kinds of frames for making photographic prints and suitable for all sizes in negatives, are obtainable. Although generally made in wood, some are made of metal, two kinds of the former being shown in Figs. 1 and 7. The framework of the first is shown in detail in Fig. 2, and for sizes up to whole plate the material can be the same size in section.

Taking the dimensions of a $\frac{1}{4}$ plate frame as a guide, the two sides A should be 6 in. by 1 in. by $\frac{3}{4}$ in., and the ends 5 in. by 1 in. by $\frac{1}{2}$ in. In order to reduce the thickness of material close to the negative, the top edge of the wood should be planed to a chamfer, as in Fig. 3, and the mortise and tenon joint cut as in Fig. 4. The thickness of the tenon is $\frac{1}{4}$ in., but, before cutting, allowance must be made for the chamfer and also the rebate, this being $\frac{1}{4}$ in. deep and $\frac{1}{8}$ in. inward. The rebate is cut in order to leave a projection at the ends. Fig. 2.

The simplest way of making the frame is to chamfer the two lengths A, cut out the recess to leave $\frac{7}{8}$ in. at each end and to cut the mortise to a depth of 1 in. The ends B are first notched on the side so that the bottom of the inclined shoulder is 1 in. from the end. After glueing up, the corners can be rounded as shown. An alternative method of forming the joint is shown in Fig. 5, the top chamfer being made after the joints are cut. The spring should be of hard rolled brass, hammered to form a curve, as in Fig. 6, a suitable width being $\frac{5}{8}$ in., the length for a $\frac{1}{4}$ plate being $4\frac{5}{8}$ in. Staples as at S should be made from $\frac{1}{8}$ in. hard brass wire and driven in the wood.

For the plywood frame in Fig. 7 the bottom piece C should be for a frame of the same size as Fig. 1, 6 in. by 5 in., the top pieces D 6 in. by 1 in. by $\frac{1}{2}$ in., and the end pieces E $1\frac{1}{4}$ in. by 1 in. by $\frac{1}{2}$ in. Cut the sloping recesses in the sides D to a length of about 2 in. and a depth of $\frac{1}{4}$ in., and then glue on, with end pieces E butted against them.

The springs are now prepared and screwed on as in the section in Fig. 8, and a staple fitted to each spring. The hinged back for the first frame is made from $\frac{1}{4}$ in. wood, each portion being $3\frac{1}{4}$ in. by $2\frac{1}{8}$ in., hinged together with small brass butts. The back for the second, shown in Fig. 9, is made from two pieces, one to fit in the recessed portion and the other beyond it. Brass hinges can be used, or a strip of linen cloth glued on.

PRISONER'S BASE. This game can be played in a garden or playground by any number up to about 40 players. The ground should be marked into two equal portions, and at each end a base established. If played in a yard these can be marked with chalk, the base being 5-6 ft. each way.

When the players have been divided into two equal parties the game begins. At first they risk capture by venturing into the enemy's ground, or remain on the watch for those who enter their own. Those who are caught by being tagged are placed as prisoners in the base, but can be released if touched by a free member of their own side. Both prisoner and rescuer can be tagged and brought back to prison before reaching their own ground. A game is won when one side has made prisoners of all its opponents, or when a free man enters his opponent's prison when it is empty.

PRIVET: The Shrub. This is the commonest of all hedge shrubs and it is scarcely surpassed for forming a close hedge quickly, but it needs to be clipped frequently during the summer months and impoverishes the ground near by. The plants should be set in autumn at 15 in. apart; a thick hedge is assured most quickly by planting a double row, the plants in one row alternating with those in the other. In the following spring they should be pruned to within 12 in. or so of the base to make them branch out. The common privet is *Ligustrum vulgare*, but the ovalleaved privet (*Ligustrum ovalifolium*) is a better shrub with larger leaves which are almost evergreen. The golden-leaved privet is a favourite hedge shrub; it varies a good deal in colour and it is wise to choose the plants in a nursery.

Several of the privets are worth cultivation as decorative shrubs: two of the best are japonicum, 4-5 ft., and lucidum, 15 ft.; both bear white flowers in summer. Privet is easily increased by cuttings inserted out of doors in October or in a frame in August. *See* Hedge; Quick.

Privet. Sprays of Ligustrum vulgare, the common privet.

PROBATE: Of a Will. When a man dies leaving a will his executors cannot handle his estate until they have proved, or taken out probate of, his will. This is accomplished by taking the will either to a local registry or to Somerset House, together with a copy: leaving the original there, and receiving from the officials a copy written on parchment and sealed with the seal of the probate division of the high court. This is called a probate copy, armed with which the executor can collect the estate and deal with it.

Any person who wishes to dispute a will must enter a caveat on a form provided by Somerset House in London (fee 1/-) or a probate registry. This form is to the effect that no will of X Y deceased is to be admitted to probate without notice to the objector or his solicitor. The caveat remains in force for six months and may be renewed. Anyone who wishes to prove a will of X Y deceased must first search and see if there is a caveat. If he finds one, he must give notice to the objector called a 'warning summons' (fee 2/6). Unless the objector enters an appearance to the warning summons the caveat expires. If an appearance is entered by the objector it will be necessary to prove the will in solemn form by litigation.

The action is heard in the probate division of the high court, when the witnesses to the will come and give their evidence on oath; the objector is allowed to call evidence to show either that the will was not executed according to law or that the testator was of unsound mind or subject to undue influence or the like. If the will is pronounced valid, it is then said to be proved in solemn form.

The ordinary probate of a will is called proof in common form. The following documents are required: (1) an affidavit according to the form which can be obtained from Somerset House or the local registry containing all particulars of the deceased's estate; (2) an oath of executors proving the death, will, etc.; (3) renunciation by any executor where necessary; (4) engrossment of the will and any codicils on official engrossment sheets of special paper; (5) where necessary an affidavit of due execution of the will; (6) a certificate of reason of delay where the application is made after a lapse of 3 years from the testator's death in order to enable the estate duty to be assessed. If the deceased left a will but either named no executor or the executor whom he named is dead, then the person who would be entitled to administration if he had died intestate is also entitled to be administrator with the will annexed. As a rule, administration is granted to the residuary legatee, because it is clearly to his interest that the deceased's estate should be properly administered, he being entitled to what is left after paying debts and the various legacies devised under the will. *See* Executor; Legacy; Will.

PROGRESSIVE PARTY. A progressive party may be held, in one's own house, or, if it is desired to invite a large number of people, it may be equally well held in a hall hired for the occasion. Whist is the most suitable game, as bridge is too scientific to admit of the casual play and constant change of partners and talks which occur during the evening's entertainment. It is important that the tables should not be too close together, and that circulation should be easy. Also that one or two people should be in reserve in case some player disappoints. Each table should have its number clearly marked.

The best time-table is as follows: Allow $\frac{1}{2}$ hour for the guests to arrive, to serve coffee or any light refreshments, to hand out scoring cards, and for the arrangement of partners; play may last for $1\frac{1}{2}$ hours; and another $\frac{1}{2}$ hour will serve to circulate refreshments and present the prizes. It is a great mistake to allow the play to last too long, as after a certain time things may begin to drag.

It is best to leave the arrangement of partners to chance, and to let them find each other by one of the ordinary methods, such as the pairing of words. Each man's card should have the table number written on it, and there should be two men for each table.

Play must start with the ringing of a bell; it should continue from 5 to 10 min., and cease when the bell rings again. The winning couple, when the scores have been filled in, then move to other tables. Usually the woman moves to the next highest number and the man to the lower one. This ensures that the majority of people shall meet each other in the course of the evening. The losing couple remain at the same tables as before, but when the new arrivals come they change partners. When play ceases the scoring cards should be handed in to host or hostess, and the players go into another room for refreshments while the results are checked and graded. These will then be announced and the prizes presented. There should be at least one prize for the first woman and one for the first man. Beyond that, the matter is left to the means and discretion of the host and hostess. *See Evening Party; Whist.*

PROHIBITED DEGREE: In Marriage. In the Book of Common Prayer of the Church of England there is printed a table of kindred and affinity showing whom a man or a woman may not lawfully marry.

It is now permissible for a man to marry the sister of his deceased wife or for a woman to marry the brother of her deceased husband. It is not, however, lawful to marry the sister (or brother) of a divorced wife (or husband) who is still alive. A marriage is now legal also between a man and his deceased wife's niece (i.e., by marriage) and between a woman and her deceased husband's nephew (i.e., by marriage). A clergyman is not subject to any penalty for refusing to officiate at any of the above marriages. *See Marriage.*

PROMISSORY NOTE. By the Bills of Exchange Act, 1882, a promissory note is defined as an unconditional promise in writing made by one person to another, signed by the maker, engaging to pay on demand or at a fixed or determinable future time a sum certain in money to or to the order of a specified person or bearer. The form of a promissory note is as follows:

August 1, 1938.

Three months after date I promise to pay to Mr. Arthur Smith or order the sum of One Hundred pounds with interest at 6% (Six per cent) for value received.

£100. (Signed) John Jones

In this note John Jones is called the maker and Arthur Smith the payee. The payee of the note can negotiate it, i.e. by endorsing it on the back with his signature he can transfer it to anybody he pleases, with or without consideration. It may be negotiated in the same way by the holder as often as he chooses. In this way the note can pass through any number of hands and the holder at the end of the 3 months has the right to present it for payment to John Jones.

If John Jones does not pay it, the holder can call upon any of the persons or all of them whose names are on the back of the note as endorsers to pay. Any of such endorsers who does pay can in turn call upon anyone whose name was upon the note before his own to pay him until it gets back to John Jones, the maker. It is no defence to John Jones or any of the other people, if sued, that they received no consideration. If anybody in the whole series of transactions has given any value at all,

either in money or money's worth, the note becomes one for valuable consideration in his hands, and also in the hands of anyone who takes it after him.

The value of a promissory note is that it is negotiable, i.e. the holder of it has a good title to the money quite independently of the title of anyone from whom he took it.

As between the original parties, i.e. the original maker and payee of the note, the maker may have a good defence on the ground either that there was no consideration given for the note or that it was obtained from him by fraud or for some illegal consideration. But if the note gets into the hands of someone who is a holder in due course, i.e. a holder who received the note after consideration has been given for it by somebody and who takes it without receiving notice of any fraud or illegality at its inception, the holder can sue upon it.

If in the note set out John Jones received no value from Arthur Smith, that is a good defence of John Jones if Arthur Smith sues him upon it. But if Arthur Smith sells the note to William Brown for £5, William Brown can sue John Jones for the £100. He can, of course, also sue Arthur Smith. Again, suppose John Jones was induced to sign the note by some fraud on the part of Arthur Smith, John Jones can set this up as a defence against Arthur Smith, but if Arthur Smith sells the note to William Brown, who had no notice of fraud, then John Jones must pay William Brown if he is asked.

A note is only fully negotiable so long as it is current, i.e. until it becomes overdue. The note is overdue after the time when it is stated on the face of it to be payable. Thus, the note above is overdue after the expiration of the three months. It can still be transferred even after that date, but anyone who takes the transfer takes the risk of the note having been bad at its inception. In other words, it becomes like an ordinary contract or debt, and the maker may set up any defence or fraud against any holder, and it will then lie upon the holder who took the note after it was overdue to show affirmatively that he had no knowledge of such fraud. *See Debt: I.O.U.*

PROPAGATION: Of Plants. The chief methods of propagating plants are by seeds; cuttings; division; layering; bulbils; offsets; grafting; inarching: leaves, as in gloxinia; runners, as in strawberries; stem-rooting, as in the castor-oil plant; eyes, as in vines; and by pipings. Most of these are dealt with under separate headings.

Aids to propagation are pots, pans, and boxes, a fine sieve, some panes of glass, 2 or 3 cloches, a fine-rosed watering pot, a good syringe, a keen budding knife, and a few minor appliances, such as bast, clean crocks, etc. To these may be added a propagator and a garden frame. A propagator can be made from any ordinary box, with sheets of glass from old picture frames, or from a pot with charcoal and fibre, and covered with glass. Suitable soil is required, and, generally, any good light soil opened with a little sand will suffice, but certain other combinations will often be called for, including rich loam, sandy peat well rubbed down, decayed leaf-mould, silver sand.

A few hints on preparation for sowing may be of value. Pots, boxes, or pans must be well crocked with clean potsherds, over which a thin layer of moss or fibre is placed. This is followed with compost to within $\frac{1}{2}$ in. of the top, the whole then being made moderately firm by pressure, and gently watered. Excess water should be allowed to drain well away, then the seeds are sown thinly and covered with soil put through a fine mesh sieve.

After sowing, seed receptacles should be covered with a sheet of glass to conserve moisture. Should the soil show signs of dryness, immerse the pot gently in tepid water and moisten the plunging material. It can be shaded from sunshine with sheets of brown paper; when the first rough leaf is formed it should be removed to a naturally shady place until ready for transplanting, every precaution being taken to avoid damping off.

There are various kinds of cuttings. Shoot cuttings should always be taken with a heel or cut at the base of a joint, the lower pair of leaves being removed. Other types are rootcutting and leaf-cutting. Receptacles with soil should be prepared in the manner already devised, but instead of the fine top

covering of soil, well-washed sand should be used. The cuttings are inserted with a dibber, and their bottoms must touch soil at the base of their holes; the soil is pressed firmly round them, and they are removed to a propagator.

Propagation: the various methods employed. 1. Budding. 2. Grafting. 3. Inarching. 4. Multiple layering. 5. Stem rooting. 6. Rootlet of monkshood. 7. Propagation by eyes. 8. Rhizome of perennial. 9. Crinum offset. 10. Root propagation. 11. Hardwood cutting.

Most hardy herbaceous perennials are easily increased by division, i.e. by lifting the clumps in autumn or spring, separating them into pieces and replanting the latter. Only the young outer pieces should be chosen. Border carnations, various shrubs and strawberries are propagated by layering in summer. The shoots or stems are slit and the slit portion is pegged into the soil and kept moist. Budding is practised in July-August, chiefly for the purpose of raising a stock of fruit trees and roses. Grafting is carried out in spring both out of doors and under glass. Raspberries, chrysanthemums, and some shrubs are propagated by suckers, i.e. shoots which grow through the soil from the parent rootstock. *See* Bedding; Cuttings; Division; Edging; Grafting; Pruning.

PROPELLER SHAFT. This (also known as cardan shaft) is the driving shaft placed between the gear box and the back axle in a motor vehicle, and may be classified under two heads—open and enclosed. With the open type a universal joint is employed at each end, one of which is capable of longitudinal as well as universal movement. The reason for this is that the radius of the axle movement is governed either by the point of the spring anchorage to the frame or, where fitted, by the point of anchorage of the torque stay. The object of the torque stay is to relieve the springs of the twisting tendency of the axle, which is created by the driving and braking stresses.

Unless the centre of the universal joint next the gear box is the same distance from the axle as the other centres that govern the axle's movement (e.g. the spring or torque stay anchorage), the up and down movements of the axle will cause the length of the propeller shaft to alter slightly, and this sliding movement must be provided for. Therefore one of the universal joints is made to permit longitudinal movement. The open shaft is usually constructed of large diameter steel tubing, which affords rigidity and strength.

With the enclosed shaft, the difficulties of centres do not exist to the same extent, because the casing for the shaft is also a rigid part of the back axle, and acts as the torque stay with its forward end anchored close up to the gear box by a ball and socket joint.

Apart from the attention to lubrication which all universal joints require, there is one other point which may be mentioned in connexion with the propeller shaft, namely faulty alinement. This may be detected by a regular rhythmic whining noise when the car is running quietly. The trouble can be put right by any service garage, and is not an expensive job. *See Brake; Motor Car.*

PROPERTY TAX. This name is given to that part of the income tax which is derived from property. This is paid by the occupier of the house or premises, and if he has a landlord he is entitled to deduct the amount from the rent. *See Income Tax.*

PROTEIN: As a Food. In animal and vegetable tissues there are found complex organic compounds of carbon, hydrogen, nitrogen, oxygen, and sulphur, which are known as proteins. Food must contain a certain proportion of these nitrogenous substances, because they are absolutely necessary for the building and repair of the tissues. White of egg, serum albumin, fibrinogen, peptone haemoglobin, and casein are examples of proteins.

The patent food sold as protein food is used largely in vegetarian cookery, but may also be served as a breakfast or supper drink. To prepare this, put 3 tablespoonfuls of the food in a jug, mix it slowly with half pint of hot water, milk, cocoa, tea, or coffee. Grated nutmeg, cinnamon, or ginger flavouring may be added to taste. *See Diet; Food; Vitamin.*

Protractor. Instrument used by the draughtsman for measuring angles.

PROTRACTOR: For Measuring. Used for measuring angles, the protractor is generally made in brass or celluloid, the commonly used pattern having a base of 4 in. The method of using the protractor is here illustrated. The two ends A and B are placed on a line with the centre-point C exactly at the place where the required angle is to start from. If a mark is made at the point 60 as indicated at D and the point D joined to the centre point C, the angle made by the lines A C D contains 60° . In the same way an angle of 25° can be set off from the point E, and the angle contained by the lines F C B is 45° . Other are 55° at G, 77° at H; the right angle is at K and an angle of 115° is contained by the lines L C A. *See Drawing.*

PROUD FLESH. The flabby, unhealthy tissue that sometimes projects from the edges of a wound or ulcer is popularly termed proud flesh. It may result from an excessive use of poultices and ointments. The remedy is the application by the surgeon of an astringent, such as a solution of sulphate of copper or nitrate of silver.

PROVENCE ROSE. One of the oldest garden roses, this is commonly called the cabbage rose because of the shape of the blooms, which lack the graceful contour which is characteristic of many modern varieties. The Provence rose, which was derived from *Rosa centifolia*, bears rose-pink fragrant blooms. It forms a fair-sized bush, flowers in summer only, and should be pruned in March by cutting out old worn-out branches and shortening the previous year's shoots slightly.

PROVERBS: The Game. There are various games of this name. One of the best known is as follows: One person is sent out of the room. The others select some proverb which contains as nearly as possible the same number of words as there are people present. The words are then given out in order and the person outside is summoned in. He proceeds to ask a question of each player in turn, and the answer must contain the word of the proverb which has been given to that player. When all have been questioned the newcomer must guess the proverb.

Should there be insufficient words to go round, the people for whom there is no word must keep silence. If there are more words than players, some of the players must be responsible for two. Obviously the proverb chosen must have as few distinctive words as possible if it is to present difficulties in guessing. "It is never too late to mend" is an example of an easy one to disguise, while "a rolling stone gathers no moss" is remarkably difficult. There are few ordinary questions an answer to which would naturally contain "rolling" or "moss"; the latter word alone would identify it.

A Variant. In another form of the game a list is made of as many proverbs as are considered necessary, the number being regulated by the number of guests expected. Each is then written out in separate words on separate pieces of paper. The key word of each is kept out, and the others, having been well shuffled, are pinned up in different places all over the house. This must be done before the guests arrive. It is advisable to keep the original list as a reference in case of questions.

The guests are each given a key word and are set to complete the proverb which it suggests to them. They must be shown which rooms may be included in the search and must all start at the same moment. Each proverb when completed must be brought to the hostess, who will then issue another key word.

The person who completes the largest number in the time given receives a prize.

This is an excellent game for an afternoon or evening party and the less formal type of at home. At least three proverbs should be allowed for each player, but the larger the number the more difficult they are to find and the keener will be the interest. *See Children's Party.*

PRUNE. The dried fruit of the many varieties of plum is known as prune. Prunes form a health giving addition to the diet because of their content of carbohydrate, and also because they increase the palatability of cornflour and other starchy dishes. They have a mild laxative effect, and are taken with advantage by those who have a marked tendency to constipation.

Before stewing, wash the fruit thoroughly and soak it for 12 hours or more in a covered basin contain¹/₂ing sugar and water. To 1 lb. prunes, ¹/₄ lb. or a little more sugar and enough cold water to cover them should be allowed. After soaking, put the fruit and syrup into a pan with a little lemon rind and juice. Stew these slowly until the prunes are tender, and serve them with the syrup.

Prune Fritter. Cold stewed prunes may be used to make fritters. Take out the stones, and in their place put some blanched almonds. Then coat the prunes with frying batter and try them to a golden brown colour in a pan of boiling fat. Serve the fritters sprinkled either with castor sugar and grated chocolate or with sugar alone.

Prune Mould. This sweet is made by washing $\frac{3}{4}$ lb. prunes, covering them with cold water, and letting them soak for 12 hours. Dissolve a $\frac{1}{2}$ pint packet of lemon jelly in hot water, and pour about 2 tablespoonfuls of it into the bottom of a mould previously rinsed with cold water. Put the prunes, together with their liquor, into a saucepan, add 3 dessertspoonfuls sugar, 1 oz. candied peel cut into small pieces, and the grated rind of a lemon, and cook all gently until the fruit is tender. Take out the prunes and stone them; boil up the syrup for a few minutes until it thickens, and then set it aside to cool.

Prune Mould, a jelly sweet which can be made richer by the accompaniment of thickly whisked cream.

In $\frac{1}{2}$ gill of it dissolve $\frac{1}{2}$ oz. leaf gelatine, put the prunes back into the remainder of the syrup, and add the strained juice of a lemon, $\frac{1}{2}$ oz. blanched almonds cut up roughly, $\frac{1}{2}$ gill sherry, and the rest of the jelly. Strain in the gelatine, stir all together until they thicken, then colour the mixture with a few drops of cochineal and pour it into the mould. When it has set, turn it on to a dish, and with an icing bag force round its base 1 gill thickly whisked cream, sweetened and flavoured to taste. Sprinkle the cream with some pistachio nuts which have been blanched and chopped.

A prune and rice mould can be made by soaking $\frac{3}{4}$ lb. prunes as already described, and then putting them into a saucepan with the water in which they have been soaking. Add also a dessertspoonful Demerara sugar and 1 oz. candied peel cut into small pieces, and cook them until the fruit is soft. Then take out the prunes, stone them, and boil the syrup rapidly for about 5 min. The candied peel may be left in the syrup or strained out. Wash 3 oz. rice, put it in a saucepan with $1\frac{1}{2}$ pints milk and 2 dessertspoonfuls sugar, and cook it slowly until it has absorbed the milk. Then stir the prunes into it, turn the mixture into a wet mould, and leave it to set.

Prune Pie. A pie can be made from prunes by preparing 1 lb. as already described and putting them in a deep pie-dish. Cover with a lid of short pastry and bake in a hot oven half an hour. Six oz. pastry will be required.

Prune Pudding, a wholesome steamed pudding which might be served with hot custard.

Prune Pudding. To make a pudding with prunes they should be stewed and then rubbed with a little of the syrup through a fine sieve. Mix together $\frac{1}{4}$ lb. flour, the same quantity of breadcrumbs, a little less than $\frac{1}{2}$ lb. sugar, 4 oz. suet, a teaspoonful baking-powder, and a little salt. Form a well in the centre, and into this put a well-beaten egg, a breakfastcupful of the fruit pulp, and a

little milk.

Mix these gradually, adding more milk if necessary, and then turn the whole into a greased basin. Cover it with a piece of greased paper, and steam the pudding for about 3 hours. Hot custard makes a good accompaniment. *See* Batter; Custard; Pastry.

PRUNELLA. This dwarf-growing perennial, commonly known as self-heal, is suitable for carpeting bare ground. The best form, Webbiana, has crimson-purple flowers.

PRUNING OF TREES AND BUSHES

Directions for an Essential Gardening Operation

The gardening reader may be referred to such headings as Apple; Gooseberry; Pear; Plum; Rose.

See also Disbudding; Grafting; Kitchen Garden; etc.

Pruning is the process of cutting trees and bushes in such ways and at such times as will help their productive qualities. Pruning is chiefly employed for trees and bushes that bear fruit and flowers.

Dealing with fruit trees, the objects of pruning are several. One is to form the tree, as trees are grown to certain forms for certain reasons, and these forms are secured by pruning. Another is to secure for all parts of the tree their due share of air and sunlight, so that they will perform their functions properly. Pruning is also necessary to induce fruiting and to improve the quality and quantity of the fruit; to facilitate cultural functions, such as tillage, spraying, and finally gathering; and to remove dead and diseased fruit.

Knife and Other Tools. The pruner needs several tools. The first is a good knife, which he should keep thoroughly sharp, particularly towards the tip of the blade. The reason for this is that long, slicing cuts, finished well through to the tip, are the safest and best. Such cuts can be drawn boldly on to the thumb with the keenest of edges on the knife without the slightest risk of injury, whereas short, jerky cuts are unsafe. The knife is the best tool for use on small trees, but for larger trees secateurs or pruning shears may be used, especially if the pruner is working on a ladder, because he can steady and cut the shoot with one motion. For heavy pruning a saw is necessary. The best is a tiny one with a blade not more than 5 in. long and an inch wide, with small, fairly wide teeth. A pruning hook is useful for cutting high branches.

Saw-cuts and large wounds should be trimmed to smoothness with the knife and sealed over with white lead, oil paint, or carpenters' knotting.

Two Groups of Trees. To enable pruning to be done correctly some knowledge of the way in which trees and shrubs bear their flowers or fruits is essential. Fruit trees and bushes fall naturally into two groups so far as their pruning is concerned; those of one type produce fruits chiefly on spurs—short, sturdy shoots which bear blossom buds; those of the other type yield the best fruits on shoots or branches of the previous year's growth. The fruits of the spur-fruited type are apple, pear, plum, sweet cherry, apricot, gooseberry, red and white currant and vine.

Pruning Hook, a device for cutting high branches.

Briefly, the way to prune these fruit trees is to shorten the side shoots of the current season's growth in July or early August, and to cut them back still further in winter. At the latter season weakly and crowded branches must also be cut out. Plum, gooseberry and apricot are most fruitful under a modified form of this treatment; in the management of apricot and plum

trees care should be taken to preserve promising young shoots and to cut out parts of old branches to make room for them. The pruning of gooseberry bushes is done principally by thinning out the branches to such an extent that the hand can be passed between them, though the side shoots may be pruned in the orthodox way. During the summer vine shoots must be pruned; if this is not done it will become overcrowded and weakened.

Pruning: some of the necessary tools. Top, strong folding knife for the amateur gardener. Centre, pruning shears. Bottom, pruning saw, which has a row of teeth on each edge.

Fruit trees which bear chiefly on the branches of the previous year's growth are peach, nectarine, black currant, raspberry, loganberry, blackberry, and other allied berried fruits, and the morello cherry. They are pruned as soon as the fruits are gathered by cutting out old branches or parts of them and preserving the shoots of the current year's growth to replace them. In dealing with peach and nectarine trees disbudding, that is the removal of superfluous young shoots while they are small, is necessary.

The Lorette System. A practice which is gaining favour among fruit growers is the Lorette system of pruning, so called because it was introduced by M. Lorette, a French expert. It differs from the orthodox summer and winter pruning of side shoots as practised by British growers, for the non-blossoming shoots are cut hard back in spring, leaving only the very small leaves at the base.

Pruning. 1. Comparison of fruit (a) and wood (b) buds. 2. Pruning cuts: a, correct, b, incorrect: snag left above eye; c, altogether wrong; d, cut too deep. 3 and 4. Different pruning for red (3) and black (4) currants. 5. Principle of pruning bush apple. 6. Pruning a rose bush: black parts to be cut away. 7. Pruning side shoots to encourage fruit spurs.

In June the trees are again examined and all shoots of the approximate thickness of a lead pencil are shortened to about half an inch. This system is based on the discovery that if the buds at the extreme base of the shoots (buds which remain dormant under the orthodox pruning) are forced into growth by hard pruning

they will form fruit buds earlier than those higher up the shoot. Similar pruning is carried out periodically until the end of the summer, and no pruning is done in the winter months.

Ornamental Trees and Shrubs. These are conveniently classified in two groups in respect of pruning. In the first group are those kinds which bloom in spring and early summer; in the second group those which flower in late summer. Many spring and early summer flowering shrubs bloom chiefly on the branches of the past year's growth; therefore pruning must be done as soon as the flowers have faded by shortening the old branches to encourage the development of fresh ones which will provide blossom the following year. Among them are the winter jasmine, golden bell shrub (*forsythia*) flowering currant, mock orange (*philadelphus*), weigela, lilac, deutzia and the spring blooming spiraeas. Shrubs which flower in late summer should be pruned in spring, because it is the new shoots—those which have still to develop—which will yield the flowers. Familiar kinds which need this treatment are the rose, mauve buddleia, all varieties of clematis of the Jackmani type, *hydrangea paniculata* (not the common *hydrangea hortensis*), *hypericum* or St. John's wort, late summer spiraeas and hardy fuchsia.

There is still another type of ornamental tree or shrub—that which needs no regular or systematic pruning. They must be looked over occasionally for the purpose of thinning out crowded branches or shortening straggling ones which spoil the symmetry of the bush. These include flowering cherry, crab and plum, magnolia, rhododendron, azalea, viburnum or guelder rose, orange ball tree (*Buddleia globosa*), hawthorn and laburnum.

PRUNUS. This is the botanical name of one of the most important groups of hardy flowering and fruiting trees. It includes the almond, peach, nectarine, damson, apricot and plum. The common and Portugal laurels are also classed by the botanist as *Prunus*.

PRUSSIC ACID. Hydrocyanic or prussic acid is found in oil of bitter almonds, peach kernels, apple pips, cherry laurel leaves, and other vegetable products. When separated or prepared it occurs as a colourless liquid with a characteristic odour. Potassium and sodium cyanide are used in the extraction of gold from ores and in photography.

Prussic acid and the cyanides are extremely poisonous. In poisoning by prussic acid there is rapid unconsciousness, but if there be time an emetic of mustard and water should be given. An attempt should be made to rouse the patient by dashing cold water on the face and chest, or cold and hot water alternately. Ammonia smelling salts should be held to the nose, and warmth promoted by hot flannels, hot-water bottles, and chafing the limbs. If breathing fails, artificial respiration should be at once begun. Stimulants should be given when swallowing is possible. *See* Artificial Respiration; Poisoning.

PSITTACOSIS. Disease of parrots. It is due to a filtrable virus and may be communicated to man. Even healthy birds may serve as carriers. After a serious outbreak of the disease in 1929, in 1930 the import of parrots into Great Britain was forbidden.

PSORIASIS. The skin disease known as psoriasis is characterized by flattish, dry patches of varying size covered with white or silvery-grey scales. The backs of the elbows, the fronts of the knees, and the scalp are the favourite sites, but the trunk and other portions of the body are not uncommonly involved as well. As a general rule the patient does not complain of symptoms beyond itching, and the patches can generally be made to disappear under treatment. Relapses are common, and the disease is subject to sudden increases in its rate of speed. If untreated this skin disease may last for many years.

The drugs used include arsenic, potassium iodide, thyroid extract, etc. The first step in local treatment is to scrub the patches with hot water and soft soap, or bathe them in warm olive oil. An ointment consisting of tar ointment, 2½ drams, and lanolin, enough to make 1 oz., is applied night and morning after the patches have been thoroughly cleared of scales. Another useful drug is resorcin, which may be used in an ointment composed of resorcin, 15 gr.; lard, 1 oz. Pron. So-ri-as-is.

PSYCHO-ANALYSIS. A method of investigating the subconscious part of the mind, which has proved of great value in the treatment of certain forms of neurotic disorders, is known as psycho-analysis. The method was devised by the Viennese physician Prof. Sigmund Freud, and, with its applications, has led to the development of a school of thought which recognizes the influence of the subconscious in a large number of mental processes.

Speaking broadly, the psycho-analyst regards the mind as composed of two parts, the conscious, which appears to control our thoughts and actions, and the subconscious, which, without our being aware of it, does in fact exercise a powerful influence upon our motives and conduct. The subconscious becomes the repository of painful memories and primitive tendencies which are described as being suppressed or repressed, and often date from early childhood.

The exigencies of civilization and social life clearly demand a very considerable degree of inhibition of the primitive instincts and impulses. Abnormal tendencies present in infancy and childhood are by painful experience and education (in the broadest sense) gradually eliminated from, or prevented from ever entering, the conscious part of the mind as normal growth and development proceed.

It is clear that very often the impulses to action of the conscious and subconscious must be in direct opposition to each other. In the normal individual these two parts are so adjusted that no conflict of which he is aware arises. In the hysterical individual, however, the adjustment between the two parts of the mind has not been satisfactorily effected, and the result is the appearance of the various symptoms which are characteristic of hysteria.

The ultimate object of treatment by psychoanalysis is to effect an adjustment between the conscious and subconscious, and thus bring about a resolution of the conflict which is responsible for the symptoms. For this purpose, by means of a special technique, the patient's immediate and free associations with events in his life which have had an emotional effect, slips of the tongue, errors in writing, etc., are obtained, and furnish a clue to the underlying cause of the trouble. In particular, dreams provide material of great value for investigating the subconscious.

Little by little under this treatment the patient comes to understand the warring mental processes which are going on within him; the symptoms gradually disappear, and in favourable cases a complete cure can be effected. The patient who seeks relief by this method is advised to place himself only in the hands of a skilled physician.

PTARMIGAN. A small species of grouse found in mountainous regions, the ptarmigan is also known as the white grouse, because of the colour of its plumage in winter. It needs to be well hung, and is cooked in the same way as ordinary grouse. Ptarmigan is best eaten young, otherwise it may be found to have rather a bitter flavour. These birds make an excellent salmi and game pie. *See* Game. Pron. Tar-mi-gan.

PTERIS: The Fern. The bracken (*Pteris aquilina*) is the commonest of all British ferns and a familiar feature of the landscape in many parts of Great Britain, especially in woodland districts. It is scarcely suitable for planting in gardens of moderate extent. Bracken fronds provide useful material in winter for the protection of roses and tender shrubs. Several of the pteris ferns are

admirable plants for the slightly heated greenhouse and room window; they are easily grown in pots in a compost of loam, leaf-mould, and sand. *Tremula*, *serrulata*, *serrulata cristata*, *cretica* and *cretica albolineata* are some of the most attractive. They need a good deal of water in summer but much less in winter. They are propagated by sowing spores in pots of soil covered with glass in the greenhouse.

PTOMAININE POISONING. By their action on animal and vegetable matter, bacteria may produce alkaloidal substances, called ptomaines, some of which are poisonous. It would appear, however, that in the great majority of cases of food poisoning this is not due to ptomaines, or to the products of putrefactive organisms generally, but to disease-producing bacteria and their toxins. A poisonous ptomaine may occur in cheese, pork, ice cream, and other commodities. Almost any kind of food may give rise to poisoning, but some kinds are more dangerous than others, and should be eaten with caution in hot weather. These are veal and pork pies made from stale meat or kept some time after cooking; cold veal, pork, and badly cured ham, sausages, mussels and other shell-fish, mackerel, crab, canned fish, and contaminated ice cream. To these may be added goose and venison kept too long.

Both the living microbes and the chemical substances they produce in the food may be poisonous. The microbes are killed by thorough cooking, but the poisonous substances within them may not be affected. Consequently cooking is not always a protection.

It should be remembered that cooked food is as liable to infection by microbes as raw food. Meat may be quite wholesome when first used and then, when put away in a dirty or ill-ventilated larder, it may become contaminated. This very often occurs, poisoning being frequently caused by cold or re-heated meat that has been kept some time after cooking.

One of the great dangers arises from the fact that the meat or fish may contain a fatal dose of poison without having any appearance of odour or decay.

The symptoms may set in soon after a meal, or be delayed for twelve hours, or even longer. The patient suffers from violent pains in the abdomen, with nausea, vomiting, and purging. His pulse beats quickly; he has a severe headache, is very weak, and in a state of extreme nervous depression. There may be cramp in the calves of the legs, sleepiness, dizziness, dimness of sight, difficulty in breathing, and finally collapse and death.

At the outset give an emetic of a tablespoonful of mustard in $\frac{1}{2}$ pint of warm water. Follow this with a quickly acting purge, such as a large dose of salts, 1 oz. of castor oil, or 5 gr. of calomel. For weakness give stimulants, and keep the patient warm with blankets and hot-water bottles. Any of the following stimulants may be used: whisky or brandy, in doses of 2 to 4 teaspoonfuls frequently repeated; sal volatile, a teaspoonful in a little warm water; or hot, strong tea. Pain may be relieved by hot poultices or flannels wrung out of hot water to the abdomen. When the patient recovers sufficiently to take food, it should consist at first of boiled milk only. *See Food; Poisoning.*

PUBERTY. The critical age when the sexual functions become active is usually referred to as puberty. In Great Britain it occurs in girls between the ages of thirteen and fifteen, but may be a year or two earlier or later in exceptional instances. In boys the average age of puberty is between fourteen and sixteen.

Profound changes take place at this period, and parents should exercise great care and watchfulness over their children's health, bodily, mental, and moral. The physical and mental change is very sudden, and there is a great expenditure of energy on the quick development. It is not uncommon, therefore, to have signs of nervous disturbance and exhaustion showing themselves at this time.

There is a great increase in glandular activity, and the effect of this on the skin glands is a reason for the onset of acne at puberty. The whole outlook of life becomes altered, the feeling of sexual difference asserts itself, emotion deepens, and the boy or girl may become very impressionable, self-conscious, and perhaps shy and awkward in manner.

Plenty of nourishing food and outdoor exercise and abundant time for sleep are essential. The following shows the minimum of sleep required as a rule:

13 years old	10½ hours
15 „ 10 „	
17 „ 9 „	

Do not let a boy or girl be overworked in body or mind. If school-work seems too much it should be cut down. With regard particularly to girls, their management at the appearance of menstruation (q.v.) will influence their health for life.

PUDDING. Puddings may be boiled, steamed, or baked, according to their ingredients. Those made of suet are boiled or steamed, being wrapped in a scalded and floured cloth, or turned into a greased basin and covered with a cloth or a piece of greased paper. Batter and custard puddings, as well as those made with a covering of pastry, are baked in a deep dish. Ice puddings come into a different category, as they are made by a freezing process.

Pudding Cloth. The calico cloths in which boiled puddings are cooked should be sprinkled with flour before use. They need to be kept scrupulously clean, and after use any of the mixture adhering to the cloth should be scraped off, the cloth washed in hot water to which a little soda has been added, and, if necessary, boiled. Rinse it well to remove the soda, and dry the cloth in the open air. No soap should be used either in washing or boiling. Cloths used for tying over the tops of puddings cooked in basins are treated in the same way. *See* Apple; Batter; Beef Steak Pudding; Cherry; Chestnut; Chocolate; Christmas Pudding; Coconut; Dried Fruit; Gooseberry; Ice; Jam; Lemon; Macaroni; Marmalade; Pastry; Pineapple, etc.

PUERPERAL FEVER. Quite shortly after labour a woman may become feverish for a few hours, from some slight cause, or she may become seriously ill from septic infection of the womb or other neighbouring part. The name puerperal fever is popularly given to this condition.

Symptoms of infection may appear a few hours after the birth of the child, but most frequently the first symptoms manifest themselves about the third day. Fever is usually the first sign to attract attention; it may be accompanied by a chill and headache. Puerperal fever is a notifiable disease and immediate medical treatment is required.

PUFF PASTRY. The most delicate of all baked pastries is puff pastry. It is made with equal quantities of butter and flour, a little lemon juice, water, salt. The method of making puff pastry is given in the article on Pastry. Sometimes an egg is added to the other ingredients to enrich the colour of the pastry, which requires a steady but brisk oven. *See* Pastry.

PUG: The Dog. The pug is a quiet, clean, and affectionate dog. His strong attachment and faithfulness to his master or mistress, his docility and good behaviour, make him a very attractive home companion, especially when it is not desirable to spend so much time over the dog's toilet as is requisite for pets with long, silky coats. Short, thick, and rounded in body, with a smooth, short coat, the pug has well-developed hindquarters, straight, short legs, and a tightly curled tail. The head is rather large, with square, wrinkled face and a short black muzzle. The eyes are large and

black; the small, silky ears hang close to the head. Pugs were formerly all fawn-coloured, with a black line down the middle of the back, a black spot in the centre of the forehead and one on each cheek; the toenails were black. These points are no longer insisted upon. There is now an entirely black race, and the fawns vary from silver grey to apricot colour. The weight should be from 13 lb. to 17 lb. *See Dog; Kennel.*

PULLET. From the time when she emerges from chickenhood until she becomes an adult the female fowl is known as a pullet. In the past a fowl was considered a pullet from the day she was hatched until Jan. 1 in the year following. But with the advance of egg-laying properties, and the institution of egg-laying competitions in which the birds are entered as pullets, it has become customary to speak of the number of eggs a bird laid in her pullet year. To avoid confusion, a bird is considered a pullet until she has completed her first laying year, which is termed her pullet year, though strictly speaking she became a hen on the previous Jan. 1. For exhibition purposes the old definition remains, and a pullet becomes a hen on Jan. 1 following her birth. *See Chicken; Fowl; Incubator; Poultry.*

PULMONARIA. These hardy herbaceous plants of the borage family are suitable for the rock garden or border. The flowers of most of them are blue on opening and change to rose colour as they fade, and the leaves have white markings. The common name is lungwort. The best sorts are *angustifolia*, 12 in., *arvernensis*, 10 in., and *rubra*, 12 in., reddish. The flowers open in spring and early summer. Propagation is by dividing the plants in autumn. *See Border; Rock Garden.*

PUMICE. There are a number of uses for pumice. It is employed in the form of a powder in soaps and cleansing mixtures of many kinds, and is also present in a number of polishing compositions. Pumice is chiefly employed in the home for cleaning purposes. A small lump is rubbed on the fingers to remove stains and paint markings. The powder, wrapped in a linen or muslin bag, can be employed for rubbing down a painted surface, especially if worked with a little water to act as a lubricant. In addition pumice is employed as an ingredient in a certain kind of soap known as pumice soap.

Purpice stone is usually greyish white in colour, but can also be obtained in yellow, brown and black. It is especially effective in removing obstinate ink stains from the fingers, and is also used to produce a gloss on unpolished marble, and for rubbing down papier mâché articles before painting them. *See Lubrication; Marble.*

PUMPS FOR THE SUPPLY OF WATER

A Household Necessity in Country Districts

This article is one of those that deal with the important subject of the water supply. See that entry:
also Frost; Pipe; Rainwater; Ram; Well.

In country districts, and also to some extent in towns, households are dependent for their supply of water, or at least for some part of it, upon a pump, which may be situated either inside or outside the

dwelling. Such pumps are of two main kinds. The one more frequently seen is known as a reciprocating pump; but the other, the chain pump, is also used. There are three main kinds of reciprocating pumps: bucket or lift pumps, piston or force pumps, and combined bucket and plunger pumps.

The principles of the bucket or lift pump are fairly simple. A bucket works in a barrel, being raised or lowered by the movement of a handle. When the bucket is first raised a partial vacuum is created in that part of the barrel that is below it, and water rushes in through the suction pipe which is beneath the barrel, lifting the foot valve that divides the two. Then comes the down stroke caused by the upward movement of the handle, the water below the bucket being trapped by the closing of the foot valve. This, therefore, forces open a valve nearer the top of the barrel, or one in the bucket itself; and the water gets above the bucket. The bucket then rises again and carries with it the water above the upper valve, which is discharged through the mouth of the pump. Simultaneously, more water is sucked into the barrel through the lower valve. The sequence is illustrated in Fig. 1. In Fig. 2 a typical lift pump is seen, the valves being shown separately. The latter may vary in type, but the working principle is as above described.

The lift pump is useful for raising water from a well to the surface, and is recommended for suction lifts up to about 25 ft. Trouble associated with this pump is usually restricted to incorrect valve seating owing to the material used being perished or worn, or to a badly fitting plunger, also due to wear. New leathers can be had quite cheaply, so that it is not worth while to continue using defective ones. Where considerable pumping is required before water is drawn, indicative of faulty valves, the operation may be considerably quickened if a quantity of water is poured into the top of the pump before pumping is commenced.

Lift and Force Pumps. When, in addition to lifting water from a well, it is desired to force water into an elevated tank a combined lift and force pump is used. The pattern illustrated in Fig. 4 has an air chamber on the delivery side, and is provided with a draw-off cock, permitting water to be obtained at the pump if desired. A hose may be attached to the nose of the cock. The principle of the force pump is shown in Fig. 3, which illustrates what is known as a ram type, used for working against considerable pressure.

An excellent pattern of force pump is that known as a semi-rotary, illustrated in Fig. 5. The internal construction comprises a rocker or movable plate, which oscillates within a circular cast-iron casing. The water enters at the bottom, is forced to the upper side of the rocker through a simple flat valve, and then through the upper chamber into the delivery pipe, other valves serving to check the return of the water.

This type of pump is very easy to work, and will lift water from a depth of 10 or 12 ft. without the need of a holding-up valve. It will lift from greater depths if such a valve is fitted to the suction pipe, but no pump will lift more than about 27 ft. It can force water to a great height, depending largely upon the energy with which the handle is operated, and the amount of friction in the pipes.

Left. Pump. Fig. 2. Bucket or lift pump, with valves shown separately. A, plunger, showing mushroom valve in open position. B, flap valve at base of pump.

Right. Pump. Fig. 3. Mechanism of common type of force pump.

Fig. 4. Force pump with air chamber on delivery side.

Left. Fig. 5. Semi-rotary pump. Fig. 6. Diaphragm type of hand pump. (Figs. 4 & 6. courtesy of Joseph Evans & Sons, Ltd.)

Another good pump for domestic purposes, quite inexpensive, is the diaphragm pump shown in Fig. 6, which at 60 strokes per min. will deliver $4\frac{1}{2}$ gal. water per minute. With the addition of a foot valve and strainer it will lift from 25 ft. and force water to a vertical height of 50 ft. In this class of pump a flexible diaphragm of leather or rubber replaces the piston or plunger.

Chain Pumps. The chain pump (illustrated in Fig. 7) consists of an endless chain, passing over a pulley which is driven by a crankshaft mounted in suitable bearings in a framework or casing situated over the well head. The lower end of the chain should reach well below the surface of the

water, which is raised when the crank is turned. The water clings to the rising chain and is flung off into the casing by centrifugal force as the chain passes over the pulley.

The turn of the chain must be at least 2 ft. below the surface of the water in the well. The spout should deliver the water over a barrel or into a shute or pipe, whence it can flow to any desired point. The only attention necessary is an occasional cleaning of the chain and frequent lubrication of the crankshaft bearings. This type of pump is specially adapted for lifting thick fluids, such as liquid manure, sewage, etc. Normally it is arranged for a depth of 12 ft. below the spout, but can be made for any depth not exceeding 25 ft. At 45 revs. per minute a 2 in. pump will raise 650 gal. per hour with a depth below spout of 12 ft.

Fig. 7. Endless chain pump for thick liquids. (Joseph Evans & Sons. Ltd.)

Below. Pump. Fig. 8. Section of a deep well force pump.

Deep Well Pumps.

In these the working barrel is located at or near the normal water level. The suction pipe projects down into the water, and terminates in a foot valve with a strainer to exclude dirt and other foreign matter. The delivery pipe extends to the wellhead and thence to a cistern or storage tank. The pump is actuated by a well-rod made of wrought iron, or sometimes of wood, which is guided by rollers in metal brackets fixed to the well side, as in Fig. 8, or mounted on a central staging. The well-rod in the pump illustrated is worked by a wheel and crank type of pump motion.

A deep well pump of a simpler kind is shown in Fig. 9. A branch for the delivery pipe is provided 18 in. below ground level, and a draw-off cock 3 ft. above surface level.

This type is adapted for wells up to 80 ft.

deep, and for delivery to an elevated tank about 20 ft. above the well top. A smaller pump has the lever motion work attached to a plank (Fig. 10), the working barrel—not illustrated — being fixed below near water level and connected by iron rods with the motion.

Fig. 9. Deep well pump, showing standard (left) and working barrel. Fig. 10. Smaller pump with lever motion attached to a plank. (Courtesy of Joseph Evans & Sons. Ltd.)

Power Pumps. As a rule a pump for the domestic supply is not required to work continuously, and therefore a hand-operated apparatus which is employed for an hour or less per day usually suffices to fill the overhead cistern. However, we give brief particulars of a horizontal double acting power pump which can be driven by an oil engine. The Petter pump shown in Fig. 11 is coupled to a paraffin-petrol engine, one rated at $1\frac{1}{2}$ B.H.P. being used. Such an equipment will deliver about 350 gal. water per hour under a total head (including friction) of 150 ft. Suction must not exceed 25 ft. A foot valve and strainer are supplied with the pump.

Pump. Fig. 11. Self-contained power pump driven by a $1\frac{1}{2}$ B.H.P. paraffin-petrol engine. (Courtesy of Petters, Ltd.)

A miniature pumping plant is sometimes employed to operate a small fountain in the garden. An underground rain-water tank can be arranged as the source of supply, the water from the fountain falling into an ornamental pool, whence the overflow drains back to the rainwater tank. A suitable plant might

consist of a small centrifugal pump operated by means of a $\frac{1}{4}$ horse power electric motor.

Useful Data. A pump in theory should lift water from a depth of about 33 ft., but owing to various causes the average pump will not work with a vertical suction of more than 27 ft., reduced in the case of deep wells to about 20 ft.

In the case of some rotary and semi-rotary pumps the suction depth is much less. Factors governing the output of the reciprocating pump are the length of stroke and the inside diameter of the working barrel. Taking, for example, a single-acting pump with a 2 in. barrel and a 6 in. stroke, operated by hand at 30 strokes per minute, the apparatus should deliver about 120 gal. water per hour. This is the theoretical quantity from which an allowance of from 10 p.c. must be made for slip, etc. If the number of strokes per minute is increased or diminished the output will be correspondingly affected. When the source of supply is at ground level, as in the case of a spring or stream, and a fall can be arranged, it is often possible to use a ram (q.v.) to raise the water.

PUMP: For the Motor Car. Pumps of various types are used in motor cars and motor cycles to inflate the tires and to circulate the oil in the engine and the water in the cooling system. The cylinder, piston connecting rod and crank of any internal combustion engine form a pump: the piston will draw air into the cylinder via a valve on the down stroke and following this the air will be expelled on the up stroke.

Pump for motor vehicles. Fig. 1. Centrifugal pump for circulating cooling water. Fig. 2. Plunger oil pump, operated by a cam. Fig. 3. Gear-wheel oil pump. Fig. 4. Eccentric vane type of oil pump. (Courtesy of The Autocar)

This is the principle adopted in the case of most mechanical pumps such as are used in garages, but the ordinary hand-operated tire inflator carried on the car consists of a plunger on a rod working in a tubular cylinder. A third type of pump consists of one or more vanes working in a disk eccentrically disposed in a circular chamber of a

slightly larger diameter, so that as the disk and the vanes revolve in the chamber the space between the vanes is constantly increasing and decreasing.

Oil Pumps. For circulating lubricant in an engine various applications of these principles are adopted. The plunger pump comprises a cam which is rotated by the engine and depresses a plunger (returned by a spring), oil being drawn in on the up stroke through a small ball valve and delivered on the down stroke through a similar valve. In the gear pump two small gear wheels are arranged within a casing which fits them fairly closely. One gear wheel is on the end of a shaft usually driven from the camshaft by skew gears, and the other wheel meshes with it. As the engine rotates, therefore, both the gear wheels turn also. A hole in the pump casing admits oil, which fills up the spaces between the teeth on the gear wheels and is carried round by the teeth to the other side of the casing. There a pipe is provided along which it is forced at considerable pressure.

In the vane pump the shaft is eccentric to a circular casing. In a slot in the end of the shaft there slides a vane consisting of two flat pieces of metal with small springs between them. As the shaft rotates it forces the vane to turn within the casing, and accordingly the spaces between the shaft, vane, and casing alternately increase and decrease in size. A hole admits oil to the space which is increasing in size, and a pipe conducts oil from the space that is decreasing in size.

In most cars the oil pump is attached inside the crankcase, projecting downwards into the sump. The pump is then submerged in oil, and there is no chance of its failing to begin work as soon as the engine is started. When the pump is attached to the outside of the crankcase above the oil level it is usual to arrange the suction and delivery pipes so that when the engine stops the pump remains full of oil and is ready to start again. If a pump fails to work it may require priming, i.e. filling with oil. On motor cycle engines similar principles are employed, but the oil-circulating pumps are usually run at a slower speed and are smaller. They are called upon to deliver a definite supply of oil only a

little in excess of the actual amount required by the engine, as motor cycle engines—except on some of the most modern types—do not carry a supply of oil in a sump. Those motor cycle engines, however, which have been designed to carry oil in the sump employ methods resembling those used in a car engine.

Pumps for Water Circulation. Engines with water circulation on the thermo-siphon system do not require a pump, but in large and medium-sized cars a centrifugal pump is used. Cool water from the bottom of the radiator flows into the centre of the casing, and the vanes of the rotating member carry the water round with them so that the water is caused to flow through the outlet pipe on the periphery of the casing to the cylinder jackets.

PUMPKIN. The pumpkin is a fruiting plant of the *Curcubita* family, to which the gourd and the marrow also belong. It is not as largely grown in Great Britain as in N. America. Culture is the same as for marrows.

Pumpkins, like marrows, have their uses in cookery, and can be made into soups, pies, and other dishes. They may also be served as a vegetable, when they should be prepared according to the directions given for cooking marrow. For soup making, old pumpkins may be used, but for all other purposes they should be young and tender.

Pumpkin Pie. This pie is made by cooking some thin slices of pumpkin in boiling salted water, and when tender, rubbing them through a sieve. Measure out $\frac{3}{4}$ pint of the pulp, and to it add 3 well-beaten eggs, $\frac{3}{4}$ pint milk, $1\frac{1}{2}$ teaspoonfuls lemon-juice, and sugar and spice to taste.

Mix these well, then turn them into a pie-dish lined with short-crust pastry, and bake the pie for about 40 min. or until the pastry is golden-brown in colour and the filling of a firm appearance. Serve it either hot or cold, and sprinkled with castor sugar.

Pumpkin Pudding. To make this dish take a pumpkin, 2 oz. Butter, $\frac{1}{2}$ pint milk, 2 or 3 eggs. 3 oz. moist sugar, $\frac{1}{4}$ teaspoonful powdered mace and a little grated nutmeg. Peel the pumpkin, remove the seeds, and steam or boil it until it is soft. Drain the pulp well, pass it through a sieve and measure it. One pint is required for the quantities mentioned; if more or less is used they must be varied accordingly.

Beat in the butter and spices; add the sugar and the milk, which should be made hot; beat up the yolks of the eggs and stir them in. Mix these all together, put them into a greased pie-dish and bake the mixture in a moderate oven for an hour or until it is firm when touched. Whip the whites of the eggs to a stiff meringue, sweeten this to taste, flavour it with vanilla and pour it over the pudding, which should then be put back in the oven to get brown and set. It can be served either hot or cold. *See* Gourd; Marrow; Pastry.

PUNCH: The Tool. In the domestic sense a punch may be considered as any small wood or metal bar used for intervention between the hammer and the object to be smitten. The nail punch is a piece of mild steel bar, either hollow or flat at the small end, and slightly rounded at the upper end. This is applied to the head of the nail, and the upper end is struck with the hammer to drive the head of the nail below the surface of the wood, or in order to prevent the wood being bruised.

Punch. Using a nail punch to drive the nail head below the surface of the wood.

Punches of various kinds are used for the perforation of leather. The wad or saddler's punch has a hollow, tube-like cutting end, with the hollow carried upwards and increased in diameter at its mouth. A smart blow with a hammer drives the punch through the material, leaving a clean, round hole. The part cut out is driven up into the hollow portion of the punch, succeeding cuts gradually forcing the disks out at the mouth. Other small, hollow punches are used for making round holes in leather. A hand-tool can be had with several punches of various sizes, and is used like a pair of pliers. Matting punches are made of steel, and are used by wood and metal workers for working up a diaper pattern. One end is shaped to produce the pattern, the other slightly rounded off. Soft punches are used by metal workers for many purposes.

A centre punch is for making an indentation on a metal surface (e.g. when starting to drill a hole). A similarly shaped punch with a sharp point is used for piercing holes in corrugated iron. A bell centre punch has a conical shroud surrounding the point and is used for centring the ends of cylindrical rods. Spring actuated punches are made which need only a gentle pressure to operate the marking point. A spacing punch has an additional or guide point which can be set at varying distances from the marking point.

Name or letter punches are employed for punching names or monograms. Buttonhole punchers are used by dressmakers and tailors for cutting cloth. Eyelet punches are used for closing eyelets on sails and the like. Pinking punches are about 1 in. in diameter and are employed for cutting soft material with a serrated edge. Automatic, mechanically actuated punches are made for cutting cardboard and paper for filing purposes. *See* Leather Work; Nail; Repoussé Work.

PUNCH: The Liquor. Five ingredients, lemon, sugar, spices, spirits, and water, are usually employed in brewing a bowl of punch, which was originally an Indian drink.

In making punch the juice of several lemons, together with one lemon cut into slices, is put with sugar into boiling water, allowed to stand for half an hour, then strained into the bowl, and the spirits added, rum, brandy, gin, or whisky, with some grated nutmeg. The recipes vary, the quantities of each ingredient required being more or less a matter of taste; the proportion of water to spirits may be 2 to 1, or less. Rum and brandy may be mixed; sometimes milk takes the place of water, or champagne is used instead of spirits. Egg punch is made by adding 4 eggs to each pint of whisky, brandy, and rum in equal proportions.

Punch Jelly. Rum, sherry, and kirsch are used to flavour this jelly. Put the thinly peeled rind of 2 lemons into a pan with $\frac{1}{2}$ lb. loaf sugar and 1 pint water; boil the whole to a syrup, and then add $1\frac{1}{2}$ oz. leaf gelatine, the strained juice of the lemons, a wineglassful each of rum, sherry, and kirsch, and an inch stick of cinnamon. Let the gelatine melt slowly, then boil up the whole and add a crushed eggshell, together with the stiffly whisked white of an egg. Whisk the contents of the pan over a fire till they boil up, let them settle for a few minutes, and then strain them through a cloth until they are clear. Pour the jelly into a mould to set, and serve it in small glasses, with a teaspoonful of whipped, sweetened cream on top of each, decorated with half a glacé cherry and strips of angelica. *See* Milk Punch; Rum.

Punch Bowl. Very capacious punch bowls were at one time a recognized article of household equipment. To-day when one is possessed it is sometimes used on New Year's Eve and other special occasions when punch is brewed. The bowls were usually of polished oak or other wood, plain or with silver mountings. The bowls were also made of silver, and some fine pieces date from the latter part of the 17th century, when they were introduced into England. A few existing specimens are of Sheffield plate, but this metal was not much used for them. They are sometimes provided with a ladle, made of whalebone or wood, in the bowl of which a coin was inserted. The monteith,

sometimes classed as a punch bowl, differs from the latter in that it is notched at the rim so that the glasses may hang by the foot down into the bowl. The rim could be removed when the glasses were required for use.

Punch Bowls in antique silver. 1. Engraved bowl, originally used as a monteith; period of James II. 2. Queen Anne punch bowl with embossed

shield, mask handles and castellated loose rim; maker Richard Green, 1711. (Courtesy of the Goldsmiths' and Silversmiths' Co., Ltd.)

Porcelain was employed in making lighter and more delicate forms of punch bowl, and decorated vessels of this kind are still made in Japan for ornamental purposes, and form an article of export. There are some annual customs and ceremonies at which a punch bowl filled with spiced ale is passed round.

PUNCTURE: How to Mend. When a leakage occurs in a cycle or motor tire, it is well to make sure the valve is not at fault. A glass of water held up to the valve will reveal a leakage by the presence of air bubbles. If the valve passes the test, take out the inner tube, attach the valve, and pump up again. If the leak is a bad one, it will be sufficient to run the hands over the tube to detect the stream of escaping air. If the leak is a small one, the inflated tube should be immersed by 6 to 8 in. lengths in a bucket of water. Air bubbles will locate the puncture, and its position can be marked with an indelible pencil.

The patch had better be a prepared one, as sold with the puncture outfit. The surface of the tube near the puncture should be thoroughly cleaned with glass paper and a little petrol. The solution should be rubbed well into the surface of the tube on and round the place of puncture and on the patch until the two surfaces are tacky. The prepared surface of the patch is protected by linen, and should not be touched with the fingers after the linen has been removed. The patch should be held firmly on to the tube until it is dry. In dealing with a large patch care must be taken that air is not imprisoned between tube surface and the patch. This can be avoided by first pressing the middle portion into contact and then slowly working down the remainder.

Plenty of time should be given to let the patch dry thoroughly, and it should be dusted with french chalk to dry the sticky edges. If the inner tube has punctured on the rim side and not on the tread side, the wheel rim should be carefully examined while the patch is drying. The puncture may have been caused by the nipping of the tube between the edge of the cover and the rim, or by chafing on the spoke heads, which may not have been filed down properly, or the tape which protects the tube from direct contact with the heads has slipped or worn through. Perhaps the tube is not the correct size for the cover, or it has not been properly inflated. The cover may be a bad fit on the rim, or the rubber may have perished.

A common cause of punctures is nipping of the inner tube, owing to lack of care in replacing it. The deflated tube should be placed inside the cover on the wheel, the cover having one free edge. Fit the valve and pump up the tube just sufficient to make it round. The cover can then be levered on the

rim with little danger of the tube being pinched. In any case, when the cover has been finally placed on, the rim should be examined all round, to make sure, before the tube is finally blown up.

Before replacing the tube, the inside of the cover should be carefully examined to locate the nail, scrap of flint, or other object that caused the puncture. This may be hardly visible, but unless removed will cause trouble again. Any considerable gash in the cover should be sealed up with one of the patent compounds sold for the purpose. *See Motor Car; Motor Cycle; Tire; Valve.*

Purgative. *See* Aperient; Cathartic.

PURLIN: Of a Roof. The purlin is the horizontal member of the roof that supports the common rafters between the ridge and the wall plate. The purlin is supported by the principal rafters, which are the top members of the truss of the roof; the ends are supported by the walls at the end of the building, or, in the case of a hipped roof, they are framed to the hip timbers. *See House; Loft; Roof.*

Purlin. Showing the situation of this piece of roofing timber.

PURPLE CONE FLOWER. This is the popular name of a hardy herbaceous perennial, *Echinacea purpurea*, which grows 2-3- ft. high and bears large reddish-purple flowers with a raised cone-like centre. The newer varieties should be grown in preference to the old one ; two of the best are Taplow Crimson and The King, which have reddish flowers. Propagation is by division in autumn.

PURSE. Leather is the material principally employed in purse-making, pigskin in particular being favoured for men's purses, because of its hard-wearing qualities. Suède purses, though attractive in appearance, are less durable. Venetian leather purses, ornamented with medieval designs in colours, are sometimes carried by women inside large purse bags. Velvet, silk, and satin, elaborately beaded and embroidered, are also favourite materials for small purses to be used with various evening dresses.

To make a brocade purse, as illustrated, cut out a circle of brocade 7 in. in diameter, and a circle of silk or other lining of the same size. Sew the two together neatly around the edge with a running stitch, then gather them up and attach them to a bone or ivory purse-top. Trim the inside, where the material meets the frame, with a little rose-trimming or ribbon ruching. Bone, metal, and tortoiseshell purse-tops can be bought at drapery stores. *See Bag; Beads; Leather.*

Purse. Brocade purse, the silk being gathered to an ivory top.

PURSLANE. Purslane is an annual plant (*Portulaca oleracea*) grown for the value of its leaves as a summer salad. Seed must be sown early in April, the seedlings being thinned to 6 in. apart. As soon as the shoots are about 3 in. in length they should be cut off close to the ground. If desired, a succession may be had until the late autumn. *See Calandrinia.*

PUSH-PULL: In Wireless. A system in which two valves are used in an amplifying stage of a receiver or transmitter instead of one. The input is divided by means of a special transformer: one valve receives the positive, the other the negative half-cycle. While one is “pushing” the other is “pulling.” The disadvantage of push-pull amplification, especially of battery-driven receivers, is that the high-tension current for that stage will be doubled. By means of a development of the principle known as quiescent push-pull, this drawback can be overcome. In this system each of the two valves concerned is given a considerable negative grid bias so that it remains “quiescent” with very little anode current flowing during that half-cycle when the other valve is actively amplifying.

Class B Amplification. The “Q.P.P.” development is carried a step farther by the “Class B” valve which is, in effect, two valves in one.

For this method no grid bias is required as only a small anode current passes when the grid is at zero potential. Therefore, it will always give a maximum efficiency for any given H.T. without any adjustment.

PUSS MOTH. The larva of this moth is one of the most peculiar found in the garden, the caterpillar bearing a curious resemblance to a kitten, whilst the parent moth is covered with soft down.

The caterpillars hatch out from eggs deposited on the leaves of such trees as poplars and willows, feeding upon them and gnawing the shoots. In due course they form a cocoon, under cover of which the chrysalis stage is reached, from which they emerge as moths during June. The caterpillars should be picked off by hand and destroyed, or the trees sprayed with Paris green wash.

Puss Moth.

PUTLOG. On a builder's scaffold putlogs carry the boards that form the floor. They are placed at right angles to the wall that is being built, with one end resting on the ledger of the scaffold; the other end is let into a hole specially left in the wall to receive them.

Putlogs are about 5 ft. long and 3 in. square. They are made usually of birch, and they are split and not cut, in order to obviate injuring the fibres of the wood, thus affording greater strength. The putlogs are as a rule placed about 4 ft. apart along the ledger. *See Scaffolding.*

PUTTEES. Worn at times by men round the legs, puttees consist of long, narrow bands of material usually cut from woollen cloth, but they may be specially woven fabric bands. They are warmer and more comfortable than leggings, and in addition they have the advantage of giving substantial support to the legs, thus acting as a preventive of varicose veins. Being spirally wound from the ankle to just below the knee, the leg is protected by at least a double, and mostly by a treble, thickness of the material, so that there is little danger of scratches and other injuries being suffered by the wearer. They are, therefore, very suitable for farmers and others engaged on the land, and for those who go out shooting and walking. They are usually made in khaki colour, but navy blue ones

are occasionally seen. Great care and some skill are necessary in winding them round the leg, as, if badly wound, they will look untidy.

To obtain a smart effect puttees should be firmly and closely wound, but this must not interfere with the circulation. The method is that of ordinary bandaging, a reverse being made in the puttee whenever necessary so that it may be flat to the shape of the leg. The usual procedure is to begin at the inside of the ankle and wind upward, but the artillery method is to start below the kneecap and wind downward to the ankle.

PUTTING: On the Lawn. Putting can be practised on a lawn too small for croquet or lawn tennis. Apart from the land, the only requirements are a few balls and two or three putters.

Putting resolves itself into the playing of two kinds of putts, a long approach putt and a short putt, which drops the ball into the tin with a definite click. The approach putt involves, two ideas: first, the imagination of the line to the hole, and the ability to hit the ball along the imagined line; and, secondly, judgement or instinct, born of habit, of the strength necessary to make the ball travel firmly to a spot close to the hole. The ball lies, say, 10 yd. or so away; a putter is taken, and the line of the putt inspected. It is well not to move either head or body until the putter is still and the stroke is quite finished.

The short putt is of a different character, and is apparently a simple business which requires little more than confidence. Many players see the ball and the hole, and, holding themselves quite steady, tap the ball firmly yet smartly towards the back of the hole, and are successful.

Making a Green. A golfer can obtain putting practice and also a good deal of quiet recreation on an ordinary lawn. One way of doing this is to make the lawn into a miniature golf course, say, one of nine holes, although any other number can be substituted. Suitable holes can be made in the ground and a small flower-pot put in each, or, if preferred, a metal cup can be bought for the purpose.

Putting Green. Diagram showing how to lay out a lawn as a miniature golf course of nine holes.

The holes should be disposed so as to give the greatest possible variety in the length and direction of the strokes. One will be made as long as the ground will allow, and the others arranged to give putts, each shorter than the other. The diagram offers a suggestion as to the laying out of the ground. A simpler way of obtaining practice is to make a single hole in the lawn and to aim at this from various distances. See Clock Golf; Golf, Midget.

PUTTY. As generally used in the household, putty is the material known as glazier's putty, and is composed of whiting and linseed oil. The word is used in plastering to describe the fine stuff consisting of lime and water; it is also the name of a powder used in polishing glass and steel. Small quantities of glazier's putty can be obtained from any oil shop or from an ironmonger; but if a quantity is required, it is more economical to purchase a 7 lb. keg; when not in use, the lid should

be kept on tightly. It is sometimes advocated that the top be covered with a small quantity of linseed oil to prevent the putty hardening.

Should putty when purchased be very soft and sticky, a very small quantity of whiting may be added, by taking a lump of the putty in the left hand, sprinkling it with powdered whiting from the right hand, then rolling and kneading the putty. This process should be continued until the putty is an even paste, perfectly free from lumps.

When putty is too dry, the same operation is performed with linseed oil, which softens the material. Should it be short, or tend to crumble, it is an indication that it requires linseed oil, and the process can be hastened by slightly warming the putty. In some cases the putty may be prepared by placing a quantity on a clean board and beating it with heavy pieces of wood, one in each hand, much as if beating up butter. Usually, however, the best method is to knead the putty between the hands, as by this means its consistency can be judged. When exposed to the air, putty gradually gets hard, until finally it becomes almost as hard as soft stone.

Putty. Applying putty in glazing a window frame.

A putty knife is a thin, broad bladed knife with a wood handle, the blade somewhat pointed at the end and more or less pear shaped. It is an indispensable tool for applying putty, stopping up small holes in woodwork prior to painting, and for other purposes. *See Enamel; Glass; Lime.*

PUZZLE JUG. This name is given to a type of jug which has some unusual and unexpected feature. For instance, some have a series of hollow tubes running round the rim of the jug and through the handle. The tubes contain the liquid, and the spouts, which project from the rim, are so arranged that the drinker will be drenched unless he knows exactly which of the spouts to cover with his fingers and thumb.

Puzzle Jug. Quaintly fashioned jug in Wrotham slip ware. (British Museum)

These jugs have always a suggestion of rough humour about them, and many were made for the use of ale houses. To-day they are sought by collectors. A few puzzle jugs were made in England in the 16th century. Later they were made in large numbers, especially by the Staffordshire potters, but also at Leeds, Liverpool and Bristol. Some were imported from Holland. They are often found with humorous inscriptions upon them.

Pyæmia. *See* Blood Poisoning.

PYORRHOEA. Pyorrhoea is a disease commencing at the margin of the gum where this encircles the neck of the tooth. In the early stages it may be recognized by a redness of the gum margin, and a

tendency to bleed when rubbed, e.g. with a toothbrush. It is caused by stagnation of secretions, which harbour multitudes of microbes.

The natural method of preventing the disease is to eat or masticate the foods which necessitate or stimulate mastication, and which rub, cleanse, and promote movement in the secretions surrounding the necks of the teeth. The foods which do this most effectually are generally of a somewhat fibrous nature, such as meat, fish, and particularly uncooked vegetables. The mastication of fresh fruit also is very suitable for preventing the stagnation of matter around the necks of the teeth, and the type of fruit which is most useful is such as is of a firm consistency, and somewhat acid or tart, such as apples.

Artificial methods follow the same principles. A toothbrush is generally used to supply the friction necessary to keep the necks of the teeth clean, and should be used with an up and down motion, rather than across the teeth. As the toothbrush cannot be forced between the teeth very far without injury to the gum, a mouth wash of a slightly acid nature should be used to rinse the mouth, and this should be done fairly vigorously. A pinch of cream of tartar to about a wineglassful of water may be used. The importance of preventive measures may further be emphasized by recognizing that as age advances the predisposition to the disease increases. *See Teeth.*

PYRACANTHA. This is a favourite evergreen shrub which bears white hawthorn-like flowers in spring and red or yellow fruits in autumn. It will thrive in the open, but is more commonly planted against house walls, where it forms a decorative covering in spring and autumn, and is pleasant to look upon all the year round; the common kind is *Pyracantha coccinea* (the fire-thorn), which bears red fruits; the variety *Lalandii* has orange-red fruits, while those of *angustifolia* and *rogersiana* are orange yellow.

Pruning, which should be done in winter or early spring, takes the form of thinning crowded or weakly branches, or if the shrub is on a wall of keeping it within bounds. Propagation is by sowing seeds out of doors as soon as they are ripe.

PYRAMIDS: The Game. The game called pyramids is played on a billiard table with 15 coloured balls, usually red, and the white ball which is used as the striking ball. The coloured balls are arranged in the form of an equilateral triangle, and the object of the players is to strike one of them with the white ball in such a manner as to pocket a coloured ball, points being scored accordingly. The balls used in pyramids are slightly smaller than ordinary billiard balls.

Pyramids is usually played by two persons, but it can be played by four, or by any other convenient number forming sides. It is a game of winning hazards exclusively, cannons being ignored.

When the 15 red balls are placed on the table, practically everything, between players of approximately equal skill, who strike a good winning hazard, depends on getting an opening for a break. Safety play is so greatly the deciding factor that first-class players often make stroke after stroke without the least intention of pocketing a ball. But when at last the desired opportunity does present itself, 4 or 5 balls are almost sure to vanish, and it is by no mean unusual to see a break of 8 balls made, which ends the game at once.

Shell-Out. It is different when playing shell-out, a game often confused with pyramids, because it is played with the same number of balls and points are scored in the same way. But there is the important difference that shell-out is a round game for a number of players, whereas pyramids is a game between two players. When playing shell-out, a man draws a stake from each of the other players for every red ball he can pocket, and it is consequently the game to concentrate on every possible chance of taking a ball. The trouble is that while safety may close the game up for the next player, it is long odds against a bout of safety lasting until a man has another chance at the balls, a

circumstance which makes safety the exception rather than the rule when playing shell-out. *See* Billiards.

PYRETHRUM. The most valuable plants in this group are the florist's varieties of *Pyrethrum roseum*, which grow from 18 to 24 in. high and bear single and double longstemmed flowers in rose, crimson, blush and other colours in May and June. They are hardy herbaceous perennials which thrive best in well-drained soil. The way to propagate the plants is by lifting and dividing the clumps as soon as they have finished flowering. Seeds may also be sown under glass in spring, the seedlings being grown on a reserve border in summer and planted finally in autumn. There are numerous named varieties. The noon daisy (*pyrethrum* or *chrysanthemum*) *uliginosum* grows 5 ft. high and bears large white daisy-like flowers in late summer. It flourishes in ordinary soil, even on a shady border, and is increased by division in autumn. *Pyrethrum aureum* is the well known golden feather sometimes used as an edging to flower beds; it is raised from seeds sown in a heated glasshouse in spring. *See* Border; Carpet Bedding.

Pyrethrum, the variety H. Robinson.

PYRIDINE. It is believed that the benefits derived in asthma from burning various fumigatory powders are due to pyridine. For use in asthma pour a dram on a plate and allow it to evaporate in a small room in which the patient remains for half an hour.

Pyridine is used with soap as an insecticide. Leaflet No. 106 of the Ministry of Agriculture gives the following formula for the treatment of apple aphid:

Pyridine (i.e. tar-distillate)	4 oz.
Soap (soft)	$\frac{1}{2}$ lb.
Water (soft)	10 gal. <i>See</i> Asthma; Insecticide; Nicotine.

PYRO or PYROGALLOL. Often, but wrongly, known as pyrogallic acid, pyro, as it is known to photographers, is more widely used than any other developer. Mixed with an alkaline substance or another developing agent, it produces negatives of fine quality, showing the characteristic yellow stain of pyro, which, however, often improves the printing value, especially of thin negatives.

Dissolved in water, pyro quickly oxidizes the solution, turning dark brown and losing activity as a developer accordingly. It is best kept in strong solutions containing an acidifying agent, potassium or sodium metabisulphite being added, when it will keep for several months. Pyro is sold in two forms, compact crystals and light feathery crystals, easily soluble in water. It is very poisonous, and must be kept in well-corked bottles.

Pyro is never used alone, but combined with an alkali, sodium carbonate or caustic soda, or another developing agent. In making up any formula the quantity of pyro in grains per ounce of developer mixed ready for use gives a useful indication of the strength of the developer. When weak, pyro brings out the first details in a negative quickly, but requires a comparatively long time to build up proper density; when strong, the image appears slowly, but density is rapidly gained, so that development is complete soon after the image appears.

Following are formulae for standard pyro combinations:

	Pyro-Ammonia
A. Pyro	1 oz.
Potassium metabisulphite	1 „

Water	to	9	„
B. Potassium bromide		1	„
Distilled water	to	9	„
C. Ammonia (·880)		1	„
Distilled water	to	9	„

For normal use take 10 minims A, 10 minims B, 5 minims C, and 1 oz. Water.

Pyro-Caustic Soda

A. Pyro	110	gr.
Sodium sulphite, 1 oz. (or 1¾ oz.)	300	„
Water to	10	oz.
B. Caustic soda	35	gr.
Water to	10	oz.

For use take 1 oz. of A and B and 1 oz. of water. This is a quick acting and very economical developer.

Pyro-Metol

A. Pyro		40	gr.
Metol		35	„
Potassium metabisulphite		90	„
Potassium bromide		10	„
Water	to	10	oz.
B. Sodium carbonate, crystals		1½	„
Water	to	10	„

For normal exposures take equal parts of A and B. This will contain 2 gr. of pyro to the oz. of developer. For under-exposures take 1 part of A, 1½-2 parts of B, and add 2 parts of water. This developer combines the characteristics of strong pyro and metol, and gives both detail and density quickly, the negatives being slightly greenish black. It is a good and reliable developer for the snapshot photographer.

The Watkins' development factor for pyro varies with the number of grains per oz. For the pyro-metol formula given above it is 9. *See* Developing; Photography; Pyro-Soda.

PYRO-SODA. The most commonly employed of pyro developers, and perhaps the most economical of all photographic developers, is pyro-soda.

When used without potassium bromide restrainer, which is quite unnecessary, it gives brownish or greenish black negatives of very good printing value, without the risk of fogging.

Pyro-soda is so called because the alkali which it contains is carbonate of soda, though ordinary washing soda is liable to contain impurities, and the photographic quality should be obtained. There are many pyro-soda formulae differing principally in the proportions of the preservative and alkali, but that which follows will meet the amateur's requirements. The developer is always made up as two stock solutions, which are mixed and diluted when required for use. One contains the pyro with preservative, and the second the alkali. First make up the following:

TEN PER CENT PYRO STOCK SOLUTION

Pyro	1 oz.
------	-------

Potassium metabisulphite 20 gr.
 Water to 9 oz. 1 dr.

A half-pint stoppered bottle is required. The water is boiled briskly to get rid of dissolved air, which would cause oxidization of the pyro, and allowed to stand until cool without being disturbed. Crush the metabisulphite, the preservative, and dissolve it in the water. Pour it carefully into the $\frac{1}{2}$ pint bottle, add the pyro, and leave it to dissolve, the bottle being kept stoppered. Do not shake the bottle, or oxygen will be reabsorbed. This solution will contain almost exactly 10 per cent by weight of solid pyro. That is, every 10 minims of solution will contain 1 gr. of pyro. Made up exactly as described, it should keep for two years or more.

NO. 2 ALKALI STOCK SOLUTION

Sodium carbonate 8 oz.
 Sodium sulphite 8 „
 Water to 40 „

The carbonate and sulphite are dissolved in about 1 pint of hot water, which has boiled for some time, and the total made up to 40 oz. Keep it in a large corked bottle; a glass stopper is liable to stick on account of crystallization in the neck. It should keep for about a year. For use make up in the following proportions:

PYRO-SODA DEVELOPER

10 p.c. stock pyro solution, 20 minims (or drops)
 No. 2 solution $\frac{1}{2}$ oz.
 Water to 1 „

This developer will then contain 2 gr. of pyro per fluid oz., and will be suitable for practically any plate or film. For tank development 20 minims of the 10 per cent solution and 1 oz. of No. 2 may be used for each 4 oz. of developer, then containing $\frac{1}{2}$ gr. of pyro per oz. When pyro is used for tank development it is essential to pour off the whole developer from the tank and return it once or twice to avoid uneven development. Merely shaking or tilting the tank is not sufficient. The Watkins' development factor for pyrosoda varies according to the number of grains per oz. When potassium bromide is not included, the factors are as follows:

1 gr. per oz.	18
2 „	12
3 „	10
4 „	8
5 „	$6\frac{1}{2}$

When required pyro stain can be removed from a negative by a clearing bath containing the following, alum, $\frac{1}{2}$ oz.; hydrochloric acid, 1 dr.; water, 10 oz. *See Developing.*

PYRUS JAPONICA. A hardy leaf-losing red apple-blossom-like flowers in spring is familiarly known as japonica. It is an excellent shrub for a sunny house wall where it blooms earlier than in the open where, however, it may be planted.

Pyrus Japonica. Flower spray of this decorative shrub. (Courtesy of Amateur Gardening)

The way to induce it to blossom freely is to prune the side shoots in summer and again in winter. There are several named varieties. In a warm summer *Pyrus* (*Cydonia*) *japonica* bears quince-like fruits which do not ripen, but may be used to make an excellent jelly. In recent years a new race of Japanese quinces, called *Cydonia Maulei*, has become popular; there are many varieties with flowers in salmon, red and bluish.

QUADRILLE: The Dance. In quadrilles the set is composed of 4 couples, who form a square, each couple facing the centre, the men standing on the left of their partners. In the first figure, the leading couple and their vis-à-vis start by crossing over and returning. In each case 7 walking steps are used and the left foot is brought up behind for the eighth.

This movement is called half right and left, because each dancer passes on the right-hand side of the first person met in crossing and the left-hand side of his own partner. They cross and return to the first 8 bars; setting to partners in the next 8 bars. This is passing on the right-hand-side, using 3 steps forward and the left foot brought behind and 3 steps back, bringing the right foot up to the left to finish, giving the right hand to partner and returning.

Then comes the ladies' chain, in which the women cross giving the right hand to each other and the left hand to the opposite men and the same back to place, while the men move round behind their partners giving the opposite woman the left hand and repeating the same movement to meet their own partners when they promenade holding hands, over to the place of their vis-à-vis, then return and perform half right and left to finish. There are 16 bars of music. The side couples now repeat this figure.

In the second figure, the woman of the leading couple, and the man of the vis-à-vis, advance and retire, using 3 steps and the foot brought behind, and then move to right and left, cross to each other's place, advance and retire. This is danced in 16 bars. Then all return to place, set to partners, and turn in 8 bars. This movement is repeated by the other couple, each woman dancing with the partner of the opposite woman.

The woman of the leading couple and the opposite man change places in the third figure, giving the right hand, and return, giving the left to each other and then the right to their partners, so that the 4 dancers form a chain. They take a step forward together and one back, do this twice, then cross over to the opposite couples' place. The two people who started the figure advance and retire twice, giving the nearest hand to their respective partners. All 4 advance and retire and then left and right to places. This is danced in 32 bars. The figure is repeated in the same order as the preceding one.

In the fourth figure, also 32 bars, the leading couple advance and retire, again advance and the woman remains on the left of the man of the opposite couple while her partner returns to place.

The 3 advance from the other side and retire, then cross over, give hands round, cross to their original places and half right and left to finish. The side couples then repeat the figure.

The fifth figure starts with all 4 couples joining hands, advancing and retiring twice. Then the top and bottom couples promenade to each other's places and turn. These two movements are performed in 16 bars. Then the ladies' chain follows for 8 bars and final promenade to places and turn for another 8. This figure is repeated, being started by each of the four couples in turn and sometimes again by each of the couples.

Another form of this dance is known as the Caledonian quadrille. In this the set is composed in exactly the same way as in the ordinary quadrille and there are 5 figures. The chief difference between the two is that reel time is used throughout the Caledonian quadrille. The first figure is danced in the same way as in the quadrille, but there are slight differences as regards the others. The finale of the dance is a promenade all round. *See* Lancers; Reel.

QUAIGH. The Highland drinking cup known as a quaigh or quaich was rarely seen south of the Grampians until towards the close of the 17th century. It is in the form of a shallow bowl of oak or other wood, with two small ears or handles, and usually without ornamentation, being one of the simplest of drinking vessels and probably of very ancient origin. It was also made in pewter and horn, and some were of silver, but the earlier quaighs were all carved from blocks of wood and made with staves and hoops.

Quaigh. Shallow Highland drinking cup in wood, with two handles.

In the 18th century the quaigh found its way to the lowland houses, and was embellished with silver mountings. Other uses were found for it, and quaighs were utilized as alms dishes and served in some Scottish churches as communion cups.

Quail. These birds may be cooked in the same ways as pigeons. *See Pigeon.*

QUAKING GRASS. This is an ornamental flowering grass about a foot in height. It is quite hardy and is easily raised from seed sown in the spring in ordinary garden soil. It may be cut and dried for the purpose of indoor decoration. The commonest is *briza maxima*; others are *media* and *minor*. *See Grass.*

QUAMASH. This is a hardy bulb belonging to the lily family. It grows from 12 to 24 in. high and bear spikes of white or blue flowers in May and June. They thrive in ordinary well tilled soil and should be planted in autumn about 5 in. deep.

The botanical name of quamash is *Camassia*. The chief species are *esculenta*, blue and its white variety *Leitchlinii*, *Cusickii*, pale blue and *Fraseri*, pale blue.

Propagation is by offsets taken off in autumn or in early spring or by seeds sown as soon as ripe in boxes of soil in a frame.

Quamash. Bulb of the lily family with blue or white flowers.

QUARANTINE. The period during which a ship on which an infectious disease has occurred is kept out of port, or, at any rate, from free personal communication with the shore, is called the quarantine period. The word quarantine has, however, also come to mean the period of isolation of persons suffering or convalescing from an infectious disease, and of others who have been in contact with such persons, wherever they may be.

The question of quarantine, in the general experience, mostly arises in connexion with the attendance of children at school. In the table herewith the dates at which a convalescent or contact may return to school are duly set out, but children who have actually been ill will probably require a little holiday before going back to school.

The date from which the quarantine of contacts is to be calculated is that of the last exposure to infection. When a child has been suffering from or exposed to infection of a notifiable disease, he

must not return to school without a certificate from the medical officer of health. *See* Infectious Disease.

Quarantine for Dogs. No dog can be landed in Great Britain without a licence, which must be obtained from the Ministry of Agriculture, 4, Whitehall Place, London, S.W. When landed, the dog must go into quarantine, that is, it must be detained and isolated for a period of six months from the date of landing on the premises of a veterinary surgeon.

The following premises, which can accommodate large numbers of dogs, have been approved by the Ministry for the reception of all classes of imported dogs:

T. J. Brain, M.R.C.V.S., 5, St. George's Terrace, Cheltenham.
 A. S. Brooksbanks, M.R.C.V.S., 132, Wilmslow Road, Withington, Manchester.
 Major A. A. Comerford, M.R.C.V.S., The Limes, Potton, Bedfordshire.
 Hugh Ferrier, M.R.C.V.S., Claver House, Dundee, Scotland.
 F. C. Gillard, M.R.C.V.S., Leas End, Sandgate Hill, Folkestone, Kent.
 F. C. Golden, M.R.C.V.S., Woodlands Farm, Lyminge, Kent.
 R. C. G. Hancock, M.R.C.V.S., Greenacre, Beaconsfield, Bucks.
 G. P. Male, M.R.C.V.S., Westcroft, Earley, Reading, Berks.
 C. Masson, M.R.C.V.S., 61, Abbey Road, Torquay, S. Devon.
 W. S. McMurrich, M.R.C.V.S., 32, Sinclair Street, Helensburgh, Dumbarton.
 A. E. Payne, F.R.C.V.S., Hanger Hill, Weybridge.
 K. F. Quin, M.R.C.V.S., 131, Lancaster Road, N. Kensington, W.11.
 R. Scott, M.R.C.V.S., 13, Oliver Crescent, Hawick, Roxburgh.
 H. G. Tabuteau-Herrick, M.R.C.V.S., Fleet Hospital for Dogs, Fleet, Hants.
 J. Stow Young, M.R.C.V.S., The Croft, Holmwood Gardens, Wallington, Surrey.
 F. W. Chamberlain, M.R.C.V.S., Cheam Village, Sutton, Surrey.
 Major J. Facer, M.R.C.V.S., 20, Archers Road, Southampton.
 Mr. Ingram, M.R.C.V.S., Cotswold, New Oxted, Surrey.
 M. G. Byerley, M.R.C.V.S., 56, South Street, Greenwich, S.E.10.

In case of difficulty—kennels are often already full—ring up the Ministry of Agriculture, Whitehall 3400, ext. 192.

The owner or importer of the dog at the time of importation must provide the manager of the quarantine station at which the dog is detained with a permanent address at which any necessary communications will at all times reach him.

Severe penalties are inflicted upon persons who bring dogs into the country, by aeroplane or otherwise, in order to avoid sending them to a quarantine station. *See* Dog.

Disease	Quarantine Period (Period of Exclusion from School)	
	Patient	Contacts
Cerebro-spinal meningitis.	Three months at least from onset of disease.	Three weeks.
Chicken-pox.	Until all scabs have gone; usually three weeks.	For those who have not had the disease, three weeks.
Diphtheria.	Depends on bacteriological tests.	As for patient.
Encephalitis lethargica.	Until recovery (at least six weeks).	Three weeks.

Erysipelas.	Until rash and peeling gone.	May attend if doctor certifies.
German measles.	Not less than a week from appearance of rash.	For those who have not had the disease, three weeks.
Influenza.	Until recovery.	May attend usually.
Measles.	Until morbid discharges have ceased (three weeks at least).	For those who have not had the disease, three weeks from onset of last case in the house.
Mumps.	A week after the subsidence of swelling (at least three weeks).	Three weeks.
Poliomyelitis.	Until pronounced free by a doctor.	Three weeks.
Scarlet Fever.	Two weeks after release from isolation or from hospital.	Ten days; seven days after patient is released from isolation allowed by some authorities.
Smallpox.	Until free from scabs (at least six weeks).	If not recently vaccinated, sixteen days.
Typhoid Fever.	Depends on bacteriological tests.	May attend.
Whooping Cough.	Until six weeks from commencement of whoop.	For infants only, three Weeks from last exposure.
Impetigo }	Until cured.	If free on inspection, may attend.
Ringworm }		
Scabies }		

Quarantine. Table showing quarantine periods for various infectious diseases.

QUARRY. This name is given to a square or lozenge-shaped piece of glass sometimes set in leaded lights. Quarries are painted with figures or patterns and inserted in otherwise plain lights. They are also seen as plain squares set diagonally in 15th-century church windows to divide panels or roundels painted with pictorial subjects. *See Stained Glass.*

Quart. This measure is used for milk, beer, and other liquids. It consists of two pints; and four quarts make a gallon.

QUARTER: The Measure. This measure or weight is the fourth part or quarter of a hundredweight, containing therefore 28 lb or 2 stone. As a measure of capacity, used for grain, etc., the quarter contains 8 bushels. From it has sprung the words quart and quartern, used in measuring food and drink. *See Avoirdupois Weight.*

QUARTER: Of Meat. This word is used for the parts of a beast when it is cut up for human food, the idea being that it is quartered or divided into four. The parts are known from their position on the animal as the forequarters and the hindquarters. *See Beef; Carving; Joint; Lamb; Mutton.*

QUARTER DAY. Quarter days are days on which are due the rents of houses taken by the quarter and certain other payments. In England, Wales, and Ireland they are March 25 (Lady Day), June 24 (Midsummer Day), September 29 (Michaelmas Day), and December 25 (Christmas Day). In Scotland they are Feb. 2, May 15, Aug. 1, and Nov. 11. *See* Rent.

QUARTERING: In Woodwork. Quartering as a form of decoration in woodwork consists of the division of a surface into 4 parts, the grain of each portion running in a direction contrary to that next to it. Its most general use is in furniture, as a decoration for panels, table tops and other flat surfaces. *See* Graining; Oak; Veneer.

Quartering: Of Timber. This term applied to timber means timber having scantlings from 2 in. square up to 6 in. square.

QUARTERN LOAF. A loaf of bread weighing 4 lb., which is known as a quatern loaf, is not a fancy bread, but a household quality, and must be sold by weight. In making a batch of bread the dough for each loaf should be weighed off before baking, or it will be impossible to obtain equal-sized loaves. *See* Bread.

QUASSIA. The wood of the quassia tree in the form of chips is used both as a tonic in medicine and in gardening to destroy insects. The chief medical preparations are infusion of quassia, dose $\frac{1}{2}$ to 1 fluid oz., concentrated solution of quassia, and tincture of quassia, $\frac{1}{2}$ to 1 fluid dram. Quassia is frequently combined with iron in bitter tonics prescribed for anaemia and debility. The infusion is often made at home by letting the chips stand overnight in cold water, or by leaving water in a bowl made of quassia wood. The action of quassia is mainly in the mouth, where it stimulates the gustatory nerves; the gastric vessels are reflexly stimulated, with the result that the gastric juice pours out. This secretion is temporarily diminished when the bitter saliva itself passes into the stomach. It is sometimes employed to kill threadworms, $\frac{1}{4}$ to $\frac{1}{2}$ pint of it being injected into the rectum.

Garden Uses. In the garden quassia is useful for clearing gooseberry or currant bushes of caterpillars in spring. The chips are boiled in the proportion of 1 oz. to a quart of water; a similar quantity of soft soap is added, and the bushes are sprayed with the mixture thus obtained. *See* Insecticide; Spraying.

QUARTREFOIL. The quartrefoil is a conventional treatment of a flower form with four lobes which is employed in stone and wood carving, and is a common feature of Gothic ornament. Like the trefoil and the cinquefoil, it is based on a geometrical construction. *See* Stone; Woodcarving.

QUEEN ANNE STYLE : DECORATION & FURNITURE

The Graceful Elegance of the Walnut Period

Pieces of furniture made in this style are referred to in a number of articles in our work. The reader may therefore consult such entries as Chair; Drawing Room; Screen Settee; Tapestry.

See also Furniture; Lacquer; Marquetry; Mirror; Silver; and the articles on the immediately preceding and subsequent period styles, William and Mary; Georgian.

In England the end of the 17th and beginning of the 18th century were marked by a period of great beauty in furnishing and interior decoration. At the end of the reign of Charles II walnut had

superseded oak for finer pieces; by the time of Queen Anne the age of oak had practically finished except for strictly useful and farmhouse furniture. In the main her period was distinguished from those of the Restoration and of William and Mary by greater comfort and less stateliness, by elegance and grace rather than opulence of ornament and the grandeur which made the best furniture of the preceding periods only suitable for the homes of the magnificent.

Queen Anne furniture is also simpler than that of the Georgian styles, including Chippendale, which followed. It is this simplicity of line combined with exquisite beauty of workmanship, the lovely use of colour in lacquer and needlework, ornamental china and mirrors, imported Oriental carpets and rugs, which made her period style at once compact and homely and yet richly varied. It was open to Eastern artistic influence and the comforts which commercial overseas trade were making more generally possible.

The architecture also underwent a change, largely brought about as the result of fresh ideas from Holland during the previous reign moulded and reproduced by such distinguished men as Sir Christopher Wren and Sir John Vanbrugh. The last named was responsible for the most famous house of the period, Blenheim Palace. Dutch architects also did much work in the royal palaces and had a great influence on Queen Anne style in building, as also had the carvings of Grinling Gibbons on the interior decoration.

The smaller houses were of brick, and built for the most part on rectangular plans. The shaping of the gables with scrolled outlines was one of the most characteristic Dutch features. The window frames were flush with the walls and had thick sash bars. The windows had comparatively small panes. The front door was often surmounted by a bold hood or pediment, and flanked by fluted columns, while black and white marble was used for the curved steps.

Interior Decoration. As the principal rooms of the house became co-ordinated in design, the upper and lower parts of the chimney piece were designed to harmonize as a whole instead of as separate features. Internal doorways were made decorative by the introduction of boldly moulded architraves and pediments. Carving was employed in the decoration of mouldings on the panels, but was on the whole sparingly used and with good effect.

Queen Anne Style. Fig. 1. Drawing room or parlour decorated in typical Queen Anne style, with large panels surrounded by broad raised moulding enriched by carving. The chimney piece has a panelled picture and pilasters, and the carpet is Oriental. (Courtesy of White Allom & Co.)

A beautiful drawing room or parlour of this period style is illustrated in Fig. 1. The panels are 3 ft. wide and reach from dado to cornice. The dado shows a projecting moulding running all round the room, while the panel mouldings

are enriched with carving and pediments, the detail of which forms part of a co-ordinated scheme enhancing also the fireplace and the door (not seen in illustration). Over the fireplace is a picture let into a panel arranged for its reception. Swags of carved fruit and foliage surmount it, pilasters are employed at either side.

Bolection moulding is characteristic of this style. Up to this time it had been usual for the panels of a room to be recessed below the level of the stiles and muntins which surround them, the

intervening moulding being practically an elaboration or agreeable modification of the square section of the edge of the board. But the bolection moulding became a feature in itself and projected in front of both panel and stile.

Walnut was employed in some cases for panelling, but less expensive was the pine panelling, which was usually painted cream or light green. Occasionally it was lacquered and painted in Chinese or Indian style with coloured decorations and raised and gilded portions on the panel designs.

Wallpapers were imported from China and a few were manufactured in England with hand-blocked and part stencilled designs showing Oriental influence, but these were rare, and the most general form of interior decoration was painted panelling.

The plaster ceiling of a Queen Anne room was usually panelled out in a large way in conformity with the walls. The mouldings would be prominent, and the decorative enrichment, although bold, would be confined to suitable positions and not scattered indiscriminately. The floor would be of oak boards or parquet. The fire basket grate for burning coal was speedily ousting the open hearth for logs.

Typical Furniture. Domestic furniture of the Queen Anne period was chiefly of walnut, although beautiful pieces are existent made of other fruit woods such as pear, plum and apple, and much fine work was lacquered, especially cabinets and chairs. Oak, chestnut, cedar, and other woods were used for constructional or foundation work, and walnut for the outer parts of the pieces. The bulk of this walnut furniture was veneered, probably as much upon deal as upon oak, although naturally the existing pieces are mainly the oak ones. For veneering, burr walnut, acacia, olive-wood, and laburnum were employed, and finely grained walnut logs were set aside for oyster grain veneer.

The most beautiful Queen Anne walnut furniture does not rely on ornament, but on perfection of grain, line, and proportion. The varnish used cannot be imitated by the acid bleaching preparations employed to simulate the effect of period walnut.

Inlaying and marquetry were as much used in Queen Anne's time as they were in that of William and Mary, and this is a feature of many pieces in those styles. Cross-banding, feather-edging, and herringboning were used upon bureaux, chests, and grandfather clocks. A characteristic feature of the marquetry of the time was its enclosure in panels outlined by parts of circles, and frequently combined with oblongs having rounded ends. The grounds of these panels were of wood differently coloured from that of the rest of the piece. The scalloped shell is a characteristic detail of the period. It is shown above the panels in Fig. 1 and also on the chair decorated in lacquer work. Fig. 3.

The general lines of furniture became curvilinear instead of vertical and horizontal, and the cabriole leg was now first introduced and reached the form in which it was standardized for the next 50 years, with variations in knee ornaments of shells and acanthus leaves, and in scroll, club, hoof, claw, and claw and ball feet. Stretchers disappeared from chairs and settees during Queen Anne's reign and re-appeared in some of Chippendale's pieces, especially in the Chinese style.

Queen Anne chairs, settees, and stools had upholstered seats. Moreen was employed as an upholstering fabric, velvets and brocade sometimes, but the bulk of these pieces for parlour use were covered in needlework. Cross-stitch and petit and gros point were employed in coloured wools on canvas. A winged or grandfather style chair covered in beautiful needlework is shown in Fig. 2.

Some of the chairs were made with pierced, scrolled, deep rails, and with turned or scrolled legs; while others, more typical of the period, were without the piercing and scrolling, but had hoop and splat backs. Settees in the form of two linked chairs were also products of Queen Anne's day. The broken pediment and also the lunette or semi-circular shaped pediment observed in architecture were seen in mirror frames, bureaux, and china cabinets.

Queen Anne Style. Fig. 2. Chair covered in petit point needlework and having cabriole legs with club feet. (Courtesy of M. Harris & Sons)

Fig. 3. Chair, dating from Queen Anne's time, with cabriole legs and stretchers. Fig. 4. Walnut knee-hole chest with seven drawers and a cupboard, the walnut toilet mirror completing a beautiful piece of bedroom furniture. (Courtesy of Country Life and Gill & Reigate, Ltd.)

Dressers on cabriole legs replaced the heavier ones of the 17th century; sideboards and large dining-tables are apparently not known in this style. Many side tables, however, are in existence.

A representative piece of furniture is shown in Fig. 4. This knee-hole dressing-table is exactly like the knee-hole writing-table of the period in construction. The handles should be noted as they are typical of Queen Anne style. Bureaux of the bureau-bookcase type were made in great variety and also double chests of drawers or tallboys. Built-in cupboards with shelves were used for the display of china and for books, though movable bookcases are to be found protected by small oblong latticed doors. The Queen Anne style is famous for its mirror frames, which have been much copied. These were in pine, gilt, or walnut, and relied almost entirely for effect upon their flat shapings. A bird or shell was frequently introduced above the mirror itself. Another decorative piece was the screen. These were covered in stamped leather or brocade, or lacquered in Oriental style. The firescreen, usually a needlework panel framed in walnut on a stand, also appeared with the established use of coal fires.

The immense increase of trade with the East and the more general use of tea as a beverage caused china to become a fashion, with the consequent increase in the output of beautiful ware. For the same reason many cabriole-legged tea tables of various designs belong to this period, and, as gambling was a favourite pastime, it became necessary to provide card tables that were fitted with receptacles both for counters and for glasses. These card tables showed the varieties of cabriole legs, and often had enlarged comers for candlesticks. The legs were movable and hinged to the back of the underframing. All the well known pieces of Queen Anne style furniture are reproduced more or less successfully to-day according to the beauty of the materials selected and the workmanship employed on their manufacture.

QUEEN CAKE. These very small fruit cakes can be made by beating together 5 oz. castor sugar and 5 oz. butter, whisking in an egg quickly, and beating the whole for a few minutes. Add another egg, continue beating for about 6 minutes, then fold in 9 oz. flour, previously sieved together with one teaspoonful baking-powder and mixed with the grated rind of a lemon, $\frac{1}{4}$ lb. clean currants and $1\frac{1}{2}$ oz. candied peel, all cut into small pieces. Turn the mixture into some small greased fancy cake tins and bake the cakes in a hot oven for 20 min.

QUEEN LILY. Three species of the queen lily, *phaedranassa*, a S. American half-hardy bulbous plant, may be grown in Great Britain in a warm sheltered border out of doors, or in the greenhouse. Some of the best are the scarlet *ventricosa*, vermilion-shaded *schizantha*, and yellow *chloracea*.

QUEEN OF THE PRAIRIE. This is a herbaceous species of meadow sweet botanically named *Spirea lobata*, about 4 ft. high, producing heads of rosy carmine flowers in June. It should be planted in a shady, moist border during autumn.

QUEEN POST. In building, this name is given to two posts in a roof truss used for supporting a large roof with a span of from 30 to 45 ft. It is not so generally employed as the shorter king post truss, but is suitable for a small roof with a lantern light.

The roof truss comprises at least 9 elements. The horizontal member, called the tie beam, reaches from one side of the building to the other, and rests on the walls. The queen posts are tenoned into the tie beam, and the principal rafters are framed into the latter and the top of the queen posts. A straining beam is fitted between the two queen posts, and struts are placed between the latter and the rafters. A straining sill is fixed between the queen posts to prevent the stress from the struts shearing the tenons of queen posts.

Iron stirrup straps connect the queen posts and the tie beam, and three-way straps are secured on each side of the rafters, queen posts, and straining beam. A typical example of a queen post roof truss is illustrated. *See King Post.*

Queen Post. Illustration showing the employment of two uprights in a roof truss.

QUEEN'S CUSHION. The popular names of queen's cushion and dovedale moss are given to one of the mossy saxifrages named *hypnoide*. This is a hardy low growing plant which forms spreading moss-like tufts and bears white flowers in May. It flourishes in the rock or wall garden, or as a border edging, in well drained soil in sunshine or slight shade. The variety *Kingii* is of particularly dense growth and makes a delightful moss-like cushion though it does not flower freely.

QUEEN'S FLOWER. This is one of the names of the Indian crêpe flower, *Lagerstroemia indica*, a shrub or small tree suitable for cultivation in a greenhouse having a minimum temperature of about 50 degrees. It bears beautiful rose-coloured flowers which have prettily curled or crimped petals,

hence the name crêpe flower. It may be grown in large pots or in a border; a well drained compost of loam, peat and sand suits it.

QUEEN'S PUDDING. To make queen's pudding, boil up $\frac{1}{2}$ pint milk with 3 oz. castor sugar, a little lemon rind, and 1 oz. butter, then pour this on to 3 oz. breadcrumbs. Allow the whole to cool slightly, and mix in the yolks of 2 eggs and the juice of a lemon. Line a piedish with 3 oz. short pastry, and put a strip of pastry around the edge. Fill it with the mixture, and bake it for $\frac{1}{2}$ hour. When it is nearly cold spread on it a layer of jam, and on top of this pile the stiffly beaten whites of eggs. Put the pudding back into the oven until the meringue is a good biscuit colour. *See Meringue; Pastry.*

QUEEN'S WARE. This term was first adopted by Josiah Wedgwood about 1765 to describe his improved cream-ware, of which he presented a breakfast service to Queen Charlotte. Cream ware was the basis of all the earthenware fabrics produced at an earlier date by Whieldon, even when the nature of the body was concealed by agate and other decorations. The paste was a mixture of flint and clay, as used for Staffordshire salt-glaze.

The improvements made by Wedgwood resulted in an earthenware of light texture, in various shades of cream, straw, and saffron, well potted, with a soft glaze. His final improvement was to introduce Cornish growanstone. The effect was such that delft and salt-glaze were driven out of the market Wedgwood's own services of dinner, dessert, and tea ware were usually made in this material, which is still produced at Etruria. He decorated it in hand-painted designs, and a sparing use of fire-gilding, and sent large quantities to Liverpool to be transfer-printed. Gold lustre was also employed.

The collector may usually identify this ware mainly by the Wedgwood mark, because some rivals attained a very close imitation of its qualities, notably Elijah Mayer of Hanley. Queen's ware was produced in most of the styles already mentioned at Leeds, while at Stockton, down to about 1848, a reproduction of the Etruria fabric was made by Smith and marked W. S. & Co.'s queen's ware. *See Pottery; Wedgwood.*

Queen's Ware. Cup and saucer bearing the Wedgwood mark; the transfer was printed at Liverpool. (British Museum)

QUENELLE. The rich white forcemeat known as quenelle is served sometimes as an entrée, but is also used as a garnish for soups and made dishes. Quenelle may be made either with meat or fish, but the meat must consist of veal, poultry, or game, and the fish of some delicate variety that can be pounded very finely.

When quenelles are served as a garnish for clear soups they are made up with teaspoons, then are poached and laid at the bottom of a hot soup tureen, the soup being poured over them gently.

Chicken Quenelles. For these put 10 oz. cold chicken through a fine mincer and pound it well. Melt $\frac{3}{4}$ oz. butter in a saucepan, add twice as much flour, and mix the two ingredients well before adding $\frac{3}{4}$ gill white stock. Bring the whole to the boil, cooking it until it ceases to adhere to the sides of the pan, and keeping it well stirred. When the mixture has been allowed to cool slightly,

add the minced chicken, season the whole with pepper and salt, and beat in an egg. Pound all these ingredients together, then rub them through a sieve.

Quenelle of chicken served with white sauce and garnished with green peas.

Shape them into quenelles in the following way. Well fill a tablespoon with some of the mixture, shaping the latter with the aid of a knife dipped in hot water to form the quenelle into an oval. Then dip another tablespoon into hot water, and with it remove the quenelle from the first spoon into a well-greased frying-pan filled with boiling water or stock. Poach the quenelles for about 12 min., keeping them basted with the water.

When they are cooked, take them out of the pan, drain them well, and arrange them on a dish, afterwards coating them with some white sauce made from 2 oz. each flour and butter, 3 gills milk, 1 gill good, flavoured white stock, a squeeze of lemon-juice, and a sufficiency of seasoning.

Quenelles of veal and rabbit are made in exactly the same way. They may be varied by adding equal quantities of lean ham or bacon, and a little finely chopped onion. In making all quenelles, seasoning is important. Care must be taken to prevent them being insipid. Garnish with green peas, or chopped French beans, or sprigs of parsley.

Fish Quenelles. For these use whiting for choice, as it is easier to work with; but most fish can be used. Skin 3 large rock whiting and remove all the flesh from the bones, then pass it through a wire sieve. The back of a wooden spoon is best to use for this purpose. Allow for each whiting 4 oz. bread or flour panada, 2 eggs, and seasoning of cayenne pepper and salt, also a little mace or nutmeg. Mix these ingredients with the flesh of the fish, shape the quenelles and poach as for chicken quenelles.

A very simple fish quenelle mixture may be quickly prepared by pounding the flesh of 2 large whiting in a mortar with the hard-boiled yolks of 2 eggs, 2 oz. bread panada (the bread to be soaked with boiling milk, hot stock or water), 3 oz. fresh butter, and seasoning. Separate the yolks and whites of the eggs, and steam the yolks in a cup or jar by themselves, leaving the whites raw. When other ingredients are well mixed work in one tablespoonful chopped parsley and the whites of the eggs whipped to a stiff froth. When all are incorporated the quenelle meat is ready.

**'Q' AND 'R'
RECIPES: A
SELECTION IN
ACTUAL COLOUR**

Raspberry Trifle: Spread $\frac{1}{2}$ lb. raspberries on a large dish, sprinkle with castor sugar and leave for about $\frac{1}{2}$ hr., mixing with them 3 mashed bananas. Split 6 small sponge cakes, spread cut sides with raspberry jam, arrange in glass dish and soak first with 1 gill hot milk and then with $\frac{1}{2}$ gill sherry. Make 1 pt. thick, vanilla-flavoured custard, and leave to cool. When sugar has well soaked fruit, pile latter in small heaps on sponge cakes. Pour custard over and leave to cool. Decorate top with 1 gill whisked cream, sweetened and flavoured with vanilla and garnished with chopped pistachio

nuts and raspberries. *Raspberry Fool:* Use either fresh or tinned fruit. Rub 1 lb. fruit through a hair sieve, and to purée add $\frac{1}{4}$ lb. castor sugar and some cold custard made with $1\frac{1}{2}$ gills milk and yolks of 2 eggs. Whisk whites of the eggs to a stiff froth, fold in lightly and colour with a few drops cochineal. If tinned raspberries are used, strain syrup off before rubbing fruit through sieve. *Raspberry Cream:* Crush $\frac{1}{2}$ lb. Osborne biscuits to fine powder. Add 1 lb. raspberry jam and 1 wineglass sherry. Place mixture in glass dish. Make 1 pt. vanilla-flavoured custard, pour over mixture, and on top shake 1 gill stiffly whipped cream. Decorate with chopped almonds and glacé cherries. *Ribbon Jelly:* Jelly divided into differently coloured sections. Divide some clear jelly into equal parts, flavour and colour each to taste, and allow each layer to set firmly before adding the rest.

QUICK. The hedge plant quick, or hawthorn, may be planted during late autumn, winter, and early spring in soil which has been dug over to the depth of about 2 ft. The plants should be put in about 6 in. apart. A double row will make a much stiffer hedge.

Quickset Hedge. This is a very old term signifying a live fence or hedge set with quicks, a name generally applied to *Crataegus Oxyacantha*, the common hawthorn. For the production of a quickset hedge thorough soil preparation is essential, the ground being deeply trenched and allowed to settle down before planting either in Oct. or early Nov.

Four-year-old plants of quick are to be preferred; they should be planted about 8 in. apart, and cut back to about 6 in. of the ground level. Cutting back in drastic fashion induces strong growth from the base. Some growers prefer a double row of plants. Hedge bottoms should always be kept clean, and the soil regularly forked over. *See* Hawthorn; Hedge.

Quicksilver. This is an alternative name for the chemical element mercury (q.v.).

QUICKSTEP: The Dance. The fundamental steps of the quickstep are the natural and reverse turns, from which all variations are built up. The natural turn is generally used on corners, the reverse (usually a section only) on the straight. As in the Fox Trot (q.v.), a slow step (S.) takes two beats, a quick step (Q) takes one; the latter is danced on ball of foot. Only one walk or, at the outside, two should be done between the steps. The weight of the body should be forward (without leaning forward) towards partner.

The natural turn, counted S.Q.Q.S.S.S., is danced as follows. The man steps forward with right foot (on heel first, but going immediately on to ball) turning on it to R. (S.); steps to side with left foot (Q.) and closes right foot (R.F.) up to it (Q.); steps back with left foot (L.F.), turning on it to R. (S.), closes R.F. back to L.F., turning from L. heel to R. heel (S.) and steps forward with L.F. (S.). (*See* Fig. 1). The girl (*see* Fig 2) steps back with L.F., turning on it to R. to side with R.F., still turning, closes L.F. up to R.F., steps forward with R.F., turning on it to R., to side with L.F., and brushes R.F. through (close to L.F.) as she steps back with it.

A three-quarter turn should be made on the complete step. Contrary body movement (C.B.M.) is used on the 1st, 4th and 6th steps. The 2nd, 3rd and 4th steps (Q.Q.S.) constitute a chassé; this figure, however, may be taken straight, turning, or to the side in other variations of the Quickstep.

The reverse turn (Figs. 3 and 4) is counted S.S.S.S., Q.Q.S. The man steps forward with L.F., turning on it to L., to side with R.F., still turning, back with L.F. back with R.F., turning on it to L., closes L.F., back to R.F., turning to L. on R. heel (Q.Q.), and steps forward with L.F. C.B.M. is used on the 1st, 4th and 7th steps. It should be noted that on the counts "Q.Q." the man actually makes one step only; but the girl makes two steps, therefore it is so counted.

The girl's reverse is as follows: Step back with R.F., turning on it to L., close L.F. back to R.F., turning from R. heel on to L. heel, step forward with R.F., forward with L.F., turning on it to L. Take small step to side with R.F. and close L.F. up to R.F. (Q.Q.), and step back with R.F. C.B.M. is used on 1st, 4th and 7th steps.

The most popular variations are the Quarter Turns and the Zig-Zag, and an attractive movement can be made by joining them together, making the last step of the quarter turns the first step of the zig-zag.

The Quarter Turns, Figs. 5 and 6, are counted S.Q.Q.S., S.Q.Q.S. The man begins facing diagonally to R. He steps forward with R.F., turning on it to R., to side with L.F., still turning, closes R.F. up to L.F. and steps diagonally back with L.F. Steps back with R.F., turning on it to the L, closes L.F. back to R.F., turning to L. on R. heel (Q.Q.) and steps forward with L.F.

Both girl and man make a quarter turn to the R. on the first four steps and a quarter turn to the L. on the last four. C.B.M. is used on the 1st, 5th and 8th steps. It will be noticed that the 1st, 2nd and 3rd steps are similar to the 1st, 2nd and 3rd of the natural turn and the 5th, 6th, 7th and 8th similar to the 4th, 5th, 6th and 7th of the reverse turn. The girl's quarter turns are executed by stepping back with L.F., turning on it to R., to side with R.F., still turning closing L.F. up to R.F., and stepping diagonally forward with R.F. She then steps forward with L.F., turning on it to L., takes a small step to the side with R.F., closes L.F. up to R.F., and steps back with R.F. C.B.M. is used on the 1st, 5th and 8th steps.

The Zig-Zag is composed of five slow steps, as follows: The man steps forward with L.F., turning on it to L., to side with R.F., still turning, back (and across behind R.F.) with L.F., bringing partner outside, closes R.F. back to L.F. and steps forward with L.F. The girl steps back with R.F., turning on it to L., closes L.F. back to R.F., turning from R. heel on to L. heel, steps forward with R.F. outside partner, to side with L.F., and brushes R.F. through (close to L.F.) as she steps back with it. In this figure a quarter turn is made to the L. on the first two steps, and a quarter turn to the R. on the last three. C.B.M. is used on the 1st, 3rd and 5th steps. It should be noticed that the first two steps are similar to the reverse turn and the 4th and 5th to the 5th and 6th of the natural turn.

Another attractive variation that may be used with advantage after the quarter turns or the natural turn is the Cross Chassé, counted Q.Q.S. Following the last step of the quarter turns or natural turn, as the case may be, the man takes a small step to side with R.F., closes L.F. up to it, and steps forward with R.F. outside partner, going straight into the 2nd, 3rd, 4th, etc., of the steps of the Quarter Turns or other suitable variation. C.B.M. is used on the 3rd step. The girl takes a small step to side with L.F., closes R.F. up to it, and steps back with L.F. to go straight into next variation. C.B.M. is used on 3rd step.

Other well-known variations are the Quickstep, the Corté, and the Drag.

In the accompanying diagrams the R.F. is shaded, the left in outline only. The dotted outline shows the position of foot after a turn has been made on it. Diagrams will be easier to follow if the dancer faces the direction in which the toes are pointing and turns the diagram as he or she turns. See Dancing; Fox Trot; Tango; Waltz.

Quickstep. Diagram showing the fundamental steps of the quickstep dance. Figs. 1 and 2 show details of the natural turn. Figs. 3 and 4. The reverse turn. Figs. 5 and 6. The quarter turn.

QUILLAIA BARK. Panama or quillaia bark, because of its chief constituent, saponin, has the peculiar characteristic of forming a frothy solution in water. It is inodorous, but has an acrid taste, and is used as a febrifuge and diuretic. It is useful in forming emulsions, and in the form of tincture of quillaia is an ingredient of numerous shampooing preparations. It is an expectorant, but care has to be taken in using it internally, as it may cause irritation of the digestive tract.

Cleaning Uses. One ounce of quillaia bark, stewed for an hour in enough water to cover it, provides a simple means of freshening up suits that have become shiny. The liquid should be strained when ready for use, and then applied on a piece of material of the same colour as the suit itself. Fairly vigorous rubbing is required, and when this has been completed a clean, damp cloth should be placed over the suit and a hot iron used for pressing. *See Emulsion.*

QUILTS AND QUILTING

Modern Coverlets Worked in Simple and Traditional Designs

This article includes instructions for making a down quilt, patchwork quilts and some details for hand quilting work. Readers should also consult the entries on Down; Embroidery; Night Wear Case; Patchwork; Woolwork.

A quilt is a padded bed coverlet usually of silk, satin, or sateen, with an interlining of sheep's wool, flannel or cotton wool or packed with a down filling. The down obtained from the eider duck is the best, and, incidentally, the most expensive. Some kinds of patchwork quilts are made without interlining and used over a separate lining, but the original idea was that the patchwork was the outer covering stitched through to a foundation lining. The stitching which holds a lining padding in place under another material is known as quilting.

Down Quilts. The down padded quilt is sometimes called an eiderdown, but only the most expensive are filled with the down from the breast and neck of the eider duck which is the softest filling known. Less expensive ones are cygnet and goose down, separated from the feathers and purified before use. Vegetable down is not suitable for this purpose as it so soon loses softness and becomes lumpy. Occasionally kapok is used mixed with bird down when a cheaper filling is required.

Down quilts are sold in double or single bed sizes and in many qualities. They can be made at home and covered with self-coloured material, or with panels, borders, or centre pieces of plain material, used in conjunction with a patterned fabric. When both plain and fancy materials are to be used, the panels and borders must be cut out and machined together. If the quilt is to be made entirely of one kind of fabric, the quilting design can be first marked out in chalk and then with a tacking thread on to the silk. Artificial silk is quite suitable for this purpose and cotton backed satin is also used. Some people prefer sateen for the underside of the quilt as it is less likely to slip off the bed than the other fabrics. For a quilt to be used on a double bed the silk will need joining, but this will probably not be necessary for a single bed or cot quilt.

Sometimes an inner case of down proof sateen is made, but this adds to the weight of the quilt. The case is formed by joining together the two pieces of silk or other fabric cut or made up to the required size. The wrong side of the material should be soaped or waxed, as shown in Fig. 1, before making up in order to retard the passage of the down. A piping of the same or contrasting material along the seam gives a professional appearance when the quilt is finished. One end must be left open for filling.

In the home the down has to be carefully put into the case by hand, and the end which was left open must be sewn securely. It should then be placed quite flat on to a large table or bed, and the down

arranged as evenly as possible by careful shaking and tapping with the outstretched hands. Without moving or disturbing the down, tack along the lines marked out for the quilting, ascertaining that all the tacking stitches go right through to the underside of the case. This process is most important, as otherwise, when quilting, the depth of the down padding will become uneven, and the whole appearance of the quilt will be spoilt. It is best to use a tacking thread of a contrasting colour. Fig. 2 shows the quilt filled with down and tacked for quilting.

Quilt. Fig. 1. Showing the wrong side of the material being soaped or waxed. Fig. 2. Quilt filled with down, and tacked ready for machining.

Quilting can be done by hand by stitching along the lines of the pattern and taking the needle through to the underside at each stitch, but this would make the work rather laborious. It is therefore more often done by machining. Test the machine on a piece of material similar to the cover; the stitch should be long, and neither top nor bottom tension should be tight. No trace of any puckers should be seen in the stitching.

When the machine is satisfactorily adjusted, raise the pressure foot to its greatest height, pass the quilt under it, commence stitching, and do not hurry the process. With the left hand carefully smooth out any creases in both the top and underside of the eiderdown cover.

If a hand sewing-machine is being used, a second person to guide and arrange the eiderdown is a great help. The quilting completed, the tacking cottons should be removed carefully so that no down is drawn through in doing so, and five or six eyelet holes should be buttonholed at convenient distances from the centre of the quilt to provide ventilation. In another form of quilted bedspreads, the designs of the patterned silk, satin, sateen or chintz used for the covers are outlined with running stitches taken through the interlining of wadding. These spreads are finished with brightly coloured plain shantung or cotton linings and are most effective.

Patchwork Quilts. For cottage bedrooms and for use with four-poster beds patchwork quilts are always suitable. They may be made of cambrics, gingham, sateen and other similar materials, or of silks. Sometimes they are composed of blocks of linen 6 or 8 in. square embroidered in woolwork and joined by alternate plain squares of a contrasting colour. Edges may be finished with plain banding or with a binding. Transfers can be obtained for such blocks. Another idea is to use alternate squares of a small patterned chintz and plain sateen. Designs for quilts which more strictly deserve the name are made with patchwork and hand quilting and are interlined and lined, the quilting being worked on the plain border and plain squares.

Patchwork quilts can also be made by adapting the directions given in the first part of the article on patchwork. Sometimes the work forms a panel in the middle of the quilt and a border of 18 in. is added of plain material. Such patchwork requires a foundation. Haphazard, crazy patchwork is a way of using up odd scraps, but is only suitable for a cottage quilt. Fancy stitches such as feather-

stitch, chain-stitch or blanket-stitch are used to attach the patches to the foundation. Whatever the design decided upon, begin by tacking the first patch to the centre of the foundation and arrange the others round it.

A foundation for a quilt should be cut and made to allow $\frac{1}{2}$ yd. drop at either side of the bed and also at the end. When the top is completed turn in $\frac{1}{2}$ in. hem all round. If only the centre panel (large enough to cover the actual top of the bed) is of patchwork, a cotton foundation is cut just of the same size as the panel and the lining may be chosen of a suitable colour and cut the full size required so that it also forms the border.

Otherwise cut the lining material exactly the same size as the quilt, tack it in position, turn in the raw edges, and fell to the patchwork. The most suitable material for lining depends on the kind of fabric used for the patches. Sateen, woolback satin, jap, or Shantung silk is preferable for backing more elaborate silk or brocade patchwork. For cotton quilts use only cotton or linen for lining, a small patterned old English print, casement cloth, crash or coloured lawn are the materials which are generally employed.

A more formal type of quilt is not made upon a foundation, but the patches are cut out in geometrical shapes, such as triangles, squares, hexagons, and octagons, each piece being mounted on fairly stiff paper. Black and white triangles placed so as to form a boxshaped pattern is a familiar design that imitates tiling, but the best effect is gained with octagonal shapes. Cut out a template the exact size of patch required and cut the pieces of mounting paper from this so that all the patches correspond. Place a paper hexagon on the table and see how the edges may best be joined to the surrounding patches without overlapping.

Cut out all pieces of material allowing $\frac{1}{4}$ in. turnings, place them on to the paper shapes, turn the raw edges, and tack to the paper.

Prepare a number of pieces in this way before commencing to join them together. Place them edge to edge, right sides outside, and sew them with very small stitches, taking only a few threads of the material, or the patches will not lie flat.

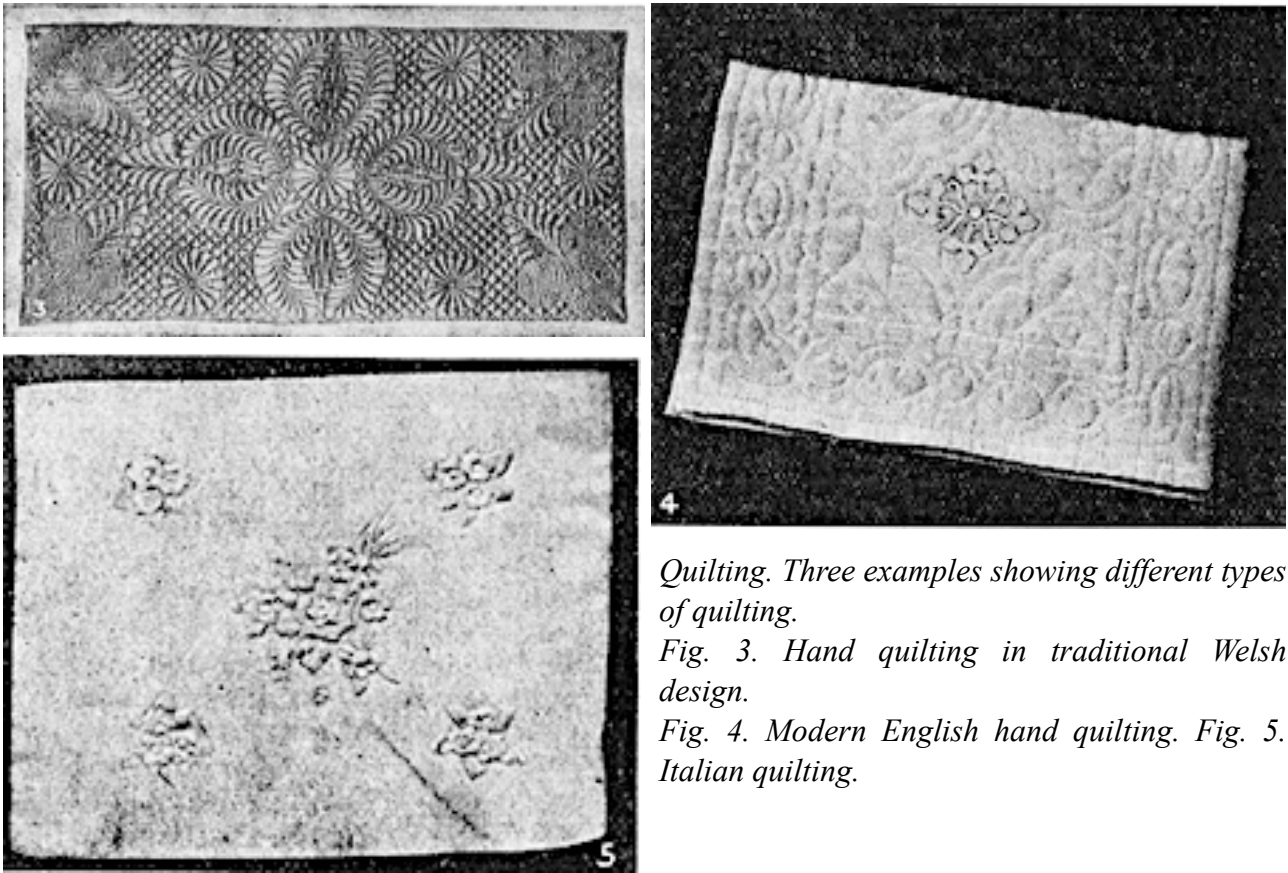

When all the shapes have been joined together, a plain or quilted border can be stitched by hand or machined on to the patchwork, and the lining made in the way already described. It is particularly necessary when making such a patterned quilt to cut each shape with accuracy, or the effect is spoilt, inaccuracies showing much more readily on a large surface than on small ones. The paper used for mounting the patches must be torn away before the quilt is lined.

Rosette Quilt. Most attractive for a country bedroom is a form of quilt dating from the 18th century, or earlier, made of rosettes. Some originals seen came from the West Indies, the materials used for the rosettes being soft, patterned cottons as worn by the plantation negroes. Any prints, patterned lawns or sateens may be used, provided that the scheme is harmonious and the effect light and dainty.

The method of making is simple. Cut out a cardboard template the size of a small saucer (about 5 in. in diameter), the paper shapes to correspond, and the pieces of material allowing for turnings. Having tacked these to the paper, whip round the edges of the material, and before drawing up tear away the paper. Each patch or rosette is like a little flattened circular bag with the gathered top uppermost and is joined by a few stitches to the adjacent patches, but made up in such a way that the quilt has an openwork effect through which the separate lining of some pretty, plain-coloured sateen shows.

Fancy Quilting. Plain quilting usually consists of lines of back-stitching arranged to cross diagonally about 1 or 2 in. apart. This is used sometimes with an interlining of wadding to make

comforters, or small quilted spreads, and cot coverlets of silk or satin and may be done by machine or hand.

Quilting. Three examples showing different types of quilting.

Fig. 3. Hand quilting in traditional Welsh design.

Fig. 4. Modern English hand quilting. Fig. 5. Italian quilting.

Fancy quilting in which the stitchery forms a pattern is also employed on materials for such coverlets. Fig. 3 shows a traditional design from Wales for a full-sized quilt. This style of work dates at least from the Tudor and is still carried on by women in the colliery villages.

The quilts are interlined with sheep's wool or cotton wool, covered with sateen or silk or other washable material and stitched all over by hand, as shown in the illustration.

An example of English quilting is shown in Fig. 4. This cot coverlet is of quilted satin, back-stitched by hand with embroidered motifs worked in padded satin-stitch, stem-stitch and darning-stitch. Designs for quilting may be obtained through embroidery pattern services. Traditional quilting patterns are adapted to transfer form. Designs are also obtainable for quilting babies' shoes and bonnets, and for bedroom slippers, dressing-gowns and jackets.

Italian Quilting. Small decorative pillows and night wear sachets to match the bed quilt are dainty accessories. They may be made of satin, taffeta or crêpe, the quilting, lined with muslin and padded with cotton wool. The pillow foundations may be made of sateen and stuffed with down or kapok. Fig. 5 shows an example of a charming sachet in Italian quilting in which the design stands out with a raised effect. This work is equally suited to decorating a comforter, to be laid over the foot of the bed, to match the sachet or for a cot quilt, and such work would form a beautiful present.

The example illustrated is made of white georgette quilted over pink crêpe-de-Chine. The padding of the design consists of bright coloured wools. These are threaded between the two materials in the lines of the design and show through the georgette with the most delicate effect when quilted.

QUINCE. This Persian tree (*Cydonia vulgaris*) is hardy in Great Britain and is worth planting in small numbers in southern districts for the sake of its flowers and its large, hard, pear-shaped fruits,

which make excellent marmalade. They need more than the usual quantity of water when used in this way. The quince is chiefly valued, however, as a stock on which to bud pear trees; it is known as a dwarfing stock, because it has the effect of dwarfing or restricting the growth of the pear trees and thus encourages earlier fruiting. For gardens of restricted size pear trees of the quince stock should be planted. The chief varieties are the apple-shaped, pear-shaped and Portugal. One named the Serbian quince, introduced from the Balkan countries, is said to produce good crops even on young trees.

Quince. Hardy fruit resembling the pear, and much used for jams and jellies.

Quince Jam. The ingredients required for making quince jam consist of 6 lb. quinces, 3 pints water, and 1 lb. lump sugar to every pint of pulp. Peel and quarter the quinces, and, after removing the cores, put them into a preserving pan with the water. Stew them slowly for several hours until the fruit is soft, then rub all through a wire sieve and measure the pulp. Put the whole back into the pan with the requisite amount of sugar, and boil it for $\frac{3}{4}$ hour, or until it sets.

Quince Jelly. To make this jelly, peel and quarter a few quinces, and, after removing the cores, weigh the fruit, and to every lb. of this add $\frac{1}{2}$ pint water. Cook slowly until the fruit is soft, then strain the whole through a jelly bag, and measure the juice. To every pint of this add 1 lb. sugar; put both into a preserving pan, and boil rapidly for about $\frac{1}{4}$ hour, or until they set. *See Fruit Jelly.*

QUININE. Along with other alkaloids quinine is contained in cinchona bark. A large number of salts are formed with it, those most in use being the sulphate, the hydrochloride and the acid hydrochloride. The drug has a marked power to reduce fever. Its most striking characteristic is its power to cure malarial fever by killing the parasite.

The ammoniated tincture of quinine is a common and efficient remedy at the start of a cold in the head, or influenzal attack. A teaspoonful in a wineglass of water, at hourly intervals until 4 doses have been taken, will often cut short such an attack, if begun early.

QUINOL: In Photography. This is a photographic developer which is slow in action and tends to produce density in the high lights of a negative rather than to bring out details in the shadows or low lights. It thus gives negatives with great contrasts, which, while useful for special purposes, such as copying black and white drawings, are excessive for ordinary negatives. When quinol is mixed in the right proportions with metol, a very valuable developer, known as metol-hydroquinone, or M.Q., is obtained, in which the defects of both quinol and metol are overcome, the combined developer being quick acting, clean, and giving good gradation. *See Hydroquinone; Metol-hydroquinone; Negative.*

QUINSY. Acute inflammation of the tonsils going on to the formation of pus is known as quinsy. It most commonly attacks children and young adults. An attack often follows exposure to wet and cold, and a person who has one attack is likely to have another.

Usually the patient first complains of sore throat, with dryness and some pain in swallowing. Pain may be felt in the ear and on opening the mouth. The swelling of the tonsils increases rapidly, and the temperature rises, sometimes to 105° , while the pulse goes up to 120 or 130 beats per minute.

The tonsils are very red and are coated with mucus. The patient's strength may rapidly decline. An abscess generally forms between the second and fourth day of the disease, and it bursts commonly into the mouth, but sometimes in the pharynx. This may occur during sleep or in a fit of coughing. Instant relief follows the bursting of the abscess. Frequently in children the disease does not follow this severe course. Treatment should be supervised by a doctor.

Quinsy is infectious; the patient should therefore be kept isolated. To guard against further attacks the neck should be bathed with cold water every morning, and the mouth should be rinsed morning and evening with solution of potassium permanganate, 4 drops in a half glass of water, diluted glycerin of borax, 1 in 20, or a similar wash. *See* Tonsillitis.

QUINTAL. This measure of weight is really a hundredweight, being either 112 or 100 lb., according to the scale used. *See* Hundredweight.

Quire. This measure is used in selling writing-paper. A quire contains 24 sheets, and 20 quires make a ream. *See* Notepaper.

QUIRK. This is the name given to a narrow channel or groove separating one portion of a moulding from another. The name is also applied to the bead or fillet of a beading plane, and a tool, similar to a metal spokeshave, known as a quirk router, is obtainable for use in forming quirks. *See* Moulding.

Quoin. This is the name given to the external angle, or corner, of a building. *See* Brick: Concrete.

RABBIT KEEPING FOR PLEASURE OR PROFIT

With Some Attractive Recipes for Cooking Rabbit

The reader may consult the article *Fur* and those that will help him to make a simple rabbit hutch, e.g. *Amateur Carpentry*: Chisel: Hammer. *See* also *Belgian Hare*; *Havana Rabbit*.

Rabbits can be kept in a comparatively small space, and be maintained to a considerable extent on waste products from the garden or allotment. Green food for a few animals can usually be obtained for the labour involved in collecting it. Rabbits are worth keeping both for their flesh and their fur, while their manure is of value to the soil.

The principles of rabbit keeping are outlined in Bulletins 14 and 50 issued by the Ministry of Agriculture. The animals must be fed wisely, as unsuitable food quickly upsets them and prevents them from thriving. A properly balanced ration of sound and nourishing food should always be provided. Green food and roots judiciously given ensure good digestion. Generally speaking a rabbit thrives on a daily supply of food equal to 2 oz. per lb. of its live weight. Water should always be supplied. Changes of diet must be effected very gradually and feeding should always be at regular hours. A prospective purchaser of rabbits should visit a show and study the rabbits there. He should also read the papers devoted to them, note the names of successful breeders, and make inquiries about their reliability. A breeder should not start operations with more than one breed. If the rabbits are to be kept for pleasure and for their flesh, one of the heavier breeds, such as *Belgian hare* or *Rhenish giant*, should be selected.

Suitable Foods. Feeding materials are divided into two classes, bulk food and concentrated food. The bulk food represents the main part of the ration for ordinary cases. Concentrated food is used to supplement the bulk food. It is required in larger quantities for breeding does and for young and growing stock than for older rabbits.

Bulk food, in the case of rabbits, covers a very wide range, almost all growing or dried plants, not directly poisonous, being useful. A few only need be mentioned: cabbage, cauliflower and broccoli leaves, carrot and parsnip tops, pea haulms, strawberry runners, the leaves and twigs of nearly all deciduous trees, e.g. apple prunings, poplar twigs and leaves, clippings from hawthorn hedges, etc. Kohlrabi, dried nettles, brambles, swedes before Christmas, mangolds, after Christmas, oat, straw, etc., are all useful. Beet leaves and potato parings may be given, while such plants as dandelion, sow thistle, clover, chick-weed and groundsel are good.

With regard to greenstuff, special care should be taken to avoid sudden changes of any kind. Thus, if rabbits have been fed during the winter on a bulk food composed mainly of roots and hay, it is dangerous to change suddenly to large quantities of cabbage or dandelion. Care should also be taken to avoid the use of grass or other plants which may have been contaminated by the excreta either of other rabbits or of dogs, or trouble from internal parasites will certainly ensue sooner or later. Frosted greenstuffs or roots should also be avoided, but, contrary to common belief, there is no harm in wet greenstuff so long as it is fed in reasonable quantities. Greenstuff of some kind or other, or roots, should be fed to all rabbits at least once a day.

As regards concentrated foods, an albuminoid ratio of about 1 to 5 is suitable for all rabbits, but this proportion may be varied according to age. The materials commonly employed for other farm stock are also useful for rabbits, and cover a wide range. The following mixture has been found to give good results in practice: bran 6 parts, barley meal 2 parts, best white fish meal 1 part, all by weight, mixed well together and water added till it is crumbly and moist. Separated milk, buttermilk, or whey, if available at a cheap rate, forms a valuable foodstuff, and may be used to moisten the mash in the place of water. Milk in any shape is particularly useful for very young rabbits and breeding does, and less fish meal is necessary where it is used.

Rules for Feeding. All rabbits should be fed twice daily at any convenient fixed times in the morning and evening. The bulk of the ration is better given in the evening. The following plan will be found most convenient: In the morning all rabbits should be given as much concentrated food as they will clear up in about 1½ hours. In the evening they should receive a liberal ration of greenstuff or hay, or other bulky food. All nursing does and youngsters up to the age of about three months should be given the same amount of concentrated food at night as they had in the morning, and rabbits from about three months to six months old and pregnant does should be given about half this proportionate amount. Other rabbits should be given no concentrated food at all at night; only in the morning. In the early spring and summer the feeding value of greenstuff is far higher than it is later on, and it is quite possible during that time to rear rabbits on food of this kind alone. Later on, however, concentrated food becomes increasingly necessary if the best results are to be obtained, while if rabbits have been fed on bulky food alone it is difficult to get them to take to concentrates. It is better, therefore, to feed a small quantity of concentrated food even in the spring and early summer.

It is important always to inquire as to the previous feeding of newly purchased rabbits and to introduce any changes gradually.

Stock should be watched and individual requirements studied. Most rabbits will eat a good deal more than they really require, and some suffer in consequence. The rate of growth of youngsters of breeds which have an adult weight of about 6 to 7 lb. should be 3 to 4 oz. per week. If large quantities of succulent greenstuffs or roots are being fed, water is not very necessary, but it is prudent to keep a supply of clean water in the nitches of breeding does and young stock.

Pedigree Rabbits. Pedigree rabbits of the best known and most popular breeds are just as hardy and as prolific as their humbler relations. They may be fed on anything which a pig would

ordinarily eat, excepting salty things, with this proviso, that all food given to rabbits must be absolutely sweet and fresh. Every imaginable type of table scraps, oddments of left-over pudding crusts of bread, vegetable parings, apple peel, banana skins, orange peel, cooked potato peelings, even tea leaves, if set aside during the day in a white enamelled pail or bowl, may be utilized. These are chopped up roughly, scalded with boiling water, well drained, mixed to a dry, crumbly mash with a few handfuls of dry bran, and given to the rabbits just before bedtime.

4. Lop-eared Rabbit.

Rabbits for Fur. The following are the best known and most popular breeds of pedigree fur rabbits: The Giant Blue Beveren is a very large and beautiful rabbit, whose thick, soft fur is of a blue-grey colour. It makes up into all sorts of wraps intended for hard wear, full-length fur coats, capes, stoles, and muffs, besides being in much demand for trimmings of every description. There are certain cleverly dyed blue-grey furs on the market which may be at once detected by gently blowing the fur apart. The natural-coloured fur grows from a creamy white skin, but the dyed variety will be found to spring from a blue-grey one.

The Giant White Beveren is a snow-white rabbit with a rather long, soft coat and pale blue or pink eyes. Its fur makes evening wraps, children's coats and caps, and fur trimmings. For furs for home wear this rabbit is well worth breeding, but it would not be, as a rule, worth while to breed it for selling, on account of the strong competition in imported white rabbit furs.

The Black Beveren, or Sitka, as it is sometimes called, is a big rabbit with long, lustrous, soft, black fur, which makes excellent coats, stoles, muffs, and wide bands of trimming for frocks and suits. The Chinchilla enjoys special popularity, on account of its very beautiful soft, grey-shaded coat, which should resemble real chinchilla as closely as possible in colour. It makes good wraps and coats and is much used for summer wear.

The Havana is a good-sized rabbit, not quite as big as the foregoing breeds. Its fur is an attractive and useful shade of brown. It makes good coat collars and cuffs, stoles, muffs and trimmings. The Argente de Champagne is a large rabbit whose rather long coat is of a very pale grey. When born the young ones are quite black, but they silver gradually through the black fur, so that at about 13 weeks they become silvery pewter colour. Their fur is useful for all ordinary purposes.

The Silver Grey is a rather smaller rabbit with a short, hard coat of closely mingled black and white hairs. Its fur makes good hard-wearing collars, cuffs, muffs, and stoles to wear with tailored suits. Of uncommon and attractive appearance, it makes up well into useful short coats. The Black and-Tan is quite a small rabbit, very prettily coloured. Its coat is a fine glossy black, with dull orange points and hairs, which makes narrow dress trimmings, and is much used for fur-backed gloves and fur-lined bedroom slippers. The White Polish rabbit, which has pink eyes, has a short white coat so

closely resembling Russian ermine that it is in great request for trimmings as a substitute for that very expensive pelt.

In all breeds alike a furrier cares only about the thick winter coats of fully grown rabbits, and the quality of the fur makes more difference in the actual value than the choice of breed. It is best to start with only one or two varieties of pedigree rabbit, of which the Chinchilla and the Blue Beveren would be a very suitable choice. It is, of course, necessary to keep the different breeds absolutely separate; to mix the strains would be to spoil the pedigree stock.

Pedigree fur rabbits should be bred from three times a year, after the age of 7 months, preferably from January to July. The youngsters should be in full adult fur at from 5 to 7 months old, and must then be watched very carefully and caught at the right moment for killing, i.e. when the fur is fully through, and before there is the slightest sign of the impending moult. Good pedigree stock can usually be obtained at prices ranging from 10s. for a promising youngster to as many guineas for a prize-winning adult, from reliable breeders. A start may be made with a buck and 2 to 6 does of the same breed, according to the accommodation available. Each must be housed in a separate hutch from the age of 11 or 12 weeks onward until old enough to breed from or for killing, as if run on together they fight or soil each other's fur, which spoils it for selling purposes.

Diseases of Rabbits. Canker of the ear is caused by an itch mite burrowing in the skin. Its symptoms show the base of the ear hot and inflamed, and the orifice and interior crusted with scabs. To treat it, the scab should be softened with a warm 5 per cent solution of lysol, using a small brush or a stiff feather. When it is soft the scab should be carefully scooped out with a hairpin or a wooden skewer, and burned. The inside of the ear should be freely dusted with flowers of sulphur, this treatment being repeated after 4 or 5 days. If the animal continues to hold its head on one side it means that the ear drum has been pierced. In this case the disease will probably be fatal, so the rabbit had better be killed at once.

An itch mite in the skin is also responsible for the complaint known as scab. In this a scurfy scab is seen on the nose, eyelids, lips, forehead, or the base of the ears; later it spreads over the body. In the early stages the skin is inflamed and scaly, and small red pimples form. The hair falls out and the animals scratch themselves a good deal. To cure it, the hair should be cut off. The scab should be thoroughly softened with soft soap, washed off with a warm 2 per cent solution of lysol, using a stiff brush, and anointed every day with one part of Peruvian balsam in one part of the spirit. Daily painting with tincture of iodine is recommended, but care must be taken to avoid the eyes.

Some rabbits suffer from inflammation of the eyes. In these cases the eyes are red, with a tendency to water. The eyelids stick together and discharge matter. The trouble may arise from draughts, dirty or damp hutches or injuries and scratches. The eyes should be washed with camomile tea and 2 per cent boracic acid.

Other rabbits suffer from loss of hair, this taking the form of bald patches on the coat. It may be caused by a weakening of the hair follicles through poverty of blood or nervous trouble; or it may be due to hair mites which are seen as small white spots, especially on the flank, chest and tail. When it is due to a weakening of the hair follicles, the cure is to restrict the amount of food to very little. The food given should be good and nourishing, with a high content of oil; for example, carrots, cloves, linseed, hemp, lucerne, sunflower seed, and linseed oil in a mash. When it is due to mites, the complaint can be cured by anointing the bald patches with petroleum or linseed oil. The best cure, however, is to bathe the animal in a 2 or 3 per cent solution of lysol, afterwards rubbing it dry and placing it in a warm spot away from the draughts. Care should be taken to avoid getting any lysol in the animal's eyes, while the hutch must be thoroughly cleaned and disinfected.

Rickets, evidenced by crooked forelegs and an irregular gait, is usually inherited. It may, however, be accentuated by giving the animal an undue proportion of food that lacks lime salts, potatoes and

roots, for instance. To cure it is impossible, but it may be prevented by frequent changes of food and putting some salt in the mash. A small saltspoonful of calcium phosphate, two or three times a week, is also helpful.

Rabbit Hutch. Fig. 1. Small and easily constructed hutch, with two compartments. Figs. 2 and 3. Front and side elevations. Fig. 4. Section showing cut in partition. Fig. 5. Corner joint of framed door.

Rabbit Hutches. The hutch should be located in a dry place under shelter; it should be large enough for its inhabitants, and it should be so arranged as to admit of being cleaned quickly and easily. The hutch, moreover, should be ready before any stock is bought. With the exception of the hay rack, there need be no internal features of any kind in it. Partitions are not necessary, since movable nesting boxes can be used in their place. Outdoor hutches should stand on tarred bricks. They should always be arranged to face a wall or hedge, or some other object that will give shelter from the wind.

Two kinds of hutches may be used, one being at least 4 ft. and the other 3 ft. long. Both kinds should be about 3 ft. deep, from back to front, and about 18 or 20 in. high. The large hutches are used for breeding does and their progeny; the smaller ones for stud bucks, resting does, and growing youngsters. If rabbits are kept in any number there should be about three large hutches to every two small ones.

For the need of those who only keep rabbits on a small scale, a strong and easily constructed hutch is shown in Fig. 1. It has two compartments and is sufficiently roomy for breeding purposes. Figs. 2 and 3 show the front and side elevations, and other details are given in Figs. 4 and 5.

The sides should be made first; they are 24 in. high in front, 18 in. at the back, 19 in. wide, and formed from $\frac{3}{4}$ in. boards. Unless the wood is glued up to provide a piece of the required width, and this will mean very careful planing, tongued and grooved matchboarding should be fitted together to form the correct width when the outer tongue and groove have been removed. A 1 in. square fillet should be nailed or screwed across the bottom and a 2 in. by $\frac{3}{4}$ in. length secured in the same way across the top; the latter piece should be fastened on before the top is trimmed to the correct slope. The two ends are joined by the flooring at the bottom, suitable $\frac{3}{4}$ in. boards to a width of $18\frac{1}{4}$ in. being nailed to the bottom fillets to give a length of $42\frac{1}{2}$ in. between the sides. At the top (front) a 44 in. by $3\frac{1}{2}$ in. by $\frac{3}{4}$ in. length is let in as shown, and a similar length should be let into the sloping top so that the outer edge is $\frac{3}{4}$ in. away from the back.

The middle partition is fitted in position, suitable slots being cut to allow for the top pieces, and an opening must be cut at the bottom back corner; this should be about 6 in. or so square. A horizontal batten can be fastened to the partition on a level with the edge of the opening. The back is nailed on direct to the bottom boards and the top piece, and nails driven in from the ends as well as into the partition. The solid door is of tongued matching nailed to lengths of 3 in. by 1 in. wood, and carefully fitted in the space; either cross garnet or ordinary back flap hinges, as shown, can be used to hang the door. The wire-covered framed door is made from 2 in. by 1 in. wood, either halved at the corners, or preferably, joined with the mortise and tenon joint.

Securing the Wire Netting

The frame should be covered with stout wire netting on the inside, but the ends of the netting should be turned in neatly and secured with wire staples. The four legs or supports are cut from 2 in. square material and notched out at the top half-way through, allowing a distance of 12 in. below and from 6 in. to 8 in. above the notch. These pieces are screwed on to the ends a short distance from the edges. The roof is composed of pieces of matchboarding 4 ft. long joined together to project about 2 in. in front and at the back. A groove to prevent the water running from the roof into the interior should be planed or cut with a gouge. Another method of forming it is to plane a V-shaped cut with a rebate plane.

A good way of housing a number of rabbits is to have a stack of hutches one above the other. These can be made on the lines suggested, but for protection against the weather it may be well to coat the whole of the woodwork with creosote. The floors can be waterproofed by melting some pitch in an old saucepan, adding about a tablespoonful of tar to every lb. of pitch, and basting all the cracks and crannies of the floor with the hot mixture. The whole should then be treated with a hot flat-iron to work the pitch well into the wood. The floor should be strewn with sand, which may be thoroughly incorporated in the pitch by the aid of a blow lamp. Great care should be exercised in melting the pitch, and the job is best done out of doors.

How to Cook Rabbits. Boiling or stewing are the most usual methods of cooking a rabbit, but it may be roasted, baked, or made into soup or pies. When buying rabbits select those that are plump and free from discoloration, and pay attention to the ears, claws, and teeth. The ears should tear easily, the claws be smooth and sharp, and the teeth small.

Unlike hares, rabbits should be paunched immediately after they are killed, the stomach and intestines being removed, and the inside thoroughly cleaned. If the rabbit is not to be cooked at once, hang it up until it is required, then remove the ears and cut off the legs at the first joint, skin it, and remove the eyes. This is usually done by the poulterer if the rabbit is bought from a shop.

The kidneys and the fat that surrounds them should next be taken out, the diaphragm broken, and the heart and lungs drawn. The liver, heart, and kidneys only should be reserved. Wash the rabbit well in two or three bowls of cold salted water, then let it soak for about ½ hour in some salted tepid water.

Only young rabbits should be roasted or baked, the older ones being better suited to stewing. Simmer the liver, heart, and kidneys in salted water. When tender chop them finely and add them to some veal forcemeat. Stuff the rabbit with the forcemeat, sew up the opening, and truss with the forelegs backward, the hindlegs forward, and the head in an upright position. Tie a piece of fat bacon over the back, then put the rabbit into a tin with some dripping, and cook it in a moderate oven.

Baste it frequently, and when it is almost done take off the bacon, dredge the rabbit with flour, baste it again, and let it brown. Serve it on a hot dish after removing the string and skewers, pour some thickened brown gravy round it, and serve more of the latter separately in a hot tureen; ¾ hour to 1

hour is the time required for roasting. Red currant or rowanberry jelly, forcemeat balls, and rolls of bacon may be used as a garnish.

The dish called jugged rabbit is prepared in the same way as jugged hare. For boiling, first prepare the rabbit as directed. Truss it neatly, put it into a stewpan with enough white stock or water to cover it, and add 2 peeled and sliced onions, a bunch of parsley and herbs tied together, 4 cloves and the same number of peppercorns, and a little salt. Bring the whole to the boil, then skim it well and let it simmer gently for 1-2 hours, according to the age and size of the rabbit. When it is tender, lift it out of the pan, remove the string, and put the rabbit on to a hot dish, pouring over it some onion or parsley sauce. Some neat rolls of toasted bacon should be used as a garnish.

Casserole of Rabbit. Draw and clean a rabbit, cut it into neat joints, and leave these to soak for about $\frac{1}{2}$ hour. Then dry them and put them into a pan containing 1 oz. hot melted dripping, adding also a chopped onion. When the rabbit is browned, take it out, and add 1 oz. flour to the fat in the pan. Brown that also, then pour in $1\frac{1}{2}$ pints stock, and stir the sauce until it boils.

Into a casserole put alternate layers of rabbit and thick slices of peeled and par-boiled potato, using about $\frac{1}{2}$ lb. of the latter. Add a small bunch of herbs and seasoning to taste, then pour in the sauce. Put another $\frac{1}{2}$ lb. thickly sliced potatoes on top, cover the casserole, and cook its contents in a moderate oven for about $1\frac{1}{2}$ hours, or until the meat is tender. Then take out the herbs and serve the whole in the casserole, using a few rolls of lightly fried bacon as a garnish.

Rabbits also make excellent curries, fricassées and quenelles. Recipes for these three methods will be found under the general headings, Curry, Fricassée and Quenelle in this work. Cold cooked rabbit can be used as a filling for patties by mixing 4 tablespoonfuls chopped rabbit with 1 gill white sauce. Add chopped parsley and seasoning to taste.

Rabbit Stew. To stew a rabbit, cut it, after soaking, into neat pieces. Fry them lightly with an onion as for casserole of rabbit, and put the pieces in a stew-jar. Add the flour and stock to the fat in the pan, and when smooth add two sliced carrots and a diced turnip. Boil up, add $\frac{1}{2}$ lb. belly pork cut in small pieces, simmer for a few minutes, then add to the rabbit in the stew-jar. Season well, and stew gently for $1\frac{1}{2}$ to 2 hours.

Another excellent way of cooking rabbit is to stew it in milk. Put it in a pan with enough milk or milk and water to cover it, add an onion, a blade of mace, a bay leaf, and pepper and salt to taste, and stew it gently until it is tender. Then take out the rabbit, place it on a hot dish, and pour over it some thickened gravy. Fried rolls of bacon should garnish this dish of stewed rabbit.

Rabbit Pie. To make a rabbit pie cut a prepared rabbit into joints of a convenient size, and coat them with flour. Then mix them in a pie-dish with $\frac{1}{4}$ lb. bacon cut into small pieces, 2 teaspoonfuls chopped parsley, the grated rind of half a lemon, and seasoning to taste.

Pile the mixture fairly high in the centre, pour in enough good brown stock to make the dish three parts full and garnish the sides with some small forcemeat balls. Cover the pie with rough puff pastry or short crust (*see* Pastry), leaving a hole in the top, and bake it in a hot oven until the rabbit is cooked and the pastry lightly browned.

Rabbit Soup. To prepare a nourishing soup, cut up the remains of a cooked rabbit, dipping the pieces in flour. Melt a lump of dripping in a saucepan and lightly fry the rabbit in it, together with a chopped onion. Pour in a pint of water and bring the whole to the boil, skimming it well. Slice a fairly large carrot, and add it with a bouquet garni to the soup. Simmer the latter for 2 hours, then strain and thicken it with 1 oz. flour mixed with any good brown sauce. Cook the soup for a further 5 min., and season it well before serving.

RABBIT WOOL. The soft, fluffy wool manufactured from the skin of the Angora rabbit is popularly known as rabbit wool. Because of its silky texture it is employed in white or a pale colour to make babies' knitted and crocheted caps, and it is used extensively as an edging for knitted coats and frocks.

When the garment is finished, the rabbit wool should be brushed with a wire brush such as is used for cleaning suède.

RABIES: In Dogs. The disease known as hydrophobia when it affects human beings is called rabies in animals. The most commonly affected of these are dogs, wolves, and foxes, but almost every warm-blooded animal is susceptible to the poison of rabies. The dog is the chief propagator of the disease.

Rabies practically no longer exists in Great Britain, having been banished by the muzzling order and other sanitary measures. It exists abroad, however, and this renders necessary the enforcement of quarantine with regard to imported dogs.

The first signs of rabies in a dog are as follow: He becomes sullen and fidgety, he has a suspicious look in his eyes, and continually licks the injured part through which he has been infected. If his ear has been bitten, he scratches it without cessation. Occasionally he vomits, and very often eats such things as straw, grass, pieces of cloth, or carpet, etc.

The madness develops rapidly, and in the next stage the dog becomes exceedingly bad-tempered. It is not safe for even his master to go near him. He attacks other dogs, flies at strangers, destroys his bed, and if he is chained up, gnaws the wood of his kennel. About the second day of the disease a large quantity of saliva flows from the dog's mouth. This continues for only 8 or 10 hours, and then the animal suffers from insatiable thirst. Unlike a human being suffering from hydrophobia, a rabid dog has no difficulty in swallowing, and therefore he has no dread of water. The rabid dog drinks constantly, but in many cases paralysis of the jaw muscles sets in. This may quickly extend to the body and limbs, and the animal then staggers or falls. If he barks the bark is hoarse and unnatural. About the fourth, fifth, or sixth day death comes, sometimes with convulsions, but more often without a struggle.

If anyone has been bitten by a dog, the animal should on no account be killed, but should be confined and observed. If he appears to be rabid, the bitten person should undergo the Pasteur preventive treatment of hydrophobia. The animal is killed, and its spinal cord, packed in glycerin, accompanies the patient to the Pasteur institute. *See Dog; Hydrophobia; Quarantine.*

RACE GAME. Games of this type exist in great variety and new ones are constantly appearing. The principle of all is the same. A piece of cardboard is marked for the course, and on it horses, counters, or other articles are placed, one for each of the players. The latter are provided with dice and each moves his horse or counter according to the number of his throw.

In some of these games obstacles are marked, and if a player, instead of passing over one of these, just reaches it, he is penalized by having to go back a certain distance or in some other way. Sometimes the course is the map of a country, across which the players must go.

RACQUET. This implement is used in several ball games, notably lawn tennis, while the battledore is in origin the same. In selecting a tennis racquet it is essential to choose one that feels thoroughly comfortable when swung in the hand. This is the main consideration; others are weight, balance, the size of the handle and the nature of the gut. *See Badminton; Lawn Tennis.*

RADIATOR: In Heating. In the home the term radiator is used to denote a heating element, such as a gas fire or an electric heater, but by far the most frequent use, though scientifically incorrect, is to denote the multitubular unit in a central heating system from which the heat is dissipated into the room. Actually the heat from such a unit is convected, and not directly radiated to any extent. However, radiator is the accepted trade term for this type of heating unit.

The most common form of radiator consists of a series of cast-iron loops, or pipes, through which the heated fluid passes. This fluid may be hot water, steam, or hot air. In most domestic central heating systems the heating fluid is low-pressure hot water. With separate gas-heated radiator units steam or hot air is employed. *See* Boiler; Central Heating; Electricity; Gas; Heating; Hot Water Supply.

RADIATOR: On Motor Cars. A radiator is an important part of the internal combustion engine. Considerable heat is generated in the cylinder walls by the firing of the compressed gases on the explosion stroke, these explosions occurring at from about 200 to 2,000 a minute.

Rising in proportion to engine speed, a very high temperature is reached, and, unless a suitable means is provided by which to cool the cylinders, the walls would be made red hot, and the pistons would seize or even melt, if of aluminium. With air-cooled engines the temperature is kept within reasonable limits by providing the outside of the cylinder with fins (cast integral with the cylinder block), by means of which the heat generated is the more quickly drawn off and dissipated to the air. In the water-cooled system the radiator is used to cool the water after it has flowed round the cylinders, and before it again passes to the cylinder jackets, where the water once more becomes heated up before flowing to the radiator. The cycle of operation continues either by the thermo-siphon or pump system, so long as the engine is running. Beyond occasionally replenishing the radiator with water, the system requires no attention. Only soft water, such as rain water, should be used, otherwise the whole of the system will, sooner or later, become coated with a deposit similar to that on the inside of a kettle, which will seriously interfere with its efficiency.

The radiator and water passages must be so designed that free circulation is obtained, and the water temperature does not exceed 212°F., that is, boiling point at atmospheric pressure. Boiling may cause trouble in several ways. Steam locks may cause a burst, and at frequent intervals it will be necessary to fill up to replace the loss caused by evaporation and splashing over. In the latter case, the loss may cause the water to fall to a level at which the circulation, if by thermo-siphon, will cease to function.

Should this happen, it may be unsafe to fill up with stone-cold water, because its sudden contact with the excessively hot cylinders may quite easily cause the metal to crack.

Further, if all the water has boiled away the heat of the cylinders will be such as to cause the fresh water to boil the instant it is put in, with the risk that a serious explosion will result. The only safe course to adopt in this case is to allow the engine at least an hour in which to cool down.

The efficiency of the radiator is dependent upon the speed at which air passes through its interstices, which in turn is governed by the wind and road speed of the vehicle, i.e. as the engine speed rises, so will the road speed increase, presuming the car is in top gear, thereby increasing the air pressure on the radiator. This cools the water more quickly, but since the engine speed will often be very high in relation to the road speed, as when climbing a hill in a low gear, it is common practice to fit a suction fan, driven off the engine, behind the radiator, to ensure as far as possible a draught of air that shall be proportionate to the demands of the engine.

Radiator efficiency depends very considerably also upon climatic temperature, i.e. the radiator that is efficient in very hot weather will be too efficient in cold weather. In these circumstances, the fan, if fitted, should be disconnected, or a part of the radiator screened off. If this is not done the petrol consumption will be excessive, owing to the fact that the thermal efficiency of the engine will be

too low. In other words, at a given road speed a wider throttle opening will be called for than would be needed during the summer months. From the foregoing it will be seen that over-efficiency can be easily remedied, whereas over-heating of the engine, caused by too small a radiator, cannot be cured, except by the fitting of a larger one, which will be found a costly business.

There are two main types of radiator—the gilled tube pattern and the honeycomb. The former is the least costly to construct, but each tube must be of a fairly strong section of about $\frac{3}{8}$ in. inside diameter to be of sufficient strength to support itself. Consequently, the volume of water contained will amount to a fair quantity, and, owing to the fact that the cooling power of the gilled tube is less than the honeycomb pattern, a greater volume of water has to be carried by all radiators of the former class.

Radiator on Motor Cars. Fig. 1. Diagram showing construction of a gilled tube radiator. Fig. 2. Section through honeycomb radiator.

Fig. 1 shows in detail the method of construction of the gilled tube radiator, from which it will be seen that there are only two points that are likely to leak, namely, the top and bottom junction of the tubes with the body of the radiator, discounting the rest of the radiator that is common to both types. The tubes are arranged in vertical rows, those in the second row standing behind the gaps in the first, and so on.

Radiator. Fig. 3. Portion of a honeycomb type radiator, built up on the Gallay principle.

The honeycomb radiator is constructed on entirely different lines. There are two forms, the original tubular one, as shown in Fig. 2, and another in which shaped plates are used as the components (Fig. 3). In the original type the tubes are used in short lengths, arranged horizontally across the body of the radiator, the ends being left open so that the air can pass through the tubes instead of round the outside, as is the case with the gilled-tube pattern just described. The tubes are all shaped at each end in the form of a hexagon, making them similar in appearance to the double-ended box-spanner.

The ends of the tubes are slightly larger in diameter than the remaining portion; therefore, when the tubes are packed closely so that the flats of the hexagons fit up together, a space is left between the round portion of the tubes, and it is between these spaces that the water flows.

All the tubes are held together by soldering, one method being to immerse to a depth of about $\frac{3}{8}$ in. the hexagon faces of the block of tubes.

With the thermo-siphon system the height of the radiator in relation to the engine is of considerable importance. On no account should the bottom of the radiator be more than a little if any below the level of the cylinder water jacket. This is very important, because, as is well known, cold water will not rise. Owing to the lay-out of the chassis this feature cannot always be observed, and in such cases a water pump is installed to ensure a proper flow.

The repair of the gilled-tube radiator is a simple soldering job, but the repair of the honeycomb type is far more difficult. A temporary repair can be made by securing a plate coated with red lead over the leak, holding it in position by a long bolt passed through one of the tubes and screwed up tightly. *See Motor Car.*

Radio. *See Broadcast Receiving Set; Wireless.*

Radish. An attractive salad vegetable. Those illustrated are of the variety known as the turnip radish.

RADISH. This popular salad vegetable is grown for its red or white roots, which may be long, round or oval. The quality depends largely on the rate of growth, therefore seeds should be sown on rich, friable soil to ensure rapid development. Successive sowings may be made out of doors from February to August. The earliest sowings should be on a sheltered border, and during summer a slightly shady place is most suitable; seeds are sown in shallow drills 9 inches apart. Radishes should be pulled while the roots are young.

For spring sowing the long-rooted varieties are preferred and the round or oval sorts for sowing in summer.

By sowing seeds on a bed of fine soil on a hotbed in a garden frame in January or early February, excellent small roots will be available long before those raised out of doors are ready. The large Black Spanish and Chinese Rose radishes are useful for winter salads; they are raised from seeds sown out of doors in July-August; as the plants are vigorous they must be thinned to 6 inches apart.

RADIUM: Medical Uses. The element radium, obtained from pitchblende, emits rays of three sorts: α , or atoms of helium; β , or electrons; and γ , which resemble X-rays. When these fall on living tissues they produce irritation. This may only be of such a degree as to stimulate the tissue cells to increased activity, but it may reach a point where the cells are killed. The healthy cells of the body exhibit a greater resistance to irritation than do those composing growths; hence it is possible, by regulating the amount of irritation produced, to kill the abnormal cells without scathe to the normal ones.

It requires judgement and experience to accomplish this, because it is clear that if the dosage is not sufficient for the purpose it may actually encourage tumour growth; while if it is excessive, damage may be done to the healthy tissues.

A large number of morbid conditions are treated with radium; some it cures and in others it acts as a palliative. Amongst these may be mentioned birth marks, rodent ulcer, and other forms of cancer,

sarcoma, lupus, myomata, cataract, keloid scars, ringworm, leukaemia, pruritus, Graves' disease, and so on. Radium emanation, a heavy gas, in glass or metal tubes, can be introduced into the substance of tumours, and into the cavities of the body, e.g. the larynx. The latter is a great advantage, allowing, as it does, of a direct effect on diseased tissues which cannot well be treated with X-rays.

Drinking water containing radium emanations is said to have proved markedly beneficial in rheumatoid arthritis, a disease which often shows little response to other forms of treatment. The waters at Bath, Droitwich, and other spas are radio-active. Sea-water contains both radium and radium emanation. It is probable that the benefit derived from mud baths in rheumatism and allied disorders is due to radio-activity.

RAFFIA: For the Garden. A fibrous material greatly used in garden and greenhouse for tying plants, raffia is commonly confused with bast. Actually raffia is a natural grass imported from Madagascar, whilst bast is usually obtained from the inner bark of the lime tree. They are similar in appearance and, horticulturally, serve the same purpose. Another substance known as raffia is made from strippings of the palm *Raphia*. *See* Apple; Bast; Grafting; Mistletoe; Rose.

RAFFIA WORK: EMBROIDERY AND WEAVING

Methods of Decorating Useful Articles with this Fibre

Some ideas are here given of the wide possibilities of this work which may easily be varied or elaborated. The reader should also consult the entries on Bread Basket; Embroidery; Hairpin Work; Rush Work; Wastepaper Basket; Work Basket.

Strands of raffia are woven into mats, baskets, hats, and other articles. They are also used for embroidery purposes and for making motifs which may be applied as trimmings. In its natural colour, which is similar to that of straw, raffia can be bought from the florist, and then dyed to the desired shade; but it is sold ready dyed in a wide range of colours at handicraft stores and in most art work departments in big shops, together with raffia varnish, special canvas, needles and raffia cloth.

If dyeing is done at home, the raffia should first be soaked in warm water for an hour. This process makes it more pliable and enables it to take the dye more easily than would otherwise be possible. Almost any kind of dye used for household purposes is suitable, hat dye, applied with the brush with which it is usually sold, giving particularly good results. When a brush is used, the dye is best applied to the finished article, not to the unwoven strands of raffia, for the latter would be a tedious process and an even effect difficult to obtain.

Raffia Embroidery. The most suitable trimming for rush baskets, mats, hats or garden cushions is embroidery in raffia. It is equally useful for table mats in American cloth, raffia cloth or for tea cosies with canvas foundations. Sometimes beads are employed and also wools in order to enhance the effect; sometimes the embroidery completely covers the surface, as in the tea cosy illustrated, (Fig. 1), or is only used to form a border, as shown in the American cloth tea-trolley mat (Fig. 2).

When embroidering with this fibre select designs that are suitable. Conventional or geometrical patterns are best. Natural raffia should be soaked in warm water and allowed to dry for a few hours before working. Dyed raffia having been already soaked does not require damping unless it feels brittle to the touch. Designs can be traced on canvas or raffia cloth over carbon paper. When the embroidery is meant to be flat, a warm iron may be pressed over a damp cloth on the back of the work when finished. Satin, blanket, lazy-daisy and stem stitch (*see* Embroidery) are the stitches most suitable for working the fibre, and special needles are sold for use with raffia, or crewel

needles may be used for finer work. Raffia strands are split into narrower threads when the embroidery demands it.

A stiff canvas is preferable to a soft one and the mesh must be large enough to take the raffia strands. Rug canvas is suitable for large pieces of work. Special raffia canvas has only a single thread mesh. Broad strands of raffia cover backgrounds best. Raffia cloth is a pleasant fabric for garden cushions and cosies and is also very useful for covering such things as blotters and book-ends to be embroidered with designs in raffia.

It is always advisable to strengthen the back of this cloth with thin muslin or canvas before embroidering. The edges of a large piece of work such as a cushion cover should be tacked between strips of muslin to prevent fraying whilst embroidering. The raffia cloth is obtainable both natural and dyed and in three qualities, fine, medium and coarse.

Raffia. Fig. 1. Tea cosy embroidered in natural, black, yellow, blue and orange raffia on coarse canvas and lined with deep blue sateen.

Left. Raffia. Fig. 2. Mat for a tea trolley made of green American cloth with an applied geometrical design worked in coloured raffia on canvas.

Book-ends of white wood, raffia cloth to cover, raffia strands in various colours for embroidering the design for which a chart is provided, leather for the base of the book-ends to prevent it scraping a polished table and gold galon for finishing the edges of the work are obtainable for a few shillings from the Francis-Lewis Studio, 18, Soho Square, London, W.1. The book-ends make a charming gift or add a decorative note to a table. A pretty blotter or writing pad can easily be made to match, using raffia cloth over a cardboard foundation lined with shot taffeta and finished with gold galon. Raffia cloth covers for bridge markers are also decorative, and pochettes can be made from this material, or of canvas embroidered with designs in coloured raffia.

For the tea cosy (Fig. 1) a piece of canvas 16 in. by 22 in. is required. The width of the cosy at the bottom should be 13 in. across and the depth should be 9½ in. Make the outline 1 in. larger than the finished article to allow for shrinkage in working.

The simple design of apples and leaves may be copied free hand on to paper and transferred by means of carbon paper. Alternately, any fruit border transfer of suitable size (about 3 inches wide) may be used. Begin by working a straight edge of bright blue raffia over two holes and then a row of black. Fill in the background round the fruit with the blue. The apples are worked in yellow and two shades of orange. The leaves are filled in with green, working from centre to edge in satin stitch. Above the border a row of black is worked.

RAFFIA: EXAMPLES OF WEAVING EMBROIDERY AND OTHER METHODS OF DECORATION FOR THE HOME WORKER

1. Tea cosy. Colour picture of article shown in black and white under Raffia, Fig. 1. 2. Mat, embroidered with bright-coloured raffia on canvas and mounted on Roman satin. 3. Cushion of green hessian cloth with raffia design. 4. Woven raffia bag. 5. Flower design in embroidered raffia for waste-paper basket. 6. Fruit basket decorated with raffia flowers with darned wood centres, sewn on to canvas. 7. Plaited work basket with raffia flowers. 8. Raffia flowers for hat trimming.

The rest of the design is filled in as follows: Work a vertical line in black exactly in the centre of the cosy. Work over 2 holes. Then work a similar line on either side 2 in. from the centre, and another at a similar distance. Fill in the spaces between, using a series of vertical stitches over 4 holes, then over 5 holes. Continue in this manner until the whole of the cosy is filled in. Then work the other side in the same way.

When finished place the two sides face to face and machine together, turn right side out, make a plait of black and white raffia and stitch this round the join, making a loop at the top for a handle. The ends of the plait should be knotted, leaving the raffia loose to form a tassel. Split this up very finely to simulate silk.

Wrap some large wooden beads with orange raffia by passing the needle through the hole and over the bead. Thread a needle with a strand of green raffia, pass it through the wooden bead, thread a small black bead on to it, pass back to make the stalk, leaving the black bead as a finish to the base of the large bead. Make 6 berries in this way, tie them securely together with some green raffia and stitch this at the base of the handle. Pad the cosy with layers of cotton wool wadding and line it with blue sateen to match the blue raffia used for the border. Raffia cloth may be used instead of covering the canvas with raffia embroidery. The border and finishing would be worked in the same way and $\frac{1}{2}$ yd. of the raffia fabric would be required.

Luncheon mats for garden or loggia table use and tray cloths for service trolleys are most practical when made of almond green American cloth with an applied canvas border embroidered in raffia and with coloured beads at the ends. The trolley mat illustrated in Fig. 2 should measure 18 in. by 12 in. (without the beaded ends).

Cut the American cloth to this size, place a piece of canvas under it and cut $\frac{1}{2}$ in. larger all round. Trace or draw the geometrical design on the canvas and embroider in brightly coloured raffias, using black for the outer edge. Leave half inch of canvas for turning. A large-eyed needle should be used.

When the border has been worked, cut out the inside of the canvas and catch down the embroidery to the American cloth with a fine needle and silk. Turn the edge of the canvas over that of the American cloth and buttonhole round both with black raffia. Buy or make a fringe of wooden beads to match the colours of the embroidery. Attach this to the raffia buttonholing at each end and finish off the two sides of fringe by using a large black bead and a small coloured one.

Fig. 3. A, mat made of coloured raffia strands wound over a cardboard foundation and woven in the centre. B, edge worked with running stitch. C, method of placing strands for central weaving. D, details of knotting.

Weaving and Plaiting. Other effective uses for raffia consist of weaving and plaiting the strands to make baskets, mats, hats, and other articles. Table mats are extremely simple to make in this manner. Oval and round cardboard foundations may be purchased or a set may be cut from a strong sheet of cardboard (imperial size). Six round mats 7 in. in diameter, 2 oval dish mats 9 in. by 6 in. and one large oval 11 in. by 8 in. make a set. For a 7 in. mat (see Fig. 3) a centre should be cut out in the cardboard of $2\frac{1}{2}$ in.: for the ovals cut out an opening in proportion. The raffia is simply bound

over the card board through the centre opening, taking care to overlap the strands each time so that the cardboard does not show through. Near the end of each strand, thread it with a sharp pointed crewel needle and take it through the cardboard and make firm by pushing the end beneath the already wound raffia strands. Continue winding till the cardboard shape is covered. Two or three strands may be used together to cover the cardboard more quickly. The edge (see diagram B) is worked by threading the needle with a contrasting shade of raffia and using a running stitch. Bring the needle up through the cardboard each time, then reverse the mat and bring the needle up through the same holes so that the stitches cross.

The centre weaving is begun by taking a strand of the same coloured raffia as used for the edge straight across the opening; threading through the cardboard on the other side and bringing the strand back to the other side of the opening to give a double thickness. Fasten off and repeat round the opening; eight strands should be sufficient for a small mat (see Fig 3, C).

Now weave in and out of these strands from the centre for about 1 in. in diameter. Make a row of knots all round close up to this weaving, one on each strand, and then a second row of knots, leaving a small space between them and the weaving. Detail for the knots is shown in Fig. 3, D.

More elaborate borders can be made to such mats introducing several colours with fancy stitches. An example of weaving with raffia on a cane foundation is given in the article on Bread Basket.

Fig. 4. Work basket in plaited raffia embroidered with raffia flowers. Fig. 5. Raffia flowers suitable for an applied trimming to a wastepaper basket or garden hat.

A plaited raffia basket is illustrated in Fig. 4. Rush may be used instead of raffia and instructions for making the plait, which can be equally well used for raffia, are given in the article on rushwork. The five-way plait with five strands is particularly good for the purpose, start at the bottom, making a small flat mat by sewing the plait, together with raffia of the same colour. The base should be about 9 in. in diameter.

Make a circle of plait exactly the same size, and build this up to form the sides of the basket, which should measure 5 to 6 in. high. Fasten it off by stitching the end of the plait inside, arranging it so that the edge is even. Sew this part firmly to the base, then take two plaits, and twist them to form a handle. The two ends must be firmly stitched inside the basket, one being sewn where the side was finished off. The raffia flowers are embroidered on to the basket direct, using a long needle. Pink, mauve and fuchsia shades are always pretty if the lining of the basket is chosen to match one of these colours. Make a few rather short loop stitches for the centre of each flower, and round these make long loop stitches of a contrasting colour for the petals. The less raffia is handled the better the result. For the stems twist a little green raffia round a piece of string or piping cord, stitching it here and there to hold it in place. One or two pockets should be made in the silk or sateen lining of the basket, and a cover can be made by cutting the lining sufficiently deep to meet over the top when drawn up by a slotted ribbon. A small bunch of flowers provides a pretty finish at each end of the handle, or beads may be used as explained in Fig. 1.

Applied Raffia Trimming. Flowers or fruit may be worked separately like the spray shown in Fig. 5. These are effective for trimming beach or garden hats, for ornamenting fruit, bread or wastepaper baskets. A piece of canvas larger than the spray required is used to work on. Sketch the design and fill in with the coloured raffia strands, using long buttonhole stitches from centre to edge. Use green for stalks and leaves. The centres of the flowers are of beads. Cut away the superfluous canvas from the spray when the embroidery is finished.

RAFFLE. A raffle is a way of selling an article by chance or lottery. The price is subscribed by all the persons who take a share therein, and by drawing lots, or by some other chance method, one of them wins the article. At bazaars, and also privately, articles are disposed of in this way. A raffle, however, being a lottery, is illegal, except when held in connexion with some fête or limited to a special class of persons. *See* Lottery.

RAFTER. A rafter is a support for the roof of a building, particularly those members running upwards from the wall plate to the ridge board. Rafters are generally made of timber, although metal is occasionally employed. The size most commonly used for a house is 4 in. deep and 2 in. wide, placed not more than 14 in. apart. The dimensions of the rafters should be in accordance with the following table, in which the first column gives the distance between two points of support and the second column gives the respective depth and breadth of the rafters. The sizes given are those in commercial use and approximately the size of the material as it leaves the saw.

Length of bearing not exceeding	Dimensions.
	Inches.
5 ft	3 by 2
6 „	3½ by 2
7 „	4 by 2
8 „	4½ by 2
9 „	5 by 2

Rafters are practically always put in one continuous piece: they are generally notched to fit on to the plate, which is the timber on the top of the wall, and are cut at an angle at the opposite end, so that they bear against the ridge board or other point of support. They are usually supported in the middle

of their span by a long, horizontally disposed timber known as a purlin. They are prevented from sliding outward by means of collars, horizontal timbers fixed between opposite pairs of rafters, and have to resist heavy tensile strains.

Rafter. Method of fixing rafters for a simple lean- to roof. Left. Fig. 1. Top end spiked to wall plate.

Fig. 2. Feet bird-mouthed to plate.

A serviceable method of fixing small rafters is illustrated in Figs. 1-2, which show how the rafter is fitted to a single or lean-to roof. At the upper end the rafter bears against the single wall plate, and at the lower end it is bird-mouthed or notched to the wall plate (Fig. 2), both ends being secured to these two plates by means of stout nails. The same method is adopted in the case of a span roof, and the construction answers all requirements for any kind of roof

that the amateur craftsman is likely to undertake. The correct angles are obtained by the use of a bevel square and by accurate measurements. The best plan is to cut one of the rafters to fit perfectly and then use it as a pattern. *See Ceiling; Eaves; Gutter; House: Roof, etc.*

RAGGED ROBIN. This is the common name of a familiar wild plant (*Lychnis flos-cuculi*). Two varieties are worth growing in gardens, *alba*, white, and *rubra plena*, with double rose-coloured blooms. They grow about 18 in. high and thrive best in moist soil.

RAGOÛT. This term is applied to certain rich meat stews, generally brown in colour and flavoured with vegetables and herbs.

For beef ragoût, any of the cheaper cuts, such as steak for stewing, round, etc., may be used. Wipe 1½ lb. beef, cut it into neat pieces about 2 in. square. Heat 2 oz. good dripping in a saucepan, lay in the beef, a few pieces at a time, and fry them quickly till lightly browned on each side. Lift them out on to a plate and stir into the fat 1 oz. flour. Fry this carefully until a rich brown, stir it frequently with a wooden spoon, as flour quickly burns. Pour in 1 pint good stock or, failing that, water and a little of some variety of meat extract.

Stir this sauce until it boils. Add the meat and 2 tablespoonfuls each of carrot, turnip, and onion, cut in large cubes, a small bunch of herbs, and 6 allspice. Simmer the ragoût for about an hour, or until the meat is thoroughly tender.

Arrange the pieces of beef in a circle, or some other neat style. Season, skim and strain over the sauce, and put some of the best pieces of the vegetable in the centre, adding, if liked, a few stoned olives heated in the sauce. Other vegetables in season can be added, such as green peas, finely cut French beans, etc. Mutton can be made into a ragoût in the same way, a few tomatoes being used in addition to the other vegetables.

RAGS: Their Uses. Household uses can be found for many kinds of rags. Thus kitchen rugs can be made from woollen rags by clipping the cloth into oblongs of uniform size, say 4 by 1 in., and looping these through a canvas back-cloth, pierced for the purpose. Coloured patterns of a simple sort can be formed, and if rug-making is contemplated it is advisable to save scarlet and other brightly coloured woollen rags for the ornamentation of rugs predominantly of a darker colour. Mop-heads for polishing floors can be made by cutting old blanket into uniform strips and joining the pieces at the centre. Iron-holders and stair-pads are other uses for thick woollen cloth. Linen and silk rags are valuable for polishing furniture and cotton ones for applying metal-cleaning liquids and pastes.

Too large an accumulation of rags is to be avoided, but by keeping an orderly system of rag-bags, one for one sort and one for another, the household need never be short of kinds suitable for all purposes. *See Rug.*

RAILING: For House and Garden. A railing is essentially a fence composed of rails or poles, and is used to mark a boundary of one kind or other, or to serve as a protection (e.g. around a basement area, or the well of a staircase, guarded by balusters and handrail).

Borders and open spaces, such as lawns or flower beds, are often provided with light, low railings made of wrought iron, either painted or galvanized. These are purchased in lengths, complete with standards, generally having an inverted U-shaped foot, and have merely to be driven into the ground. The joints between the sections are united by means of bolts passed through holes in the standards.

When erecting railings on a low brickwork wall, one method is first to put up the standards, then the flat top rail, placing the railing bars through the holes in the top rail, plumbing them with the aid of a plumb line, and alining them with a cord stretched between standard and standard, and then making the feet secure with strong Portland cement mortar worked up into the form of a capping on the wall.

Another method is to use the standard iron coping, which is generally 9 in. in width and more or less V-shape in cross-section. This is bedded in cement mortar on top of the wall, and provided where necessary with holes for reception of the standards. In some designs of villa railings complete panels of an ornamental pattern are provided, and these are set on the upper and lower rails. A common arrangement is to use cast or wrought iron standards and to hang the gate on them. The standards are generally provided with braces to give them stability, and are set in concrete or stonework. The horizontal members are fixed to the standards, and the whole completed by the addition of the necessary ornamental panels or railing bars. An alternative plan is to build two brick pillars, one on each side of the gate, and hang the gate between them. In such cases the horizontal rails are embedded in the brickwork.

To preserve railings they should be painted at frequent intervals, certainly not less than once every three years. The paint used should be of good durable outdoor quality, and before it is applied the railings should be thoroughly well brushed and all traces of rust and dirt removed. The paint should be well brushed into all cracks and crevices, as it is here that decay is most likely to occur.

RAILWAYS: MODEL ENGINES & ROLLING STOCK

Practical Advice on Installing and Equipping a Miniature Railroad

This contribution describes the construction and running of a Gauge No. 0 Railway, with all its details. Information is given on the selection and operation of clockwork, steam and electric locomotives. The model engineer should refer also to the associated articles on Engine and Locomotive.

A model railway built for the private pleasure of its owner and friends may take one of many forms. It may comprise a tiny No. 00 ($\frac{5}{8}$ in.) gauge system complete with all sorts of buildings and scenic effects in a space not much larger than an average dining room table. At the other extreme is the railway laid in a park perhaps several miles in extent, constructed to a gauge sufficiently large to serve some useful purpose. Passenger-carrying miniature railways form a popular feature of certain of our pleasure grounds.

For an indoor model railway—a type of line which comes within the scope of this article—the standard gauge of No. 0 ($1\frac{1}{4}$ in.) is recommended.

The average tank engine model measures 13 or 13½ in. long over the buffers, and a six-coupled express engine from 15½ to 19½ in. overall length, according to type. A four wheeled goods wagon is 5½ in. and an average model bogie carriage 13 in. in length. This means that a goods train consisting of a tank engine and ten trucks measures just under 6 ft. in length, allowing for looseness of couplings, and a passenger train of an engine and three coaches will measure at least 5 ft. long. These dimensions will be useful to remember when it comes to planning a model railway to fit a given space.

An attic room can be made to accommodate a system providing reasonably interesting possibilities in both the construction and the final operation of the line. The minimum curve recommended is 3 ft. radius, but, for the larger types of express engines so often modelled, curves with 4 ft. radius may be used for points and in station yards, with 4 ft. 6 in. to 6 ft. 0 in. radius curves on the main or other fast running lines. Super-elevation of the outer rail need not exceed ⅛ in. on the sharpest curve.

Lay-out Plans. The question of the lay-out of the track must eventually be determined by the shape of the available site and its overall dimensions. The clockwork engine is more suited to the non-continuous type of plan, but with the electrically driven engine controlled from a point alongside the line it does not very much matter whether or not a circular lay-out is adopted. For a steam model a continuous portion of main line is essential, as most models will run for about fifteen to twenty minutes non-stop, and the methods of outside control provided are somewhat primitive.

Where the plan is arranged on a terminus to terminus system a railway operated by clockwork engines should be designed with regard to the length of run to be obtained, with a train load, at a single winding. This length varies from 60 to 100 feet. The distance between the starting and finishing points should therefore be a definite fraction of—or equal to—the average run of the weakest locomotive used on the system. In this way a model railway can be successfully operated by clockwork locomotives to a time table working without the labour of winding becoming a noticeable factor, so long as several locomotives are available.

Where a long room is available the two main stations may be at the adjacent ends of a non-continuous plan, such as that shown in Fig. 1, the distance between the termini being equal to one half, one third or the total minimum length of run of the clockwork engine. In the case of an electric engine each station and half of the main line can be under the control of a separate operator.

Where the exigencies of the site demand it, the terminals may be placed quite close together, as in Fig. 2, or may be combined as one unit. In the plan illustrated an additional (passing) station—a country roadside station with a simple equipment—is shown in about the middle of the main line. This railway, if electrically controlled, could be worked by either one or two operators, the sections being arranged to suit.

Fig. 3 illustrates a plan much used for all types of locomotives, but particularly suited to the steam engine. The main line is continuous, and at the same time a short-distance or local train may run from terminus A to terminus B, and an express train starting from A may make as many circuits of the continuous track as the signalman at the junction signal box desires before being switched over into terminus B. The order of departure and arrival is reversed on return journey. The terminal stations are comparatively close together and are inside the circle, an advantage where a one-man control is necessary. For electrical control the rails may be divided into three sections. The junction signal box may contain switches for the continuous main line and the junction, and stations A and B can be controlled from their respective signal boxes. The stations may be different in plan. In addition to the passenger platforms, terminus A has a locomotive depot, while terminus B may be provided with a goods yard.

Railway. Fig. 1. Non-continuous lay-out with stations at the adjacent ends. Fig. 2. Two terminals with passing station. Fig. 3. More elaborate plan suited to steam working.

Fig. 4. Electrically operated system. A, arrangement of conductor rail at crossings. B, extension of collector shoe to reach outside conductor.

Lines on Different Levels. In some cases, to get more features in a given space, the lines are arranged on different levels. For instance, it may be an advantage in the plan shown at Fig. 3 to extend the stations over the top of the continuous main line, which is made to run in a tunnel under the station. This is possible only where a sufficient length is obtainable from the junction where the upper and lower levels

meet. The head room required for an over and under crossing is about 5 in. in No. 0 gauge, this dimension allowing for the depth of the track and its supports. This means 2½ in. up and 2½ in. down, and since the maximum gradient should be about 1 in 40, a length of 100 in. is necessary to effect a crossing. It is possible to steepen the grading to 1 in 30 (the length between the level portion and the over and under crossing being 75 in.) where the trains can be rushed down and up the necessary inclines.

Points to Note. Other points to be considered in planning are the following:

- (1) If possible always provide a means for the engine to run round its train at an arriving platform or station.
- (2) Where a train has to shunt into a siding there must always be enough room beyond the points for the longest train contemplated.
- (3) A turntable may be used to switch engines into various sidings, taking up much less space than that occupied by points.
- (4) An oval plan without any straight line is much better than a square plan with short straight lines and curves at the corners. Straight portions are necessary, of course, to accommodate stations.
- (5) Points to branches leaving the fast main line portions should emerge from the straight or slightly curved sections.

Electrically Operated Systems. Electric third-rail systems are often provided with a central conductor rail raised 5/32 in. or 3/16 in. above the level of the running rails. The return for the current is via a running rail. Since at points and crossings the collecting shoe on the engine or car must not touch a running rail at the moment of crossing, the shoe must be suitably adjusted in its range of vertical movement. To prevent such accidental contact a good plan is to solder a piece of 14 S.W.G. copper wire to the shoe so that it extends clear of all wheels and other parts of the engine outside the running rails (Fig. 4, B). At the points the conductor rail is omitted from between the tracks and extended along the outside of the tracks. The shoe is thus always in contact with a conductor rail, either inside or outside, and cannot fall below its proper level. The rails are arranged as shown on the plan (Fig. 4, A). The made-up tinsplate track usually supplied for toy electrical locomotives has an all-level system of rails, and the above remarks do not apply. The standard points and crossings are made in such a manner as to cut out (i.e. render electrically dead) that portion of the running track that is crossed and touched by the collecting shoe on the locomotive, and no short-circuiting can therefore occur. With amateur-built tracks using points of orthodox design some such device as that shown in Fig. 4, B, is necessary.

Signal Systems. Signals are used in full-size railway engineering to indicate to the driver the state of the road ahead of him, and also to show the direction in which the points and crossings he may encounter are set for his train.

Railway. Model Signal Systems. Fig. 5. Home signal. Fig. 6. Distant signal. Fig. 7. Upward inclining signal. Fig. 8. Siding or branch line semaphore. Figs. 9 and 10. Colour light signals.

The semaphore signals are of various patterns and values, including home, distant, and shunting or subsidiary signals. The absolute stop signal, termed a home signal, is shown in Fig. 5. The permissive signal known as the distant signal indicates the state of the home signal which follows it. The distant when at danger (see Fig. 6) is a warning to the driver that the home signal ahead is against him, and that he must be prepared to stop at it. It may be "off" (i.e. at "line clear") when he arrives within sight of it, but that does not matter, for he has had the warning. On model railways distant signals are not absolutely necessary, as in the case of an electrically operated railway the signalman is also the driver. They are therefore useful as ornaments only. In a clockwork railway the distant signal can be on the site of the trip gear operating the brake on the engine, or the latter may be used instead of a visual "distant."

Dealing with shunting or subsidiary signals, the ringed semaphore arm shown in Fig. 8 is used for sidings or branch lines. For shunting purposes a small or "calling on" arm is often fitted lower down on the same post as a home signal to call on an engine for a limited distance past the main home signal at danger.

The home signal semaphore is coloured red on the front with a white stripe, and white on the back with a black stripe. The lenses are red for danger and green for the lowered "all right" position. In the distant signal yellow takes the place of red both on the signal arm and in the "danger" lens. The chevron stripes on the arm are coloured black, back and front, and the end of the semaphore is always "fish" or "swallow" tailed, as shown in Fig. 6.

In many of the latest types of signals the semaphore arm has an upward inclination from the horizontal for the line clear position as shown in Fig. 7. In this kind of signal, therefore, the arm rises into the air instead of falling. The dotted outlines in Figs. 5, 6 and 7 show the line clear position of the arms.

Railway. Fig. 11. Diagram showing the standard dimensions of roiling stock and permanent way for model railways, gauges No. 0 and No. 1. A scale of measurements for each gauge is given at foot. For references see accompanying table.

Colour Light Signals. These are now coming into use, especially on urban lines of railway. In such signals a powerful electric lamp is placed in a funnel-shaped recess facing the driver, and this light can be seen quite clearly both day and night. The systems are numerous, as the final development is not yet complete. Light signals may be very easily modelled by using the small light bulbs now readily obtainable in the lower voltages.

One system in which two lights are employed (Fig. 9) is very suitable for model railway work. The danger position of the pair of signal lights is shown at A in Fig. 10. The combination functions as a home signal, and a distant signal for the next section. One (the stop signal) lamp shows red and the lower one yellow. A train must not pass this signal. The next state (B), the upper light showing green, indicates that a train may pass up to the next signal. The third state (C), in which both lamps show green, means that two sections ahead are quite clear.

Model Buildings. Station buildings, bridges, tunnels, embankments and cuttings are accessories essential to any permanent lay-out. For a railway that must be dismantled after use these units may be made in separate components, laid alongside the line when in operation. For any railway that is permanently installed in a room allotted to it, proper track material obtained in loose parts is recommended. A firm foundation about 2 ft. 10 in. or 3 ft. from the ground level should be built up, and the sleepers nailed to this. Ballasting can be effected by glueing the surface of the base and sprinkling chicken-grit on it while it is tacky. Where the track is purchased in lengths, with the wood sleepers made up on longitudinal battens, the ballast should be laid in loosely, as a considerable depth is necessary to reach to the top surface of the sleepers. Ready-made tinplate track should only be employed when a permanent track is not possible.

Electric Locomotives. It is important, before purchasing an electrically driven model locomotive or the component parts for making one, to know something of the various systems employed.

For use with direct current of any voltage the ordinary electric motor with a series-wound field and armature is the best possible unit for traction purposes, whatever the size of the locomotive may be. The only disadvantage it has is that reversing must be done either by a hand switch, or an automatic polarised relay switch on the engine. It is necessary to reverse the relation between the direction of the currents in the armature and the wound field magnet. Simply reversing the supply of current to the rails will not make any difference to the direction of rotation of the motor.

All the larger and better qualities of model electric locomotives have a wound field, and since reversing from a distance is desirable, a permanent magnet switch or reverser is usually fitted in the locomotive. This switch is sensitive to the direction of the current, and when the operator changes it over from positive to negative, or vice versa, the switch follows this movement and changes over the connexions in the motor, thereby effecting a reversal of the engine. Smaller models, in gauges Nos. 0 and 1 more particularly, are fitted with motors having permanent magnet fields (like a car magneto). The field polarity is therefore constant, and the only path for the track current is through the armature of the motor. Changing this over reverses the motor.

Railway. Well arranged gauge No. 0 indoor railway with tracks on two different levels. (Courtesy of W. J. Bassett-Lowke)

Electric locomotives fitted with permanent magnet fields and also those with series motors and polarised relay switches are usable only on railways operated by direct current. Accumulators are the only really satisfactory source of supply. However, it is possible to break down the house supply (direct) current through a resistance or lamps, and this method can be used on model railways where one or two engines only are employed.

The voltages used vary from 4 to 25, the higher voltage, of course, decreasing the amperage consumed, and getting over many other difficulties. For a 4 volt loco, a 6 volt accumulator should be installed to allow for drop in voltage and speed regulation. For a 25 volt installation the source of supply should be about 30 volts maximum.

Model London, Midland and Scottish express locomotive. Royal Scot. (Courtesy of Messrs. Bassett-Lowke, Ltd.)

In every section of the line governed by a separate operator a resistance switch to regulate speed and a commutator switch to change over the current direction and effect reversal are necessary. These may be combined and worked by one handle. The line may be sectionalised by tumbler or other plain switches between this main controller and the various parts of the railway.

A type of locomotive with a series motor having a wire-wound laminated field and armature has been placed on the market for use with alternating current. The house supply can be utilized, a static transformer cutting down the house voltage to a low one that is safe and suitable for a model railway.

These locomotives require a hand-switch on the engine to effect reversal, a polarised (permanent magnet) relay switch not being possible. A magnetic device is fitted to some makes of engines whereby the act of switching on the current turns through a mechanical ratchet motion a barrel reversing switch. The apparatus employed works in a sequence of operations, first forward and then backward. The switch can be also operated by hand. A disadvantage of the scheme is that any accidental breaking of the current supply operates the reversing switch, and the next time the current is switched on the locomotive travels in the opposite direction.

Clockwork Model Locomotives. Clockwork is to be preferred as a mechanism for driving model locomotives where juveniles have to be catered for. The youngster can do no harm to himself or his surroundings in its use. At the same time this form of motive power is often employed by the more advanced model railwayman. Where the latter's concern is chiefly railway operation, and he desires accuracy of visible detail both in the track and rolling stock, then the spring motor has many advantages. The railway should be designed to suit the length of run at one winding.

The modern mechanism can be supplied with reversing gear, brakes, and speed changes. Within recent years a variable speed governor on the lines of the gramophone governor has been applied to the better quality motors. A means of reversing from the track is usually fitted, but it is rather a clumsy device not recommended except for the small four-wheeled shunting engine, a type of model for which the arrangement was first introduced. However, although the trip-gear is provided on the locomotive, the reverser need not be used, as special trigger rails are required to operate the mechanism. Clockwork locomotives should not be run with the wheels spinning in the air, nor should the engine be left wound up for indefinite periods after use. The gears should be kept quite clean, washed occasionally with paraffin, and lubricated frequently though not copiously with a light sewing machine or cycle oil.

Spring motors were at one time fitted to model engines as large as 2½ in. gauge, but the tendency now is to limit the use of this motive power to gauge No. 0 (1¼ in.) and gauge No. 00 (⅝ in.) locomotives.

MODEL RAILWAY SYSTEMS IN GENERAL USE

Gauge No. 00 (⅝ in.).

Scale, 4 mm. to the foot; 1/76 th. full size.

Rather small for average model maker; allows for a complete railway system in small room. Rolling stock and track parts obtainable in various styles. Locomotives, except for two or three designs of a very cheap kind, rather more expensive than No. 0 gauge models.

Gauge No. 0 (1¼ in.).

Scale 7 mm. to 1 foot; 1/44 th. full size.

Most popular gauge. Steam, electric and clockwork locomotives of all kinds and values readily obtainable. Almost every accessory necessary to a complete railway available. Recommended for electric and clockwork operation.

Gauge No. 1 (1¾ in.).

Scale 10 mm. to 1 foot; 1/30 th full size.

Somewhat larger than No. 0 gauge but quite as satisfactory. This gauge is recommended for steam models.

Gauge 2½ in. ("Half-inch" scale).

Actual scale 17/32 in. to 1 foot; approx, 1/23 rd full size.

Smallest outdoor gauge that can be recommended. Suited to locomotives of the "engineer made" type. Smallest practical size for coal and charcoal fired boilers.

Gauges 3½ in., 4¾ in., and 5 in.

¾ in. scale and 1 in. scale.

Standard gauges used in making locomotives of an engineering character, without regard to the tracks on which they may run. Used for passenger hauling at Model Railway club exhibitions.

Gauges 6 in., 7¼ in., 9½ in., and 15 in.

Scales 1¼ in., 1½ in., 2 in., and 3¼ in. to the foot.

Gauges suitable for garden, estate and pleasure ground railways. Operated with locos, working by steam or internal combustion engines.

Steam Models. The steam loco, as a working model depends for its success on the provision of a satisfactory fire to turn the water in the boiler into steam at sufficient pressure. There are practical reasons against making scale models of any type of locomotive in the gauge No. 0 size to work by steam power. The larger engines—those of American proportions more particularly—are quite easily modelled, and if the boilers are raised up, without regard to scale, to give more room for the flame of the lamp, it is possible to make a small type of locomotive steam well. Of course, a small boiler means a short length of run.

All successful No. 0 gauge model steam locomotives are fired with methylated spirit burned in a special form of vaporising lamp. The pilot wick vaporises the fuel and keeps the lamp alight. As a rule plain cylindrical boilers with the flame underneath are employed in conjunction with these vaporising lamps. The same system is also used for No. 1 gauge models, and as the boilers of these locomotives have a more generous capacity, the length of run can be increased from 20 minutes in a gauge No. 0 scale model to 40 minutes in a similar gauge No. 1 engine.

The steam pressures used are somewhat low, varying from 15 to 25 lb. per sq. inch. This allows thin plates to be safely used in the construction of the boilers, increasing incidentally the value of the surfaces heated by the lamp. The cylinders are usually of the piston valve type, and work with very little frictional loss. There is no packing of any kind, and therefore pressures used must be comparatively low. Care is required in lubricating the cylinders and valves, and the oil should be of the proper type and grade recommended by the makers, quite free from dirt and grit. Friction must be kept at the minimum, so that the low boiler pressure can be used with effect.

Spirit reservoirs are usually proportioned so that the fuel is exhausted before the water in the boiler reaches a dangerously low limit. The safety valve should be examined each time the engine is used to see that it has not stuck up during the period of disuse. Reversing is usually arranged by a change-over valve, worked from the cab, which commutates the directions of the “live” and “exhaust” steams.

RAINPROOF CLOTH. Oilskin or mackintosh cloth is needed to resist really heavy wettings, but the treatment which makes it waterproof closes up the pores of the fabric. Rainproof cloth, while fairly resistant to ordinary showers, is just as well ventilated as un-waterproofed fabrics. Cottons, woollens, and silks can all be rainproofed, and, although principally employed to make raincoats, they can be used for ordinary suits and dresses.

The processes used affect only in an imperceptible degree the appearance, touch, and colour of the article. These processes cannot, however, be attempted at home without inviting disappointment and courting risks. The goods need first to be prepared and to have all grease removed, and the most efficacious results are obtained from a combination of chemical and mechanical methods. The cloth is best impregnated with a chemical (acetate of alumina), and this, unless properly done, may spoil the colour.

The goods are then dried and given an infinitesimally fine film of wax, and it is important to have the right mixture of waxes. The wax may be rubbed on dry, when it is almost impossible to avoid the production of shiny streaks; or be applied in a melted state, for which purpose a trace of wax is laid on by means of a metal roller; or the wax may be dissolved, e.g. in petrol, into which the cloth is dipped.

A rainproof coat when wet is best dried near a fire. Mackintoshes are spoiled by heat; rainproofs are benefited, if not placed too close.

RAINWATER: Domestic Uses. The collection and storage of rainwater is important, especially in the case of any country house that depends upon a well for its water supply. Care has often to be exercised in the consumption of the drinking supply, owing to the well or other source of supply

being low during prolonged dry weather. In this case it is a great boon to have a good supply of fairly clean rainwater. Rainwater has the advantage of being soft, and is therefore very effective for washing purposes.

The uses to which the rainwater can be put depend upon the condition of the water itself. If it is stored in a clean tank or cistern, and properly filtered, it can be used for almost any purpose in emergency, even for drinking, if first boiled. As so much depends upon the state of the water, it is worth while to see that it is caught and stored in clean tanks where it will not be greatly affected by the surroundings. The rain will wash dirt off the roof, making the water in the collection tank dirty. To overcome this trouble, an apparatus known as a "rainwater separator" may be used. The action is for the first foul washings of the roof to be turned away to waste, only allowing the cleaner portion of the rainfall to be stored. The apparatus is automatic in action, and the area of the roof governs the size of the separator.

In many cases it is almost essential to filter the water before it is used for any domestic purposes, this being done by connecting the collection tank by means of a pipe to a modern filter. If the collection tank is in an exposed position the top should be covered by a wire gauze, of as fine a mesh as possible; this prevents small sticks and the like from finding their way into the tank. If the tank is placed near the roof an overflow should be made, flowing to another tank or water butt, on the ground level or other convenient position. If this is not done, and the roof tank should overflow after a heavy rain, the interior of the house would probably suffer.

It is sometimes difficult to place a single tank so that it collects the whole of the rainwater, as the gutters cannot all slope in the same direction. For this reason water butts or tanks should be placed at the various down pipes, while it is sometimes possible to lead some of the water to an underground tank and then pump it out by means of an ordinary hand pump, as required. The diagram shows how a large underground tank can be built of brick and rendered in cement. The rainwater passes first through a filter bed containing clean washed gravel and coke.

Rainwater. Sectional view of underground tank and filter bed, showing how the water is purified in clean washed gravel and coke, before being delivered into the cement lined storage tank.

RAISIN: In Cookery. The dried fruit of the grape vine known as the raisin is extensively used in cookery. Muscatel raisins, which are dried on the vines, are considered to be the best, and, together with almonds, are often used as a dessert fruit. Sultana raisins are prepared from a special seedless grape.

Raisins should always be cleaned before use. The simplest way of doing this is to rub them on top of a sieve with a tablespoonful of flour, but if they are very dirty they may be washed in the same way as currants.

Before raisins are mixed with other ingredients, the stalks should be carefully removed, and the stones taken out with a fruit-stoning machine, if available. Raisins are usually cut into small pieces. A little butter rubbed on both sides of a knife will prevent the fruit from sticking to it; if a food chopper is used, a few drops of lemon juice should be added instead. Raisins can be bought ready stoned.

Raisin and Apple Pie. Raisins and apples together make the following excellent pie. Wash and stone $\frac{1}{2}$ lb. raisins, leave them to soak in a basin of cold water for a few hours, and then peel 1 lb. apples, cut them into thick slices, and remove the cores. Strain off the water from the raisins, reserving it; stand a funnel in the centre of a pie-dish, and fill the latter with the raisins and apple mixed together, a few slices of thinly pared lemon rind, and 3 oz. Demerara sugar.

Add about a gill of the water in which the raisins were soaked. Make 6 oz. flaky pastry, roll it out to a thickness of $\frac{1}{4}$ in., and cut from it a piece large enough to cover the top of the pie and some narrow strips for the edges. Damp the edges of the dish, put on the strips, damp these also, and then lay on the top covering. Trim the edges, brush over the top with milk, and bake the pie in a hot oven for about $\frac{1}{2}$ hour, or until the pastry is lightly browned and the fruit cooked. Serve it dusted with castor sugar.

Raisin Batter. To make this steamed pudding, add 4 oz. prepared raisins to an ordinary batter pudding mixture. Decorate a greased mould with a few raisins, and pour in the mixture. Cover with greased paper and a floured pudding-cloth, and steam it for about 2 hours.

Raisin Batter. A wholesome, steamed pudding appreciated in the nursery.

Raisin Chutney. Chutney made from equal quantities of apple and raisins can be prepared thus: Peel and cut 1 lb. apples and half that quantity of shallots into dice, mix them with 1 lb. stoned raisins, $\frac{3}{4}$ lb. brown sugar, 2 oz. salt, $\frac{1}{2}$ oz. mustard seed, $\frac{3}{4}$ pint vinegar, and cayenne to taste. Simmer them gently in a pan over the fire for about $1\frac{1}{2}$ hours, then put the mixture into a dry jar or bottle and tie it down when cold.

Raisin Dumpling. Add 6 oz. prepared raisins to ordinary suet dumpling mixture, divide it into small even-sized portions, and roll these into balls on a floured pastry-board. Cook them rapidly in a saucepan of boiling water for about $\frac{1}{2}$ hour, or until they rise to the surface of the water, then take them out and serve them with sugar, and, if liked, some custard sauce.

Raisin Wine. Boil together 6 lb. raisins and 6 gallons water, and when the fruit is soft rub it through a sieve so as to remove the stones. Then put the pulp back into the pan, pour it, with the water, over the sugar, and add $\frac{1}{2}$ pint dried yeast spread on toast. Leave the mixture to ferment, and when fermentation has almost ceased, put in 2 quarts of elder flowers tied in a muslin bag, taking them out again when the wine is sufficiently flavoured. Bottling may be done as soon as the wine is clear. See Batter; Dumpling; Pastry; Sultana.

RAISING PLATE. The name is given to a small beam which rests upon the tie beams in a roof for the purpose of supporting the lower ends of the common rafters. The expression is also applied in some districts to the pole plate, or wall plate.

The general purpose of this timber is to raise the rafters above the level of the brickwork composing the wall so that air can circulate around it. Another function is to tie the ends of the rafters together and also to distribute the load by spreading it over a large area. *See* Rafter; Roof.

RAKE. The garden tool named a rake is used for covering in newly sown seed, dragging out surface weeds from beds and borders, for tidying top soil, and as an implement to separate corks and stones from fine earth. Rakes with steel-toothed heads about 12 in. long are both efficient for open-ground work; but for flower-bed raking and dressing, tools of half that length are more suitable. A wooden-toothed rake is useful for levelling large areas. *See* Casting; Gardening; Nail.

Ram. Fig. 1. Diagram illustrating principle of hydraulic ram. Fig. 2. Small hydraulic ram suitable for working falls from 3-10 ft.

RAM: For Raising Water. The hydraulic ram utilizes the momentum of a volume of moving water to force a portion of the water to a higher level than that of the original head. The principle is illustrated in Fig. 1. Water falls from the reservoir through pipe A to a ram chamber having a valve V^1 . The delivery valve V^2 is kept closed while V^1 is open, owing to the greater pressure of water in the delivery pipe. When the velocity of the water escaping past V^1 through the holes O O reaches a certain figure this valve is suddenly forced up against its seating, and the trapped water opens V^2 and enters the delivery pipe until its momentum is expended. Then V^2 closes, and V^1 opens again, the cycle of

operations continuing as long as water is supplied with sufficient head to pipe A. The greater the lift, the smaller is the proportion of the water forced into the delivery pipe.

As a guide, it may be taken that the quantity, D, delivered will be equal to half the quantity (F) that enters the ram chamber multiplied by (W : Y) in feet, where W = the working fall and Y = the total lift from the ram. Thus if the working fall be 10 ft. and the delivery head 100 ft., and F = 200 gal. per minute, then $D = (200 : 2) \times (10 : 100)$ gal. per minute.

The ram illustrated in Fig. 2 is suitable for working falls from 3 ft. to 10 ft., with delivery up to a height of 100 ft. This latter figure does not take into account losses due to friction, which virtually increase the delivery head and diminish the practicable height to which water can be raised. *See Pump; Water Supply.*

RAMBLER: The Rose. This term is applied to vigorous climbing roses chiefly of two types, those raised from *Rosa multiflora* and others raised from *Rosa wichuraiana*. The multiflora ramblers are rather less rampant than those of the wichuraiana type; favourite varieties are Blush Rambler, Goldfinch, Pemberton's White Rambler, Tausendschon, Tea Rambler, and Violetta and Veilchenblau (the so-called blue roses). All these are suitable for covering poles, pillars and arches. Some of the best ramblers of the wichuraiana type are Alberic Barbier, American Pillar, Aviateur Blériot, Chatillon Rambler, Pink Climber, Dorothy Perkins, Dr. Van Fleet, Emily Gray, Fraicheur, Hiawatha, Sander's White, Scarlet Climber and Thelma. These are suitable for covering arches, arbours and trellis. *See Rose.*

RAMMER. An earth rammer is used to consolidate the surface of the ground when making a path, or after erecting a post. A heavy wooden rammer is employed when setting paving stones or cobbles. It measures about 3 ft. in height and 8 or 9 in. in diameter, tapering towards the top, where it is furnished with a single hand grip. A second grip is fitted at right angles about halfway down, and the lower end, or head, is shod with hoops to prevent it splitting.

A rammer with an iron head is handy in the garden and costs little. The shaft is about 5 ft. long, and the head may be from about 7 lb. to 10 lb. in weight and either circular or rectangular in shape. A head which is not too heavy should be selected. In use the shaft is grasped between both hands, raised about a foot off the ground, and driven downward with a throwing action. For lighter work the rammer is held firmly in the hands, and the ramming is effected rather more by pressing or pushing the earth downwards.

RAMONDIA. This is a charming rock garden plant with a rosette of large leaves; it bears pretty purplish flowers in early summer. The best are *Heldreichii*, lavender blue; *pyrenaica*, violet purple; and *Nathalide*, purple. *Ramondia* must be planted flat against a shady rock with its roots in a crevice filled with a compost of loam, peat (or leaf-soil) and sand. Propagation is by sowing seeds or by division in late summer.

RAMPION. This is the common name of *phyteuma*, a genus of hardy plants belonging to the bellflower family. They thrive in well drained gritty soil in the rock garden. Some of the best are *canescens*, lavender blue; *comosa*, blue and white; and *orbiculare*, purplish: they are increased by division in spring. The dense clusters of bloom on rather short stalks give these plants a bizarre appearance.

RANCIDITY. A chemical change which is termed rancidity takes place in fats or oils when exposed to unfavourable conditions of the atmosphere, or kept too long without proper preservation. This change produces a most disagreeable taste and smell, and renders them unfit for food.

Butter particularly has a tendency to become rancid, and this tendency is increased if it is made up without the addition, or the very scanty addition, of salt. But once butter has acquired a rancid taste it is not possible to restore it completely, though it can be much improved. Wash it well and melt it slowly over the fire, skimming it from time to time; then strain it and let it cool. Sometimes butter which is actually fresh possesses a rancid flavour; this is due often to uneven churning or neglect to extract all the buttermilk.

Both olive and almond oil have a tendency to become rancid. Neither of these should be kept too long, and never in a very warm place; the bottles must be well corked. Fish oil quickly acquires a rank, unpleasant taste. *See Butter; Fat; Food; Oil; Suet, etc.*

RANDIA. This is the name of the plant from which Indian ink is made. It is a hothouse, evergreen flowering shrub with white or yellow fragrant blossoms, borne in spring. The soil required is a mixture of loam, peat, and charcoal, and the temperature should average not less than 60°. Propagation is by cuttings taken in the spring.

RANGES FOR LARGE AND SMALL HOUSES

Advice on Choosing and Fixing this Adjunct to the Kitchen

Articles related to the one below include those on Anthracite Stove; Coal; Fuel. *See also* Boiler; Central Heating; Kitchen; Oven, Etc.

The older type of kitchen range earned for itself an unenviable reputation, consuming as it did large quantities of fuel; often with poor and variable results. The cause was generally to be found in badly designed or inefficiently built flues; open fires and badly constructed fire grates; the absence of proper means of draught regulation; the absence of insulation from the front and sides; the lack of a highly polished top, and in the design and placing of the hot-water boiler. These defects are overcome in modern types of kitchen range, which are scientifically designed and provided with various fuel and labour-saving devices.

Range. Fig. 1. Small portable range, very easy to work. (Smith & Wellstood, Ltd.)

Instead of supplying merely the working portion of the range and leaving the flue to be built up in brickwork by the builder, the stove manufacturers provide iron flues, which can be filled around with brickwork when the range is being fitted into the house. The design of a flue is the work of a specialist just as much as the design of the regulation of the air to the fire. Too small a flue will give an ineffective draught, as will unnecessary projections, sharp angles or cracks in the flue itself. Too large a flue will cause much of the heat given out by the fire to be lost up the chimney. A badly constructed flue may give rise to back draughts, causing the smoke to be blown out into the kitchen.

Well designed ranges are by no means expensive, and the purchaser should not be satisfied with just what the builder cares to supply, but should take the trouble to enquire of one or two manufacturers, stating the duty required of the range and the approximate amount he wishes to spend on it. If there is enough cooking to keep the range going during the cold weather, some stoves can be made to give a plentiful supply of hot water for baths and other domestic uses, but it must not be supposed that this will be obtained without an extra consumption of fuel, over and above that normally entailed in cooking.

Range. Fig. 2. Larger type, with high-pressure boiler and hot closet. Fig. 3. Single-oven range of conventional pattern, having enamelled base and tiled upper part. Fig. 4. Cooking stove which stands out and permits of side lighting. Fig. 5. Heat storage cooker which can be fitted with a boiler unit. (Photos, Smith & Wellstood, Ltd.)

In the warmer months, when the range is required only at intervals for heavy duty, recourse can be had to the gas cooker which is generally installed in most houses as a matter of course. The problem of hot water supplies can be overcome by the use of a gas or electric circulator, this being brought into operation during the time that the range is out of use.

When a boiler and a gas cooker are fitted in the kitchen it is often a convenience to install a small portable range in the scullery. Fig. 1 shows an efficient and inexpensive range obtainable in quite small sizes, varying from 24 in. wide to 42 in. wide to suit different kitchens. This range can be obtained with enamel finish at an extra charge.

Fig. 2 illustrates a larger range of the same type, with a plate rack above, and fitted with a high pressure hot-water boiler. A useful hot closet can be provided in the skirting underneath. When the cooking requirements are greater there are two types of range which can be considered, the one (Fig. 3) following conventional lines and the other, (with glass and steel canopy), an approach to a pattern favoured on the Continent, where the stove stands out in the kitchen, thus getting sidelight and permitting access to the side of the range. In the latter an L-shaped boiler is fitted enclosing three sides of the fire-box and thus having a high degree of efficiency.

The single oven range shown in Fig. 3 is made in sizes to suit a recess from 36 in. to 54 in. wide. The back and sides are tiled, and the base is enamelled. The type of boiler fitted depends on the quantity of water required to be heated, and the least powerful will deal with a 20 gal. cylinder. The bigger boilers are somewhat expensive, and run into as much as a small independent boiler. It is generally better, when the hot water requirements are large, to install a separate coke-fired boiler for the purpose.

An Oil-Fired Range. A larger range is the kind which includes two ovens and also a glass and steel canopy. These may be conveniently arranged for oil firing, a method quite practicable with stoves of this magnitude, though it involves some considerable outlay on the oil burner plant, storage tank, etc. Such a system generally makes use of a trough shaped horizontal burner. The oil is fed by gravity at the bottom of the trough, and the air necessary for combustion is supplied at low pressure from a blower. The same pattern of range is available for coal firing.

Heat Storage Cookers. These are quite a recent introduction and are becoming very popular owing to the economy, cleanliness and ease of working. The construction is on the lines of the old hay box principle, the cooker itself being embedded in thick insulating material within an enamelled outer casing, and in consequence (unlike the ordinary range) practically none of the heat is wasted. The heat is conducted from the fire-box to the various parts of the cooker by means of heavy castings and the ovens are of different temperatures for the various classes of food to be cooked. Boiling operations are carried out on the boiling hotplate, which when not in use is insulated by the asbestos bolster. The consumption is exceedingly low, from $\frac{3}{4}$ cwt. anthracite per week, according to the size, and the cookers can be supplied to suit from the smallest household to any large establishment. Fires are alight continuously and the flue and chimney cleaning is reduced to the minimum because anthracite is smokeless. Some models can be fitted with a boiler unit to give necessary hot water for domestic purposes. Under the heading Range may also be included the popular "Aga" cooker, for details of which see Cooker.

Range. Fig. 6. Combination stove which cooks, heats bath water, and warms the room. (Smith & Wellstood, Ltd.)

The Fuel to Use. Some of the combination appliances are specially designed for burning anthracite and coke, with which they give very good results, but in most ranges a good long-flame coal is the best fuel, as the flames are extremely useful in heating the oven. The advice of the maker should be

taken as to the most suitable fuel. Where kitchen coal, nuts or cobbles are recommended, care should be exercised to find hot, free-burning, clean coals which are well sized.

When lighting the fire, wood or paper or a firelighter should be employed in the ordinary way, care being taken to allow air to pass through freely from below. Coal and cinders from the previous day's fire should be built up lightly above the wood, and when combustion is well established further coal may be added. The dampers should be adjusted according to whether heat is required first for hot water or cooking purposes. Much time will be saved if care is taken to use only paper and wood which are thoroughly dry, and it will assist matters greatly if the coal has been kept in a dry place. Trouble is sometimes experienced in lighting a fire, owing to the flues being cold, in which case wood should be burned freely for a short time in order to warm up the range.

It is not advisable to allow a fire to become too low; but if this has been done, only a very small quantity of fuel should be added to the dull fire. The fire should then be raked, the draught opened, and when the fire is burning more briskly fresh fuel added, due care being taken not to put on too much at a time.

In those ranges which depend to a great extent upon flame for heating the oven and boiler, the fire should be stoked at the time when oven or boiler heating is required, so that full advantage may be taken of the flame produced in the early stages of combustion.

RANUNCULUS. Some of the worst garden weeds as well as many beautiful hardy flowering plants are contained in this genus. The weeds are the various wild buttercups, of which the most troublesome is the common buttercup (*Ranunculus acris*). Fair Maids of France (*Aconitifolius florepleno*), which bears small double white flowers on stems 20 in. high in May is a charming plant for moist soil: it is happy by the waterside or in the bog garden. *Amplexicaulis*, 10 in., with grey leaves and white flowers, and *lingua*, 2 ft., yellow flowers in summer, are also good plants for moist soil.

Several alpine buttercups are delightful flowering plants for the rock garden; the best of them are *montanus*, yellow; *alpestris*, *glacialis* and *parnassifolius*, with white flowers in early summer: they need well drained gritty, loamy soil and slight shade.

There are some brilliantly coloured flowers among the florists' varieties of tuberous rooted ranunculus of which there are various types—French, Turban and Persian: the double Turban varieties are very handsome. The tubers should be planted, claws downwards, in early autumn or in February-March in well-drained soil with which sand has been mixed freely, if necessary: they should be set about 2 in. deep. It is wise to protect the bed with bracken or evergreen branches in severe weather and to lift and store the roots after the leaves have died down. *See Bachelor's Button.*

Ranunculus. Bright gold flowers of an attractive little plant for a shrubbery or rock garden.

RAPE. Rape is the popular name of a salad vegetable, *Brassica napus*, which is usually grown and sold as mustard in the mixture of mustard and cress. Cultivation is the same as for mustard. When used as mustard in mustard and cress the proportions of seed to be used should be as two of rape to one of cress in bulk. If sown thickly on vacant ground and dug in when a few inches high, rape makes an excellent green manure. *See Cress; Mustard.*

RASH. An eruption on the skin or the mucous membranes is popularly called a rash. It may consist of redness, pimples, blisters, pustules, or mixtures of these. Most of the infectious diseases have characteristic rashes, which observe a fairly constant rule with regard to the time of their appearance in the course of a particular disease. They may be summarised thus The usual day of appearance:

First day: erysipelas, chicken-pox, rubella or German measles (may be on second or third day).

Second day: scarlet fever.

Third or fourth day: small-pox; the fourth, measles.

Fifth day: typhus.

Eighth or ninth day: typhoid fever.

The distribution of the rash: Erysipelas, unless there is a wound, on the bridge of the nose and the cheeks usually. Chicken-pox, over the body and in the mouth. German measles, the face and neck, then over the trunk and limbs. Scarlet fever, the neck and chest, then over the body. Small-pox, the forehead and wrists, then over the body. Measles, the forehead, face, neck, fauces, and over the body. Typhus, the abdomen, then over the body. Typhoid, the abdomen, back, chest and elsewhere.

A rash may also be due to poisons, either those formed within the body in digestive and other disorders, or those which are introduced into the body; and a rash often follows the use of antitoxic sera.

RASP: Its Uses. A rasp is a kind of rough file used for shaping wood and other comparatively soft material. Amongst many varieties the ordinary pattern is that known as the half-round, one side being flat and the other semicircular in cross section. Rasps are also obtainable flat, circular and square in cross section.

A cabinet rasp is a half-round rasp with rather finer teeth than the ordinary kind. The rougher types are employed for primary shaping and the cabinet rasps for further finishing the wood.

RASPBERRY AND RASPBERRY DISHES

Success in Growing the Fruit and its Table Uses

The following article follows our usual plan. The growing of the bush is first described and information given about diseases and pests that attack it. Then come details about preparing raspberries in various ways for the table.

Rich soil is essential to the successful cultivation of the raspberry, an invaluable hardy bush fruit. Before the canes are put in, the ground ought to be dug deeply and manured. A mulch or top dressing of manure in spring is also advised. Every 3 years basic slag, 4 oz. to the square yard of ground, should be applied in autumn. The plants ought to be 2 ft. apart in rows 5 ft. from each other. In spring the canes of newly planted raspberries should be cut down to within about 6 in. of the ground to force the development of fresh strong shoots which will bear fruits the following year. No further pruning is needed until after the fruits are gathered. The old canes ought then to be cut right out and a limited number of new ones, five or six on each plant, ought to be tied to the support. Similar pruning should be done every year when the fruits are over. Early in the summer numerous fresh shoots or suckers will develop, but those in excess of the number required should be pulled up. They may if necessary be transplanted to form a fresh plantation.

Some of the best red varieties of summer fruiting raspberries are undoubtedly Norfolk Giant, Pyne's Royal and Red Cross. Lloyd George is called a perpetual-fruiting variety because it bears fruit in autumn as well as in summer. It is pruned in the way described above. Yellow Antwerp is one of the best yellow raspberries.

Autumn fruiting raspberries, which bear crops in September and October, need quite different pruning from the summer fruiting raspberries. All the canes must be cut almost to the ground in spring, for the fruits will be produced by the fresh shoots. Good varieties are Hailsham, October Red and November Abundance. If required for jam or for cooking purposes, raspberries should be gathered as soon as they come readily off the cane, just in advance of perfect ripeness. Choice raspberries intended for dessert should be picked with the stalks just before they are ripe enough to drop off.

Raspberry. Left. Large and luscious berries of the Perfection variety, a favourite kind with fruit growers. Right. Perpetual fruiting variety known as Lloyd George.

Raspberry Pests. The chief pests which damage this fruit are the raspberry beetle, raspberry weevil and the caterpillars of the raspberry moth.

The raspberry beetle makes its appearance during early summer and begins to attack flowers and flower buds, any blossoms left to mature as fruit being devoured in due course by its hungry, voracious larva. The latter result occurs because during flowering time the female deposits eggs near blossoms, out of which the young grubs hatch and feed upon the raspberries. When fruiting ends, the full-fed maggots pupate in some crack of stem or bark, remaining in the pupal state until they again emerge as beetles.

One remedy is dusting with derris powder before the flower buds open. Another is shaking of canes over paper smeared with a sticky substance, the whole then being burnt. In addition an autumn soil fumigant of 1 part naphthaline to 10 parts fine coal ash should be forked in.

The raspberry weevil is difficult to deal with, because of its nocturnal habits. It must be sought at night-time while engaged in feeding, when all affected shoots must be well shaken over a board smeared with tar or with some similarly sticky substance.

Activity of the raspberry weevil is generally evident by badly eaten foliage, appearing without the presence of insects during daytime. Soil fumigation with a recognized preparation during late autumn is a good remedy, also spraying with lead arsenate before any of the canes fruit. A more homely remedy consists of ashes soaked in paraffin and sprinkled round the plants. The weevil hides in the soil during the day.

Raspberry Cultivation. 1. Soil preparation: a, well-dug bottom soil; b, manure. 2. Planting up to old soil mark: a, firm soil. 3. Maiden cut down (a) after planting. 4. The result. 5 and 6. Theory of pruning: a, removal of tips encourages tip fruit only; a, b, and c graded pruning, the best method. 7. Planting too close. 8. How to train a clump. 9. Training on wires: a, old canes cut out.

Raspberry Moth. The raspberry moth is sometimes a serious pest. If an infected plantation be examined early in May it will be seen that many young shoots have withered owing to the attacks of the small red caterpillars of this moth, which bore their way into the shoots. The remedies are to keep the ground clean, free from rubbish, weeds, old sticks, etc., and to spray the raspberry canes in winter with paraffin emulsion. A further remedy that will be found effective in destroying the raspberry moth is to spray late in March with lime wash made by using 12 lb. of quicklime in 10 gallons of water.

Raspberry Moth, an injurious insect pest which attacks the young shoots. Below is seen the larval form of the insect. (By permission of the Ministry of Agriculture and H.M. Stationery Office)

Raspberry Sawfly. The larvae of the pest called the raspberry sawfly feed upon the pith and cause the canes to shrivel. Caterpillars are about $\frac{1}{2}$ in. long and may be identified by their colouring of insipid green. The only remedies are burning of canes containing grubs and spraying with lead

arsenate paste during the late autumn. The paste should be purchased ready mixed, and used in the proportion of 4 oz. to 5 gallons of water. The mixture is very poisonous.

How to Cook. If required for jam or for cooking purposes, raspberries should be gathered as soon as they come readily off the cane, just in advance of perfect ripeness. Choice raspberries intended for dessert should be picked with the stalks just before they are ripe enough to drop off. Discard any damaged berries and place the others in a glass or china fruit dish. Castor sugar may be sprinkled over them a little while before they are to be served, or it may be handed round at the table. Like strawberries, raspberries may also be served with castor sugar and cream. Raspberries are mixed with red currants for stewing or for making into pies and tarts or for jam. With bananas, raspberries can be made into a good fruit purée.

Raspberry Jam. To every lb. of fruit used in making raspberry jam, 1 lb. sugar should be allowed. Pick over the raspberries, and put them into a preserving pan with the sugar; cook them very slowly, and keep them well stirred until the sugar has dissolved. Then bring the whole to the boil, and continue boiling for about one hour or until the jam sets when tested on a cold plate.

Raspberry Jelly. A very good raspberry and claret jelly can be made as follows: Boil up $\frac{1}{2}$ pint raspberries, $\frac{3}{4}$ pint claret, $\frac{1}{4}$ pint lemon juice, 4 oz. sugar, the rind of a lemon, two cloves, and $2\frac{1}{2}$ oz. melted leaf gelatine. Strain the whole through muslin, and then pour a little of it into a wet mould.

When it sets, decorate it with some chopped pistachio nuts, cover these with a little more jelly, and let this set also. Then pour in what remains and put the mould in a cool place. When its contents are set, turn them into a glass dish and it will be ready to serve.

Raspberry Pudding. A raspberry pudding, in which red currants also are used, is made thus: Line the edges of a deep dish with a strip of short-crust pastry, and into the dish put 1 pint raspberries and half that quantity red currants. Sprinkle over them 2 oz. castor sugar; then beat up the yolks of 3 eggs, add to them another 2 oz. sugar, and lastly stir in lightly the stiffly whisked the custard over the fruit, whites. Pour and bake the pudding in a moderate oven until it is set.

Raspberry Trifle. Spread $\frac{1}{2}$ lb. raspberries on a large dish, sprinkle them with castor sugar, and leave them for about $\frac{1}{2}$ hour, mixing with them 3 mashed bananas. Split 6 small sponge cakes, spread the cut sides with raspberry jam, then arrange them tastefully in a glass dish and soak them, first with 1 gill hot milk and then with $\frac{1}{2}$ gill sherry.

Make a pint of thick, vanilla-flavoured custard, and leave it to cool, and when the sugar has well soaked the fruit, pile the latter in small heaps on the sponge cakes. Pour the custard over them, stand the trifle in a cool place, and then decorate the top with 1 gill whisked cream, sweetened and flavoured with vanilla and garnished with chopped pistachio nuts and raspberries.

Raspberry Trifle. A very delicious fruit trifle made with fresh fruit.

Raspberry Vinegar. This fruit vinegar is made by putting $1\frac{1}{2}$ lb. raspberries into a jar, covering them with 1 pint white wine vinegar, and letting them stand for 10 days. Stir them daily, then strain off and measure the liquid, allowing 1 lb. cane sugar to every pint. Boil the vinegar and sugar

together for about 10 min., taking the scum from the top, and let the whole cool before bottling it. It should be kept in a cool place.

Raspberry Wine. This wine is made by putting 6 quarts ripe raspberries into an earthenware vessel, bruising them well with a heavy wooden spoon and then pouring over them 6 quarts cold water. Let them stand until the following day, stirring them frequently, then strain the liquor through a fine hair sieve, draining the fruit thoroughly.

To each quart of liquor add 1 lb. lump sugar; stir the whole occasionally until the sugar is dissolved, and then turn it into a cask. Bung the latter loosely for several days until fermentation ceases, then tighten the bung and let it remain thus for 3 months. The wine may then be bottled for use.

RASPBERRY BUN. For this bun take 1¼ lb. flour, 8 oz. margarine or butter, 2 eggs, a pinch of salt, ½ lb. sugar, 2 teaspoonfuls baking powder, some raspberry jam, and some milk. Rub the margarine into the flour, add the dry ingredients, the eggs (beaten) and sufficient milk to make a stiff paste. Make into about 24 buns, and place them on a well-greased baking sheet. Make a hole in the top of each, and put in a little raspberry jam, pinching the dough together about it. Bake them in a hot oven for about 15 min. *See Bun; Coconut Cake; Rock Bun.*

RASPBERRY GÂTEAU. This rich sweet can be made by sieving together 6 oz. flour, 2 oz. cornflour, half teaspoonful baking powder, and a pinch of salt. Rub into them ¼ lb. butter, then stir in 1 oz. castor sugar, and mix the whole to a stiff but pliable paste, with the yolks of 2 eggs, adding milk as required. Roll the paste out to a round shape about an inch thick, line a deep, greased sandwich tin with it, brush it over with milk, and bake for 20 min. in a brisk oven.

Raspberry Gâteau. A rich sweet suitable for serving at parties.

Let it cool on a sieve, then split it into halves, and spread the inner sides with raspberry jam, fitting the two pieces together again. Whisk the whites of the 2 eggs to a stiff froth, fold into them ¼ lb. castor sugar and what remains from ½ lb. raspberry jam, and add a few drops of cochineal. Shake the mixture on top of the cake in small heaps, put the cake back into the oven so that the meringue may set, and sprinkle over it a few blanched and chopped pistachio nuts.

RASPBERRY SHORTCAKE. For this cake take ½ lb. flour, 3½ oz. butter, 2 oz. lard, ½ teaspoonful baking powder, a pinch of salt, teaspoonful lemon juice, and an egg. Sift the flour, baking powder, and salt into a basin, then rub in the fat lightly with the tips of the fingers. Beat the egg, pour it into the centre of the flour, add the lemon juice, and mix all into a firm dough. Knead it thoroughly and divide it into two portions, and roll these portions into two rounds about ¾ in thick and 8 in. across.

The paste must not be rolled out more than once, so it must be shaped during the rolling. Lay one round in a cake ring, brush the top with oiled butter, and place the other round lightly over it. Bake these in a moderately quick oven from 15 to 20 min. and let the cake cool. Strain the juice from a bottle of raspberries and make the fruit into a purée. Cream 2 oz. fresh butter, and add 4 oz. icing sugar and the raspberry purée. Split the shortcake in half, and arrange a layer of the filling between the two halves and garnish the top with the remainder of the mixture and whipped cream. Put the shortcake into a dish, make a syrup with the raspberry juice and pour it round.

RAT: How to Destroy. There are no more unwelcome visitors to a house than rats, which not only raid the larder but do much damage to property and are notorious carriers of disease.

The two kinds of rats found in Great Britain are the black and the brown rat. The former has increased rapidly in numbers during recent years, and is well known as a carrier of the plague. It has a tail an inch longer than its body, which is about 7 or 8 in. long. The brown rat, which more commonly infests houses, is heavier in build and longer in body, with a shorter tail and a coarser fur, grey-brown above and white below.

The first intimation of the rat's arrival is very often the discovery of a biggish hole beside a garden path, generally near a dustbin or the back door. If a fox terrier or other dog is kept it will often be the first to give the alarm by scraping furiously at the hole. Very often the intruder has got inside the house undiscovered, and announces its presence by unmistakable gnawings and crunchings at the woodwork. It may have visited the larder during the night, and scraps of food dragged about the floor tell their own story. The rat is not usually to be detected by smell, although he is a confirmed scavenger and may have come straight out of drains that need overhauling. Where poultry are kept the presence of a rat is soon announced by feathers lying about; eggs begin to disappear and chickens, too, unless prompt measures are taken.

Preventive Measures. One of the first things to be done is to cut off all possible sources of food supply, for rats seldom remain in any place where they cannot easily obtain food for their young ones. The practice of leaving grain or other food lying about in poultry runs encourages their visitations, and the same remark applies to refuse allowed to accumulate in gardens or back yards instead of being put away in dustbins. Where the foundations of a house are concreted and the brickwork laid in cement the building is rendered to some extent rat-proof, and preventive measures of this kind, together with the use of galvanized iron sheeting, are particularly advisable for stables, granaries, and farm buildings.

Basement windows are protected by a covering of heavy galvanized wire netting of $\frac{1}{2}$ in. mesh. Burrows under floors from which rats have been driven should be tilled with concrete, broken glass, or crockery and cement. But the most important, as well as the least expensive, of all preventive measures is to cut off food supplies, particularly in the form of garbage, and see that the dustbin is properly covered, especially at night.

Use of Poison. So far as private houses are concerned, the two principal methods of destroying rats are by the use of poison and by traps. Various preparations containing phosphorus, strychnine or arsenic are sold everywhere by chemists, grocers, and oil merchants. Many of these are in the form of a paste, which is spread on some strong smelling food, such as a piece of kipper or bloaters, a scrap of bacon or cheese.

The bait thus prepared is placed far enough down the hole to be beyond the reach of cats and dogs as far as possible. A point to be noted in purchasing these rat poisons is that if they have been kept a long time in the tradesman's shop the virus may prove less effective, at least in its immediate results. This explains why rats have been known to consume repeated doses of poisoned food without apparently experiencing any ill effects, and other measures have had to be resorted to.

The greatest care should be exercised in keeping these poisons where neither children nor domestic pets can get at them, or where they might be mistaken for something else, with disastrous results. Children should be specially warned not to touch the tin or box containing the poison, which should either be put away on some high shelf, or preferably kept under lock and key. It is always a difficult matter to safeguard hens unless the poison can be placed outside the run, and even then there is the

risk of fowls getting out and being poisoned, while in addition birds have been known to pick up the poison and drop it inside the run.

Another Kind of Bait

A less dangerous variety of bait is provided by the use of either barium carbonate or red squill, as powder or liquid extract. An effective mixture of the first kind consists of one part each by weight of barium carbonate powder, grated cheese, dripping and fine oatmeal. The fat is melted and mixed with the dry ingredients into a thick paste. Two parts of rolled oats may be substituted for the cheese and oatmeal. A good red squill recipe is made up of 1 part of red squill, 2½ parts of fine oatmeal or rolled oats, and 1½ parts of dripping. Sugar is also used as an ingredient in rat poisons, another recipe consisting of 1 part of red squill and 2 parts each of fine oatmeal and castor sugar, which should be rubbed through a fine sieve and thoroughly mixed.

Liquid extract of red squill can be obtained from any chemist. The method of using it is to mix some of it with an equal quantity of cold milk that has been boiled, add sufficient bread to form a thick paste, and lay it in saucers or tin lids in places frequented by the rats. Should only the powdered form of red squill be available, it should be mixed with bread and milk in the proportion of 3 or 4 oz. to a pint of milk. Preparations containing red squill are probably the safest to use for poultry runs.

Another method of waging war on rats is by employing a scientifically prepared virus composed of cultures of microbes. The effect of such a poison is to infect the rat with intestinal disease, which is contracted by others. This method, however, is attended by a considerable element of uncertainty, and it has the grave objection that the infected rats become carriers of the disease, with serious risk to human beings. Fumigation with sulphur dioxide gas is resorted to in warehouses, etc., but is not advisable for houses.

Use of Traps. The oldest contrivance for killing rats is by means of a trap. The chief point in its favour is that it involves no such risks as accompany the laying down of poison about a house, and when properly baited and set it very often achieves its purpose when other methods have failed. The principal varieties include the wire trap in the form of a rectangular box, 1½ to 2 ft. in length, which opens with a powerful spring. The door of the trap is held open by a catch so as to afford access to a baited hook, and the slightest displacement of the hook, as when a rat enters and nibbles at the bait, releases the catch and closes the trap, leaving the rat a prisoner. Steel gins or toothed spring traps are in use, and also the ordinary spring trap which kills the rat when the spring is released. In the varnish or birdlime trap strong lithographic varnish is spread on a piece of cardboard about 15 in. by 12 in.

It sometimes happens that a rat, after eating the poisoned bait, goes to its nest and dies there, with the result that an offensive smell invades the house. In such cases a good deodorizer is found in chloride of zinc, which should be applied in the following manner:

A hole is bored as near as possible to the spot from which the evil odour is supposed to emanate. It may be necessary to use a brace and bit for this purpose. The chloride of zinc is dropped into the hole, which is then closed with a cork.

Legal Points. The legal side of the subject has been dealt with in several Acts of Parliament in recent years, as the necessity for destroying rats became more generally recognized. Under the Protection of Animals Act, 1911, restricting the use of poisons, it is a complete defence to a charge of contravening the Act that the poison was used to kill rats, provided all reasonable precautions were taken to safeguard domestic animals.

A more important change was made by the Rats and Mice (Destruction) Act, 1919, by which the occupier of land or buildings is bound to take all reasonable and necessary steps for the destruction of rats and mice, and in default is liable to a fine of £5, or £20 in a case where he was served with a notice under the Act.

RATAFIA: Its Uses. This name is given to a flavouring essence made from the kernels of certain fruits, as apricots and cherries. It has an almond-like flavour, and should be used only in small quantities, a few drops being sufficient for most purposes. It can be bought in small bottles from most grocery stores, but can also be made at home.

To prepare it, pound the stones from 2 lb. morello cherries, with 1 oz. blanched bitter almonds and a little brandy, then turn them into an earthenware jar, and pour over them four breakfastcupfuls good brandy. Cover the jar tightly, and let its contents stand for 1½ months, shaking them twice daily. Then strain them through a sieve lined with blotting-paper, and add 8 oz. or more of white sugar-candy previously dissolved in a gill of cold water. The liquor may then be bottled for use. The ingredients may be reduced provided that the same proportions are maintained.

Ratafia Biscuits. The ingredients for ratafia biscuits are ¼ lb. ground almonds, 7 oz. castor sugar, mixed well in a clean bowl into a paste with the whites of 3 large eggs, a few drops of ratafia essence and a squeeze of lemon juice. These ingredients should be added gradually. The paste is transferred to a bag, made with stiff paper or with canvas (cornet shape), and with the bottom aperture—made by cutting off the point with scissors—about ½ in. in diameter.

The little biscuits are then forced out by simple pressure on the bag, which is properly closed at the top. They are laid out, a little apart, on paper, then flattened on top with a wet brush and sugar dusted over. They are baked in a warm oven until nicely coloured. The paper is afterwards wetted on the back, and the biscuits removed, after which they are dried for some time in any warm place.

Ratafia Pudding. Beat up 3 eggs and put them into a pie-dish, and in the meantime heat 1½ pints milk in a pan with 2 dessertspoonfuls sugar. Pour the latter when hot over the eggs, mix all well together, and then add a little ratafia flavouring. Cover the surface of the custard with ratafia biscuits, and bake the pudding in a moderate oven for about 40 min., or until the custard is set.

Care must be taken in cooking that the pudding does not brown on top, and to prevent this it may be covered with a plate. The oven should be cool, otherwise the pudding will boil and cause the eggs to curdle. *See Custard, Forcing.*

RATCHET. The purpose of a ratchet is to permit movement in one direction and not in another. The shape of the teeth and also that of the pawl may vary and may often be disguised in various forms, but essentially the principle remains the same throughout. In general, when a ratchet forms part of a mechanism, the pawl is kept in engagement with the teeth of the ratchet by means of a light spring.

The ratchet is employed in watches and clocks to prevent the spring flying backward after it has been wound up. In some lawn mowers a ratchet drive forms part of the gearing which rotates the knives. Another application is in the free wheel of a bicycle, while further examples are found in the ratchet brace and ratchet screwdriver. *See Pawl.*

RATEABLE VALUE. The rateable value of a dwelling house is the amount at which it is assessed or valued for the purpose of paying the local rates.

Usually this value is the rent less an allowance for repairs, the exact amount of which varies with the size of the house. A house for which £60 a year is paid in rent will have a rateable value

somewhat under £50. On this amount the rates are paid. The valuation for income tax is not necessarily the same. At intervals houses are revalued, and householders who think their rateable value too high can appeal against it to the local authority. *See* Income Tax; Rent.

RATES. Money needed to meet the expenses of local authorities, such as town and urban councils, is raised by means of a rate levied on the occupiers of all property within the district. Rates are thus the complement of taxes, the one providing the national and the other the local revenues.

In raising rates the first thing is to make a valuation of all the property in the area covered by the council. Each house and building is valued at a certain sum, known as the rateable value, this being something less than the annual rent. Thus a house for which the occupier pays a rent of £60 will be rated at £50, or thereabouts. The deduction thus made represents an allowance for repairs, etc.

On this rateable value the rates are assessed, being at the rate of so much in the £. For instance, if the yearly rate is 7s. 6d., a man whose house is rated at £48 will pay £18 a year in rates. The rates are assessed and collected by the local authority, being paid in some places half yearly and in others every quarter. With the money the local authority meets, directly or indirectly, the expenses of roads, sanitation, free libraries, workhouses, etc.; also part of the expenditure on education. If a man owns the house he lives in, he himself pays the rates. The rating authority may in the case of houses whose rateable value does not exceed £13 (or any higher value previously in force in the district) require the rates to be paid by the owner instead of by the occupier. The owner is entitled to an allowance of 10 per cent, if he pays in advance. It is also frequently arranged, even in the case of large houses, that the owner shall pay the rates. The amount in these cases is charged to the tenant, who pays a sum, every week or month, for rent which is really rent and rates together. For doing this the landlord is usually allowed to deduct something from the amount he pays in rates.

In London and other large cities flats are usually let on the same terms as small houses. The landlord pays the rates and charges an inclusive sum to the tenant. When comparing rents this important consideration should not be overlooked. A flat for which £70 a year is charged may be cheaper than a house let at £50. It all depends upon which party pays the rates and upon their amount.

Under the Rent Restriction Acts landlords who are responsible for rates can add to the rent any extra amount they are called upon to pay for rates; also they must reduce the rent if the rates are reduced. Rates are not charged on buildings that are unoccupied. The local authority can issue summonses and then distrain if rates are not paid, and in cases of bankruptcy any amount owing for rates is treated as a preferential debt.

Ratepayers dissatisfied with the amount at which their houses are valued can appeal, but such an appeal must be supported by very strong evidence to have any chance of success.

To make an appeal, the ratepayer should first communicate with the clerk of the local authority for the district in which he lives, who will inform him what steps are to be taken.

The only other remedy is to use whatever influence he has to secure the election to the local authority of men who will practise economy in spending the public money and so reduce the annual amount that is payable in the £ on the rateable value.

In Scotland the system differs. There the rates are divided between the owner and the occupier, each paying about one-half.

Societies instituted exclusively for the purposes of science, literature, or the fine arts, and supported wholly or in part by annual voluntary subscriptions, are exempt from all rates, as also are churches and voluntary schools.

By the important Act passed in 1928 hereditaments occupied as railways, canals or docks, and those occupied as factories or workshops, unless primarily occupied and used for any of the following purposes: (a) dwelling house; (b) retail shop; (c) distributive wholesale business; (d) storage; (e)

public supply undertaking (e.g. gas or water works), are rated at only one-quarter of their net annual value. By the same Act agricultural land was entirely relieved by rates. In cases where premises are used partly for the above purposes and partly for other purposes, the annual value must be apportioned between them. *See* Income Tax; Rent; Repairs.

RAT TAIL. This phrase is used for the tapering formation found on the backs of many table spoons and table forks. It was introduced by English silversmiths about 1660 in order to strengthen the handles of spoons. This rat tail formation or shaping lasted for nearly a century, when it was replaced by the tongue or shell, but it has been reproduced by modern makers. *See* Spoon.

Rat Tail. A tapering formation as seen on these two spoons. (Courtesy of Chapple & Mantell)

RATTAN: For Basket Work. For domestic purposes rattan cane forms a convenient material for cleaning drains, but it is also extensively used in basket making. The whole cane is utilized to a large extent for making chairs and many kinds of strong baskets; the outer skin is peeled off and used for caning chairs, one side of it being quite smooth and bright.

The inner portion, known as pulp or pith, is treated by machinery and drawn through holes in a metal plate, the resulting material being available in lengths of several diameters, ranging from the finest, 00, to the thickest. No. 15. The appearance of the prepared pith cane when made up in the form of a basket can be improved by singeing the minute fibres which are left on the outside. Generally the material is used quite plain, but it can be dyed or stained.

The main advantage of rattan for basket work is its length, and for this reason it is largely used, and forms a most convenient material for beginners in basket weaving. Owing to its lightness the rattan is particularly adapted for making light and fancy baskets. Used in combination with raffia, it forms an excellent material for making table mats. *See* Basket Making; Osier.

RATTLESNAKE PLANT. Also termed the rattlesnake orchid, this plant belongs to a genus of orchids botanically known as *Goodvera*. It is generally grown in stove or greenhouse, but there are two hardy species, *pubescens* and *repens*, which may be grown outdoors where the position is mild and sheltered.

Pubescens grows about 3 in. high, bears white flowers, sometimes called adder's violets, during summer, with dainty foliage of green veined with silver; it should be planted in pockets of peat and leaf-mould during spring. *See* Orchid.

RAVIGOTE SAUCE. Cold ravigote sauce can be made by adding 3 teaspoonfuls chopped parsley, chives, chervil, tarragon, and shallot, mixed in equal quantities, to $\frac{1}{2}$ pint mayonnaise sauce, and tinting the whole green with vegetable colouring.

To make hot ravigote sauce, boil together $\frac{1}{2}$ gill each white wine and tarragon vinegar and a chopped shallot. When the liquor is reduced to $\frac{1}{2}$ gill, pour in a breakfastcupful of white sauce, and add also $1\frac{1}{2}$ dessertspoonfuls of chopped parsley, tarragon, and chervil, mixed in equal quantities. Boil up the whole, and then simmer it all a few minutes before serving. *See* Mayonnaise.

RAVIOLI. This is a popular Italian dish composed of noodle paste with a savoury stuffing. Directions for making the paste will be found under the heading Noodle.

For the stuffing use the following proportions of ingredients: 4 oz. cooked chicken, 2 oz. cooked ham, 1 oz. grated Parmesan cheese, 1 yolk egg, 1 tablespoonful thick white sauce or cream, 1 tablespoonful tomato sauce, 2 teaspoonfuls finely chopped parsley, salt, cayenne, grated nutmeg to well season, a few brown breadcrumbs.

Pound all the ingredients until smooth, and rub through a wire sieve. Season well. Roll out the noodle paste as thinly as possible, and stamp out rounds about 2 in. in diameter. Place a small spoonful of the stuffing in the centre of half the rounds and wet the edges.

Cover each with another round and press the edges well together. Put them in a pan of rapidly boiling salted water and boil quickly for about 2 min., stirring gently, then boil slowly for 10 min. Lift them out with a fish slice, drain well and place in layers in a well-buttered dish, coating each layer with tomato sauce and a good sprinkling of grated cheese. Cover the top with a good layer of sauce, sprinkle with brown breadcrumbs, and dot with pieces of butter. Re-heat in a hot oven for a few minutes, and serve at once. Any kind of cooked poultry or game may be used for the stuffing.

RAY: How to Cook. When smooth-backed this fish is usually called a skate, but if the surface of the back is studded with spines it is called a thornback. It must be skinned and crimped, and may then be boiled or fried, and served with a suitable garnish and shrimp or caper sauce.

As a rule the fish is purchased from the fishmonger ready skinned and crimped, but if this work has to be undertaken at home, proceed in the following manner: Cleanse the ray, reserving the liver, and remove the skin both sides, then lay it flat on the board, and with a sharp knife cut off the tail and detach the fleshy parts from the spine bone on either sides. Cut the pieces into long strips by cutting through the cartilaginous or finny parts. Place these strips in cold water, then turn the fish over and repeat the process, adding the strips thus obtained to those already in water. Leave the pieces of fish in water, changing it frequently until the strips appear crimped.

To boil ray, put the crimped pieces into a saucepan with sufficient water to cover them, and add 1 wineglassful vinegar, 2 oz. salt, and a bunch of parsley. Let the water boil up, and then simmer for 15 min. Drain the fish and keep it hot. Put the liver of the fish in a small saucepan, and cover it with some of the liquor in which the ray was boiled; cook gently for 5 min, and then strain. Dish the pieces of ray, cut the liver in slices, and lay over them. Pour over Hollandaise or some piquant sauce.

Slices of the crimped ray can be curled round with a small piece of liver in the centre: they can then be dried in seasoned flour, egged and crumbed, and fried in boiling fat. The liver is very rich in oil, therefore only small portions must be served with each slice. Blanch the liver before dressing it. *See* Fish; Hollandaise Sauce; Skate.

RAYNAUD'S DISEASE. The condition that is known as Raynaud's disease consists in a disordered action of the vaso-motor nerves to the blood vessels, principally those supplying the extremities. By firm contraction of small arteries a part is deprived of blood and is blanched, or by dilation of the small veins the part is engorged with venous blood and is blue, or from interference with their nutrition certain tissues actually die.

Men may be affected, but women are more liable. The disease is most likely to occur between the aged of 15 and 30. It may follow the acute infectious diseases, and is often associated with Bright's disease; other diseases and heredity may also play a part. Cold is the chief exciting cause. The whitening of the fingers is popularly referred to as dead fingers. *See* Gangrene.

RAZOR. The varieties of razor in general use, which are known as the hollow-ground and the safety, are made and used on different principles. One of the main distinctions is in the matter of blades. A good hollow-ground razor consists essentially of a strong steel blade, which will last a

lifetime. In the safety, on the other hand, the blade is only one part of the mechanism, and it requires to be renewed from time to time, for which purpose a supply of suitable blades usually accompanies every razor.

In use the hollow-ground has a more or less diagonal movement, and can be applied at any convenient angle. The safety must be held in a vertical position and moved straight down, never horizontally nor transversely. Each of the two varieties provides an effective means of shaving when properly used; the choice of one or the other is a matter of individual preference.

There are various patterns of safety razor. In general they comprise a head on which the blade is secured, and a stem or handle. Some are provided with a means of stopping the blades. The blade is sometimes a solid steel one, hollow ground like the older type of razor, but is more often a very thin steel plate of fine grain.

The chief characteristic of the hollow-ground razor is the contour of the blade. It is thinnest in the centre, so that it has the appearance of being hollowed out. The cutting edge is slightly wedge shaped, the back thick and strong. The width of the blade is from $\frac{1}{2}$ to $\frac{5}{8}$ in., the length about $5\frac{1}{2}$ in., of which the actual blade measures 3 in., the remaining $2\frac{1}{2}$ in. being the tang.

The care of a hollow-ground razor consists mainly in keeping the edge keen by the use of a good leather strop. At rare intervals it may require setting on the stone. After use it should be aside for at least one day, as the rest is good for the edge, which otherwise will very soon become dull.

The same razor should never be used every day, nor even on two successive days. The best plan to keep them in good condition is to have 3 or 4 razors, and never less than two.

As it is not easy to tell a good razor from a bad one by inspection, it is best when buying razors to be guided by the name of the maker and the reputation of the retail shop.

Sharpening the Razor. The routine sharpening of a razor consists of 20 or 30 double passes on the leather side of the strop every time the razor is used, and is preferably done after shaving, so that the edge has a few days' rest between stropping and use. The strop is hung up on a strong hook at the height of the chin from the floor, the handle is grasped in the left hand and pulled hard to keep the strop quite flat. This tension is important, as a weak pull will result in the strop curling minutely round the blade so that the edge gets rounded instead of properly keen. With the other hand the razor is then swept boldly up and down the strop with the blade lying flat, the back pressing only lightly, but the edge firmly. The reversal at the end of the stroke is effected by a turn of the right wrist, which lifts the edge and lays its other face on the strop as the return stroke is commenced.

During stropping a faint drag should be felt and a swishing sound heard, not a scraping noise, and the blade may emit a ringing note, but this is almost inaudible. If a strop gets accidentally gashed, it is best discarded and replaced. The only dressing required on the leather is a mere touch of oil or grease, and the application should be postponed as long as the leather retains its soft pliability and its velvety appearance.

After a period of regular use and stropping a razor loses its keenness of edge; it should then be given 10 or 12 light double passes on the canvas side, keeping a very heavy tension on the strop, followed by the ordinary work on the leather. A blade that is not restored by this treatment, or that is found to require it at frequent intervals, needs a touch of the oil stone; if the owner has enough confidence to attempt this operation himself he should use a fine carborundum stone moistened with paraffin, using light pressure and much care and patience. A magnifying glass may be employed to examine the progress of the work from time to time.

The blade must be held with the edge on the stone, but the back overhanging so that the two planes ground on the steel meet on the edge at a very fine angle. This is facilitated by the faces of the blade being ground hollow. Before resorting to such a drastic remedy as stoning it is well to try if a dull razor can be restored by a month's rest out of use or by 10 min. immersion in water kept boiling all

the while. A keen edge must be maintained on a razor both for the sake of getting a clean and comfortable shave, and to avoid cutting the face, an accident generally due to a dull blade. *See Shaving.*

REACTION: In Wireless. The “feeding-back” system of amplification. Reaction is possible only with a device which has the power to magnify electrical impulses. Although systems for its use in the high and low frequency circuits of radio receivers have been advanced, it is normally confined to the detector.

A proportion of the energy is transferred back from the anode circuit to the grid circuit for further magnification by the valve. It should be understood that a detector valve of the normal three-electrode type amplifies as well as “detects.” (For the purpose of this explanation screened-grid and pentode valves used as detectors can be considered as “triodes” or three-electrode valves.) If the “feeding back” is allowed to go beyond a certain point, a state of oscillation (q.v.) will be created. A sustained howl will result in consequence of there being built-up a “vicious circle” of self-magnification.

Reaction. Example of a reaction condenser for wireless reception, as described in the text.

The sustained oscillation of a valve circuit through the close coupling of its anode and grid circuits is an essential factor in wireless transmission. It is also employed in superheterodyne receiving circuits (q.v.), and in receivers designed for the reception of the continuous-wave signals of commercial and other wireless telegraph systems.

For obtaining additional sensitivity in a valve detector used in a broadcast receiving set, however, it is necessary widely to avoid the state of oscillation. Even a close approach to it will cause distortion of the speech and music.

In order to maintain a rigid control of “feeding back” between the anode and grid circuits of a modern set, screened-grid valves and metal shielded components are used.

The reaction control with which the effect can be adjusted almost invariably takes the form of a small variable condenser. The greater the capacity to which this is adjusted the more the “feeding back” which occurs until the point of oscillation is reached. This will be marked by a squealing which changes its pitch as the tuning condenser is operated.

If the receiver has no high-frequency amplifying stage or stages, this squealing will cause interference with other listeners. Such is the sensitivity of present-day receiving sets, especially those used for short-wave reception, that the unauthorised, interfering transmission may interfere with the reception of listeners over an extremely wide area. *See Condenser; High Frequency; Oscillation; etc.*

Ream. A ream consists of 20 quires of paper. A quire contains 24 sheets, and therefore a ream contains 480.

Rear Axle. *See Differential Gear; Live Axle; Propeller Shaft.*

REBATE: In Cabinet Making. This is a kind of groove that is made on the edge of a piece of wood in the form of a step. An example is that found on the back of almost all picture frames. The

purpose of the rebate is to provide a space in which some object, such as a panel, can be used so that its surface or one of its surfaces may finish flush with the top surface of the framework.

Generally speaking, the rebate should be used in places where one piece is to fit into, and be supported by, another. For example, boards may be rebated to a half of their thickness so that, when the two prepared boards are brought together, the rebates in each will enable both faces of the boards to finish flush and form a level surface. This is a rebated joint.

Rebate Plane. This is a tool specially made for cutting rebates. The simplest form is a narrow, hardwood plane with an iron that is the full width of the body of the plane. Useful sizes are those of $\frac{1}{2}$ in., 1 in., and $1\frac{1}{4}$ in. wide.

*Rebate Plane. Fig. 1. Simple form of the plane in use.
Fig. 2. Bull-nosed rebate plane.*

The plane may be made with either a skew or square mouth; the skew generally is preferred, because the shavings escape more freely, so that there is less liability of the plane choking. Such a tool, however, is not very satisfactory for the actual work of making the rebate; it is generally used for cleaning it out, after it has first been prepared with the cutting gauge or by chiselling.

To be effective, a rebate plane requires some means to prevent it from slipping sideways on the wood. The tool known as a fillister is a development of the simple rebate plane with the addition of a fence or guard to prevent the plane wandering over the surface of the wood. The fence is a movable piece of hardwood clamped to the sole of the plane by setscrews. These may be adjusted so that the width of the rebate can be regulated. A small brass shoe-piece controls the depth of the rebate, and a separate cutter is provided for cutting the inner edge of the rebate. The sash fillister is somewhat similar to the moving one, but the fence is supported on two rods which slide through the body of the plane. It is used by first adjusting the fence and the stop to the requisite width and depth of the rebate. The cutter is similarly adjusted, and the plane is worked along the edge of the timber, taking care to keep the face of the fence against the edge of the job, and planing until the rebate is completed.

Another type of rebate plane, as used for cleaning up the rebate, known as the bull-nosed plane, is generally made in metal. This is only 3 or 4 in. long, and is extremely useful for all kinds of work. It is virtually a small metal plane in which the plane iron terminates on the front of the tool, so that it is possible to clean out rebates, or any other hollows, right up to the end of the slot. *See Plane.*

RECEIPT: In Law. A receipt is a formal written acknowledgment that a debt or bill has been paid. In Great Britain receipts must bear a twopenny stamp for £2 or over, which must be cancelled by writing across it. Any person who gives an unstamped receipt for £2 or more is liable to a penalty of £10, and the unstamped receipt is worthless as evidence if the creditor again claims the money, although it may be after-stamped within a month and so become available as evidence if the penalty is paid.

A receipt serves as evidence that a debt has been paid, but the person who gave it is always at liberty to show, if he can, that although he gave a receipt he did not receive payment; or that there was a mistake of some kind. The receipt is not conclusive against him, although a court of law would require very strong evidence for it to decide against a receipt which had been properly worded.

A receipt, however, is not necessary in English law. A debtor, for instance, cannot refuse to pay what he owes because his creditor refuses to give him a receipt, but a creditor who refuses to give a receipt in cases where the receipt should bear a stamp— i.e. where the amount is two pounds or over—is liable to a fine of ten pounds.

If the debt is paid in cash, a receipt should always be obtained, and kept for a time so that it can be produced in case a claim is made for payment. If the debt, however, is paid by cheque, a receipt is not so necessary, as it is always possible to prove that the cheque has been passed through the bank. A cheque, however, proves only that money has been paid; it does not prove that the money was paid in respect of the debt which the creditor is claiming. It is not necessary to keep receipts for more than six years, as after the lapse of that time, a debt cannot be claimed. They are, however, useful as evidence of the prices which have been paid for various articles.

Files for keeping receipts in order are sold by stationers and others. If they are placed on the file in the order they are received, as they should be, there will usually be little difficulty in turning quickly to a particular receipt when required. *See Bill.*

RECEPTION: How to Arrange. The usual form of reception is that which follows a wedding, and is given by the bride's parents or nearest relative. Invitations are issued about three weeks before the ceremony and are included in the invitation to the wedding.

Invitations for other receptions, which are merely formal "At Homes," are issued on "At Home" cards. Such receptions are given either in the afternoon or evening to introduce some specially important newcomer or guest; or by persons in an official position, such as the mayor of a town or the member for a constituency, to enable them to meet all householders or voters as their guests, the sole qualification being that the guest should be a member of the municipality or a voter.

Such receptions are naturally large, and are usually held in some public hall or rooms, where light refreshments are provided. The catering is generally given out to some competent firm, which will quote a price for the numbers to be catered for and submit a statement of what that price will include. It is usual to provide some form of amusement for the guests, music being popular. The musical items should not follow each other without a pause, but at rather long intervals, and people should have plenty of opportunity for meeting each other. *See At Home; Evening Party; Invitation; Wedding.*

RECESS: Its Fitting. In a house a recess is a small semi-enclosed space formed by a depression contrived in a wall or near the juncture of two walls. Typical examples occur at either side of the break-forward breast of a fireplace, and are usually terminated at their outer sides by the adjacent walls of the room. These recesses are particularly useful for the erection of fitments, as the two sides and the back are already formed by the walls. In a sitting-room shelves can be fitted for books, or glazed doors can be framed and shelves provided for china and glass. For a dining-room with two recesses in a bungalow or cottage, the dresser illustrated, with instructions for making, under that heading, would be a most useful fitment, with shelves for books or china in the recess on the other side of the fireplace. Corner seats with shelves above for books are also space-saving furnishing ideas.

For bedrooms, cupboards are usually the best fitments; one with shelves and the other with space for hanging clothes. Such cupboards are fully described with diagram for construction under the heading Cupboards.

RECIPE. A recipe is a formula for the preparation of a mixture or compound of any kind. It is chiefly used in cooking and medicine. Directions for making cakes, puddings, sweetmeats, etc., are known as recipes, as are directions for making up medical prescriptions. Other classes of recipes are those for making up various household requisites, such as glue or starch, and for compounding the scents and mixtures used for toilet purposes.

RECTIFIER. In electricity this is an apparatus for converting an alternating current into direct current. Examples are the crystal or the thermionic valve rectifiers used in wireless receivers, and the metal or valve rectifiers employed to charge L.T. batteries or provide H.T. current for receiving valves. In the latter case the rectified current is passed through a filter circuit in order to smooth out any irregularities.

Valve rectifiers may be either half-wave or full-wave. A half-wave rectifier comprises two electrodes, viz. filament and anode. If the filament is heated and an alternating current applied between the anode and filament, then current will flow through the valve during the positive half-cycles of alternating current and will cease to flow during the negative half-cycles. Thus, the valve will deliver unidirectional pulsations which can be smoothed into ripple-free direct current. By suitably arranging two half-wave rectifiers both the positive and negative half-cycles of alternating current may be rectified. This is the principle of the full-wave rectifier, in which two anodes are contained in one glass bulb.

Metal rectifiers are dissimilar metals in contact. A number of metallic plates are clamped in alternate layers, the combination being arranged so that a free passage is offered to alternations of one polarity and a path of extremely high resistance to alternations of opposite polarity. One combination possessing this rectifying property is copper plates covered with copper oxide interleaved with lead plates.

Metal rectifiers may be connected in circuit to give either half-wave or full-wave rectification, and may also be constructed to supply large D.C. outputs. They require no upkeep. Other types include electrolytic rectifiers, in which two electrodes are immersed in an electrolyte (e.g. lead and aluminium in a solution of sodium phosphate), gaseous rectifiers, which may take the form of a glass bulb containing an inert gas such as argon and the positive and negative electrodes, mercury-vapour arc rectifiers and electro-magnetic mechanical devices. *See* Wireless, etc.

RED CABBAGE. This is a reddish leaved variety of cabbage, grown principally for pickling. The finest plants are obtained from seeds sown in August, but a sowing in March will provide useful pickling cabbages in late autumn. Blood Red is one of the best varieties.

REDCAP FOWL. This breed, which is essentially British, takes its name from the large rose comb, which in a first-class specimen measures about 5 in. by 4 in., and is covered with fine red points which are known as work. Its eggs weigh about 2 oz. each, and the cockerels when fatted are much appreciated as spring chickens. The weight of adult males runs from 6½ lb. to 7½ lb., and that of the females from 5 lb. to 6½ lb. *See* Chicken; Fowl; Poultry.

RED CAP PUDDING. This is identical with black cap pudding except that the currants which give the latter its name are substituted by small pieces of glacé cherries. *See* Black Cap Pudding.

RED CURRANTS FROM GARDEN TO TABLE

Hints on the Successful Cultivation of this Fruit

Attention may be drawn here to the articles on other fruits that can be grown in English gardens, e.g. Black Currant; Gooseberry; Loganberry; Plum. See also Jam

The red and white currants are profitable bush fruits and their management is simple. They should be planted in autumn—at 4 ft. apart—in well tilled and manured soil in a sunny place. In the spring following planting the branches of young bushes should be shortened by about half. In subsequent years the pruning consists of shortening the side shoots in July to within about six leaves of the main branches from which they grew, and in winter pruning them again to within about $\frac{1}{2}$ in. of the base of the past summer's growth. This treatment will result in the development of fruit spurs. Care must also be taken to thin out the bushes to prevent overcrowding. Red and white currants may be grown as single, double or treble-stemmed cordons on a wall facing north: there the fruits will ripen later than those on bushes in the open garden. Cordons are pruned in the way already described.

Red Currant. Excellent example of a cordon variety of red currant.

Some of the best varieties of red currant are Fay's Prolific, New Red Dutch, Perfection, Laxton's No. 1, and Raby Castle. Of white currants Transparent and White Versailles should be chosen.

Both red and white currant bushes are easily propagated by cuttings, 10 in. long, inserted out of doors in autumn in narrow trenches 6 in. deep: a layer of sand must be placed in the bottom of the trench and the cuttings made firm at the base. They will be well rooted by the following autumn and may then be transplanted to a reserve plot until large enough for planting permanently.

Currant bushes benefit by a top-dressing of manure on the soil in spring, and once in three years basic slag should be put on the ground in autumn, at the rate of 4 oz. per square yard.

Pests of the Bush. Among the many pests that are harmful to red currants is the clearwing moth, which causes shrivelled foliage, the only remedy being removal and burning of affected shoots and leaves. The shoot borer bores into buds and shoots, the remedy being a spraying with caustic wash in winter and burning of affected shoots during growth. The currant sawfly defoliates bushes, and its larvae may be cleared by repeated spraying with a good insecticide emulsified in soft soap. Other pests include the magpie moth, white woolly, brown scale, and winter moth.

Currant-leaf spot is a disease appearing in the form of dirty black markings upon the foliage, shrivelling the leaves and weakening the remaining growth. Bushes thus affected should be sprayed during summer with a solution of sulphide of potassium, all fallen leaves being promptly burned. Handy preventives of currant troubles are syringing with strong lime-water, or soot-dusting in early morning while the leaves are damp with dew.

For protection against birds there is nothing better than old fish netting. When wasps are troublesome the bushes should be enshrouded in old curtains or butter-muslin.

How to Cook. When added to other fruits red currants serve to bring out the flavour, as, for example, when a tart is made of raspberries and red currants. The juice is frequently added to red fruit while boiling, and improves both the flavour and the colour.

Red currants should be stewed in a strong syrup of sugar and water. Pick and wash the fruit and put them with the syrup in a stewpan. Let them boil up and then remove them from fire till cool. Replace on fire to boil up again before serving. Red currants are better when mixed with raspberries for puddings, tarts, or flans.

Red Currant. 1. Soil preparation, showing bottom spit well manured. 2. Planting. 3. Good cutting. 4. The same suitably prepared. 5. Cutting planted: a, sandy soil. 6. First year pruning. 7. Second year pruning. 8. Encouraging fruit spurs (a). 9. Mulching: a, manure under top soil.

Red Currant Cream. This is made with 1½ lb. picked red currants. Put them into a stewpan, mash them with a wooden spoon and then stew them gently in the oven or over the fire until all the juice runs out. Strain the liquor through a hair sieve, measure it, and return to the stewpan. To every pint of juice add 6 oz. granulated sugar and 2 oz. gelatine dissolved in 3 tablespoonfuls warm water. Stir all together until the sugar is melted, then boil them for a few minutes, skimming the top. Put into a basin 1 pint cold milk or cream, and when the currant juice is nearly cold, strain it in by degrees. Turn the whole into a mould to set. If the currants do not yield 1 pint juice a little water may be added.

Red Currant Ice. Use ½ lb. red and ½ lb. white currants and 1 gill raspberry or strawberry purée to 1 pint rich custard, and proceed according to the general instructions which are given for making ices.

Red Currant Jam. To make well-flavoured and bright-coloured jam with red currants, pick the fruit, which must be very dry, and put it into a preserving pan. letting it boil up, and continue boiling for 5 min.

Then add 1 lb. lump sugar for each lb. fruit, and boil all together, stirring and pressing the fruit with a wooden spoon and skimming well; 35 min. should be sufficient to obtain a firm jam, but it may be tested by dropping a little on a cold plate.

Red Currant Jelly. To make this, top and tail 8 lb. red currants, and put them into a jar with 2 gills water and $\frac{1}{2}$ lb granulated sugar. Cover the jar with a saucer, put it into a large saucepan of water, and cook its contents gently at the side of the fire until the fruit is soft and all the juice extracted from it. Pour off the juice and drain it through a jelly bag, then put it into a preserving pan, adding $1\frac{3}{4}$ lb. lump sugar to every quart of the fruit juice.

Boil the whole for about 40 min., or until it will set when tested on a cold plate, and in the meantime keep it well skimmed and stirred. When cold, put the jelly into dry pots, tie it down, and store it in a cool, dry place. Red currant jelly is served with hare, roast or jugged rabbit, venison and saddle of mutton; some people serve it with leg of mutton.

Red Currant Syrup. To make this, pick $1\frac{1}{4}$ lb. red currants and $\frac{3}{4}$ lb. white currants, and put them into a bowl with $1\frac{1}{2}$ lb. strawberries or raspberries. Press the fruit with a potato masher or wooden spoon in order to crush it, and strain off the juice. Leave this to ferment for about 6 days, then strain into a preserving pan, add 1 lb. lump sugar, and boil all together, taking off the scum as it rises. When thoroughly boiled, cool it and bottle it for use.

RED HOT POKER. This is a familiar hardy perennial with large tufts of narrow leaves and dense cylindrical clusters of small, brilliantly-coloured flowers on stems varying in height from 2 to 3 ft. Its botanical name is *Kniphofia* or *Tritoma*, and it is known also as the torch lily, on account of its torch-like inflorescences. The plants are hardy in well-drained soil, but they are apt to perish in ground that becomes water-logged in winter. In cold districts the plants should be protected by placing bracken or other material round them. During the winter some of the leaves will be disfigured by frost and wind; they should be cut off in spring when fresh growth begins.

Red Hot Poker. Torch-like red and yellow flower heads of the handsome Kniphofia.

The best time to plant is in March or early April; if the ground is heavy, sand and leaf mould should be added. An increased stock can be obtained by division in spring, but the plants dislike being disturbed.

The common red hot poker is *Kniphofia aloides*, which grows up to 5 ft. high and bears orange-red blooms, there are many varieties of this. A few other first-rate sorts are *Macowanii*, coral red, 2 ft.; *Nelsoni*, yellow, $2\frac{1}{2}$ ft.; *Northiae*, red and yellow, 4-5 ft.; and *Tuckii*, yellow and red. Of the modern varieties *Royal Standard*, orange-red, 3-4 ft.; *Goldelse*, yellow, $2\frac{1}{2}$ ft.; and *Mount Etna*, reddish. 6 ft., are very showy.

RED LEAD. Red lead is a crystalline powder known in chemistry as triplumbic tetroxide, or lead orthoplumbate, according to its purity. It has many commercial usages, of which one is the

manufacture of flint glass. Its use as a pigment is common, and it forms the base of the priming coats in painting.

The mixture of red lead and gold size is a useful drier for painting; the same mixture is applied to the screwed joints of gas or hot water piping to ensure a leak-proof joint. A length of tow or hemp is smeared with the paste and twisted into the threads of the pipe, which is then screwed home. *See Plumbing.*

RED MULLET. Superior in flavour to the grey mullet, the small, rose-coloured fish known as red mullet may be cooked in a variety of ways. Baking and grilling are the best methods, but boiling is unsuitable.

For grilling, clean and dry 5 fish, score the skin across at frequent intervals on both sides, and then let them soak for about $\frac{1}{2}$ hour in a mixture consisting of 1 gill melted butter, $1\frac{1}{2}$ tablespoonfuls lemon juice, and seasoning to taste. Turn the fish occasionally so that both sides may be equally well soaked, then grill them before a clear fire for about 8 min. Serve them garnished with a few pats of maître d'hôtel butter.

To bake red mullet, prepare two large fish, score them as directed for grilling, and then lay them in a greased baking-dish previously sprinkled with a little chopped parsley and fine breadcrumbs. Add seasoning to taste, squeeze over a little lemon juice, finally adding some more parsley and breadcrumbs. Just before putting the fish into the oven to bake, lay a few small lumps of butter on top. The baking should take about $\frac{1}{4}$ hour. *See Fish; Grey Mullet.*

RED SPIDER. This minute pest attacks the leaves, chiefly of plants growing under glass and on sunny walls out of doors, sucks the sap from them and, if not destroyed, seriously weakens the plants. This pest is most troublesome in warm, dry conditions; it can be destroyed by syringing the lower leaf surface with a solution of salt, 1 oz. in one gallon of water.

REDUCER: In Photography. Negatives which are too dense or too nearly opaque to print properly may be reduced by chemical solutions, just as negatives which are too thin may be intensified. These processes are only to be used with caution by the amateur, owing to the risk of permanent damage by staining.

Attempts should always be made to get satisfactory prints from a dense negative by choosing a soft printing paper before resorting to chemical reduction. Soft grade or portrait grade gaslight paper will frequently give pleasing prints from dense negatives, which on the ordinary grade paper show harsh results.

There are three classes of dense or semi-opaque negatives, due to (1) over-development of a correctly exposed negative; (2) overexposure and over-development; (3) underexposure and over-development; the last case being probably the most common with amateur photographers.

The first variety of dense negative is sometimes due to not making sufficient allowance for temperature in hot weather when developing in a tank. The negative is dense all over, though detail is clearly visible; but the shadows, which should be nearly clear glass, show a good deal of deposit, and the high lights are nearly opaque, all delicate tones being lost.

The print is harsh in contrast. Thus white dresses in portraits print dead white without detail. The best and safest reducer for such negatives is ammonium persulphate, made up as follows:

SOLUTION 1

Ammonium per sulphate	40 gr.
Cold distilled water	4 oz.

SOLUTION 2

Sodium sulphite	20 gr.
Cold water	2 oz.

The negative having been soaked for about half hour in plain water or, more safely, in distilled water, to re-wet it uniformly and soften the gelatine, it is placed in a small, clean dish and about 2 oz. of solution No. 1 poured over it, rocking the dish gently. In about 2 min. the solution will turn cloudy, and reduction will have begun. The process should be observed carefully, and the negative examined at short intervals to see that reduction is not proceeding too far. In 5 min., or less, reduction should be complete, and the negative should be taken out, quickly rinsed, and at once placed in solution No. 2 for 3 or 4 min., which stops the reduction. Plain water is not effective. Afterwards wash well in the ordinary way.

On no account should the negative be kept for more than 5 min. in the persulphate solution. If one application is not sufficient, a second bath of persulphate solution may be used after the No. 2 bath and washing. It is equally important that No. 1 solution should not be used twice, nor should more than one negative be treated at a time. Fresh solutions must be used, or immovable stains will result. This reducer acts proportionately to the density of the negative, i.e. it attacks the densest parts more than the thinner parts and so reduces harsh contrasts. Used as described, it is safe in operation with properly fixed and washed negatives. Do not touch the surface with the fingers during the process or permanent marks will be produced.

Clearing Dense Over-exposed Negatives

In the second variety of undue density, caused by over-exposure and over-developing the negative generally appears of almost uniform density, shadows as well as high lights, and may be even so dense that the subject can only be seen with difficulty when the negative is held up to a strong light. Long printing gives flat or foggy prints with plenty of detail. Enlargement is impossible. Here the best reducer is Farmer's solution, used fairly strong. This solution, when strong, attacks the shadows more than the high lights and so increases contrasts; when weak it acts more evenly. This property is taken advantage of by using it both strong and weak in reducing these opaque negatives. Either take the negative straight from the fixing bath or after washing is completed, but not drying. If the negative has been dried it must be soaked for at least $\frac{1}{2}$ hour. Place it in a bath of freshly made and unused plain hypo, 4 oz. hypo to 20 oz. water, without any acid alum or other chemical as used in acid fixing salts. Make a solution of 1 oz. potassium ferricyanide in 10 oz. water. Pour the hypo off the negative; mix in a few drops of the ferricyanide solution until the solution has an orange tint.

Return the mixture to the dish containing the negative and watch the result carefully. Reduction proceeds quickly, and if details in the shadows disappear they cannot be restored. Remove the negative, therefore, while it is still somewhat too dense, and wash well in running water for $\frac{1}{2}$ hour. Reduction continues in the first portion of the washing period.

Next prepare fresh hypo and repeat the process, using less ferricyanide solution, making the mixture of hypo and ferricyanide a pale lemon tint. This second reduction will proceed more slowly and will be much more even, but must be carefully watched. The first reduction increases contrasts, the second printing qualities. The negative must finally be well washed to remove all yellow stain.

The third case, under-exposure and overdevelopment, is most common with the amateur, and is the most difficult to remedy. In fact, it may be said that the best thing to do is to make another, but

correct, exposure. The negative is hard with opaque high lights, thin, detailless shadows, and poor gradations. The print shows excessive contrast.

When under-exposure is not too great, improvement can be made by using the ammonium persulphate reducer described above, taking great care not to carry the reduction so far as to destroy what detail exists in the shadows. In this case reduction only makes the best of a bad job. Local reduction is often useful, as when the sky portion or some high light in a negative is too dense. This can be effected with Farmer's reducer, made as explained above, and applied with a camel-hair brush to the parts to be reduced after the negative has been bathed in the plain hypo solution. *See* Developing; Exposure; Intensifier; Photography.

REED: The Grass. The giant reed of New Zealand (*Arundo conspicua*) is a vigorous ornamental grass, which bears pale flower plumes in late summer and autumn, on stems 8 feet or more high. The Provence reed (*Arundo donax*), which is equally tall, has reddish flowers. *Arundo phragmites* is a common waterside reed in this country; a variety with variegated leaves (*aureo variegata*) is ornamental. The New Zealand and Provence reeds should be planted in a sheltered place in moist loamy soil, and it is wise to protect them with leaves or other covering in winter. They should be planted in spring; that also is the season to propagate the reeds by division of the clumps.

REED: In Moulding. As used in woodwork, a reed is a narrow convex moulding which can be worked by hand with a carving tool or a special plane, or by machinery. It is the opposite of the flute in moulding, and is used as a cabinet decoration, principally on table legs and also on picture frames. *See* Beading; Moulding.

REED MACE. Reed mace is a hardy aquatic perennial herb bearing brown inflorescences. It is best planted at the margins of shallow ponds, lakes, and streams, during spring or autumn, and is propagated by division in February or March. The botanical name is *Typha*. Two British species are *angustifolia* and *latifolia*: these are the plants commonly called bulrushes. They may be cut in autumn for indoor decoration.

Reed Mace, a perennial plant which is very effective in the water garden.

REEL: The Dance. The Scottish reel for ballroom dancing is either a foursome or an eightsome. In the foursome two couples engage, but there may be any number of sets on the floor. The two men take up position by standing back to back with their respective partners facing them. In the Opening movement the dancers trace the figure 8 with a skipping step and finish it setting to partners, when the dance is continued with variations of the two essential steps. These are the high cut, or beating movement of the free leg on the supporting leg, which remains stationary with perfectly straightened knee, and a travelling, kicking step known in the schottische.

Both steps require the turning out of the knees, and all work is done on toes and ball of the foot; in neither hop nor spring should the heel touch the ground when coming down. In the high cut the beating of the free leg should be on the calf of the supporting leg behind, and not on the ankle. In the travelling step a spring is made on the first beat; on the second and third beats there is no forward movement, but a closing movement with the front foot and beat behind with the back foot.

The Eightsome Reel. For the eightsome reel four couples take up position in a set as if for the Lancers. The same steps as for the foursome are used in a modified form in the first part, but the special feature of the dance is in the second part, when each woman dances in turn in the centre with each of the four men, while the others form a ring round the couple. Then each man goes into the centre and dances with each woman in turn, and finally the first part of the dance is repeated.

The essence of Scottish dancing is the brilliance of the footwork; every step is performed with angular precision and has a perfect place in the dance. When a reel is to be introduced into a programme it is quite usual for those who intend to engage in it to practise together, as, though there are only the limited number of correct steps, the arrangement admits of great variation. The arm work in Scottish reels should be below the level of the head, with a bend in the elbow, emphasising the angularity which is characteristic of the national dancing.

In the Irish reel the body is held erect and the arms passive at the sides almost throughout, so that nothing should distract the attention from the beauty of the footwork. The reel is a much quieter dance than the jig, the tapping movements being executed with great delicacy, and the whole effect should be of sparkling lightness. The technique of Irish and Scottish reel dancing can only be acquired by most people, after lessons from a good teacher, with a great deal of practice. Reels should be danced with spirit, but without exuberance or exaggeration. *See Highland Fling; Irish Jig; Schottische.*

Reflex Camera. *See Camera.*

REFRIGERANT. Any drink which relieves thirst and allays feverishness is called a refrigerant. Examples include lemonade and all drinks made with fruit juice or with citric and tartaric acids. Thirst may often be best relieved by demulcent drinks, such as barley water, oatmeal water, or milk and water. A free use of iced drinks upsets digestion. *See Imperial Drink: Lemonade.*

REFRIGERATORS FOR USE IN THE HOME

Modern Methods of Keeping Food Fresh

Our articles on Kitchen and Larder may be consulted in association with the one below. See also Ice Safe; and the entries on the various foods, e.g. Apple; Beef; Milk; Mutton; Pork.

Mechanical and other devices for reducing the temperature of the air in an enclosed space are known as refrigerators. Until recently the sole method of refrigeration or cold storage available for use on a small scale was that of utilizing natural ice as the cooling agent. This system is exemplified in the ice safe described and illustrated under that heading. There are now several other systems available which are entirely automatic in action, needing simply a connexion to the electric mains, or the maintenance of a tiny jet of flame beneath the generator, according to the type of apparatus employed.

Refrigeration by the systems just mentioned depends upon the difference at a given pressure between the boiling point of certain volatile fluids (e.g. ammonia, boiling at 28° F. below zero, or sulphur dioxide, boiling at 14° F.) and that of water (212° F.). The process is also dependent upon the law that when the pressure applied to a liquid is raised the boiling point is raised also. In order to freeze water it must be exposed to a temperature lower than 32° F., and in order to obtain this lower temperature the water must be brought in contact with a medium (the refrigerant) which has a lower boiling point than water. To make the process continuous and automatic the refrigerant must be caused to yield up the heat extracted, and then be made available for further use.

Heat abstracted from the substance in the cooling chamber is caused to evaporate a volatile fluid circulated in pipes around the chamber. The volatile fluid is then compressed, and its boiling point thus raised, so that it can be condensed and re-liquefied at available temperature, and the heat removed. The fluid now flows back to the coil surrounding the cooling chamber, again to abstract heat from the food, etc., therein contained.

In the mechanical refrigerator the compressor is a pump operated by the electric motor. In the non-mechanical type there are no such moving parts, the necessary pressure and movement of fluids being obtained by heating the generator cylinder with a gas or paraffin flame, or with an electric element.

The cycle of operations in a non-mechanical absorption system is illustrated in Fig. 1.

Heat applied to the aqueous solution of ammonia in the "boiler" liberates ammonia gas, which is then liquefied in the condenser. The liquid ammonia (as it is then) evaporates in a cylindrical vessel projecting into the refrigerator chamber, abstracting heat from the latter. The now gaseous ammonia passes next to the absorber, there to be taken up by water. The aqueous ammonia falls by gravity to the pumping coil, where the heat generates gas bubbles and so lifts the liquid through the pumping pipe to the boiler. This pumping action also causes the weak liquid in the boiler, after liberation of the ammonia, to be returned to the absorber.

The function of the hydrogen is to assist by its pressure the evaporation of the ammonia gas. The hydrogen, being freed from the ammonia gas by the dissolving of the latter in the absorber, returns to the evaporator via the gas heat exchanger. It is cooled by passing through pipes on the outside of which circulates the cold gas mixture exhausted from the evaporator. The liquid heat exchanger lowers the temperature of the weak liquid as it passes from the boiler to the absorber. The vessels and pipes forming the refrigerator unit are charged with the necessary hydrogen, ammonia, and water at the factory, and are then hermetically sealed. The condenser and absorber are cooled by air passing through the unit and a heating flame or electric element is kept in action while refrigeration goes on.

The compression refrigerator system illustrated works as follows: Liquid sulphur dioxide from the receiver is admitted to the cooling coil by an expansion valve and evaporates, extracting heat from brine surrounding the coil, and thus cooling the refrigerating chamber. The gas goes on to the compressor, is compressed, and so made condensable at ordinary temperature. It is then passed through a radiator coil and changes to a liquid, being stored in the liquid receiver ready for further use. A thermostat controls the electric motor for the compressor, starting up the latter when temperature rises above a predetermined degree, and stopping the motor when the desired low temperature has been attained.

Choice of a Refrigerator. Whether an apparatus of the absorption type (Fig. 2) or one of the compression (mechanical) type (Fig. 4) is selected depends mainly on the operative agent available to the purchaser. The former can be obtained in rather smaller sizes, and has the advantage that no motor is needed. It is slower in operation, however, and not so efficient in working as the compression type. Unless oil is used for the heater flame, the apparatus must be connected also to the gas or electric service. In the mechanical refrigerator the condenser is air cooled, a fan sometimes forming part of the apparatus. Both types are controlled by thermostats, and effective safety devices are incorporated. A gas, oil or electrically operated refrigerator will prevent waste of food in summer and in muggy winter weather. It will also enable the housewife to turn out dainty frozen dishes for the table with a minimum of trouble and expense.

Refrigerator. Fig. 1. Diagram of absorption type non-mechanical system : the Electrolux Cooling Unit.

Refrigerators. L-R. Fig. 2. Small household model operate by a gas flame. (Courtesy of Electrolux, Ltd.); Fig. 3. This little oil refrigerator suits a very small house or flat. It can be hung on the wall without the legs, which are detachable. (Courtesy of Electrolux, Ltd.); Fig. 4. Large compression type apparatus, operated by electricity. (Courtesy of H.M.V. Household Appliances)

With its assistance a cream or jelly can be mixed early in the day and will be set in time for lunch, or can be kept for the next day. Sundaes and ice cream can be mixed and left in the refrigerator until the mixture is frozen. When making, it is a good plan to add 1 teaspoonful gelatine, which has been placed in a cup and covered with cold water, left till soft, and then mixed with 3 tablespoonfuls of boiling water and stirred. Pour this amount of dissolved gelatine into every quart of milk and cream used. The cream should be whipped and the tray containing the mixture should be removed every half hour until frozen and the ice cream stirred thoroughly. Salads, cold pies, melon and other fruit, milk, beer or soda water are all greatly improved by refrigeration.

Oil-operated refrigerators have made considerable progress during recent years, and have enjoyed increasing popularity, especially in country districts where gas and electricity are either expensive or difficult of access. We illustrate a model of this kind of refrigerator in Fig. 3. Points of interest are that this refrigerator is motorless, permanently silent when working, requiring no water, and running often for as little as 1d. per day. It operates by a small paraffin burner, which is draught proof, odourless, and absolutely safe. Similar refrigerators are supplied to operate by Calor Gas, at only a little extra cost.

Now that first-class refrigerators can be obtained on the hire-purchase system extending over several years for two or three shillings a week, they have become within the reach of many more people. The housewife should consider the advisability of including one in her kitchen equipment, not only from the points of view of efficiency and labour saving, but also because fresh food is of more importance to the family than anything else. Every year there are cases of food poisoning which could be avoided if proper refrigeration of food was the rule.

In the best models shelves are arranged to afford maximum space for storage and to ensure that milk, meat, butter, eggs, iced sweets, etc., can all be kept fresh and pure simultaneously by giving each type of food its allotted space. Choice of a refrigerator must to some extent be governed by size of family, room available for accommodation, and cost. For those who live in the country where an electric plant is not installed, a gas or oil-operated refrigerator might be selected. If a non-

mechanical one is possessed which is worked by electricity and the family move to a district where such operation is not possible, the refrigerator can sometimes be adapted to use oil or gas and vice versa.

To caterers especially the refrigerator offers reassurance; for complete meals may be prepared and stored in the refrigerator cabinet for a day, and foundation recipes for several days. Thus it is always worth while to get as large a cabinet as possible: it is itself a whole larder. British Electrical Development Association publish an excellent booklet of recipes (price 1s.) for "Cold Cookery."

Careful attention should be given to a refrigerator. Naturally it must be kept spotlessly clean, or its end is defeated. It should be looked at every day, washed out with a weak solution of bicarbonate of soda and water whenever necessary, and regularly wiped over with a clean, damp cloth.

REFUSE: Its Removal. This term includes excreta refuse from house and stable, ashes, dust, waste from food, street sweepings, and trade waste. The removal by hand of dustbin refuse and street sweepings is known as scavenging. The removal from time to time by hand labour of excretal matters from privies or cesspools is known as the conservancy system. This method has to be resorted to in country districts, but in towns and cities excrement and waste water are removed in drains and sewers by what is called the water carriage system.

All forms of refuse are likely to cause a nuisance or encourage disease if kept stored in or near the house for too long a time. For this reason the householder has a clear duty to see that the storage and disposal of refuse is carried out on hygienic lines. The quantity of refuse stored on the premises should be reduced as much as possible by burning the easily destructible refuse every day. Vegetable and food scraps generally should be dealt with in this way, as they are particularly prone to give rise to trouble by decomposition.

The material that is not burnt should be stored in a hygienic type of metal ashbin with a well-fitting cover. The latter should always be kept in place to prevent the refuse from being blown away by the wind, and also to protect it from rain, as dampness favours decomposition. The contents should be removed at least twice a week if possible. Horse manure should be removed frequently from stables. Nuisance from smell and flies is often caused by this form of refuse, but can be reduced by storing the manure in the cart in which it is to be removed.

In country districts, where refuse is frequently dumped on the land, care should be taken to see that the refuse is well covered by at least 6 in. of soil until it has been well purified by natural means, otherwise nuisance from smell and flies will result. Excretal refuse must be treated with particular care, and where a cesspool system is in use it should be kept in good order, and care taken that any water supply in the near vicinity is not polluted thereby.

The practice of disposing of house refuse by dumping it on the surface of waste land and so making a shoot is not to be recommended, unless it is strictly controlled by the local authority. What is known as the Bradford System is the best form of controlled tipping. This is successfully carried out in many large towns without causing any nuisance, and at a very great saving to the ratepayers. The main feature of this system is that the refuse is tipped in layers about 6 ft. deep to proper levels. Care is taken that all tins and hollow receptacles are filled up solid. At the close of the day's work all refuse is covered up with soil or road sweepings about 6 to 9 in. deep. Special care is taken with any fish offal or other foul matter, which is buried deeply. Screens are provided to prevent light materials from blowing about.

There is no doubt that the most sanitary way of disposing of house refuse is by burning it in some form of destructor. Excretal refuse in most towns is carried away by the drains to the sewer, and so to special sewage works.

Duties of the Local Authority. The collection and removal of house refuse is a duty that devolves upon the local authority in every district. It is usually assigned to the sanitary department in towns and cities, and a staff of dustmen is employed for the purpose, who go from house to house with the dust carts. Ashpits are cleared by the dustman without assistance, but in some towns the householder is expected to get his dustbin taken out into the street and put back in its place after it has been emptied. It is not an ideal or sanitary method, since people must pass rows of dustbins on the pavement, often standing in the hot sun. Fortunately this practice is rapidly dying out.

Should there be any neglect or omission to clear a dustbin or ashpit, as may occur where a tenant has just come into a house that has been empty for some time, the sanitary authority should be at once informed in writing, as they are bound by law under a penalty to make the necessary arrangements. The tenant on his part should ascertain the time at which dust is collected in his neighbourhood, and make arrangements accordingly.

Open dust carts without protection of any kind are still employed, but the closed or partly closed type now used in many towns is more hygienic, as it involves little or no risk of dust being scattered about the roads in stormy weather.

The insanitary, high dust cart is rapidly giving way to the motor dust van with a low loading line.

Many of these have automatic covers to secure dustless loading.

It should be noted that local authorities are only bound to remove house refuse; where a trade is carried on, and there is nothing in the nature of domestic work associated with it, responsibility for the removal of the refuse rests with the person who is carrying on business on the premises. It is not always an easy matter to decide in which category a given case may fall, and litigation has been necessary to clear up doubtful points. Thus, clinkers from a steam laundry are trade refuse, but those from an hotel are house refuse; but most authorities make arrangements to remove on payment of a small fee.

Garden rubbish should not be put in dustbins, although this is frequently done; if the quantity is not excessive the dustman may take it if he chooses, and as a rule there is no difficulty, but with large quantities the occupier must arrange for the removal as if it were trade refuse.

A better way of disposing of garden and other similar refuse is to bum it in an incinerator. *See* Cesspool; Drains; Dustbin; Incinerator Rubbish; Sanitation; Sewage.

REGENCY STYLE. In furniture decoration and architecture this is the term employed for designs created between (about) 1795 and 1830. Regency style was an off shoot of Empire style and the designers were the modernists of the late Georgian period, though they were influenced by the work of Sheraton and Robert Adam. Regency style at its best was a wholesome revulsion from the trivial debased ideas borrowed from French furniture of the worst school which had become fashionable at the end of the 18th century.

An archaeological revival produced the Empire style in France and its English derivative. An attempt was made by the leading designers to adapt Greek, Roman and Egyptian types of furniture and architectural features to contemporary use. Classical influence had largely swayed the Adam designs, but the Regency adaptations were on heavy, simple lines and some connoisseurs consider that beauty of form is rare in pieces of this period except in those which show direct development from the Sheraton school and in some of those designed by George Smith.

The originator of the Regency style in England was Henry Holland, architect to the Prince Regent and designer of Carlton House. He applied detailed drawings of Roman fragments to designs for furniture, etc., and the work produced from these belongs to the more graceful examples of Regency style. The most characteristic work, however, was the result of designs made by Thomas Hope, who, besides other sources of classical inspiration, drew on the cult for Egyptian designs which were the vogue in France, in 1804, after Napoleon's invasion of Egypt. In 1807 he published

a book entitled "Household Furniture and Interior Decoration," which contains illustrations of the pieces most sought by collectors of Regency furniture.

Rooms were usually papered, marbled effects made to resemble blocks being particularly liked and classical designs were popular on satin papers. Borders and mock pilasters were used. Marbled paper pillars, tinted to appear round were another feature, while doorways were sometimes grained to simulate rose and green marble. Pelmet and curtains were severe in form: heavy satins, striped fabrics, and silk damasks were used for these and for upholstering furniture. Pictures were hung by tasseled cords instead of wire.

The association of strongly figured woods with inlay of brass and bronzed metal is characteristic of Regency furniture. Amboyna wood and zebra wood were used as veneers for secretaires and cabinets which were often enriched at the corners by Egyptian terminal figures with heads and feet of ormolu. Mahogany and rosewood pieces were frequently decorated with gilded carding. English cabinet making of this period was of a high standard.

Regency Style. Fig. 1. Chair-back settee, a combination of four chair backs with cane panels. Fig. 2. Armchair, showing typical brass inlay decoration Courtesy of Our Homes & Gardens.

Chairs of this style commonly have a scroll-over back, and the legs splay out in a curve. The settee illustrated is characteristic of the solid type of furniture made during this period, while the armchair shown in Fig. 2 is an example of the lighter style and is decorated with brass inlay. The seats and backs are in some instances of cane mesh. Circular tables, supported by a centre pillar and four splayed-out and curved supports, were made, and sofa tables with two end supports having yoke-shaped feet were introduced. Reeding was a favourite decoration. Towards the end of the period the short fluted straight sofa leg displayed the splayed support. Regency and Empire style frankly inspires certain modern designers and is particularly suited to the formal houses built at about this period. *See Empire Style; Sheraton; Victorian Style.*

REGISTRATION. In Great Britain certain facts must be registered—i.e. an official record of them must be made and kept in some public place. Such are births, marriages and deaths, which must all be registered with a registrar appointed for the purpose. Names used for business purposes, if they are not the exact names of the persons using them, must be registered. There is also a scheme in practice for registering the title to land. Letters and parcels can be registered for safety. Motor cars and motor cycles must be registered. *See Birth; Death; Marriage; Motor Car; Motor Cycle; Postage.*

REGISTRY OFFICE. This name is given to a shop or other place of business that serves as an agency for engaging domestic servants, governesses, etc. Usually those requiring servants pay a fixed fee on entering their names and stating their requirements and a further sum, which is a percentage on the wages given, when they are suited. Servants are not charged.

REHMANNIA. This is a herbaceous perennial, 2 or 3 ft. high. It is hardy in well-drained soil in the comparatively mild southern and western counties, and in summer-bears rosy-purple flowers somewhat resembling those of the foxglove but having a pronounced “lip.” A variety named Pink Perfection is usually preferred to the typical kind because of its more attractive colouring. Rehmannia thrives in ordinary non-clayey garden soil with which sand and leaf-mould or peat have been mixed; it is an excellent pot plant for the cool greenhouse. Propagation is by seeds or division in spring. The seedlings must be raised under glass.

Rehmannia, The rose-purple flowers of a plant suitable for the greenhouse or for out of doors in mild districts.

REINS. The reins are part of the harness of a horse, being used to hold it when it is ridden or driven. They consist of two long straps of leather; one end is fastened to each side of the bit and the other is held in the hands of the rider or driver, who is able by this means to control and direct the movements of the horse. Reins are sold by saddlers and should be kept clean and bright by polishing. *See Driving; Harness.*

REJECTOR: In Wireless. The technical term applied to one form of the device more popularly known as a “wave trap.” The other form is an “acceptor.”

The purpose of a wavetraps is to reduce the interference with reception caused by a powerful broadcasting station. In view of the greatly increased selectivity of many modern wireless receivers, wavetraps are much less often required to-day than in former years. For instance, it is seldom that a receiver employing a superheterodyne circuit requires the aid of such a device. However, with certain of the simpler and cheaper receivers there may be instances when a wavetraps would perform a useful service.

The acceptor type comprises a coil and variable condenser joined in series across the aerial and earth terminals of the set. At signals of the frequency of this acceptor circuit (the value of which will depend upon its inductance and capacity) an easy path from the aerial to earth is formed. Thus the circuit readily accepts the frequency to which it is tuned and by-passes it to earth, leaving the desired signals free from interference to pass on to the set. This type is not, however, as effective as the rejector. The rejector type also comprises a coil and variable condenser, but in this case they are joined in parallel and then placed in series with the aerial. In other words, the aerial of the set is connected to one end of the coil and the other end of the coil is connected to the aerial. The variable condenser is connected across the two ends of the coil. This rejector circuit presents a high resistance to H.F. currents of the frequencies to which it is tuned while permitting others to pass with relative freedom.

Therefore, having adjusted the device to oppose the passage in the aerial circuit of the energy developed by an interfering station, the set can be tuned in the normal way without further reference to the rejector.

In practice, it is generally found that the strength of the signals of stations close in frequency to that of the interfering station is reduced to some extent by the rejector. On the other hand, a complete rejection of a very powerful local station is not always possible by means of a rejector wavetraps alone. There may be a direct “pick up” of that station on the tuning coil or other components of the set.

For rejecting any one station on the medium wave broadcasting band, a coil of 60 turns of wire on a tube 2½ inches in diameter and a .0005-mfd. variable condenser can be used.

RELAPSE. By a relapse is understood a repetition (not a complication) of an illness, or at any rate of certain characteristic features, such as fever, occurring after the original illness is passing away and the patient is entering upon convalescence.

A relapse in scarlet fever may be expected in about one case in four hundred.

In cerebro-spinal meningitis several relapses may occur in the same patient, and one may ultimately prove fatal. Serious relapses in diphtheria, measles and typhus fever are very rare. In erysipelas, on the other hand, a relapse is quite a common event, and may be repeated several times.

Although there is no sure way of preventing a relapse in the infectious fevers, skilled nursing, medical care, attention to hygienic details of treatment and proper dieting are undoubtedly of value in minimising the risks of a relapse.

RELAPSING FEVER. An acute infectious fever, which is liable to a relapse or a series of relapses with intervening periods free from fever, is, on this account, known as relapsing fever. The disease has occurred in epidemics in Great Britain and Ireland. Its incidence is favoured by overcrowding and want, and from the latter circumstance it was also known as famine fever.

RELAY. This is an electrical device usually comprising an electro-magnet having an armature which is arranged to close a switch in a local circuit when a relatively weak electric current flows through the magnet windings. One household application is in the wiring of burglar alarms.

A relay station is a low power broadcast transmitter which radiates the programmes supplied by land line from a distant studio. Relay stations are intended to serve only small areas. *See* Bell; Burglar Alarm.

RELISH: In Cookery. A relish is any savoury ingredient calculated to give a piquancy to plain or tasteless dishes. The term is applied also to special dishes which give a zest to the appetite. Pickles, sauces, chutney, and all table condiments are considered relishes, and are added to meat and sauces to enhance the flavour. *See* Chutney; Cocktail; Condiment; Hors d'Oeuvres; Pickle; Sauce.

REMOTE CONTROL. This is a device for operating electrical apparatus at a distance. A locally controlled relay is usually employed to make or break the main circuit. *See* Relay.

REMOVAL. When a move to another house or flat has been decided on, it is advisable to obtain estimates from several firms of removal contractors. Representatives will call at the house and make a calculation of the quantity of goods that has to be dealt with, and on their reports the estimates sent in by the firms will be based.

It is always best to deal with a firm which has a staff large enough to cope with all emergencies and experienced in the careful handling of all kinds of domestic furnishings. They will probably have a fixed scale of charges, and their estimate will include all the costs of packing, removing, unpacking, carrying furniture upstairs, fixing overmantels, etc. They provide their own packing cases, and take all responsibility for the goods while they are in their charge and which have been packed by their staff.

The sum charged depends largely on whether the goods can be packed into a single van or whether two or more may be required. It is advisable to sort out and dispose of all rubbish before moving, both on the score of less property to remove and of the opportunity afforded for getting rid of useless possessions.

Preliminary Arrangements. Before the removal there are various matters connected with the new house that should receive attention. Plumbing should be overhauled to see that all the taps and pipes are in working order. Roof gutters may need cleaning out, and the cisterns should be tested. Perhaps a new gas cooker is required; a geyser may have to be installed and new gas fires. As this work may entail fresh pipes it should be finished before removal.

Where electricity is used the fittings should be decided on and all electrical work done before decorations, which also should be completed as far as possible before the furniture is brought into the house. Another labour-saving point worth noting is to have carpets cleaned and delivered at the new home in time to be laid before the furniture is placed in the rooms. This does not apply to stair carpets, rugs or small carpets. The first would have too much traffic over them and the others are easy to lay and no heavy furniture need be placed on them. Linoleum may also be fitted and laid wherever necessary. The house will, of course, have been thoroughly cleaned when the decorators have finished their work.

Curtains and blinds may also be put up when the windows have been cleaned. Sometimes the incoming tenant arranges to take over such fixtures as pelmet boards, curtain poles and rods, blinds, lighting fittings and linoleum, and this also facilitates removal. If these preparatory arrangements are all properly attended to and personal belongings are carefully packed in drawers of wardrobes and chests and well covered over, it is surprising how quickly a new home can be settled.

Packing Smaller Articles. Where there are many ornaments and much plate, china and glass, these things are usually packed the day before the removal under the supervision of the foreman. In any case packing cases are provided for smaller articles and pictures and for books. Large pictures should be protected by plenty of thick wrapping paper and moulded frames by sacking. The firm will naturally only be responsible for goods packed by their own men, so that while it is always advisable to mention articles of particular value, it is best to leave the actual packing of them to the foreman.

Kitchen utensils and gardening implements are generally put in last. The former are packed in cases, with the exception of things which will be immediately required and which are best placed in a special box, so that they are easily got at on arrival. When the furniture is being taken out, wardrobes and sideboards may be unscrewed and removed in sections if necessary, and this is the safest plan where heavy furniture is concerned, as well as the most convenient. The leaves should always be taken out of a dining table and the table firmly screwed up to its smallest proportions, otherwise the screw underneath is liable to become strained or warped in transit. Trouble with the piano depends mainly on its location in the house. If it has to be fetched down from an upstairs room careful handling is required not to damage walls and banisters; should there be sharp corners to negotiate, it may have to be taken out through a window, and an extra charge is made by the firm for the necessary apparatus.

On arrival at the new premises the contractor's men look to the mistress of the house for instructions as to where all the things are to go, so it is always best for her to be on the spot. Besides directing the disposal of the furniture, she will also see that any heavy pieces which were removed in sections are properly screwed together again, and that mirrors, etc., over fireplaces are fixed in position.

Where the removal involves a railway journey from one town to another the work of packing has to be very efficiently performed if breakages are to be avoided. Not only ornaments and small articles, but every piece of furniture requires to be carefully wrapped up and all edges and corners protected with straw or other material. Mirrors and the more delicate pieces of drawing-room furniture need

special attention, so that the packing-up takes longer to complete. The journey is made by goods train or motor vans, the contractors making all the necessary arrangements.

Legal Points. The important point for the householder to remember is that goods in transit are carried by the railway at the owner's risk, and, however carefully safeguarded, they are exposed to the risk of fire, whether in the goods yard or on the journey. It is therefore false economy not to take out an insurance policy covering the risk of fire while the furniture is in transit. Another point to note is that when more than one firm are engaged in the removal the householder should specially stipulate for an inclusive estimate, that is to say, an estimate which covers any charges made by the firm at the other end. *See Electricity; Fixtures; Lease; Rent; Warehousing, etc.*

REMOVE: The Course. A remove consists of the substantial dishes of the meat course. Roast, boiled, or braised whole joints are removes, also beef à la mode, larded fillets of beef or veal, saddle of mutton, haunch of venison, or braised ham, etc. The remove follows the entrée.

RENANTHERA. This epiphytal orchid, shy blooming and suitable only for culture in a stove house, may be grown on blocks of wood, as described for other species in the article on orchids. It requires a minimum temperature of 60°. The growing period is from March to October, when roots require syringing twice daily. Plants rest during the winter period, and then require less moisture at their roots. *See Orchid.*

RENDERING: With Mortar. Rendering consists in covering the surface of brickwork or other structure with a coat of Portland cement mortar. The rendering coat applied to the exterior of a house makes it more resistant to the weather. In a cement water tank the rendering keeps the water in the tank, or it may be used on the walls of a cellar to keep out damp. Rendering is often carried out for no other reason than to produce a smooth, impermeable, hard surface, an example of this being in the internal walls of a kitchen or of a scullery.

Rendering. Fig. 1. Preliminary spatter dash coat to provide a key on brickwork. Fig. 2. Combing to furnish key for second coat. Figs. 3-5. Various surface finishes. (Courtesy of the British Portland Cement Association, Ltd.)

The amateur will find that rendering with cement mortar is particularly beneficial to house property. The procedure to be followed must be guided largely by the nature of the work. In the case of small work, such as the brickwork immediately surrounding a trapped gulley at the outlet from the sink, it suffices to daub the wall with cement mortar, applying it with a trowel and smoothing it off. With a large area, as, for instance, the whole of the exterior walls of a house, the rendering coat is kept uniform in thickness with the aid of screeds.

These are battens of wood about 2 in. wide and 1 in. thick, nailed to the wall to act as guides. They should be placed not more than 10 ft. apart, and set vertically with the aid of a plumb-line. Some horizontal screeds should also be put up. These can be kept straight by stretching a light line from one end of the building to the other, and adjusting the screeds until they are exactly parallel with it. The screeds should be packed up so that the back of them is about $\frac{3}{4}$ in. away from the normal wall surface, as this is necessary to provide for the first coat of mortar being worked underneath the screed. The screeds are removed when the first coat has set. Another plan that is sometimes adopted is to make the screeds in strong cement mortar by working them up until they are flat and true, and then allowing them to set hard. The wall surface at this stage has a series of ridges upon it both vertically and horizontally, the upper surfaces or tips of the ridges being on a level and true. In either case, the surface of the screed is used as a guide when finishing off the rendering coats.

Rendering on Brickwork. With brickwork it is first necessary to rake out all the joints between the bricks and also to hack over the surface of them to roughen them so that they act as a key for the first rendering coat. In new brickwork which is intended afterwards to be rendered, facing bricks are often used which have a serrated surface. Another method of providing a key is to apply a spatter dash coat of cement and sand (1 part sand, 11 parts coarse graded sand, and 1 part water, all measured by volume). This is dashed on to the brickwork, leaving an uneven surface (Fig. 1). The spatter dash coat is left to dry for a couple of days.

Before applying the first coat, the face of the work is brushed down to remove the dust, and the bricks thoroughly wetted to assist the adhesion of the mortar. The latter may be prepared on a banker, or platform of wooden boards, in the proportion of one part of Portland cement and 4 parts of sand, for the first or rendering coat. The sand must be good, clean, and sharp, and free from salt and earthy matter.

The proportions are obtained by measuring in bulk, using a pail or rough box for the purpose. The sand is measured up first, putting it on the banker, and then measuring up the amount of Portland cement. This is put on top of the sand, and turned with the shovel two or three times. The remainder is stirred in with the shovel. Water is added and the whole mixed to a working consistency. It is applied to the brickwork with a large trowel, working as quickly as possible, filling the whole of one of the spaces between the screeds, working off the surface to an approximate fair surface, and trueing it up and straightening it by means of a floating rule.

The work proceeds until the whole of the required surface is covered. The second or fining coat is applied usually about $\frac{1}{8}$ in. thick, and should be composed of 1 part of Portland cement and 2 parts of sand, both measured by bulk. The same grade of sand should be used in the fining as for the rendering coat. The fining coat should be applied to the rendering coat as soon as the latter has set, but before it is too dry, otherwise the fining will not adhere properly. A key is needed for the second coat and this is effected by combing the surface of the backing coat when the latter has commenced to dry out and harden. The indentations should be about $\frac{1}{4}$ in. apart and not more than $\frac{1}{8}$ in. deep (Fig. 2).

The surface is generally finished with a hand float, made of pine or other soft wood; in better-class work it is brought first to a uniform face with a traversing rule, and then finished with a hand float. During the finishing process, the surface of the mortar must be kept wet with a brush, working up the face with the hand float in a kind of circular motion, as this tends to eliminate inequalities on the surface. This process is often known as scouring; in addition to keeping the surface clear, it has the effect of hardening and consolidating the face.

Finished in this way the mortar will dry out with a closely grained, compact, and smooth surface. If desired, it can be relieved by jointing, that is, forming lines on the face about $\frac{1}{4}$ in. wide and $\frac{1}{8}$ in. deep, ruling them with a jointer. Other surface finishes are by various methods of trowelling (Figs.

3-5). Alternatively, the work, if brought to a smooth level surface, may be painted with one of the branded paints specially prepared for concrete and cement work. The ordinary paint is useless under these conditions. If it is desired that the surface shall be waterproof the best plan is to use a recognized waterproofing material, which is generally obtained in powder form, and should be thoroughly mixed up at the time of preparing the mortar. *See Cement; Damp; Mortar; Plaster.*

RENNET. This is used in order to obtain a curdled condition of the milk. It is also employed for a similar purpose in making junket and curds and whey. Rennet is prepared from the stomach of a newly killed calf. The stomach is thoroughly cleansed with salt and then drained for 3 or 4 hours. Afterwards it is stretched and well salted, and kept in the salt.

A very small portion of rennet is sufficient to curdle a gallon of milk, and all that has to be done is to cut off a little piece, soak it in warm water, and add about 1 dessertspoonful of the rennet liquid to 1 quart of milk.

Rennet is prepared and sold ready for use either in tablet or liquid form. With a good make of prepared rennet the best results can be obtained. Several acids will produce curds in milk, but in the preparation of sweet dishes rennet is by far the best. *See Cheese; Curd; Junket.*

RENT AND THE RENT ACTS

The Legal Relations Between Landlord and Tenant

Agreements; Distraint; Landlord; Lease; Rates, are a few of the other articles that touch upon the subject of rent. *See also* Furnished House; Ground Rent; House; Removal; Repairs

Rent is the money paid for the use of houses or land. It is usually paid either weekly, or monthly, or quarterly, although landlord and tenant are at liberty to make any other arrangement about it. For nearly all the smaller houses in the country rent is paid weekly, the collector calling for it on Monday or Tuesday of each week. For the larger houses it is paid quarterly. Monthly payments are less common, but in London, many persons pay rent for houses and flats by monthly instalments.

Furnished houses are usually let at a rent calculated by the week, but in this case it is not, as a rule, paid weekly. This division between weekly and monthly or quarterly corresponds roughly to the division between salaries and wages.

The tenants of small houses usually pay rent and rates together, the weekly payment covering not rent only but also rates. The landlord in such cases pays the rates from the money he receives. A number of flats are let on the same principle of an inclusive rent, as are most furnished houses. The landlord is obliged to show the amount he pays in rates, and under the Rent Restriction Acts he can increase the rent in order to cover any increase in the rates. Conversely, he must reduce the rent if the rates are reduced.

In some localities the plan of charging the rates on small houses direct to the tenants has been tried, but usually it is found that the other scheme is the more economical. The weekly rent paid by the tenant of a small house covers also any income tax which the landlord may have to pay on the property in question. In the case of larger houses, the tenant pays this, but he can deduct the amount from the rent, and the landlord, if he is not liable to pay income tax, can recover it in the usual way. Rent is not due until the midnight of the day upon which it is reserved to be paid, e.g. if rent is payable on Midsummer Day, it is not payable until midnight of June 24. Therefore it is not overdue until after midnight, and cannot be distrained for until it is overdue.

Rent Restriction. At common law landlord and tenant may agree on whatever rent they lease, but with regard to certain dwelling houses this power is restricted by the Increase of Rent and Mortgage

Interest (Restriction) Acts, 1920 and 1923, following certain earlier acts passed in 1915 and onward. These acts applied to dwelling houses built on or before April 2, 1919, where the annual amount of the standard rent or rateable value does not exceed: in the metropolitan police district £105; in Scotland £90, and elsewhere £78. As from Sept. 29, 1938, the act does not apply to any house if the rateable value on April 1, 1931 (London, April 6; Scotland, May 16) was greater than £20 (London and Scotland £35). One month's notice must be given.

The acts do not cover furnished houses, or rooms where attendance is provided at an inclusive rent, provided always that the furniture or attendance forms a substantial part of the letting. A house is none the less a dwelling house because part of the premises is used as a shop or office, or for any other business or professional purposes, but the acts do not apply to premises let for business purposes only.

Attendance always means attendance within the premises let; so that where the tenant of a flat which forms one of a large number in some London mansions pays for the services of someone to scrub the common staircase, and this payment is included in his rent, he is not apparently excluded from the act by reason of that circumstance.

For all dwelling houses within the acts there is a standard rent, and this standard rent is in the first place the rent at which the premises were let on Aug. 3, 1914. If they were not then let, the standard rent is the rent at which they were last let before that date, or, if not let before, the rent at which they were first let after that date. Rateable value means the rateable value on Aug. 3, 1914.

Suppose the premises to have been let to tenants in the normal way continuously, no landlord can charge more than the standard rent until he has given a lawful and proper notice of increase. The notice must be one to expire at the end of 4 clear weeks, unless such notice is given on account of an increase in the rates, when it need only be one clear week. Every notice must be true in substance, i.e. not false or misleading. No notice of increase of rent is valid unless the tenancy has been determined either by the lease running out or by notice to quit having expired.

In other words, the landlord can only give a notice of increase of rent where the tenant is holding over by virtue of the act, and, but for the act, could be evicted. But if a tenancy may be terminated by notice, e.g. a weekly or yearly tenancy, if the landlord gives notice of increase, it operates as though it were a notice to terminate the tenancy from the earliest date at which it could be terminated by notice.

Rent Increases Allowed. The amount of the increases which may be charged is as follows:

- (a) On any amount spent by the landlord on improvement or structural alteration, excluding decorations and repairs, 6 per cent interest on the capital sum if expenditure before July 2, 1920, and 8 per cent if after. The tenant may apply to the county court on the ground that the expenditure was unnecessary.
- (b) The amount by which the current rates exceed the rates payable on Aug. 3, 1914.
- (c) 15 per cent of the net rent. The net rent is, in cases where the tenant pays an inclusive rent (i.e. a rent which includes some payment in respect of the rates, which are then paid by the landlord), the standard rent less the amount of the rates: in other cases (i.e. where the tenant pays his own rates to the rating authorities), the net rent is the same as the standard rent. Where the landlord is responsible for the whole of the repairs, 25 per cent of the net rent, and where he is responsible for part of the repairs some smaller amount to be either agreed or decided by the county court.

When the tenancy is a sub-letting of part of a house, the sub-tenant may have his rent increased by 10 per cent on the net rent of his part, and an amount equivalent to 5 per cent of the net rent of the dwelling house comprising the sub-tenancy may be charged to the tenant of the whole house. The tenant of a house who sublets it in parts is bound to give his landlord, on demand, a statement of

particulars of the sub-tenancies The effect is that a tenant who sublets may increase the rent of his sub-tenant by 10 per cent, but must hand over half of that increase to his own landlord.

A tenant who has been served with notice of increase under (c) or (d) above may, if the house is not in a reasonable state of repair, apply to the sanitary authority and obtain a certificate to that effect, and serve it upon his landlord; and thereupon he will have a good defence to any action brought for increase of rent and will not be bound to pay the increases till the place is put into proper repair. The certificate is not a defence if the state of the premises is due to the tenant's own fault. A landlord who transfers to a tenant any liability which he himself was under is to be deemed to have increased the tenant's rent to the extent of that amount.

Decontrolling Houses. By an act of 1923, dwelling houses which had been protected by the Rent Act might be "decontrolled," i.e. taken out of that protection in certain cases. The restrictions will cease to apply in any of the following events:

(1) If the landlord was in possession of the whole of the dwelling house on the July 31, 1923, or came into possession of it at a later date. "Landlord" here means either a freeholder or a tenant under a long lease at a small rent, and a dwelling house is not decontrolled if the tenant of a house who sub-lets rooms (and so is in a sense a landlord) comes into possession of one of the "dwelling houses" into which he has divided the house, for he is not a "landlord" for the purposes of the act. Further, where a landlord has let a house and his tenant has sublet part of it, that part will not become decontrolled if the landlord gets possession of the rest of the house on the tenant going out. Possession means actual possession, and the dwelling-house will not become decontrolled if there is merely a change in the tenancy with no interval between the end of the old tenancy and the beginning of the new tenancy. Thus, if a tenant whose tenancy runs from Saturday to Saturday, goes out on a Wednesday, having paid rent for the full week, and the new tenant enters on the following Monday, paying rent from the Saturday, the landlord will not at any time be entitled to possession, although he may actually enter, and the house will not be decontrolled. There must be an interval between the tenancies for which no rent is due by anyone. The landlord should always enter the premises between the tenancies or send his agent there, in order to establish definitely that he is in possession. Acts such as having the dwelling-house cleaned or painted are very satisfactory evidence of being in possession.

(2) If the landlord grants to the tenant after the 31st July, 1923, a lease of the dwelling-house for a term of not less than two years, ending not earlier than one year after the date fixed at the time at which the lease is granted for the expiration of the Rent Restriction Acts. No house can be decontrolled after May 26, 1938. From July 31, 1923, to July 18, 1933, any house could be decontrolled; but if the rateable value was not over £13 (London £20, Scotland £26 5s.) the house must be registered with the local authority before August 27 1938. This meant almost a return to the system practised before the war. Between July 18, 1933, and May 26, 1938, only houses whose rateable value exceeded £13 (London £20, Scotland £26 5s.) could be decontrolled. Houses with rateable values between £13 and £20 (London and Scotland, £20 and £35 respectively) decontrolled before May 26, 1938, must be registered with the local authority before August 27, 1938, or with special leave from the County Court up to May 26, 1939.

Arrears and the Rent Acts. A landlord cannot levy a distress for rent in the case of a dwelling-house within the Rent Restriction Acts without previously obtaining the leave of the county court. Whether a house is within the Rent Restriction Acts or not, an under-tenant or lodger may obtain protection for his property against any distress levied by the superior landlord for rent due by his

tenant (i.e. the immediate landlord of the sub-tenant). He should serve on the superior landlord or his agent a declaration in writing made and signed by him stating that the landlord's immediate tenant has no right of property or interest in the goods sought to be distrained, and that the same are the property of the under-tenant. An inventory of the goods referred to must be annexed to the declaration.

Tenants and Sub-Tenants

The declaration must also set forth the amount of rent (if any) due from the subtenant to the tenant, the times at which future instalments become due, and their amount, and must contain an undertaking to pay direct to the superior landlord instead of to the tenant any rent due or to become due until the arrears for which the distress has been levied have been paid off. A landlord, when the rent due by his tenant is in arrear, may serve upon any sub-tenant of that tenant a notice requiring him to pay all future rent to the landlord, instead of to the tenant until the arrears have been paid off. When a sub-tenant receives such a notice he must pay his rent to the landlord.

Deductions from Rent. Rent is invariably a net amount and not subject to any discount or other reduction, such as is customary in trade. It is only under exceptional circumstances that a tenant is entitled to make a deduction when paying his landlord. An example of this is where the tenant has been called upon in an emergency to pay the ground rent and has done so in order to protect his own interests and to avoid trouble, or perhaps simply for the convenience of the landlord, or in his absence. In such a case the tenant is entitled to deduct the amount from his next payment of rent. In the same way, when a lodger's goods are included in a distraint for rent due by his landlord to the owner of the property, he can deduct their value, if they should be sold, from the amount of rent.

Quarter Days. For the larger houses rent is usually payable in England on one of the four statutory quarter days, namely Lady Day, March 25; Midsummer Day, June 24; Michaelmas Day, Sept. 29; and Christmas Day, Dec. 25. In some tenancies where no quarterly payments are expressly stipulated for, the rent is payable at the end of each year, but in the great majority of leases and yearly tenancies rent is payable on the quarter days.

When a house is vacant a tenant may be allowed to enter before the quarter day stated in his agreement. Before the Great War, and the consequent shortage of houses, it was not unusual for a landlord to charge no rent for this extra period as an inducement to the tenant to take the house. Now, however, the tenant will generally be expected to pay the full rent from the date of entry. If he decides to leave the house before the tenancy has expired he is not entitled to make any deduction from the rent.

Recovery of Possession. When premises are let for a fixed period the landlord cannot as a rule recover possession until the end of the period. It is, however, invariably provided in a lease or agreement that the landlord shall be entitled to recover possession if the tenant commits a breach of any of the terms of the letting —e.g. fails to pay the rent due, or to keep the premises in repair or uses the premises for some purpose for which he is forbidden by the agreement to use them. In such a case, however, the landlord must first serve a notice on the tenant and give him an opportunity of making good the breaches, and the court will not allow the tenant to be evicted if he does so and pays reasonable damages and costs.

When premises are let for an indefinite period, e.g. weekly, monthly, or yearly, the landlord cannot recover possession until he has served a notice to quit on the tenant, or the tenant has served one on

the landlord, unless the tenant has committed some breach of the terms of his tenancy which gives the landlord a right to recover possession.

Giving Notice. The length of the notice to quit may be stated in the tenancy agreement. If not, it will depend on the nature of the tenancy. In a weekly tenancy, a week's notice is required, expiring on the day of the week on which the tenancy commenced. Thus, in a Monday to Monday tenancy, the notice must require the tenant to give up possession on some Monday at least one week after the notice is served. A month's notice must be given in a monthly tenancy, expiring on the date of the month on which the tenancy commenced. In a tenancy from year to year, six month's notice, expiring on the day of the year on which the tenancy commenced, must be given. If the tenancy commenced on a quarter day, e.g. June 24, notice given on the previous quarter day but one, i.e. Christmas Day, will be sufficient, although there are not 183 days between Christmas and June 24th; but if the tenancy commenced on a day not a quarter day, the full six months' notice (183 days) must be given.

The notice should be in writing, addressed to the tenant and signed by the landlord, and must state clearly the premises to which it refers and the date on which it expires. A common printed form of notice much used by landlords requires the tenant to leave "on or before" a certain date. This form of words has been stated to be a bad notice and should not be used. A tenant is entitled to remain until midnight on the last day of his tenancy, so a notice expiring at noon would be bad. This branch of the law is very technical and all the requirements must be strictly complied with. The notice may be served either personally or by post. A suitable form is as follows:

26, Plowden Road,
W.29.
October 1st, 1938.

I hereby give you notice to quit the premises now occupied by you as my tenant at 176, Fountain Road, W.29, on Wednesday, October 12th, 1938.
(Signed) John Doe.

To:

Richard Roe, Esq.,
176, Fountain Road,
W.29.

No rent must be accepted for the period after the notice to quit has expired (i.e. after October 12th in the illustration) or the notice will be completely invalid. Arrears may be accepted at any time. This does not apply to premises within the Rent Acts.

Notice and the Rent Acts. When a house is protected by the Rent Acts the landlord can only recover possession by applying to the court. He must serve a notice to quit in the ordinary way and prove either that there is alternative accommodation or one of the following facts:—

(1) That the tenant has failed to pay his rent, or to perform some other obligation of the tenancy (see below).

(2) That the tenant, or some sub-tenant of his, or some person living or lodging with him, has been guilty of conduct which is a nuisance or annoyance to other occupiers, or that he has allowed the house to deteriorate by his neglect.

(3) That the tenant has given the landlord notice to quit and the landlord has in consequence taken some step, such as selling the house with vacant possession, which will seriously prejudice him if he cannot get possession. It follows, therefore, that a tenant in an ordinary case is not bound by any notice to quit he may give.

(4) That the landlord reasonably requires the house as a residence for himself, or for some child of his over 18, or for his father or mother. This, however, does not apply where the landlord has become landlord by purchasing the dwelling-house after December 6th, 1937. Further, the court will not give the landlord possession on this ground if it considers that, having regard to all the circumstances of the case, including the question whether other accommodation is available for the landlord or the tenant, greater hardship would be caused by giving possession than by refusing it.

The effect of this is that the landlord need not prove that other accommodation is available if he was the landlord before December 7th, 1937, but even in that case he will have a greater chance of success if he can prove there is other accommodation available for the tenant.

There are other grounds on which the landlord is entitled to recover possession, notably when the tenant has sub-let the whole of the dwelling house, but the above are the most important in practice.

It should be noted that even if the landlord succeeds in establishing one or other of the facts above, the court will nevertheless not grant him possession unless it is satisfied that it is just and reasonable to do so. This is very important in practice, especially in a case where the landlord claims because the tenant is in arrear with his rent. In such a case the court will allow the tenant to remain in possession so long as he pays his current rent and a small sum weekly off the arrears. If he fails to do this, the landlord must again apply to the court, and if the court is satisfied that there is no reasonable prospect of the tenant paying, it will grant an order for possession. When premises are within the Rent Acts, the landlord may accept rent after the expiration of the notice to quit.

These provisions restricting the right to recover possession will cease to apply to any house which is decontrolled, but the obtaining of an order for possession on one of the grounds set out above will not of itself decontrol a house.

It is a criminal offence for a landlord to ask any premium for letting a house to which the Rent Acts apply. A tenant, however, may agree to accept a lump sum for giving up possession, but landlords should exercise great care in entering into such an agreement, for it may be impossible to enforce it against the tenant, who may take and spend the money paid by the landlord and then refuse to perform his part of the bargain.

The Law in Scotland. In Scotland rent is paid half-yearly as a rule on one or other of the two term days, which are Whitsunday, May 15, and Martinmas, Nov. 11. These are called the legal terms to distinguish them from the other dates in the Scottish legal calendar, Candlemas, Feb. 2, and Lammas, Aug. 1, which are conventional terms. Rent may be paid on either of these latter terms if there is an agreement to that effect, but so far as the ordinary business of house letting is concerned the term days observed throughout Scotland are Whitsunday and Martinmas.

A peculiarity of the northern system is that a tenant may enter on May 15 or Nov. 11, but in all the burghs he moves out at the end of his tenancy on different dates. The moving-out dates are fixed a fortnight later than the term days, namely May 28 and Nov. 28.

The equivalent of the written or printed form of agreement by which many English tenancies are governed is a document known as a missive, in which is set out the duration of the tenancy, the

amount of the rent and when it is payable, the rates for which the tenant is responsible, and whatever conditions have been agreed upon as to repairs. No tenancy is effective until the missive has been signed by the tenant.

House Letting in Scotland

The business connected with the letting of houses is carried on as in England by house agents or factors, but a considerable portion of it is in the hands of lawyers. This applies especially to property let on weekly or monthly tenancies, but it also includes larger houses and flats which are let by the year or leased for longer periods. The law agents undertake the advertising and letting of the property, collect the rents, and see that the conditions set out in the missive are duly observed.

Notice to terminate a letting of a house must be given in writing forty days before Whitsun (May 15) or Martinmas (Nov. 11) if the letting is for over a year. If the letting is for four months or less the notice must be given some time not less than a third of the total let before the end, and if over four months then forty days before the end. All these periods may be altered by agreement between the parties concerned.

Special provisions apply to small houses entered in the valuation roll at a small amount. The maximum figure varies according to the size of the burgh in which the house is situated. No agreement for any letting of such a house is valid if made more than two months before the let is to begin; lets for more than a month can only be ended on the 28th of a month at noon, and those for less than a month on a Monday at noon; 40 days' notice must be given if the let is for 3 months or more, and a notice equal to a third of the let if the let is for less than three months. None of these conditions can be altered by agreement. If a tenant of such a house is seven days in arrear with his rent, the landlord may give him 48 hours' notice.

REPAIRS: To Houses. When a house is let for a term of years the agreement usually contains a clause stating whether the landlord undertakes all reasonable and necessary repairs, or whether the liability rests on the tenant. In the absence of such a clause there is no liability on either side so far as the agreement is concerned, but there may be a statutory liability. In Scotland, on the contrary, the landlord is liable for repairs, and if he fails to carry them out the tenant may do so and deduct the cost from the rent.

Sometimes there is a covenant in a lease under which the premises are to be delivered up in a good state of repair on the expiry of the lease. The tenant should understand that in such a case he is liable to put the house in proper repair whatever may have been its condition when he entered it. In this and all other cases everything depends on the terms of the agreement, and before he puts his signature to that document a tenant should always take the trouble to ascertain exactly what his position is in regard to repairs. Thus the tenant is liable to the landlord for any disrepair if under an express agreement to yield up the premises in good repair.

The usual covenant in an ordinary tenancy other than by lease is that the tenant must keep the premises in a proper state of repair, fair wear and tear excepted, and leave them in such a state at the end of the tenancy; and that the landlord shall have the right to enter the premises at any time or within reason to see that they are in a proper state of repair. The landlord is under no liability to do repairs unless he has expressly agreed to do so, or there is a statutory duty imposed on him. Where liable, and he refuses, the tenant can do them and sue the landlord for the cost. The tenant cannot deduct such cost from the rent.

The tenant is bound to take ordinary care of the premises and to make good any damage done during his tenancy. He is not bound to replace windows or door panels that were broken before he

entered into possession, but if these or any other fittings should get broken afterwards he is liable for the repair.

A roof which leaks after a tenant has taken over is often a matter of dispute. Apart from agreement or statute the landlord is not liable. It has been held in the courts that it is the tenant's duty to see to its repair, but this is a doubtful proposition. In most cases a landlord, in his own interest, will repair it so as to preserve his property; but he would be quite within his rights in refusing to do so, and then the tenant in his own interest would probably do it.

Repairs and the Rent Acts

Under the Rent Acts the subject of repairs acquired increased importance. Where the landlord is responsible, increase of rent is conditional upon a house being kept in proper repair, and he is deemed to be responsible for all necessary repairs for which the tenant is not expressly liable. A certificate from the sanitary authority that a house is not in a reasonable state of repair is a good defence to any claim for increased rent.

A landlord is liable to his superior landlord or freeholder for repairs if the property is leasehold, and those who own their own house should carefully study the covenants of their lease. The ground landlord can compel him periodically to re-point the brickwork, etc. The landlord who is his own freeholder is liable to the local authority if his property becomes dilapidated.

Houses inhabited by the working classes stand on a different footing. The landlord here is deemed to warrant that the house is in a habitable state when the tenancy begins and to contract that it shall be kept in reasonable repair during the tenancy. Such houses are those the rent of which does not exceed £40 a year in London; £26 elsewhere. In no case does the implied warranty hold when the letting is for three years and upwards, not determinable before that time by either party, and when the lessee has agreed to put the house into habitable condition.

A tenant who has agreed to repair and keep in repair his house is not bound to make a new house of it. Unless he has expressly agreed to paint he need only paint so far as is necessary to preserve wood or ironwork, and not for decoration. Regard must be had to the kind of house, its age, situation, and the like. Thus a tenant of a house in Grosvenor Square, London, undertaking to keep it in repair, must conform to a much higher standard than a tenant in Mile End Road.

If the tenant fails to repair, when bound to do so, he will be liable in damages, but these damages must not exceed the actual loss suffered by the landlord. When a house is shortly to be pulled down or structurally altered, no damages can be recovered for failure to repair it.

A tenant should take care to see that the house is in good order before he enters it, for there is no implication of law, except as to working-class houses, that an unfurnished house is habitable; so if the new tenant finds the drains unsound, he has no remedy. Where the rateable value does not exceed £100, a landlord cannot, without the leave of the court, enforce a covenant to repair five years or more before the lease expires. *See Dilapidations; Drains; Rent.*

REPOTTING. As plants raised from seeds or cuttings increase in size it becomes necessary to repot them, i.e. to place them in larger pots of soil to provide the roots with the extra nourishment needed. The first repotting of the seedlings or rooted cuttings is in small flower pots, 2½ in. wide; the next shift is to 5 in. pots, which are large enough for many kinds of flowering plants: 6, 7 or even 8 in. flower pots are required to ensure the full development of certain kinds, e.g. chrysanthemum, cineraria, herbaceous calceolaria.

Before disturbance for repotting, a plant must receive a thorough soaking some few hours in advance. To turn a plant out of its pot hold the stem between the fingers and invert the whole; then

give the edge of the pot a sharp rap on the edge of a bench, and lift it clear of roots and soil. With a stick pick out the old drainage crocks and remove loose soil.

The new pot must be scrupulously clean, and it is worth while ensuring this condition by scrubbing it out with hot water. Clean crocks are desirable also. Suitable composts vary with different classes of plants. For palms and aspidistras, 2 parts loam and half portions of leaf-mould, peat, and sand will be found excellent. The same materials in equal portions will satisfy ferns, whilst 2 parts good fibrous loam, 1 part well-decayed manure, and a little well-washed silver sand will suit such plants as fuchsias and geraniums. *See Fern: Potting.*

REPOUSSÉ WORK IN BRASS AND COPPER

Particulars of a Process that Gives Charming Results

This contribution should be read in conjunction with the article on Bowl, where the elements of simple repoussé work are explained. See also Metal Work Napkin Ring; Piercing; Silver Work

In its strict application, repoussé work means the formation in relief in thin metal of a pattern beaten up from the reverse side, but it now generally includes the shaping as well as the decoration of the article. It is a handicraft that can easily be done in the home, a workshop not being essential for its processes. Brass and copper are commonly employed, the most useful thicknesses of metal being from 26 to 22 imperial standard wire gauge.

In selecting the metal its ductility is of importance. Silver, although expensive, will bear considerable expansion and is pleasant to work on. Of the inexpensive metals copper is extremely ductile; it can be finished with an agreeable surface and is not liable to crack. Brass is harder, and not so suitable for high relief, but for many small articles it is very useful. Pewter is extremely soft and easily worked, but it is liable to split, and only in the thinnest sheets can it be used for high relief with any success. Iron and steel, particularly if thin, are capable of considerable expansion, but the repoussé ornament should be restrained.

Fig. 1. Good outfit for the amateur; by means of which most of the work illustrated can be done. (Courtesy of C. J. Plucknett & Co., Ltd.)

Repoussé work may be begun with a few tools, the principal ones being shown in Fig. 1. The first is the hammer, the head of which should be steel, or at least steel faced; the handle of special form is about 10 in. long, quite slender for two-thirds of its length, and terminating in a knob of a flattened oval form. A boxwood mallet with a similar handle is also necessary.

A selection of small punches is required; these for a beginning should comprise a tracer, a number of raising tools, pearls, punches, and matting tools. A steel scribing point is necessary, but it can be made from a knitting-needle; a pair of shears, compasses, try-square, and steel rule complete the worker's equipment.

Although a number of small articles can be made without it, a pitch block is essential for good work. This is a block of wood covered with a thick layer of cement made by melting 4 lb. of best black pitch in an iron pot and stirring in $\frac{1}{4}$ lb. powdered resin and $\frac{1}{2}$ lb. Russian tallow. When thoroughly mixed, add 4 to 5 lb. of plaster of Paris.

Another cement is made by substituting powdered bath brick for the plaster. These mixtures are highly inflammable, and if overheated a vapour may be given off which will easily take fire. Wherever possible the melting should be done out of doors. A wood fire can be used and the vessel supported on a couple of bricks. For small work it is convenient to pour the cement into a tin bowl, but generally it is better to use a block of wood about 12 in. by 10 in. by 2 in., and form a border on top of this to a height of 4 in. with strips of stout cardboard, so that the molten cement will not run off the board.

The tallow renders the cement soft, and it is advisable to have two blocks, one with a little less tallow than the amount stated above, and another with a little more. The block should be rested on a pad of stout canvas or leather filled with silver sand. If made with leather the pad can be used for working high relief without any risk of perforating the cover.

Making an Ash Tray. Fig. 2 shows a simple piece of work made from a piece of sheet copper or brass of about 24 S.W.G. and 6 in. square. In the first place the metal must be flattened on a hard, flat and true surface, such as that of an old flat iron mounted on a wooden stand. Only the lightest possible blows are needed, otherwise the metal will become buckled.

Fig. 2. Ash tray which can be made in brass or copper, suitable for the amateur's first attempt.

The metal is cleaned with emery cloth and a little oil, circular scouring marks being made all over the surfaces. The oil is wiped off, and the surface is ready for work. The design is now transferred with carbon paper on to the best surface, or, if preferred by the worker and he has some artistic ability, the pattern can be drawn direct on the metal. To prevent the lines getting rubbed off they are scratched over with a scribing point, which must be kept sharp for this purpose.

The next step is to indent the lines with the tracer, and probably some little difficulty will be experienced with this tool at first. It is necessary to make an even indentation which will show as an even line on the other side of the metal, and the best way is to mount the metal on the cement block. To do this the surface of the pitch must be melted, either by placing it in front of a fire, in an oven, under the grill of a gas stove, or by using a blow-lamp. It is not necessary to melt more than $\frac{1}{2}$ in. down, and then the metal is pressed on the cement so that it is just below the level of the surrounding surface, and the cement pressed out is allowed to run over the edge sufficiently to hold it in place.

The tracer is held in the left hand with the thumb and first two fingers and with the edge on the line, but tilted slightly away from it. The third and little finger should be behind the tracer and resting on the metal. The hammer is poised directly over the tool, and then a series of light, even, and continuous taps are directed on to the tool. There should be no need to assist the tool forward, as the

action of the hammer should have a propelling effect. The blows must be light, but the exact weight of the blow can only be gauged by experience. A fairly accurate estimate can be obtained by making a few tracer indentations on a piece of spare metal rested on a block of soft wood.

Raising the Design. When all the lines have been traced, the cement can be chipped off the edge of the metal, which is then prized off the block. If the metal is warmed and wiped with an oily rag, any adhering pitch can be removed. The pattern should be plainly visible on the other side of the metal, and that side is now placed uppermost and fixed in the cement. A brass punch is placed between the raised marks and the hammer used to drive it into the metal.

It is better to work along gradually, making a slight hollow, and to repeat the process several times, rather than attempt to reach the required depth at one blow. It will be seen that much depends on the shape of the punch. If some hard brass rod and bar is obtained, it will be possible to form suitable shapes with a file. The shaped end of the punch must be quite smooth and polished, as any uneven marks will show on the other side of the punched surface. Having sufficiently deepened the pattern, the metal is removed from the cement, warmed, cleaned, and then replaced with the raised surface uppermost.

The shape of the pattern is now adjusted with the tracer, but this time it is placed on its side, so that hammer blows properly directed will work the raised pattern to its correct shape. This is a simple operation, but care must be taken that only the lightest hammer blows are given, otherwise there is risk of driving the tool through the metal. If the metal has become uneven during the previous work, it can be levelled with the mallet, removing it from the cement and placing it on the sandbag, and when necessary on the flat iron, taking care not to damage the raised surface.

Ornamentation of the Ground. If it is desired to punch or indent the surface of the ground, or give a matt effect, the metal must first be thoroughly cleaned. Useful tools are the pearls, made of round steel rod ground to a round point and polished; these are usually provided in 3 or 4 sizes. By obtaining a number of 5 in. lengths of 3/16 in. steel rod, it will be possible to make suitable pearls, and also a tracer, which requires grinding to a blunt edge on both sides. Steel punches are made in the same way, by using rod of suitable thickness and grinding the ends to the required shape. All steel punches must be hardened and tempered, and the ends of them must be highly polished.

The methods described are suitable for all raised work, but with high relief it is necessary to remove the metal frequently for the purpose of annealing. Continual hammering, either direct or through a punch, has the sure effect of hardening the metal, and it is only when it is soft and ductile that the material can be thinned out. As a rule, the harder the metal is the more frequently must it be annealed.

More Elaborate Work. When the repoussé worker has had experience in raising simple forms, and desires to attempt more elaborate work, it will be necessary to do some of the preliminary sinking on the sandbag. Owing to the skill required in the successful manipulation of the mallet and the prevention of undue straining of the material, it is not advisable to attempt this stage of the work until a fair knowledge of the properties of thin metal has been gained.

When the sandbag is used, the surface of the flat iron, or a suitable hard surface, should be used in conjunction with it; after every few blows with the mallet, held as at Fig. 3, the work must be straightened on the flat surface, and frequent annealing must not be forgotten. The deeper the sinking is carried the thinner the metal becomes.

The surface finishing of repoussé work is an important matter, and consideration of the purpose of the finished work enters largely into it. If it is desired to tool the raised surfaces to any extent, it will be necessary to fill up the hollows before the metal is placed on the cement block. The surface

modelling is done in the same way as ordinary raising, but using greater care. Punches suitable for working the particular shapes are used. The tracer, employed as described above, is a useful tool to define shapes.

Above l-r. Repoussé Work. Showing how the various tools are held and used for the successful execution of this decorative metal work. Fig. 3. Inclination of the mallet when beating out a hollow in a flat piece of metal. Fig. 4. Method of holding the tracer. Fig. 5. Tracer held on its side to true-up shapes in the design.

L-r. Fig. 6 How to hold the punch. Fig. 7. Method of holding the mallet for flattening metal.

Repoussé decoration of bowl shapes is not so simple as in flat work, and different methods must be employed. Figs. 4 to 7 illustrate some of the

progressive stages in the process of decorating a small fruit dish. For a small bowl where it is impossible to use a punch, the method is to use a snarl held in the vice and a hammer. Several shapes of snarl must be provided, and it is hardly possible for the amateur to attempt much of this work without a large equipment. The raising is carried as far as possible with the snarl, and then the bowl is filled with cement, so that the main portion of the work can be done from the front. Professional workers rely almost entirely on surface modelling to obtain the effect, and are content to bulge the decorated surface beforehand.

The selection of suitable designs is not difficult; many are to be found in the pages of this Encyclopedia. It is important that the shaping should be done as far as practicable before the ornament is worked. It is often possible to do the shaping and the decoration at the same time; but it is only with a few shapes that it is possible to shape the work after raising a portion of it. Simple forms for trays and dishes can be done on the sandbag, and with the aid of one or two metal worker's stakes of varying shape (*see Silver Work*) all but the most elaborate forms can be worked.

The method of procedure in advanced work is very little different from ordinary raising, the main consideration being that of modelling. It is not always easy to gauge correctly the amount of sinking necessary to produce a pleasing surface effect; only experience enables the worker to obtain the approximate depth so that removal from the block can be reduced to a minimum. With large bowls it is always advisable to complete the shape as far as possible before the decoration is applied, and also to use the sandbag and mallet to beat out prominent portions of the design. This method assists the raising, because the metal is spread more evenly than is possible on a large surface when only raising tools are employed.

Final surface finishing should not be attempted unless the hollows have been filled completely with pitch; if there is much work to do, it is advisable to use a harder pitch than is generally employed. Matting tools should be used always with discretion, and in large work must be avoided for purposes of background effect. The main object in employing them should be to give texture to leaves and drapery.

Cleaning and Finishing. The metal when worked is warmed and cleaned and then dipped into an acid bath; it is washed and dried and then polished with a hard brush and powdered pumice. If a highly polished surface is desired the prominent portions should be burnished and finally coated with lacquer, but it is usual for a plain surface to be left and then lacquered. A common finish for copper is oxidization; this is effected by dipping the metal in a solution of ammonium sulphide and thoroughly washing when the desired colour is reached. Owing to the offensive odour of this liquid, the work should be done out of doors. To retain even the oxidized surface it should be lacquered.

REPP. The name rep or repp of this furnishing and dress fabric comes from the fact that the surface is ribbed.

The best furniture repps are made with threads of two different thicknesses running in both directions of the cloth. The structure is firm, and in good colours repp is a suitable material for covering chairs, settees, etc. *See Upholstery.*

RESEDA. This is the botanical name of mignonette, a familiar plant with sweet-smelling flowers. It is sown out of doors in April for summer bloom, and in pots in August to produce winter blooms under glass. *Reseda glauca*, a hardy perennial with grey-green leaves and pale flowers in summer, is a useful border plant.

RESIN. The best-known resin, or rosin, is obtained by the distillation of crude turpentine, which exudes from pine-trees. It varies in colour from a pale amber to dark brown, according to its purity or method of preparation. It is a brittle solid with a glasslike fracture.

The solid resin is used for giving violin bows a grip on the strings, and in powder form is employed by golfers and tennis players to increase the grip of the hands. Dissolved in turpentine or benzine a simple form of varnish is obtained, but the surface of the varnish is not sufficiently hard unless copal or mastic resins are also used with it.

Resin is used in soap making, and resin soap is supplied in the form of a coarse powder for household cleaning purposes, but owing to its colour it is not suitable for washing linen.

RESISTANCE. This is the opposition offered by an electric circuit to the flow of electric current. The resistance of a wire is directly proportional to its length and inversely proportional to its cross sectional area.

Copper and silver have a low resistance per unit length, whereas certain alloys, e.g., manganin, nichrome, etc., have a high resistance per unit length.

Resistances are frequently employed in wireless receivers to prevent the passage of high frequency currents, to reduce voltages, and in certain methods of coupling valves in cascade. The practical unit of resistance is the ohm (q.v.).

Resistance. Showing a complete resistance coupling unit as described in the text,

Resistance Coupling. In a wireless receiver this is method of coupling the valves of a low-frequency magnifier in cascade by means of resistances.

A resistance is connected in series with the anode of the valve and the signal voltages across the resistance are applied to the grid of the following valve by way of a coupling condenser. The coupling condenser acts simply as a means of preventing the high tension voltage from reaching the grid of the valve. It offers a free path to the amplified signal voltages. A grid resistance or leak is joined between the grid of the valve and grid bias negative to allow the negative charge on the grid to leak away and to maintain the grid at a

steady negative potential.

The amplification per stage in a resistance-capacity coupled amplifier can never exceed that of the valve itself, and this figure is reached when the value of the anode resistance becomes infinity. In practice it is possible to obtain a magnification of about two-thirds the amplification factor of the valve. The use of a high value anode resistance in an endeavour to achieve the maximum amplification results in a loss of the upper musical frequencies and reduces the general brilliancy of tone. Reproduction tends to become low pitched.

In general the value of the anode resistance should not be greater than 250,000 ohms. When faultless reproduction is desired the values of the anode resistances may be 100,000 ohms or even lower. The use of too high a value anode resistance in the anode circuit of a detector valve may produce a complete lack of reaction. The coupling condenser should be sufficiently large to pass the lower musical frequencies, and 0.01 mfd. is a common value. It is essential for the condenser to possess high insulation, and for this reason the dielectric should be preferably of good quality mica. The grid resistances may have a value of 1-2 megohms.

A properly designed resistance-capacity coupled low frequency magnifier will give very faithful reproduction, but the magnification per valve stage is considerably less than that obtainable with transformer coupling. *See Capacity; Condenser; Dielectric; Grid; etc.*

Respiration. *See Breathing.*

REST CURE. In the treatment of a large number of disorders rest is an important, or it may be a necessary, element; but the form of treatment for functional nerve diseases, such as neurasthenia, etc., associated with the name of Weir Mitchell, is popularly known as the rest cure. The patient is kept in bed, but besides this is isolated, so that mental rest is secured as well as bodily.

The treatment includes more than rest, however, as an effort is made to improve nutrition by a generous diet, including milk, and electricity and massage are used to improve muscular tone. The treatment is very suitable in some cases of neurasthenia.

REST HARROW. This is the common name of a group of hardy perennials or shrubs (ononis) which bear pea-shaped flowers in summer. One of the best, suitable for the rock garden, is *Ononis aragonensis*, 18 in. high, with yellow flowers. *Ononis fruticosa* bears rose-pink blooms. They

should be planted in light or well-drained soil, and in a sunny position. Seeds sown in summer or cuttings taken at the same time provide an increased stock. The common rest harrow which grows wild in Britain is *Ononis spinosa*, a low-growing somewhat shrubby perennial with rose-pink blooms.

RESTRAINER: Use in Photography. Chemicals used to prevent too vigorous a developing action on a negative or development paper are known as restrainers. Potassium or ammonium bromide is most commonly employed. They tend to delay density in negatives or bromide and gaslight papers while detail is formed. Potassium bromide is best kept as a 10 p.c. solution, i.e. containing 1 gr. of bromide in 10 min. of solution. Dissolve $\frac{1}{2}$ oz. potassium bromide in $4\frac{1}{2}$ oz. of distilled water and add about 5 min. of the solution to each ounce of developer.

RESURRECTION PLANT. This is a most curious plant, known also as the Rose of Jericho: its botanical name is *anastatica*. If placed in water it has the extraordinary power of reviving even after it has been kept dry for many months, hence its popular name. Seedlings may be raised under glass in spring and planted out of doors in summer. After the leaves fall the plants become somewhat woody and remain dormant until put in water.

RETAINING WALL. Where the special function of a wall is to resist strain imposed upon a structure by adjacent earthwork it is known as a retaining wall. A common application of it is found in basement houses where a low wall is provided to keep the earth in position around the area. *See* Wall.

RETCHING. An involuntary and unsuccessful effort to vomit is called retching; gas is sometimes expelled. When it exists it is often a useful thing to drink large draughts of warm water, or very hot water may be sipped. *See* Sickness; Vomiting.

RETINOSPORA. This is a group of hardy evergreen conifers which is now merged in the genus *cupressus* or *cypress*. In gardens, however, the name *retinospora* still persists. One of the most beautiful is *Retinospora pisifera*, of which there are many varieties: *argentea* and *squarrosa* are handsome grey-leaved kinds while *plumosa aurea* has yellow or golden leaves. Another species is *Retinospora obtusa*, of which attractive varieties are *aurea* and *gracilis aurea*. Planting should be done in September or early October or in April-May in loamy soil. Propagation is by cuttings in a frame in September. *See* Cypress.

Retouching. *See* Spotting.

RETRIEVER. Of the four varieties of retrievers the curly-coated are so few in number that they are seldom seen except at shows. The handsome flat-coated dog has small dark eyes which give him a kindly appearance, and he is as intelligent as he looks. The shoulders are so well placed as to give freedom of action. The body is shortish, of medium length in couplings, thus enabling him to gallop. The front legs are perfectly straight.

Retriever. Prize-winner of the sturdy short-coated Labrador variety.

The Labrador is another variety. Here the coat is peculiar, being short, very thick and somewhat like fur to the touch. There is scarcely any feathering on legs or thighs. Altogether he is squarely, sturdily built. The eye, which should be a dark hazel, is sometimes still too light. The retriever is a first-class dog for work, and very frequently proves the winner at field trials. The golden retriever is of Russian extraction.

Training. A retriever puppy may be broken in very early, the first step being to gain his confidence. Encouraged by the reward of a biscuit he should be taught to come at a gallop in response to a low whistle. To teach him to drop, take him into a quiet spot, secure his attention, and hold up one hand, pressing him into a recumbent position with the other. The command drop should be repeated every time. He should remain in this position even when his master walks away; but if he refuses, he may be fastened to a peg until he does so. At six months old he may start learning to retrieve. He is first taught to fetch some soft object, such as a rolled-up handkerchief, which his master throws a few yards in his sight, with the order "go fetch." The distance is extended gradually, until the object is dropped when he is not looking and he is ordered "hie seek." *See Dog; Kennel; Mange, etc.*

REVERSI. This indoor game is played with 64 counters on a board resembling a chess board, but usually somewhat smaller. It can, however, be played on a chess or draughts board. The 64 counters are red on one side and green on the other. They are divided between the two players, one treating his as red and the other treating his as green. The players in turn place one on any vacant square on the board, each keeping his own colour uppermost.

The object of the game is to place the pieces so as to enclose one or more of the hostile pieces between two of his own. This done, the enclosed pieces, which must be in a straight line, join the other side, i.e. they are turned over and so changed from red to green or vice versa. The game continues until all the pieces have been played out, and the player who has the most of his colour on the board is the winner.

REVOLVER. A revolver may be described as a pistol with a revolving cylinder, in which are a number of cartridge chambers. Several shots can therefore be fired without re-loading the weapon. With revolvers may be classed the weapons known as automatic pistols, which have a magazine. The law about owning and carrying revolvers is the same as it is for pistols and other firearms. In brief, these regulations decree that no person may possess any firearm or ammunition unless he holds a certificate to do so, such certificate being granted by the chief police officer of the district in which he resides. To secure a certificate of this kind the applicant must satisfy the police that he has good reason for needing the revolver or other firearm, and that its possession is not likely to cause any danger to the public safety or any breach of the peace.

For these reasons a certificate will not be granted to anyone who is of intemperate habits, or is in any other way considered unfitted to possess a firearm. The cost of a certificate is 5s. It lasts for three years and may then be renewed for a further three years (fee 2s. 6d.). The law provides also that any dealer who sells a revolver or other firearm must take the name and address of the person to whom it is sold. These facts must be communicated to the police, and also put on record. A certificate is not required for a smooth bore shot gun at least twenty inches in length.

Revolvers are distinguished by the size or calibre of the bore, the usual sizes being .22, .32, .38, and .455. The smallest size, i.e. .22, is of little value except as a target weapon. The .38 is the smallest calibre that can be relied upon to stop an assailant, but the defensive uses of the others are by no means negligible. Cartridges are sold according to the calibre. *See Gun.*

RHAMNUS. Several hardy shrubs of no great decorative value are included in this genus. The British buckthorn (*Rhamnus cathartica*), a leaf losing shrub, 12-15 ft. high, bears black berries in autumn. The wood of *Rhamnus frangula*, another British shrub or small tree, makes excellent charcoal. *Rhamnus alaternus*, an evergreen, and its varieties with variegated leaves, are useful for shrubberies: they reach a height of 8-10 ft. The bark of one species of *rhamnus* supplies the medicinal preparation *cascara sagrada*. Propagation is by cuttings in a frame in late summer.

RHEUMATIC FEVER. The disease called rheumatic fever, or acute rheumatism, has been known as a scourge of childhood for more than two thousand years, but the exact causation, whether it be a germ or virus or other cause, is still disputed. It is considered probable that in some cases infection enters by way of the tonsils. The chief danger in rheumatic fever or acute rheumatism is that the heart may become affected. There is fever, profuse sweating, inflammation and great pain in the joints, the attack lasting from 2 to 6 weeks, or longer, and the sufferer is liable to be attacked again. The younger the patient the greater is the liability to heart injury. In children the pains may be slight, and may be described as growing pains. There may be very little fever, but anaemia may develop, and a frequent accompaniment is chorea, or St. Vitus's dance.

Rheumatic Fever. A dangerously high temperature may be reduced by wrapping the patient in a sheet wrung out of ice-cold water. This should only be done under a doctor's supervision.

As soon as the disease is recognized the patient should go to bed, and should wear a flannel nightdress made to open all the way down; the sleeves should either be very loose or be slit from shoulder to wrist, and fasten with buttons. This is to facilitate the frequent bathing which is necessary because of the sweating. Four or five nightdresses should be prepared. Remove the sheets and let the patient lie between soft, fine blankets, or provide flannel sheets. Absolute rest is essential, and there must be no visitors. The general treatment is that of fever (q.v.), but a thorough course of salicylates must be administered. When the patient is convalescent, attention should be paid to the state of the throat, and the question of removing diseased tonsils may have to be considered. The patient, especially if a child, should be seen by a doctor from time to time for some years after an attack of acute rheumatism.

RHEUMATISM. This term is applied very loosely to a number of diseases differing from one another fundamentally. They are all, however, characterized by pain and inflammation in the joints or muscles or tendons, etc. *See Fibrositis: Lumbago.*

RHEUMATISM ROOT. This name has often been applied to a species of *Jeffersonia*, a hardy dwarf plant suitable for shady crevices in the rockery or as an edging for borders. It bears white dower's during spring, and is best planted in October in ordinary sandy garden soil. Propagation of the plant is by seed or by division of roots.

Rheumatism Root. A spring-flowering dwarf plant suitable for a shady rockery.

RHEUMATOID ARTHRITIS. The chronic joint disease known as rheumatoid arthritis is not a rheumatic affection, and must also be distinguished from osteo-arthritis in which bony changes are early and distinct. It is a chronic inflammation of the synovial membranes of joints and of the fibrous tissues which surround the joints.

As in other chronic arthritic diseases pain, swelling, and stiffness are likely to be increased by cold and damp, or by unaccustomed or undue strain on the joints. The joints of the fingers just below the knuckles are generally those first affected, and usually in both hands, then the disease appears in the knees and feet; but it may involve nearly all the joints of the body.

The prime cause of rheumatoid arthritis is the activity of certain bacteria of low virulence. These form foci of infection, most commonly at the roots of the teeth or in the tonsils, but it may be at other situations in, or on, the body. The treatment of the disease should therefore begin with a search for some such focus and an attempt to clean it up, with, possibly, a course of vaccine treatment in addition.

During the acute stage the patient should be kept at rest, and, as the deformity is caused in the first place by spasm of muscles, the affected joints should be splinted in such a position, as to prevent deformity. When, however, the acute stage has passed off, the joints are freely and fully moved by the doctor or someone under his direction.

Various methods, including fomentations, baths of various kinds, diathermy and electrical treatment, are used to diminish pain and swelling. Massage, whirlpool baths and electrical stimulation are also useful in preserving the tone of the muscles.

The diet should be generous. Cod-liver oil is often a useful addition. Ultraviolet rays are often used in order to increase the general resistance to infection, and guaiacol carbonate of sulphur may be given to disinfect the bowel.

RHODANTHE. This is a pretty half-hardy annual with pink or white everlasting flowers which last a long time when cut. It is chiefly suitable for cultivation in pots in the greenhouse, although seedlings may be planted out of doors for the summer. Seeds are sown under glass in March or out of doors in May. The chief kind is *Rhodanthe manglesii*. The correct name of this plant is *Helipterum manglesii*.

Other *helipterums* supply the immortal flowers which when dyed in various colours are used by florists in making wreaths and other floral devices.

RHODE ISLAND RED. There are two varieties of this American breed of fowl, the single combed and the rose combed, and it is one of the best winter layers. The rich brown eggs in some strains average 2¼ oz., the general average being 7 or 8 to the lb. It carries a lot of flesh, which is of good colour and fine flavour.

The hens are most excellent mothers; the chicks are hardy and mature quickly. Adult males weigh 6 lb. to 8½ lb., and the females 5 lb. to 6½ lb. They do well on free range, also on the semi-sensitive system, but are not to be recommended for intensive or confined quarters, as they become very broody.

The colour should be deep, rich red and even throughout; the tail should be black, and the wings should show black in both primaries and secondaries when opened out. The two colours must be clear and distinct; what is known as a peppered wing is a bad fault in an exhibition bird. The neck hackle of the male should match the body colour; in the female it should be tipped with black. The comb, lobes, wattles and eyes should be red, the legs and feet rich yellow. *See Fowl; Poultry.*

RHODIAN WARE. Some modern faience bowls and jugs which attempt to recapture the colour and design of medieval Rhodian pottery are brilliant and decorative, but it is hardly possible to mistake them for the genuine old ware. This was produced from the 14th to the 18th century in the island of Rhodes.

At first, owing to the fact that it was made by Persian exiles, it followed very closely the inspiration of Persian ceramics. It was fabricated of a sandy, artificially fused, and highly vitrified clay, covered with a hard, thick, glassy paste.

Rhodian Ware. Sixteenth century Turkish jug having a blue background decorated with cream and red flower buds. (By permission of the Director, Victoria and Albert Museum, S. Kensington)

The forms include shallow dishes, ewers, flower-holders, lamps, and domestic ware generally. The decorations comprise naturalistic flowers such as roses, tulips, and carnations, besides birds, arabesques, and various other types of oriental designs.

Sometimes the designs consisted of ships and coats-of-arms, done for the Knights of St. John. There are also decorated tiles, based on the patterns of tapestry hangings. Very thick pigments, red, blue, or turquoise, outlined in black, and often on soft grounds, impart to the decorative scheme an opulent effect. The inscriptions are usually Persian.

After the departure of the early craftsmen they were replaced by Latin potters, who derived their ceramic motives from European tapestries, and continued at work until the middle of the 16th century.

After that Turkish workmen carried on the tradition, but the pottery gradually deteriorated, until by the 18th century good work was no longer made. *See Pottery.*

RHODODENDRON. This is the finest evergreen flowering shrub suitable for cultivation out of doors in the British Isles. In recent years numerous new species have been introduced from Western China and other far Eastern districts, and many hybrids have been raised in gardens at home. A representative selection will provide blossom from early spring until June. The leaf-losing azalea, which is regarded by gardeners as a distinct shrub, is now merged in the genus rhododendron by botanists. A few evergreen rhododendrons are beautiful shrubs for the heated greenhouse.

Rhododendron. Flower clusters of one of the numerous beautiful varieties.

The rhododendrons of chief value to the amateur gardener are those hardy evergreen kinds which provide such a brilliant display of blossom in May and June. Almost all of them are hybrids or crossbreeds which have been raised in gardens and nurseries, and new varieties are introduced every year. These are some of the most attractive: Bagshot Ruby, Broughtonii, rose-crimson; Corona, pink; Cynthia, rose-crimson; Diphole Pink; Doncaster, red; Everestianum, lilac-rose; fastuosum fl. pl., mauve; Gomer Waterer, blush; Loder's White; Michael Waterer, bright red; Pink Pearl, rose

pink; and Sappho, white with dark blotches. Nobleanum bears its red flowers in spring, sometimes in winter if the weather is mild. Other early flowering varieties are: Ascot Brilliant, red; Hands-worth White; and Rosa Mundi, blush.

Ruby-red clusters of flowers of the rhododendron, named Bagshot Ruby.

There are many beautiful rhododendrons among the species or wild types of other lands. Some of them are low growing and suitable for planting in the rock garden, e.g.: dauricum, rose-purple; fastigiatum, lavender blue; hirsutum, rose-red; moupinense, blush; and racemosum, pale rose. Augustinii, a taller shrub, bears beautiful lavender blue flowers in spring. The Swiss alpine rose is *Rhododendron ferrugineum*, a dwarf with rose-red blooms.

The Himalayan rhododendrons develop into immense bushes in sheltered gardens in mild parts of the country, but they are scarcely suitable for general planting—not because the shrubs are not hardy, but because they bloom early, and the flowers are liable to be spoilt by frost. Among them are: campylocarpum, yellow; argenteum, cream-white; Falconeri, with very large handsome leaves and pale flowers; and grande, white.

Hardy azaleas make a brilliant display in May and June. The colours of the flowers range through pink, salmon, apricot, rose, yellow and orange. No shrub surpasses them in splendour when they are in full beauty. There are numerous named varieties.

Rhododendron. 1. Tub planting: a, sand; b, sandy peat; c, chopped turf; d, wood blocks. 2. Lawn planting: a, grass; b, sandy peat. 3. Cutting, with heel. 4. Pot prepared for cutting: a, silver sand. 5. Cutting plunged for rooting: a, moss; b, fibre; c, steam pipes; d, glass; e, box. 6. Old plant plunged in open border on base of cinders.

The rhododendron is perfectly easy of cultivation if planted in lime-free loamy or peaty soil that does not dry out in hot weather. A slightly shaded situation is to be preferred to one in full sunshine, though the latter is suitable providing the soil is deep. The two most important details of cultivation are to remove the faded flowers to prevent the development of seed pods and to mulch the soil with leaf-mould in April. When rhododendron bushes have become overgrown and need to be cut hard back this work should be done in April.

The evergreen greenhouse rhododendrons should be potted in a compost of sandy peat: a minimum winter temperature of 60° is shitable. Two of the most beautiful are javani-cum, yellow, and jasminiflorum, white. The white-flowered Veitchianum flourishes in a minimum temperature of 45° or 50°. The evergreen Rhododendron indicum, which bears a profusion of flowers in various colours in spring, is a favourite kind for forcing, and the mollis azaleas, which are imported in immense numbers, are largely grown under glass for early blooms.

RHODOTHAMNUS. Also called ground cistus, the Rhodothamnus chamaecistus is a dwarf shrub suitable for growing in a partially shaded position, in loamy or peaty soil in the rock garden. It grows about 6 in. high, and bears pink heath-like flowers during spring or early summer. Spring is the best time for planting, whilst propagation by cuttings may be accomplished in late summer. *See* Layering.

RHUBARB AND ITS HOUSEHOLD USES

How to Grow Successfully and Cook Appetizingly

The entries Forcing; Kitchen Garden contain further information bearing on this subject. See also Flan; Fritter; Pastry and other cookery entries.

The edible rhubarb is *Rheum raphonticum*, a hardy perennial which thrives in a deep rich soil. The roots are planted in February, about 3 in. beneath the surface, and in rows 2 to 3 ft. apart every way. Before planting, some well-rotted manure should be worked into the soil. No stalks should be gathered from freshly planted rhubarb, and all flower stems should be removed. Forced rhubarb is obtained by covering 2-year-old plants with headless casks or barrels and surrounding the latter with fresh manure or dry leaves.

Rhubarb. Showing the result of forcing beneath a barrel.

After large roots have been forced and cut, the old stools may be divided in March, and replanted.

For forcing in artificial heat under glass, 3-year old roots are the best. They should be lifted and placed in dark corners in the heated greenhouse, or in frames with bottom heat. Moisture and darkness are the conditions which are required in order that forced rhubarb may thrive best.

Some of the best varieties are Champagne, Albert, Victoria and The Sutton. All except Victoria (a late variety) are suitable for forcing. Of the ornamental kinds of rhubarb which are grown solely for the decorative value of the leaves and flowers the best are Alexandrae, Emodii and palmatum. They are vigorous plants which flourish in ordinary soil and may be propagated by division in autumn.

Use in Medicine. The rhubarb used in medicine is obtained from the root of a plant grown in China and Tibet. It is one of the safest and most widely used purgatives for children, and it has a secondary astringent effect which makes it particularly useful in checking diarrhoea. Rhubarb increases the flow of gastric juice into the stomach, stimulates the normal digestion, and also the liver. Consequently it is often prescribed in small doses as a stomachic.

Uses in Cookery. Rhubarb is widely used in cookery, being made into preserves, puddings, pies, compotes and many other sweets. Stewed rhubarb with custard is a very popular dish in spring. It

should be used when young and tender. The stalks only should be cooked, these being first wiped with a damp cloth and then cut into convenient lengths. For stewing, pies, etc., a generous allowance of sugar is needed, the quantity varying according to the age of the rhubarb. Add a little water and about 2 in. of lemon rind. Young forced rhubarb and one or two varieties of young outdoor rhubarb stalks need not be peeled.

Rhubarb. 1. Typical root. 2. Good planting: a, manured soil. 3. Division of clump. 4. Forcing in a box: a, covering box; b, rests for same. 5. Another method: a, manure litter; b, straw; c, old zinc bath with bottom removed; d, covering box.

Rhubarb makes excellent pies to be eaten hot or cold. Use short crust pastry. The rhubarb should be cut into short lengths and need not be stewed previously.

Rhubarb Charlotte. Stew $\frac{3}{4}$ lb. rhubarb cut into short lengths in a pint of water, the grated rind and juice of a lemon, and $\frac{1}{2}$ lb. sugar, and when the fruit is soft, add the stiffly whisked whites of 2 eggs and $1\frac{1}{2}$ oz. gelatine previously dissolved in pint water and then strained. Line the sides of a mould with sponge fingers, pour in the mixture and leave it to set. When cold, turn it out, and serve it with some vanilla-flavoured custard.

Rhubarb Chutney. Stew 2 lb. rhubarb cut into short lengths with $\frac{1}{2}$ lb. sugar, and in the meantime mix together 3 minced onions, 2 tablespoonfuls fine salt, half that quantity curry powder, $\frac{1}{2}$ teaspoonful cayenne pepper, $\frac{1}{4}$ lb. stoned raisins, and about $\frac{1}{2}$ pint malt vinegar.

When the rhubarb is tender, pour the mixture over it, and stir the whole over the fire until it is well cooked.

Then turn it into jars and tie it down.

Rhubarb Flan. Wipe 1 lb. rhubarb, cut it into thin slices, sprinkle it with 3 oz. castor sugar, and leave it for an hour. In the meantime make 6 oz. flan pastry and bake it a light brown. When the rhubarb has stood for the required time, let it cook slowly in the oven until it is tender, then put it aside to cool. Add more sugar if required.

When the pastry is cold, fill it with the rhubarb, reserving a few pieces for decorating the top, and over it heap the stiffly whisked whites of 2 eggs sweetened with 2 dessertspoonfuls castor sugar. Put the flan back into warm oven so that the meringue may set and place a few small pieces of rhubarb on top. It should be served cold.

Rhubarb Fool. Rhubarb fool is made in the same way as gooseberry fool, $\frac{1}{2}$ lb. sugar being allowed to each pound of rhubarb.

Rhubarb Fritters. For these fritters, cut some young, tender rhubarb into pieces about 3 in. long, dip them in batter and fry them in boiling fat. When they are a golden-brown colour, lift them out and drain them, and serve them sprinkled with castor sugar.

Rhubarb Jam. The ingredients are 1 lb. each rhubarb and sugar, $\frac{1}{2}$ oz. lump ginger and the rind of half a lemon. Cut the rhubarb into pieces about $\frac{3}{4}$ in. square and put these into a preserving pan with the sugar. Heat them slowly until the sugar has dissolved; then add the ginger, bruised and tied in a muslin bag, and the thinly peeled lemon rind tied in another bag. Bring the jam to the boil and continue boiling for about $1\frac{1}{2}$ hours removing the ginger and lemon before putting it into pots and finally tying it down.

Rhubarb Pudding. A baked pudding can be made from 1 lb. rhubarb, $\frac{1}{2}$ lb. fine breadcrumbs, and sugar to taste. Peel and cut the rhubarb into short lengths, put a layer of it into the bottom of a deep buttered dish and sprinkle it with castor sugar. On the top put a layer of crumbs, and continue in this way until the dish is full, making the last layer of breadcrumbs. On top place a few small lumps of butter and a little more castor sugar and bake the pudding in a hot oven until it is lightly browned. A boiled rhubarb pudding can be made in a basin lined and covered with suet crust. Cover with greased paper and a cloth and boil $1\frac{1}{2}$ -2 hours. *See the directions for making Apple Pudding.*

Rhubarb Wine. This fruit wine is made by cutting $5\frac{1}{2}$ lb. rhubarb into short lengths, leaving them unpeeled, and putting them into a wooden vessel. Mash them well to extract the juice, pour over them 1 gallon cold water, and leave the whole for eight days, stirring occasionally.

Strain and measure it, and to every gallon of liquor add $3\frac{1}{2}$ lb. white sugar and the juice of $1\frac{1}{2}$ lemons. Stir the mixture at intervals until the sugar has dissolved, then pour the wine into a cask and leave it in a warm place to ferment. When fermentation has ceased, cork up the bung-hole and leave the wine in a cool place for about five months before bottling it.

RHUS. These hardy shrubs are grown for the sake of their ornamental leaves or flowers. The sap is poisonous. One species, *Rhus toxicodendron*, or poison ivy, is a dangerous plant, for touching the leaves may lead to serious illness in people who are susceptible. There is, however, no need to cultivate this plant, for several others are more decorative. The most familiar is the Stag's horn sumach (*Rhus typhina*) which has very long, deeply-cut leaves. The Venetian sumach (*Rhus cotinus*), known also as smoke bush, is very attractive when the cloud-like inflorescences are in full beauty in summer. *Rhus cotinoides* is valued for the sake of the brilliant autumnal colouring of its leaves. The sumachs, which form large bushes, thrive in ordinary soil and are increased by seeds or root cuttings in spring.

RIB: Of the Body. There are 12 ribs on each side of the chest, of which the upper 7 are united by cartilages directly to the breastbone. These are called true ribs. The remaining 5 are known as false ribs. Of these latter the eighth is joined by cartilage to the seventh, the ninth to the eighth, and the tenth to the ninth. The ends of the eleventh and twelfth ribs are free, and for this reason these are called floating ribs.

Fracture of a rib is a common accident. Occasionally the fractured end may penetrate the lung. The symptoms of fracture are often very slight, but when such an accident is suspected, a doctor should be at once consulted. First aid consists in applying the centre of a broad fold bandage over the painful spot and tying on the other side of the chest. According to the situation of the fracture another bandage is applied above or below the first. Their object is to limit the movement of the chest wall, but they should not be tight enough to cause pain. If any pressure at all is painful they should be left off. Later the doctor may continue with bandages.

RIBBON WORK AND TRIMMING

Effective Uses and Methods of Making Applied Decorations

Directions for making accessories which can be charmingly trimmed with ribbon work may be found under such headings as Bag; Curtain; Cushion; Night Wear Case. See also Appliqué Work; Artificial Flowers; Embroidery; Laid Work; Raffia; Transfer.

The simplest form of ribbon work consists of making bows, rosettes and gathered ruchings; the most elaborate is combined with embroidery or appliqué work, and used to decorate furnishing accessories. Although frequently seen on cushions it is perhaps most suitable for pieces of needlework such as bedspreads, pelmet and curtain borders, handkerchief and nightwear sachets. The raised or looped formations of ribbon, often used in the work, make it less practical for hard wear than ordinary embroidery unless narrow ribbon is actually employed like a coarse thread, as in the example of the cushion illustrated in Fig. 1.

Ribbon Work. Fig. 1. Embroidered cushion, the chrysanthemum heads being worked in narrow embroidery ribbon, while the stalks and leaves are in stem and satin stitch.

Bows and Rosettes. Even a bow for trimming requires to be properly made, especially if the ribbon is wide. Leave an end and form a loop with small pleats, twist it round with cotton. Repeat the making of loops, measuring their length carefully until the required number is made. Arrange the loops to lie in even numbers each way and leave an end to match the one at the beginning. Make a tie over with a separate piece of ribbon, sewing it tightly or loosely according to taste.

Flat bows are made by folding ends of ribbon over without pleating to form the desired size, and tacking them down. A shorter piece of ribbon is then folded in the same way, so that the shorter bows lie flatly above the longer ones, and stitched down. A flat tie-over strip is placed across the ribbon and finished off neatly at the back.

Ribbon rosettes are made in various ways. A small circle of stiff muslin or buckram is first cut out. To this are tacked the ribbon loops, any length desired, beginning at the edge and working towards the centre, longer loops being used towards the centre to make a rounded rosette. For another kind of rosette a wide ribbon can be used and folded over and the edges gathered strongly together. These are drawn up and sewn to the muslin or buckram foundation, beginning at the centre and working round to the edge. If a narrow ribbon is used it is not folded, and if one with a picot edging is selected it gives an attractive finish.

Wheel-like ribbon decorations which form corner trimmings for cushions or sachets are easy to make on a muslin foundation. The centre is of puffed or ruched ribbon, and the edges are finished with loops and ends cut diagonally, the effect being like a big daisy. Garters can be quickly made of ruched ribbon. Two lengths are needed of $1\frac{1}{4}$ yd. each of 1-in. wide ribbon. Contrasting colours may be used and stitching on both sides connects the two lengths through which an elastic, $\frac{3}{4}$ -in. wide, is run. The ribbon is gathered over this to the required size. The garters are finished with tiny rosettes or a ribbon flower.

Covering Small Articles. Ordinary wooden coat hangers can be made attractive when covered with satin or chine ribbon. They need first to be padded with cotton-wool, sprinkled with sweet-smelling essence, or some perfumed powder, and then covered with ribbon gathered to fit the arms. One yard of 3-in wide ribbon is enough to cover the wooden portion, and narrow ribbon to match is used to cover the metallic hook. At the base of this a bow, rosette or ribbon flower may be stitched if the hangers are being made for a gift or sale of work.

Ribbon-covered perfume sachets are easily made by sprinkling little pads of cotton wool with perfume or with sachet powder, covering them first with fine muslin, and then with ribbon. An attractive effect is obtained when 2 narrow ribbons are interlaced to form a lattice work, the ends being mitred and left free. Long sachet pads to line the bottom of a chest of drawers or wardrobe are made of perfumed wadding covered with coloured muslin, which is bound by ribbon in a contrasting colour.

Inexpensive shoe trees are made daintier if the wooden portion is painted or gilded and the metal bar is covered with about 1 yd. of 1-in. wide ribbon. The ribbon is doubled and gathered over the metal, the gauging being drawn up entirely to cover it. A looped bow in the centre of the metal bar may be added if liked.

Plaited ribbon and jap silk to tone make a pretty sachet set. Two different-coloured double satin ribbons, $\frac{3}{8}$ in. wide, should be obtained, the quantity needed depending upon the size of the sachets. Having cut out the silk for the cover and for the linings, the ribbon must be cut in lengths, each piece being in duplicate, one of each colour. The longest strip should go diagonally across the cover from corner to corner; the others follow in order of length.

The plaiting may now begin. Assuming the colours chosen are pink and deep rose, a pink strip is started from the left top corner and is carried across to the opposite one. This is stitched down to the edge of the cover. Across it lay a piece of rose ribbon, the shortest length used, and stitch the two ends of this down, one on the left side and one on the right. For the next two rows, one on either side of the first row, two lengths of pink ribbon are needed and over them a piece of rose-coloured ribbon is placed, this passing under the first strip. Two more pieces are then laid across, and over and under these a piece of ribbon of the other colour is plaited.

The work proceeds in this way until the whole is covered. It will be easy to see whether the alternating colours are in the right order; but other points need watching. The edges of the ribbon lengths should just touch one another, and the ends should not be cut until they are stitched down. The stitches must be small and neat and the lengths must be out off slantwise. The corners need especial care, for here the ribbon is liable to bulge and refuse to lie flat. Care must be taken, too,

that no uncovered spaces appear in the plaiting. When the plaiting is finished a cording of silk should be made to match the rose or pink, or the sachets may be finished off with a silk or tinsel bought cord or with a narrow gimp. For making up see Night Wear Cases and Sachets.

Ribbon Embroidery. For certain kinds of embroidery ribbon makes an excellent medium, the flower-embroidered cushion illustrated in Fig. 1 providing a good example of the work. Choose a design that is not overcrowded, transfer it to the material, and then stretch the latter on a frame. First embroider the stalks and leaves in thick silk, using stem stitch for the stalks and satin stitch for the leaves.

The large flowers should be rather paler than the small ones, and, if a chrysanthemum design such as that illustrated is chosen, make the undersides of the flowers a darker shade than the tops. Cut a piece of thin embroidery ribbon about 9 in. long, thread one end through a needle with a very large eye, and pull up from the centre of the flower. Hold the ribbon flat with the left hand and put the needle down through the material at the tip of the petal. Use 2 or 3 shades of ribbon, making any petals that are underneath darker than the rest. Do not pull the ribbon too tight.

Embroidery ribbons can be successfully used to work designs on tea-cosies, blotters and sachets. Beads may form centres to ribbon flower, or French knots in silk may be worked for this purpose. Many designs for raffia work can be adapted for ribbon work. These narrow ribbons can also be used according to instructions given in the article on Laid Work, being couched down on to the material instead of being pulled through. More elaborate embroidery can be done in this manner, which is suitable for working signs on fine fabrics.

Ribbon Work. Fig.2. Applied ribbon trimming spray of garden roses made of pink and green taffeta ribbon, with diagrams for cutting out and sewing. See text.

Raised Ribbon Work. Sprays of flowers which can be made separately and then applied to trim cosies or sachets are not difficult to make with a little practice. Roses are effective flowers for this type of ribbon work details of making are illustrated in Fig. 2. For the centre of a rose cut strip of pink taffeta ribbon 1½ in. by 7 in. Fold it in half lengthways and gather twice as shown in B. Draw up the two threads tightly and finish off. Roll up and stitch firmly (C). Next take an oblong 2½ in. by 2 in. to make a petal. Fold it in half lengthways and slope off the edges to the fold, as shown in

D, and gather round the raw edges, folding over each edge at the fold. Draw up the thread and fold this finished petal over the centre (E). The other petals should be each a little longer and wider and shaped as shown in Fig. 2, F. When all the petals are separately made, stitch them round the central ones and the rose is finished, as shown in G.

The leaves are from green ribbon cut in wide by 2 in. Fold it in half lengthways and slope off the top (H). Gather down the point and the fold (J), then draw up, turn the ribbon right side out, and open up the leaf: flatten out, pleat the base into proper shape and stitch it down firmly (K).

The various pieces of the spray can be first sewn to a piece of muslin if liked or applied directly on to the article to be decorated. No stalk is visible in the spray illustrated in Fig. 2, A, but one is easily made by taking a short length of string, twisting a narrow green ribbon round it, inserting a leaf and continuing to twist to the desired length. For a bud have an oblong (on the cross if the pink ribbon used is wide enough) 2½ in. by 2 in. Fold it in half lengthways and the corners to the centre (L). Pleat it twice each side so that the pleats meet in the centre (M). Cut a piece of ribbon the same shape, slightly larger and fold round the first piece (N). Make a cup from the green ribbon 1 in. wide, cut as for the leaf (H), fold in turnings down the V shaped end, fasten one point to one side of the bud and the other point to the other side. Wrap the cup over and twist ribbon below to make the stalk (O).

Ribbon Fern. This is the popular name of a greenhouse fern, *Pteris serrulata*.

Ribbon Grass. Close growing clumps of the decorative border plant. The variegated leaves are very attractive in bouquets, or in vases of cut flowers.

RIBBON GRASS. This name is given to a perennial grass with pretty green and white leaves (*Phalaris arundinacea variegata*). Known also as gardeners' garters, it flourishes in ordinary soil, grows 2 ft. high and is increased by division in autumn. *Phalaris canariensis* provides the well-known seeds for cage birds: it is an annual raised from seeds sown in spring.

RIBES. The family name of the currant and gooseberry is *Ribes*. In practice, however, the name is usually applied to the flowering currants, which are

grown for decorative purposes only. These shrubs thrive in ordinary soil, and may be planted at any time during the autumn, winter, or early spring. The only attention they need is pruning after flowering, and a top-dressing of well-decayed manure in autumn. Propagation is best effected by means of seeds sown in the autumn, or by cuttings, layers, or suckers struck at the same period.

The chief kinds are *aureum*, fragrant yellow flowers; *aurantiacum*, yellow, and *sanguineum*, red. There are several varieties of the latter, of which the best are *atrosanguineum* and *Edward VII*. *Ribes speciosum*, the fuchsia-flowered currant, should be grown on a wall; it bears crimson, somewhat fuchsialike flowers.

RIBSTON PIPPIN. The dessert apple known as Ribston Pippin is of medium size, russet-brown in colour, and possesses a flavour second only to Cox's Orange Pippin. It is a self-fertile variety, requiring a warm, well-drained soil, and is in season from November to January. *See Apple; Dessert*

RICE: The Food. Being very light and easily digested, rice forms a valuable article of diet, but as it is almost entirely a starchy food and deficient in protein, meat or pulses should be taken with it. Its good value is increased by cooking or serving it with milk. On the average rice contains about 80 per cent of starch, 7 per cent of protein, fat less than $\frac{1}{2}$, water 12, and a trifle of mineral matter.

When it is boiled rice absorbs about five times its weight of water. If not sufficiently boiled it is liable to cause indigestion. To many people one of the disadvantages of rice is that it has a slight binding effect. This fault can be corrected by eating it with prunes, stewed fruit, or jam. But in cases of looseness of the bowels this effect makes rice a valuable remedy.

The polished rice, which is commonly used, is deficient in the vitamin which prevents beri-beri. This has been removed in the thin skin. Where the dish consists almost wholly of polished rice beri-beri develops, but there is not this danger in a mixed dish including milk, eggs, etc.

Two kinds of rice are employed, of which the pure white Carolina is usually preferred for puddings. Rice flour and ground rice are also much used for cakes, etc. The former is much more finely ground than the latter. Curry is served with Patna rice, which has long, pointed grains that separate easily after cooking. Rice should always be thoroughly washed before using, and to boil plainly should be scattered into fast boiling salted water; keep the lid off the pan and boil for about 15 min.

An excellent rice and apple sweet can be made from 4 large apples, $\frac{1}{2}$ lb. rice, 4 teaspoonfuls castor sugar, 4 cloves, and a little apricot jam sauce. Boil the rice in salted water for about 10 min., then strain it, and divide it into six equal portions. Grease four small basins, and put a portion of rice in each, pressing it to the sides and bottom so that it acts as a lining. Peel and core the apples, place one in each basin, together with 1 teaspoonful sugar and a clove; then divide the two remaining portions of rice into halves, and cover the apples with them, pressing the rice well down. Put a piece of greased paper over each basin, and steam the contents for about an hour, or until the apples are soft and the rice tender. When the moulds are cooked, turn them out on to a hot dish, and serve them with a sauce made by boiling two tablespoonfuls of apricot jam with a gill of water.

Rice Gâteau. Boil together 18 lumps of sugar and $\frac{3}{4}$ gill of water until they become a golden brown colour, then use them to coat the inside of a hot pudding basin. Wash $\frac{1}{4}$ lb. rice and cook it, until it is soft, in a saucepan of boiling water; then drain it and mix it in a basin with 2 oz butter.

Leave the mixture to cool before adding 3 oz. granulated sugar, $\frac{1}{4}$ lb. seedless raisins and a little vanilla flavouring, and when these are well mixed stir in 2 beaten eggs mixed with 3 or 4 tablespoonfuls of milk. Turn the whole into the caramel-lined basin, cover it with a greased paper, and steam it for 1 hour in a saucepan of boiling water. The water should reach no higher than a third of the way up the basin. When the mixture is cooked, turn it on to a hot dish and decorate it with cream. The caramel will be found to coat the pudding.

Rice Meringue. Cook $\frac{1}{4}$ lb. rice in a pint of milk until it is soft and has absorbed all the liquid, and let it cool a little before adding sugar to taste, and the beaten yolks of 3 eggs.

Pile the mixture up high on a flat dish, spread a thick layer of jam over it, and on top of this put the whites of eggs, sweetened and whipped to a stiff froth. Dredge the whole with castor sugar, and then put it in a warm oven for a few minutes so that the meringue may set and become lightly browned.

Rice Pudding. The requisites for a rice pudding consist of 2 oz. rice, 1 pint milk, 1 oz. sugar, 1 oz. butter, and a little grated nutmeg. Wash the rice and mix it in a pie-dish with the sugar, pour over the milk, and on top grate the nutmeg, adding the butter with it. If time allows, stand the pudding aside for about an hour before cooking it, so that the rice may soften; then bake it in a moderately warm

oven for 1½ to 2 hours, first bringing it to the boil and then letting it cook slowly. Another method is to put the rice with water to cover in the pudding dish, and cook in the oven until the rice swells and softens. Then add milk, etc., and proceed as above.

Rice Soup. A thick rice and tomato soup can be made from 2 oz. rice, a large tin of tomatoes, a carrot and an onion, a pint stock, a few celery seeds, and pepper and salt to taste. Put the rice, together with the peeled and sliced vegetables, into a saucepan, add the tomatoes with their liquor, the stock, the celery seeds tied in muslin, and the seasoning.

Bring all to the boil and then cook them slowly until the rice and vegetables are soft, stirring occasionally to prevent the rice from sticking to the pan. Then take out the celery seeds, rub the soup through a sieve and reheat it. If it is not of a good colour, add a few drops of cochineal.

Rice Water. For sick persons and convalescents rice water is a cooling drink. To make it, wash 1 oz. Carolina rice, soak it for 3 hours in a pint of warm water, then boil it for an hour and strain it. To check diarrhoea rice water is thickened with isinglass, a teaspoonful to the pint. Cinnamon stick, clove, or lemon may be added to flavour the drink and a little sugar if desired.

A pleasant and also nourishing beverage for an invalid is made by boiling a tablespoonful ground rice with ½ oz. candied peel cut small in 1½ pints of good milk. The rice is first mixed into a smooth paste with cold water and should be boiled for at least ½ hour and then strained.

Risotto. For a dish of risotto fry a chopped onion in 2 oz. butter in a stew-pan, then dilute it with 1½ pints stock. Stir in ½ lb. prepared rice and cook for 20 min., stirring frequently. When swelled, sprinkle in 3 oz. grated cheese, 1 gill tomato sauce, a grate of nutmeg and seasoning. Cover the pan for a few minutes and serve very hot.

Another savoury way of cooking rice, known as rice à la Milanaise, can be prepared by boiling some rice as directed for curry making, draining it thoroughly, and then frying it lightly in smoking hot fat. When it begins to brown, sprinkle in enough grated cheese to give it the desired flavour, and add also some cold, cooked and shredded fish, poultry, or game, and seasoning to taste. Mix and heat the whole thoroughly, and then serve it on a hot dish. *See Curry; Ground Rice; Kedgeree.*

RICE FLOWER. The Australian evergreen flowering shrub *Pimelea*, or rice flower, grows about 3 ft. in height, and there are pink and white flowering varieties. It requires greenhouse treatment. The potting material should be loam, peat, and silver sand, and the temperature that of a warm, well-ventilated greenhouse. The points of shoots should be nipped off to induce bushy growth, and water must be given freely except in winter-time. Propagation is by seeds sown in light sandy soil in springtime under glass, or by cuttings taken at the same season of the year. *Pimelea spectabilis* possesses white flowers in dense globular heads.

RICHARDIA. This is the botanical name of the white and yellow arum lilies which are so much valued for cultivation in pots under glass. The common white arum lily, *Richardia* (or *Calla*) *aethiopica*, is a South African herbaceous perennial which bears large white flowered spathes in winter and spring under glass: in mild districts it may be planted by the waterside out of doors.

The usual method of cultivation is to pot the roots in Sept, in a compost of loam with a little 4 decayed manure, keep them in a frame for 6 or 8 weeks and then force them into bloom in a heated greenhouse. The soil must be kept thoroughly moist when the plants are in full growth. When the flowers have faded arum lilies may be planted out of doors for the summer or gradually dried off in the flower pots. In September they are repotted.

The yellow arum lilies, *Elliottiana* and *Pentlandii* bloom in summer under glass. During the winter the roots are at rest, the soil in the pots being kept dry. In February they are repotted and started into growth in a warm greenhouse.

RICHELIEU WORK. Although this form of work comes under the class of linen embroidery and has been mentioned in the general article on Embroidery it is so effective and wears so well that fuller details are here given. It may be used on house linen and also for dress and women's and children's underwear. It may be worked equally well on crêpe-de-Chine, silk or linen. Floral, geometrical and figure designs are employed as motifs.

The materials required are the ground material such as those mentioned above, embroidery cotton of loose twist, linen lace thread, or embroidery silk, according to the ground material. All these working threads are made in many sizes, and that which is used should correspond with the texture of the ground material. A firm thread is used for the outlining, while a softer twist may be employed for the bars and filling stitches. Ordinary long sewing needles are required and a pair of small embroidery scissors, very sharp, and with fine points, as the material has to be cut away right under the pearl edge.

Richelieu Work. Fig. 1. An effective form of linen embroidery consisting of motifs of conventional or original design joined by worked bars. Fig. 2. Adaptation of ladder work for a border, showing the use of buttonhole-stitch.

A transfer design is needed, suitable for this work. It should have bold patterns for the motifs, which are held together with worked bars. Those who can do freehand drawings can make their own designs and trace them on the material with the aid of carbon paper. In the design illustrated four small motifs are placed together and an outline drawn to form a square; this can be varied with a diamond, circle, or other shape to suit the purpose. Black has been used for the material so that the white stitchery should show up more clearly. This in reality would be ugly and the needlework always matches the ground material in colour.

Richelieu work in its original form consisted only of buttonholed motifs and buttonhole bars with bullion picots; but in its modern form it is mixed with Reticella work, hence the appearance of twisted bars and woven bars. Filling and veining stitches are introduced to make the motifs more interesting. Stem stitch, back stitch and satin stitch are the most used together with French knots for

flower centres. After the design is transferred to the material, work over all the outlines of motifs and the outside edge of the design with small running stitches, then proceed to work the bars. By the old method the outlines were buttonholed first and the bars laid as they were reached; but experience has proved that stronger work is the result of working all the bars first and passing a buttonhole-stitch through the end of each bar as the outline progresses.

Working the Picot Bars. The lower part of the illustration shows the outlined motifs and the connecting bars worked in various ways. To work a bar with bullion picot, secure the thread on the wrong side of the material and bring it up on the main outline of design; pass the needle under one of the stitches on a small motif, picking up a tiny piece of the material. Pass the needle back again under the stitch on outside of design, then back again under the stitch on the motif; there should now be three threads laid. Now buttonhole from right to left half way across this bar, placing the stitches close together.

When the centre of the bar is reached make a picot thus: Pass the needle up through the last buttonhole-stitch made, to about two-thirds of its length, holding the needle in place with the right thumb, and with the left hand twist the thread ten times over and round the needle, from right to left, pushing the twists towards the eye of the needle, but still keeping the right thumb on them. Draw the needle through with the left hand until the thread can be felt pulling under the thumb; then remove the latter and draw the needle through. Pass the needle up from below through the last buttonhole-stitch, draw through, and continue buttonholing to the end of the bar.

A bullion picot often comes on the outside edge of a piece of work, when a Richelieu border forms the edge of a tea-cloth, for instance, and in this case the picot is worked on the outline of the design. When the needle is inserted in the last stitch the thread is passed under and round the needle from right to left; push the needle through the twists, pull up the thread so that the spiral forms a semicircle, then continue to buttonhole the outline until the next picot occurs.

Where the space to be spanned is wide, cross-bars are used as seen in the centre of the illustration between the two motifs on the upper half of the design, and where a space is long, branched bars are worked as seen at the lower left-hand corner of the design. In order to work the cross-bars lay three threads obliquely across the space, fill one half with buttonhole-stitches and a picot in the centre; now lay three threads from the last buttonhole-stitch to the opposite corner of the space to make the third arm of the cross. Fill with buttonhole stitches and a picot, and bring the needle up through the last stitch at the centre. Lay three more threads right opposite to form the fourth arm of the cross. Bring up the needle again through the centre of the bars and fill the remaining fourth arm, which is half of the first long one laid.

A branched bar has the first threads laid between one motif and another, half of which is buttonholed with a picot halfway if the space permits. If it is a short space, the picot is omitted. Then the threads are laid for the branch bar either to the outline of the design or to another motif, as the case may be; work this bar in the usual way, then the needle is passed under the first bar and the remaining half is worked to match.

Twisted and Woven Bars. Twisted bars have only one thread laid, the second is twisted two or more times round it according to the length of the bar. This should only be employed where strong linen thread is used for working or where the space to be spanned is quite short, as between points of petals and the outside line in the illustration. Woven bars have three threads laid, and the needle taken under and over each thread as in darning, always taking the working thread round the outside edge of the laid threads.

To work the main outlines buttonhole from left to right as in scalloping, so that the pearl edge comes on the outside of the motif and on the inside of the square outline seen in the illustration. When all the buttonholing is done the material has to be cut away under the pearl edge, taking care not to cut the bars. In the illustration the top half of the material is cut away and shows how the bars connect the motifs.

Ladder Work Borders. On a linen of loose texture effective borders to Richelieu designs can be worked with buttonholed edges and bars under which the material is cut away.

Draw two threads about $\frac{1}{2}$ in. apart. These will form two lines for the buttonholing, the pearl edge coming on the drawn thread line. Begin at the bottom left-hand corner and work upward, buttonholing the whole side, then turn the work so that the opposite edge or line will be at the left, and proceed to work upward as on the opposite side. When about $\frac{1}{2}$ in. is done begin to lay a bar, the distance between the bars depending on the fineness of the material, and according to how much work it is desired to put into it. The illustration given has been enlarged in order to show the detail more clearly. Pass the needle upward through the pearl edge of the buttonhole-stitch exactly opposite, now cross the ladder and pass the needle up through the pearl edge of the last buttonhole-stitch made on the second side of the ladder. Cross the ladder again and pass the needle up through the same stitch, on the opposite side. There are now three threads laid, and these should be buttonholed as shown, working under the threads only, not through the material, as this will be cut away afterwards. Continue buttonholing on the second side of the ladder for $\frac{1}{2}$ in., or according to the space to be left, then work another rung. When all the work is finished cut away the material right under the pearl edge, taking care not to cut the stitch, and buttonhole the cut ends at the top and bottom of the ladder. *See Embroidery; Transfer.*

RICKETS. A nutritional disease of children, rickets, or rhachitis, usually begins in the period between the sixth and the thirtieth month. An important factor in its production is the absence, or even shortage, of the supply to the tissues of a substance described as vitamin D. This vitamin is present in sufficient quantities in the mother's milk when this is good. If, however, the mother's milk is thin, or if a child is fed on starchy foods, even with the addition of fat in the form of margarine, there will be starvation as regards this essential vitamin. This may apparently occur, also, if a child suffers from constant indigestion, especially if diarrhoea is present.

A deficiency of the anti-rhachitic vitamin is made good if the body is sufficiently exposed to ultra-violet rays, either in natural sunlight or artificially produced. Fats deficient in the vitamin acquire it by being submitted to these rays.

Rickets begin insidiously, but sooner or later the child becomes restless and peevish, with a certain amount of fever and free sweating, from the head especially, when it sleeps. There is great tenderness over the body, the slightest touch being resented. The appetite and digestion are impaired, and commonly there is constipation alternating with diarrhoea. The child tends to become pot-bellied. Another symptom is that teething is delayed, the ends of the long bones become swollen, so that the wrists and other joints are unduly large, and there are rows of enlargements down each end of the chest in front. The child is slow in beginning to walk; the muscular weakness may be so great as to suggest paralysis.

As time goes on, the frontal eminences on the skull become enlarged, producing a broad, square forehead, and sometimes portions of the skull towards the back of the head become thin and papery. The bones of the legs bend, causing bow leg or knock knee, and there is commonly flat foot. The spine develops a hump and the walls of the chest are flattened; the breast bone may be pushed

forward, a condition described as pigeon breast. Sometimes, however, particularly if there is nasal obstruction, as from adenoids, the breast bone is depressed, forming the funnel-shaped chest. Children suffering from rickets are prone to certain nervous troubles, such as convulsions, tetany, and a spasmodic type of choking, known as laryngismus stridulus.

It is most important to prevent rickets. This can be done by giving a child the diet, the sunshine, the fresh air, and the exercise which it requires.

A list of foods containing vitamin D is given under the heading Diet. If natural sunlight is not available, a course of treatment by artificial ultra-violet light should be procured, if possible. Cod-liver oil is a very valuable addition to the diet, but should be given in an emulsion, or with malt, in view of the difficulty of digesting the plain oil.

The child should not be allowed to get on its feet until the bones are sufficiently strong, and to prevent its doing so it may be necessary to attach long splints to either side of the body and the corresponding limb. When tenderness has disappeared, gentle massage of the muscles should be employed, however. *See* Bow Legs; Convulsions; Diet; Light; Vitamin.

RIDDLE. More usually known as a sieve, this is an implement used for separating coarser material from that which is finer. *See* Sieve.

RIDGE BOARD. The topmost timber of a roof which is known as the ridge board is a horizontal board, and runs along the ridge or apex of the roof. The upper ends of the rafters bear upon it. *See* Corrugated Iron; Rafter; Roof.

RIDGING: In Gardening. This is a method of cultivation which exposes the largest possible area of ground to frost, snow, rain and wind, which help to disintegrate hard lumps and render the soil friable. It is carried out in autumn or early winter, and is done by throwing up the soil in the form of ridges.

RIDING. A good rider must have good hands and a good seat. Hands, by which is understood a natural sensitiveness and responsiveness, together with a capacity for understanding animals ridden, cannot be acquired; they are inborn. The rules for good riding are summed up in the lines, "Your head and your heart keep up, your hands and your heels keep down. Keep the knees close to your horse's side and elbows close to your own."

To mount a horse the rider should face its left side and, standing well forward, gather the reins up short in his left hand. He should take care not to hold the off rein tighter than the near one, as that may make the horse move in a circle with the prospective rider on the outside of it.

Having with the left hand, which still holds the reins, taken a firm grip of the horse's mane, he should steady the near stirrup with the right hand and then put his left foot into it. He should place the right hand on the further side of the cantle, or back of the saddle, and keeping the right leg straight and high, so as to swing clear of the croup, should spring on to the horse. He then steadies the right stirrup, into which he places his right foot, and is ready to start.

Both hands should hold the reins, the knuckles being upward, not downward as when driving. They should exert only the minimum amount of pressure necessary to control the horse. The rider should learn, however, to grip with the thighs, knees, and sides of the legs, but should not grip hard unless it is necessary. The shins should be kept vertical and the feet parallel to the sides of the horse. When going slowly he should keep the ball of the foot on the tread of the stirrup, but when galloping he should push it further through. *See* Bit; Bridle; Horse; Pony; Saddle, etc.

RIFFLER FILE. A riffer file is a double-ended file of peculiar formation, comprising a plain metal part, or bar, curved at either end, these ends being cut to form the teeth of the file. They are made in a wide variety of shapes and coarseness of cuts, and are invaluable when working hollow and rounded shapes in metal, fibre, or other material.

This type of file is used largely for cleaning up the corners and angles in chasings and engravings. It can be manipulated in odd corners in a manner that would be impossible with any other tool. *See Casting; File.*

Riffer File. Cleaning up the interior of an awkwardly shaped casting

RIGOR MORTIS. The stiffening of the muscles which occurs soon after death is known as rigor mortis. The commencement and duration of the rigidity vary considerably. *See Death.*

RIM LOCK. In this type of lock the case has a rim round it by which it is fixed with screws to the surface of the door. The bolt, or bolts, shoot into a box staple fixed in position on the door jamb in the ordinary way. This type of lock is more unsightly than the mortise lock, owing to the case being exposed, but it has the advantage of not weakening the door to the same extent. For this reason, it is very extensively used. In better-class houses it is only fitted to the domestic rooms, such as the kitchen and servants' quarters, spare bedrooms and the like. *See Latch; Lock.*

RIND. The peel or skin of fruits and vegetables is called the rind. The outer skin of pork, ham, or bacon also is spoken of as the rind. In reality this term means an outer crust. To rind is a north country equivalent for to render. Preparing and clarifying fat and butter by melting is to rind or render. *See Candied Peel; Clarifying.*

Ring. Some examples of antique rings. Fig. 1. 16th or 17th century poison ring in gold, the lid of poison box engraved with winged Eros or Cupid. Fig. 2. Poison ring shown open. Fig. 3. 17th century ring set with small diamonds in form of basket of flowers. Fig. 4. Scaraboid ring engraved with Egyptian signs, 17th dynasty, modern setting. All are slightly enlarged to show the details. (Courtesy of Spink & Son, Ltd.)

RING: In Jewelry. Two ancient designs in rings are still often reproduced. One is the snake ring and the other is seen in the gemmel rings with clasped hands, of which some fine specimens have been preserved. One in the Londesborough collection is of silver with two hands clasped, and on one side of each of the twin

hoops there is an engraving, showing that this ring belonged to some personage of high rank in the 16th century. There are earlier examples in the Braybrooke collection, not only with twin hoops but also with three hoops, a fine one dating from the end of the 15th century.

Signet rings were used for signing documents from a very early date, while the Egyptian scarab was mounted on a ring and worn as a charm against evil. An interesting old ring is illustrated in Figs. 1-2. Deadly poison was contained under the ornamental top, which could unobtrusively be opened and the poison dropped into wine or food. Rings were used in connexion with betrothals and weddings from the earliest times.

Rings connected with ecclesiastical usages have always been regarded as symbolical of dignity and authority by priests, and on all state occasions there is a special ring that is invariably worn by the Pope. The stone in this ring contains a very fine cameo of the head of Christ. The stone from which this cameo is cut is a peculiarly beautiful specimen of a blood-stone. This ring is placed upon the Pope's finger immediately after his election, and it is handed down from one Pope to another.

Thumb rings were frequently worn, and many of these are in private collections or in museums. Some are regarded as of great value, and are known as decade-rings, having ten projections at intervals round the shank, which were used as beads for repeating Aves. Many of these rings are engraved with the figures of saints. A favourite inscription on the signets or the inner lining of the shank on religious rings is that of St. Christopher, the patron saint of Roman Catholics, as regards protection in times of accident or danger.

Silver rings are not frequently found; but in all well-known collections there are many specimens that are made of iron, also of other base metals with enamel. Some beautiful specimens of glazed earthenware rings have been unearthed at various times, set with very fine mosaic ornaments or with cornelians or lapis lazuli.

Care of Rings. The cleaning of gem rings should be regularly undertaken if the gems are set in open settings. Diamond rings can be placed in hot water, and then a soft toothbrush should be applied to the backs of the stones, and any dirt or dust should be carefully brushed away from the setting. Rings can be dried best by covering them in a small receptacle containing very fine boxwood sawdust, which has been heated. They should then be brushed with a soft, dry brush.

A simple method of cleaning gems in finger rings, providing the stones are not foiled, is to brush the backs of the stones through the open setting with a moderately stiff toothbrush which has been dipped in a small quantity of whisky or gin. The spirit evaporates, and thus saves the necessity of drying them.

In all cases where imitation or foiled coloured stones need cleaning, these should never be touched with anything moist, and must not on any account be immersed in water or brushed with a damp brush. Imitation stones are usually covered at the back with a foil, and it is necessary that this should never be allowed to become damp. The best method for cleaning foiled stones is to brush the settings round them with a bristle brush, to which a small quantity of powdered chalk should be applied.

Rings containing valuable gems should be left occasionally with a practical jeweller to examine the settings through a microscope, and to remedy any defects that may be discovered in the settings.

The simplest way of removing a tight ring from the finger is to wash the hand in cold water, rubbing the joint of the finger with plenty of soap. If this method fails, draw three or four lengths of thread across a piece of soap, put them through the finest needle that will take them, and then pass the latter between the ring and the finger, drawing the threads after it.

If the point of the needle is kept slanting upwards there will be no danger of pricking the finger. Hold the threads close to the finger, then slip the ring along them. It will usually be found to work off quite easily. If neither of these methods is successful, it will probably be necessary to have the

ring filed. The hand should never be washed in hot water when a ring is to be removed, as heat causes the finger to swell. *See Jewelry; Napkin Ring.*

RINGING: In Gardening. A process sometimes adopted for the purpose of inducing vigorous barren fruit trees to bear fruits. It consists of cutting out narrow rings of bark all round or almost all round the branches; if the rings are only one-eighth of an inch wide they may encircle the branches; if wider than that the rings must not be completed. April is a suitable month for this work.

RINGWORM: How to Treat. The term ringworm is commonly applied to certain skin diseases caused by parasitic fungi. It may be found on the scalp, the beard, non-hairy parts of the body, and the nails.

Ringworm of the scalp, which is highly contagious, is characterized by the appearance of one or more roundish, partially bald patches, the skin being red in colour and covered with fine greyish scales. The disease is more common in children than in grown people. One of the commonest means of spreading it is by using the brush and comb or wearing the cap of a child suffering from the disease.

The disease is treated by the application of parasiticidal lotions or ointments. Every day the whole scalp should be thoroughly shampooed with soap and hot water. Then the more patently diseased hairs, which will come away easily, should be plucked out with a fine pair of tweezers. Finally, a colourless iodine should be applied once or twice daily to the patches. This treatment must be continued for a long time. The treatment which gives the quickest results when obtainable is the exposure of the patches to the X-rays.

RIP SAW. This is a hand saw particularly adapted for cutting in the direction of the grain of wood. The teeth are specially shaped for that purpose, the front of them being vertical instead of sloping slightly backwards, as in the cross-cut saw. It facilitates the cutting of long lengths of timber, cutting rather faster and more freely than the ordinary saw. *See Saw.*

Rising Front. *See Swing-back.*

RISSOLE. To make cold meat rissoles, pass 6 oz. cold cooked meat, weighed after it has been trimmed, through the mincer twice, adding 2 shallots and 3 sprigs parsley, then make a thick sauce with 1 oz. butter, 1 oz. flour, 1½ gills stock, 1 teaspoonful lemon juice and seasoning of salt and black pepper. Add also a pinch of ground mace. The flour should be fried with butter, and the stock must be well flavoured with vegetables. Add the minced meat to the sauce, mix and spread the whole on a plate to cool. Chicken and game can be used, with the addition of a little bacon.

Meanwhile prepare a small quantity of rough puff pastry, using about 6 oz. flour and 5 oz. butter, or butter and margarine mixed together. This pastry should be rolled about the thickness of a penny. If the pastry is too thick it is liable to become too deeply coloured before it is cooked, or before the meat is heated right through.

Roll the pastry out into a square, thin sheet, then take portions of the mixture (about 1 dessertspoonful) and lay these in a row along the near edge of the pastry, leaving about 2 in. between each and keeping the heaps far enough from the edge to allow of the pastry being folded over a little beyond the mounds. Now wet the edge of the pastry, fold the flap over the heaps and press them with the thumbs in shape of a half circle. Cut out each with a 3 in. fluted cutter.

The rissoles are now ready to be egged and crumbed, and should be fried in deep boiling fat. Use a frying basket, and shake them while frying gently to detach them from the sides of the basket and from each other. Dish on paper and garnish with fried parsley.

The rissole may be fried without any coating. When so treated, the half circle is laid on a floured plate, turned over quickly and then fried as if egged and crumbed. It must not be dipped in flour, but only dusted with it.

Fish Rissoles. Lobster makes good rissoles. Cut the meat of a very small lobster into dice, add to these 1½ gills good white sauce, 1 teaspoonful lemon juice and seasoning, also a little anchovy butter. Mix all thoroughly together and heat up to boiling point in a small saucepan. Cool the mixture, make it up into rissoles, and fry in the manner previously directed.

Almost any kind of fish, except very coarse fish, is suitable for rissoles, but the flesh must be mixed with good white sauce and pounded. Cooked fish should be used, and 4 oz. will need 1½ gills sauce. With the more delicate varieties of fish add a little cream to the sauce.

Cheese Rissoles. For these mix 1 dessertspoonful cornflour with 1 gill milk, then cook and stir them over a low fire for a few minutes. Move the pan to the side of the stove, and when its contents have cooled slightly add 1½ oz. grated cheese, the yolk of an egg, and a small lump of butter. Add pepper and salt to taste, together with a little mustard; then turn the whole on to a plate and leave it to cool. When it has set, form it into rissoles, using a little flour to make it adhere; coat each with beaten egg and breadcrumbs, and fry in smoking hot fat. Drain, and serve at once, grating a little cheese over each.

Egg Rissoles. For egg rissoles shell, cut in half and remove the yolks of 6 hard-boiled eggs; then rub the yolks through a sieve and mix with them 1 teaspoonful chopped parsley, a pinch of mixed powdered herbs, 1 teaspoonful breadcrumbs, and a little seasoning. Beat up a raw egg, and add sufficient of this to bind the mixture together; then take teaspoonfuls of it and shape them like eggs. Roll ¼ lb. pastry on a floured board to the thickness of notepaper and then cut it into neat rounds with a pastry cutter or the lid of a tin. Put a ball of egg forcemeat on each round, wet the edges of the pastry, and close them together by folding one edge over like the flap of an envelope. Egg and crumb these, and fry them a delicate brown in smoking hot fat. *See Anchovy Butter; Jam Rissole; Pastry.*

RIVETS AND RIVETING EXPLAINED

Practical Information for the Amateur Mechanic

The metal worker should consult the articles under the heading of Metal; also Bent iron Work , Casting; Repoussé. Reference is also suggested to Crockery; Pocket Knife; Perambulator, etc.

A rivet is a metal peg, resembling a short nail, which is clinched over at the ends after being driven in place, as shown at Fig. 1. It provides a permanent fixing for two plates or for the attachment of objects with thin ears, or lugs, to plate work. Rivets are used in many ways in other spheres than engineering and metal work. For example, soft metal rivets are employed to fasten the parts of leather and textile work together, and also for attaching metal fittings to bags and straps.

For use on wood, as in the planking of small boats, copper rivets or nails are employed with washers or burrs of the same material. The rivet is driven through the two planks, and the washer put on and closed up to the work. The superfluous projection is nipped off and the end riveted over

the washer as in Fig. 2. The head of the rivet must be supported by a heavy hammer, or other suitable mass of metal.

When leather or a like material is being joined, it is necessary to provide rivets with heads of a large area and washers of a corresponding size. When a metal fitting is being riveted on to leather, it almost always takes the place of a washer. Bifurcated rivets used in leather work have large, flat heads and a shank divided into two prongs. When driven into leather of suitable thickness, and the job is resting on a metal surface, the prongs turn up, hook fashion, into the lower surface of the leather. The result is a good fixing, as will be seen by reference to Fig. 3.

When using a bifurcated rivet a suitable hole should be made in the parts and the rivet inserted. The work is then laid on a block of wood (end grain is best) with the prongs downward. The rivet is driven home, so that the prongs project, and the work levered up from the block, when the prongs can be prized apart and hammered over into the leather. The head of the rivet should rest on the vice or some other metal surface.

Large flat-headed rivets are used in joining thin metal sheets. They may be made of any material—aluminium, copper, tinned or plain iron—comparable with that for which the rivet is used. The generic term for this style of rivet is tinman's rivet (Fig. 4).

Rivet. Fig. 1. Three types of rivet heads. Fig. 2. Rivet used with a washer for joining two planks. Fig. 3. Bifurcated rivet used in leather work. Fig. 4. Tinman's flat-head rivet. Fig. 5. Showing the tendency of metal plates to shear the rivet when the latter is not securely fastened. Fig. 6. Result of an unusual strain on a rivet. Fig. 7. Single riveted lap joint. Fig. 8. Double riveted lap joint. Fig. 9. Possible space for leakage between two plates. Figs. 10 and 11. Caulking and fullering to prevent this leakage. Fig. 12. Driving the plates together by means of a hollow punch. Fig. 13. Three stages in forming a snap head. Fig. 14. Another type of punch used in riveting.

Where the rivet is of a metal dissimilar to that of the plates being joined it should be the softer of the two. All rivets should be quite soft. If found to be too hard, so that the heads break off, the rivets should be annealed.

Joining Metal Plates. Riveted joints in metal plates requiring to be secured to each other in the strongest possible manner should be made so that the rivets themselves are subjected only to a shearing stress. This means that the strain should be such that the two plates tend to cut the rivets in

the same manner as the blades of a pair of scissors, as seen in Fig. 5. There should be little or no tendency to pull the head off the rivet, as is shown occurring in Fig. 6. For thin sheet metal work, rivets from 1/16 in. to 3/16 in. are commonly employed. The spacings may be from 1/4 in. to 1 in. respectively.

Rivets in tanks and boilers subjected to pressure, and those used in steel structures, usually have a diameter equal to about twice the thickness of the plate. The spacing depends upon the kind of joint and the relative strengths. For a single riveted lap joint, as illustrated in Fig. 7, the spacing would be about five times the single-plate thickness. Rivets under 3/8 in. in diameter are usually driven cold. A single riveted lap joint of good design has a tensional strength of only about 55 per cent of the solid plate. In a double riveted joint, as at Fig. 8, the proportionate strength may rise to 70 per cent. In no case can a riveted joint be made as strong as the original plate unless the plate is thickened up in itself at the rivets.

Caulking and Fullering. In larger work, that is to say, where plates of over 3/16 in. are employed, the joints are made pressure tight against liquids and gases by caulking and fullering. Although the plates may be drawn closely together around the rivets, they may not touch each other between them, as indicated in Fig. 9. There may be small open spaces under the heads and around the stalks of the rivets capable of creating a leak. The process of caulking and fullering burrs the metal over at these places. It is done by blunt chisels of various shapes, and requires skill and experience to be a success. Fig. 11 shows at A the edges of a rivet being caulked over; at B, the plates of a single riveted lap joint are being similarly operated upon. The use of a fullering tool is shown at C in Fig. 10. In a thin sheet metal object such caulking is impossible, and the same result may be accomplished by soldering, brazing, or welding.

Forming the Snap Head. In order to pull together the plates of a riveted joint in sheet metal preparatory to hammering the rivet over, a hollow set punch may be used. Fig. 12 shows a combination set punch having in addition a recess or snap for forming cup or snap-headed rivets. The holding-up tool used beneath may also be provided with a sinking to suit the shape of the rivet being driven, and act as a snap in addition.

To form a snap head, the projection of the shank of the rivet before it is hammered over should be about 1 1/4 times its diameter, as shown at D, Fig. 13. The final neat rounded shape is obtained by the use of the rivet snap, as at F, after the head has been formed roughly into a conical shape, as shown at E. The blows, in the first part of the operation, should be delivered at an angle, following around the rivet with a hammer of suitable weight. It should not be hit directly end on in the centre. The only exception to this method would be in the case of a countersunk rivet, as in Fig. 11, where the metal would for the most part be spread out by means of directly central blows.

The holes in the plates may be drilled, or punched out in a machine for the purpose. In either case, the burr thus formed should be removed so that the sharp edges of the holes are slightly chamfered, or rounded. A drilled hole is to be preferred to a punched one, as the metal around a punched one is weakened in the operation, and the strength of the plates is thus locally impaired.

Rivets for cold driving should always be thoroughly annealed before use. Iron rivets are to be preferred for this purpose, as the heads of steel rivets are apt to crystallize when hammered over cold. Copper rivets used in a pressure-tight joint, to be soldered subsequently to riveting, should be tinned before use. This will ensure their taking to the solder. First they should be cleaned by dipping in nitric acid. The use of countersunk or flush rivets should be avoided where-ever it is possible, especially in cases where the rivets are subjected to the slightest tensional stress. A pan head, or snap (cup) headed rivet is much to be preferred. Rivets should be purchased with one head already

formed. Plain wire should only be employed where both heads are of the countersunk form, and where the rivet is a long one.

ROACH: The Fish. The best season for this fresh-water fish is from early autumn until the end of March, and it should not be eaten before the beginning of August. To tell when roach is in good condition, examine the fins and the scales; the former should be red in appearance and the latter smooth to the touch, if rough, the fish is not good. To prepare the fish, wash it, scale and gut it, and then wash again in clear water.

Roach may be boiled or fried. To boil, wipe the fish and score them each side in 3 or 4 places. Put them into a stewpan and just cover them with lukewarm water. To each quart of water add 1 tablespoonful vinegar, 1 dessertspoonful salt, a bouquet garni, and 1 tablespoonful grated horseradish. Simmer from 12 min. to a quarter of an hour, and serve with parsley or anchovy sauce. For frying, prepare the fish, washing them well in salted water, then wipe them quite dry. Dip in seasoned flour and fry them in a frying-pan in butter, or in deep boiling fat. When the fish are brown and crisp dish them on a dish paper, and brush them with a little butter, which should be ready melted, and scatter over them dried and sifted sage, with seasoning of pepper and salt. The sage should be heated, and must be used sparingly. Garnish with fried parsley and cut lemon.

ROAD. Except on private roads, of which there are only, comparatively speaking, a few in existence, all persons have the right to travel on the roads at any time they like. As regards pedestrians, this right is unrestricted, save by the danger from moving vehicles; but drivers of motor cars, carts, carriages, and the like are legally bound to observe certain regulations, known as the rule of the road. They must also stop when directed to do so by a policeman on duty. Where a structure is erected on a road, the local highway authority may compel the person who erected it to remove it. The extensive use of the roads by motorists has led to special regulations for this form of traffic (for which see the article on Motoring) and also, on the part of the associations of motorists, to special measures of assistance.

Warning Signs. To facilitate the safe and proper usage of the roads warning and direction signs of a distinctive character have been erected. At many road junctions and corners a white line is drawn in the middle of the road to induce vehicles to keep to their proper side. Traffic signs must now be of the size and type prescribed by the Ministry of Transport.

Roads and Property Owners. The owners of property have certain liabilities and duties with regard to the upkeep of roads. A householder who lives in a street which has not been taken over by the local authority is bound to bear his share of the cost of keeping the road in order, according to the length of his frontage to the road. Before a street is taken over the local authority will always require it to be properly made up at the expense of the owners of the property abutting on or served by it. In most towns and many rural districts the procedure is under the Public Health Acts or under the Private Streets Works Act. Street for this purpose includes a highway, road, lane, square, court, alley, or passage, whether a thoroughfare or not.

The first step is for the local council to pass a resolution to do such works as they deem necessary to any street or part of a street which is not sewered, levelled, paved, metalled, flagged, channelled, made good and lighted to their satisfaction. They must say whether they intend to proceed upon a mere frontage basis, or to take into account any works previously done by the owners or occupiers of the premises; or to take into account the greater or less degree of benefit to be derived by the respective premises. They may assess any premises which do not immediately front, join or abut on the street, but access to which is readied from the street via a passage or otherwise. They may

resolve to pay some or, indeed, all of the expenses out of the rates; but this is rarely done. They may include in the works the bringing of the street into level with other streets.

Further Work of the Local Authority

The council's surveyor next makes plans and specifications, and prepares an estimate of the cost, and submits to the council a provisional apportionment upon the several premises intended to be charged. In the absence of a special resolution, as above, the only premises which can be charged are those fronting, adjoining or abutting on the street, according to their frontage. Places of worship and burial grounds are not chargeable, but their share of any street making must be borne by the rates.

Once a street has been taken over by the local authority, it is repairable by the inhabitants at large, and the householder-owner has no more trouble with it. The most common objection to street works is that they are unreasonable, e.g. that the sewer proposed is too small, or unnecessarily large. A local authority may, however, lay an unnecessarily large sewer if they bear the surplus cost themselves. Again, an owner may object that the street has already been sewered once. After the scheme is finally approved by the justices, the authority proceed to do the work; and, when they have completed it, make a final apportionment on those liable, in the same proportions as the provisional apportionment.

Notice is served on the owners, any of whom may, within three months, object to pay. The only ground of objection is that the apportionment has not been validly made.

The cost of the work becomes a charge on the premises from the date of the completion of the work. Therefore, if A buys a house the owner of which has had the proper notice, and he sells it to A free from incumbrances, the owner must bear the cost of the paving, etc., if the work is completed before the day fixed for completion of the contract of rate. Otherwise A must pay. As between the owner and a tenant of a house, the owner is liable to the local authority, but if the tenant holds on a lease wherein he has agreed to pay, in addition to rates, all imposition and charges imposed on the landlord in respect of the house, the landlord may claim reimbursement from the tenant. The local authority may make the amount payable by instalments spread over 30 years with 5 p.c. interest, and recover each instalment from the tenant, the latter in turn being able to deduct it from the rent. *See Rates.*

ROASTING: Of Meat. Before attempting to roast or bake meat, preparations should first be made for heating the oven, either by building up a good fire and pulling out the damper over the oven or lighting the gas, or switching on the electric current. Gas or electric heat should be turned on at least 20 min. before the oven is needed. The kind of meat to be cooked, its shape, proportion of lean, fat and bone must all be taken into consideration.

The time required for roasting various kinds of meat and joints will be found under the different headings, Beef, Lamb, Pork, etc., and also in the Cook's Time-table in page 4 of wrapper. Part 4.

To prepare the joint quickly, scrape, wipe, trim, and tie it in shape. The use of string is better than skewers, as the holes made by the latter allow the nutritive juices to escape. Be careful that the loins and neck are jointed. Score the skin of pork with a sharp knife and rub it over with a little salad oil. Tie greased paper over fatless meat, such as veal, to prevent it from drying and scorching, always removing the paper for the last 20 min. to let the joint brown.

Put the joint on the trivet in a double baking tin if possible. The water in the lower pan keeps the dripping from burning and causing an unpleasant smoke. Alternatively put a second tin containing water on the shelf below the joint, or add a gill of water to the tin in which the joint has been placed, adding more as it evaporates.

Place the joint in the hottest place in the oven for the first 10 min. This is most important, the object being to harden the meat-albumen on the surface, and thus seal up in the meat the juices that give flavour and nutriment. Then slacken the heat in order that the joint is cooked through, not dark nor burnt on the outside and raw in the centre. After the preliminary sharp heat, the rule is— the larger the joint the slower the oven.

Basting the meat, that is, pouring a few spoonfuls of the hot dripping from the tin over the meat, must be done frequently, to prevent it drying and shrivelling. When cooked, place the joint on a hot dish and remove the string. Keep the meat hot whilst the gravy is made. Clear gravy is served with beef, mutton, lamb: thick with veal, pork, and stuffed joints.

Roasting Jack. The use of a roasting jack facilitates the turning of meat when set to roast in front of the fire. The spit is occasionally called a jack, and the mechanical contrivance a bottle jack. The bottle jack is provided with an inside spring. When wound up it gives the spit, which is fastened to it, a rotary movement backward and forward, so that the meat is constantly changed in position and is cooked evenly on all sides.

The roasting jack is a great convenience, as it does not require the constant attention of the cook to prevent the meat from scorching on one side. By the aid of a roasting jack and a meat screen, meat can be roasted in front of the fire and cooked to perfection. It is thus actually roasted, whereas when placed in the oven it is baked. When roasted the air circulates freely round the joint, and all noxious fumes are entirely dissipated. *See Baking; Beef; Dutch Oven; Lamb; Mutton, etc.*

Robinia. *See Acacia.*

ROCAMBLE. A member of the onion family, rocamble is often called Spanish garlic, but is much milder than the true garlic. It is of perennial growth, and produces clusters of bulbs at root and stem, the former of the two being the most suitable for propagation.

Cloves, or divisions, of bulbs are best planted in spring in light soil 2 in. deep and 6 in. apart. If preferred seed may be sown in drills at the rate of $\frac{1}{2}$ oz. per 25 ft., crops taking about 8 months to reach full maturity. Bulbs should be lifted when the foliage becomes yellow, and placed in the sun to dry, afterwards tying them in bunches and storing them in a dry place. *See Garlic; Onion.*

ROCHEA. These greenhouse plants bear succulent leaves and flat bunches of showy flowers in spring or summer. They are easily grown in pots in a compost of well-drained sandy loam and need a minimum temperature of about 50 degrees. During the winter months they need comparatively little water. Propagation is by cuttings inserted in pots of sandy soil in spring. *Rochea coccinea*, with scarlet flowers in summer, is the favourite kind.

Rochea. Greenhouse pot plant with crimson flowers and succulent leaves.

ROCK BUN. Plain rock buns or rock cakes can be made from $\frac{1}{4}$ lb. butter, $\frac{1}{2}$ lb. flour, 3 oz. castor sugar, 2 eggs, salt, and $\frac{1}{4}$ teaspoonful baking-powder. Rub butter into flour, add sugar and eggs (beaten), also flavouring of vanilla. Mix all well together and drop the mixture, with two forks, in small rocky heaps on to a tin lined with buttered paper. Cook the cakes in a moderately hot oven until they are lightly browned and firm to the touch.

To make fruit rock cakes, mix together $\frac{1}{2}$ lb. flour, a pinch of salt, and 1 teaspoonful baking-powder; then rub in 3 oz. butter and add 3 oz. sugar, $\frac{1}{4}$ lb. cleaned currants or sultanas and 1 oz. mixed peel, cut up finely.

Stir a beaten egg into the mixture and then a little milk, keeping the whole to the desired stiffness. Bake the cakes as directed in the previous recipe.

ROCK CRESS. This name is popularly given to the white arabis. It is a low-growing, spreading plant much used in the rock garden and for spring flower beds; it thrives in ordinary well-drained soil and is increased by cuttings in June.

The plants should be hard pruned after flowering. Aubrietia is the purple rock cress. *See* Aubrietia.

ROCK CRYSTAL. A variety of colourless or nearly colourless and transparent quartz, rock crystal is found in different forms in many parts of the world. In all forms it is an extremely hard mineral, being fusible only by the oxy-hydrogen flame and the electric furnace. Rock crystal is impervious to most acids, hydrofluoric acid being practically the only exception.

A modern use of rock crystal is in the construction of lenses for photographic and optical work, the pebbles for which are obtained in Brazil. Large crystals, used in optical work, are found in the northern parts of Madagascar. The vellum stone of Madras is a form of rock crystal that is cut and polished and is then fashioned into ornaments. *See* Lens.

ROCKER. The curved pieces added to the legs of a chair to permit it to oscillate, or rock, to and fro are known as rockers. They are also used on cradles.

A projection or lever arm attached to a shaft that is capable of motion in alternate directions is known as a rocker arm. This mechanism is found, for example, in the overhead valve gear of a motor car or motor cycle engine.

ROCKERY. This term is commonly used in reference to a small rock garden or a mound of soil and stone so arranged as to provide a miniature representation of a rock or Alpine garden. Often a rockery is but a heap of soil and stones set in a shady part of the garden and planted with ferns, London Pride, and a few other common plants. But if it is in a sunny place and built correctly many choice Alpine or mountain flowers can be grown in a rockery. It should be constructed in the way explained in the notes describing the rock garden (q.v.)

ROCKET: The Plant. This is the popular name of an old-fashioned hardy perennial plant (*Hesperis matronalis*). Belonging to the wallflower family, it bears fragrant purple flowers in summer; the variety *alba* has single white blooms. The double rockets, with white, lilac, or purple

flowers, are very beautiful, but more difficult of cultivation than the single kinds; they should be increased by cuttings inserted in sandy soil in a frame or greenhouse in late summer. There is no difficulty in raising the single rockets from seeds in early summer. Both single and double rockets flourish in ordinary well-tilled soil.

Rocket. A delightful perennial suitable for a sunny bed or border. This variety is well known for its delicate perfume.

ROCKFOIL. This is the popular name of saxifrage, a large group or genus of charming flowering plants chiefly suitable for cultivation in the rock garden, adding greatly to its attraction. See Saxifrage.

ROCK GARDENS: THEIR CONSTRUCTION And the Plants that Give the Best Results

The reader of this article is referred to the entries on the various plants and flowers suitable for the rock garden, e.g. Aubrietia; Columbine; Edelweiss; Fern; Gentian; Heron's Bill; Moss.

The building of rock gardens, both large and small, on which to cultivate alpine or mountain plants has made remarkable progress in late years, and this is not a matter for surprise, for no plants are more fascinating than those which grow wild on the alpine heights of Europe and other countries. Most of them bloom in astonishing profusion and provide an enchanting display chiefly in spring and early summer. Most of them can be cultivated to perfection in this country in a properly constructed rock garden.

Rock Garden: An effective arrangement of plants. 1. Anemone hepatica caerulea. 2. Androsace alpina. 3. Campanula Raineri. 4. Primula denticulata cashmiriana. 5. Achillea argentea. 6. Adonis pyrenaica. 7. Rock yarrow. 8. Alpine pink. 9. Houseleeks. 10. Aubrietia, Dr. Mules. 11. Arabis alpina plena. 12. Aethionema grandiflora. 13. Gentiana acaulis. 14. Lychnis Lagascae. 15. Double gold dust. 16. Erigeron aurantiacus. 17. Iberis correaefolia. 18. Aubrietia, Mrs. Lloyd Edwards. 19. Saxifraga apiculata. 20. Erodium macradenum. 21. Anemone pulsatilla. 22. Linum tenuifolium. 23. Saxifraga Aizoon. 24. Edelweiss. 25. Phlox amoena. 26. Aubrietia, Fire King. 27. Lychnis viscaria. 28. Incarvillea grandiflora. 29. Saxifraga burseriana. 30. Geranium Lancastriense. 31. Primula Forestii. 32. Daphne rupestris. 33. Ramondia pyrenaica. 34. Gentiana acaulis. 35. Saxifraga Camposii. 36. Lithospermum prostratum.

The secrets of success are to choose a site in a sunny place and to provide thorough drainage. Alpine plants are thoroughly hardy, and do not succumb to frost, however severe; but they will not flourish in ill-drained soil. Perfect drainage is of the first importance.

There are innumerable ways of building a rock garden; it is scarcely possible or advisable to work to a set design. The aim should be to make it as natural in appearance as possible, whether it be a miniature representation of a mountain chain, a boulder-strewn slope, a rocky valley, or merely a grouping of rocks and soil arranged informally.

An attractive feature of a rock garden made out of an old stone sink. (Humphrey & Vera Joel)

If the soil is clayey it should be excavated to the depth of 10 or 12 in., this space then being filled with stones or broken bricks for drainage. On naturally light land no such preparation is required. In setting the rocks care should be taken to place most of them on their broadest bases, and to ensure that they are firmly embedded in the soil; they should slope towards the mound of soil, not away from it. Very few, if any, of the rocks should be placed on end; they have such an unnatural appearance. Here and there, however, to ensure a bold rock group or greater variety of outline it is permissible to set some on end. A limited number of large rocks or stones is more effective than numerous small

ones; it is difficult to build a rock garden of distinction with the latter.

As the placing of the rocks proceeds, soil must be placed behind them, care being taken to see that all spaces between them are filled with soil made firm. Most alpine plants root deeply, and unless there is a fair depth of soil between the rocks they may deteriorate or even perish in dry weather. It is a mistake to place one rock or stone directly on another; there should be a good layer of soil between them, for many alpines flourish best in crevices between the rocks.

Rock Garden: how to arrange the stones. 1. Simple rock garden with base drainage. 2. Bad placing of stones. 3. Good placing. 4. Typical rock formation. 5. Good method of planting in pockets and fissures. (Courtesy of Amateur Gardening)

Ordinary non-clayey garden soil may form the bulk of the material used in the rock garden; sand, leaf-mould and gritty material, such as broken stone or brick, must be mixed in freely. Such a compost will suit numerous plants: others which need special soil can be provided for at

planting time by taking out holes and filling them with peat, or whatever is needed. If the available site is narrow, care must be taken not to build too high; otherwise the plants are almost certain to suffer from the effects of drought in summer.

The best time to put in rock plants is in September-October and early April. As they are grown in small pots by nurserymen they can however be planted at any time, though it is unwise to set them in winter. In spring and early summer the rock garden must be watered very freely in dry weather, for it is then that the growth of the plants is most active. They ought to be watered thoroughly a few

hours before being planted. It is an excellent plan to place a layer of stone chips on the soil round about choice plants; this helps to keep the roots moist, and that is essential to success. Vigorous spreading plants, such as pink, aubrietia, alyssum, dwarf phlox, iberis or evergreen candytuft, and arabis should not be set near choice kinds, or the latter may be overrun and spoilt.

Rock Garden. The blocks of stone have been laid out in rough terraces. On these terraces, between the crevices of the rocks and even on the shallow steps, cluster such dainty rock plants as columbine, saxifrage, gentian, white rock cress, candytuft, aubrietia, and a host of others. (Courtesy of Amateur Gardening)

Stone for the Garden. The choice of a stone for building should be well considered. In many parts of Great Britain igneous rocks, slates, shales, sandstone, and limestone are readily obtainable, and of these the latter is unexcelled for rock work, except in its crumbling form. Limestone in its best forms is beautiful alike in colour, outline, and texture; it possesses also the porosity that is essential for the conveyance of moisture direct to the roots of alpine plants. In those localities where natural rocks are difficult to obtain, stone-trimmings may be procured from a stoneyard, these being cemented together to form large blocks. If stone-trimmings are not available, and the cost of natural rock is too heavy, burrs may be secured from a brick-kiln and, if necessary, cemented together with thin cement. Brick-rubbish may also be adapted, or blocks of old concrete.

There are disadvantages in the use of cemented material because of its imperviousness to water and its ugly appearance: nevertheless, plants may be encouraged to thrive in such environment, provided they are planted in deep pockets of suitable compost. It is necessary to be frugal in the use of rock, making every piece firm in its position.

Plants for the Garden. There is an immense number of alpine and other plants suitable for cultivation in a rock garden. The following is a selection of beautiful and easily managed kinds. All bloom in spring or early summer. The commonest are aubrietia, yellow alyssum, white arabis and iberis or evergreen candytuft, all of which are easily grown in well-drained soil in a sunny place. The bellflowers are very beautiful, especially *campanula pusilla*, which bears a profusion of tiny blue bell-like flowers. Other good ones are *garganica*, *G. F. Wilson*, *pulloides* and *muralis*, all of low growth, and *carpatica*, which grows about 12 in. high. Most of them like slight shade.

The silvery saxifrages are indispensable. They flourish if planted in sunny pockets or crevices of gritty soil among the rocks; mortar rubble or a scattering of lime should be added. A few beautiful sorts are *Aizoon*, *Engleri*, *lingulata*, *Cotyledon*, and *cochlearis*. The mossy saxifrages form moss-like evergreen cushions, and bloom very freely in spring. They need well-drained soil in sun or shade. *Wallacei*, *hypnoides* and *muscoides* are a few of the best. The Cheddar pink (*Dianthus caesius*) is easily managed in gritty soil, and edelweiss (*leontopodium*) flourishes in stony, loamy soil. *Veronica teucrium dubia* bears masses of lovely blue flowers and thrives in ordinary rock garden compost.

Other indispensable sorts are the primulas *frondosa* and *hirsuta*, dwarf phlox, rock jasmine or androsace, yellow flax (*Linum flavum*), stonecrop or sedum, and houseleek. Many of the gentians

are somewhat difficult they may grow, but often fail to bloom. One of the most reliable is *Gentiana septemfida*.

Miniature bulb flowers should be planted in autumn—e.g. hoop petticoat, angel's tears and cyclamen-flowered daffodil, squill, snowflake, and glory of the snow. In spring seeds of low growing annuals may be sown to fill spaces here and there; suitable kinds are toadflax (*linaria*), portulaca, leptosiphon and violet cress (*ionopsidium*). Dwarf varieties of conifers, daphne, rhododendron, and other shrubs are often used in furnishing a rock garden.

ROCKING CHAIR. In a rocking chair the legs are mounted on curved rails, or rockers, so that the chair can be rocked backward and forward by a slight effort on the part of the occupant. *See* Chair.

ROCKINGHAM WARE. Two classes of pottery known by this name should be clearly distinguished. There is the ever-popular ware consisting of a cream-coloured earthenware body, covered with a lead glaze heavily stained with manganese oxide, which imparts to it a rich purplish-brown bloom, resembling a warm madder. This was introduced about 1788 by the Swinton works near Rotherham, and named after the Marquess of Rockingham, on whose land the factory stood.

Rockingham Ware. Plate of this ware made about 1823. (British Museum)

It was at its best down to 1806, the earlier pieces having a pleasing variation in the glaze, which darkened as it slowly flowed down.

The modern Rockingham glaze, which is made at many factories at home and abroad, tends to be flat and uniform, but in technical excellence modern Wedgwood and Ridgway. Rockingham surpass anything ever done at Swinton. Pieces to collect include also the antique Cadogans—which were lidless puzzle-pots filled

from below, usually in the form of a peach, and a sprig of blossom for the handle—as well as the Toby snuff-takers, often described as portraits of the great American, Benjamin Franklin. The old mark was Brameld, with or without Rockingham Works. The Rockingham family crest of a griffin was adopted in 1823.

There was also an output of cream-coloured and other ordinary wares, including dishes and plates enamelled with sprays of flowers, identified by the botanical name written on the back. After 1806 much gaudy ware was turned out, and after 1820 porcelain was also made. This continued down to 1842, when the factory was closed. A characteristic form of tea-sets had the views painted inside the cups, with a simple gold design outside.

ROCKING HORSE. There are two main types of this toy, one somewhat simpler than the other, and each can be bought in several sizes and in various qualities of material and fittings. The simpler type is mounted upon two curved rockers, the other on rocker bars. It is advisable, when buying, to choose a thoroughly strong horse, otherwise it will not stand the rough usage in the nursery to which it will probably be put. Most of these toys are portable, but in some cases the horse is fixed to the nursery floor.

ROCK ROSE. This is the English name of *cistus*, a group of beautiful flowering shrubs, most of which are suitable only for planting in well-drained soil and a sunny place. The hardiest is *Cistus laurifolius*, 4 ft., white. Other beautiful sorts are *crispus*, 3 ft., rose colour; *florentinus*, 2 ft., white;

and ladaniferus, 3 ft., white and red. They flourish best in warm, southern gardens where the soil is dry. Propagation is by cuttings in summer or by seeds in spring.

ROCOCO. This word is used in both architecture and furniture design for a style that is marked by an excessive use of curves and other forms of ornamentation, including shells, rockwork, scrolls, and foliage. It is usually introduced without regard to the constructional character of the work, and the figures are jumbled together.

This style prevailed in France and elsewhere in Europe in the 18th century, especially in its latter part. A few pieces of furniture by Chippendale and other English designers are in the rococo style, but these are by no means their best work. *See* Louis Style.

ROD: The Measure. This measure of length, which is also called a pole or perch, and is much used in measuring land for allotments, etc., consists of $5\frac{1}{2}$ yards, or $16\frac{1}{2}$ ft. Forty rods make a furlong. A square rod consists of $30\frac{1}{4}$ square yards, and 40 square rods make a rood. In brickwork a rod or rood consists of $16\frac{1}{2}$ ft. by $16\frac{1}{2}$ ft., i.e. $272\frac{1}{4}$ cubic ft. It contains about 4,500 bricks and about 75 cubic ft. of mortar.

RODGERSIA. These are hardy ornamental plants which are grown in the bog garden, or in other deep, moist soil. One of the most striking is *Rodgersia aesculifolia*, which has large, handsome leaves and bears spikes of white flowers in summer. *Pinnata*, with bronze-coloured leaves and cream-white flowers, is another striking plant.

RODINAL. This is a photographic developer with paramidophenol as the reducing agent and sodium sulphite as preservative. The original developer of the paramidophenol class was a German patent. Similar developers of British make are azol, certinal, kodol, and rytol. They are all concentrated solutions which keep exceedingly well and only require the addition of water for use. *See* Developer; Paramidophenol.

ROE. The milt or spawn of fish, which is known as roe, may be cooked in the fish or removed and made into savoury dishes. The soft roe is used in the preparation of savouries and hors d'oeuvres, and the hard roe also has its culinary uses. *See* Cod's Roe; Herring; Hors d'Oeuvres; Salmon.

ROGER DE COVERLEY. This is one of the old country dances and has its own individual tune. The dancers form up in two lines, men on one side, women on the other, partners opposite to each other. The top woman and the bottom man then chassé between the lines with their right hands extended, take hands and turn round, after which they return to their places. The top man and bottom woman do the same.

The manoeuvre is repeated by the original couple, this time with the left hand, and is followed by the second couple as before. Next time they circle round each other back to back, and finally bow and curtsy; in each case the second couple follow.

When all these figures have been done the leading woman and man face towards the top of the room and, wheeling outward, lead the other couples down to the bottom. Here they take hands and form an arch, beneath which the other couples pass. The couple which originally began the dance is now at the bottom of the row, while a fresh couple is at the top, and the dance continues as before. It follows that each couple goes through the figures twice, once when at the top of the row and once when at the bottom.

Roll. *See* Bread.

ROLLER BEARING. The essential difference between the roller and the ball bearing lies in the point of contact. With the ballbearing the point of contact may be said to be a mathematical point, whereas with the roller bearing it is a line equivalent to the length of the rollers. The roller bearing provides a far greater bearing area, and a much heavier load can be sustained than by the ball type of equal size. With the latter, light thrust loads are borne by the point of contact of the balls with the groove in which they run; heavy thrusts are catered for by the specially designed thrust bearing that is usually employed in conjunction with a journal ball bearing.

Owing to the absence of a groove in the races of the roller bearing, a thrust load is not possible, and to overcome this a roller bearing is produced having taper rollers that run in taper races. This will take a heavy thrust in one direction; where opposed thrusts are present, two bearings are employed. *See Ball Bearings; Lubrication.*

ROLLER SKATE. Several kinds of roller skate are manufactured, the best being those fitted with ball-bearing wheels. They are made in several sizes, and generally each size is adjustable within certain limits. The wheels are made in boxwood, aluminium and steel. Roller skates should be strongly made, and, as serious accidents may occur through the use of skates made of cheap materials, it is advisable to purchase only the best quality.

The rollers should be kept well oiled, using a good quality lubricating oil. For rollers with plain bearings thin oil should be used, but for ball bearings it is advisable to use a thicker oil of the mineral kind which will not dry. Rust may be avoided by keeping all the metal parts rubbed over with vaseline. It is not enough merely to wipe the parts over with a vaselined rag; the metal surfaces must be thoroughly well rubbed with a soft rag impregnated with vaseline. If the skates are to be placed on one side for any length of time, it is advisable to wipe them over with melted tallow.

Small repairs, as new axles, wheels, screws, and rubber pads, can be done at home, but the necessary materials should be purchased. Parts can be obtained from the makers generally much cheaper than they can be made at home. *See Skate.*

ROLY-POLY PUDDING. There are several varieties of this pudding: the plain suet roll, currant roll, or plum duff, jam roll, treacle roll, and raisin roll. These are all boiled: The roll is sometimes baked instead, and filled with jam, syrup, or a kind of Banbury cake mixture. When baked, the crust is often made with dripping or dripping and butter mixed. *See Pastry; Suet Crust.*

ROMAN HYACINTH. Bulbs of this favourite early flower are less plentiful than formerly and are therefore expensive. Other hyacinths of which the bulbs have been specially prepared for forcing are grown instead. If Roman hyacinths are potted in August-September in loamy soil, placed in a shady frame for five or six weeks until well rooted, and grown in a slightly heated greenhouse or room window, they will bloom towards the end of the year. They also do well in bowls of fibre indoors. The bulbs are useless after flowering. *See Bulb; Hyacinth.*

ROMNEYA. This striking perennial is commonly called the tree poppy; it reaches a height of about 5 ft., has grey-green leaves, and bears large white poppy-like flowers in summer. There are two kinds, varying only slightly in appearance, *Coulteri* and *trichocalyx*. The most suitable position for these plants is in a border at the foot of a sunny wall in loamy soil. In cold districts the stems are usually cut down by frost in winter, but if the roots are protected fresh shoots will develop in spring. These plants are increased by root cuttings placed in a box of sandy soil in a frame in spring.

ROMULEA. This is the name of a group of spring flowering bulbs with flowers somewhat resembling those of the crocus. They should be planted in autumn in sandy, loamy soil in a sunny sheltered position, or they may be grown in flower pots in the greenhouse. Some of the best sorts are bulbocodium, blue and yellow, Clusii, lavender, and speciosa, lavender-rose.

RONDELETIA. This evergreen flowering shrub, suitable for the greenhouse, grows to about 5 ft. in height. Its fragrant flowers are borne in compact heads in the summer. Rondeletias flourish in a compost of loam with a little peat and sand added.

The temperature of the house should vary from 50° to 70° F., according to the season. Propagation is by cuttings struck in sand in the springtime. The favourite kind is speciosa or odorata, which has red flowers.

Rondeletia. The fragrant red flowers of R. odorata, an attractive greenhouse pot plant.

Rood. This measure of surface contains 40 square rods or 1,210 square yards. Four roods go to the acre. *See Square Measure.*

ROOFS OF MANY KINDS

Features of the Principal Types Used in Domestic Architecture

This article, after describing common methods of roofing, and the materials used, deals in detail with the construction of a typical roof. See Corrugated Iron; Cottage; Eaves; Gutter; House; Key; Mansard; Parapet; Purling; Rafter; Slate; Thatching; Tile. etc.

Roofs are distinguished firstly by the materials used for covering them, and secondly by their form of construction. They may be covered with thatch, stone, tile, slate, lead, zinc, copper, iron, glass, bitumen, or asphalte, etc., and according to the kind of material so will the form and method of construction vary.

There are flat, lean-to, couple or span, hip, mansard, and M roofs. These are further divided into low or high-pitched roofs, as their sides make greater or lesser angle with the horizon. In carpentry the roof is the timber framing by which the covering materials are supported; this in general consists of plates, principal rafters, common rafters, purlins, ridge boards, etc.

Flat roofs are covered with lead, zinc, or asphalte after being formed with the necessary wood construction, but roofs of ferro-concrete are common. Flat roofs are given a slight pitch or inclination, in order to throw off water that may fall on them in the form of rain or snow. The pitch may be anything between 4° and 8°. The smallness of the pitch in the case of a lead covering is on account of the fact that lead will creep with the varying influences of the temperature. For this reason the sizes of the pieces of lead are restricted to a maximum of 7 ft. by 2 ft. 6 in. It will be appreciated that the bigger the piece of lead used the more evident will be expansion and contraction. For similar reasons the sizes of zinc are restricted when used on a flat.

The formation of flat roofs varies according to their size. Plates and joists form the main structure, the size of the joists varying with that of the roof. To the joists are nailed, T. and G. boarding, which should be laid lengthways to the fall; the flat area is divided up into bays by the use of rolls and

drips. For an asphalt covering the structure of the roof is similarly formed, or the base may be ferro-concrete.

Lean-to Roofs. Lean-to roofs have only one side or slope, the top part of which is generally fixed to the main wall of another building; they are commonly used for covering outhouses and sheds. The construction is very simple. A plate is fixed on to the main wall of the building that is to carry the top of the rafters, and another plate is fixed to the main wall of the shed or outhouse. Rafters are nailed to the two plates; an intervening purlin would be fixed if the common rafters were more than 10 ft. in length between the supports.

The pitch varies according to what kind of covering material is used. If the roof is tiled or thatched, 45° would be a suitable pitch, 30° for slate, and 10° to 20° for corrugated iron. If tiles, slates, or thatch are used the common rafters should not exceed 12 in. apart, but with corrugated iron they may be placed 2 ft. apart.

Roof. Typical example of a span roof.

Top right, mansard type of roof. Right, tiled gable end with edge tiles arranged on Winchester underhang system.

Pavilion roof, with four sides sloping to the ridge. Above valley roof on two semi-detached houses.

Span Roofs. Span or couple roofs have two sloping sides. They are composed of rafters that have their heads cut and fixed to a ridge board, and their feet to the wall plates at the base. The common rafters are arranged so as to project beyond the walls of the building at least 6 in. in order that any water falling from the roof will fall clear of walls. This kind of roof depends entirely upon the stability of the walls that carry it, because it has no tie beam to hold it in, hence if used for work of a permanent nature the span should not exceed 12 ft. If an addition to this kind of roof is made in the form of a tie beam it will take a wider span, 2 ft. may be added to that given in the former case, but the roof then becomes what is known as a closed span or couple roof. The span on a roof may be increased by placing a piece of timber across the ties as a binder. Ties and binder are spiked together, and a long bolt known as a king bolt connects the binder with the ridge board at intervals of 7 ft. to 8 ft. If the tie beams were not so supported they would sag towards the centre. These tie beams may be used as ceiling joists, but the clear span for such a roof should not exceed 20 ft.

If it is desired to take advantage of some of the space in a span roof the tie beams may be raised above the wall plates to a maximum height of half-way up the rafters; the ties in such a case are called collars, and the roof is termed a collar roof. This is not so strong a roof as the two preceding ones. In the ordinary couple roof much of the strain is placed upon the walls to which the plates are fixed. There is a tendency of the roof to spread, and the walls are thrust outward.

Most buildings require a roof with a span bigger than those mentioned, and additional timbers in the form of purlins and struts have to be introduced. In houses of moderate size intermediate supports are found in the form of partition walls, upon which the ceiling joists or tie beams rest, and from which struts are supported, while at the ends the purlin is built in the wall. In order to carry this type of purlin a collar is fixed to about every sixth pair of rafters. The collars are supported in turn by the struts that take their bearing from the supports beneath. This type of roof will take a span of 30 ft., and may be formed at 30° to 45° pitch.

With a roof of the span mentioned it is best to employ two purlins if it has a pitch of 45°, thus dividing the length of the rafters into three. The top purlin is fixed on the collars. The lower purlin is of a trussed design; that is, it has a top and bottom member, with intervening struts and ties in order to stiffen it up, and to prevent any sag.

Two span or couple roofs may be built side by side to cover one span, such roofs being called M roofs. A valley gutter, formed between the two roofs, is lined generally with lead, and arranged so as to fall towards both ends; that is, its highest bay is in the middle of the length of the roofs. A curb roof is one having the slope broken on two or all of its sides. In such instances the head of the rafters, where the slope changes, is cut and fixed to a heavy purlin or curb, these purlins being held together by tie beams or joists. In addition to the top purlin another is fixed midway between the head and the feet of the rafters which are attached to the wall plate. The curb roof may be finished in the form of a flat roof. As a means of lighting curb roofs, dormer windows are invariably introduced; when these roofs are used under suitable conditions they have a very pleasing effect, and they have the further important advantage of utilizing all the available space in the roof.

Roofs framed on to trusses form the best but the most expensive type of roof. The trusses most generally used are the king post and queen post truss. These are formed of fairly large timbers, and consist of a tie beam, principal rafter, struts, and a king post; the queen truss has two posts, called queen posts. These frames or trusses are supported by the walls, and rest on the wall plates; the trusses support the purlins and the pole plates, which in turn carry the common rafters, the feet of the latter resting on the pole plates. A truss roof is better able to withstand heavy loads than any of the roofs mentioned. All its members are either in tension or compression, and with careful design it can be arranged so as to convey the load of the roof on the angular points of the truss.

The head of the king post is prepared to receive the ridge board; at the head of the truss there is a 3-way iron strap, and at the base there is also a strap of iron fitted with a gib and cotter. These straps

both assist in producing a rigid structure. The purlins are arranged so as to rest on the principal rafter at the point of intersection of the strut; the pole plate is fixed on the end of the tie beam.

The queen post truss is intended for roofs with a wider span. The 3-way strap, bottom straps, gibs and cotters will be used in duplicate, seeing there are two posts. Between the posts a straining sill is placed at the base, and at the head a straining beam.

The joints used in framing the two kinds of trusses are common to both. The head of the principal rafter is secured to the king post by stub tenon and shoulder, in addition to the 3-way strap. The struts and the base of the king post are joined with a joint like that used at the head. The head of the struts is joined to the principal rafter by the use of a stub tenon immediately under the purlin. The bottom iron strap with the gib and cotter allow for the tightening up of the joints on the tie beam and base of the king post in the case of slight shrinkage or sag of the materials.

A mansard or a French roof is formed by a combination of the king post and queen post trusses; the former is placed over the latter, a combination which allows much of the space in a roof to be usefully employed. This type of roof is used in connexion with business houses, but it is not a common feature in the construction of smaller dwelling houses.

Materials for Roofing. Roofing materials comprise slates, tiles, asbestos-cement tiles, galvanized iron, either corrugated or in flat sheets, lead, zinc, bituminous feltings and many branded roofing materials, flat stones, thatch, tarred felt, concrete, asphalt, timber, and glass. Of these slates and tiles are the most extensively used for domestic purposes. Bituminous felt and similar materials are most commonly employed for roofing quite small buildings.

Stone roofs are seldom met with except where the material is naturally abundant.

They are very heavy, and often prone to be damp. Concrete is much used for flat roofs, and when blended with a suitable waterproof composition and properly laid, it undoubtedly gives excellent results.

Thatch, carried out in straw, reeds, or heather, is held in disfavour by fire insurance authorities, and is generally considered to harbour vermin and insects. A thatched house is warm in winter and cool in summer, so that thatch has much to commend it when it can be properly used. It is not practicable as a roofing material in any place where it is liable to be ignited by sparks, or from any other cause.

Corrugated and other galvanized irons are not suitable for dwellings, despite the fact that they are fairly lasting, fire-proof, vermin-proof, and impervious. Galvanized iron is hot in summer and cold in winter, and the noise made by rain falling upon it is against its domestic use. Nevertheless it is probably the cheapest practicable roof covering, and for outbuildings, poultry houses and the like is a highly satisfactory material, provided it is used in a reasonable manner with due regard to its limitations.

Construction of a Typical Roof. As an example of the construction of a roof of a small house, Figs. 1 to 7 show progressive stages of the work. The walls having been erected to plate height, that is, the height at which the brickwork terminates and the roof begins, a wooden tie, or plate, is laid horizontally upon the wall and bedded in mortar.

The next step is to prepare a number of rafters. These will generally measure about 4 in. deep and 2 in. broad, and will reach from approximately 12 in. beyond the face of the wall to the apex of the roof, that is, the junction with the ridge board. One end of the rafter is cut at an angle, so that it bears up against the ridge board, while the other end is notched to fit on to the opposite portion of the plate. Having prepared a number of rafters, the work of erecting the ridge commences, for which purpose it is convenient to lay the ceiling joists in place on the top of the wall plate (Fig. 1).

Roof: stages in construction. Fig. 1. Showing how ends of rafters and ceiling joists fit to the plate. Fig. 2. Valley board and common rafters in place.

Fig. 3. Purlins in place, also hip and valley and tile battens. Fig. 4. View from beneath showing how rafters are

trimmed round a chimney stack.

Fig. 5. Valley boards in place to support guttering. Fig. 6. Filling between the rafters to prevent ingress of wind. Fig. 7. Verge on gable end.

The joists are simply placed in position, being spaced at appropriate distances apart, about 14 in. centres, and spiked to the plate to prevent them shifting. Two rafters are placed in position on the plate and against a ceiling joist, two or three rafters' length from the end of the ridge. The upper ends of the rafters are pressed together so that they bear against the ridge board, which is placed in position between them. The feet of the rafters are spiked to the plates, and their upper ends to the ridge board, the other end of which is meanwhile supported in any convenient manner. The same operation is gone through near the other end of the ridge, after having plumbed up the first pair of rafters by comparing with a plumb-line suspended from the ridge to the ceiling joists. A cross strut is generally nailed temporarily between the rafters and the plate to keep them from shifting.

Another pair of rafters is added near the centre of the ridge, after having tested the latter to see that it is not sagging or twisting, when the rest of the rafters are set in position in pairs. One pair of rafters is set up against the inside edge of the brickwork, and if the barge board is to overhang the walls more than a few inches, an outside rafter is needed. The ridge board projects a few inches beyond the line of the barge board. Where the roof terminates against a chimney stack, the ridge board is supported on a brick corbel built out of the stack, or is carried on the end of a pair of rafters.

The junction of two such roofs results in the need of fitting a number of short rafters to a diagonally placed member known as a hip ridge board, when it is at an outside angle, and a valley board when it is an inside angle. These are fitted in much the same way as the other rafters, except that it is necessary to cut the ends to a different bevel, and to bevel the sides so that the board fits snugly into the angle between the two ridge boards. This stage is illustrated in Fig. 2. The triangular space between the ridge and the valley or hip board is then filled up with short or jack rafters, the ends of which are cut to a bevel in two planes, that is, the top and side of the rafter each shows a bevel. These are spiked in position similarly to the rest of the work.

Supporting the Rafters

To support the rafters, long horizontal beams of considerable strength are provided, called purlins (Fig. 3). They are placed in position and provided with adequate means of support at each end, and also at intermediate stages. At the ends they are generally built into the brickwork of the gable, and at the hip are jointed to the hip or valley boards, and further supported by collars or horizontal crosspieces of timber spiked to the rafters immediately beneath the purlins. Struts are then fitted to intervening wall supports, unless the partition walls are carried out in brick, when they may be built in position. Braces, or diagonal timbers running from the plate to the junction between the purlins and the gable ends are then spiked to the underside of the rafters, to take up the strain due to the pressure of the wind on the end of the house, and to prevent the roof from twisting.

An opening round the chimney stacks will have to be worked by means of a trimmer—that is, a piece of wood jointed into the nearest continuous rafters—and to this trimmer the short rafters which have to terminate against the stack are fixed (Fig. 4). A bracket piece is fitted to them and some roof boarding whereon to set the flashing for the chimney stack.

Valley boards (Fig. 5) are fitted to support the guttering material. These are simply rough boards nailed to the rafters and run from the eaves to the ridge in the angle between the two roofs. The eaves are formed by cutting the overhanging ends of the rafters in two different directions, one a vertical cut to provide a bearing surface for the fascia board and the other horizontally cut, to provide a support for the soffit board. These boards are spiked to the ends of the rafters and to each other. The near side of the soffit board, where it bears against the wall, may be supported by rough grounds to which it is nailed. The space between the rafters above the plate is filled in with brick, or any other material that will close up the aperture, to prevent the wind from driving underneath the rafters (Fig. 6).

At this stage the roof may be finished in several ways. The whole may be boarded with rough boards (or tongued and grooved boards in very good-class work), and the tile or slate battens set upon them. Or weather boarding may be used set the wrong way up; that is, with the thick end uppermost, thus providing ledges whereon to lay the tiles. Otherwise, tile battens may be simply nailed to the rafters, and the boarding omitted. On the score of economy this can be recommended, but it is generally considered that boarding before tiling the roof makes it perfectly weathertight, and gives a more equable temperature. In the case illustrated the rafters were simply battened for tiles. The battens terminate against the valley boards, or any other boards, such as those for the gutter. The next step is to lay the gutters, such as the valley and those around the chimney stack, and also to put up the flashings. After this process has been completed the roof may be either tiled or slated.

The verges, or overhanging ends, are finished in various ways, but the method in Fig. 7 results in a good appearance and is economical. A 9 in. board is cut to shape and set vertically against the ends of the purlins and plate, and the tile battens nailed to the top edge. A moulding is then run along the upper edge, the tiles laid flush with the edge of the moulding, and the joints pointed or filled in with cement mortar. The roof is completed by fixing the guttering. If stack pipes or any other projections such as lightning conductors or flagstaffs are to be fixed to the roof, the fitting of the framework or brackets for them is best effected before undertaking the tiling.

Sheds and Outhouses. A simple method of covering a boarded roof suitable for a small shed is by using bituminous felting material. The boards are generally set vertically—that is, they run from the plate to the ridge—and are supported by two or more purlins, according to the size of the roof. The roofing material, if similar to tarred felt, should be laid in a continuous strip from eaves to eaves, and should be nailed to the boards with regulation felt nails. The edges should overlap about 2 in. and be made watertight by the cement generally obtainable from the makers of the roofing material. The edges are then covered on the outside with laths of wood about 2 in. wide and ½ in. thick, which should be bedded on the roofing cement and secured with stout wire nails.

A flat roof, as of an outhouse, can be laid in much the same way. In this case, it is of paramount importance that the joints between the strips of roofing material be rendered watertight with a liberal application of roofing cement. The seams should then be nailed with felt nails, spaced about 2 in. apart; but with this type of roof the difficulty is to render the side wall joints watertight. One way to do this is to employ efficient flashings, while another is to turn up the edges of the roofing material so that, when finished, the whole is very much like a large, shallow tray. A fall must be provided in two directions so that the rainwater can drain away to a down gutter, and thence to a rainwater head or other discharge pipe.

Repairing Leaky Roofs. The repair of leaky roofs, and the way in which these difficulties are overcome, depends upon the nature of the roof covering, and is dealt with under such headings as Damp; Gutter; Slate; and Tile.

There is a number of patent preparations sold for repairing roofs. An old slate roof can be made waterproof by using a plastic bituminous compound. This is applied to the bottom edge of loose slates, which are bedded down to the underlying slates with a joint of the same compound. Cracks, holes, etc., are filled up, and the surface of the roof is treated with a liquid preparation of bitumen. Sheet metal roofs can be reconditioned in a similar manner, using both the plastic and liquid preparations.

In the case of a small roof covered with bituminous material, if this gets punctured through any cause, it can generally be dealt with by fixing a patch of similar material upon it and cementing down and nailing around the joint. Should it crack or split for any length, it would be best to cut out the affected section and provide a whole new piece.

ROOF GARDENS: PLANTING AND TREATMENT

How to Utilize Accessible Leads and House Tops

This article suggests ideas for transforming flat roof spaces into welcome open-air additions to the home. See also Arch; Garden Furniture; Loggia; Trellis; Veranda; Window Box, and the entries on the various plants and shrubs mentioned.

If a tiny garden or balcony loggia, with growing flowers, creepers and shrubs to give a fresh, countrified air, can be made on a drab lead, the recessed roof or the top of a town house, it will usually afford both interest and pleasure. Where window boxes are not allowed a small flat piece of roof can often be utilized for flowers without infringing regulations. An awning can be fixed at no great cost which can be raised or lowered at will, and such garden furniture provided as can be easily moved, adjusted and folded away when not in use. A grass mat is a pleasant addition when the surface of the roof is level, and adds to the gay appearance of the garden. Where there are children the double protection of a strong railing and a flower box should be constructed on the open end wall of the lead or roof. The railing should also be fenced so that it affords no foothold. Trellis screens, as shown in Fig. 1, make a delightful background and also afford privacy. When possible walls—unless of an attractive brick—should be washed with some good colour, such as deep cream, pale leaf green, ochre, or lemon yellow. Simple wind-screens can be contrived of Japanese matting.

Roof Garden. Fig. 1. Boxes of ivy-leaved geraniums and fuchsias, with wistaria, etc., on the trellises.

In Fig. 1 fuchsias, geraniums, violas, petunias, etc., are planted in boxes painted green, and hanging baskets are attached to the trellis. In some of the newer houses architects have planned a terrace, balcony or roof garden, and such gardens are also to be found on the top of the more recently-built London flats. The discovery of the value of light in the prevention of various diseases is now fully recognized, and a terrace garden such as that shown in Fig. 2 is of immense value as a place where sun and air can be enjoyed. Such a roof space is formed by a set back upper storey.

The use of reinforced concrete for flat roofs makes the planning of a roof garden easier, as it is possible to plant hedges in troughs and to lay out formal gardens with clipped box and other shrubs.

Rock gardens in miniature have also been successfully made high above the traffic of city streets. Quick growing vines provide a green background; garden ornaments can be added, and in some cases a playing fountain.

Fig. 3 illustrates a kitchen roof garden. Tomatoes do particularly well grown in boxes and runner beans are both practical and decorative. On a large roof space the amateur may plan both flower and vegetable gardens, dividing them by means of a vine-covered trellis. Marrows, cucumbers and

mushrooms will grow together with minor crops of lettuce, radishes and mustard and cress. In addition parsley, mint and sage may be usefully cultivated.

For this more ambitious type of roof garden a tank for supplying water at air temperature with which the plants can be conveniently watered during dry weather, and a good-sized can for the purpose, will be found useful.

Roof Garden. Fig. 2. Roof garden on a country house. In the boxes antirrhinums and other plants are growing, while trellis work is provided for climbing shrubs. (Courtesy of Our Homes and Gardens)

Cultural Details. General cultural details essential to the success of roof gardens are careful and regular watering during spring and summer; spraying of foliage in the evenings of hot days; forking-in of some good fertilizer once a fortnight during summer, and gentle pruning of trees and shrubs to keep their growths compact as they increase with age.

In the many cases where it is impracticable to lay down beds and borders, roof gardening is usually accomplished by means of pots, tubs, and boxes. Common butter-tubs are excellent for small plants, but larger specimens, such as trees and shrubs, are best accommodated in halved barrels or paraffin casks. The latter will require thorough cleansing, and a good method is to fill it with shavings and

fire the interior until the oil is burnt out. All receptacles brought into use will require holes drilled to allow water to escape as well as thorough drainage crocking.

Soil must be of good heart and quality, owing to the difficulty of frequent change. Rich loam, leaf-mould, peat, decayed manure, coarse silver sand, and some good chemical fertilizer, will form excellent stock for compost. Each box or tub should be nearly filled, with sufficient space left for watering. Arrangement is a matter of individual taste and structural convenience, a tub in each corner, with boxes between, being a common base for most roof-garden schemes. All receptacles should be given a coating of preservative.

Fig. 3. A kitchen garden on the house tops. Tomatoes are grown in boxes at the back, runner beans at the sides, and a marrow in the tub in the centre. (Courtesy of Our Homes and Gardens)

Trees, Shrubs and Flowers. The roof gardener has at disposal a variety of trees, shrubs, climbing plants, perennials, annuals, bulbs, and alpine plants if the garden is suitably planned for the growth of the last named.

Among other shrubs that will thrive with care are the spindle tree, rhododendrons, spotted laurel, Jew's mallow, barberries, skimmia, privet, mock orange, flowering currants, and small standard bay trees. Single specimens of these need to be grown in tubs or boxes at least 18 in. wide and deep. There is scope for plants of climbing or semi-climbing habit, attached to chimney-stacks or poles, or trailed across trellis. Perennials that do well include Virginian creeper, Ampelopsis Veitchii, white and yellow jasmine, mountain clematis. Clematis Jackmanni, and climbing roses. Amongst annual climbers which are of great use are canary creeper and nasturtium.

Annual flowers that are easily grown from seed sown in boxes are godetias, clarkias, candytuft, nasturtium, sweet peas, alyssum, marigolds, eschscholtzias, annual chrysanthemums, and Virginian

stock. Tender annuals and biennials, such as stocks, zinnias, petunias, Phlox Drummondii, lobelias, geraniums, ageratum, fuchsias, and tobacco plants may be procured as seedlings.

Hardy perennials are not always successful on roofs, but early flowering chrysanthemums, Solomon's seal, irises, creeping Jenny, carnations, polyanthus, London pride, periwinkles and sweet-williams, will do fairly well. All the above must have plenty of water, preferably early in the morning and after sunfall. Bulbs, including lilies, may be grown, but the crocus has a special attraction for town sparrows, and is not recommended.

ROOK PIE. Only young birds should be used to make a rook pie. The following is an old country recipe: Take 6 to 8 young rooks, draw and skin them carefully, and immerse them in cold water for 2 or 3 hours. Then split them and remove the backbones. Wash them carefully, changing the water twice, and dust each bird with a seasoning of salt and pepper, then pack them closely in a pie-dish. Pour over them a breakfastcupful of good stock well flavoured with vegetables, and spread over them 8 oz. fresh butter or butter and clarified beef dripping mixed.

Make a paste of flour and water, and with this cover the dish. Bake the rooks for about 2½ hours, then take them up, remove the flour-and-water paste, and let them cool. When cold, arrange over them a lid of rough puff pastry as for pigeon pie; glaze, ornament, and bake for about ¾ hour or until the paste is thoroughly cooked.

A modern method is the following: Prepare the birds as in the first recipe, cutting each in half and removing the backbone, then stew them gently in stock for 1½ hours. Slice 1 lb. rump steak into strips and roll up each one, then cut 4 oz. lean ham into dice. Season the rolls of steak and lay them at the bottom of a pie-dish, then arrange the rooks on the top of them interspersed with the dice of ham. Season the birds and strain over them the stock in which they were stewed. Cover with a good puff or rough puff pastry as for meat pie, and bake from 1¼ to 1½ hours. *See Pastry.*

ROOT: Of Plants. A plant draws the nourishment that it requires from the soil through its roots, tiny points at the end of the root acting as imbibers and always turning in the direction from which most nourishment is to be obtained. In all roots the fibrous parts are annual, decaying in winter and coming to life again in the following spring.

Roots are diversified in structure, as, for example, the elongated tap-roots of parsnip and carrot, the globe-like form of turnip and swede, the deep and spreading roots of firs, the cord-like roots of the fan palm, the fibrous roots of the melon, etc. Some plants develop roots in water, like duckweed, whilst others, such as mistletoe and certain orchids, are parasitic and attach themselves to the tissues of other plants.

Roots act also as supports for the tree, plant, or shrub. Excessive root development is inimical to seed production, and vice versa. Thus fruit trees often bear poor crops owing to root luxuriance, but again produce fine crops after root-pruning. On the contrary, frequent transplanting of young green crops develops many fibrous roots, which in turn prevent the early running to seed of mature plants. There are certain plants which are most easily propagated by cuttings actually taken from the root. Such plants include the horseradish, bouvardia, seakale, oriental poppy, Japanese anemone, anchusa and burning bush.

Root Pruning. This practice is carried out by gardeners chiefly for the purpose of restricting the growth of vigorous unfruitful apple, pear, and plum trees and of encouraging the development of fruiting spurs. The method is to dig a trench at 3 to 4 ft. from the trunk of the tree in autumn after the leaves have changed colour and to fork away the soil from beneath the tree until the thick roots are exposed; these are then shortened by half or even two-thirds and fresh loamy soil is placed among them and pressed firmly.

Root Pruning. 1. Root growth requiring pruning: a, top soil; b, subsoil. 2. Trench (a) dug half way round. 3. Roots pruned, as shown by unshaded portions and trench refilled with good soil. 4. Second season's pruning: circle completed, pruned and refilled (b). 5. How to prune roots.

The result of this treatment is to check the growth of the trees severely for the next year or two. A better plan is to lift the young trees annually in autumn during two or three years following planting, shorten long thick roots and replant immediately. This will probably prevent the need for severe root pruning in later years. If it becomes necessary to root-prune old-established trees the roots on one side should be pruned one year and those on the other side the following year. *See Division; Propagation; Pruning.*

ROPE. Although this name is often given to cord over $\frac{1}{4}$ in. diameter, rope is properly cordage over 1 in. diameter. It is made with threads of hemp and other fibre, such as flax, twisted together with the aid of a wheel used by rope-makers. For domestic purposes rope is used for lifts and lifting apparatus, such as blocks and tackle, and for various other purposes. It is liable to deterioration through damp, and for outdoor use it should therefore be protected from rain.

Generally rope wears out through becoming frayed, therefore all rope used for lifting purposes should be examined frequently, and all sharp corners liable to come into contact with the rope should be rounded off or otherwise protected. New hoisting rope should be oiled soon after it is put to work, using the best sweet oil. The process should be repeated at least once a month for the first six months, and to preserve the rope to an almost indefinite period all that is necessary is an occasional rub with an oily rag. *See Guy Rope.*

ROQUEFORT: The Cheese. This cheese is made at Roquefort in France from ewes' milk with a mixture of goats' milk, and the curd is broken very small. When ripening, it is exposed to strong currents of air.

ROSES: VARIETIES OLD AND NEW

How to Obtain the Best Results in Garden Display and for Cutting

The amateur gardener may consult Flower Garden; Pergola; as well as such entries as Disbudding; Pruning. Attention is also drawn to the colour plate with this article.

The rose is the loveliest of all garden flowers; it is now represented by hundreds of varieties, of which many have been raised within recent years. The new ones are far superior to the old ones for garden display and for cutting for decorative purposes indoors; they bloom freely not only in summer but, in autumn too, and a collection of the up-to-date varieties must be considered indispensable by every garden lover. It is often said that the new roses are less fragrant than the old ones, but that is not wholly true, for many of the latest novelties have sweet-scented blooms. A garden planted with a representative selection of the best roses is almost as gay in September as in June and July; the plants continue to make fresh growth during the summer and early autumn months and almost every shoot is crowned with blossom.

Roses may conveniently be grouped into five main classes—ramblers, climbing roses, dwarf or bush roses, standards, and shrub roses. The modern types and varieties in each of these classes are immensely superior to those seen in the gardens a generation ago and they ought chiefly to be planted.

Rambler Roses. There are two chief types of rambler rose—the *wichuraiana* and the *multiflora*. The varieties of the *wichuraiana* type are more popular, for they are vigorous and easily managed, many of them have handsome lustrous leaves and all bear a profusion of blossom in high summer. The following is a selection of the best: Alberic Barbier, pale yellow; Aviateur Bleriot, yellow; American Pillar, rose and white; Chatillon Rambler, pale pink; Dr. Van Fleet, blush; Dorothy Perkins, rose pink; Emily Gray, yellow; Excelsa, crimson; François Juranville, salmon yellow; Gardenia, cream; Hiawatha, crimson; Lady Gay, rose pink; Fraicheur, pale salmon; Minnehaha, deep rose; Sander's White, and Thelma, salmon pink.

Their management is simple. They ought to be planted in autumn or in early spring in deeply dug and well manured soil, and in March all the stems or branches should be cut down to within six inches of the ground. This treatment will force the development of fresh strong shoots from the base which will bloom well in the following year. In subsequent years pruning should be done as soon as the flowers have faded by cutting out the old stems which have flowered and tying the new shoots to the support.

The *multiflora* type of rambler is less commonly known than formerly; it is being superseded by those of the *wichuraiana* type. Favourite varieties are Blush Rambler, with apple blossom-like clusters of bloom; Crimson Rambler, bright red; Tea Rambler, salmon and copper; Mrs. F. W. Flight, rose and white; Pemberton's White Rambler; Tausendschon, rose pink; and Violetta, lavender violet. These need the same treatment as given for *wichuraiana* rambler roses.

A few of the old rambler roses are still planted. Among them are *Félicité Perpetué* and *Aimée Vibert*, white; *Rêve d'Or*, yellow, very rampant, and the yellow banksian rose which must be planted against a sunny wall and left unpruned until it is well established, and then needs to be thinned out.

Climbing Roses. The true climbing roses are less rampant than the rambler roses, though still vigorous enough to cover poles, pillars and arches; they are suitable also for walls. There are two types of these, those which are naturally of climbing growth and others called “sports,” which have developed accidentally from dwarf roses and are distinguished by the prefix Climbing, e.g. “Climbing Ophelia.”

Of the former, some of the best are Allen Chandler, red; Gloire de Dijon, salmon buff; Lady Waterlow, carmine-salmon; Lemon Pillar, pale yellow; Madame Alfred Carrière, almost white; Scarlet Climber; Souvenir de Claudius Denoyel, red; Wm. Allen Richardson, orange and yellow; and Zephirine Drouhin, the thornless rose, rose pink.

Of the climbing “sports,” the following are favourite roses—Climbing Caroline Testout, pale rose; Climbing Independence Day, yellow; Climbing Lady Hillingdon, orange yellow; Climbing Madame Herriot, orange salmon; Climbing Ophelia, blush; Climbing Sunburst, yellow.

The way to prune roses in the first group, which are naturally climbers, is to cut out parts of the old branches in late summer or early autumn to make room for new shoots. Special care is needed in pruning the climbing “sports.” They should not be cut down in the spring following planting as is advisable with the other climbing and rambling roses: merely the tips of the branches are cut off.

Bush Roses. The dwarf or bush rose is perhaps the most important type of all: it reaches a height of from 18 in. to 2 or 3 ft., according to the variety, and if suitable sorts are chosen will supply blooms from June until November. If the weather is mild the trees may be planted between then and the middle, or even the end, of March. Those planted early will be most satisfactory the first year.

Success depends very largely on correct preparation of the ground. This ought to be dug not less than two spits, about 20 in. deep; farmyard and stable manure or hop manure must be mixed freely with the lower spit, and basic slag, 4 oz. per square yard, should be scattered on the soil when digging is finished, and forked beneath the surface. The rose bed or border ought to be prepared a week or two in advance of planting. Before the trees are put in the branches should be shortened by half. In exceptionally cold or exposed gardens it is wise to protect the bases of trees by heaps of old ashes or soil, but in most places they do not need this protection.

Pruning the Trees. This important task should be carried out early in April. All newly-planted trees, i.e. those put in between the previous October and March, must be pruned severely. Thin weakly shoots should be cut out and the three, four, or five remaining branches must be shortened to within five or six buds of the base of the previous year’s growth. This treatment will force the trees to send up fresh vigorous shoots which will bloom in summer.

In subsequent years the spring pruning must not be so severe unless it is wished to obtain blooms for exhibition. Weakly shoots must be cut right out and the remaining branches shortened by about half or two-thirds, according to whether they are vigorous or only moderately vigorous.

The summer pruning is just as important as the spring pruning. If the blooms are cut for home decoration they should be removed with long stems; if the roses are left to fade on the trees the shoots which produced them should be cut to within three or four buds of the base. As a result of this treatment fresh strong shoots will grow that will bear blooms later on. It is an excellent plan to cut back all shoots in this way as soon as the blooms have faded; there will then be a succession of new shoots which in due course will bear flowers.

Best Garden Roses. The following is a list of the best bush or dwarf rose trees which will furnish a good display in the garden and provide flowers for cutting; Angels Mateu, rose, flushed orange; Betty Uprichard, carmine and salmon; Caroline Testout, pale rose; Clarice Goodacre, white; Emma Wright, salmon orange; Etoile de Hollande, crimson; General McArthur, red; Golden Gleam,

yellow; Julien Potin, yellow; Lady Alice Stanley, rose; Lady Pirrie, salmon and copper; Lieutenant Chauré, red; Crimson Glory, crimson; Mabel Morse, yellow; Madame Abel Chatenay, carmine rose; Madame Butterfly, deep blush; McGredy's Yellow; Mrs. Henry Morse, bright rose; Mrs. S. McGredy, salmon-apricot shades; Mrs. Wemyss Quin, yellow; Ophelia, blush; Picture, deep blush; Rev. F. Page-Roberts, yellow; and Shot Silk, cerise and salmon. All these belong to the class called hybrid teas. They grow and flower freely and are strongly to be recommended to amateur gardeners. The other types of rose which are grown as bushes or dwarfs are the tea, hybrid perpetual, pernetiana and dwarf polyantha or baby rambler.

The tea roses thrive best on well-drained soil: they are ideal for planting in a sunny border at the foot of a house wall. Most of them are of rather twiggy spreading growth, and after the first year they should be pruned lightly. The best varieties are: A. Hill Gray, lemon yellow; Anna Olivier, pale rose and buff; G. Nabonnand, pale rose; Lady Hillingdon, yellow; Lady Roberts, apricot and copper; Maman Cochet, rose; Marie Van Houtte, pale yellow and rose; Madame Antoine Marie, rose and white; Molly Sharman Crawford, white; Mrs. Foley Hobbs, white tinged pink; Mrs. Herbert Stevens, white; Muriel Wilson, palest lemon; White Maman Cochet and W. R. Smith, blush white. For garden decoration the tea roses are less commonly grown than formerly, as the hybrid teas have superseded them.

Rose: four beautiful varieties. 1. Hugh Dickson, in colour midway between crimson and scarlet. 2. Mrs. Bryce Allen, a rose of great fragrance, with rose-pink petals. 3. Clarice Goodacre, a vigorous, free-flowering rose which bears ivory-white blooms. 4. Betty Uprichard, an excellent variety that bears blossoms ranging in colour from delicate salmon-pink to glowing coppery carmine, suffused with orange.

Pernetiana Roses. The Pernetiana roses, named after M. Pernet, a French grower who originated this type, are remarkable for their intense and brilliant colouring; the first yellow roses were pernetiana varieties. Very few of the true old pernetiana roses are now grown; they have been cross-bred with the hybrid teas and as a result a new race with the vigour of the latter and the rich colouring of the pernetianas has been raised. The best of this type are the following: Angele Pernet, orange yellow; Cecil, rich yellow, single; Madame E. Herriot, deep salmon; Dazia, orange scarlet; Golden Emblem, yellow; Gwyneth Jones, orange carmine; Hortulanus Budde, red; Independence Day, yellow; I Zingari, orange and scarlet; Lady Roundway, copper yellow; Mrs. G. A. Van Rossem, orange apricot; Ruth, carmine and orange-salmon, and Souvenir de Claudius Pernet, yellow. The flowers of many of these varieties are "thin," that is, they have few petals. The trees seem more susceptible than others to the attacks of black spot, the worst disease of roses. They need the same treatment as the hybrid teas; the shoots are rather liable to die back in winter, therefore at the spring pruning the damaged parts must be cut off.

The hybrid perpetual roses form one of the oldest groups in cultivation. They are distinguished by vigorous growth, large well-formed double blooms chiefly of one colour, but they do not flower so freely in late summer and autumn as the hybrid tea roses.

Favourite varieties are: Alfred Colomb, red; Captain Hayward, red; Charles Lefebvre, crimson; Duke of Edinburgh, red; Fisher Holmes, crimson; Hugh Dickson, red (vigorous, makes a large bush), Mrs. John Laing, pink; Ulrich Brunner, rose; and Victor Hugo, crimson. In spring, thin weakly shoots must be cut out, and the main branches of the past summer's growth cut back by about two-thirds.

The dwarf polyantha or baby rambler roses are very popular for filling formal flower beds, for they bloom more or less all through the summer and early autumn. In spring they may be hard pruned to keep them dwarf, or pruned lightly if it is wished to have bushes two feet or more high. A few of the best are Betty Prior, carmine; Else Poulsen, pink; Fairy Cluster, blush-pink; Fortschritt, salmon-yellow; Heidekind, pink; Karen Poulsen, scarlet; Mrs. Finch, pink; Poulsen's Pink.

Certain beautiful roses of vigorous growth soon develop into bushes from 2-4 feet or more high; they are not suitable for planting among the ordinary dwarf or bush roses, but look well in beds on the lawn, or they may be set in a sunny shrubbery. If planted in deeply dug and manured soil and pruned in late summer by cutting out old branches or parts of them they will soon become established. Some of the best are the modern hybrid musk roses, which bear bunches of bloom throughout the summer and early autumn months: Clytemnestra, salmon-rose; Felicia, rose-pink with yellow flush; Pax, white, and Penelope, salmon-pink.

Others are Hugonis, single, yellow,, early flowering; Moyesii, deep rose-red flowers and handsome fruits, and rubrifolia, grown for the sake of its reddish shoots, which are most useful for cutting for decorative purposes. The Japanese Briars (varieties of *Rosa rugosa*) form large bushes and bear single and double flowers; the fruits of the single-flowered varieties are handsome in autumn; the showiest variety is Conrad F. Meyer, a very vigorous shrub with thorny branches and bearing large double fragrant rose-pink blooms in May and June.

The old-fashioned roses, e.g. the moss, Provence, York and Lancaster, are little grown nowadays, probably because they bloom only in summer. They should be planted in a sunny place in well tilled and manured soil; pruning, which is done late in March, consists of cutting out all thin weakly shoots and shortening the main branches of the previous year's growth by about half.

ROSES: SELECTION OF FAVOURITE MODERN VARIETIES EASILY GROWN IN BUSH OR STANDARD FORM

Standard Roses. Standard rose trees need similar treatment to the bush and dwarf roses of the same name. In planting care must be taken to keep the uppermost roots within 2 or 3 in. of the surface of the ground. The stems of standard roses are briars, and all shoots which grow on them should be cut off. They ought to be staked securely at planting time to prevent damage in windy weather. The stems of standards are 3-4 ft. high: those of half standards 2-2½ ft. high.

Some of the best roses to grow as standards are Betty Uprichard, Caroline Testout, Clarice Goodacre, Emma Wright, Ethel Somerset, Frau Karl Druschki, Golden Gleam, Hugh Dickson, Independence Day, Lady Hillingdon, Lady Pirrie, M. D. Hamill, Madame Butterfly, Etoile de Hollande, Mrs. H. Bowles, Mrs. Wemyss Quin, Ophelia, Shot Silk, and Mrs. Sam McGredy.

The tea roses do well as half standards, but many other varieties can also be obtained in this type of tree. A few suitable sorts are Christine, Emma Wright, General McArthur, Lady Pirrie, Los Angeles, Lord Charlemont, Madame Butterfly, Miss C. E. Van Rossem, Mrs. H. Morse, and Rev. F. Page Roberts.

ROSE GARDEN: TWO SUGGESTIONS FOR ITS LAY-OUT

Above, an arrangement within the scope of any small, suburban garden, the effect being procured by means of trellises covered with ramblers and climbers. Standards and bush roses are cleverly alternated to prevent too monotonous a line.

A more ambitious design with a paved path and a lily pond in the centre. The clipped hedges add greatly to this garden's beauty. (Drawn by William Evans.)

Fragrant Roses. The following varieties of roses, which may be grown as dwarfs or standards, have sweet-scented flowers: Angele Pernet, orange yellow; Avoca, crimson; Bedford, crimson; Cherry, yellow and rose; Clarice Goodacre, white; Cornelia, rose; Dame Edith Helen, pink; Daily Mail scented rose, crimson; Ethel Somerset, pink; Etoile de Hollande, crimson; Felicia, pale rose and yellow; General McArthur, red; George Dickson, crimson; Golden Gleam, yellow; Gustav Grunerwald, carmine rose; Hadley, crimson; Hoosier Beauty, crimson; Hugh Dickson, red; Ivy May, blush with deeper shading; Julien Potin, yellow; Lady Alice Stanley, rose; Lady Helen Maglona, dark red; Lady Pirrie, salmon; Lady Worthington Evans, crimson; Laurent Carle, carmine; Lieut. Chauré, red; Mabel Morse, yellow; Miss C. E. Van Rossem, crimson; Madame Abel Chatenay, salmon rose; Madame Butterfly, blush; Mrs. Bryce Allen, rose pink; Mrs. G. A. Van Rossem, apricot; Mrs. John Laing, pink; Ophelia, blush; Penelope, salmon rose; Shot Silk, cerise salmon; The General, red; Victor Hugo, crimson; Ulrich Brunner, rose red; Viscountess Folkestone, blush.

The best artificial manure for rose beds is known as Tonks's manure. It can be purchased from horticultural sundriesmen, and should be applied in March at the rate of 2 oz. per square yard of ground. Regular attention to such details as hoeing, weeding and cutting out weak useless growths helps to ensure success in rose growing. Suckers, i.e. shoots from the briar stock on which the named variety of rose was budded, must be uprooted as soon as they are seen; they can generally be distinguished by their prickly stems and light green leaves composed of seven leaflets.

Roses: the best ways to plant them. 1. Correct planting of dwarf bush. 2. Bad planting. 3. Standard, staked and planted; a, tarred end. 4. Planting a climber; a tarred end. 5. Dwarf, potted and pruned. 6. Pruning cuts: a right; b, c and d, wrong.

Diseases of Rose Trees. The worst disease is black spot. This is a most serious trouble; the leaves are disfigured by dark blotches, and in a bad attack they fall, sometimes to such an extent that the trees become leafless in summer. All diseased leaves should be gathered and burnt, and in winter sulphur should be scattered freely on the soil and on the rose trees. Further precautions are to spray with Bordeaux mixture or with liver of sulphur (one oz. in two gallons of water) occasionally in spring and early summer. All shoots cut off in pruning ought to be burnt.

Mildew is another common disease of rose trees; it is recognized by the presence of greyish mould-like patches on leaves and stems, and is most prevalent in late summer, especially in continued wet weather. Sulphur is the best antidote, and measures similar to those recommended for destroying black spot should be practised.

Insect and Other Pests. Rose trees are subject to the attacks of numerous pests. The commonest is aphid or greenfly, which can be destroyed by spraying with one of the advertised insecticides, or with paraffin emulsion, which is made by dissolving a handful of soft soap in a little hot water, adding two gallons of warm water and an eggcupful of paraffin. Various caterpillars attack the leaves, and the rose maggot often damages the flower buds; these pests should be searched for and destroyed. Rolled leaves ought always to be examined.

The attacks of the rose leaf hopper cause white blotches on the leaves, especially of rose trees on walls; red spider and thrips, two minute pests, are chiefly troublesome on roses under glass and on walls—they attack the lower leaf surface; the frog-hopper or cuckoo spit infests the young shoots,

the rose slugworm eats away the tissue of the leaves, and the leaf-rolling sawfly rolls up the leaves until they become mere strips.

A nicotine insecticide, sold by horticultural sundriesmen, is the best wash to use against most of these pests. The leaf-cutting bee, which cuts semicircular pieces from the leaves and uses them in its nest, is difficult to deal with; it should be watched, and if possible traced to its nest so that the latter can be destroyed.

Roses in Pots. Pot roses grown under glass should be lifted from the ground in October, placed in 6 in. pots in a loamy compost, and placed in a cold greenhouse. No artificial heat whatever should be given the first season. After flowering, which will be scanty in result, plunge the pots out of doors in ashes during the summer months, re-pot in early autumn, prune in November, and then remove to a heated greenhouse. All indoor roses should be stood out of doors, after flowering, in the summer. Climbing roses grown under glass should be planted in a well-drained border of loamy soil.

ROSE BAY. The name of rose bay is applied to *Nerium oleander* and *Epilobium angustifolium*. The former, which is described under *Oleander*, is a greenhouse evergreen flowering shrub. The latter, a hardy perennial herb of the evening primrose order, sometimes called the French willow herb, produces willow-like foliage with crimson flowers. It grows to a height of 4 ft., and flourishes by the waterside or in ordinary soil. The illustration shows a dwarf species of *Epilobium* known as *obcordatum*. See *Oleander*.

Rose Bay. Dwarf form of Epilobium with rose purple flowers.

ROSE CAKE. Rose cakes are small vanilla flavoured cakes, so called because of their colour. They can be made by creaming together 3 oz. butter and 3 heaped tablespoonfuls sugar, then adding by degrees 2 or 3 eggs and 3 oz. flour, beating the mixture well as each egg is added. Then mix in 3 heaped tablespoonfuls of cornflour, a little vanilla flavouring, and a few drops of pink colouring. Bake the mixture in small greased tins in a moderately hot oven for about $\frac{1}{4}$ hour.

ROSE CAMPION. Sometimes called rose of heaven, this is one of the showy border plants known as *Lychnis*, or *campion*. It grows about 18 in., and produces rosy flowers in summer. See *Campion*; *Lychnis*.

ROSE GARDEN. The ideal aspect for a rose garden is south or south-east, and all beds and borders will repay thorough trenching before planting. The design shown in the diagram is easily adaptable to larger or smaller spaces, and, if planted with good varieties, will provide an attractive rosery. Its length and width respectively are 40 by 34 ft. The round centre bed has a diameter of 4 ft., whilst those placed in the grass panels are 2 ft. wide. Paths uniformly have a breadth of 2 ft., except under the entrance arch, where 2 ft. extra is allowed. South, east, and west borders are 3 ft. wide, and the north border 4 ft.

Pillar or weeping standards are planned A, B, C, D, and E F to K are ordinary standards.

Beds T, U, V, and W are devoted to half-standards.

The outside panel beds, numbered 1 to 46, and the side borders numbered 8 to 51, are entirely planted with bush or dwarf roses.

The top borders, facing south, and numbered 1-7, 52-58, accommodate tea-scented roses.

Hybrid perpetuals are placed from 59 to 77; the first 12 being fragrant reds and the other 7 whites and pinks.

Behind these against the south fence, A₁ to I₁, a delightful background consists of Penzance briars. Suitable climbers for the trellis and remaining fences are arranged at A_A-C_c and T_T-V_v. Varieties should be chosen from the selections given in the article on Rose on the previous pages. See Pergola; Trellis, etc.

Rose Garden. Plan of an effective rosery laid out in a small garden. A-E, weeping or pillar roses; F-S, standard roses; T-W, half-standards; numerals, bushes: double letters and A_j-I_i, climbing roses.

ROSE MALLOW. The shrub *Hibiscus*, or Syrian Mallow, is known as rose mallow. It is hardy, grows 5 ft. or more high, and bears single or double flowers of various colours in late summer. *See Hibiscus; Lavatera.*

ROSEMARY. This favourite shrub, which grows from 3 ft. to 5 ft. high, has fragrant leaves, and bears pale mauve flowers in spring. It thrives best in well-drained soil, and must have a sunny place; a border at the foot of a house wall suits it well. Its botanical name is *rosmarinus officinalis*. Regular pruning is unnecessary, but straggling shoots should be cut back as soon as the flowers are over. Propagation is by cuttings in boxes of sandy soil placed in a frame in August.

British grown rosemary yields essential oil in the proportion of 24 oz. to 1 cwt. of leaves. This oil, which is distilled from rosemary leaves, is much used by manufacturers of scented soaps and perfumes like eau-de-Cologne.

Rosemary. Sprays of the fragrant evergreen shrub, from the leaves of which oil is distilled for medical and other uses.

Medicinal Uses. In medicine the essential oil of rosemary acts as a carminative and stimulant, and is a useful remedy for flatulence. The dose is $\frac{1}{2}$ to 3 minims on a piece of sugar. The oil or the spirit is often included in hair lotions. Insects do not like it, and it may be used to keep them away.

Rose of Jericho. This is another name for the resurrection plant (q.v.).

ROSE OF SHARON. This is the popular name of a low-growing evergreen plant which bears large single yellow flowers in summer (*Hypericum calycinum*). It will thrive beneath trees, and if cut down each spring provides attractive greenery.

ROSETTE MULLEIN. This beautiful rock garden plant (*ramondia*) has large wrinkled leaves and bears bunches of purplish flowers in early summer. It must be planted in a crevice facing north or east, the rosette of leaves flat against the rock; a compost of loam, peat, and sand is suitable. *Ramondia pyrenaica*, pale violet-purple, and *Nathalae* purple, are the two best kinds.

ROSEWATER. As its name implies, this is a water manufactured from rose petals. It is made from what remains after the distillation of otto or attar of roses, and has to be diluted with twice its volume of water before use. It is used in toilet preparations and is also mixed with glycerin and applied to relieve chaps, etc. Occasionally, rosewater is employed as a flavouring agent in cookery. *See Otto of Roses.*

ROSEWOOD. This is a fancy hardwood of a rich dark colour, red or brown, with wavy streaks that are almost black. Formerly it was much used for pianos and cabinets, and as a veneer on plainer woods. To-day it is used to a slight extent for pianos and also for handles to carving tools and to the squares and levels used by woodworkers. It takes a good polish, but, as it is rather oily, glue is unable to get a good hold on it. One reason for its decline in popularity is that it has a tendency, even when well polished, to develop minute cracks in the pores of the wood.

The finest rosewood is the Brazilian variety. In character this is of a heavy, dense nature, rather coarse and open in the grain. Indian rosewood, known also as blackwood, has the same general characteristics as the Brazilian. *See Wood.*

Rosin. This is an alternative name for resin. (q.v.).

ROSIN PLANT. Bearing two other names, Silphium and compass plant, this is a hardy herbaceous perennial belonging to the daisy order, bearing yellow flowers in summer. It is most suitable for a wild garden, and best grown in bold groups, requiring little or no attention, and ordinary soil.

ROTATION: Of Garden Crops. This may be termed a scientific method of cultivation, based on the principle that, although plants extract the same foods from the soil, there is a marked difference in the amount used by any given kind.

As the requirements of all plants differ in regard to potash, nitrogen, and phosphates, any undue depletion of one or another has to be prevented by rotation in order to maintain an equable fertility. Under systematic rotation, crops of the same family should not succeed each other, whilst those with long perpendicular roots that feed at some depth should always be followed by shallow feeders extracting nourishment only from the upper layer of soil.

A simple method of rotative cultivation is to divide land for vegetables into 3 plots of equal size, recording them as 1, 2, and 3, and cropping each on a three years' turn-about system in the following manner.

Plot 1. First year: Beet; carrots; parsnips; potatoes. Second year: Celery; beans; leeks; lettuce; onions; peas; spinach; turnips. Third year: Brussels sprouts; broccoli; cabbage; cauliflowers; kale; savoy.

Plot 2. First year: Celery; beans; leeks; lettuce; onions; peas; spinach; turnips. Second year: Brussels sprouts; broccoli; cabbage; cauliflowers; kale; savoy. Third year: Beet; carrots; parsnips; potatoes.

Plot 3. First year: Brussels sprouts; broccoli; cabbage; cauliflowers; kale; savoy. Second year: Beet; carrots; parsnips; potatoes. Third year: Celery; beans; leeks; lettuce; onions; peas; spinach; turnips.

ROUGE: The Make-up. No cosmetic requires such careful and individual choice by its users as rouge. The exact shade which enhances the particular type of face and colouring of hair and eyes, the right amount for use by day or artificial light, and the correct placing on the cheeks should all be considered by anyone who wishes to improve her appearance by the application of rouge. Another important point which is frequently overlooked is the harmony of lipstick and rouge. It is not uncommon to see an orange shade of the latter and a cerise shade of the former applied at the same time, with unfortunate facial results.

Rouge is obtainable in liquid, powder and cream form. Powder rouge is the most convenient and should be applied as follows: first, powder foundation; second, powder all over the face; third, rouge; fourth, a light dusting of powder all over the face, dusted on with a complexion brush or clean puff.

The edge of the rouge must be imperceptibly blended into the complexion, so that no beginnings or endings are visible. If you want to make your face look thinner, apply a dark shade of rouge up to

the highest point of the cheek bone, blending it carefully into a lighter shade on the lower part of the cheek.

To make your face look fatter make a large circle or rouge over the whole cheek.

If you have hollow cheeks, you should use a darker shade of rouge on the upper part of the cheek and a lighter one on the lower, but keep to a circle as the general outline.

A very light application of rouge taken up well under the eyes will disguise dark rings, but this must be worked in carefully with your usual rouge on the cheek.

The nearest shade to the natural colour is the right one in all cases.

Older women if they use a brilliant rouge may look hard and unnatural. If very pale a delicate shade of coral or rose should be faintly suggested. Dry rouge is the best for occasional evening use, as it is easier to apply the exact amount required by this means when rouging is not part of the daily facial make-up. *See Beauty; Make-up.*

ROUGH CAST: For Walls. The surface treatment for walls known as rough cast consists in coating the face of the wall with mortar and, while it is still wet, throwing fine washed gravel or other hard material on to it. The surface becomes broken up and more or less filled with the small pieces. Rough casting is often used in lightly built houses for improving the weather-resisting qualities of the walls, and also for its decorative value.

In some buildings the whole of the work may be rough cast, but in others only the upper storeys or particular parts. In any case, the general treatment is the same. First the mortar, which should preferably be made with Portland cement, is prepared and the whole of the wall surface rendered with it. A supply of clean, washed gravel, finely broken stone, or similar hard material should be prepared. It is then picked up on a trowel, thrown against the wall surface of the cement, and allowed to set hard. The surface is often finished by washing it with cement wash. Lime mortar can be used, but it has not the weather-resisting qualities of the Portland cement mortar. The properties of the latter in this respect may be further increased by using one of the weatherproofing preparations.

Rough cast as a structural material is easily and quickly applied to framed buildings, such as are built up of a timber framework and covered with expanded metal lathing. In such cases the lathing is first covered with a sufficient thickness of the mortar. This may consist of coarse stuff applied in one or two coats, according to the nature of the work. The rough cast may consist of stone and grit or washed gravel, mixed with hot lime and thrown on with a trowel.

The rough cast may be made up in buckets, and should be applied to the walls in a semi-liquid state. The surface should be finished by immediately washing it with lime mixed with a little ochre to act as a colouring material. In many forms of timber and half-timber construction the rough cast is applied to a timber lathing, and the first coat is made of lime mortar well mixed with hair. The second coat is also of lime mortar, and the rough cast is applied to this. *See Cement; Mortar; Plaster; Rendering.*

ROUGH PUFF PASTRY. Although it is not quite equal to the real puff pastry, this is more economical, and can be made to serve many of the purposes for which puff pastry is necessary. *See Pastry.*

ROULETTE: The Game. Although large sums are staked on roulette, the game can be played with counters. For this purpose a table fitted with a wheel, or a wheel alone can be bought, these being reproductions or modifications of the one used at Monte Carlo. The main principles are as follows, although variations can be and are introduced.

The wheel is sunk into a cavity, either in the table or elsewhere. The base is on ball bearings, and it is made to revolve very rapidly by turning with the hand a small crossbar that rises from its axis. Round the wheel is a circular board divided into numbered compartments, and on one or other of these the players stake. As the machine moves, a ball is thrown into it, and when it comes to rest the winning number is indicated by the resting ball.

The numbers on the board are arranged as follows: 0, 32, 15, 19, 4, 21, 2, 25, 17, 34, 6, 27, 13, 36, 11, 30, 8, 23, 10, 5, 24, 16, 33, 1, 20, 14, 31, 9, 22, 18, 29, 7, 28, 12, 35, 3, 26.

Zero is coloured green; the others are white and red alternately. In the full game there is a lay-out at each end of the table, and this is marked out into various divisions for the stakes.

Down the centre of each are 12 rows of 3 squares each; these contain the figures 1 to 36, and at the top is a square for 0.

On each side of these squares are spaces representing *passe*, *manque*, *pair*, *impair*, *black*, and *red*, and at the bottom are spaces marked out P 12, M 12, and D 12.

The stakes may be laid on any of these squares.

Stakes can be placed on any single number, or on two, three, four, or six numbers, and on various other combinations. Stakes are placed on P 12, M12, and D 12, which refer to *premier*, *milieu*, and *dernier*, and on the numbers 1 to 12, 13 to 24, and 25 to 36 respectively. On *rouge*, or red, the stake is that the winning number will be red, and on *noir*, or black, that it will be black. *Impair* means that it will be an odd number, and *pair* that it will be an even one. *Manque* means that the number will be from 1 to 18, and *passe* that it will be from 19 to 36. Players can stake on zero as a single number. The odds against any single number are paid at the rate of 35 to 1.

Roulette wheel for home players. It is sunk in a circular wooden surround, the latter being divided into compartments, each bearing a number from 0 to 36 on either a red or a black ground.

ROUP: A Poultry Disease. One of the most contagious diseases known to poultry breeders is roup. There are several forms of the disease. Diphtheric roup may be known from the swollen head and faces, and the yellowish and whitish

patches or ulcers. In nasal roup there is a yellow discharge from the nostrils. When the yellowish and whitish patches are seen in the mouth and throat, it is styled Avian roup. Another form causes the eyes to swell and exude matter, and the numerous membranes carry cheesy deposits. Roup in any form calls for complete isolation of all affected birds and of any that have been in contact with affected stock. If the birds are kept together, the disease will rapidly spread, with serious consequences to the poultry keeper.

Remedies. In mild cases permanganate of potash will effect a cure. Crystals are mixed with the drinking water sufficient to make it a rosy pink, say as much as will cover a sixpence to 2 gallons of water.

Another remedy is sulphate of copper. One ounce of the sulphate should be dissolved in 8 oz. of water, and given in the proportion of 1 oz. to each gallon of water. The face and head should be bathed with warm water, in which some disinfectant has been sprinkled, and the mouth and throat painted with carbolized glycerin. In bad cases the birds should be given warm food only.

Carbolic powder should be well sprinkled about the houses, runs, and pens, and all houses and runs thoroughly cleansed and disinfected after the attack has passed. They should not be used again for several months. *See Poultry.*

ROUT CAKE. The rich, sweet cake or biscuit mixture known as rout cake is made up into small fancy shapes and served with tea or light refreshments. To make it, sift 1 lb. fine flour and mix with $\frac{1}{2}$ lb. picked and clean currants. Put these in a warm place. Now beat to a cream $\frac{1}{2}$ lb. fresh butter, add the same quantity of castor sugar, and beat again till very light. Keep the basin just warm, and use a wooden spoon to beat with.

Add alternately the flour and 3 eggs, which should have been beaten.

Mix these ingredients in by degrees and very lightly, pour in a little at a time 1 teaspoonful each rose and orange flower-water and 1 tablespoonful madeira or brandy. Dust a baking-tin with sugar and flour and drop the mixture, which should be rather stiff in texture, on to it in little heaps. These must be even. Bake them in a hot oven. The cakes will cook in a few minutes, and should be about the size of a two-shilling piece.

Rout cakes are sometimes made up as light spongy biscuits and baked in fancy tins, or they are moulded on wooden blocks. The mixture for these cakes is rather different from the first recipe. Rub 4 oz. butter into 1 lb. flour, add 1 dessertspoonful grated lemon rind, and $8\frac{1}{2}$ oz. castor sugar; make up the paste with 2 eggs well beaten and 1 very small teaspoonful carbonate of ammonia dissolved in a little milk. Bake the cakes in greased and floured fancy tins in a sharp oven.

ROUTER: The Plane. The router is used for inlay work or for finishing the bottoms of recesses. A typical pattern is made of malleable iron, not unlike a spokeshave in appearance. It comprises a working face through which a cutter projects, the amount of projection governing the depth of the recess. The carver's router has a hardwood block through which the iron, or cutter, projects, and is fixed in position by means of a hardwood wedge. Various widths of cutter may be used. The tool is a combination of chisel and plane. It is worked forward and backward and in various directions until a flat surface has been obtained on the bottom of the recess.

A modification of the router is used for cutting reeds and mouldings in positions remote from the edge of the timber, or for similar purposes in curved work. Some routers are provided with adjustable fences so that grooves may be cut in the work parallel to the edge. *See Plane.*

Router Plane. Wood carver's router, with wooden stock, the cutting iron being secured by a wedge. (Courtesy of R. Melhuish, Ltd.)

ROWAN. This familiar ornamental tree, which is known also as the mountain ash, is, botanically, a crab (*Pyrus aucuparia*) and its red fruits, which are very showy in autumn, are useful for making into jelly.

It grows 20-30 feet high and flourishes even in poor soil, is an excellent tree for town gardens and for planting in streets.

Rowan Jelly. This is served with game and venison. To make it, the berries are first carefully washed, then placed in a preserving pan with enough water to cover them, and allowed to boil until

soft. This takes $\frac{1}{4}$ hour or longer, according to the quantity. The berries are then transferred to a jelly bag, and crushed slightly before straining.

When all the juice has been extracted and has been thoroughly strained through the jelly bag into a basin or other dish, it is poured into the preserving pan, and sugar is added in the proportion of 1 lb. to each pint of juice. The liquid is then put on to boil and left until it jellies, which can be tested in the usual way by pouring a little into a saucer. The jelly is then poured into jars and sealed up. It should not be used for some time, as rowan jelly improves with keeping, and may be stored away for two years. *See Jelly.*

ROYAL FERN. This is one of the most handsome of hardy ferns and is especially suitable for planting by the waterside, though it will thrive elsewhere in deep soil that does not dry out in hot weather. It belongs to the group of so-called flowering ferns, for the spores are on separate shoots, not, as is usual, on the backs of the fronds. The royal fern (*Osmunda regalis*) grows wild in some parts of Great Britain and in moist soil reaches a height of 3-4 feet.

Royal Fern. Osmunda palustris, an evergreen species of royal fern grown as a pot plant.

ROYAL ICING. To make this icing use 2 lb. icing sugar, 4 whites of eggs, and the juice of 2 lemons. Rub the icing sugar through a hair sieve into a basin, make a well in the centre, and put in the slightly beaten white of egg. Mix in a little sugar from the sides, add half the strained lemon juice, and mix the whole to a rather moist paste, adding more lemon juice as required. If the lemons are large, all the juice may not be needed. Use the icing at once, smoothing it over with a large knife, dipping the latter in cold water occasionally. *See Cake: Icing.*

RUBBER: Its Domestic Uses. Rubber has many practical applications in the home in the form of mats and floor coverings, gloves, waterproofs, footwear and toys; also countless uses for accessories in kitchen equipment, for games, the car and the garden, etc.

One of the most important furnishings is rubber floor covering, the outstanding advantage of which is its durability. It will last from 10 to 30 years, according to its thickness and the amount of wear it receives; being of self colour, or inlaid, it does not show wear. It can be had in a variety of plain colours, also in marbled designs, so that colour schemes can be maintained, and by using borders of the same material in different shades various effects can be obtained. The marbled patterns are much more serviceable as they do not show footmarks so readily as the plain colours.

Laying the Rubber Floor. The material is made 3 ft. and 4 ft. wide by $\frac{1}{8}$ in. thick, but it can also be had in narrower widths for borders, and in. thick if desired. It can be laid direct on concrete, and in the case of a new building this is a great advantage as it saves the cost of floorboarding. The concrete must be thoroughly dry, otherwise the rubber, being impervious to water, would hold any damp and cause the covering to sweat underneath, eventually becoming loose and uneven. It is exceedingly comfortable to walk on, quite silent, and, being a non-conductor, does not allow cold to pass.

If laid on a stone floor any unevenness will quickly show through, as the rubber, being pliable, fills the joints underneath and beds into every crevice; it is advisable, therefore, to see that the floor is levelled up before laying the covering. Where large areas are covered and long lengths of the

material used, the flooring need not be fastened down; it will lie flat by its own weight, providing it is not displaced by moving heavy articles over it.

To stick the covering to a wooden floor certain varieties of glue or cement can be used; this is advisable in doorways or where small pieces are used to fill up comers. Special cements are used for sticking rubber floor covering to concrete.

The following is the method: Put a coating of the cement on both the underside of the floor covering and on the concrete, using a brush about 3 in. wide; allow both coats practically to dry before putting the covering down. It is better to cement the whole of the covering rather than the edges only, as in the latter case the material may bulge in the centre. Trim with a sharp knife, dipping the knife in water to make it cut easier.

There is no difficulty in cleaning rubber floor covering, but it is necessary to scrub with cleaning powder, in addition to the use of ordinary soap and hot water, and wipe thoroughly dry. Petrol or ammonia must not be used, as these tend to soften the rubber, and milk or oily substances are also injurious.

Rubber Tiled Flooring. Rubber inlaid tiling is a more expensive type of floor covering, but very good designs are made, and more elaborate patterns can be obtained than in the sheet form of rubber covering. The inlaid tiling is made to suit the area to be covered, and laid by men who specialize in this class of work; for this reason a plan or accurate measurements of the floor is necessary. For the house, 3/16 in. thick will be quite serviceable, and this is the thinnest made. The design being made to suit the shape and size of the floor allows for great scope in this direction, such as the use of panel designs, black and white tiling effects, or plain art shades. It makes an excellent floor covering for the entrance hall, having the advantages of variety of design, durability and silence. It should be washed in the same way as ordinary rubber covering, but need not be polished, as the surface is good and readily cleaned.

Such floorings also have a beautiful effect for a dining room. Nearly 100 colours and shades are available, enabling many designs and colour schemes to be effected. These floorings are non-absorbent and hygienic. They are therefore also most suitable for the nursery or bathroom.

Rubber stair treads can be of inlaid tiling. They are generally made the exact measurement of the stairs and fitted with a rubber nosing to come over the edges. Risers can be fitted to give continuity of design, and very pleasing effects can be obtained, particularly in marbled designs, if these are related to the larger designs used for hall and landings.

Stair treads can also be made with corrugated or pyramid rubber matting, 1/8 in. or 3/16 in. thick, and separate nosing can be supplied to suit. The rubber mattings can be tacked on to wooden stairs or cemented on to stone stairs, although in the latter case it is advisable to plug the stairs and screw the treads down.

Rubber Mats. For the bathroom there are marbled rubber mats, rubber tiling mats, sponge rubber mats, and diamond or corrugated patterns. It is advisable to have such mats with a roughened surface to prevent slipping, a smooth surface of rubber becoming very slippery when wet. One rubber mat that can be placed in the bottom of the bath is fitted with suckers on the underside which keeps it in place; this mat enables a person to recline comfortably.

Rubber door mats can be made in practically any size or shape to fit into a well or doorway. The general thickness is 3/8 in., and they are perforated in various patterns, and can be had lettered or with monograms inlaid in a contrasting colour. The perforated rubber door mats are very seldom worn out; they are generally broken by misuse and made unsightly. Care should therefore be taken

not to fold or double the mat when it has been removed; it should be laid flat or rolled. It can be scrubbed in the usual way.

There are rubber mats made for use in the kitchen sink; these usually fit on the extension piece of porcelain sinks, and have a grooved or roughened surface to prevent the dishes from slipping whilst draining. Other mats are the protective rubber table mats, usually made in coloured marbled designs. Being thin and non-slipping they are useful under linen embroidered mats to prevent marks from hot plates and dishes on the polished surface of the table.

Rubber Gloves. Thin rubber gloves protect the hands when doing housework. They should be one or two sizes larger than ordinary gloves, and the hands must be dry when they are put on, or rubbed with French chalk to allow the gloves to slip on easily. If these gloves get torn or punctured they can be patched in the same way as a cycle tube, care being taken that the place to be patched is clean and dry before applying the solution. The small cycle patches with tapered edges are the most serviceable because they are not likely to turn up at the edge. The same method of mending may be applied to goloshes.

New Uses for Rubber. One of the uses to which rubber is now being put is for the upholstering of articles of furniture. For this either pneumatic or sponge rubber is employed. Rubber is also much used for brushes of all kinds, while buckets and other household utensils, egg cups for example, are made from it. In the kitchen and scullery the sink can be lined with rubber and the tables covered with it. Flowers made of rubber are sold for household decoration, while articles made from it include bulb bowls, napkin rings and knife handles. Handbags for ladies are also made from rubber.

Rubber Solution. The name is given to a substance mainly consisting of rubber dissolved in benzol or naphtha. The composition varies with different makers. It is used for cementing rubber, and particularly in connexion with the repairing of cycle or motor car tires and tubes. *See* Floor; Goloshes; Hose Pipe; Hot Water Bottle; Motor Car, etc.

RUBBER PLANT. The true rubber plant, *Hevea braziliensis*, is the one from which the rubber of commerce is collected. It may be grown under hothouse conditions, but has little attraction for foliage purposes.

The name is sometimes applied to the semi-hardy evergreen plant *Ficus elastica*, which is usually grown as a specimen in ornamental pots for the purposes of room decoration. The plants flourish in ordinary potting mixture on tables and in windows free from draughts. *See* India-rubber Plant.

RUBBER STAMP. Used for printing initials, dates, names and addresses, etc., with the aid of an inked pad, stamps made of rubber are obtainable in many shapes and sizes, mounted on a brass plate or metal frame and provided with a wooden handle.

RUBBISH: In the Garden. Accumulated rubbish in the garden is a common eyesore in plots of modest dimensions. Its disposal is not a difficult task, however, if dealt with in a systematic manner, and heaps of refuse may easily be utilized to advantage.

There are two methods of disposal—burning and deep burial. Every garden of modest size might be planned with facilities for the disposal of waste. In one corner a fair-sized hole should be dug, and therein may be thrown every bit of decayable vegetable matter from household and garden; indeed, this may be augmented with sweepings from flue and chimney and scrapings from the fowlhouse, all being made fairly firm and sprinkled with lime.

Early in the year the whole mass should be turned out and sprinkled with lime. In such manner rubbish is converted into a natural fertilizer of much value, particularly when trenched in for deep-rooting crops.

Everything that will not easily decay, such as hardwood, tree prunings, and cabbage stalks, together with weeds like dandelion and dock, should be burned, the ash being stored in a dry place for use in spring.

Rubbish. Showing how to dispose of garden refuse by means of burning. 1. Ground base for furnace. 2. Method of building body. 3. Incinerator in operation. 4. Method of shelter: a, iron or zinc cover.

A Brick Destructor. The burning of this hard rubbish is best accomplished by means of a destructor built of bricks as shown, a simple structure with free circulation of air, which will burn steadily and quickly reduce its contents to a fine ash rich in fertilizing power. The lid is necessary to the contrivance, because it keeps refuse in a dry state, and allows accumulation until time is convenient for burning. Autumn leaves should be collected and placed in a large heap, covered with wire netting and left in the open until decayed.

All straight sticks from tree-prunings, with the exception of soft ones, should be kept for staking. *See Incinerator; Manure.*

RUBBLE: For Masonry. The term rubble refers to pieces of stone of irregular size and shape, and is applicable to practically any kind of stone. Small and irregular pieces of brick known as brick rubble are used in the formation of concrete for the foundations of buildings. Rubble walls are constructed of irregular-shaped stones. *See Crazy Paving; Path; Stone.*

RUBUS. This is the botanical name of an important group of shrubs which includes the raspberry, loganberry, and blackberry, and others of purely ornamental value. Of those with handsome flowers the best are *Rubus deliciosus*, with large white single flowers, and *odoratus*, with purple blooms.

RUBY. The value of the ruby is determined by its colouring, which varies in different specimens from a pale rose tint to dark red. The latter, known as masculine rubies, are the more valuable, some of the finest being more costly than diamonds of the same size. In hardness, the ruby equals the sapphire. Garnets and red tourmalines, which are used as a substitute for rubies, sometimes resemble these gems closely in colour, but they are softer, and can be detected with a file.

RUCHING: In Needlework. The trimming, known as ruching, consists of a strip of material, with a gathering thread run down the middle, from end to end, and sewn along the gathering to the article it is to trim. Ruchings, or ruches, as they are often termed, may also be pleated or boxpleated. The strips of material for gathered ruchings are nearly always cut on the cross of the grain, so that their edges can be pulled out with the fingers into flutes, to emphasize the frill. Strips for pleated or boxpleated ruches are cut on the straight.

Ruching. Gathered taffeta ruche, the edge being frayed with a pin.

Ruchings may be of any width, ranging from very narrow to very wide. The length the strips should be cut depends upon the nature of the ruche. For a gathered ruche a strip measuring half as long again as it is when finished should be allowed. That is, if

a strip of gathered ruching about 20 in. long is wanted, a strip of 30 in. must be allowed. For pleated or boxpleated designs, strips three times the length are required.

When joining crossway strips to gain the length required for gathered ruchings, make the joins on the straight of the grain, which means they will run slantwise across from edge to edge.

The edges of ruchings may be hemmed, bound with narrow strips of material, picot-stitched, or rolled. A finish for the edges of ruchings made of taffetas is a fringe, this being achieved by fraying out the edges with a pin. Another finish is pinking.

To make a gathered ruche, cut and join the strips wanted, and neaten the edges; then fold it up into halves, quarters, and further subdivisions, if possible, and mark each fold with a pin or chalk line. Fold the article it is to trim into an exactly similar number of sections, and mark to match. Next run a gathering down the middle of the strip, draw it up slightly, and pin it to the article so that the marks correspond, thus making certain of the fullness being distributed evenly; then run the ruche to the article along the middle. If desired, a line of fancy stitchery can be used to secure the ruche.

To make pleated or boxpleated ruchings, cut, join, and neaten the strips; then set them in pleats, running a tacking along top and bottom edges as they are formed, and well press them afterwards. Run a cotton through the middle, to keep the pleats permanently in position, and sew them to the pelmet, cushion cover, garment, etc. *See Bag; Pleating.*

RUE: The Herb. This familiar herb is of some decorative value in the garden: it grows 3 or 4 ft. high, has greenish-blue leaves and yellow flowers in summer and flourishes in ordinary soil in a sunny border. Propagation is by seeds sown in spring.

RUGS: ORIENTAL AND OTHER MAKES

How to Make Wool and Rag Rugs at Home

In connexion with this article on floor rugs see also Canvas; Carpet; Colour; Hall; Kirman Rug; Mat; Nursery; Persian Carpet; Turkey Carpet; Weaving; Wool. Information about Travelling Rugs is given under that heading.

With the increase in number not only of smaller rooms, but also of parquet and wood block floors, and the employment of rubber and composition paved and tiled floorings, rugs are in greater demand than ever. There are also the hygienic and labour-saving merits of rugs to be considered, which make them suitable for nursery and bedroom use in place of the all-over carpet, which cannot be daily removed from the floor for cleaning purposes.

Rugs may be roughly divided into six classes: Oriental rugs; those made at Axminster, Wilton and other western carpet manufacturing centres; skin rugs; hand-woven rugs in geometrical and other

modern designs; rugs worked with wool on canvas; rag rugs.

Rug. Persian prayer rug, crimson and green velvet, embroidered in silver thread. The field has a niche with scrolling stems and inscriptions. From the Mashhad Shrine.

Oriental Rugs. Although European weavers began to employ their looms for rug and carpet making in the 15th century, copying the knotted examples which were imported from Turkey, until the age of machinery Oriental rugs far exceeded the supply of those made in the West.

Like other textile fabrics, Oriental rugs have interlacing warp and weft threads; in addition to these fundamental threads they are composed of countless short pieces of coloured yarns, the cut ends of which form the pile. Each knot or tuft is tied by hand. Many or few dyes may be employed, but in most Oriental rugs an immense number of shades are selected to make the design, thus giving the weaver great scope for original work.

Knotting may be fine, which adds to labour but enhances beauty of forms employed; or it may be coarse, in which case bold patterns are generally worked.

With regard to Persian rugs, it should be noted that many rugs not strictly made in Persia are described under that title. Indo-Persian rugs are well woven and of fine colour, but the detail of the designs is not usually so good as in the Persian carpets which influenced them. Some of the Caucasian rugs are notably rich in colour, interesting in pattern, and of luxuriant pile. Bokhara rugs include the styles called Turcoman, Afghan and Samarkand. The patterns are based upon roses turned into octagons, with hooked diamonds and other geometrical motives woven all over. Similar borders are in soft, brownish-reds with blue and greens. The wide webbing at the sides should on no

account be sacrificed. Modern pieces are exported coloured with aniline dyes and of inferior designs.

Rug with effective pine cone design worked in shades of terra-cotta, biscuit, pale green, gold, tan, and deep blue.

Chinese rugs are beautiful, and in many Persian rugs there is a prevalence of Chinese designs and motives. The two

best known are the cloud band and the dragon. The former is symbolical of heaven. Symbolism plays a prominent part in the designs of Oriental rugs. Even mistakes sometimes occur deliberately to divert the evil eye, or because the devout worker considers it impious to produce perfect work, as only Allah is perfect.

Animal designs occur in many Persian rugs. The antelope is often figured, and stands for the moon, night and restfulness; while the lion stands for the sun, power and day. Hounds and leopards symbolise success.

Garden carpets and rugs have designs of gardens with walks, trees and flower-beds, such patterns were made as far back as the 6th century in Persia.

Other rugs come from Turkey. The demand for them is a large and growing one, and the industry that meets it has its headquarters at Istanbul and Smyrna. Imitation Turkish rugs are produced in British and continental factories, but in these lighter shades predominate, and, though they are excellent reproductions of what are known as fancy Turkish rugs, they are not truly Oriental in character, as they lack the typical eastern colouring. They are designed chiefly for staircase and corridor use.

Rug worked in wool of five colours on coarse canvas, in a simple design suitable for either bedroom or living-room. The method of work is shown in the illustrations below.

The best eastern rugs fetch high prices, and their colour and texture last through many lifetimes. Good modern examples can, however, be bought at moderate prices, which are woven by hand, the colouring of the better kinds being beautiful owing to the dyeing processes still in use for this class of work.

Among the most interesting Oriental rugs are those known as prayer rugs, made primarily for the devotions of Mahomedans. They usually comprise a niche, the point of which is directed towards Mecca, and beneath it is supposed to be placed a morsel of dried earth from Mecca, upon which the worshipper rests the forehead when he is at prayer. Ritual objects may be portrayed near the niche, and from the point there sometimes hangs a lamp or a floral pendant. The shape of the niche is a guide to the make of the rug.

There are at least thirty types of niches, those from Persia being usually curved, and all others woven in straight lines. Caucasian and Turcoman are always, and Persian usually, recognizable by having the field well filled with ornamental motives; while Turkish have plain fields, as the more conservative Mahomedans obey the Koran, which forbids them to copy figures. These rugs seldom exceed 6 ft. by 4 ft.

Rug: method of making. Fig. 1. The wool is cut in short uniform lengths by means of a grooved gauge. Fig. 2. Regulation rug-making hook resembling an ordinary crochet hook with movable latch. Fig. 3. Another method is by use of a hollow metal tube into which the wool is threaded. Fig. 4. Knot-making tool in use. Fig. 5. Using regulation hook: to knot the wool on the canvas it is first doubled and drawn through under a ridge. Fig. 6. The hook is pushed through the loop so that the wool lies behind the latch, and the two loose ends are hooked. Fig. 7. These ends are pulled through the loop, the latter sliding over the latch. Fig. 8. The knot is then pulled tight and a similar tuft made in the next ridge, and so on. Fig. 9. A row of eight tufts. Fig. 10. To make a neat selvedge an inch of canvas should be turned up on to the face of the work.

The Persian prayer rug illustrated has two borders filled with 18th-century conventional floral patterns and inscriptions of the profession of the Islamic creed. The field has the curved and pointed niche with scrolling stems, flower motives and inscriptions. The rug is lined with silk and gold tissue dating from the same period.

English Rugs. Another class of rugs is manufactured in England by the Axminster Wilton and other carpet factories at home. These differ little except in size from carpet squares, and are frequently made to match these, being useful for filling odd pieces of floor space in a carpeted room. Mohair

rugs in black and self colours, though uninteresting, are very durable. Tufted wool rugs are excellent for bedroom or nursery, and most of them are reversible. Fibre rugs woven in good colours are suitable for bungalow and informal rooms. Skin rugs of leopard, tiger, wolf, raccoon, bear and goat are handsome, but when laid on parquet floors have the great disadvantage of slipping easily. Skin hearth rugs are best removed in summer weather, as they tend to give a room a hot appearance.

Beautiful rugs are hand-woven in straight geometrical designs. The colourings are harmoniously graded and often in browns, natural wool colour, and a variety of beige shades. The interest is gained by subtle shading, and the patterns are usually of the simplest kind, such as cubes and broken stripes, and just sufficient to introduce pleasing light and shadow effects. Colours may appear to contrast violently, but this contrast is obtained in the same way as in old tapestry—by the skilful use of several gradations of each colour so that it never appears dead or crude.

Handworked Wool Rugs. There are various methods of making wool rugs, but the general one is to hook the wool through the canvas or hessian to give a series of little tufts so closely worked together that they form a pile like that of a carpet. The canvas takes the place of the warp and weft threads of the Oriental rug. There is special canvas to be obtained for the foundation marked in squares of 8 ridges. If the wool is of fine quality like the 6-ply Turkey rug wool, it is worked into every ridge, but if of the coarser 2-ply cable wool it is only knotted into every alternate one.

By means of a gauge, the wool is cut into little equal pieces, each about 2 in. long (Fig. 1), ready to be hooked into the canvas. To make the actual knot, a coarse crochet hook will do, though there are several patent instruments on the market. One, Fig. 2, is like an ordinary crochet hook with a movable latch, which prevents the hook from catching when drawn back through the canvas.

Another, Fig. 4, is like a pair of pliers which by a simple device knots the wool on the canvas in one operation. Both make the same slip knot.

Chart designs are available from the various wool shops marked in squares to correspond exactly with the squares on the canvas. This makes the working out of an intricate design very simple indeed. But simpler still for the plainer designs is the canvas which has been stencilled with a pattern. Line the rug when finished with black hessian which will make it softer to the feet and more durable in wear. When beginning a rug, turn in the end for 1½ in. and work through the two thicknesses. This will give a firm edge, and when the other end of the rug is reached that should be turned in in the same way. (See Fig. 10.) The selvages at the side of the canvas are strong enough without turnings. The easiest manner to work is to place the canvas on the table and knot in rows from left to right, the finished part being nearest the worker.

Patterns may be inspired by Oriental motives such as the pine cone design illustrated, or they may be simply geometrical and worked in dark brown, havana brown, and three shades of beige, as in the other example shown. Designs should always be conventional even where figures are introduced into nursery rugs. Squares, circles, triangles, and simple designs of flowers and leaves are all suitable for rug making, but the art of the designer lies in combining them successfully.

The particular kind of wool used is a matter for individual taste. What is known as cable wool is a curly 2-ply yarn. It is more lustrous than Turkey rug wool, and produces a rug of a softer and longer pile. The pile of Turkey wool, however, is wonderfully firm. It measures about ½ in. in depth, and resembles more closely the pile seen in Eastern rugs.

A most ingenious way of making a pile rug on hessian is by the Kwikumak method. The instrument, Fig 3, which is fitted into a wooden handle, is a simple hollow metal tube pointed at the end and having a hole about 1 in. from the end. Through this hole the wool is threaded. As the instrument is pushed through and through the hessian, following a stencilled pattern, it leaves loops on the other

side of the material. These loops, when afterwards they are cut evenly with the scissors, form a close pile.

Rag Rugs. There are two methods of making rag rugs. In one the rag is pulled through the canvas with a large crochet hook, while in the other the rags may be braided or twisted and sewn together. All kinds of rags are suitable for this purpose. For a hooked rug a piece of strong open-meshed hessian or sacking is required. Having measured off the required size, hem or crochet it all round to give a firm edge. Stencil or draw in chalk a pattern upon it; an old-fashioned posy or wreath of flowers worked in bright colours in the centre suits these old world rugs. Various grotesque animals and birds were also worked in the brighter rags, leaving the more nondescript coloured ones for the background.

Rug. Fig. 11. Braided rug made with plaited strands of coloured rags arranged to form an attractive design.

For a hooked rug, the rags need to be about $\frac{1}{2}$ in. in width, more or less, according to the thickness of the various materials. It is not essential to sew the strips together, though the longer they are the

quicker they can be hooked through. Use a coarse crochet hook for the work; the canvas is often stretched in a frame, but it is easy to work without. Place the pile of strips under the canvas either in the lap or under the table. Hook the strip of rag through the canvas to form a loop about $\frac{1}{2}$ in. in length. Then make another loop close by and continue until the canvas is covered. The loops are then clipped to give an even, mossy surface. A hooked rug should be lined with hessian to give it greater strength. To braid a rug like that shown in Fig. 11, it is necessary to cut the rags about 3 in wide. If they are made narrower than this it is rather difficult to turn in the edges as neatly as is necessary for tidy work. The edge should be turned in about $\frac{1}{2}$ in., and the strip folded over in half lengthways, so that the raw, fray-able edges are inside. This may be done while braiding, but if the material is stiff and wiry it is better to press it into its proper folds. Strips may be joined together to give lengths of about $1\frac{1}{2}$ yards each, and are best folded and pressed beforehand, and wound on to pieces of cardboard to keep them in good shape.

Rug. Fig. 12. The strands are plaited closely and evenly to make braid for the rug shown below.

Plait the strips closely and evenly, just as hair is plaited, with 3 strands, as illustrated in Fig. 12. The ends must be sewn together and pinned on to something firm. As soon as 1 ft. or more of the plaiting is finished, the sewing together is begun. This is done with strong, waxed thread. When making a circular rug, the braid is then wound round and round flatly, edge to edge, and the needle passed through and through in close, invisible stitches. A little practice is required to make the braid lie flat. If too tightly wound it will buckle, but it must not be too loosely done, or the work will look rough.

To make an oval rug, begin with a longshaped centre, and wind round it. A dark

centre usually looks well with outer rings of light and dark alternately. A skilful braider can work in the colours while she is plaiting to a definite design. As the end of each strip of rag is reached, sew on another one. It is just as well if the strips are uneven in length, as then the joins will not come all in one place; but this, of course, must happen when introducing a fresh colour, and then the join must be neat. Rag strips, $\frac{1}{2}$ in. wide, can be crocheted, using a large hook. Before beginning, join the strips together and wind into a ball. Begin by making 5 chain, join into a circle and then crochet round, increasing in order to make work lie flat.

RULE: For Measuring. Of the many varieties of rule in ordinary use some are of wood and others are made of steel and other materials. Those made of wood range in size from the 6 in. rule supplied with small sets of drawing instruments to the 6 ft. lath used by the glazier. For amateur use the most convenient is the 4-fold 2 ft. rule. This is marked on both sides in opposite directions, and although usually divided into $\frac{1}{8}$ ths and $\frac{1}{16}$ ths, it can be obtained in $\frac{1}{10}$ ths and $\frac{1}{12}$ ths.

Rule. A, method using folded 2 ft. rule as a square; B, use of the rule to divide a board into equal parts.

In making accurate measurements with a wooden rule, the edge should be used so that the marks can be transferred direct, and when several measurements are required on the surface of a board, they should be added together. For example, if distances of 2 in., then $\frac{5}{8}$ in., then 1 in. and $\frac{5}{8}$ in. are required, the method is to mark off 2 in. first from the edge next $2\frac{5}{8}$ in., then $3\frac{5}{8}$ in., and finally $4\frac{1}{4}$

in. The 4-fold rule can be employed as a square by folding it in the centre and the two halves together at the knuckle joint between 5 in. and 7 in., as at A, below. In dividing wide boards into equal parts, the quickest method is to lay the rule diagonally across the wood so that opposite corners are touching. For example, supposing the board to be $10\frac{3}{4}$ in., and it is required to divide it into 4 equal parts, the pencil should be placed at 3 in. 6 in., and 9 in., and lines drawn through these points parallel with one edge, as at B, above. The rule is again useful in the latter operation, as it can be held between the fingers of the left hand, the pencil placed on the point, the brass tip of the ruler placed against it, and, with the fingers of the left hand acting as a guide, both ruler and pencil can be drawn down the wood. This is called lining with rule and pencil.

The engineer's steel rule is obtainable without a joint and engine divided into 12 in., with the usual sub-divisions; the rule is also made as a 2-fold 2 ft., a 1 ft. 2-fold, and a 1 ft. 4-fold. The steel rule is essential for accurate metal working, the first-mentioned size being the most suitable.

Steel rules should be rubbed occasionally with an oily rag, as perspiration from the hands and dampness will soon make them rusty. *See Measurement; Plumb Rule.*

RULE JOINT. Used for tables and drop leaves, the rule joint is a method of hingeing two pieces of wood together so that a neat, closed joint is shown when the leaf is down. It is better than the square joint, which shows a space between the two hinged pieces. The joint is shown in Fig. 1 with the leaf up and in Fig. 2 with it down; A is the fixed top, B the leaf, C the centre pin of hinge, and D the commencing point of the curve of the joint. It will be seen in Fig. 2 that a semicircle is formed when the leaf is down, the centre being at C, and that this necessitates the hinge being let into the wood. The hinge (Fig. 3) is specially made for rule joints, and is known as the table hinge; it is

similar to a back flap, but as it is attached with the knuckle in the wood, the screw holes are countersunk on the opposite side. Hinges are made in sizes from 1 in. to 1½ in., 1¾ in. and 2 in. The table hinge should not be confused with the rule joint hinge shown in Fig 4, which is used for another purpose. The method of marking out is shown in Fig. 5; the two pieces of wood should be the same thickness, and the gauge line at C should be the depth of the hinge. The distance of the centre C from the end of the wood should be about $\frac{3}{4}$ of the thickness of the wood. Special planes are made to form the joints, but the latter can be easily cut with ordinary rounds and hollows.

Rule Joint for the drop-leaf of a table. Fig. 1. Sectional view of rule joint with leaf up. Fig. 2. Same with leaf down. Fig. 3. Detail of the table hinge. Fig. 4. Rule joint hinge for use with a flap folding flat over itself. Figs. 5-7. Details of construction of the rule joint shown in Fig. 1.

The first stage in working the round is shown in Fig. 6, a rebate being cleanly cut to the level of D. The second stage, in Fig. 7, consists of rounding the corner to a true quadrant, and then forming the hollow in the opposite piece so that the edge at the top equals that at D and the curve is the exact opposite to the round. The two parts are placed together and the slots for the hinges marked out and cut. The short part of the hinge is on the side with the round and the pin of the knuckle is exactly under the top at D. The work can be polished in the ordinary way before the hinges are attached, but they should have been fitted previously. The rule joint hinge shown in Fig. 4 can be employed for narrow flaps, the edges of wood being shaped as above, but it is more suitable for hinging flaps which are to fold over flat, and is used in some card tables. *See Hinge; Joint; Rebate.*

RULE OF THE ROAD. By this phrase is understood the rules that should be observed by persons who drive vehicles of any kind on the roads. In Great Britain the main rule is to keep to the left. Another important rule is when overtaking another vehicle to pass it on the right. In crossing, the

driver should bear to the left and pass behind a vehicle coming from the left. Drivers who infringe these rules are liable to legal penalties. *See Driving; Motoring; Road.*

RULER. The two words rule and ruler are often confused; the former relates to measuring and the latter to the drawing of lines. Although the rule can be used for the latter purpose, the jointed rules are not convenient. The ordinary boxwood 12 in. rule serves the double purpose; but the round ruler, generally made of ebony and about 1 in. in diameter, is useful for drawing parallel lines as well. *See Rule.*

RUM: The Liquor. Rum is a spirit distilled from fermented juice of the sugarcane or from molasses. It is coloured with caramel and improves with keeping. Sometimes pineapple and guavas are added in the making. Rum and milk is said to be one of the most powerful restoratives, and an old-fashioned remedy for a cold is a steaming tumbler of rum and hot water with a piece of butter melted therein. It should be taken in bed. *See Omelette; Punch.*

RUM BUTTER. A favourite recipe in the north of England, this is made by putting 1 lb. moist brown sugar into a bowl with a grated nutmeg, a little cinnamon, and a pinch of mace, mixing them together and then moistening them with a wineglassful of rum. Melt 1 lb. butter, pour it gradually on to the sugar and spices, leaving out the dregs, and stir the whole slowly until it is almost setting. Then pour it into a china bowl and leave it to get firm.

RUMEX. The botanical name of the dock, which is most familiar to gardeners as a troublesome weed. One kind, however, the giant water dock (*Rumex hydrolapathum*), is a vigorous waterside plant grown for the sake of its large handsome leaves, which colour well in autumn.

R. acetosa is the common sorrel of the garden. Its leaves are sometimes used as a substitute for spinach, and it is propagated by seeds sown in drills in early spring. The flowers should be removed as soon as they show themselves, and the leaves may be plucked for the purposes of cooking, at frequent intervals.

RUMMER: The Glass. This word is used for a large glass made chiefly at the end of the 18th century and valued by collectors. In size it is between a wineglass and a tumbler, and was used for grog. They have moulded flutes at the base and are sometimes decorated in the festoon style. Others are larger and more solid, and are made with a collar at the base of the bowl above the stem. Other varieties of the rummer include one with a rounded bowl and a fluted base; one with a bowl in the shape of a barrel, and one, less common and more beautiful, with a wide-spreading bowl in the shape of a funnel.

Rummer. Large-sized rummer, the engraved decorative design including agricultural implements. (Courtesy of Cecil Davis.)

RUNNER: In Woodwork. In chests of drawers or most pieces of cabinet construction, runners are fitted to rest the drawers upon. Usually they are tenoned into the framework and in addition support the dustboard. *See Chest of Drawers; Dresser.*

RUNNER: The Cloth. This word is used for a narrow cloth, usually embroidered or ornamented in some other way, that is placed across a dining table, dressing table, or sideboard.

RUNNER BEAN. The colloquial name of runner bean is given to the climbing or trailing forms of edible beans. They are also alluded to as scarlet runners, from the colour of the blossom. *See* Bean; Scarlet Runner.

RUNNING: In Needlework. This is the simplest stitch, and the first to be taught in needlework. The needle is passed in and out of the material at regular intervals, taking up 3 or 4 threads at a time in a horizontal line. If the fabric is sufficiently soft and thin, several stitches are taken on the needle at once before the thread is drawn out. This stitch is used for plain seams and for making gathers. *See* Gathering; Seam.

RUPTURE: Its Treatment. In its widest application rupture or hernia is the abnormal protrusion of part or the whole of an organ of the body through the wall of the cavity that contains it. It occurs chiefly, however, in relation to the contents of the abdomen, and in the majority of cases the part which thus comes through is a portion of the intestine. The cause is generally either weakened areas in the abdominal wall or increased pressure of the abdominal contents due to some injury or sudden strain, as in lifting heavy weights, but there are also other causes, as, for example, severe chronic cough in old people.

There are several kinds of abdominal rupture, the most common being inguinal hernia in the groin; femoral hernia is also in the groin, and umbilical hernia at the navel. A ventral hernia is a protrusion through a weak spot such as may be present in the scar of a wound, as, for instance, after the operation for appendicitis. A strangulated hernia is one in which the circulation of the blood is obstructed, and is always dangerous.

A rupture appears as a rounded or pear-shaped swelling, the lower end usually being the broader. It increases in size when the patient stands, coughs, or makes a muscular effort. If it is a reducible hernia, it slips back into the abdomen when the patient lies down and presses on the swelling with his hand. On his standing up it again comes out.

The treatment of inguinal hernia consists of the wearing of a truss, or an operation for what is known as the radical cure. When a truss is used, great care should be taken never to let the intestine come down even once, for whatever closing of the part has been effected will be at once undone. In adults a truss should fit perfectly, otherwise it may do harm by causing inflammation and favouring strangulation.

Femoral hernia is more common in women than in men. A rounded swelling appears in front of the thigh towards its inner side just below the junction with the abdomen. As in other forms, the treatment is either palliative by means of a truss or curative by operation.

There are three varieties of umbilical or navel hernia: the congenital, which is very rare; that in infants and children, which is common; and that which occurs in adults, most frequently in women who have had several children. If properly treated this form of rupture in infants can be cured easily. The edges of the opening should be drawn together and held so by a strip of plaster; or a penny or a disk of lead may be wrapped in lint, placed over the navel, and held in place by strips of plaster. In adults the palliative treatment consists in wearing a truss, or sometimes an abdominal belt which requires the addition of a truss pad. If obstruction occurs, the lump becoming larger and firmer, the doctor should be summoned immediately.

In strangulated hernia severe pain extends through the abdomen, and there is vomiting, constipation and collapse. The doctor should be instantly summoned when a patient who has a hernia suddenly finds that it will not go back; when he has pain or discomfort in the lump; when he suffers from

obstinate constipation, or from nausea or sickness. The alarm may prove to be groundless, but it is important that no risk should be run.

To prevent hernia, infants should be kept, if possible, from excessive crying, and constipation should be prevented. Adults should avoid wearing belts, and excessive muscular straining after operations on the abdomen. Women should avoid tight lacing, and wear an abdominal bandage after childbirth.

RUSCUS. A group of low-growing, hardy evergreen shrubs of which the chief kind is the butcher's broom (*Ruscus aculeatus*): this grows 2½ ft. high, has spiny, so-called leaves (which are really modified branches), and small greenish flowers.

Male and female flowers are on separate plants and both kinds must be planted to ensure a crop of the red fruits in autumn. The butcher's broom will thrive in shady places.

RUSH: In the Garden. A few of the rushes are attractive waterside plants, but most of them are of little value in gardens. One of the most striking is the porcupine rush (*Juncus lacustris zebrinus*): the leaves are marked with bands of green and white. In *Juncus spiralis* the leaves are spiral.

Rush Lily. Another name for the satin flower or sisyrinchium (q.v.).

RUSH WORK: A USEFUL HANDICRAFT

With Directions for Making and Repairing Chairs, Stools and Baskets

For information on related subjects the reader is referred to the entries Basket Making;
Cane; Osier; Raffia; Wicker Work, etc.

When dried the rush is used as a chair seating, as in Figs. 1 and 2, and for making baskets and mats, and more rarely as a floor covering. It provides a strong, soft, comfortable and inexpensive seat, and has the advantage of being easily worked.

Two varieties are commonly used, ordinary rush, known as green, but more of a brownish green in colour, and salt rush, known as golden rush, and of a yellow colour; the latter is considered to be the better quality for general work. The rushes should be gathered in the late summer and carefully dried; they require no other preparation, as the drying leaves them in the form of fibre. They are obtainable in large bundles in lengths up to 6 ft., and after dipping them in water and leaving them for a few hours they are ready for use.

Rush Work. Left, fig. 1. Seat of rush-seated chair, showing method of weaving the twisted rush in sections. Fig. 2. Underside of seat with rush left untwisted.

Reseating a Chair. Although the framing of chairs is of special design when the seating is of rush, it is possible to re-seat almost any kind of frame provided that the corners, which will not be covered by the weaving, are built up to the same level as the rest of the

seat. If a chair is to be re-seated with rush, all the old material must be removed and the framework thoroughly cleaned; but it will be helpful to the beginner if he or she notes carefully the method of weaving when removing the old rush, to see where the rushes are twisted and where they are used singly, and also where and how extra lengths are added.

The rails of the rush seat chair frame are mortised in about $\frac{1}{4}$ in. below the top of the legs, and a corresponding amount is left on the outsides, but the inner sides of the rails are usually flush with the inner faces of the legs.

Rush Work. Fig. 3. How weaving is begun. Fig. 4. Reef knot for joining lengths of rush. Fig. 5. Professional knot. Fig. 6. Two lengths twisted to form a strand. Figs. 7 and 8. Stages in weaving. Fig. 9. Small rush-seated stool. Fig. 10. Two-colour twist.

Begin with one long, stout fibre and secure the thick end to the inside of the framework, as in A, Fig. 3, using a stout tack or a clout nail. Bring it over to the front rail, quite close to the raised corner, and commence to twist from left to right. Carry the twisted portion down on the front, underneath the rail marked 1, around the back of the leg, and bring it up over the left-hand rail marked 2. The twisting should be continued for about 1 in. past the rail, and then the length should be carried to the opposite side and twisted again to carry it over the right-hand rail.

The rush should now be brought to the inside under the rail, over the first twisted strand on to the front rail, and carried underneath it, as at B. Next carry it untwisted to the opposite corner at C, alongside the right-hand rail marked 3, then take it over the back of the rail marked 4. Bring it up inside, carry it over rail 3 and under it right across to rail 2 at the corner at D. The length is next carried under rail 2, over the twisted strand and rail 4, and underneath again to the front rail. As the lengths of rush are taken round the frame it is necessary to add new lengths continually. The strongest method of joining two lengths of rush is shown in Fig. 4, and is known as the reef knot. The method generally employed by the professional, as in Fig. 5, is quick and simple. After a little practice the twisting will be easily done with the right hand alone, but the direction of the twist from left to right should not be overlooked, and the twist should not be allowed to get slack. When the single rush is twisted, it gives a fine strand, and it is usual to twist two lengths of rush together at the same time, to produce a thicker strand, as at Fig. 6. This will not be found difficult after a start has been made, but care should be taken to keep the twisted strand an even thickness.

When the weaving has been continued for a few complete rounds, Fig. 7, it will be seen that a pocket is formed between the upper and lower strands. This must be kept well stuffed with waste or broken rushes; it helps to keep the strands together and give a fullness to the seat. Continue with the same order as indicated in Fig. 3 until the centre of the chair is reached, Fig. 8, keeping the pockets between the rushes neatly packed so as to give a sweep to each of the sections. Usually a chair is narrower at the back than in front, and in this case the easiest way to bring the sections to an even centre is to have a finer twist at the back than in the front, in order to make up the difference in the lengths of the two rails.

When the corners of the sections do not come to a point in the centre of the seat, the remainder of the work can be done by carrying the strands over one rail and under the next alternately in the form of a figure 8. This method fills up the space effectively and is particularly useful when dealing with rectangular frames. The twisting of the rush as the work proceeds has the effect of bringing the points of the twist to the inner side of each corner; this effect should be continued when filling up straight portions.

A Rush Stool. The easiest piece of work the beginner can have to practise on is a small stool, Fig. 9. This can be moved round as the work progresses more easily than a chair, and the frame is usually rectangular. An effective method of seating is to use two colours, the ordinary brownish-green and the golden salt rush, twisted together. The alternation of colour, Fig. 10, is very effective.

Cleaning Rush Chairs. To renovate rush-seated chairs that have become dirty with age or use, but are otherwise in good condition, the whole of the framework and seating should be scrubbed with warm soapsuds to which a little washing soda has been added. When as clean as possible, the work should be thoroughly rinsed and allowed to dry slowly. The woodwork should be rubbed with an oily rag. It will not be possible to restore the rush to its original freshness of colour, but the seating can be stained with an aniline dye.

The method is to dissolve $\frac{1}{4}$ oz. green aniline dye in 1 pint hot water, then add $\frac{1}{4}$ gill strong vinegar. Apply the stain with a brush, giving the work 2 or 3 coats, according to the depth of the colour required. When the stain is quite dry, make a size by dissolving $\frac{1}{2}$ oz. glue in 1 pint hot water and apply this while still hot to the whole of the stained surface.

Rush seats that have a few broken strands need not be re-seated if the rest of the work is in good condition. The method of repairing is to pull the broken strands through to the underneath, and to join on a new length to the corresponding straight length. The new piece should be twisted and pulled through to the top, carried over the frame, and then tied with a loop after passing it under a

few strands. There is a limit to which repairs of this kind can be carried, but if the material is not very old and has not perished the work it can be done with success.

It is usually the front edges of the seating which wear away quickest, and if many of the strands have given way it will be more satisfactory to re-seat the whole.

Rush Work. Fig. 11. Combined with cane, rushes can be woven into a basket with twisted handle.

Rush for Baskets. Rush is used in making baskets, bags, and in other small ways. It is often combined with cane to produce such useful articles as the basket illustrated in Fig. 11. It is worked in its natural form and also twisted and plaited. Examples of plaiting are shown in Figs. 12-16.

L-R. Fig. 12. Simple twist. Fig. 13. Three-way plait. Fig. 14. Plaited braid. Fig. 15. Five-way plait. Fig. 16. Rattle twist. (Fig. 11. courtesy of Dryad Handicrafts).

The simple twist at Fig. 12 is done with two rushes as follows: Tie the thick ends together and secure them to a hook in the wall or over a convenient nail. Hold one rush in each hand and twist outward, then take the right-hand rush over the left one, at the same time bringing the latter under the right one. The rushes are transferred to the opposite hands and the movements repeated, inserting a new rush when required and keeping the twist of a uniform thickness.

A double twist is accomplished by first making 2 simple twists as above and tying them together and treating them as single rushes, but the twisting should be in the opposite direction, that is, from left to right; this prevents the twist curling.

The 3-way plait at Fig. 13 is commenced with 3 rushes tied together and held in the left hand, using the thumb and fingers to keep the plait even. The right hand is used to do the plaiting, each length of rush being brought from the back over towards the centre. New lengths are placed on the inside of a right-hand length, and the 2 lengths plaited together, leaving the end of the old one underneath when finished with.

The plaited braid at Fig. 14 is particularly effective; it is formed by first plaiting 3 rushes as at Fig. 3 for 6 in., then one of the lengths is held firmly in the left hand while the right hand is used to push up the plait to reduce its length to about 2 in. Note the length which was held tight, so that when another 6 in. of plait is done, the same length can be held while the other two are pushed up close to the first.

The 5-way plait at Fig. 15 is made with 5 rushes by interweaving each rush diagonally under one and over one, the outside rushes being so arranged that they start from the back and come forward

over the next rush and towards the centre. Wider plaits can be made in the same way by using 7, 9 or 11 rushes.

The rattle twist at Fig. 16 is made with 5 rushes of even size tied together and held vertically by the tied portion in the left hand. Take one of the rushes and bend it behind the two next to it on the right; do the same with the others in order, until they are laid down. Continue by laying each rush in its turn across the centre and over the last one turned down and the one next to the latter on its right. The same movements of the thumb and finger should be used in every stroke for the building up of the twist. As the thin portion of the rushes is reached, add a new length.

Rush and Cane Combined. The melonshaped basket in Fig. 11 is a very effective way of using rush, the framework being made of split cane. The first stage is to make an oval band with a length of stout split cane, the joint being made by making 2 tapering cuts so that the ends of the cane can be joined up evenly and bound together. A useful size is 12 in. by 9 in. A second band is now made in the same way, but a trifle larger; this is fitted over the first oval so that the two are crossing each other.

The ends are bound together with raffia over and under until a small pocket is formed underneath on each side of the vertical oval. Two lengths of split cane equal in length to half the horizontal oval are bent and slipped into the pockets and then the binding is continued, but the extra lengths are included in the over and under binding. These two pieces should be equally spaced, and when the pocket formed by the raffia is large enough similar lengths of split cane should be fitted in. The 9 lengths are bound together, weaving the raffia over and under alternately until they are firmly secured. Both ends are worked alternately, and can be finished off with raffia of a different colour.

The remainder of the basket is filled in with flat rushes by commencing at one end and running a length out in plain weaving over and under alternately, repeating the operation from the other end. This is continued to the centre of the basket, the work being kept as close as possible, because the damp material used in the first place will shrink when it dries.

The handle can be given a decorative finish by twisting the rush spirally round it and carrying a wide length of coloured raffia with, it, so that the raffia is covered in one turn and exposed in the next, and so on throughout the length. A stronger basket can be made by using tapered ash splints.

Plaited rush forms a most convenient and cheap method of filling up the sides of many kinds of basket woven either in cane or osier and suitable for wastepaper or work baskets.

RUSK: The Biscuit. Rusks are made in small round shapes. As soon as they are baked they are split open and reheated until they are so crisp and dry that they will keep fresh for some time when packed in airtight tins lined with grease-proof paper.

To make, sift 1 lb. fine flour, with a pinch of salt, into a basin, then dissolve 2 oz. butter in $\frac{3}{4}$ gill milk. Cream $\frac{1}{2}$ oz. yeast with 1 teaspoonful castor sugar and stir into it the warm milk and butter. Now beat in 3 eggs. Pour these ingredients into the centre of the flour and work them into a dough. Cover the bowl over and let it rise till very light. When risen, knead it till smooth, then make the dough into balls about the size of a large egg, only flatter. Lay these in rows on a floured baking-sheet and let them prove. Bake in a hot oven for about 15 min. Take up the rusks on to a sieve, split each in half and return to the tin with the broken side uppermost. Crisp them in the oven, then cool and store them.

Rusk Pudding. A very good steamed pudding can be made with rusks. Soak 4 rusks in 1 pint milk for $\frac{1}{2}$ hour, then beat these up fine, add 6 oz cleaned and picked currants, 2 oz. chopped candied peel, the rind of a lemon (grated), $\frac{1}{4}$ teaspoonful nutmeg, and a pinch of salt. Cream 2 oz. butter

with 3 oz. castor sugar, add by degrees 2 well-beaten eggs, and stir this to the rusk mixture. Steam in a buttered basin for about 1¼ hours. Serve it with sweet or brandy sauce.

RUSSET: The Apple. Apples of the russet family are distinguished by a skin of rough texture and russet-brown colour. Generally these are of brisk flavour, and include the well-known Ard Cairn, Boston, Brownlee's, Egremont, Golden, Pineapple, and Royal russets.

RUSSIAN CAKE. Whisk 4 eggs with 9 oz. castor sugar for about 15 min., or until the mixture is free from dark streaks, then fold into it ½ lb. flour previously sieved with 1 teaspoonful baking-powder. At the same time add ¼ lb. melted butter and, if necessary, a small quantity of milk. Mix the whole lightly, then turn half of it into a small greased baking-tin lined with greased paper that reaches just above the sides. Colour the remainder of the mixture with a few drops of cochineal, put it into another prepared tin of the same size, and bake both in a hot oven for about 10 min. Then turn the cake carefully on to a sieve to cool and take off the greased paper. When cold, cut each cake into long strips.

Russian Cake, made in four separately prepared blocks and coated with almond icing.

Warm a little plum jam, thinning it down, if necessary, with a little water, rub it through a sieve, and then take two strips each of the white and pink cake. Brush one side of each with the jam and stick

them together, arranging the colours alternately. Wrap the block tightly in grease-proof paper, lay it on one side, and then proceed to make another block in the same way.

Prepare some almond paste, rolling it out to a long, thin sheet. Brush the outsides of the blocks with warm jam, then cover them with the icing, smoothing the surface with a knife which has been dipped in hot water. *See Almond Paste.*

RUSSIAN POOL. This billiard game is played on an ordinary billiard table by two or more players. Five balls are necessary, white, yellow, green, blue, and black. The white is the ball struck by the cue. A game consists of 200 points, or any other number that may be agreed upon.

To begin the game, the black ball is placed on the spot, the blue on the centre spot, the green on the left, and the yellow on the right corner of the D. The striker then plays the white ball from within the D, and his opening stroke must directly strike the black ball. He can then play at any of the others. The play is very similar to that in ordinary billiards. Scores are secured by making cannons, by sending the white ball into a pocket off one of the others—a losing hazard, as it is called—and by sending a coloured ball into a pocket, a winning hazard. In Russian pool, however, the black ball can only be used for the two top pockets; the blue for the two middle pockets, and yellow and green for the bottom two pockets. For a simple cannon 2 points are scored. If the black is used for a hazard 9 points are scored. The blue scores 7, the green 5, and the yellow 3.

The rules of the game are drawn up by the Billiards Association and Control Council. *See Billiards; Pool; Snooker Pool.*

RUST: How to Avoid. In the home all fittings or articles that are made of steel or iron are liable to rust. This appears in the form of yellow spots, and is due to damp, exposure to the atmosphere, and other causes which set up chemical action in the metal.

There are a number of methods of protecting domestic utensils from rust. Stainless steel and rustless iron have been perfected. The former is used not only for table knives, but for fireirons, stair-rods, and other articles of the kind. Rustless iron is employed for making garden tools, fire grates, kitchen utensils, name plates, and blind fittings.

Galvanizing is a protection against rust in certain cases. It is suitable for bolts, chains, and other door and window fittings, as well as for bedstead and other springs, but not for anything that comes into contact with soap, as it cannot resist the alkalis therein. Gas and electric light fittings, grates and radiators, are among the great number of articles that can be protected from rust by a galvanizing process.

Cleansing Agents. There are various compositions for removing rust, but probably the most generally useful cleansing agent is paraffin. Where the rust has been allowed to eat into the metal some special kind of lubricant may be needed. For example, if the fireirons have got badly rusted, a mixture of two parts of rottenstone and one part of sulphur is generally effective.

A useful method for cleaning up any iron kitchen utensil that has developed rust in the interior is to put potato peelings in it with water and a lump of soda, and boil it up. For a tin kettle or pan that has rusted, a good plan is to boil up borax and water in it and afterwards scour it thoroughly.

Articles that are not in regular use or that have been put away for a time, during the holidays, for instance, should be safeguarded against rust. Many housewives are in the habit of using vaseline for this purpose, others apply lard. An effective preservative may be made with lard and camphor, in the proportion of $\frac{1}{2}$ oz. of the latter to 1 lb. of the former; a little blacklead may be added as colouring. Grates, fireirons, etc., should be rubbed with this composition, left for 24 hours, and then dried with a cloth. They will be rustproof for some time afterwards.

RUST FUNGI. Roses, carnations, chrysanthemums, and other garden plants are liable to be attacked by rust, a fungoid disease appearing in the form of brownish or deep orange patches. It is very common among wild roses, and its spores are carried to cultivated kinds by wind, insects, and birds.

Leaves and stems of roses are both liable to infection, and infected leaves must be carefully collected and burnt, whilst other parts should be sprayed with a solution of potassium sulphide, 1 oz. to a gallon of water. Other plants may be treated in the same manner. *See Rose.*

RUSTIC WORK IN GARDEN FURNITURE

The Making of Seats and Other Requisites for Outdoor Use

For this form of craftsmanship, the reader should consult, in addition to the contribution below, the entries on Arch; Pergola; Summer House; Trellis

Under the heading of rustic work is grouped all that class of work, such as the construction of garden seats, small summer houses, arches, and the like, which is built up by the most simple methods from unhewn timber. The material can be obtained at low cost in country districts, and is variously known as cordwood and poles. The best material is oak, but any of the hardwoods, such as chestnut or hornbeam, answer very well.

Opinions differ as to stripping off the bark; where flowering plants are to be trained over the structure, there is far less risk of harbouring insects if the bark is peeled off. The timber may be varnished or treated with wood preservatives, but many people prefer to retain the natural colour.

Rustic work includes decoration with cleft timber, which offers considerable scope to the amateur woodworker.

So far as joints are concerned, these are almost always made with stout nails, either of the French or wire pattern, or of the wrought iron cut class. To ensure firm contact between the joints, both of the meeting surfaces should be slightly axed, to form a more or less flat surface where the parts fit together, as in Fig. 4. It is impossible to get any set design for this class of work, as the material, being in its natural state, will be of quite different shapes.

The timber used may be either the smaller branches of such trees as oak, the roots of fallen trees, or if straighter wood is required, having at the same time the natural appearance, the branches may be trimmed off the tops of such trees as larch, so as to leave the branch knots sticking out a few inches in a very rough state.

Rustic Work. Fig. 1. Armchair; with details of the principal joints employed in its construction.

Rustic Armchair. Fig. 1 shows a rustic armchair that is simple to make. Fir sapling or oak with the bark removed may be used. The front and back legs may be $2\frac{1}{2}$ in. or 3 in. in diameter; the seat rails, arms, and top back rail about 2 in.; other rails $1\frac{1}{2}$ in.; and uprights on sides and back from $\frac{7}{8}$ in. to $1\frac{1}{4}$ in. The general sizes for the chair are as follows: Width over legs, 2 ft. 3 in.; depth over legs, 1 ft. 10 in.; height to seat, 1 ft 4 in. or 1 ft. 5 in.; height to arm, 2 ft. 4 in.; height to top back rail, 2 ft. 10 in.; total height to top of back, 3 ft. 2 in.

The principal joints are affected by means of dowels, preferably of oak. If we take the fixing of the seat rails to the legs as an example, the ends of the rails are slightly hollowed to fit the leg, as A, Fig. 1. The dowel is then prepared and glued or painted in as indicated by the dotted lines. In the same way the top ends of the legs are hollowed to fit the arms and back rail respectively (see B). The arm is similarly fixed to the back leg.

The narrower rails and the uprights are fixed as at C. The end of the entering part is pared to a blunt point, and then driven tightly home into a hole bored to receive it. Fixing otherwise is done with nails, these as a rule being driven in slantwise to provide a wedge. The seat is made from ten to twelve lengths of material 2 in. to 3 in. wide, semicircular (or rather less) in section. These are fixed by nailing fillets to the inner faces of the seat rails. Across these fillets the seat laths, after being cut and trimmed to fit, are laid and nailed. Care should be taken to drive all nails well home. The back has a slight rake, so as to make the lean more comfortable.

Garden Seat. A strong rustic garden seat, such as that illustrated in Fig. 2, may be constructed in the following way. One end is first made up from three pieces of the wood, with the piece for the back, about 9 to 12 in. longer than the piece intended for the front, which should be about 2 ft. long. These two pieces are joined together by the third or arm rest piece, using stout nails, and two cross-members fixed in the shape of the letter X between them as a support. The other end is constructed in the same manner.

The two ends are joined together by longer pieces, about 4 ft. in length, one to the front legs and one to the back. These should be straight poles, or ordinary prepared wood of sufficient strength, as they represent the framework of the seat. Other lengths of rustic material are arranged as cross-braces between rails and front and rear legs, so as to hold them firmly together. The next step is to

prepare the back, the top rail of which may be formed of a single piece of wood, or of two or more pieces, as illustrated in Fig. 2. The exact construction will be governed by the material at hand. In any case means should be provided to support the back, so that it will be firm and rigid. The space between the top rail and the rear seat rail should be filled in with odd pieces of rustic material, arranging them so as to form rough diamond-shaped openings, and nailing them firmly to the top and seat rail respectively. The flat seat itself is of strong battens fixed to side rails on the legs at either end of the seat.

Rustic Work. Fig. 2. Strong garden seat with three-piece back rail and flat seat of strong battens. Fig. 3. Garden seat of rustic wood built around a tree.

Fig. 3 shows how a seat can be built around the stem of a tree, so as to make a very pleasant garden seat for the summer time. The seat is supported by three legs, but where it surrounds the tree entirely, more support will be necessary. The legs are cut to the required length, set in position, and the arm-rest pieces fixed between the back uprights and the tops of the legs. The whole is rigidly braced with cross-pieces between the supporting legs; and the rails and supports for the seat. The seat itself may be made in a similar manner to that described above.

Rustic Work. Fig. 4. Axing the joint. Fig. 5. Making a strong joint. Fig. 6. Nailing with flat iron at back for support. Fig. 7. Finishing off ends with spokeshave. Fig. 8. Another finish, with gouge and mallet.

Joints in Rustic Work. In constructional work (e.g. the building of a summer house or the erection of a trellis) the important point is to see that the structure is rigid and stable. This is accomplished by diagonal bracing— that is, arranging the timbers more or less in the form of the letter X. The joints are mostly simple butt joints, and are not inherently rigid. To remedy this defect the most practical plan is to cross-brace the uprights and horizontal members. The leading methods are described below, and other details will be found in the articles on Arch; Summer House; and Trellis. Fig. 4 shows the method of axing the joints, that is, roughly flattening one side of each of the two pieces to be jointed, in order that they may fit together more conveniently for nailing.

Fig. 5 shows a good method of making a strong joint for, say, the seat rail to the legs of a chair. It consists of sawing and chiselling out a small piece of the leg in the manner shown, in the requisite position on the leg, and of such width that the rail will fit exactly into it. The joint is secured by means of a nail, or nails, driven through the leg into the top of the rail. The end of the rail should be sawn off as flat as possible.

The method of nailing the cross-pieces is illustrated in Fig. 6, which shows a flat iron being held at the back. It is necessary that some means should be provided for the support of the material against the blows of the hammer. In some cases it might be better to use a large hammer as a support, or the head of a small axe, but in general the means provided are governed by the position of the joint to be nailed. If some support is not given, the repeated blows of the hammer may not only cause the jointing pieces of wood to slip about, but might also break some other joint that has already been made. All nails should be driven well home, and if the points project, these should be clinched and flattened down, so that there is no possibility of their catching into and tearing garments.

Two methods by which the ends of the rails and arm rests may be finished are shown in Figs. 7 and 8. In Fig. 7 the edges are being rounded off with a small spokeshave. This has the advantage that the chance of getting splinters in the hands is greatly minimized, and avoids a good deal of damage to the ends, as often, if the end is knocked, and the edge is still in the rough state, the outside grain is splintered, necessitating the splintered piece being torn right off. In the method shown at Fig. 8 a gouge and mallet are employed and the end worked round as indicated.

RYE: Its Uses. Flour made from rye grain is supposed to contain more gluten than any other flour except wheat. Because of the many diseases that attack rye, this flour is used only to a small extent, but when free from disease, it forms a palatable and nourishing food for those with whom it agrees. With others, however, it sometimes causes stomach trouble and diarrhoea, and a great number of epidemics have been traced to its use. It makes good, if rather coarse, bread, and can also be used instead of flour for making girdle cakes.

RYTOL: The Developer. This is a photographic developer in tabloid form which is made by Burroughs, Wellcome & Co., Ltd. It is an all-purpose developer of the paramidophenol class. It is clean-acting and non-staining and needs only to be dissolved in water with a tabloid of rytol accelerator.

The tablet form makes it very convenient to store and to take about when developing has to be done on a journey or away from home. For normal dish development rytol is used as follows:

Rytol	1 tabloid
„ accelerator	1
Water	4 oz.

The tabloids are broken up in the water with a glass rod, and, if stirred a little, dissolve quickly. Tables for development with rytol by time and temperature, for all brands of plates and films, are

given in the Wellcome Photographic Diary. The Watkins' development factor for normal contrast at normal strength is 12. *See* Developing.

SABLE: The Fur. The costly and highly prized fur known as sable is obtained from the animal of the same name, a species that is closely allied to the common marten.

There are several varieties of sable, that known as Russian sable being the most valuable. This is glossy and dark brown in colour, and in the best skins merges into a dim black towards the back. The darker the fur is the more valuable it becomes.

Cheaper kinds of sable are those exported from Canada. These also are thick and soft, but they are of a lighter shade, and are tinged with yellow. Experts are employed to brush the tips of such sable with dye so that they more closely resemble the best Russian variety. *See* Fur; Kolinski; Marten.

SACCHARIN. Glucidum, or saccharin, is an intensely sweet coal-tar product used instead of sugar by those suffering from diabetes, corpulence, and other affections in which sugar may be injurious. It ranges in sweetness from 300 to 600 times that of cane sugar, but has no nourishing qualities, and is excreted from the body unchanged. *See* Diet; Sugar.

SACCOLABIUM. The stove epiphytal orchid called saccolabium requires a temperature from 65° to 75°. It may be grown in hanging baskets of teak, attached to blocks of wood, or in pots filled to the rim with crocks, charcoal, and sphagnum moss. Its growing period is March to November, and extent, everything depending upon the make resting time November to March. The plant and the care which has been bestowed upon demands a moist atmosphere, and must them. The life of a saddle is increased many always be grown near the glass. It should be years by proper attention, whereas it is dewatered generously from March to September, creased through careless treatment. It is a and moderately afterwards. Propagation is safe plan never to buy a saddle that has been by offsets. *See* Orchid.

SACHET. The small perfumed cases sold by chemists and used to impart a delicate fragrance to women's clothes are known as sachets. They are less strongly scented than liquid perfumes, but are often more lasting.

Larger sachets are made for holding handkerchiefs, gloves, stockings, etc. They are simply large squares or oblong pieces of wadding, plentifully sprinkled with perfumed powder, covered with fine muslin, and finally sewn into satin or silk coverings and trimmed with embroidery, painting or ribbon work. The edges may be finished with piping or a cord. Still larger sachets are made in the same way and used as nightdress cases. A long strip of wadding can be perfumed, covered with muslin and used as a lining to a drawer. On it rests the underwear, which absorbs the faint perfume, and can be protected with a similar covering sachet to keep out the dust. *See* Lavender; Night Wear Case; Pot Pourri.

Sachet. Glove sachet made of coloured taffeta and trimmed with padded silk fruit.

SACK: A Spanish Wine. The old name of a dry Spanish wine resembling sherry was sack. The following is Sir Walter Raleigh's recipe for sack posset: Boil together ½ pint of sherry and ½ pint of ale and add gradually a quart of boiling cream or milk. Sweeten the mixture well, and flavour with grated nutmeg. Put into a heated dish, cover

and stand by the fire for two or three hours.

SADDLE: For a Horse. A good fitting saddle is just as important as a good fitting pair of boots. A badly fitting saddle is one of the most fruitful causes of injury to the back and withers of the horse and may either temporarily or permanently disable the animal. No matter what the shape of a horse may be the saddle has always a tendency to work forward, so that unless it fits properly, bruised withers and galls will result. Apart from this, comfort to the horse means comfort to the rider, both of which features are inseparable from a properly fitting saddle.

The rules for saddle fitting may be summarized as follows: There must be no pressure on the withers. There must be no pressure on the central line of the back. Shoulder-blade movement must be absolutely free. There must be no pressure on the loins. The ribs must bear the weight in an evenly distributed manner, extending from the play of the shoulders to the last rib on either side.

In buying saddles many persons purchase second-hand ones, preferring one that has been used to a new one. The best saddlers have generally a number of these on sale, and are quite willing to fit them, or allow approval to approved clients. Good second-hand saddles are always in demand, and can be bought for about 75 per cent. of their original cost, in some cases for less than half.

If it is a second-hand saddle that is desired, particular care should be taken to note the condition of the leather, the stuffing, the strength of the saddle-tree, the breadth and width of the arches, and the quality of the leather. Second-hand saddles vary to a large extent, everything depending upon the make and the care which has been bestowed upon them. The life of a saddle is increased many years by proper attention, whereas it is decreased through careless treatment. It is a safe plan never to buy a saddle that has been either patched up, restitched, or repadded.

A saddle suitable for a hunter or hack should be made of the choicest pigskin, light in weight, and have a framework of steel and wood, with hair stuffings. The side saddle, though still used by horsewomen, has been largely superseded by the seat astride.

Directly a saddle is taken off the horse's back it should be exposed to the air in order to dry the lining, after removing the girths and stirrup leathers, and sponging the surface of the leather with warm water to remove mud stains. In saddle-rooms airers and wooden horses are kept for this purpose. As soon as the saddle is dry, the lining should be brushed with a stiff brush, and the leather treated with a good saddle soap, polished with a brush and rubber.

The saddle should be kept covered up when not in use, and never left exposed to the emanations arising through decomposing organic matter from the stable, as nothing tends more towards rotting the leather. It is a great mistake to have saddle brackets placed in stables, and what applies to the saddle is equally applicable to harness. Another matter is to avoid the use of too much water. A sponge and chamois leather will do all that is necessary towards the removal of mud and mud stains. In summer the saddle should always be aired in the open, as artificial heat destroys the vitality of leather. *See* Harness; Horse; Riding, etc.

SADDLE: Of Mutton. This is a large joint consisting of the double loin from both sides of the sheep. The usual method of cooking is roasting as described under the general article on Mutton. *See* Carving.

SAFE: For the Home. A safe is a strongly built container, usually of steel or iron, in which money and other valuables can be kept secure. In its construction special devices have been introduced in order to guard against the risk of fire and the attacks of burglars. There are various patterns, some of which are suitable for the home, and a few of these are here described.

In one form the safe is very small, and equal in dimensions to an ordinary brick, being built into the wall in the place of a stretcher, that is, a brick which is laid lengthwise to the direction of the brickwork of the wall. The brick is removed from the wall and the safe built into the cavity. Such a safe is located usually behind a picture or other article of furniture to conceal its whereabouts. A hiding place for a small safe or a strong box can be contrived beneath the floor boards, locating it in a situation where it is ordinarily concealed by a carpet.

The safe illustrated is $1\frac{1}{4}$ in. thick at the thinnest part, has a drill-proof door, drill-proof rivets, and two gunpowder-proof non-breakable locks. The internal arrangement usually comprises shelf and drawers, the latter being provided with locks and keys.

Home Safes. To assist saving, a home safe can be obtained from all post offices where banking business is transacted. This safe is a locked box, the key of which is kept by the post office authorities, who will open it when it is brought in and place its contents to the credit of the depositor's account.

There is no charge for a safe, but at least 2s. must be deposited in it when it is taken out.

Home safes are also supplied by the banks.

Safe. Small type suitable for home use. It is fitted with a shelf and drawers. (Courtesy of John Tann, Ltd.)

From the Midland Bank, for example, a strong box of convenient size, with separate compartments for coins of various denominations and for notes, can be obtained on opening a home safe deposit account with an initial deposit of 1s. or more.

The key is kept by the bank and the contents are credited to the holder's account from time to time as the safe is brought to the bank and emptied.

SAFE LIGHT. This is a somewhat loose term used to indicate a light by which sensitive plates or papers may safely be developed. Actually no light is completely safe. If a plate be left near an ordinary dark-

room lamp with a coin upon it for 5 min., and is then developed, an image of the coin will be seen on the plate.

The guiding rule in dark-room illumination is to have sufficient light to work in comfort without allowing any direct rays from the lamp to fall on the plate or film, and to avoid exposing the plate or film even to reflected diffused light longer than is absolutely necessary. Thus during development the developing dish can be kept covered with a card, lifting it only for a few seconds when examination of the plate is necessary.

Safe Light. Fig. 1. Hanging lamp with top screen for ceiling reflection. Fig. 2. Type with lamp inserted at top and light reflected through coloured screen at bottom. (Courtesy of Kodak. Ltd.)

A large light in the dark room is better than a small lamp. With the large lamp properly arranged there is

ample light to see all objects in the dark room, and to work in comfort, while the plates, if kept out of the direct rays of the light, are much less likely to be fogged than if they are held close up to a small so called ruby lamp, which may be, actinically, extremely unsafe, and yet leaves the dark room in an uncomfortable, murky gloom.

The ideal arrangement is a ceiling reflector lamp, such as that shown in Fig. 1, by which the whole of the dark room is illuminated, but with diffused light, so that no direct rays can reach plate or film. The screen should be about 10 in. by 8 in.

The Wratten darkroom lamp (Fig. 2) made by the Kodak Co. for gas, oil, or electric light, takes screens 7 in. by 5 in. and 10 in. by 8 in.

These screens are interchangeable according to the work in hand.

The screens for these lamps are sold separately as safe lights, so that the amateur may adapt an old lamp if sufficiently large, or may contrive one for himself out of wood if for electric light, or tin if for gas or oil, the whole of the interior being painted dead white.

Safe-light screens are of different colours according to the purpose for which they are required; pale yellow, for gaslight papers; orange, for bromide papers; red, for ordinary plates and films; deep red, for fast ordinary and orthochromatic plates; green, of various shades, for very fast orthochromatic and most panchromatic plates.

A fairly simple and satisfactory form of red light is made by placing a small electric light in a red liquid. Dissolve 100 gr. of eosin dye and 1 oz. of potassium bichromate in hot water, using just sufficient water to dissolve all but a small portion of the dye. It is essential that the solution should be filtered before use.

A small lamp, such as a pocket flashlight bulb or a motor headlight bulb, should be used, care being taken to protect the holder and the wire from contact with the solution. Holder and wire may be covered with insulating tape coated over, after it is in place, with Chatterton's compound. A wide-necked bottle is filled just below the neck with the solution, and the bulb inserted, the wire being led through the cork. This will be a safe light for an ordinary plates, but not for panchromatic plates and films. *See Dark Room; Developing.*

SAFFRON: In the Garden. In the garden this is *Crocus sativus*. In its cultivated forms it provides the saffron of commerce, a colouring matter obtained from its dried stigmas. It flowers in autumn, and should be planted in August, and will thrive in ordinary well-drained soil. *See Crocus; Meadow Saffron.*

SAFFRON: Uses in Cookery. The yellow colouring and flavouring agent known as saffron is manufactured into saffron water or essence, which can be bought in small bottles from most grocery stores, and is used to flavour and colour cakes and various other dishes. It also forms an important ingredient in the making of confectionery and certain kinds of liqueurs. Saffron has stimulative properties and, if used judiciously, is a valuable aid to digestion.

Saffron Bun. The necessary flavouring for saffron buns can be obtained by boiling 1 tablespoonful saffron in $\frac{1}{2}$ gill water to which a pinch of salt has been added. The following day, sieve 1 lb. flour into a basin, rub in 3 oz. margarine or butter, and then add, and mix in well 3 oz. currants, 1 oz. candied peel, cut into small pieces, and 2 oz. sugar.

Put $\frac{1}{2}$ oz. yeast into a small warmed basin with $\frac{1}{2}$ teaspoonful castor sugar, mix them till a liquid is formed, and then add $1\frac{1}{2}$ gills hot milk mixed with the prepared saffron water. Strain the whole into a well made in the centre of the flour, etc., mix all to a rather slack dough, then cover the basin and leave its contents to rise in a warm place for about $1\frac{1}{2}$ hours.

Turn the dough on to a floured board, knead it for a few minutes and then divide it into small equal portions. Mould each to a smooth bun shape, and place them on a greased baking-sheet, leaving a space between each to allow for them to rise. Let them stand in a warm place for another 20 or 30 min.; use more flour to mould; then bake them for about 15 min. in a hot oven.

When cooked, brush them over with a glaze made of $\frac{1}{2}$ gill milk and 1 dessertspoonful castor sugar, and return them to the oven for a few seconds so that they may dry.

Saffron Cake. The use of the saffron not only flavours the cake, but gives it a bright yellow colour. Prepare the saffron water as for saffron bun. Make the cake according to the recipe given for plain cake, saffron water being used to moisten the dry ingredients mixed with an equal quantity of milk to make rather less than $\frac{1}{2}$ gill of liquid in all.

Saffron Tea. This is made by infusing a pinch of dried saffron in a gill of hot water for about 10 min., then straining it out and adding $\frac{1}{2}$ gill or more brandy and sugar to taste. The tea may be served either hot or cold.

SAGE. Chiefly used in cookery for flavouring and seasoning, sage is a hardy herb. The seed should be sown in a sunny, well-drained soil in early spring, and the young plants shifted as soon as they are large enough to handle. Stock is best increased by slips or cuttings, which may be taken annually. When the shoots are ready to cut they should be tied up in bunches and hung, foliage downwards, in a dry loft or shed. The leaves may be rolled off when quite crisp and stored in dry, airtight bottles.

Sage. Leaves of the fragrant tonic herb.

Sage Gargle. A good gargle can be made by boiling $\frac{1}{2}$ pint sage leaves in 1 pint water until the liquid is reduced by one-half. While boiling keep the pan covered, only removing the lid to observe the reduction of the liquor. Then strain it and mix with the liquid an equal quantity of vinegar, port wine, and $1\frac{1}{2}$ oz. honey. Bottle it for use, and warm it when required as a gargle.

Sage Tea. To make sage tea, put into a jug $\frac{3}{4}$ oz. fresh sage leaves, pour upon them 1 pint boiling water. Cover the vessel over and infuse it for 10 min., then strain the tea and take as a tonic dose from $\frac{1}{2}$ to 1 wineglassful.

Sage Wine. To make 2 gallons of this medicinal wine $\frac{3}{4}$ peck sage leaves will be needed, 2 gallons water, the whites of 2 eggs. 8 lb. raisins, 2 lemons, 1 orange, $\frac{1}{2}$ pint brandy, $\frac{1}{2}$ oz isinglass, 3 oz. sugar candy (brown). Pick the sage leaves, using either red or green. Stone the raisins and cut them small. Loose dessert raisins are best.

Boil 1 gallon water with the whites of the eggs, and pour it over the sage leaves, which should be put into a wooden bowl. Put the raisins into another bowl with the rinds of the lemons and orange pared thin, also the strained juice, and pour over these the remainder of the water, which should have been boiled up and allowed to become lukewarm. Cover over each vessel and leave till next day, stirring both occasionally.

After leaving them the required time, mix both liquids together, and let them stand again, but this time for 6 days. Then strain into a cask or stone jar, previously putting into it the sugar candy. Let the wine work, and keep the vessel full while the fermentation takes place.

When the wine ceases to work add the isinglass and brandy and bung it up. Let it stand 10 weeks, then if not clear pour it off, strain, and return to the cask or jar with another ½ oz. isinglass. Keep it twelve months before bottling.

SAGINA. This is a close-growing carpeting plant, known as pearlwort, which is sometimes used as a groundwork or an edging to flower borders: it bears tiny white flowers in summer. The yellow-leaved variety, *aurea*, is a favourite plant for use in carpet bedding designs. Ordinary soil suits it and propagation is by division.

SAGITTARIA. The handsome water plant known as arrow-head or sagittaria is about 2 ft. in height, with spiky leaves and white flowers. The double-flowered variety is *linar*. It is in blossom in early summer, and should be planted in water about 10 in. deep. When first established the roots may be sunk in a basket, after the manner of planting water lilies. Propagation is by seeds sown in spring-time, or by division of the roots of the plants at that period. *See Water Lily.*

SAGO. The best kinds of sago, which is prepared from the pith of a species of palm, are known as pearl sago, and are sold in small and large grains. Sago is fairly nourishing, and its importance as a food may be compared with that of rice or potatoes. Its value for invalids consists mainly in its soothing effect on the stomach.

To thicken soup with sago, sprinkle it into the soup while boiling and cook it about 20 min., stirring often to prevent it from becoming lumpy or sinking in the pan and browning. Use 2 oz. sago to each quart of soup, and cook the grain thoroughly.

Sago Drink. Sago makes excellent invalid drinks and can be prepared in two ways. One method consists of putting 1 oz. rather large pearl sago into a saucepan with 1 pint cold water. Place the pan back from the fire, but in a warm position, and let the grain soak for 2 hours, then bring it to the boil and simmer for 20 min., stirring frequently. Add 1 wineglassful port wine, a little grated nutmeg, and sugar to taste, and serve hot. For the second method, soak 1 oz. small sago in cold water for 1 hour, strain off the water, and add 1½ pints new milk. Stir this over the fire until the food value of the sago is quite incorporated with the milk, add a little grated nutmeg, and sweeten to taste. Strain off the milk from the sago just before the latter has softened, sweeten and flavour it, and leave it to cool. It should be skimmed before serving.

Sago Mould. To make this, boil up 1 pint milk in a pan with a few pieces of thinly cut lemon rind, then sprinkle in 3 oz. washed sago, and simmer the whole gently until the mixture thickens and the sago is cooked.

Keep it well stirred, take out the lemon rind, and let the mixture cool slightly at the side of the fire before adding 1 oz. butter, 1½ dessertspoonfuls sugar, and a beaten egg. Stir all these over gentle heat for a few minutes so that the egg may cook, then pour them into a wet mould and leave them to set. Serve the mould either with jam or stewed fruit.

Sago Pudding. To make a plain sago pudding, soak 3 oz. small sago in cold water for 1 hour. Meanwhile boil up slowly 1½ pints milk, adding 1 oz. sugar and a strip of lemon rind. Pour off the water from the sago and stir it by degrees into the boiling milk; let all boil slowly for 15 min., taking care to stir frequently. Remove the lemon peel, pour the mixture into a greased pie-dish, and

bake it in a slow oven for about $\frac{1}{2}$ hour. Always boil the sago with the milk before baking the pudding; if this is not done the grain is liable to sink in a mass to the bottom of the pie-dish.

A richer pudding is made by beating 2 eggs with $1\frac{1}{2}$ oz. sugar and adding them to the sago and milk before turning it into the pie-dish. Omit the 1 oz. sugar given in the previous recipe. Butter the pie-dish for the richer pudding, and scatter 2 or 3 small pieces of butter on the top when the pudding is ready for the oven; also dust with castor sugar. Bake about 20 min.

Sago and apples together make another good pudding. Prepare it by soaking 2 to 3 oz. washed sago overnight in a pint of water, and the following day add $\frac{1}{4}$ lb. sugar and 5 or 6 moderate-sized apples, peeled, cored, and finely chopped. Mix these well, then turn them into a greased pie-dish and bake them in a moderate oven for about 1 hour. The pudding may be served either hot or cold, and with cream or custard.

SAILCLOTH. This fabric is a sort of duck made in cotton, linen or hemp, and in several degrees of coarseness and heaviness. Very stout cloths for outdoor structural uses or making hammocks and stretchers for deckchairs, can be got from firms manufacturing window blinds for shop-fronts. The choice should be guided by the purpose in view. *See Canvas.*

ST. BERNARD. This dog may be either rough-coated or smooth, points otherwise being the same. They should have enormous bone, with absolutely straight front legs, and no inclination to be cow-hocked behind. The latter, however, is not always achieved, as heavy dogs are very troublesome to rear straight. The richer the colour the better. It may be red, orange, various shades of brindle, or white with patches of either. Importance is attached to the distribution of markings, which include white muzzle, white blaze up face, white collar round the neck, and white on chest, forelegs, feet, and end of tail. There should be black shadings in face and ears. *See Dog; Kennel.*

St. Bernard. Champion of this handsome breed. (Photo, Thos. Fall.)

ST. BERNARD'S LILY. The popular name of a hardy herbaceous perennial (*Anthericum liliago*) in St. Bernard's lily. It grows 2 ft. high, has narrow leaves and bears white flowers in summer.

St. Bruno's Lily (*Anthericum liliastrum*) is 3 ft. high and has large, white, funnel-shaped, lily-like flowers.

If the soil is clayey, leaf-mould and sand should be dug in freely before planting. Propagation is by division in spring.

St. Cloud Ware. Pastille burner in modelled white porcelain; early 18th century. Height 5 in. (By permission of the Director. Victoria & Albert Museum, S. Kensington)

ST. CLOUD WARE. The soft-paste porcelain made at St. Cloud, near Paris, at the end of the 17th century represents the oldest chinaware produced in Europe, and it was the forerunner of Sèvres. The fine regular paste can be recognized by its yellowish tinge, and the forms, which imitated those of China and Japan, were decorated with simple designs in a rich blue outlined in black, and heightened by a brilliant glaze. The factory was closed in 1773.

There is an ample supply of white pieces with modelled ornament, in the form of cups and saucers, jugs, flower-pots, statuettes and grotesque figures. A Chinese pattern especially favoured for reproduction was a white porcelain with prunus blossoms in relief. In painted ware the underglaze-blue decoration prevails, but there are also pieces with red, purple, and yellow enamel. *See Sèvres.*

ST. DABEOC'S HEATH. A beautiful hardy heath (*Daboecia polifolia*) which grows wild in parts of Ireland and is often called Irish heather. It is about 12 in. high and bears urn-shaped reddish-purple flowers in late summer; the white variety, *alba*, is very pretty. This heather should be planted in lime-free loamy soil; peat may be added with advantage.

ST. JOHN'S WORT. A group of hardy flowering shrubs and plants (*hypericum*) of considerable value in the garden. One of the most useful of all is *Hypericum calycinum* (Rose of Sharon): it thrives in shady places and bears large yellow flowers in summer; it should be cut down each spring.

Androsaemum, 18 in., yellow flowers and black fruits, and *moserianum*, 12 in., are other good kinds. The best of all the shrubby species is *Henryi*, 2 ft. high. *Coris* is a charming little plant for light soil in the rock garden. All have yellow flowers and thrive in ordinary soil. The shrubby kinds are increased by cuttings in a frame in summer, the others by division in spring.

St. Joseph's Lily. This is one of several names given to the Madonna lily (*Lilium candidum*). *See Lily.*

ST. JULIEN: The Wine. One of the best-known brands of French claret is produced in the St. Julien district in the Médoc. The name is often applied loosely to cheap clarets. The higher-class St. Julien growths are of deeper colour and greater body and variety than the more delicate products of Latour and Lafite. The bouquet closely resembles the raspberry.

ST. VITUS'S DANCE. St. Vitus's dance, or chorea, is a nervous disease of young children which is much more common in girls than in boys. It may first be noticed about the age of 10 and causes the child unconsciously to jerk the hands or limbs about, twist the head, or pull faces. Instead of walking normally, the child's gait becomes a series of jerky, irregular movements. An inherited nervous disposition, debility, fright, or precociousness of mind are predisposing causes of the complaint.

A child suffering from chorea should be placed at once under medical care, if for no other reason than that it is liable to or may be actually suffering from rheumatic disease of the heart. Rest in bed may be necessary at the beginning, with a liberal diet of milk, eggs, and soups. Except in severe cases the symptoms pass off during sleep. When the child is allowed up, and particularly when it goes out of doors, care should be taken to protect it from the teasing of other children.

SALADS AND ACCESSORIES TO SALAD MAKING

Many Dainty Ways of Serving these Health-giving Dishes

This article deals with a selection of appetizing salads, which in their various seasons find a place in the menu all the year round. *See also Fruit Salad; Hors d'Oeuvres; Mayonnaise; Olive; Supper; Tarragon; Vinegar.*

Salads may be divided into plain salads which accompany some dish and skilfully composed salads which form a course in themselves. The former kind are made of salad herbs and vegetables, either

raw or cooked and allowed to become cold, with the occasional inclusion of certain fruits. The latter kind contains among other salad ingredients nuts, eggs, fish, cheese, meat, game or poultry; or are composed entirely of mixed fruits and served as the sweet course at luncheon or dinner. The secret of success lies in the proper blending of ingredients and the cool, inviting appearance of the finished salad. This may be served in a glass, china or pottery bowl, or individual portions may be placed in salad saucers, or on glass plates. Fig. 1 illustrates a plain salad appetizingly arranged in a cut glass bowl, with glass servers, oil and vinegar bottles and salad plate. Fruit salads may be served either in a fruit set or in sundae glasses.

Salad. Fig. 1. Plain salad arranged in a cut-glass bowl with glass accessories.

In making salads the first essential is to see that the ingredients are perfectly fresh. If tinned goods are used, they should be of first-class quality and removed from the tin immediately after opening it. In warm weather salad herbs, fruits, etc., gain added crispness by being kept for a few hours in a refrigerator. When this is not possible a wire vegetable rack placed in an airy larder is the best receptacle to hold such items as endives, bunches of watercress, spring onions, radishes and lettuces.

Salad vegetables should be handled as little as possible, but must be washed thoroughly in cold salted water. Watercress requires cleansing in several waters, mustard and cress should have the small black seeds removed. Endive and lettuce are prepared by cutting off the root and any outer leaves unfit for use; the smallest leaves and heart should be set aside for garnishing the top of the salad. Outer leaves of lettuces should be torn in pieces and not cut. The roots of spring onions should be cut off and the tops trimmed before washing, and afterwards the outer skins removed. Radishes may be sliced, but if small, round, and of bright colour, they form an effective garnish when left whole.

Aids to Preparation. Wire baskets are sold for straining the water out of lettuces, etc., after washing them. A clean cloth should be used where a basket is not available, held by the corners and the salad shaken gently in it until the ingredients are dry. Moisture left on lettuce and other vegetables ruins the salad and prevents the dressing from properly adhering to them. Strainers can be used as a salad basket; and another excellent device is the tomato slicer. A cutter with which cucumbers can be finely sliced is illustrated in Fig. 2. It can be cheaply purchased, and various stainless steel knives are also obtainable which are valuable aids to preparing ingredients. One with a long flexible blade is particularly useful for slicing beetroot. An ingenious egg cutter is shown in Fig. 3. It is made of aluminium and is provided with wires that press evenly through a hard boiled egg and slice it neatly.

Salad Dressings. The dressing should not be added to the salad until it is ready to serve. A good way with a green salad is to place the made dressing in the bottom of the bowl, reserving the portions of the salad to be used as garnishes, put the other ingredients into the dressing and mix thoroughly. A simple French dressing is served with salads which accompany game, poultry, etc., but a mayonnaise or thickened dressing is usually best for those served as a separate course, with the exception of a salad composed entirely of fruit. Fruits such as bananas, apples, oranges, pineapple and chopped or ground nuts are now introduced into green salads and dressed with

mayonnaise. The best oil and vinegar should be used for dressings. Rancid oil or malt vinegar completely ruin the flavour. Lemon juice may be substituted for vinegar, and cream or unsweetened condensed milk is an excellent addition to a thick dressing.

Fig. 2. Cucumber slicer with which cucumbers can be thinly and evenly cut. Fig. 3. Aluminium egg cutter with which hard-boiled eggs may be sliced for garnishing salads.

A French dressing for the lettuce and endive salad to accompany poultry, etc., is made by mixing 3 parts best salad oil with 1 part white wine vinegar. The lettuce leaves are dried, put into a basin, seasoned with salt and pepper, and equal parts of chopped tarragon leaves, chervil, parsley and chives (or onion) are scattered over them. The salad is carefully lifted out when required, leaving any moisture that may have drained from the leaves in the bottom of the basin and placed in the mixed oil and vinegar in the salad bowl. The leaves are turned about gently in the dressing until thoroughly coated and served at once on side plates. The salad bowl may be rubbed round with a crust of bread containing a clove of garlic.

A dressing for a vegetable salad may be made of 3 tablespoonfuls salad oil, 1 teaspoonful tarragon vinegar, 2 dessertspoonfuls white vinegar, salt, pepper, f teaspoonful made mustard. The same quantity of lemon juice may be substituted for vinegar where the latter is not liked and $\frac{1}{2}$ teaspoonful castor sugar may be added. Put the mustard, salt and pepper into a basin and gradually stir in the oil; then add the vinegar, mixing thoroughly.

Salad Cream. A very good recipe for a salad cream which can be made in large quantities and stored in bottles is as follows: The ingredients consist of the yolks of 6 hard-boiled eggs. 6 oz. butter, 2 oz. castor sugar, $\frac{1}{2}$ oz salt, 1 oz. dry mustard, cayenne pepper to taste, $\frac{1}{2}$ pint cream, $\frac{1}{2}$ pint salad oil, $1\frac{1}{2}$ gills white wine vinegar, 4 tablespoonfuls tarragon, chervil, and tomato vinegar mixed together, 2 tablespoonfuls Worcester sauce, and 2 teaspoonfuls anchovy sauce.

Rub the eggs through a wire sieve, then pound them in a mortar till a perfectly smooth paste is obtained. Work the butter and sugar together until they are very light and creamy; in cold weather the butter may be just melted, but it must not be allowed to oil, or the mixture will curdle. Add to the eggs the butter, sugar, salt, mustard, and pepper, and thoroughly incorporate them; then by degrees moisten the paste formed with the cream and, when that is mixed, work in the sauces. Last of all the ingredients, put in the oil and then the vinegars.

The oil must be mixed in first very carefully and a few drops at a time. When thoroughly incorporated add the vinegar. It is best to use the mortar entirely for mixing, as it prevents waste of ingredients. If by any chance the salad cream curdles, it can be restored by placing the mortar in a pan of hot water and stirring till smooth again.

A simple dressing may be made by passing the yolk of a hard-boiled egg through a sieve, beating it fine with a fork in a basin, then adding 1 saltspoonful dry mustard, $\frac{1}{2}$ salt-spoonful salt, 1 teaspoonful castor sugar, 1 tablespoonful salad oil, 1 tablespoonful vinegar, and cayenne pepper to taste.

Brazilian Salad. This salad may be served either as hors d'oeuvres or as a separate luncheon course. The ingredients are white grapes, apples, celery, brazil nuts and lettuce. Skin and pip the grapes, chop the apples, celery and nuts finely, mix with salad cream and place on crisp lettuce leaves either in a bowl or on small plates.

Butter Bean Salad. Soak and boil $\frac{1}{2}$ lb. butter beans until tender. Strain away the liquid. Add a little butter and seasoning to taste and leave the beans to get cold. Mix with mayonnaise or thick salad dressing, and garnish with half slices of beetroot, strips of pimento and finely-chopped parsley.

Carrot Salad. Raw carrot possesses dietetic value and a good luncheon salad may be made by grating enough carrot to fill a breakfastcup, sprinkling it with chopped parsley, a small piece of grated lemon rind, a dusting of pepper, salt and castor sugar. Add a little oil and lemon juice, just sufficient to moisten, and mix all together. Arrange small lettuce leaves lightly coated with the dressing round the salad, and garnish with freshly-grated carrot and pieces of olive.

Cauliflower Salad. An excellent winter salad is made with cauliflower. Divide one large cold boiled cauliflower into sprigs. Sprinkle them with salt and pepper, and heap them up neatly in a salad bowl. Cut two tomatoes in slices and arrange them as a border round, sprinkling them with a little chopped parsley. Pour about $\frac{1}{2}$ gill mayonnaise sauce or any other good salad-dressing over the cauliflower, and serve.

Slices of beetroot which have been dipped in vinegar may be used with or instead of tomatoes.

Celery Salad. Equal quantities of raw apple and celery are cut into small pieces, placed in a bowl, and covered with mayonnaise sauce. A border of sliced tomato or beetroot may be added to this dish, which must not be prepared too long before it is eaten, in case the apple should become discoloured.

Another celery salad which is excellent with cold pork, goose or chicken is made of diced celery, beetroot and potatoes and chopped nuts. Cold cooked chestnuts may be used instead of the diced potato.

Cheese Salad. Cream cheese is liked by most people as a luncheon salad ingredient, but any soft cheese may be used or a cheese crab may be prepared. This is made from $2\frac{1}{2}$ oz. dry cheese, $\frac{1}{2}$ teaspoonful each made mustard and salad oil, salt and pepper to taste and enough vinegar to bind the whole into a paste. Grate the cheese and mix with all the other ingredients until the paste is smooth. Serve small portions on a green salad previously prepared with French dressing. When

using a cream or soft cheese cut it into rounds, dip lettuce leaves in French dressing and arrange round the bowl, place the cheese on top and garnish each piece with capers. A layer of diced apple and celery may be placed at bottom of bowl.

Salad. Chicken salad, made with lettuce, eggs, olives, gherkins, and cold roast chicken.

Chicken Salad. This makes an attractive addition to the supper table. To prepare it, cut the remains of a

cooked chicken into neat strips and pile them in the centre of a salad dish. Cover these with salad cream or mayonnaise, and surround the whole with a border of lettuce, making a cross with strips of beetroot or anchovy and placing a caper in each of the four divisions.

Another good salad made with the remains of a cold chicken is prepared by removing the bones from a boiled or roast fowl, and cutting the flesh into small pieces. Mix the latter with the shredded heads of 2 lettuces, add 1 tablespoonful white tarragon vinegar, and season the mixture with pepper and salt. Then pile it high in the centre of a dish, cover it with mayonnaise sauce and garnish it with alternate groups of lettuce leaves, quarters of hard-boiled egg, shredded gherkin, and stoned olives. Endive may also be used as a garnish.

Crab Salad. A good fish salad can be made by chopping up the flesh of a crab, moistening it with a little mayonnaise sauce, and then putting the mixture into 3 or 4 prepared tomatoes. The latter are scalded in boiling water for a couple of minutes, the skins removed, and an incision made in the top of each so that the inside can be scooped out with a small spoon. Sprinkle a little pepper and salt inside the empty tomato cases, and let them drain before filling them with crab. Garnish the salad with lettuce and cress.

Crayfish Salad. An equal quantity of crayfish flesh should be mixed with cold white fish which has been flaked and boned. Layers of lettuce, cress and endive, of fish and of hard-boiled eggs are placed in the bowl, each layer being moistened with salad cream. Sprigs of tarragon and chervil, cut gherkin, and strips of red chillies are used to garnish. Mayonnaise dressing may be used and a salad composed of turbot, halibut or hake without the crayfish can be prepared, and garnished with anchovies.

Egg Salads. Hard-boiled eggs may be cut in half and placed round a shallow glass bowl. In the centre is piled a mixture of diced potatoes and beetroot, seasoned and flavoured with chopped pickles, parsley and onion, and moistened with salad dressing. The eggs may be stuffed with pounded sardines and served on lettuce with a spoonful of mayonnaise sauce on each half of egg.

Another good egg salad is made of thick slices of hard-boiled eggs. Air extra egg is boiled for garnishing and the yolk and white of this are separated; rub the yolk through a wire sieve, and chop up the white finely. Whip 3 tablespoonfuls cream until it just hangs on the whisk, stir 3 tablespoonfuls mayonnaise sauce into it, and season the mixture carefully.

Put a layer of crisp, clean lettuce in the bottom of the salad bowl, then one of egg, next of cold cooked macaroni cut into pieces about 1 in. long, then a sprinkling of chopped celery and parsley, and a little dressing.

Continue these layers until the dish is full, arranging lettuce on top. Garnish with the sieved yolk and chopped white of egg.

Lettuce and Fruit Salad. The ingredients are, 1 grape fruit, $\frac{1}{2}$ cupful chopped nuts, 1 cupful white grapes, 2 oranges, 2 tomatoes, 1 lettuce. Peel the grape fruit and oranges and divide into sections, skin and remove pips. Also skin and remove pips from grapes. Place fruit and nuts on top of lettuce, cover with mayonnaise and border with tomato slices. Garnish with a few grapes.

Lobster Salad. To make a lobster salad, take the meat from a lobster, cut it into pieces of a convenient size, and season these slightly with salt, vinegar, and pepper. Shred some inner leaves of lettuce into the bottom of a salad bowl, cover it with a layer of lobster and sliced cucumber, and cover again with lettuce. Continue with these layers until the salad is complete, and decorate the top

with slices of egg, tomato, or beetroot. Just before serving pour over some mayonnaise sauce and add a sprinkling of powdered coral.

Orange Salad. A salad that goes well with roast meats, or accompanies wild duck, is made from a small cucumber, sweet oranges and chopped nuts. Most of the cucumber should be peeled and soaked for an hour in cold water before being cut into very thin slices. Prepare the oranges, removing all pips and pith. Arrange on cucumber slices and cover with salad cream, garnishing with the nuts and a border of very thinly cut unpeeled cucumber slices.

A good orange salad can be made by mixing the prepared orange quarters with chopped potatoes, apple and olives. The dressing for this salad is made of oil and orange juice, pepper and salt, and the salad is served on lettuce leaves, or in half orange skins placed in grape fruit glasses.

Prawn Salad. Take 1 pint shelled prawns, and sprinkle them with French dressing. Wash 2 moderate sized cabbage lettuces, and pull the leaves into small pieces. Put a layer of lettuce in the dish, cover it with prawns, then pour over it some mayonnaise sauce. Add another layer of lettuce and prawns, and continue until the bowl is full. Mayonnaise sauce should cover the whole. The top should now be decorated with slices of tomato, cucumber, and hard-boiled egg, sprigs of cress, etc.

Salmon Salad. To prepare, take out the bones, break the fish into flakes with a fork and pile it high in a salad bowl on a bed of green salad.

Pour over it some mayonnaise or salad dressing and leave it in a cool place for a little while before serving it; garnish with some sliced hard-boiled egg, a few crisp lettuce leaves, some cress, sliced gherkin and strips of pimento.

Sardine Salad. This salad is best served in individual portions. To prepare it, put a layer of thinly sliced celery in the bottom of each bowl, cover it with a little boiled and finely chopped onion, and then add a layer of sardines, skinned, boned, and cut into small pieces.

Cover this with some more celery, pour over it a little oil and vinegar dressing, and finally put on a layer of sieved hard-boiled egg. Coralline pepper makes a good garnish for these salads.

Russian Salad. To make this salad, take 1 lb. mixed cooked vegetables such as carrot, turnip, peas, French beans, potato and beetroot, and cut them into dice. Arrange them neatly in a glass salad bowl, adding a little cucumber and celery if liked; dress them with salad dressing made with cream or condensed milk instead of oil, and garnish with a border of sliced tomato and chopped celery.

If preferred, a few sardines or anchovies boned, tailed and cut into halves may be placed on top of the vegetables. The chopped yolk and white of a hard-boiled egg may then be used as a suitable garnish.

Another variety of Russian salad is made by arranging the flaked remains of any cooked white fish in a salad bowl, and covering the top with strips of anchovy and sardine, and some chopped gherkin, hard-boiled egg, and capers. Slice some cold boiled potatoes thickly, place a border of these round the salad, and pour some mayonnaise over the centre.

Turkey Salad. An excellent supper salad is made from pieces of cold turkey, which are cut up and mixed with diced celery and shredded endive and moistened with salad cream. Fresh, crisp lettuce leaves should be placed round the salad and it should be garnished with chopped chestnuts, slices of hard-boiled eggs and gherkin.

Salad Bowl. Because salads are served in different ways, according to individual taste, salad bowls may vary both in size and design. The larger ones, which are intended to hold salad for several persons, are deep bowls of cut or plain glass, pottery, china, or polished wood. They are accompanied by salad servers, which consist of a two-pronged fork and a spoon to match the bowl. Smaller salad bowls, designed to hold just enough for one person, are also made of wood, glass, and china. They are sometimes preferred to the larger kinds, and are always useful on occasions when salad for one is required. Semi-porcelain, wood, glass, and pottery sets are obtainable for fruit salads comprising a bowl and six individual plates.

SALAD BURNET. The hardy perennial herb, *Poterium*, or salad burnet, bears leaves used for flavouring salads and soups. It requires a sunny, dry position in ordinary light soil, and must be watered freely in time of drought. It is best planted during early spring in rows 6 in. apart and rows 8 in. asunder, removing flower stems as soon as they appear. Roots should be lifted and replanted every year. Salad burnet is raised from seed sown in shallow drills during April or September.

SAL ALEMBROTH. The combination of perchloride of mercury and sal-ammoniac or sal alembroth is a powerful antiseptic which has been used in surgery. Sal alembroth gauze and sal alembroth wool are useful antiseptic dressings for discharging wounds, ulcers, etc. The gauze and wool are usually tinted blue with an aniline dye, which becomes bleached when wet with the discharge.

SAL-AMMONIAC. Ammonium chloride is commonly known as sal-ammoniac. It is a common vapour inhalation in the treatment of chronic catarrhs and inflammations of the throat, larynx, and bronchial tubes.

Sal-ammoniac is used to make the electrolyte in batteries of the Leclanché type. *See* Ammonia; Battery; Bell.

SALE OF WORK. A sale of work is much the same as a bazaar, though strictly speaking at the former nothing but needlework should be sold. In modern parlance the terms are practically interchangeable. Small sales of work may be held in the home with the aim of collecting money for charities. *See* Bazaar.

SALES: Advice About. The disposal of goods at reduced prices is known as a sale. The time and manner of a sale vary according to the method and urgency of disposal, an auction sale being usual when the goods have to be sold without delay. The sale of secondhand goods and many small articles is often effected through the advertisement columns of daily papers.

Special and after season sales are held for clothing and household furniture and requisites. Bargains are often obtainable especially in slightly soiled house linen and blankets, in shoes, gloves, stockings and furs at the better class stores and shops.

SALICIN. A crystalline glucoside obtained from the bark of species of willow and poplar, salicin is used in the treatment of acute rheumatism. In the stomach and bowel it is converted into salicylic acid. Pron. Sal-e-sin.

SALICYLATE. A salt of salicylic acid is called a salicylate. Those most often used in medicine are sodium salicylate, methyl salicylate or oil of wintergreen, salol or phenyl salicylate, and bismuth salicylate.

SALICYLIC ACID. A colourless, crystalline substance, salicylic acid is found in various plant products, including oil of wintergreen and oil of sweet birch, from which it can be prepared; but it is also prepared synthetically. It is used in treating acute rheumatism, in doses of 5 to 20 grains; but usually sodium salicylate, dose 10 to 30 grains, is preferred.

Excessive dosage with these substances causes symptoms of poisoning, referred to as salicylism, such as fullness in the head, noises in the ears, deafness, dimness of vision, sickness, delirium and cardiac depression. Such symptoms should at once be brought to the notice of the doctor.

Salicylic acid acts as an antiseptic, and is sometimes used as such in a lotion. It assists in dissolving off the horny cells of the skin, and is used to remove corns and warts and in the treatment of skin diseases in which there is much scaling or thickening. *See Aspirin: Wintergreen.*

SALINE. Salts of the alkalis and of magnesium are used as purgatives under the name of saline. They include sodium sulphate, Rochelle salt or sodium, and potassium tartrate, sodium phosphate, and Epsom salt or magnesium sulphate. The dose varies from $\frac{1}{4}$ to $\frac{1}{2}$ oz. Salts are best administered in warm water just after getting out of bed in the morning. People who take salines habitually ought to take some other purgative, e.g. castor oil, at intervals. *See Aperient; Cathartic.*

SALISBURIA. One of the most beautiful of all trees which are hardy in the British Isles. It is popularly called the maidenhair tree, because its leaflets resemble the fronds of the maidenhair fern; its botanical name is *Ginkgo biloba* (*Salisburia adiantifolia*). The maidenhair tree is one of a limited number of leaf-flosing conifers; it will eventually reach a height of 60 ft. or more, though it is slow growing during its early years. It is of graceful growth, and its fern-like leaves, which turn to pale gold in the autumn, are very beautiful. It thrives in ordinary soil and does well in town or country gardens.

SALIVA. The fluid poured out into the mouth consists of the mixed secretions of the salivary glands. These are the parotid, between the ear and the angle of the jaw; the sub-maxillary, under the horizontal part of the jawbone; and the sub-lingual, under the tongue. The saliva is an alkaline fluid; it lubricates the mouth and food, and digests starch by means of the ferment ptyalin which it contains. Among its various contents are the carbonate and phosphate of lime, which tend to adhere to the teeth and form tartar.

Mumps is an acute infectious disease in which there is inflammation of the parotid glands, and occasionally also of the other two salivary glands. Any of these glands may suffer from simple inflammation due to exposure to cold or injury, etc. Hot applications to the skin over the gland may give some relief in early stages.

A profuse flow of saliva, referred to as salivation, may arise from dyspepsia, stomatitis, the excessive use of mercury and other drugs, such as arsenic, iodide of potassium, antimony, and tobacco and other causes. The treatment depends on the cause.

SALLY LUNN. A kind of teacake baked in a round cake tin or cake ring is known as a Sally Lunn. The following is a good recipe: Use 1 lb. flour, $\frac{1}{4}$ teaspoonful salt, a scant $\frac{1}{2}$ oz. yeast, 1 teaspoonful castor sugar, 1 egg, $\frac{1}{2}$ pint sour milk or milk and water, and $1\frac{1}{2}$ oz. butter. Save just sufficient of the egg as an egg wash for the cake when baked. Sift the flour with the salt into a bowl and make a well in the centre, melt the butter in a pan, add the milk, and bring to the warmth of new milk.

Beat the egg, reserving a little as directed, add to the milk, and warm it sufficiently to take the chill off it. Cream the yeast with the sugar, and gradually mix the milk and egg to it. Turn the liquid into the centre of the flour and work all up into a dough, kneading it smooth.

Have ready four medium-sized tins, warm and grease them. Now divide the dough into four equal portions, work each portion into a smooth round, and lay them in the tins. Place these on a baking sheet, cover them over, and set them to prove in a warm place. When they have risen to double their size, bake them in a good steady oven for 20 to 25 min. Turn the cakes out of the tins on to a cake-wire and brush the tops with egg.

Salmi. This term is used in cookery to describe a superior kind of ragoût made from game or poultry. *See Game.*

SALMON. Sometimes called the king of freshwater fish, salmon is, strictly speaking, also a salt fish, for it spends part of the year in the sea and the remainder in rivers. British salmon is considered the best, and is in season from early February to the end of August, but Canadian, Dutch, and other imported salmon can be obtained all the year round.

When buying salmon, select a fish with a small head and tail in proportion to its size, broad, thick shoulders, silvery bright scales, and flesh of a pinky red shade. Salmon may be kept for several days after it is caught so long as it is stored in a cool place, but the fresher it is when cooked, the better.

How to Cook. To boil salmon, remove the fins and gills, scrape the scales and cleanse the fish. Put it into a pan or fish-kettle containing enough boiling salted water to cover it, and let it cook slowly. The time required for cooking depends upon the weight of the fish, 10 min. being allowed for every lb. and 10 min. extra.

Salmon may also be grilled, but it should first be cut into slices about 1 in. thick, wiped with a cloth, and then brushed over with salad oil or melted butter and seasoned to taste. Cook these before a clear fire or under a gas griller for about $\frac{1}{4}$ hour, and serve them with maître d'hôtel butter, or any suitable sauce may be used.

To fry salmon, cut the fish into slices, wipe them with a cloth, brush them over with beaten egg, and then coat them with breadcrumbs. Melt some fat in a frying-pan, and when it is smoking hot put in the slices, frying them on both sides until they are golden brown in colour. Then drain them on paper and serve them hot with the addition of Hollandaise sauce.

When cooking chilled imported salmon, the flavour is improved if it is allowed to soak for an hour or longer in slightly salted water.

Then dry the fish well, and cook by any of the methods given for fresh salmon.

Smoked salmon, either cooked or in its raw state, is often served as hors d'oeuvres, while a special preparation of it, known as lax, is preserved in oil. Both are cut into thin slices and garnished with herbs or pickles. Tinned salmon makes up into good sandwiches, fish cakes, and various other delicacies.

Salmon Cakes. Tinned salmon may be used to make fish cakes or fritters. Break about half a tinful of salmon into flakes, mix it with $\frac{1}{4}$ lb. boiled rice, and bind the two with the yolk of an egg. Add a little lemon juice and seasoning to taste, and heat the mixture in a pan over the fire. Then spread it on a plate to cool, shape it into round cakes, brush these over with white of egg, coat them with breadcrumbs, and then fry in smoking hot fat.

Salmon Chartreuse. Rinse a plain border mould in cold water and coat it thinly with melted aspic. While it is setting remove the skin and bones from 1 lb. cooked salmon and pound the flesh in a mortar with 6 boned anchovies and the yolks of 3 hard-boiled eggs. When the mixture is smooth, add $\frac{1}{2}$ glass sherry, the juice of $\frac{1}{2}$ lemon; rub the whole through a hair sieve, season it to taste with

salt pepper, cayenne, and a little nutmeg, and then add to it a gill of lightly whisked cream and a little more than $\frac{1}{2}$ pint warmed aspic jelly. Pour the mixture into the prepared mould and leave it to set, serving it cold, with a little salad sprinkled with dressing heaped up in the centre.

Salmon Mayonnaise. Cold boiled salmon is needed to make a mayonnaise. Choose a middle cut of salmon, boil it according to the directions already given, and, when it is cold, take off the skin and cover the fish with thick mayonnaise sauce.

Serve it garnished with thin, overlapping slices of cucumber. If the fish is not specially cooked for the purpose, but the remains of cold salmon are used instead, they may be flaked, piled up high on a dish, garnished with green salad, and the sauce poured over them.

Salmon Mousse. To make this, take the skin and bone from $\frac{1}{2}$ lb. cold boiled salmon, pound it well in a mortar, and then add to it a small teacupful of hot and seasoned fish stock in which a little gelatine has been dissolved.

Rub the whole through a sieve, then whip it up with 1 gill thick and slightly salted cream. Turn the mixture into a prepared soufflé tin and place it in ice for a few hours before it is to be served. Chopped aspic makes a good garnish. *See Fish; Lax; Maître d'Hôtel; Potted Fish.*

SALMON TROUT. Salmon trout is a species of trout which migrate to the sea. In taste and colour their flesh differs but slightly from young salmon. Salmon trout can be cooked according to any of the recipes given for salmon and trout. *See Trout.*

SALOL. By the interaction of salicylic acid and phenol (carbolic acid), salol may be obtained. It is insoluble in water, and is usually prescribed in cachets or suspended in mucilage. The dose is 5 to 15 grains.

Externally, it is sometimes diluted with powdered chalk or talcum as an antiseptic dusting powder. Internally, its chief uses are as an intestinal disinfectant and in the treatment of rheumatic fever. In the intestine the drug is decomposed into carbolic acid and salicylic acid. A solution in alcohol, with the addition of aromatics, is used as a mouth wash.

SALPIGLOSSIS. Amongst half-hardy annuals salpiglossis is valuable for cut bloom under glass, and showy for beds and borders outside. Propagation is by seeds sown in a frame or greenhouse in spring. Care must be taken not to sow too thickly, and to give the seedlings plenty of ventilation, or they may damp off. After they have been hardened off the young plants may be safely planted out in June. Different varieties have such shades as blue and gold, golden yellow, gold-veined crimson, and purple. By sowing seeds under glass in September and growing the seedlings in slight warmth in ordinary potting compost a fine display in spring is assured.

Salpiglossis. Brilliantly coloured flowers of an annual plant much grown for indoor decoration.

SALSIFY: The Plant. An excellent root vegetable for winter use which is easily grown in well tilled friable soil, free from fresh manure, from seeds sown out of doors in May; the rows should be 15 in. from each other and the seedlings thinned to 8 or 9 in. apart.

During summer the only attention needed is to hoe frequently between the rows. In autumn, when the tops have died down, the roots may be lifted and stored in soil at the foot of a wall or fence, or

dug as required. If a few roots are left in the ground until spring, the fresh shoots, if cut when a few inches high, furnish what are known as chards.

Salsify, which somewhat resembles a parsnip in appearance and an oyster in flavour.

How to Cook. Salsify has been popularly termed the oyster plant from its supposed resemblance to the oyster in flavour.

To prepare it as a vegetable, scrape the root gently, and lay it in cold water to which has been added a tablespoonful of lemon juice. Put into a stewpan as much milk and water as will be required to cover the roots, add salt to it and let it boil up. Drain the salsify, cut each stick into pieces 3 or 4 in. long.

Plunge the pieces into the boiling milk or milk and water, add 1 oz. butter and a good squeeze of lemon juice, boil up and cook for from 30 to 40 min., or until the pieces are tender. Dish the salsify and keep it hot, then strain the liquor and keep it for making a thick white sauce with which to cover the roots. Salsify may also be cooked according to any of the recipes given for celery. *See Batter: Fritter; Sauce.*

SALT: Household Uses. Salt is indispensable in cookery and as a preservative of meat and other vegetables. One of the simplest and most effective of cleansing agents, salt removes stains and grease.

There are several grades of salt, and it is customary to keep the finest for the table and a coarser sort for cooking and other purposes. The latter is generally the pure rock salt, while the refined white table variety frequently has ground rice or some other ingredient added to prevent it from caking. All salt should be kept in a dry place, as it is highly susceptible to atmospheric changes and quickly loses its savour if allowed to become damp. Salt easily corrodes the silver or other metal of which many salt-cellar are made, and for this reason these should be lined with glass, kept clean and frequently replenished.

For culinary purposes salt is used for seasoning all dishes and is added to the water in which vegetables are cooked. Fresh fish or meat not required for immediate consumption should be sprinkled with salt before being put away in the larder, and this precaution should never be omitted in hot weather, however secure the larder or meat safe may be against flies or bluebottles. In making ices the freezing mixture consists of ice well sprinkled with salt, which in dissolving keeps the temperature of the ice lower.

Salt is an excellent cleanser for dishes of all kinds, especially for enamelled ware and for removing stains, for cleaning baths, bamboo furniture, etc. Before blackleading a kitchen range any grease spots should be got rid of, and this can be done effectively by rubbing with salt. When sweeping a carpet salt may be sprinkled over it to clean it and bring up the colour.

Amongst other uses for salt, a handful thrown in front of the fire makes it burn clear and hot for toasting. About a teaspoonful dropped into the bowl of a paraffin lamp will cause it to give a better light.

In medicine chloride of sodium, which is common salt, has valuable therapeutic properties in the form of salt and brine baths. It is often employed as a gargle for the throat and is given as an emetic dissolved in hot water. *See Emetic.*

Garden Uses. There are various uses for salt in the garden; for instance, rock salt is an excellent stimulant for asparagus, beetroot, and other vegetables. This salt should be used at the rate of 7 lb.

to the rod, but not more. Its value in this respect is due to the fact that it liberates the potash already in the soil, so making it feed the plants that need it.

Salt is also used for killing weeds. It is useful for clearing them from gravel walks, especially in cases where, as domestic animals are kept, poisons cannot safely be employed. It should be applied in dry weather. *See Fertilizer; Weed.*

SALT BOX: How to Make. Owing to the corrosive effect of salt, the use of nails and metal fastenings is avoided as far as possible in making a salt box, which is usually of wood; because of the damp nature of the material the wood should be fairly thick and close grained. Beech is well suited for the work, but ash is often used, and American whitewood can be utilized. A convenient shape, illustrated in Fig. 1, measures $10\frac{1}{2}$ in. by 7 in. at the base, $4\frac{1}{2}$ in. in front, and 7 in. at the back up to the lid. The wood is $\frac{3}{4}$ in. thick, the corners dovetailed.

Salt Box. Fig. 1. Salt box made from close-grained wood. Figs. 2-4. Showing how front, back, and sides are dovetailed into each other to avoid use of nails. Fig. 5. The parts ready for gluing together.

Commence by planing up the front, A, to $4\frac{3}{4}$ in. by $\frac{3}{4}$ in., and cut to $10\frac{3}{4}$ in. The sides, B, are the same thickness, and 7 in. wide, with a length of $7\frac{1}{2}$ in. The back, C, is $10\frac{3}{4}$ in. by $9\frac{1}{2}$ in. by $\frac{3}{4}$ in. and the bottom, D, is $9\frac{1}{2}$ in. by 6 in. by $\frac{3}{4}$ in. The pieces are set out as in Figs. 2, 3, and 4; the dovetail pins are cut on the ends of the front piece, A, the distance between the shoulders being 9 in., and then placed on the sides in turn to mark out the exact shape of the sockets, as in Fig. 3.

The same is done with the back, C, as in Fig. 4 and then a $\frac{1}{8}$ in. wide and $\frac{1}{4}$ in. deep groove is ploughed $\frac{3}{8}$ in. up from the bottom edge of each piece to take the bottom piece, D. On the latter plane a rebate to correspond with the grooves, $\frac{3}{8}$ in. up the edge and $\frac{1}{4}$ in. deep, and complete the sides, B, by sawing off the front corner and planing smooth. Mark $1\frac{1}{2}$ in. down at the top of the back each side, saw off the waste, and plane down smooth, and then bore a $\frac{1}{4}$ in. hole 1 in. down in the centre. The parts are now ready to fit together, as in Fig. 5, and if the joints are true they can be glued up and left to dry.

In the meantime the lid is prepared, one piece being $11\frac{1}{4}$ in. by $6\frac{1}{2}$ in. by $\frac{3}{4}$ in., and the other $11\frac{1}{4}$ in. by 1 in. by $\frac{3}{4}$ in. The front edge of the large piece and both ends of both pieces should be rounded and finished smooth with glass paper. The glued box can now be trimmed at the ends and cleaned up with a sharp smoothing plane, the top edge of the front being planed to the slope of the sides, and the narrow portion of the lid screwed on from the back. Its lower edge in front must be planed down $\frac{1}{8}$ in., so that the sloping lid can be fitted. The top edge of the latter is now bevelled sufficiently to fit, and then attached with stout leather hinges, 2 in. long and $1\frac{1}{8}$ in. wide. A neater job is made by cutting recesses $1\frac{1}{2}$ in. from the ends to take the leather, which should be secured with $\frac{1}{2}$ in. round-head screws.

The outside of the box should be sized and varnished; the inside is left plain, so that it can be washed out when necessary. On account of the action of salt on metal it is not advisable to use plain butt joints or to nail or screw the box together. The work can be simplified by screwing on a plain base, which can be fitted on the outside and screwed from the bottom, or fitted between the sides.

SALT CELLAR. In England the first salt cellar was a large bowl placed in the centre of the table. This was succeeded by a covered vessel known as the standing, or steeple salts, which was a fashionable piece in the 16th and 17th centuries, and was made of silver, rock crystal, and other valuable materials, some being, in addition, ornamented with gold or precious stones. Examples are highly prized.

Salt Cellar. Two beautiful examples of old silver salt cellars, belonging to the period of George III.

The modern salt cellar, which is a smaller vessel, came into vogue about 1700, and has been made in

a great variety of styles. Round, oval, and octagonal examples exist both in silver and in Sheffield plate. Some stand on four feet and others on three, while some are without feet. Others have a square base. The claw and ball, the lion's paw and the stepped cone are among the types of feet found.

Decoration takes the form of embossing, piercing and chasing. Some have beaded and others gadroon edges. Designs such as those illustrated are much copied for modern silver salt cellars; others are made of glass, china, pottery and electro-plate. These metal containers should have glass

linings, otherwise the salt is liable to corrode the silver or plate. Usually made in pairs or sets of four, salt cellars should match in style the pepper and mustard pots in use on the table. With most salt cellars a small spoon is provided. *See* Silver; Table Laying.

SALTING: Of Food. By adopting this method of preservation many foods are kept in good condition which otherwise would rapidly decay. Also many articles of diet which only last for a season can be preserved and become valuable adjuncts to dishes or may form dishes in themselves and help to vary the menu.

To salt food, the dry salt may be rubbed over the surface, or it may be made into liquid brine with water. Salt pork is treated with brine, also beef and occasionally mutton. The brine often has an admixture of saltpetre, sugar and spice.

When meat is plainly salted all kernels should be removed. The meat must be rubbed all over in every part, and any hollows left by skewers or kernels being cut out should be filled up with salt. A round of beef weighing 20 lb. will take $\frac{1}{4}$ lb. salt. Meat should be salted as soon as possible after being killed if the weather is warm, but if the atmosphere is chilly or frosty it should be kept for a few days, and if the frost is in it, it must be thawed before being salted. In very cold weather the chill must be taken off the salt before it is used. To make the meat red, a little saltpetre should first be rubbed over it.

To salt fish, clean and wash it, then dry it thoroughly and cut it open down the back. Wipe it with a clean cloth, score it, and place a layer of salt on it each side. Keep the salt on it three days, then hang it up to dry or smoke it. Sometimes the spine bone is removed from the fish before salting.

Some varieties of green vegetables may be salted and will keep all the winter. The best vegetables to treat in this fashion are French beans or scarlet runners. The beans must be cut on a dry morning, wiped, and laid in earthenware jars in layers with a good sprinkling of salt between each layer. Let salt cover the top of them. Secure them from the air and keep in a cool, dry cellar. *See* Beef; Pickle; Pork.

SALTPETRE. Commonly known as nitre or potassium nitrate, saltpetre is a natural product obtained by the lixiviation of earth, where the occurrence is in the form of an efflorescence; purification is effected by crystallization. It is used medicinally for the treatment of asthma and colds; it is a constituent of some explosives and fireworks, and in chemical fertilizers. Wall or lime saltpetre made by fixation of nitrogen from the air is used as a manure. As a brine, saltpetre is employed in the salting of meat.

Salts. *See* Epsom Salts; Saline.

SALTS OF LEMON. This preparation, which is known also as oxalic acid, consists of equal parts of cream of tartar and potassium oxalate. It is used for cleaning white straw hats, removing iron stains from linen, and fruit stains and other marks from woollen and silk materials. It is exceedingly poisonous, and should therefore be kept well out of the reach of children. Directions for treatment in cases of poisoning are given under the heading oxalic acid (q.v.).

SALUKI. Of this dog there are two varieties, the rough and the smooth, the former being the more popular. The rough coated have feathers on the ears, on the limbs and on the tail, but the smooth dogs are free from this. In height the saluki varies from 24 in. to 28 in. according to the locality of its origin. The females are smaller than the males. In general conformation the breed resembles the greyhound. In colour the saluki is either fawn, cream, white, red, grizzle, black and tan or tri-colour. As a breed they are very nice dogs, usually sweet tempered, obedient and intelligent.

The head should be long and narrow, the eyes dark or hazel, ears well feathered and also the limbs, whilst the tail should have a superabundance of feather on it and be carried in the so-called ring-tail fashion.

Saluki. Specimen of this breed of dog which somewhat resembles the greyhound.

SALVER. There is no hard or fast rule as to the distinction between a salver and a tray, but in general a salver is regarded as a smaller edition of the tray proper. It is used for carrying a single cup of tea or other drink, and also by a servant for presenting a letter or card. A small salver is generally kept for this purpose on the hall table. A larger salver makes a charming addition to the breakfast table when used as a stand for the coffeepot

and hot milk jug.

Salvers are made of silver and Sheffield plate, as well as of electro-plate. In England the earliest known specimens date from the 17th century, but those most in demand by collectors are square ones made in the 18th, and having ball and claw feet. A great variety of decoration was used thereon by the 18th century silversmiths and their successors, these including the gadroon and ornament in the shape of dolphins, masks, shells, scrolls, vine leaves, etc. Old salvers of Sheffield plate are usually tinned on the underside. *See Silver; Tray.*

SALVIA. The botanical name of sage, of which there are some splendid ornamental kinds suitable for the greenhouse and for planting out of doors. The purple sage (*Salvia virgata nemorosa*) is the best of the hardy kinds; it is a showy herbaceous perennial, 2-3 ft. high, with violet-purple flowers in July-August. Propagation is by cuttings in a frame in spring. *Salvia azurea* Pitcherii, 4 ft. high, is a lovely blue-flowered plant for a warm sheltered border, at its best in late summer.

The scarlet sage (*Salvia splendens*) is one of the most brilliant of summer bedding flowers, and is invaluable for the greenhouse also. Seedlings raised in a heated greenhouse in January-February will provide plants for putting out of doors early in June, or cuttings can be taken from the old plants in August and kept safe from frost in winter. Exceptionally fine varieties are *Pride of Zurich*, *Fireball* and *Harbinger*, which should be chosen in preference to the type.

The blue sage (*Salvia patens*) is a half-hardy tuberous rooted perennial easily raised from seeds sown in warmth under glass in February; the seedlings may be planted out of doors early in June, or grown in pots for greenhouse decoration. In autumn the tubers should be lifted, stored in sand for the winter and started into growth again under glass in spring.

The hardy annual sage called the Clary (*Salvia horminum*) is raised from seeds sown out of doors in September or in April; its beauty lies in the coloured bracts which surround the small flowers. The purple-blue variety named *Blue Beard* is the best.

SAL VOLATILE. Aromatic spirit of ammonia, commonly called sal volatile, is a reliable heart stimulant in fainting, shock, etc. It is also sometimes prescribed before meals as a gastric stimulant in chronic indigestion.

SAMIAN WARE. Modern reproductions of the lustrous red terra-cotta fabrics which go by the name of Samian ware are attractive in form, suggesting a classical atmosphere, which is emphasized by the moulded designs and scenic reliefs pressed upon them. This ware was supposed to originate in Samos.

Samian Ware. Portion of a vase found among Roman remains at Manchester.

During the Greco-Roman period the manufacture was taken up by a number of provincial potteries, especially in Gaul and the Rhineland. Almost all the so-called Samian ware found in conjunction with Romano-British remains was imported from these centres and its production did not survive that period.

This earthenware, which is more precisely called terra sigillata, is distinguished by its close-grained body, sometimes showing traces of having been turned in the lathe, and displaying, when broken, a light-red fracture all through. It is coated uniformly with a thin, transparent sealing-wax glaze, which was produced by means of a solution of green vitriol. It is usually ornamented in relief. The vases, bowls, cups and dishes are generally small, and are seldom found unbroken. *See Pottery.*

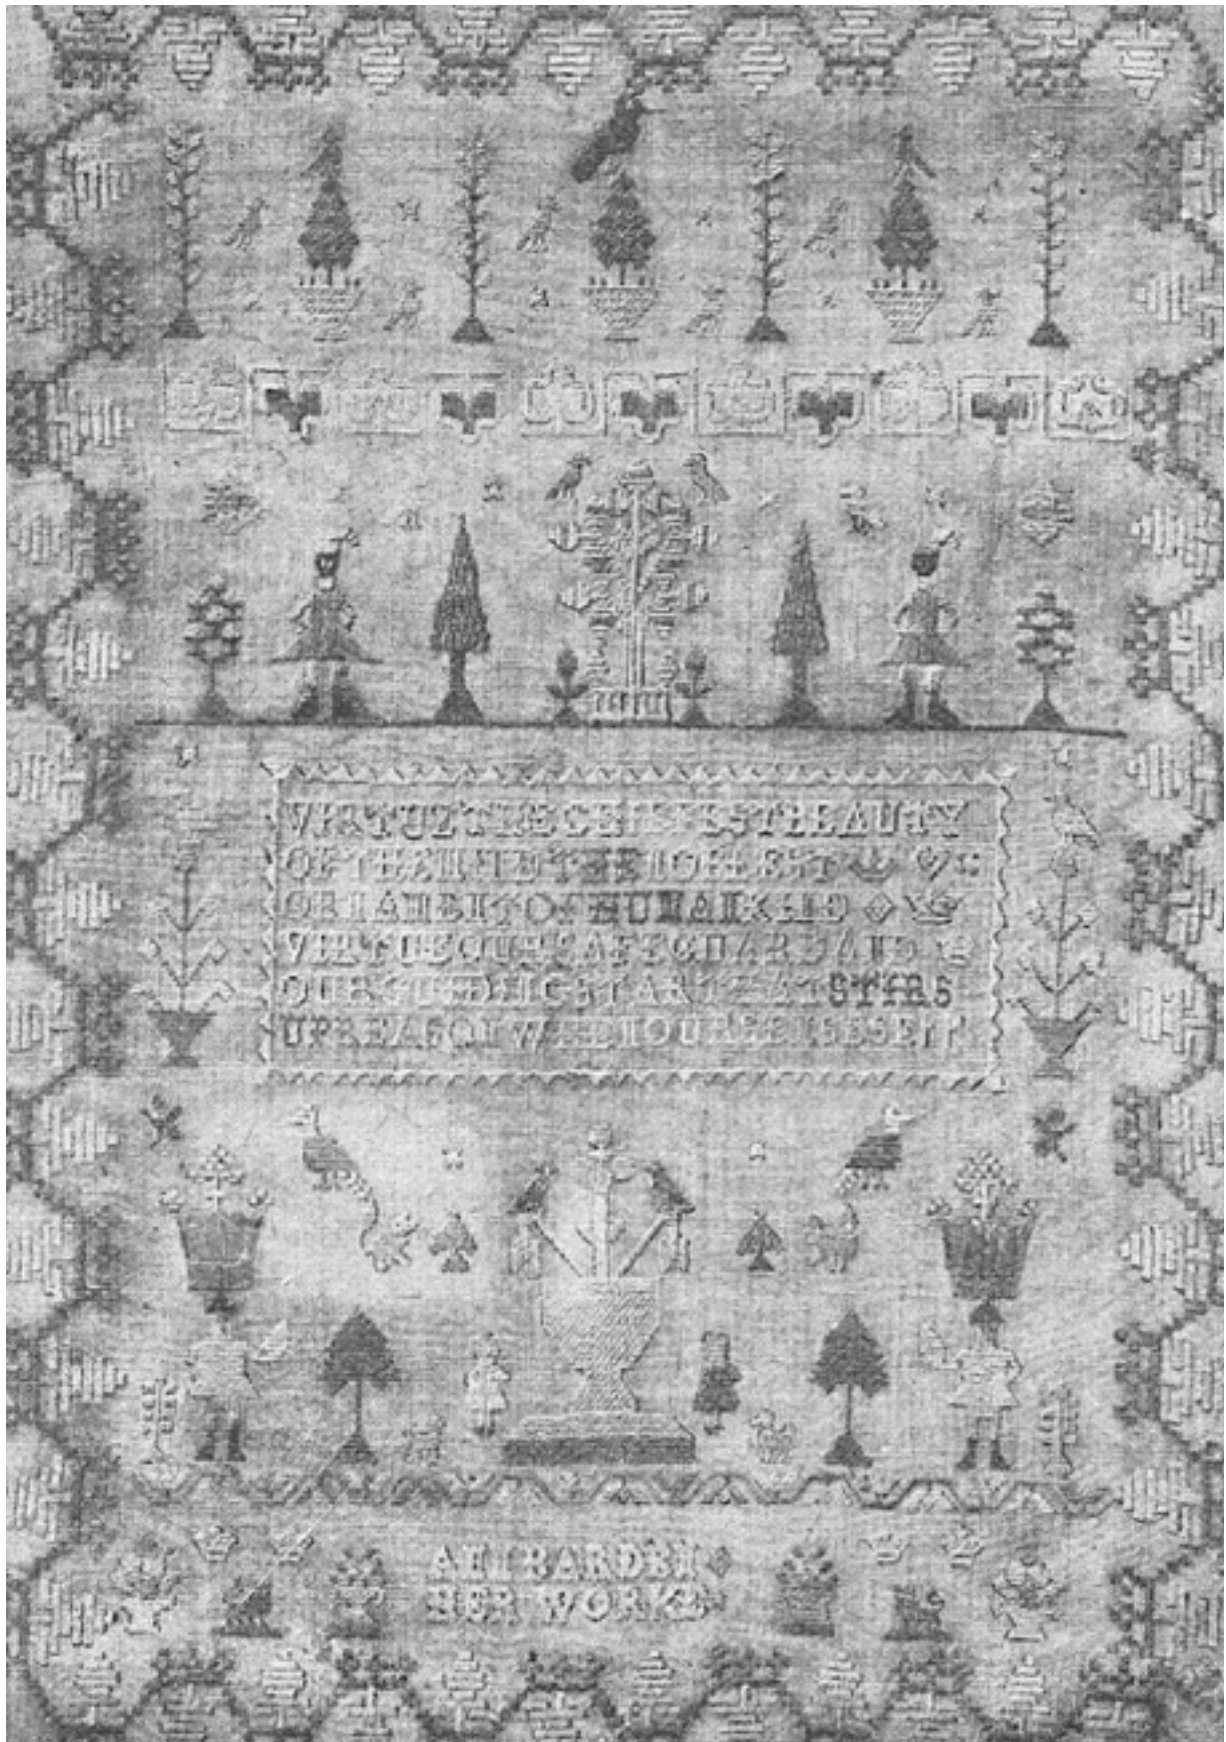

SAMOYEDE. The Samoyede dog belongs to the Arctic breeds, sharing in common with the others a foxy head, small, erect ears, a tail curled over the back, and a close, soft undercoat, through which long harsh hair grows, forming the outer coat. This is usually of a very brilliant white, and is of a texture that does not soil readily. They are smaller than one would expect in dogs that are capable of drawing heavy weights, the males weighing about 50 lb., and bitches about 10 lb. less. Those who own them find that they are very sociable and well mannered. *See Dog, Kennel.*

Samoyede. Breed of white Arctic dog which has become popular in Great Britain.

SAMPLER. In its earliest form a sampler was a piece of work that exhibits in a small space all the stitches and processes of the work which it represents. Calico samplers were provided for the young in early Victorian days in order that plain stitchery should be practised.

A sampler of that kind would exhibit plain hemming, hem-stitching, back-stitching, gathering and setting into a band, pleating, tuckrunning, running and felling, buttonholes and sewing on buttons, whipping and setting on a frill, the insertion of a gusset, piping, how to put on a crossway false hem, an ordinary calico patch, how to sew on a tape, how to make a loop and eyelet hole. Featherstitch and French knots as simple forms of decoration would also be shown.

Sampler dating from 1800, with small figures, birds and trees, embroidered in coloured silks upon fine canvas. In the centre is the following moral verse: "Virtue the chiefest beauty of the mind, the noblest ornament of human kind. Virtue our safeguard and our guiding star, that stirs up reason when our senses err."

Decorative samplers, such as the one illustrated, were worked by old and young from Elizabethan times down to about 1840, after which they went out of fashion. Now that such great store is set on period needle-work again, old samplers are being copied and originals are sought in antique shops. Samplers can be turned to charming account by being mounted on pole fire screens, blotters, work bags, etc. Under Calendars, an excellent idea for a calendar, utilizing a modern sampler in cross-stitch, is illustrated and described. Designs can be obtained in good needlework departments, and those interested in the subject will do well if able to study the examples in the Textiles Department at South Kensington.

Although modern samplers are often worked quickly in cross-stitch, this does not do justice to the beauty possible in these pieces. In a sampler such as the one illustrated a great number of stitches are employed. The proper stitch should be used to form particular objects. Satin-stitch and stem-stitch are used for animals and figures, petit point fills in vases and cross-stitch is reserved for trees and the dark portions of the border. All objects illustrated on a sampler are much conventionalized. Some interesting modern samplers have central motifs of motor cars, speedboats, airships and borders introducing modern musical instruments. In one case these subjects were copied from magazine advertisements on to fine canvas and conventionalized in the stitchery. If preserved, such samplers will have a historic interest in years to come, and to-day make amusing needlework pictures when glazed and mounted in narrow black frames.

SANATORIUM. An establishment for the treatment of the sick may be called a sanatorium, though the name is more especially used for places where convalescents or consumptives are treated. Sanatorium treatment of consumption is valuable, not only because patients are under direct supervision in conditions as favourable as possible, but because the patients receive a proper training in looking after themselves. *See* Consumption.

SAND: In Gardening. Sand is an important ingredient of garden soil. Clay land is greatly improved by an occasional application of builder's sand. Silver sand is used in the preparation of potting composts; plant cuttings often form roots better in sand than in soil.

SAND: In Building. The three main sources from which sand is obtained for building purposes are pit, river, and seashore. The fine sand is used for plasterer's mortar, the more coarse varieties for ordinary mortar. Its function when mixed with mortar is to produce regular shrinkage of the materials, and also channels for crystallization in setting.

Pit sand is the first in quality, and has sharp angular grains. It may contain impurities such as clay, earth, or organic matter. River sand is practically free of impurities, but owing to the action of the water its grains are not sharp and angular. Sea sand is not to be recommended for building work, especially plastering, because the saline matter it holds attracts any moisture that is in the air. This will result in damp walls, and prove injurious to decorating on them. Sea sand is, however, used for bricklayer's mortar, and is very useful in constructing playing pits for the children. *See* Brick; Cement; Mortar.

SANDALWOOD. This is a hard, close-grained, yellowish-brown wood. It has a fragrant smell, which increases with age, and when it is burning there is an aromatic odour. Ground into powder, it is used in cosmetics, and an aromatic oil is distilled from it, and used in medicine as an internal disinfectant. As a wood it is used chiefly for small fancy ware, carved articles, finger plates for doors, etc. *See* Wood.

SANDARAC. Among resins of the lac kind, sandarac is an important substance. It is a hard resin of yellowish tinge which melts at a heat of 300° F. and breaks with a lustrous fracture, exuding from pine trees in North Africa. It is known variously as pine gum, white pine resin, and gum juniper. It is completely soluble in spirits of wine, and practically in petrol and turps. It makes good photographic negative varnish, and is also used by bookbinders and for school blackboards. Being hard, it requires making more elastic by mixing with a West Indian resin known as elemi. This material is much used to soften or toughen varnishes. *See Resin; Shellac.*

SANDBAG. Used in repoussé and art metal work, the sandbag is a leather or linen receptacle filled with well-washed silver sand. The linen or canvas covered bag is useful for supporting the pitch block and deadening the noise made by the hammering. The leather bag of 3 in. to 9 in. diameter is made in two shapes, one with a hollow centre, known as a ring, to hold the pitch or cement bowl used in repoussé work and metal chasing. The other, in the form of a round pad, is used for beating out metal to a hollow form. To preserve leather sandbags, the cover should be wiped over with an oily rag. *See Repoussé.*

Sand Box. *See Pounce Pot.*

SAND CAKE. A variety of cornflour cake, this is made by sieving $\frac{3}{4}$ lb. cornflour, then measuring out 1 oz. of it and mixing it with $1\frac{1}{2}$ teaspoonfuls baking-powder. Separate the yolks from the whites of 3 eggs, beat up the yolks, and stir half of them into $\frac{1}{2}$ lb. castor sugar, previously creamed with 7 oz. margarine. Beat the mixture for 5 min. before adding the remainder of the yolks, continue beating for a few minutes, and then fold in the larger portion of the cornflour.

Add the whites of egg, whisked to a stiff froth, and also a little lemon or vanilla flavouring; mix the whole thoroughly, and lastly stir in the baking-powder and the remainder of the cornflour. A little milk may be used if necessary. Turn the mixture into a greased cake-tin, lined with greased paper that reaches just above the top of the tin, and bake it in a moderately hot oven for about $\frac{3}{4}$ hour. Then take it from the tin, carefully remove the paper from round it, and let the cake cool on a sieve.

SAND GLASS. Sand glasses, which are also known as hour glasses, are used to measure time; for instance, the time needed to boil an egg. *See Egg Boiler; Hour Glass.*

SAND MYRTLE. This dwarf evergreen flowering shrub belongs to the family of heaths, and botanically is known as *Ledum*. The chief kind is *buxifolium*, about 6 in. high, with small, glossy leaves and white flowers, being particularly suitable for the rock garden.

Sand myrtle thrives in equal parts of leaf-mould, peat, and sand, with plenty of moisture at all times. It is planted in spring or autumn, and propagated by layering of shoots in October.

Sandpaper. *See Glass Paper.*

SANDSTONE. Consisting of a compacted mass of sand bound together by lime carbonate, iron oxide and silicas, sandstone as a building material is comparatively soft, lending itself easily to delicate architectural decoration. For this reason it is often carved and embellished, frequently in a very elaborate manner. *See Stone.*

SANDWICH. It is always advisable at a picnic, bridge, or informal evening party to have some less well-known but really good sandwiches to introduce to the guests. When estimating quantities it is

well to allow two sandwiches per head (where other refreshments are also provided). Three quartern sandwich loaves to 3 lb. butter will make sandwiches for 100 people if the bread is properly cut.

Almost any kind of cold meat or fish can be used for sandwiches, while other savoury fillings include cheese, sliced hard-boiled eggs, potted meats, olives and cream cheese, nuts and salad vegetables. Sweet sandwiches may be filled with jam, honey and banana, lemon-curd, walnuts and stoned raisins, grated chocolate, or honey mixed with chopped nuts.

The bread should be thinly cut and fresh, though not too new, or it will break in the making. A very sharp, long-bladed knife should be used. The filling should be laid on one slice, seasoning added if required, the remaining piece of bread pressed firmly on the top and the edges trimmed. For picnic purposes the crust is often allowed to remain as the sandwiches keep a better shape. For afternoon tea or buffet service, the crumb only is left and is cut into square, diamond, or triangular shapes. For bridge parties it is sometimes stamped out with cutters into spade, heart, diamond and club shapes. Plain biscuits, rye biscuits, toast, bridge rolls and briochees are all used for making sandwiches in place of ordinary bread. The first two are good for savoury pastes and cream cheese fillings; thin, hot, toasted brown or white bread is liked for Canadian loaf cheese and for hot bacon sandwiches, while small finger rolls are suitable for any kinds of fillings and briochees for sweet sandwiches. Potted meat or fish paste sandwiches are dainty for tea when the bread used is sufficiently thin and fresh to be rolled.

The bread, biscuit, toast or roll should always be buttered. Butter adds to the food value and prevents juices from the fillings soaking through the sandwich. The butter should be creamed with a wooden spoon before spreading on the uncut loaf. Fillings must not be scanty or the sandwich will be dry and tasteless, but they must not be so lavish that they ooze out. Pack sandwiches for a picnic in waxed paper and wrap wet butter-muslin, or a napkin wrung out in cold water, round the whole until they are required.

Meat Fillings. Meat used for sandwich making should be free from gristle and cut into very thin slices or pieces of convenient size. Ham often improves beef, chicken and tongue. If savoury sandwiches are wanted either tomato sauce, finely chopped pickle or chutney may be spread over the layers of meat. Seasoning must not be forgotten. All kind of sausages, cut into thin slices and the skins removed, make good fillings. Paté de foie gras is a favourite filling. Double-decker sandwiches are liked with a layer of chicken and another of finely-chopped salad moistened slightly with mayonnaise and separated by an extra piece of buttered bread. Grated ham may be used with or instead of the chicken, and both will make an excellent filling for a hot, toasted sandwich. The meat is first warmed in a saucepan with a little butter and chopped parsley and then spread on a piece of buttered toast and covered with another piece.

Fish Sandwiches. Cold fish should be flaked and freed from bones. It requires sauce, or cucumber, tomato or lettuce salad to make it tasty. Bloaters, smoked haddocks and kippers make excellent fillings for brown bread sandwiches. Remove the skin and bones and mix with a little anchovy sauce and cayenne. Lobster or crab is good when pounded and mixed with a little thick mayonnaise sauce. Cod's roe with cream and seasoning makes popular sandwiches. Break up 3 tablespoonfuls cooked roe, season it with anchovy essence, pepper and a squeeze of lemon-juice and moisten the whole with a tablespoonful of cream. Spread the mixture on thin brown bread-and-butter and form into sandwiches.

Sardine sandwiches can be made in several ways. The fish should be drained from the oil, skin and bone removed and pounded, adding seasoning and a squeeze of lemon-juice. An excellent filling is made by adding the yolk of a hard-boiled egg, 1 teaspoonful anchovy essence, 1 dessertspoonful

anchovy paste and 1 oz. butter to the sardines, pounding them to a smooth mixture and spreading on brown or white bread-and-butter.

Egg Sandwiches. The yolks of two hard-boiled eggs make a good filling when mixed with anchovy essence, chopped olives, and sufficient cream or creamed butter to bind the ingredients. Another egg sandwich is made of slices of hard-boiled eggs and tomatoes, or the slices of hard-boiled egg may be moistened with salad cream and placed between two layers of finely chopped salad.

Cheese Sandwiches. Cheese may be grated, mixed with butter and seasoning and spread on a layer of chopped watercress between thin bread-and-butter. Alternatively it may be cut into thin slices, spread with mustard, sprinkled with seasoning and made into sandwiches, with rye crisp bread well buttered and flavoured with chopped gherkin.

Cream cheese is good mixed with walnuts or other nuts, or with chopped olives. Chopped lettuce or watercress, or finely diced apple and celery with cream cheese, may also be used as a filling for thin brown bread-and-butter.

Sweet Sandwiches. Mixed nuts and sweetened whipped cream make a good filling spread over a thin layer of apricot jam on split, sweetened brioche, white or brown buttered finger rolls, or slices of plain cake. Chopped and stoned dates with pounded almonds and lemon-curd make an unusual sandwich with buttered currant bread. Honey may be substituted for the curd if a sweeter mixture is liked. French plums are excellent with walnuts and cream. Chocolate grated and mixed with whipped cream flavoured with a few drops of vanilla essence may be used between thinly sliced bananas and bread-and-butter, or the grated chocolate with pounded almonds and enough sweetened cream to form the mixture into a paste makes an excellent filling for a sandwich of wafer biscuits. Sponge fingers are equally good when put together in pairs with whipped cream and strawberry or apricot jam between.

Sandwich Sets. Practical and decorative sets for sandwich service are obtainable in china, pottery, glass and in a variety of shapes and sizes. The dish for the sandwiches is usually oblong, and plates to match are often square in shape. Small tiered and plated stands to hold several plates of sandwiches are useful for tea and bridge parties, as they take up less space on the table.

SANDWICH CAKE. The phrase sandwich cake is usually applied to a light, spongy cake baked in two shallow tins or cut into two after baking, and then spread with jam. Directions for making such a cake will be found under the heading jam sandwich. Cream, chocolate icing and other mixtures are sometimes used as a filling instead of jam, the cake being then named accordingly. *See* Jam Sandwich.

SANDWORT. The popular name of a group of beautiful low-growing rock-garden plants (*Arenaria*) which bloom in spring and early summer. The finest of all are *montana* and *grandiflora*, which soon spread if planted in gritty soil in a sunny place and bear a profusion of white flowers. The Balearic sandwort (*Arenaria balearica*) should be planted in light soil at the foot of a shady rock, which it will cover with a veil of delicate leaves and tiny white flowers. Propagation is by seeds sown in spring in a frame.

SANITATION: Of the House. The important points about any system of sanitation are to see that the refuse of whatever kind is removed completely, rapidly, and continuously, and that it is protected as much as possible from the outside air. Methods used in the country where sewers do

not exist are called conservancy methods, and in towns where sewers and a plentiful water-supply exist, the water carriage system is used. In both of these systems waste waters and excretal refuse have to be removed.

Conservancy Methods. Dealing first with conservancy methods, the old types known as privy middens and privies are thoroughly insanitary and should be abolished, as the material is never completely or rapidly removed, and is not protected from flies, etc. Earth closets and pail closets are less objectionable and can be made reasonably sanitary if emptied frequently, at least twice a week, and kept scrupulously clean. The material should be dug into trenches well away from the house or any source of water supply, and should be covered with at least four inches of earth.

Bath and washing water should not be allowed to run into the nearest ditch, where it may give rise to a nuisance, but should be run through a series of porous drains at a depth of about 6 in. below the ground. This is better than running it on the surface of the soil. At the house end of the pipes a grid should be fixed to strain off large particles, which might clog the pipes if left undisturbed.

Cesspools should be connected with the house in the same way as a sewer. They should be placed at a safe distance from the house or water supply, and must be ventilated, and constructed so as to be watertight. Periodic removal of the contents of the cesspool is necessary if the water supply of the house is small. If taking the waste water of the house also, the overflow pipe may lead the sewage either under specially prepared land or on to a proper filter-bed, but care must always be taken that the water supply is safeguarded.

Water Carriage System. Coming next to the water carriage system, this is the ideal method, as refuse is carried away completely, and rapidly by a flow of water. The main drain is partly below and partly above ground. The latter part is called the soil-pipe and is carried well above the roof of the house and covered by a wire cage to prevent birds from building nests and blocking it; the open top allows air to circulate through the drainage system. Into the soil pipe open the discharge pipes for water closets, slop sinks and urinals, all of which have a proper trap, with an adequate seal of water to prevent drain gases getting back into the house.

Baths, washing and kitchen sinks must also have a trap, but they discharge into a pipe on the side of the house, distinct from the soil pipe, and then into a gully. This gully is again trapped before discharging into the main drain. Rain water sometimes has a pipe to itself discharging into a gully. The different discharges finally reach the drain and then pass through a final trap before entering the sewer, so preventing sewer-gas from entering the house drain.

The householder can always obtain the help of a sanitary inspector from the health office of the local authority, and would be well advised always to have a thorough inspection undertaken before entering a house. In particular it is necessary to have the drains tested by a competent inspector.

The matters that the householder himself can decide are to see that all sanitary appliances are made of smooth, impermeable material; that the water closet is of good type; that the flush is adequate; that the traps are sound, actually contain water and are not blocked; that outside and inside pipes and taps do not leak and are of sound material, and that lavatories are well-ventilated and in the right position. The sanitation of a house requires considerable supervision. All appliances, and water-closets in particular, must be kept clean. The pan of the latter can be cleansed at intervals with a rag moistened with spirits of salt, or by using one of the powder preparations advertised. If an accessible trap gets blocked it may be cleared by unscrewing the stopper which is at the bottom of the trap; but this is only possible with the traps of sinks, basins, and baths.

The kitchen sink and its trap can usually be kept clean by pouring down it every week a pailful of boiling water containing $\frac{1}{2}$ lb. of soda. A smell in a sink can be removed by pouring in a pailful of hot water containing a tablespoonful of permanganate of potash and allowing it to stand for a

couple of hours. Grids over gullies and pipe heads must be kept clear of leaves and debris. Gullies in the open must be cleansed regularly, and in summer when the water in the seal may evaporate, they should be flushed with water.

The Chemical Closet. This closet uses exactly the opposite principle to the dry earth closet; reliance is placed upon liquid chemicals for the immediate sterilization and the disintegration of sewage and paper, so as to produce an inoffensive liquid.

There are two kinds generally in use the portable and the permanent. The former consists of a ventilation chamber through which an air draught carries any chemical fumes to the outlet pipe at the back of the seat. The inner container is provided for the reception of urine and excreta. For operation in this case, a charge of 1 pint of chemical is added to 1 gallon of water and placed in the container. The matter entering the container becomes deodorized and sterilized. When full the contents may be disposed of in a similar way to that employed in the earth closet. The sewage may, however, be used as a manure after it has been mixed with slacked lime, decayed vegetation, and earth. This type of chemical closet is largely used in motor coaches, aeroplanes, small cottages, etc. The second type is for buildings of a more permanent character where no sewers exist. An underground tank is provided into which the closets empty direct. When the tank is full, the contents are disposed of by opening an outlet valve which lets the contents discharge into a soakaway, where it percolates into the earth. Should the soil not be suitable (e.g. clay), then an ordinary cesspool is used from which the contents are discharged over the earth, or it may be carried away to any convenient place for disposal. *See Cesspool; Drains; Earth Closet; Pipe; Septic Tank; Water Closet, etc.*

SANTOLINA. The botanical name of a group of hardy shrubs with fragrant leaves and daisy-like flowers in summer; they grow 18-24 in. high, thrive in ordinary well-drained soil, and make attractive low hedges, or may be planted in the rock garden. The chief kinds are the grey-leaved, yellow-flowered *Santolina chamaecyparissus* and the green-leaved, white-flowered *viridis*. Propagation is by cuttings in a frame in late summer.

Santolina. Soft downy foliage of the species *chamaecyparissus*, attractive in the rock garden.

Saponaria. *See* Soapwort.

SAPPHIRE. Sapphires are found in almost every shade of blue. In some specimens a blue-violet tint is seen, in others cornflower blue. The last named are the most highly prized. Large sapphires are generally cheaper than rubies of the same size, but a flawless sapphire of a deep shade always commands a high price. The value of the gem is best judged at night, because the cheaper stones lose their blueness, and some of them appear almost black in artificial light; but good stones retain their colour.

Rings, brooches, pendants, and bracelets are all set with sapphires. Diamonds are almost invariably used with them for the intense blueness of the sapphire accentuates the whiteness of diamonds by contrast.

Stones that are sometimes confused with sapphires include the blue tourmaline and the blue topaz. These, of course, are inferior gems, and usually may be detected by their lightness. They are also softer than the genuine stone, and are therefore more easily scratched. *See* Diamonds: Jewelry.

SAP WOOD. The wood of very young trees, known as sapwood, is generally light in colour and porous. In some trees the colour changes very little indeed as the tree grows older and such are called sapwood trees. They are found in Great Britain among the sycamores, beeches, and hollies. Although sapwood may be regarded as imperfect timber, there are one or two cases in which its value is considerable, exceeding that of heartwood or wood that is completely mature. For instance, the sapwood of the hickory has a greater value for handles and the like than the heartwood. Many of the American woods are noted for their abundant sapwood, notably the satin walnut, the loblolly pine and the basswood. *See* Wood.

SARDINE. Among the cheap varieties of the so-called preserved sardines, sprats, very small herrings, brisling or pilchards are substituted for the real fish. None of these, however, possesses the delicate flavour of the true sardine, which is caught off the coasts of Brittany and Sardinia from June to the middle of October, and is, as a general rule, preserved in oil or tomato sauce and exported.

Sardines are useful as a savoury, also for serving as hors d'oeuvres and in salads. Sardine mustard, which is employed to give a zest to fish dishes and also for spreading on savoury biscuits, is made by pounding the sardines and mixing with hard-boiled eggs, chopped shallot, dry mustard, oil and seasoning.

A good way of preparing sardines consists of cutting the tails from a small tinful of these fish, removing the bones and then flaking the flesh into small pieces. Melt 3 oz. butter in a saucepan, add 1¾ oz. flour, mixing it well in, and then pour in gradually 1¼ pints white stock, stirring all the time until the mixture boils.

Then cook it slowly for a few minutes, add to it the flaked fish, a teacupful of breadcrumbs, a little of the oil from the tin, 3 teaspoonfuls tomato sauce, a squeeze of lemon juice, and salt and cayenne to taste. Mix all these ingredients together, then turn them into a small pie-dish, sprinkle the top with browned crumbs and reheat in the oven.

Fried and devilled sardines make another good dish. The fish should be split open, boned, and folded together again, then sprinkled with dry mustard, cayenne, salt and lemon juice and allowed to stand for about 15 min. They should then be fried in a sauté pan in their own oil and served on croûtons of fried bread. Another method of frying sardines is to skin them, dip them in batter, and then cook them in a pan of smoking hot fat. Serve garnished with parsley.

To grill sardines, drain them from their oil, coat them with sieved flour, and then cook them before a clear fire or beneath a gas griller for 4 or 5 min. Serve them immediately with a plate of brown bread and butter, garnishing them with lemon. Sardine eggs can be made in the same way as anchovy eggs, substituting sardines for anchovies.

To make a sardine omelette add 3 or 4 chopped sardines and a teaspoonful anchovy essence to a plain omelette mixture and cook as described under omelette.

Another savoury can be made by removing the bones and skins from eight sardines. Then take some thin slices of brown bread, butter them, and cut them into fingers, each rather larger than a sardine. Place each sardine between two of these fingers, press them together, and fry a golden brown in hot fat.

To prepare sardine toast, remove the heads and tails from 4 sardines, split the fish open, and take out the backbone. Then lay the halves together again, heat them in the oven, and place on finger-shaped pieces of hot buttered toast.

Keep them hot, and in the meantime melt $\frac{1}{2}$ oz. butter in a small saucepan, add to it 3 yolks and 1 white of egg whisked together, 3 teaspoonfuls vinegar, and a little salt and cayenne. Whisk this mixture over a slow fire until it becomes thick and creamy; take care that it does not boil, or the eggs will curdle. Pour it over the sardines, sprinkle with chopped parsley and red pepper, and serve. Sardines and tomatoes on toast may be prepared in the same way, except that a little mashed tomato is spread over the toast before the sardine and the egg mixture are added. *See* Hors d'Oeuvres; Omelette; Sandwich.

SARDONYX. This is a particularly beautiful variety of onyx, composed of alternate layers of white or light-coloured chalcedony and rich, orange-brown cornelian. *See* Onyx.

SARSAPARILLA. The dried root of a tree imported from Central America, and known as Jamaica sarsaparilla, has been used medicinally, but it is not now included as a remedy in the British Pharmacopoeia. In the dried form it would appear to have no medicinal properties.

Sarsaparilla is a common ingredient of many tonics and blood purifying mixtures, in which other drugs are included. Common preparations are: The liquid extract of sarsaparilla, dose, 2 to 4 fluid drams; the concentrated compound solution of sarsaparilla, dose, 2 to 8 fluid drams. The drug is in no circumstances prescribed by itself. Pron. Sar"sa-pa-ril'a.

SARSENET. The name has to a large extent dropped out of use, because old-fashioned sarsenet has been superseded by Jap silk, white, black, or coloured. The material is a plain, thin, and rather shiny silk. Sarsenet ribbon is suitable for making soft binding for the edges of dress seams, perambulator rugs, cot blankets, and so on.

SASH WINDOWS: RENEWING THE CORDS

Practical Instructions for Carrying out Repairs

With the aid of the illustrations and directions here given, the amateur mechanic will be able to keep his sashes and cords in order. *See* also Burglary; Casement; Glass; Window.

A sash window is a type of opening and closing window in which the upper and lower windows are weighted to facilitate their movement in an upward or downward direction. The window is balanced by means of heavy iron or lead weights, arranged to move up or down in a well in the framework. Two such weights are used to each moving window, being arranged one on either side of it. The weights are connected to the window with sash cords, which pass over grooved pulleys sunk flush with the framework. The pulleys are placed at the extreme top of the framework.

In modern work both upper and lower sashes are movable, but in some of the old designs only the bottom sash is arranged to move, consequently the ventilation of the room suffers.

The sashes are arranged in the frame so that they pass each other as they are raised or lowered. They slide in grooves formed by the casings of the frame, and are suspended on sash cord. Although between the sashes there is a parting slip, the centre rails of the sashes are arranged so that they meet, and they are splayed so as to form a good fit in order to prevent them rattling, and to make them wind and water tight. It is on the centre rail that the fastening is fixed in order to keep the window closed.

The sash cord is attached to the window by means of 1 in. wire nails hammered through the cord. An alternative method to this employs a screw and washer which is turned home at the end of the cord. A circular recess is usually made in the side of the window in which this screw is placed. Two

common methods are used for the attachment of the cord to the weight. One has a loop threaded through an eye in the top of the weight, the free end of which is bound to the length of the cord with fine string. The other method simply has a knot tied at the end of the cord after it has been passed through the eye in the weight.

Where this second method of construction is employed care must be taken to prevent any free end of cord from fouling the movement of the weight. The weights used for window sashes are extremely long and thin, in order that they may slide in the small space in the frame allotted to them.

Repairing the Sash Cord. It sometimes happens that a sash cord breaks after the windows have been in use for some time; consequently the balance weight will fall, and the sashes will be hard to move. It is not a difficult matter, however, to replace a broken sash cord, and the process is clearly shown in the photographs on the next page.

Figs. 2 to 10 illustrate the renewal of the cords in top and bottom sashes of the double window frame, shown at Fig. 1. Proceeding with the lower window first, it should be raised some distance, and if it shows any tendency to drop down, it should be kept up with a stick of wood. In the majority of cases this precaution is not necessary, as the defective sash usually jams readily.

The bead at the bottom of the window frame is removed with a chisel. The tool should be placed as nearly as possible under the nails holding the bead down. To prevent damage to the paintwork the point of a knife should be used to break the joint between bead and sill before prizing up the bead.

One of the side beads is next removed, when the lower sash may be swung clear, and the broken cord removed from the frame. The fitting of the new sash cord is carried out as detailed below for the top sash.

In cases where it is only necessary to repair the top sash, the bottom sash must also be removed, this being done first (Fig. 2). When detaching the cord, take care that it does not come away suddenly, as if that should happen the weight would drop, pull the cord right through the pulley, and be lost inside. When the cord is nearly off it should be finally removed by hand, and a knot tied in it to prevent any risk of losing the end.

Removing the Top Sash. The top sash may now be removed, as in Fig. 3, by prizing away the parting slip. Fig. 4 shows the sash taken out, with the broken cord. An opening at the bottom of the frame is normally covered by a fillet, which has to be removed, but is frequently difficult to find owing to its being covered with paint. A few taps with the hammer will crack the joints, when it may be removed, as in Fig. 5. The weight is disclosed behind this partition, and is then removed, as indicated in Fig. 6.

In order to fit the new cord a length of a more flexible material is first run over the pulley and down the space inside. A piece of chain or a "mouse" is used with a length of string, to one end of which the cord is attached. The mouse is a long, thin leaden weight, small enough to pass over the groove in the pulley, and having a loop at one end for the attachment of the string. The other end of the string is securely fastened to the new cord. The mouse is pushed over the pulley and drops down into the weight box, carrying with it the string. Fig. 7 illustrates the use of a piece of chain for the purpose.

Having pulled the cord through to the hole from which the weight was withdrawn, this end of the cord is joined to the weight. In Fig. 8 the method adopted is to bind over the free end of the cord with strong string. The free end of the new cord is left hanging while the old cord is removed from the sash. This latter operation is performed with a small cold chisel and a hammer, as shown in Fig. 9 below.

Sash. Fig. 1. Set of double windows of which the sashes are to be repaired. Fig. 2. Removing lower sash from framework. Fig. 3. Removing parting slip, after which top sash may be swung out of frame. Fig. 4. Showing broken sash cord. Fig. 5. Removing fillet in frame to give access to weight pocket. Fig. 6. Weight being removed from pocket. Fig. 7. Chain being used to run new cord over pulley. Fig. 8. Method of attaching new cord to weight. Fig. 9. Removing old cord with hammer and cold chisel. Fig. 10. Fixing new cord to sash with nails.

The exact length to cut the new cord requires careful consideration. If it is not long enough, the weight will be drawn to the top before the window is closed, in the case of the bottom sash. If the cord is too long a top sash will not close,

owing to the weight having already reached the bottom. The best plan is to make a rough measurement of the length of the cord tacked to the sash, and to mark this length downward from the top of the pulley. The new cord is now pulled up until the weight swings clear. The cord is placed against the mark and is cut about 3 in. above the mark.

The method of securing the cord to the sash is shown in Fig. 10. It is placed in the groove in the sash designed to take it and then tacked on with 1 in. wire nails. During this operation it is important to see that the end of the cord is carefully tucked out of the way, as it may subsequently cause trouble by jamming if left loose. A nail or two at the very end of the cord will obviate any possibility of trouble in this direction. Where new sash cords are fitted on both sides of the sash they must be of the same length.

The replacement of the sashes will not present any difficulties, as the operations are the reverse to the dismantling processes. In a double window, as shown in Fig. 1, one sash should be finished before tackling a similar window on the other side, in order to avoid confusing the beads or even the sashes. The depressions made by the nails in the fillets may be filled in with putty, which is brought up level with the woodwork. If the work is carefully done a coat of paint will hide any trace of removal or replacement. While the new cord is out it is a good plan to rub it over with linseed oil.

SASH CRAMP. This is a tool used by woodworkers for cramping up a framework of considerable size. All patterns comprise a stiff metal bar having one adjustable jaw, which can be moved along the length of the bar and secured by a tapered peg or wedge. The fixed head comprises a clamp screw, which forces a movable head along the bar.

The work to be cramped is placed between the jaws and the movable jaw secured by the pin on the side of the framework. The screw is rotated and pressure brought to bear upon the frame by means of the sliding head. Generally, two of these cramps are needed for a frame, so that equal pressure may be exerted on each end.

Sash Tool. A special type of brush known as a sash tool is adapted for painting the sashes of windows. *See Paint.*

SASSAFRAS. The dried root of the sassafras tree contains a volatile oil which gives it an astringent aromatic taste. Sassafras is practically never used internally except as an ingredient of the concentrated compound solution of sarsaparilla. The oil is used to destroy lice and nits, which it does very effectively. It is also used in the treatment of ringworm.

A few chips of sassafras or wood added to ordinary tea are said to have a beneficial result if taken by persons suffering from rheumatism. Sassafras leaves abound in mucilage, and can be used for thickening soups.

SATEEN. Cheap satin that is half silk and half cotton is often called sateen to distinguish it from the more expensive all-silk satin. Cottons made with a satiny face and used principally for linings are called sateens. They show a more or less fine, round twill. They are dyed in a variety of colours, and are also obtainable patterned. Close-woven cotton sateens are suitable for covering down quilts, and the best are exceptionally close-textured, and sold as down proof, implying that the feathers will not work their way through.

SATIN. This fabric has a shiny surface, with a short nap which hides the thread structure more or less completely. Pure silk satin drapes better and is softer to the touch than either cotton backed or artificial silk satin. The last kind is most useful as a furnishing fabric.

Wool back satin is chiefly used for dressing gowns and for frocks and coats for small children.

SATIN FLOWER. The satin flower is a hardy perennial plant, excellent for small herbaceous borders, because of its neat habit, graceful growth, and bright flowers. It has narrow leaves and thickened rootstocks.

Satin Flower. Delicate blue flowers and spiky leaves of Sisyrinchium Bermudianum.

The best known species is *Sisyrinchium grandiflorum*, with purple or mauve flowers in spring; height about 1 ft.

The white form, *album*, makes charming clumps in the herbaceous border, and is also suitable for the rockery. *S. angustifolium*, with narrow leaves, and pale blue flowers in summer, and *Bermudianum*, blue, is also worth growing.

Satin flower does well in loam with a liberal admixture of

leaf-mould and sand. Propagation is by seed and by division in spring.

SATIN WALNUT. This is the name given to the wood of the sweet gum, a common tree in the swampy parts of the lower Mississippi valley, where it grows to a large size; it is also found in most parts of the United States. The tree is similar in appearance to the maple, but it exudes a liquid known as red gum or liquidambar. When cut the timber is of a brown shade, varied at times and occasionally marked with black stripes.

On account of its even, straight texture and the widths in which it can be obtained (up to 18 in. with an average of 14 in.), it is a useful wood for the amateur. It is used for furniture making, fretwork, and wood-turning; it is easy to work, takes a good polish, stains well and forms strong glued joints. The wood is liable to warp and twist, but with proper seasoning this can be reduced to a minimum. In working satin walnut, it is advisable to cut up the material some time before it is planed, but the wood should be kept in a warm room and not allowed to get damp.

Satin walnut can be used for carving on account of its soft cutting and even grain. It is also made up in the form of plywood. *See* Plywood; Walnut; Wood.

SATINWOOD. The varieties of satinwood are named after the part of the world from which they come. Satinwood is used as a veneer, for small cabinets, in fretwork and inlaying, and for the backs of hair brushes and other fancy articles. In colour it is light orange, and has a close, smooth grain with a lustrous, mottled and satiny surface, and a transparent appearance.

Satinwood works well, but takes glue rather badly, owing to the dense nature of the wood; it polishes well, and a fine finish can be obtained on it. Adam, Hepplewhite and Sheraton used the wood freely, but, owing probably to its scarcity, in small quantities. It was employed in conjunction with mahogany and fancy woods of all kinds, such as amboyna, tulip wood, and purplewood. Designs were often painted on satinwood pieces. When the satinwood is carefully selected its beautiful marking or grain requires little or no decoration beyond a banding or border of mahogany. *See* Inlaying; Marquetry; Pier Table; Sheraton; Veneer; Wood.

SATSUMA WARE. This is the highest class of Japanese pottery, and as the name is freely applied to the productions of other factories, as well as to modern counterfeits, the utmost caution is needed in the purchase of pieces so named.

Some Satsuma ware has ivory gleam with low-toned pigments, and minute pencillings in gold. Another type was produced in pure white, with a network of lines in the glaze surpassing the intricacy of Chinese crackle. Some red-clay bodies were decorated with yellow or black monochromes, especially for incense boxes and tea jars.

Others were coated with metallic flambé glazes, displaying reds and violets, and other combinations resembling shot silk. A class of faience produced during the 19th century is decorated with opulent enamelled colours and gold, is often vellumlike, or has coloured glazes.

The genuine ware, which is never porcelain, is sometimes claimed to go back to the 15th century. It may be recognized often by the string mark on the base, showing where the piece was detached from the wheel, and also by the fact that the spirals in the paste turn from left to right, because the wheel was rotated by the Satsuma potters with the left foot.

The pieces were always small. Some of the better examples of modern Satsuma are produced in the studios at Kobe and Tokyo, and are highly prized by connoisseurs. These pieces are not to be confused with the regular industry which has existed for many years in Yokohama, Kyoto, Awata, and other pottery centres in Japan, engaged in fabricating for export modern pieces of so called Satsuma. They can be readily detected by their poor workmanship, their coarse decoration, gilding, large, size, and their yellowish tinge. *See* Pottery.

Satsuma Ware. Vase in modern white Satsuma ware with crackled surface and slightly raised design.

SATSUMA: CHOICE SPECIMENS OF THE JAPANESE WARE

1. Vase, middle period. 2. Cylindrical flower vase, early period. 3. Gourd-shaped bottle, middle period. 4. Flower pot, close of 17th century. 5. Teapot, late period. 6. Tea bowl, late period. 7. Sweetmeat box, early period. 8. Basket glaze, about 1660. 9. Tea bowl, late period. 10. Covered vessel and stand, late period. 11. Dish, middle period. 12. Jar and Cover, middle period. 13. Old red ware, 1600. 14. Sweetmeat box, late period. 15. Takatsu glaze, 1600. 16. Perfume-burner, 1700. 17. Vase, late period. 18. Cylindrical vase, late period. 19. Hibachi, or heating jar, late period. 20. Vase, late period. 21. Vase, middle period.

SAUCES AND SAUCE MAKING

Recipes for Piquant, Savoury, Sweet and Store Sauces

From these foundations most sauces can be made by adding different flavourings and seasonings. See also Apple; Brandy; Bread; Cranberry; Espagnole; Hollandaise; Horseradish; Maître d'Hôtel; and Mint Sauces. In connexion with the Store Sauces, the entries Apple; Chutney; Ketchup; Pickle; Soy; Vinegar, should be consulted.

Sauces, savoury and sweet, are the liquid accompaniments to meat, fish, poultry, vegetables; sweet puddings and dessert. The savoury sauces differ from gravy in that gravy is the juice extracted from the food cooked, sometimes thickened with a little flour, whilst sauce is a mixture of thickened stock or milk and fat, with seasonings added.

There are numerous sauces to serve with all cooked foods, but with the exception of the few which have for their bases oil, wine or vinegar, or fruit (viz. mayonnaise, Hollandaise or mint sauces; apple, cranberry, gooseberry, etc.), they are all variations of two standard foundation sauces—brown and white sauces.

For successful sauce making it is necessary to use the very best ingredients. Margarine should never be used in place of butter, as it is too oily and does not mix smoothly with the flour. The flour must be a good white, especially for a white sauce, otherwise it will be a dirty, unappetizing colour. It must be quite dry and free from lumps.

Care must be taken not to overcook the fat, as this will spoil the flavour and cause globules of oil to rest on the sauce; it will also be indigestible. The flour must always be blended smoothly with the fat before any liquid is added. Flour must be thoroughly cooked, otherwise the sauce will have a rough, raw taste. All sauces containing flour should be cooked at least five minutes after adding the liquid. For savoury sauces at least half the liquid added must consist of brown or white stock. Care and judgement must be used in seasonings. Too much will destroy the distinctive flavour of the sauce; too little will make it insipid. The best rule is to taste it during the making.

White and Brown Roux. A white or brown roux is the thickening for white or brown sauces. The roux consists of the first mixing of the flour with the fat. In white roux care must be taken not to cook the flour until it browns; in brown roux the fat and flour are cooked until they turn brown. There are other liaisons, or thickenings, for sauces, such as eggs, arrowroot or cornflour mixed with water, or a blend of raw butter and flour, but for standard foundation sauces white or brown roux is generally used.

When sauce is frequently required it is a great saving of time to keep a quantity of white and brown roux ready made. It will keep for weeks if tightly covered. A heaped-up tablespoonful of roux will thicken a pint of liquid. The roux when wanted should be slightly heated by the side of the fire, and the heated liquid added slowly, stirring until boiling.

To make white roux to thicken half a pint of liquid, weigh 1 oz. flour and 1 oz. butter. Melt the butter in a thick saucepan, and then stir in the flour very gradually. Let it cook for several minutes, stirring all the time, until it becomes a smooth creamy paste, but be careful it does not change colour.

Brown roux is made in exactly the same way except that it is cooked longer to brown the flour, and to hasten this the heat may be increased, though it will need constant watching and stirring. When time is short the flour can be browned first in the oven, but as it burns very quickly it must be carefully watched and turned over to brown evenly. If the roux is for immediate use, the liquid (milk, or milk and water; stock, or stock and water) is added at this stage. Then it is only necessary

to add the seasonings and flavourings to achieve the particular sauce you wish to make. All sauces are smoother if strained through a fine pointed strainer, or tammy cloth, unless they contain parsley, capers, or other solid ingredients that must be kept in.

Unless sauces are served immediately they are apt to go lumpy, stiff, or form a skin on top. To prevent this, and also to keep the sauce hot, the saucepan containing it should be stood in a larger pan containing hot water to come half-way up the saucepan. The sauce should be covered with a lid, and if it is a thick sauce a little piece of butter, or a spoonful of the liquid from which it is made, placed on top of it. This prevents a skin forming, and can be stirred into the sauce before serving. If a bain-marie is available, it is the best means of keeping the sauce hot.

Foundation White Sauce. After making the white roux as already described, add slowly $\frac{1}{2}$ pint liquid (milk or mixture of milk and water; white stock or fish stock and water). Stir until boiling and cook for five minutes, add salt and pepper to taste, and use.

From this foundation sauce can be made Anchovy, Parsley, and Caper sauces. (See entries under separate headings in this work.) Also, Onion sauce (2 large onions, boiled, drained and chopped, added to $\frac{1}{2}$ pint white sauce); Egg sauce (1 hard-boiled egg, chopped, added to $\frac{1}{2}$ pint white sauce); Mustard sauce (2 teaspoonfuls dry mustard added with flour when making sauce); Cheese sauce (2 oz. grated cheese added to $\frac{1}{2}$ sauce); Celery sauce (add 1 small cooked and chopped head of celery to $\frac{1}{2}$ sauce). When white sauce is to be used for fish it should be made from fish stock, or half fish stock and milk.

Béchamel Sauce. This is a rich white foundation sauce. To make it, take $\frac{1}{2}$ pint milk or equal parts milk and white stock, or fish stock, 1 oz. butter, 1 oz. flour, 1 tablespoonful cream, a small carrot and same quantity of turnip, 1 small onion stuck with cloves, a few sprigs of parsley and a bay leaf, salt and pepper.

Make the roux with butter and flour. Put milk in a saucepan with prepared vegetables, parsley and bay leaf, and simmer 15 minutes. Then strain, and add liquid gradually to the roux, stirring all the time until boiling. Cook for five minutes more, season well and strain. Re-heat and add cream, and use as required. Use fish stock if for fish.

Melted Butter Sauce. This must not be confused with white sauce. It is a sauce in which butter is the chief ingredient, and is served with salmon or other choice fish, and with some vegetables. To make it, put into a small saucepan 1 oz. butter, melt it and add 1 oz. flour slowly, then add a teacupful water and the juice of $\frac{1}{2}$ a lemon. Season with salt and pepper and cook for another five minutes, stirring all the time, then add a little grated nutmeg and 3 oz. more butter. Stir until the butter is melted, but do not boil again. Milk should never be added to melted butter.

Allemande or Yellow Sauce. Half pint Béchamel sauce, yolks of two eggs, 1 tablespoonful cream, 1 teaspoonful lemon juice, pinch nutmeg. Mix the egg yolks and cream together and mix into the Béchamel sauce, away from the heat. Re-heat without boiling, then add the lemon juice and nutmeg. Stir well and serve.

Bearnaise Sauce. Half pint Béchamel sauce, 2 tablespoonfuls vinegar, 2 finely-chopped shallots, $1\frac{1}{2}$ oz. butter, 2 egg yolks, $1\frac{1}{2}$ tablespoonfuls stock.

Put vinegar in a small saucepan, add shallots and boil until vinegar is reduced to half. Stir in the hot Béchamel sauce. Beat up the egg yolks with the stock, and strain into the sauce. Whisk over gentle heat until well blended, but do not boil. Remove from heat and mix in the butter a small piece at a time. Season and pour through a strainer. Do not re-heat after adding the butter as it will curdle.

Soubise Sauce. Half pint Béchamel sauce, 4 onions, boiled, well-drained and chopped, 2 tablespoonfuls cream. Mix all well together and re-heat slowly.

Tomato Sauce. Half pound tomatoes, ½ pint Béchamel sauce, pinch sugar. Bake the tomatoes in a gentle oven until soft, rub through a sieve and add the pulp to the hot Béchamel sauce. Add about half a teaspoonful sugar, stir well and re-heat.

Velouté Sauce. Half pint Béchamel sauce, 1 teaspoonful lemon juice, 4 bay leaf, 4 peppercorns, 1 tablespoonful cream. Simmer the Béchamel sauce with the bay leaf and peppercorns for 10 minutes, strain and return to the pan to re-heat. Add the lemon juice and stir in the cream, re-heat, but do not boil.

Shrimp, Oyster, Lobster and Crab sauce are made from velouté sauce made with fish stock. Add 6 chopped oysters, or 2 oz. chopped lobster or crab, or a gill of picked and chopped shrimps to ½ pint velouté sauce, as required. A little lobster butter added to lobster sauce is an improvement. *See Lobster.*)

Foundation Brown Sauce. This is the groundwork for many savoury sauces. Take 1 oz. butter, 1½ oz. flour, 4-pint brown stock, 1 small onion, piece of carrot and turnip seasoning.

Make the brown roux as described. Fry onion lightly and add to roux. Add stock away from heat, then add the chopped vegetables and seasoning, simmer for half an hour, then strain and make thoroughly hot to serve.

Chasseur Sauce. This rich brown sauce, served with venison, is made by boiling together ½ pint brown sauce with 1 gill port wine, 2 oz. red currant jelly, 1 oz glaze, a squeeze of lemon juice and a dash of cayenne. When liquid is reduced to ½ pint, strain and serve.

Chestnut Sauce. This is made by adding ½ pint blanched, boiled and mashed chestnuts to ½ pint brown sauce. Mix smoothly and make thoroughly hot before serving.

Piquant Sauce. Espagnole (q.v.) or brown sauce forms the foundation of this sauce. Simmer together 1 gill vinegar, 1 dessertspoonful chopped onion or shallot, 2 tablespoonfuls each chopped capers and gherkins. When the onion is tender, and the vinegar reduced to about half its original quantity, pour in 1 pint Espagnole sauce, boil up, and if necessary add more seasoning. Just before serving stir in 1 tablespoonful chopped parsley.

Genevoise Sauce. This is a rich brown fish sauce. Add 1 glass Madeira or sherry, and a few drops each of garlic vinegar, lemon juice, and anchovy essence to 1 pint Espagnole sauce. Re-heat the sauce, season it, and at the last moment whisk in ½ oz. fresh butter, adding it in small fragments. Do not let the sauce re-boil.

Mushroom Sauce. Add ¼ lb. button mushrooms tossed in hot butter to ½ pint Espagnole or brown sauce.

Reform Sauce. To make it, take ¼ pint Espagnole sauce, ½ gill vinegar, 12 peppercorns, 1 teaspoonful red currant jelly, 1½ gills port wine or claret, cayenne pepper. Add peppercorns to vinegar, and boil until reduced to half quantity. Stir in jelly, wine and a few grains cayenne. Cook slowly for 10 minutes, add Espagnole sauce, strain, re-heat and use.

Sweet Sauces. There is a great variety of sweet sauces to be served with boiled, steamed or baked puddings, etc. Those most in everyday use are custard sauce (*see* Custard) and sweet white sauce, which is an ordinary white foundation sauce sweetened with 2 teaspoonfuls sugar to the $\frac{1}{2}$ pint.

Jam sauce is made by boiling together 2 tablespoonfuls jam, $\frac{1}{2}$ pint water, and a few drops lemon juice until reduced to two-thirds. Strain and serve. Marmalade sauce is made in the same way, omitting the lemon juice. Fruit sauces though classed as sweet are often served with meat and fish; e.g. apple sauce, cranberry sauce with pork and turkey, and green gooseberry sauce with boiled mackerel. Treacle sauce is made by boiling together 2 tablespoonfuls syrup or treacle, 1 gill water, 1 teaspoonful lemon juice, until reduced to two-thirds. Thicken with 1 teaspoonful cornflour. For lemon sauce add a tablespoonful loaf sugar to a breakfastcupful boiling water, having first rubbed two lumps over the rind of a lemon. Mix a dessertspoonful cornflour with a little cold water, and stir into the sugar and water. Bring to the boil, stirring all the time. Add the juice of a lemon, stir well, and serve. Orange sauce is made in the same way, using half the quantity of sugar.

Gooseberry Sauce. Top, tail, and wash a pint green gooseberries, and put them in a pan with a gill of water. Simmer until fruit is soft, rub through a sieve and put into a clean pan. Add 1 oz. butter, 2 oz. sugar, a pinch grated nutmeg, and re-heat. A few drops of green colouring may be added.

Chocolate Sauce. Two ounces grated chocolate, 1 oz. castor sugar, $\frac{1}{2}$ teaspoonful vanilla essence, $\frac{1}{2}$ pint water, 2 teaspoonfuls cornflour. Boil sugar, water and chocolate together for a few minutes. Blend cornflour with a little water and add to chocolate mixture. Stir until boiling, add vanilla, and use.

Hard Sauce. A quarter pound fresh butter, 6 sweet almonds, 2 bitter almonds, 2 oz. castor sugar, 1 tablespoonful sherry, $\frac{1}{2}$ tablespoonful brandy. Blanch, chop and pound the almonds to a smooth paste. Cream the butter and sugar, add the almonds. Add the sherry and brandy, mix well and serve hot.

Store Sauces. Besides the savoury and sweet sauces that are made for immediate use there are a number of piquant sauces or relishes that can be stored to use for cold meat, fish poultry, etc. All these take a long time to make, and great care and patience are needed. The best ingredients must always be used.

Harvey Sauce. One quart best vinegar, 3 or 1 anchovies, 1 tablespoonful soy (Indian or Japanese soy can be bought ready prepared for use), 1 tablespoonful walnut ketchup, a grated shallot, a grated clove or garlic, $\frac{1}{4}$ oz. cayenne, few drops cochineal. Place all the ingredients in a wide-necked, unglazed jar, and cover closely. Let it stand for 14 days, stirring it once a day. Then strain off into bottles, cork well, and store in a cool place.

Tomato Sauce for Bottling. Bake as many tomatoes as are available in a slow oven until soft. Then rub through a sieve and measure the pulp, and to every quart allow 1 pint chilli vinegar, $\frac{1}{4}$ pint soy, 1 tablespoonful anchovy essence, 2 grated shallots, 1 grated clove of garlic, salt to taste. Put all ingredients in a stew pan and simmer until shallots and garlic are tender. Then pass through a fine hair sieve, and store in airtight bottles.

Worcester Sauce. One quart best malt vinegar, 6 tablespoonfuls walnut ketchup, 4 tablespoonfuls essence of anchovy, 4 tablespoonfuls soy, 4 grated shallots, salt to taste. Put all ingredients in a

wide-necked unglazed jar, cover closely. Stir the contents 3 or 4 times daily for three weeks, then strain off into small bottles, cork, and store in a cool, dry place.

Thick Piquant Sauce, or Chutney Sauce. One pint vinegar, 2 tablespoonfuls mushroom ketchup, 2 tablespoonfuls soy, 4 dessertspoonfuls chopped pickled walnuts, 2 dessertspoonfuls chopped chutney, $\frac{1}{4}$ oz. bruised garlic, 7 or 8 finely chopped anchovies. Mix all ingredients together in a wide-necked jar, let it remain in a warm place for a month. Give the contents a good stirring daily. Pour off into small bottles, cover securely, and store in a cool, dry place.

SAUCE BOAT. There are two main types, and one of each kind is usually included in a dinner service. One is fitted with a lid and ladle and a stand to match, making it in effect a small tureen. The other is the sauce boat proper, with lip and handle made so that the liquid can be poured out as from a jug; of this kind there are some beautiful examples in silver and Sheffield plate.

Silver and Sheffield plate sauce boats made in the 18th century are valued by collectors. They are usually of the conventional shape, but with a variety of decoration on the handles and the feet, and sometimes round the rim. The supports are in several styles, some having a plinth and others having claw feet. Less frequently seen are oval boats with two lips.

SAUCEPAN. Enamel saucepans are very easily kept clean, but should always be of good quality, or the enamel is liable to crack and small chips find their way into the food.

Iron saucepans are chiefly needed where there is a range and are used for boiling vegetables, for certain stews and boiled puddings. They are too heavy for ordinary use.

Stainless steel saucepans afford excellent wear, but are expensive to buy.

Copper saucepans are good conductors of heat but require to be lined with tin or nickel, as these metals are not chemically acted upon by acids. Aluminium pans are most generally used, as they are light and easily cleaned. Most of the newer types of fuel and space saving saucepans are made in this metal. Figs. 1 and 2 illustrate examples of these pans, which are helpful on a small cooker.

Saucepan. Fig. 1. Saucepan made up of two semicircular pans which can be used separately or together over one burner. Fig. 2. Four square aluminium saucepans of different sizes, but made to fit together so that they can be used over one light.

Double saucepans for heating porridge, milk, etc., are made in both enamel and aluminium ware. A modern development has a lip through which water can be poured to keep the milk, custard or sauce in the upper part from burning. Another saucepan which is useful for milk has a patent lid, through the sides of which the milk can bubble and return through the centre without boiling over.

Vegetable saucepans comprise one with a wire cage, which when lifted up strains the peas, beans, etc., so that the water runs back into the pan. Another device has a special lock lid and a series of holes on one side so that vegetables can be strained without a colander after they are cooked. A dual purpose saucepan possesses a movable handle and a lid which can be converted into a frying pan by transferring the handle to it.

Cleaning Saucepans. Saucepan lids should be thoroughly cleaned and dried to keep them free from rust. As the cover should always be removed when not in use, a saucepan lid rack is illustrated in Fig. 3, which has proved a convenient little accessory when placed near the cooker. Tiered metal saucepan racks which admit a free passage of air to the saucepans take up little room in a corner.

Fig. 3. Wooden rack for holding saucepan lids.

Saucepan brushes are sold in sets to hang up over the draining board. These can be used with cleaning and scouring solutions for removing hard deposits of grease and food from saucepans. Wire brushes should not be used for aluminium ware, which should be scoured with silver sand, rinsed and dried thoroughly. No soda should be used in cleansing aluminium pans or added to food cooked in them, as it turns them black. Food should not be allowed to stand all night in any saucepan. New pans should be filled with cold water, brought to the boil, emptied, rinsed out in clear water and thoroughly dried. Iron and enamel saucepans may be washed with soapy water to which soda has been added. *See Aluminium; Copper; Kitchen.*

SAUERKRAUT. Cabbage which has undergone fermentation can be purchased ready for cooking under the name of sauerkraut. This is served usually with sausages, ham or boiled bacon.

The French way of preparing this dish is without pickling and fermenting the cabbage. Wash and shred the white hearts of two cabbages very fine, removing the hard parts. Now wash the shreds thoroughly, using several waters, and drain them quite dry. Put the shreds into an earthenware pan with about 4 tablespoonfuls salt; add 8 peppercorns and a breakfastcupful white wine vinegar. Stir the cabbage well in the vinegar and let it remain for some hours. It might, if more convenient, be soured overnight and used next day. Wash it well before cooking, then put it into a casserole with 1 pint stock, $\frac{3}{4}$ lb. sliced fat bacon. Bring gently to the boil and simmer till the cabbage is tender. Add to the stock when cooking it a tablespoonful of vinegar.

SAUMUR. The delicate French sparkling white wine known as Saumur is an excellent substitute for champagne. It is sound, wholesome and light.

SAUSAGE: To Make and Cook. Sausages should always be purchased from a reliable dealer, and as many sorts contain more or less bread as well as beef or pork they should be cooked as soon as possible. To prevent the skins from bursting through the swelling of the bread, they should be pricked with a fork or a trussing needle; there is less danger of the skins bursting if the sausages are blanched or scalded before being fried. Cook them slowly, turning them frequently until nicely browned. Serve them alone or with bacon, or on fingers of fried bread or toast. Sausages may also be toasted or grilled before a clear fire or under a gas grill.

The usual method of making sausages consists in passing the meat through a mincer and forcing it into the skin or container. The meat may be passed through the machine twice. Have ready a well cleansed sausage skin, fix it on to the machine or hold it open and force the meat into it, then separate the sausages by twisting the skin at intervals of 4 in. Only fresh meat should be used, all skin and gristle being removed and a proportion of fat added. The meat is then cut into dice, breadcrumbs mixed in if desired, together with seasoning according to taste.

Pork sausages should be flavoured with sage; beef, onion and sweet herbs; veal and ham, lemon and sweet herbs; for mutton a stronger flavouring will be necessary, and a small proportion of suet and breadcrumbs must be added. The flavouring may consist of shallots, anchovies, pepper, salt, and mace.

Sausage Force meat. The forcemeat known as sausage meat is used for stuffing fowls and turkeys. To prepare it, skin 1 lb. sausages, put the meat into a basin, and mix it with 5 oz. breadcrumbs, a pinch of powdered mace, and salt and pepper to taste, binding the whole with the beaten yolk of an egg. The finely chopped liver of a turkey can be added if desired. This forcemeat can also be made into balls, rolled in flour, and fried or baked.

Sausage Roll. To make sausage rolls, skin 1 lb. pork sausages, divide each into three portions, and put them on one side. Make $\frac{1}{2}$ lb. flaky pastry and roll it out $\frac{1}{8}$ in. thick, and cut it into pieces about 4 in. square. Turn these over to the other side, and roll the pieces of sausage into thinner rolls, not quite so long as the pieces of pastry. Place one on each piece, damp round the edges of the pastry and fold it over in half. Press the edges together, trim off any rough pieces, and with the back of a knife make two slits in the top.

Brush the rolls over with beaten egg or a little milk, put them on a baking sheet in a hot oven and cook them for about 30-40 min. When the pastry is cooked and of a golden brown colour, the heat of the oven can be reduced, and, if necessary, the browning shelf may be removed. When cooked, let the rolls cool on a sieve. *See* Hors d'Oeuvres; Pastry; Stuffing.

SAUTÉ. This French word means tossed. It is a method of cooking food that resembles frying, and is sometimes known as French frying. It differs from real frying in that less fat is used. Consequently the food so cooked should be turned or tossed frequently to prevent it from burning or sticking to the bottom of the pan. *See* Potato.

SAUTERNE. The white wine produced at Sauterne in the Gironde, France, is made from white grapes which are picked over-ripe, and is considered the finest of all naturally sweet wines. The best and most widely known sauterne is Chateau Yquem, the most delicately aromatic of wines in France, and probably in the world. It has a colour resembling liquid gold, with exquisite bouquet and flavour. Barsac is not so sweet and has a flavour of its own. Sauternes are usually served with fish and poultry, but may be drunk throughout a meal. *See* Dinner; Wine.

SAVELOY. A savoury kind of sausage often served as hors d'oeuvres, the saveloy differs from the ordinary pork sausage mainly because the pork used in its preparation is salted. When bought ready made, it is thoroughly cooked, and served cold. It is covered in a bright red skin, which must be pulled off the slices before they are eaten.

SAVINGS BANK. In Great Britain savings banks, which differ from ordinary banks in receiving money on deposit only, not on current account, are of two main kinds. These are the savings banks conducted by the state through the post office; and the trustee savings banks over which the state

exercises supervision. In addition the joint-stock banks have departments for receiving savings, and in one or two places, notably Birmingham, municipal banks have been opened. There are also savings banks in connexion with railway companies, while the army, the navy, and a number of schools have them. Some of these are worked in connexion with the post office. Canada, Australia, and other parts of the British Empire have also savings banks under state control.

All these banks receive money on which they pay interest. Deposits can be withdrawn at any time, usually after a very short notice. The rate of interest paid is usually low; in the post office savings bank it is only 6d. in the £ for the year, or $2\frac{1}{2}$ p.c.; but where security of capital is essential, banks that offer a high rate of interest should be avoided.

To open an account in a savings bank it is only necessary to fill up certain forms and deposit a sum of money. The post office will not take sums of less than 1s., but penny banks and certain others take from a penny upwards. Each depositor is provided with a book, which must be presented when money is deposited or withdrawn, and should be sent to the bank once a year in order that the interest may be added.

As regards the post office savings banks, the following conditions are laid down: An account can be opened for, or by, a person of any age, but if it is for a child under seven the money deposited cannot be withdrawn until the child is seven years old. Deposits in these banks cannot be attached in case of debt. A depositor may have more than one account in the Post Office Savings Bank, but the total amount which he may deposit in a year ending December 31 is limited to £500. There is no limit to the total balance that may be held. A depositor may also act as trustee in accounts for the benefit of others.

Money can be deposited at any savings bank post office, and if it is for more than £50 a receipt will be sent from the head office. Otherwise the stamp and signature in the depositor's book is the only receipt. On presenting his deposit book at any P.O. savings bank a depositor can withdraw on demand any sum up to £3. If more than £3 is required a form of notice of withdrawal must be filled up and posted to the Controller, Post Office Savings Bank, London, W.14. These forms can be obtained from any savings bank post office.

The depositor receives a warrant for the amount, and he can get the money by taking this with his book to the post office named in his form of withdrawal. Sums up to £10 may be withdrawn by telegraph on application at a savings bank post office which accepts telegrams and on payment of 1s.

If a depositor wishes to authorize another person to receive payments from the bank on his behalf, he can sign a form for that purpose. Forms of application for claiming the deposits of deceased persons are obtainable at a post office. A depositor not under the age of 16 may nominate a person or persons to receive any sums from the amount due to him at the time of death.

SAVINGS CERTIFICATE. National Savings Certificates, formerly known as War Savings Certificates, offer a means of investing small sums in a government security bearing interest free of income tax. The present issue, which is known as the sixth, was begun on March 1, 1935. The purchase price for a single certificate is 15s. and the certificates are repayable at any time on application, together with any interest which has accrued. A single certificate of the sixth issue becomes worth £1 at the end of 10 years. National savings stamps of the value of 6d. and cards to which such stamps may be affixed can be obtained.

Special facilities for the accumulation of small sums for investment in national savings certificates are also provided by savings associations established under the auspices of the National Savings Committee, Sanctuary Buildings, Westminster, S.W.1, and the Scottish Savings Committee, 35, Manor Place, Edinburgh, 3, who will give information and advice on this subject.

No person or body of persons or institution authorized to purchase national savings certificates may either individually or jointly hold or have any interest in more than 500 single certificates, or other equivalent in multiple certificates. A person becoming entitled on the death of another person to certificates which bring his holding above that number may, however, retain the excess, but may not purchase more.

Interest. At the end of the first year 3d. interest is added; during the second year $\frac{1}{2}$ d. is added at the end of every completed period of two months; thereafter $\frac{1}{2}$ d. is added at the end of each completed period of one month up to the end of the tenth year. A bonus of 3d. is added at the end of the fifth year, and a further bonus of 3d. at the end of the tenth year. This represents a rate of compound interest of £2 18s. 4d. per cent, per annum over the whole period of 10 years.

	£	s.	d.

Repayment. Repayment with accumulated interest may be obtained at any time on written application by the registered holder to the Controller, Money Order Department, General Post Office, London, except in the case of a child under seven years of age. Forms of application for repayment can be obtained at most post offices.

SAVORY: The Plant. Both summer and winter savories are used for flavouring soups and sauces. The annual is the summer savory, *Satureia hortensis*. It is raised from seed sown, in April in drills, 6 in. apart, in rich soil in a sunny position. As soon as the plants are 2 in. high they should be thinned out to 6 in. apart every way. When the plants flower they should be pulled up and stored for winter use.

The winter savory, *S. montana*, which is an evergreen, thrives in any ordinary garden soil in a sunny position, and may be planted in spring or autumn, about 1 ft. apart every way. Propagation is by seeds or cuttings, and the shoots may be gathered as recommended above.

SAVOURY: The Dish. A highly flavoured side dish, known as a savoury, is served after the sweet, or may take its place when the dinner is informal. Savouries may be of fish, game, white meats, dressed vegetables, or some preparation of cheese or eggs. They are frequently served in china pipkins, ramekin cases, or may be dished altogether in silver or fireproof dishes.

Sometimes the savoury is of a very simple nature, such as Scotch woodcock or mushroom toast; at other times it may be more substantial, a cheese soufflé or dressed tomatoes; but it is always chosen to contrast with the entrée. It is really a substitute for cheese after a meal. In summer it is often served cold. *See* Anchovy; Aspic; Cheese; Tomato, etc.

‘S’ RECIPES: A SELECTION SHOWN IN ACTUAL COLOUR

SAUSAGE AND EGG PIE. Prepare some stock from 1 lb. veal or pork bones. Skin 2 lb. pork sausages, put a layer of them in a pie-dish, cover with a layer of seasoned hard-boiled egg, and continue with alternate layers until dish is half full. Add a sheet of gelatine and $\frac{3}{4}$ gill stock, and continue sausage and egg layers until dish is full, with sausage at top. Make some raised pastry, cut out a piece to cover top of pie dish, and roll out trimmings to $\frac{1}{4}$ in. thick. From these cut strips of pastry, place on damped edge of pie, then damp pastry itself and put top crust on. Make a hole in centre and brush pastry with beaten egg or milk. Bake for about $\frac{3}{4}$ hr. in hot oven, lessening the heat and removing browning shelf when pastry is cooked. Dissolve 2 sheets gelatine in the stock, strain, skim off the fat, and pour into pie when latter is taken from oven. Serve cold.

SHRIMP SAVOURY. Mash 2 lb. potatoes, stir in 2 oz. grated cheese and 1 oz. butter. Stir until cheese melts, leave to cool slightly and add beaten yolks of 2 eggs. Season to taste. Make a white sauce and mix in 3 gills washed shrimps. Pour over and serve hot.

SARDINE EGG. Cut 3 hard-boiled eggs into halves. Put yolks into a mortar with 6 skinned and boned sardines. Mix in a teaspoonful of sardine oil with a little chopped parsley, 1 teaspoonful vinegar, salt and pepper to taste. Pound all to a paste and fill the halved whites.

SPANISH SAVOURY. Melt $1\frac{1}{2}$ oz. butter in a pan and fry $\frac{1}{2}$ a grated or chopped onion. When latter is soft and of a golden brown colour, add $\frac{1}{2}$ lb. tomatoes, skinned and mashed to pulp. Mix these together and cook until tender, then let them cool slightly before stirring in 2 well-beaten eggs. Cook mixture over gentle heat until it thickens, stirring well and adding seasoning to taste. Cut rind from 6 thin rashers bacon, roll each to sausage shape and thread on skewer. Cook on baking tin in moderately hot oven until lightly crisped. Cut 6 small pieces bread, each about $\frac{3}{8}$ in. thick, fry in hot fat until golden brown, and drain. Pile hot tomato and onion mixture on croûtes and arrange on hot dish with a roll of bacon between each.

SNOWFLAKE JELLY. A red jelly prepared in usual way, with 3 or 4 dessertspoonfuls desiccated coconut stirred in just before it sets.

SPINACH FLAN. Make a flan case of rough puff pastry. Prepare and cook 2 lb. spinach, chop and pass through sieve or mincer. Soak 2 oz. macaroons or some sweet, light biscuit in 1 gill cream until they are soft, and beat them fine. Cream 2 oz. butter with 3 oz. castor sugar, add $\frac{1}{4}$ nutmeg, grated, then the beaten yolks of 4 eggs. Stir in the soaked biscuit and the spinach puree and mix all together thoroughly, adding juice of $\frac{1}{2}$ lemon and a pinch salt. Thicken mixture over fire, but do not let it boil, and stir all the time to prevent scorching. Heat the flan and turn spinach cream into it. Serve with whipped and flavoured cream. This flan makes a decorative sweet dish.

SAVOY GATEAU. Melt a pint packet lemon jelly and leave to cool. Cut out a round measuring $4\frac{1}{2}$ in. diam. from a small jam sandwich. Trim side of 12 or 14 Savoy biscuits or sponge fingers, and cut off a small piece from end of each. Spread edge of sandwich ring with jam, put into an oval dish, and stand round it the prepared biscuits, cut ends downwards. Heat $\frac{1}{2}$ gill milk. Use it, with $\frac{1}{4}$ gill sherry, to soak the sandwich ring. Crush some of the biscuit trimmings to a powder, mixing to a paste with a little of the jelly. Use this mixture to fill up any cracks between the fingers. Make $\frac{1}{2}$ pt. egg custard, leave to cool, and then fold lightly into 1 gill whisked cream. Add 3 dessertspoonfuls castor sugar, a little coffee essence, another $\frac{1}{4}$ gill sherry, and $\frac{1}{2}$ oz. leaf gelatine dissolved in 1 gill hot water. Mix all these together and stir until just beginning to set, then pour into the prepared case and leave them. Whisk another gill cream until it thickens, sweeten to taste and flavour with vanilla. Pile it on top and sprinkle with crystallized violets. Chop remainder of jelly and use as garnish.

SMYRNA PUDDING. Put 1 lb. prepared dried figs into a stewpan with 1 pt. hot water, ½ lb. loaf sugar, rind and juice of 1 lemon, and an inch stick cinnamon. Cook slowly until fruit is tender. Strain off liquid and leave fruit to cool. To syrup add 3 tablespoonfuls apricot jam, ¼ oz. leaf gelatine, stirring over fire until gelatine melts. Put a soaked sponge ring in glass dish, put cooled figs in centre, and when syrup is cool and just beginning to set pour it over. Whip up a little cream, sweeten, flavour and heap on top.

SAVOY BISCUIT. Savoy biscuits are used in the making of many fancy sweets. These biscuits can be laid out on a sheet of cartridge paper by the aid of a savoy bag and baked in a fairly hot oven. Or bake them in sponge finger tins which have been floured and sugared.

The ingredients and proportions to be used would be 3 eggs to 6 oz. castor sugar and 8 oz. flour. The eggs must be whisked stiffly for about ¼ hour with the sugar, then folded in quickly with the flour and a little delicate flavouring, such as vanilla, added last; then place the mixture in a savoy bag to shape for baking.

SAVOY CABBAGE. A valuable hardy autumn and winter vegetable which is raised from seeds sown out of doors in April and May; it produces a large firm head of deep green, crinkled leaves. The seedlings should be planted out in summer, the large varieties at about 20 in. apart, the small ones at 12 in. apart. Of the large Savoy suitable sorts are Drumhead and New Year, and of the small ones. Dwarf Green Curled and Little Gem. For methods of cooking *see* Cabbage.

SAWS: THE VARIOUS TYPES

Their Different Uses and How to Sharpen Them

Other information on this subject will be found in the articles on the various kinds of saw, e.g. Bow Saw; Cross Cut Saw; Frame Saw; Hack Saw; Keyhole Saw; Pruning Saw. See also Amateur Carpentry; Tools; and the entries on the woodworking processes in which the use of the saw is essential, e.g. Dovetail; Joint Mitre; Picture Frame.

The cross-cut saw is used for cutting across the grain of wood, while a rip saw works along the grain. The average length of the crosscut hand-saw is about 26 in., and the number of teeth to the inch depends on the work for which it is intended. The tenon or back saw. Fig. 1, is 12 in. to 18 in. in length, and the number of teeth to the inch about 10. The top edge has a strip or back of grooved steel or brass, fitting the blade, and giving strength and rigidity.

The panel saw is a small hand-saw with fine teeth that may be used for the same purposes as the cross-cut and ripping saws, and also as a tenon saw and for many woodsawing jobs. The amateur who wants a general-purpose tool is advised to buy this type. The dovetail is similar to the tenon, but smaller and with finer teeth; its usual length is 10 in. It is used in making dovetail and other joints that entail very accurate work. For cutting beading and similar small work a light brass-backed saw is often used with a straight handle, like that of a bradawl.

For cutting shaped outlines in wood a bow saw is usually employed. The frame is generally of beech and the handles and blades can be obtained separately, so that the latter may easily be renewed. The saw blade is tightened for use with a tourniquet arrangement. This tightening is absolutely necessary, otherwise the blade will snap, but when the saw is out of use the blade should be slacked off. In addition to the bow saw, compass and keyhole saws are used for shaped work, and for starting a cut to be completed by the bow saw.

Saw. Fig. 1. Tenon saw in use on work supported by a bench hook. Fig. 2. Making the preliminary cut with a cross-cut saw. Fig. 3. Short board held in bench vice.

Fig. 4. Correct position to adopt when cutting a thick plank. Fig. 5. Ripping long board through the centre.

saw, is to start the cut. There is a tendency for the saw to jump about and make a series of small jagged cuts on the edge of the wood. Figs. 2 and 4 show how the preliminary saw cut should be made and how the handle of the saw should be held. The left-hand thumb should be placed on the

wood against the blade of the saw to guide it. Then take two or three gentle up-strokes before making the first down or forward stroke. The pressure should be as light as possible. The preliminary cut made, the sawing can proceed.

The two chief rules for accurate sawing are to use long strokes, and not press too heavily. Any attempt to force the saw too quickly through the wood will make it more difficult to guide for one thing, and for another it will make the blade jam, the teeth not being able to clear themselves properly. Draw the saw slowly backward and forward, and the work will be done more quickly and with less labour. About sixty strokes a minute with a 26 in. saw is right. When sawing off a piece from a long board, both ends of the latter should be supported, and the board so kept horizontal. To use only one support and hold the board horizontal by the

pressure of one knee is bad, because the board is bound to vibrate and the sawing will probably be uneven, because the attention of the worker is divided between it and the support of the board. When a long board has to be sawn across the middle, it is best to have an assistant holding it to prevent the board sagging, and so binding the saw blade. During the last few strokes, when cutting a short or long piece, it should be supported, or it will break away and split the end of the board. The last few strokes of the saw should be as lightly made as the first, to prevent the breaking away of the fibres of the wood at the corner. Short pieces of board may be held in the bench vice, as in Fig. 3.

With a tenon or similar saw nearly all the work is done on the bench. The sawing should be done against the bench stop, or by using a bench hook, as shown in Fig. 1. The bench hook is hooked against the front of the bench, and the wood to be sawn is pressed firmly against the top of the hook with the left hand.

Considerable practice is required to saw a straight line and to saw squarely, particularly when using the cross-cut saw on thick stuff. A saw may be following the line marked on the top of the material, and yet be considerably to one side of it underneath. The tendency generally is to incline the handle end of the saw towards the side on which the worker is standing. By giving what appears to be a contrary slope it will generally be found that the wood is being cut squarely, and a little practice will enable the amateur to keep his saw cuts square.

A saw may persistently saw to one side of a line when all the rules of sawing have been observed. This will be due to a defect in the saw itself. Either the blade has twisted or the teeth of the saw have been set more on one side than the other.

A point the amateur often overlooks is the waste which occurs when a saw cut is made. A board 1 ft. in length when sawn exactly through the middle does not produce two pieces each 6 in. long. Each piece is 6 in. less half the width of the saw cut or kerf. When careful work is being done this width becomes important, and must be allowed for when cutting. Saw on the outside of the line, so that the saw kerf is in the waste piece of wood. This will save much planing and fitting.

Setting and Sharpening. Saws should be set and sharpened at regular intervals, and they should be set before they are sharpened. The set is the amount to which the teeth are bent sideways. This is to make them cut a kerf wider than the thickness of the blade, to allow the latter to run freely. Saws should be set to a maximum for cutting wet wood, or cross-cutting soft wood, and to a minimum for ripping hard, dry wood.

Saw. Fig. 6. Setting the teeth of a saw with a hand saw set. Fig. 7. Showing correct method of using the file in sharpening a saw.

The simplest way of setting a saw is by means of a hand-set, Fig. 6, with the saw held in a vice. The hand-set contains a number of slots or notches of various sizes to suit different thickness of saws. A slot is fitted over a tooth, and the latter then bent over to the required angle. Alternate teeth are bent over on one side of the blade, and the remainder on the other. The accuracy of this method depends largely upon the eye of the worker, and a hand set with a gauge attachment is best for the beginner. When the tooth is bent over sufficiently the gauge just touches the blade of the saw, and this ensures that the teeth are set uniformly. There are other types of saw-set on the market. Professional saw sharpeners place the saw on a metal block with bevelled edges, and strike the teeth with a sawsetting hammer.

Saws are sharpened by filing the teeth with a three-cornered file. A proper and suitable saw-file has the same section as the tooth space and thus files the front of one tooth and the back of the

preceding one simultaneously. Such files are made in various sizes, a 4½ in. file being suitable for hand saws and a 3½ in. for tenon saws. The saw should be held, teeth upward, in a long-jawed vice, the teeth projecting only slightly above the jaws. A simple wooden vice can easily be made by the amateur. The jaws should be faced with a thickness of leather. The appliance has legs to stand on the floor against a bench or table and thus bring the tool to a convenient height for the work. Another way is to clamp the saw between two pieces of wood the length of the saw.

Before beginning, look along the top of the teeth and see that they are in a straight line. With a blunt saw it will be found that they are uneven, and the first thing to do is to straighten them. This is done with a flat file run over the points of the teeth. To ensure accuracy, fit the file in a groove in a piece of wood. The latter held against the saw blade acts as a guide and enables all the ends of the teeth to be filed with a perfect regularity.

The saw should be sharpened from the handle end. The file is held on a slight slope to the horizontal, as in Fig. 7, not more than a few degrees, and its direction should be at an angle across the teeth, not at right angles.

Two or three strokes of the file will suffice to sharpen each tooth, and the file should only be used on the forward strokes. The back of the tooth is filed to bring it to a sharp point again, though the front of the next tooth to the right gets filed away to some extent. When one set of teeth has been filed the saw should be turned over and the other set similarly treated. The file should still slope towards the handle when the saw has been turned.

The angle at which the file is pointed across the teeth varies with each type of saw. In the case of a rip saw the file is only just off the square; with a cross cut, tenon or panel saw it is off about 20° to 30°. The more the filing is done out of the square the finer the point and the keener the cutting. Naturally, the teeth are weaker, and saws thus will want more frequent sharpening. Generally speaking, sharpen finely for soft woods and squarely for hard woods.

Saws when not in use should be thoroughly greased to protect them from rust. A grooved piece of wood the length of the saw should be prepared, and kept over the teeth when the saw is not in use. To make such a cover, the grooved edge of a piece of stout matching can be ripped off to a width of about 1½ in. A couple of holes are bored to take a cord for tying it to the saw.

SAWFLY. Various kinds of sawflies are very troublesome in the garden, attacking apples, cherries, larch, pears, pines, plums, raspberries, roses, turnips, and other trees and plants. The larvae of leaf-feeding kinds should be picked off by hand, or, as an alternative, should be destroyed with sprinklings of the poisonous hellebore powder.

Pith-boring grubs can only be eradicated by removing and burning shoots that wither suddenly. Caterpillars injurious to young fruit must be combated by spraying with the poisonous arsenate of lead, whilst all fallen fruit should be immediately collected and burnt. Kainit should be applied in autumn. *See* Apple Sawfly; Currant Sawfly; Gooseberry Sawfly; Spraying.

SAXIFRAGE. This is one of the most important groups of rock garden plants, popularly called rockfoil. There are several types, two of the most notable being the mossy and silvery saxifrages. The mossy saxifrages form wide-spreading masses of moss-like greenery and bear white or reddish flowers in spring; they like well drained, sandy or gritty loamy soil and slight shade, though they will flourish in the sunshine.

Some of the best are *hypnoides* (Dovedale moss), white; *muscoides*, red; *decipiens*, red and *Wallacei*, white. Many showy crossbred forms have been raised and these are largely grown, e.g. *Guildford Seedling*, *Crimson King*, and *sanguinea superba*. Two, *hypnoides densa* and *muscoides densa*, are of dense growth.

There are some charming flowers among the silvery saxifrages, which should be planted in gritty soil containing lime, in sunny rock crevices. Most of them have grey-green leaves, and in May and June the dainty panicles of bloom are delightful. A few of the best are aizoon and its varieties, cochlearis, white; Kolenatiana, pink; lantoskana superba, white; Macnabiana, white with red spots; Hostii, cream with pink spots; and Tumbling Waters, white. Longifolia bears immense panicles of white flowers, but the plant dies after flowering.

Saxifrage. One of the large-leaved saxifrages, ligulata, which bears rose-purple flowers.

A few of the most attractive saxifrages in the remaining groups are apiculata, yellow; burseriana gloria, white; Griesbachii, crimson; Irvingii, pink, and oppositifolia, rose-purple. These, which flower early in spring, should be planted in very gritty soil or in the moraine. London pride, so useful as an edging to shady borders, is Saxifraga umbrosa; it bears pinkish flowers profusely in May. Saxifraga ligulata and cordifolia are vigorous plants with large leaves and spikes of rose coloured flowers in spring.

The usual way of propagating saxifrages is by detaching offsets, potting them in small pots of gritty soil and keeping them in a frame until they are well rooted. They may also be raised from seeds sown in pans of finely sifted sandy soil placed in a frame in spring, but the seedlings grow slowly.

SCABIES: The Disease. The skin disease popularly known as the itch is due to the presence of the female itch mite, which forms winding burrows in which she lays her eggs, her position being indicated on the surface by a small vesicle or blister. There is intense itching, increased when the sufferer is warm in bed at night, and from scratching and other irritation eczema results.

Treatment consists in anointing the body from the neck downwards with sulphur ointment on three consecutive nights. The fourth night a hot bath is taken, and the patient gets fresh underclothing. What he has been wearing may be sent to a steam disinfecter, be boiled at home, or things which would damage may be soaked in a solution of lysol.

The Disease in Poultry. A form of scabies, called depluming scabies, attacks fowls. It takes the form of feather eating, and is usually due to the small mite at the roots, but sometimes to lice. There are two kinds of feather plucking, the eating of the bird's own feathers, and the plucking of those of other birds. The disease appears usually about April, and is most prevalent in the spring and summer. Besides the loss of feathers the birds become thin and lay fewer eggs or none at all.

To cure the disease it is first necessary to isolate the affected bird or birds. The mites yield readily to treatment if oil of cloves is rubbed into the infected area, but a mixture of one part of creosote to 20 parts of lard is perhaps a better remedy. Another remedy is to wet the base of the feathers with soapy water, and then dust the birds with fresh pyrethrum. *See Gapes; Poultry.*

SCABIOUS. The pincushion flower or scabious is a delightful plant for the garden; there are perennial and annual kinds. The flowers of the latter are of various colours— crimson, maroon, lavender and pink. Seeds should be sown under glass in March, and the seedlings planted out of

doors in May; these plants may be treated as biennials, seeds being sown in summer and the seedlings set finally in autumn, when they will bloom the following year. The ordinary varieties reach a height of 2-3 feet, the Tom Thumb varieties 12 inches.

Scabious. Flowers of the annual scabious, varying from a deep wine colour to pale blue.

The finest perennial kind is the Caucasian scabious (*Scabiosa caucasica*), which bears long-stemmed lavender-blue flowers of great value for cutting. It thrives best in well-drained soil. On heavy land it is liable to perish in winter, and there should be grown as a biennial from seeds sown every year in May. Propagation may also be effected by division in September.

SCAFFOLDING: In Building. By scaffolding as applied to building works is meant the temporary platforms raised to varying heights to enable those employed on the job to work in comfort, and to support the materials which are being used for the structure.

The bricklayer's scaffold is the type used generally to assist in the erection of small houses, and it is made up with a number of members that are given different names, according to the position into which they are placed. The poles that are fixed in the ground are called standards. These are fir poles stripped of their bark, 4 or 5 in. in diameter and 25 to 30 ft. long. If longer poles are required two are lashed together. The hole dug for the standard is about 2 ft. in diameter and 2 to 3 ft. deep. Where it is not desirable to break the surface of the ground, the standards may be placed in tubs or boxes containing sufficient earth. The firm planting of the standards gives lateral strength to the scaffold.

The ledgers are horizontal poles fixed to the standards by means of scaffold cords or lashes; they are placed at the height required for comfortable working, from 4 ft. to 5 ft. 6 in. apart. Scaffold cords are made of hemp or steel wire, about 20 ft. in length. It is essential that they should be in good condition, as it is upon the proper tying and strength of these cords that the security of the scaffold depends.

The standards are planted, as a rule, about 4 to 5 ft. from the building, with the ledgers firmly attached to them. A support is formed to receive the putlogs, one end of these resting on the ledger and the other bearing on the wall of the structure, for which purpose, on a new building, holes are left to receive them. The putlogs are lashed to the ledgers and securely wedged into the wall.

Putlogs are made from birch, 5 to 6 ft. in length and 3 to 4 in. square on section. They are spaced 4 to 5 ft. apart on the ledgers and form a base on to which the scaffold boards are placed. These latter are usually 12 ft. long, 9 in. wide and 1½ in. thick, and are often bound at the ends with hoop iron to make them durable. In erecting a scaffold, and particularly in laying the boards, great care must be taken. Traps must be avoided, that is, the overlapping of the boards on the putlogs, otherwise a serious accident might occur. The boards are butted, but where the joints occur, two putlogs should be placed about 3 in. apart, in order to give ample bearing for the boards at the ends. If the scaffold adjoins a roadway it is desirable to have guard boards at the sides to prevent any materials falling on to persons below. A safety rail may be provided as an additional safeguard to the workers. A scaffolding may require bracing to give additional stability. Braces are formed with similar poles to

those used for standards; they are lashed diagonally across the framework to the standards and ledgers.

Within the area of some local authorities scaffoldings have to be approved by an officer of that authority before they may be used; this applies particularly to the London districts, where there are by-laws affecting the erection of any scaffolding used for building purposes. Scaffolding must be properly put together in spite of its temporary nature, because it invariably has to carry very heavy weights, and the lives of the men using it will be imperilled if strong and adequate framing is not provided for it. It is highly important that the services of an experienced workman should be utilized in raising anything but the most simple erection. *See Trestle.*

SCAGLIO'LA. Scaglio'la is a composition of coloured materials to imitate marble, which is sometimes known as mischia. It is composed of gypsum, or sulphate of lime, calcined to evolve the surplus moisture and to reduce it to a fine powder.

When it is required for use, sufficient water is added to the mixture to form a paste, and this causes the diffusion of the colours required. Experience alone can supply the knowledge as to which gypsums to mix in order to produce colourings. This material is laid on to brick walls in the form of a plaster, and may be trowelled to a smooth surface. *See Marble.*

SCALD: How to Treat. A burn produced by a hot liquid or vapour is spoken of as a scald.

The top of the foot is a common site for a scald, and when this happens the greatest care must be taken in exposing the injury. If the boot is on it may be better to cut the lace than loosen it in the usual way, and a sock or stocking should always be cut off. It will further help in the removal of a stocking if the foot is placed in warm water. As in burns from other causes, the first symptom to be treated is the shock-like condition. Warmth and stimulants are necessary.

In dressing the burn, if the skin is broken, greasy applications should not be used, as they interfere with the cleansing of the wound by the doctor. Cloths wrung out of warm boracic lotion are the best immediate application and they should be kept continuously moist with the lotion. *See Burn.*

SCALE: The Insect. An insect known as scale affects many shrubs and flowers, both indoors and out. The males are small black flies, and the females have the appearance of small scales, or plates, which affix themselves to the leaves or bark of plants in small brown or grey spots. Apples and pears, stone fruit, roses and palms are those which are chiefly affected.

One remedy is to spray with paraffin emulsion; while, in the case of stem infection, methylated spirit brushed into the bark is effective. Paraffin emulsion is made by dissolving a handful of soft soap in hot water, adding an eggcupful of paraffin and two gallons of water. *See Beeswax; Spraying.*

SCALES: For Weighing. A pair of scales is a necessary adjunct to every household. In addition to those used in the kitchen for weighing food, scales are useful on the writing-table. For this purpose small pairs are made of brass and other metals, or of wood with brass fittings, with weights suited to the weighing of letters and small parcels., Scales are also used by photographers.

Kitchen scales are of two main types. One requires certain weights and works by means of a balance the articles weighed being put into a shallow pan on one side and the weights on the other. An ordinary pair will weigh anything up to 7 lb., but larger ones can be bought. The other type works by means of a spring, weights being unnecessary. The articles to be weighed are placed in a pan at the top, and their pressure moves a pointer on a dial to mark the correct weight. Modern examples are made of porcelain and are washable and hygienic. They usually weigh up to 14 lb.

SCALLOP: How to Prepare. Small portions of meat or fish cooked in a savoury manner in scallop shells or dishes of that shape are called scallops. The name is that of a shellfish, and the shell itself is so hard that it is not injured by being placed in a hot oven. When the fish has been disposed of, these shells are often kept for cooking fish.

Scallops are usually obtained from the fishmonger ready for cooking, but if they must be prepared at home open them with an oyster knife in the same way that an oyster shell is opened, then trim away the beards and black parts and wash them well in two or three waters. They are somewhat indigestible, and it is essential that they be well cooked. The name is sometimes found spelt escalop on menus.

To cook scallops, parboil the fish in their own liquor for 5 min., then drain and keep them hot in their shells. Put the liquor into a small stewpan with 1 tablespoonful creamy white sauce for each fish. Add a little extra seasoning and a squeeze of lemon juice, then make all hot over the fire. Pour over each scallop in its shell a spoonful of sauce, then coat with fried breadcrumbs. The shells should be well washed.

Scallops may also be stewed. After preparing the fish well wash them, then put them into a stewpan, cover them with warm water, and simmer for from 15 to 20 min. Dish them in a china baking-dish covered with white sauce, which should be made partly with the liquor in which the fish have been stewed.

To fry scallops, prepare, wash, drain, and blanch them, then dip each in a rich light batter and fry in deep fat. Pile them up on a dish paper and garnish with fried parsley. Serve with them shrimp or oyster sauce. Add to the batter a little butter and season the scallops well.

SCALLOPING: How to Work. This is used to form a fancy edge on babies' clothes, underwear, frocks and house-linen. It is worked on white flannel with floss silk, on silk and cotton wear with embroidery cotton or silk, on linen with linen embroidery thread.

In the case of flannel, long-cloth and nainsook it can be worked on the single material, but when working on thin silk or crêpe-de-Chine it is advisable to sew a narrow strip of tissue paper or fine book muslin under the edge of the material on which the scalloping will be worked. This prevents puckering, and gives a firm, even edge.

The design is put on the material by means of a transfer which is ironed off in the usual way. These transfers are sold by the yard in various shapes. The ordinary scallop pattern is in a semicircle; there are fancy Vandykes made up of 3 or 4 semicircles on each side of it. The design illustrated is a wide one, each scallop measuring 2½ in. It is not necessary to buy a scallop transfer, as a coin and a soft lead pencil will provide various designs. For the average scallop, which is about 1 in. wide when worked, a halfpenny will act as the tracing medium.

To mark the design draw a line across the diameter of the coin, so that the exact half can be used. Pin the material taut on a drawing board, so that the cut edge is away from the worker, then place the coin on the material about ½ in. from the edge, and draw round the coin from one point of the centre line to the other when a half circle will result on the material, which forms the outside line of the scallop. To make the inside line, draw the coin inward until there is a space of 3/16 in. from the pencil line to the edge of the coin, at the centre of the scallop. Again draw round half the coin, but beginning this time on a level with the points of the first semicircle drawn, instead of in a line with the centre of the coin.

For successive scallops the coin must be placed against the previous one, taking care that the guiding line is quite straight. As a further guide the starting-point for the first semicircle could be marked on the coin. By the same method a permanent scallop rule can be cut out in stiff cardboard, making about ten scallops, and this can be moved along for any length of material. Tiny scallops for

babies' clothes can be made with a sixpence, and the larger ones with a halfpenny and a penny, marking the shapes on the cardboard.

Scalloping. The design is padded and then worked in buttonhole stitch the material being subsequently cut away from the outer edge.

Sometimes the work is padded as shown at the right side of the illustration. The buttonhole work is done from left to right, holding the material with the cut edge towards the palm of the hand. After joining the thread on the wrong side, bring it through to the right side on the lower line. Then, holding the thread down in a loop under the left thumb, put the needle down through the material on the top line, and bring it up again on the lower line, next to the spot where it came up before, as the work must be close and even. Draw the needle through, still keeping the loop down under the left thumb, and only release it as the last bit of thread is drawn through. This will make the pearl edge, and after the whole work is completed the material is cut away under this pearl edge.

For the latter purpose a very sharp pair of embroidery scissors must be employed, so that the material can be cut clean away without cutting the embroidery stitches. *See* Embroidery; Night Wear Case; Transfer.

SCALY LEG. This disease of poultry is due to a tiny mite. The scales of the leg; and feet become raised and separated, and a chalk-like excretion accumulates between and over them. The disease is slightly contagious. Infected birds are lame, have a difficulty in perching, and get out of condition. To cure the disease the isolation of the diseased birds is essential. The legs should be bathed in hot water in order to soften the crusts. These are then removed and a mixture of one part of creosote to 20 parts of lard is applied. The limb, some days after treatment, should be well cleaned with hot water and soft soap. *See* Poultry.

SCANTLING. This is a term used in building and carpentry work for the dimensions of piece of timber, i.e. its length, breadth, and thickness. The name is often applied to an actual piece of timber, which differs from other timber in not according with some series of standard sizes, in the same way as battens and planks. *See* Batten; Board; Plank.

SCAR. The tissue which takes the place of normal tissue in a healed breach of tissue from disease or a wound is called a scar or cicatrix. At first a scar is red and soft, but becomes gradually harder and whiter. It never contains hairs and sweat glands, like ordinary skin. When large, as after an extensive burn, in contracting it produces puckering of the skin which may interfere seriously with movement. Scars, if irritated, rather readily develop cancerous growth.

SCARAB. Egyptian gems that are moulded or cut in the form of the sacred scarabaeus, or beetle, were originally used as amulets, and afterwards for personal ornament. They were made in all available materials, including green basalt, lapis lazuli, serpentine, emerald, cornelian, jasper, amethyst and onyx, besides wood, ivory and gold. The most numerous were in pottery or faience, covered with a bluish-green glaze.

On the flat, oval base scarabs were usually incised with the names or representations of divine, royal and official personages, or with good luck mottoes and magical devices. Scarabs were also

used as seals, being either strung round the neck or mounted in metal signet rings. Many imitations of old scarabs are made and used in modern fancy jewelry when fashion dictates. *See Ring.*

SCARBOROUGH LILY. The common name of *Vallota purpurea*, a half hardy bulb suitable for cultivation in pots in greenhouse or room window: it bears showy lily-like scarlet flowers in August. The leaves are evergreen. During winter the soil must not be watered until moderately dry, but in summer it must be kept moist.

Scarborough Lily. Scarlet flowers of an evergreen plant for the greenhouse or room window.

The bulbs should be potted in early summer, one in each 5-in. flower pot, in a compost of loam two-thirds, and leaf-mould one-third, with a scattering of sand. The Scarborough Lily flowers most freely when the pots are full of roots: repotting should be done only when absolutely necessary. In spring some of the old surface soil should be removed and replaced with fresh compost. This plant, when well rooted, benefits by occasional applications of guano or liquid manure.

SCARECROW. Originally this was a dead crow strung up to a stake to scare other birds from the crops. Now the word is generally given to many types of bird scarer, including the familiar old man of the fields, made of a rough wooden cross upon which hangs an old coat topped with an ancient hat.

Modern scarecrows, which are known usually as bird scarers, are more effective than these examples that quickly lose their terror in the eyes of feathered raiders. They include laths strung with bunches of tin, or pieces of glass attached to swaying hoops, and so slung that when the wind blows the tin or glass tinkles, alarming the birds and causing them to fly away. Whatever type is adopted, the scarecrow must repeatedly be altered, because familiarity with the same pattern breeds contempt and ceases to puzzle the raiders. *See Bird Scarer; Netting.*

SCARF. The primary use of a scarf is to protect the throat and shoulders from cold, but frequently it is worn by women merely for its decorative qualities.

A silk scarf 1½ yd. long and 1 ft. wide can be quickly crocheted in three shades of one colour. Two hanks of crochet silk are required of the palest shades, one of the medium and one of the darkest: also a No. 11 crochet hook. Make 82 chain and work 5 in. in the darkest shade; break off, join medium shade and work another 5 in. Break off and join palest shade. Work this 34 in. and then finish off with 5 in. of the medium and 5 in. of darkest shade.

Knitted Scarves. Scarves are simple to knit. Any number of stitches may be cast on the needle, according to the width required, and plain or plain and purl knitting, or some other pattern, used. The knitting should be continued until the scarf is of the necessary length, then the stitches should be cast off and fringe added to the two ends. To obtain an even edge, slip the first stitch of each line. A fringed scarf can be made in Shetland floss; 4 oz. floss, a pair of No. 7 needles, and a medium size bone crochet hook are needed to make it. The scarf measures 48 in. long and 11½ in. wide, and the knitting is worked at a tension that will produce about 18 stitches to 3 in. in width, and 30 rows to 3 in. in depth.

Commence by casting on 60 stitches, and for the first row * knit 12 wool forward knit 2 together 6 times, and repeat from * to the end of the row, finishing with knit 12. Repeat this row 11 times, making 12 rows in all. The 13th row consists of * wool forward, knit 2 together 6 times; knit 12, repeat from * to the end of the row, finishing with wool forward, knit 2 together 6 times. Repeat this row 11 times, making 12 rows in all.

Then repeat from the first row until the work measures 48 in., and cast off. For the fringe, take 6 lengths of the wool, each about 10 in. long, and with the crochet-hook pull through the first stitch at one end of the scarf, and knot.

Repeat this all along the row in about every third stitch of the knitting, and then fringe the other end to correspond.

A scarf made from brushed wool might be composed of two different colours arranged in bands. For a scarf 2 yards long and 20 in. wide, 9 oz. of rose-coloured wool and 3 oz. of white wool are needed; but if thicker wool is used, these quantities must be increased accordingly. The white wool is used for the bands and part of the fringe, and the whole is done in plain knitting. Work at a tension of 5 stitches to the inch in width.

Begin by casting on 100 stitches, and knit 54 rows or 6 in. with the rose-coloured wool; then 18 rows or 2 in. with the white, twisting the rose wool over the white before knitting the first stitch, so as to bring it in line. Work another 2 in. with the rose wool, and then make another band of white. This also should be 2 in. wide. Knit 1½ yd. with the rose wool, allowing for a second set of white stripes, and making the latter correspond with those at the other end. The scarf will then be complete.

For the fringe, wind the wools over a card or thin book measuring 5 in. across, and cut them through at one end. Take two strands together, double them, and with a bone crochet hook draw the loop of the threads through one of the casting-on or casting-off stitches. This will depend upon to which end of the scarf the fringe is first applied. Pass the ends of the cut wools through the loop and draw them up closely. Repeat this all along both ends of the scarf, clipping the bottom of the fringe to make it even. Lastly, brush the scarf on one or both sides with the special wire brush that can be bought for the purpose.

Any other colours may be chosen instead of rose and white, and the scarf can be made a narrower width by casting on 60 instead of 100 stitches. *See Crochet; Knitting.*

Scarfed Joint: three varieties. Fig. 1. Lapped joint. Fig. 2. Splayed scarfed joint. Fig. 3. Tabled scarfed joint, a type that resists both tension and compression strains.

SCARFED JOINT. In carpentry various kinds of scarfed joints are used when it is necessary to join the ends of timbers to increase their length.

An ordinary scarfed joint is made by cutting the two ends of the timber to a long angle, and glueing,

dowelling, bolting, or otherwise securing the two parts together. It is essential to have both angles alike and both faces square to each other.

In the case of a lapped scarfed joint, instead of making the joint at an angle, half of each end is cut away so that each piece of material can lap on to the other, as shown in Fig 1. This is a useful all-round joint, easy to make, and is practically an ordinary lapped halving joint. When used in timber the joint should be square, and secured with nuts and bolts. Such a joint would not be suitable for an upright post which has to support a moving load. For the best proportions the length should be twice the breadth of the pieces that are to be joined.

The splayed scarfing joint used for lengthening tie beams is shown in Fig. 2. Proper proportions for the length of the joint are about $3\frac{1}{2}$ times the greatest breadth. The tabled scarfing in Fig. 3 has the advantage that it naturally resists tension as well as compression strains, and shrinkage of the timber does not seriously affect its security; but it requires careful fitting. The sides of the timber have to be very carefully marked out and the lines accurately worked to them, all the joint faces being kept perfectly square and true. *See Joint.*

SCARLET FEVER. A common infectious disease, scarlet fever, or scarlatina, owes its name to the vividness of its rash. The specific cause seems to be a variety of streptococcus which generally enters the body through the nose and throat; moreover, the infection is most often communicated by the secretions from those parts.

The incubation period is usually about three or four days. Then the patient becomes fevered and suffers from sore throat and probably vomiting, especially if it is a child. On the second day the rash appears, first on the neck and chest but in the course of a day or two usually covering the whole body, with the exception of the skin around the mouth. The rash consists of tiny red spots, each being surrounded by an areola of pink. The mouth and throat have also a scarlet colour.

The tongue is furred at the beginning of the fever and may have the appearance described as the white strawberry-tongue. In this the surface is covered with white fur but is dotted over with red spots due to swollen papillae projecting through the fur. Later on the fur is thrown off, leaving a clean red surface, but the redness of the papillae is of a different shade and they are still conspicuous; this is called the red strawberry-tongue.

With the appearance of the rash the temperature rises further, reaching 102° to 103° F. or more. The rash lasts for three or four days and then fades, the temperature also gradually declining. About seven days after the appearance of the rash peeling begins, and this usually goes on for two or three weeks at least.

Several very important complications may occur in scarlet fever. There may be inflammation of the kidneys. The urine becomes scanty and contains albumin and often blood, while there is swelling of the feet, ankles and face, or even more generally. Another complication is inflammation of the middle ear. Infection passes up the Eustachian tubes from the nose and throat and commonly causes a suppurative discharge from the ear. Possibly the infection may pass backwards and cause mastoid disease. A third complication is acute rheumatism.

The general treatment of scarlet fever is that of an infectious disease (q.v.) and of the state of fever (q.v.).

The mouth and throat should be kept very clean by the use of an antiseptic mouthwash (q.v.) several times daily, and it will often be necessary to use a nasal douche as well.

By inoculation with a vaccine a skin reaction is obtained in persons susceptible to scarlet fever, and these can then be given a prophylactic serum or vaccine. Sera are also used in treatment. *See Quarantine; Rash.*

SCARLET RUNNER. This favourite climbing bean yields very profitable crops if well grown. It needs deeply dug and manured soil to ensure that the plants do not suffer from lack of moisture in dry weather. It is not a success on poor land. Seeds should be sown during the second week in May at about 9 in. apart in a double row, the lines of the row 18 in. apart; it is wise first to put in tall sticks at 9 in. from each other on both sides of the prepared soil and to set one seed near each stick. A few seeds should be sown in a box of soil to provide seedlings which may be needed in case some of the seeds sown in the open fail to germinate. Another plan is to sow all the seeds in boxes of soil in a frame in April and to plant the seedlings in May. Stout sticks 7 or 8 ft. high are needed to support the beans adequately.

Although the finest crops are obtained from plants in the open garden, runner beans do fairly well in partial shade and may be sown to cover a fence or trellis in suburban gardens.

The dwarfing system is adopted by many market and some private gardeners. In this the rows are drawn about a yard apart, and the twiners pinched out regularly as soon as the plants have got well into bloom. Such a row makes a good border in a cottage or suburban garden. Under this mode of culture it is a good plan to sow a double row, the lines a foot apart, and to set the seeds in angles with each other at 9 in. apart. A pint of average runners contains about 180 beans.

The modern varieties bear large clusters of big, fleshy pods. Some of the best are Prizewinner, Best of All, and Scarlet Emperor. The old variety, Painted Lady has pink and white flowers.

Surplus beans should be stripped from the haulm at the first sign of frost. They may be stored in any glazed vessel, such as one of the old-fashioned red breadpans, if placed layer for layer between rock-salt. It is quite possible to have perfectly fresh beans at Christmas time by employing this method. Scarlet runner beans are cooked in the same way as French beans. *See Beans; French Beans.*

SCENT: The Various Kinds. The scent sold in shops consists of simple flower extracts, rose, violet, etc., and of blended bouquets. Each season new perfumes of the second class appear from the great perfumery houses, where subtle ingredients are mixed to obtain something a little different from the scents already on the market, something exclusive, which cannot be successfully imitated. The artistry which evolves a new, fashionable bouquet commands a high price; but, apart from this, the cost of materials and production renders it impossible for any good scent to be cheap.

To the make-up of these expensive scents go one or more of the natural perfumes dissolved in alcohol. Some of these natural perfumes are valuable in themselves, most are costly to extract. They include the essential oils or attars of flowers: the animal scents: ambergris from the sperm of whales: musk from glands in the musk deer, musk ox, and musk rat; civet from the civet cat; balsams such as santal and opopanax from the wood of trees and shrubs; oils like bergamot from the skin of citron fruits; oils from leaves such as verbena and geranium; from roots such as orris; and from the vanilla and tonka beans, the last developing the principle for the perfume known as New Mown Hay.

To obtain the essential oils from flowers in their absolute purity three processes are used. The first of these is distillation, in which the flowers, roses for instance, are heaped into boilers, through which steam passes, and gradually the essence oozes into a glass tube at the base of the still, to be collected in precious drops. The second process is effleurage, in which cold, purified grease is spread on glass trays and the flowers, jonquil tuberose, or jasmine, are sprinkled over the surface to yield their scent to the grease, and the next day are removed, when fresh blossoms take their place until the grease is thoroughly impregnated.

Maceration is the third process. Some grease is placed in a vessel and melted by a water bath at as low a temperature as possible. Into the liquid grease the flowers—this process is chiefly used for

violets—are stirred, left immersed for a day, and strained off, fresh flowers being added until the liquid can absorb no more of the perfume.

In these last two processes the scent is extracted from the grease by alcohol being stirred into it for hours and then left quiescent, when the fat separates, relinquishing the perfume to the alcohol, which is drawn off, evaporated, and condensed, until only the pure essential oil remains. Orris root is used to imitate the essential oil of violet, and oil of geranium that of the rose. Even in the almost priceless Turkish attar of roses the petals are often sprinkled with geranium oil before being placed in the still.

Some of the cheap scents depend largely for their composition on chemical combinations imitating the natural perfumes. Their chief defect is that often their imitative values do not last, and this accounts for the unpleasant odour of much cheap perfumery when stale, the chemicals used having been affected by exposure. Some of the cheaper flower perfumes are quite pleasant in use, but their cheapness is due either to extreme dilution of the natural scent, in which case they have no lasting quality, or to a less expensive natural oil being substituted for that of the name of the flower on the bottle. Shortly after use they possess only a vague, meaningless sweetness.

Scent should be regarded as a luxury of refinement and worthy of a good price. The best qualities are economical in use, as a few drops suffice to give the delicate fragrance. *See* Eau-de-Cologne; Glass; Lavender Water; Pot-Pourri; Sachet, etc.

SCHIPPERKE. The little skipper, to give an English rendering of its Flemish name, is an affectionate and lively small dog with an inquiring mind; a vigilant watch-dog, keen ratter and intelligent companion.

Schipperke. Champion of a breed of small alert dog which makes a trustworthy guard.

Wholly black in colour, he has a sharp foxy appearance, with a short straight back, well rounded at the hindquarters, and a dense, harsh coat which is developed into a bristling frill around the neck. The legs are straight and small boned, the feet small and cat-like. There is no tail; that is to say, some are born without one, the others have it docked in infancy. The small eyes are brown and bright; the ears small, sharp-pointed and carried stiffly erect. The weight should be about twelve pounds. *See* Hog; Kennel. Pron. Ship-per-ki.

Schizanthus. The botanical name of the beautiful half-hardy annual called the butterfly flower (q.v.).

Schnapps. Hollands gin is also frequently known as Schnapps. *See* Gin.

SCHNAUZER. This is a German variety of terrier. It is a rough coated terrier, stoutly built, docked and weighing about 24 lb. In colour they are grizzle or greyish and very active, sagacious, game and companionable. The schnauzer is a handy dog and puppies are not difficult to rear.

SCHOOL: How to Choose. For those who require a day school the difficulty is not unduly great, because the choice is distinctly limited. A school in the neighbourhood of the home must be

selected, and for many persons this will be a school supported by the local education authority. The majority of these are the elementary schools; but for the more advanced pupils there are secondary schools, where the teaching reaches a very high standard of excellence.

For those who desire to send their children to day schools of a different kind there is also ample provision. As regards boys, most towns have a public school in the shape of a grammar school, which is mainly attended by day pupils. These, with which the great day schools in London, St. Paul's, Westminster, Dulwich, and others, may be classed for our purpose, give a very good education at moderate fees. Travelling facilities make it possible for many boys living in country and suburban districts to attend them. These schools, however, do not take boys until they have reached a certain age, 12 or thereabouts, and have attained a certain proficiency.

Younger boys may be sent to the kindergarten department of a girls' school, or to some other school which provides training for juveniles, and from thence, when about seven or eight, pass to a preparatory school for boys, of which there are many excellent ones under private control. Some of the large schools, St. Paul's, for instance, run preparatory schools quite apart from the main school.

The education of girls belonging to the same social class as the boys mentioned is provided for by a chain of public schools, controlled by companies not working for profit, and by a large number of private schools. The former invariably provide an excellent education, and most of them have a junior department, where both boys and girls are taken as soon as they need a school.

The latter class vary very much, and no general statement can be made about them. Those who think of sending daughters to a school of this class should make careful inquiries, especially from persons who have themselves sent girls there. Private schools are preferred by many on social grounds, and they are certainly better suited for children who, for reasons of health, are unequal to the strain of a public school.

Boarding Schools. For the limited class of parents who send their children to a boarding school there is a wide variety of choice. Concerning the age at which they should be sent there is a certain difference of opinion. Some send boys as early as 8, and it is generally agreed that they should go not much later than 12 or 13 if they are to benefit properly from the public school training. Girls are usually sent to boarding school at a later age, not before 14, and this may be regarded as a sound principle.

For boys these schools may be divided into two classes. These are preparatory schools, nearly all private ventures, and the great public schools, as they are called. The curriculum and arrangements of the one are deliberately planned to lead to the other.

As, therefore, the private schools prepare for the public schools, parents should, if possible, choose a preparatory school that has a special interest in the public school for which the boy is intended. Monetary considerations are important here, as the fees of many preparatory schools reach a very high figure. Parents should, however, be warned against choosing a school merely because the fees are low. People only get what they pay for, or less in education, as they do in other things, and the cheapness may be made possible by economy in food or some other essential of health. Persons who cannot pay for a good boarding school will do much better to send a boy to a day school.

Entering Boys at Public Schools

Parents who wish to send their boys to one of the large public schools should enter the name as early as possible. The age at which names are received varies from school to school, but the necessary information can always be obtained from the headmaster or the bursar.

As between one public school and another, there is little to be said. The fees do not vary enormously, but it must be remembered that, though the schools at the top socially may not charge

much more in fees than do the others, they cost more in other ways, as certain expensive standards of dress and living are maintained by the boys. Moreover, generally speaking, it is inadvisable to throw a boy into the society of those who in after life will possess far more money than he is likely to have, at least as a young man.

Of the boarding schools for girls, a few are public schools, run on lines not unlike those of the boys' schools, but the great majority are private schools. For those with adequate means the public schools can be unreservedly recommended, but the private schools vary, both as regards charges and as regards efficiency, more perhaps than any other class, either for boys or girls. For one of these the choice should only be made after very careful inquiry, which should be in addition to personal inspection. Some of them make a great point of deportment, and training for the life of London society; but this is useless, except for a few girls.

Many of these schools, and also many of the preparatory schools, are situated by the sea, and this makes an appeal to a great number of parents. It is quite certain that the sea air is excellent for children, and regular sea bathing is a distinct advantage, but parents should not let these considerations outweigh all others.

Scholarships. Many boys are enabled to pass through a public school by the aid of scholarships, and in the same way boys from the elementary schools pass to the secondary ones. In both cases the competition is fairly severe, and in the case of the best public schools it is very severe indeed. Those only can hope to succeed who, in addition to marked abilities, are sent quite early to a good preparatory school and are specially coached.

Boys with good voices can obtain an excellent education in one or other of the choir schools, where also financial assistance is given towards the cost of education. For girls there are not so many scholarships.

Other methods of educating children are practised on a smaller scale. There are one or two schools devoted to co-education, in which some persons believe. Others send children abroad to be educated, Switzerland being popular for this purpose. In this way they obtain a knowledge of modern languages: but unless the school is a very good one it is probable that the loss is as great as the gain.

SCHOTTISCHE. In the ordinary schottische the first, second and third movements are the same as in the polka, the woman beginning with the right foot and her partner with the left. The fourth movement is a slight spring on the toe of the commencing foot and then, as in the polka, the step is made, beginning with the other foot.

Having performed the full step from side to side, the half step is made by a little spring on the toe of the first foot; left, man, right, his partner. The other foot is passed behind, rested on the toe, and a spring is made on the first foot again. Then the movement is repeated with the other foot. The half step is used for turning.

In the Highland schottische the couple face each other, hop twice on the right foot, give a beat in the fifth position in front and one behind with the left foot. Then each passes to the left with the first 4 movements of the ordinary schottische and repeats the whole step to the right. They then join arms, turn round with 8 hops and repeat. *See Reel.*

SCIATICA. Neuralgic pain in the great sciatic nerve running down the back of the thigh is known as sciatica. It is more common in men than in women, chiefly amongst those who are constantly exposed to the weather.

Throughout the course of an acute attack the patient is best in bed. At the start poultices along the course of the nerve often relieve the pain. At the same time they ensure the limb being kept at rest. After a day or two the poultices may be discontinued, large pads of dry cotton wool being wrapped about the limb in their place.

At the onset of the attack some aperient, such as 2 or 3 gr. of cascara, to be followed next morning by a teaspoonful of Epsom salt, is usually advisable. To control the pain, aspirin in 7 to 10 gr. doses every 4 hours may be taken under medical advice.

Stimulating applications, such as liniments of belladonna, aconite or chloroform, the galvanic electric current, hot water douches, or alternating douches of hot and cold water may be tried. *See* Gout; Poultice; Rheumatism. Pron. Si-at'i-ca.

SCILLA. This group of spring and early summer flowering bulbs is popularly known as squills and bluebells. They are planted in early autumn in ordinary soil and flourish in sunny or partially shaded places: bluebells are happy in deep shade. The bulbs of the small early kinds should be set 2 in. deep, the larger ones 3 in. deep. The best of the low growing early spring squills are *sibirica* and *bifolia* with blue flowers; they look well in the rock garden, flower border and shrubbery and on the lawn.

Scilla. Three of these blue spring flowering bulbs grown in a pot for house decoration. (Courtesy of Amateur Gardening)

The common bluebell is *Scilla nutans*, of which there are varieties with rose-pink, pale blue, dark blue and white flowers. One named *Scilla autumnalis*, 6 in., has purplish-blue flowers in early autumn. The Spanish blue bell (*hispanica*) 15 in., bears showy spikes of bloom in various colours in May. The Italian squill (*italica*) and the Peruvian squill (*peruviana*), 6 in., have pale blue flowers in early summer and are suitable for the rock garden. Scillas may be set in pots in early autumn and grown in an unheated or slightly heated greenhouse to provide bloom in early spring.

They are suitable also for planting in bowls of fibre in the home. *See* Bulb; Hyacinth. Pron. Sil'a.

SCISSORS. In a pair of scissors the flats of the blades slide over each other so that a shearing action is obtained; the blades are ground to a wide angle, not a fine angle, as for a knife. Scissor blades should be bent slightly so that their natural spring makes the cutting edges scrape each other as the scissors are closed, and the pivot should be a screw locked by riveting the point over. Many household scissors lack these features, and the scraping action has to be got by a twisting action of the thumb and finger. It is thus difficult to use a pair of right-hand scissors with the left hand. To test the shearing action of scissors, when buying them the rings should be held one in each hand and the scissors opened and shut; under this test the blades should not flap freely, but a steady grind should be felt, though a pair that is stiff to work should be rejected.

Repairs. If scissors get loose after long service the pivot should be tightened a little by laying the scissors on a heavy piece of iron with the head of the screw down and drawing the rivet tighter by

light hammer blows on the screw point, the screw having been first tightened with a screwdriver if possible.

When scissors get blunt the edges must be ground with an oilstone or on a grindstone, cutting at right angles to the plane of the flat of the blade, the scissors being held wide open for the purpose. On no account must any attempt be made to grind the flats of the blades. *See* Cutting-out; Grindstone; Pruning; Secateur; Shears.

Scolopendrium. This is the botanical name of the popular hart's tongue fern. *See* Fern; Hart's Tongue Fern; Rock Garden.

SCONE: How to Bake. Scones may be cooked in the oven or on a girdle. The mixture for these cakes is usually of a plain character, and the raising agent employed consists of bicarbonate of soda and cream of tartar or baking-powder.

If a little extra time and trouble is taken by sifting the carbonate of soda and cream of tartar with the flour two or three times, the scones will be greatly improved. Buttermilk, or sour milk, is considered to be superior to fresh milk for moistening the dough, in which case a smaller proportion of cream of tartar is required for mixing with the carbonate of soda.

Good tea-scones can be made by sifting 1 lb. fine flour with $\frac{1}{4}$ oz. carbonate of soda, $\frac{1}{2}$ oz. cream of tartar and a good pinch of salt into a basin. Work together 4 oz. butter and $2\frac{1}{2}$ oz. castor sugar adding, when properly creamed, 2 well-beaten eggs and $1\frac{1}{2}$ gills milk. Mix up the flour into a stiff dough with the liquid, roll it out about $\frac{3}{4}$ in. thick, and cut it into small round pieces.

Cut out as many as possible, then fold up the dough, roll it out again and cut another batch, proceeding in this manner until all the mixture is used up. The shaping must be done expeditiously, and as each round is cut out it must be turned over and placed on the baking-sheet. No fruit is added to these scones, and they should be served hot, split and thickly buttered. Brown scones can be made, by using half wholemeal flour and half white flour. A little more milk may be necessary to get the right consistency. For sultana scones add 2 oz. cleaned sultanas.

Excellent baking-powder scones can be made by increasing the quantity of milk for tea-scones by 1 gill, and adding to the flour 2 heaped teaspoonfuls of baking-powder in place of the carbonate of soda and cream of tartar. These scones should be shaped with a tablespoon dipped in flour, as they are too moist to handle easily. They must be baked in a very hot oven, and eaten hot from the oven. *See* Girdle Cake.

SCOOP. A scoop is a shovel-like implement used for moving food or other material. The shovel attached to a coal box is sometimes called a coal scoop, while the spoon employed for soft sugar is occasionally known as a sugar scoop. Other examples are the crumb and the marrow scoops. *See* Coal Box; Shovel; Sugar Basin.

SCORCHING. For scorch marks on linen mix together b pint vinegar, 2 oz. fuller's earth, $\frac{1}{2}$ oz. shredded white soap, and the juice of 2 onions, and boil them up until they form a thin paste. Spread this over the marks, allow it to dry on the material, and then wash it out. The process may be repeated if necessary. The onion juice is obtained by peeling and slicing the onions and then pounding or squeezing them. Silk or wool that has been badly scorched will rarely yield to treatment. *See* Ironing.

SCORZONERA: The Plant. A vegetable with long thin roots which is useful in winter though not very commonly grown in this country. It is easily managed in deep well tilled soil free from fresh

manure. Seeds are sown in April in drills 12 to 15 in. apart, and the seedlings are thinned out to 9 in. apart. In autumn or winter the roots are dug as they are needed.

SCOTCH BROTH: How to Make. The basis of Scotch broth is mutton, and it is flavoured with vegetables and thickened with pearl barley. To make it, take 3 lb. middle and scrag end of a neck of mutton joint it and cut all into neat pieces. Put these into a large saucepan with 3 quarts cold water and $\frac{1}{4}$ oz. salt and boil up, skimming off all impurities.

Now prepare and cut in large pieces 2 good-sized turnips, 2 leeks, 2 onions and 1 head of celery; add these with a large bouquet garni to the mutton, boil up again and then simmer gently for four hours. Strain through a sieve into a basin, rinse out the saucepan and return the liquor to it, adding $3\frac{1}{2}$ oz. pearl barley which has been washed and parboiled.

When the broth boils up again, add to it a mixture of fresh vegetables cut into dice. These should consist of 2 small carrots, 2 large turnips, 1 small head celery with 2 onions and 2 leeks shredded finely. Season with salt and pepper and boil gently for 1 hour, skimming the broth free from fat. Sometimes carrots are omitted. Whether the portions of mutton are served in the broth is a matter of taste.

SCOTCH BUN. This bun requires two days for making. To prepare the dough, sieve together 1 lb. flour and 3 oz. sugar. Then rub in a little less than $\frac{1}{4}$ lb. butter. When the mixture is quite smooth cream together $\frac{1}{2}$ oz. yeast and a pinch of salt; pour in $\frac{1}{4}$ pint cold milk, and strain the whole into the flour, etc. Well knead the mixture, and then leave it overnight in a warm room, covering the bowl in which it is placed with a thick cloth.

The centre of the bun must be prepared the following day with $\frac{1}{4}$ lb. of the above mixture $\frac{1}{2}$ oz. spice, $\frac{1}{4}$ teacupful treacle, a well-beaten egg, $1\frac{1}{2}$ lb. mixed raisins, currants, and sultanas, a few sweet almonds, and $\frac{1}{4}$ lb. shredded candied peel. Mix all these ingredients in a basin, afterwards kneading well and moulding the mixture with a little flour.

To make the cover of the bun, take the rest of the dough, rolling $\frac{2}{3}$ of it into a round, and lift the inside part of the bun into this. Then draw up the dough at the sides to reach the top, brushing beaten egg over the edges, and roll out the remaining dough for the top portion. Put on the top round as neatly as possible, and prick the bun all over with a fork, making deep holes all over the surface. Brush the bun over with a little milk, and bake in a moderate oven till brown. This should make a 3 lb. bun.

Scotch Fir. The common name of *Pinus sylvestris*, a conifer which is invaluable for planting in exposed places. *See* Pine.

SCOTCH KALE. This is a very hardy variety of borecole or kale and includes dwarf and tall curled kinds. No type of winter green excels it for free yielding crops during autumn, winter, and spring.

The kale reaches a height of from 2 ft. to 3 ft., with heads of deeply curled leaves, which are at their best after exposure to frost. Seeds are sown on a reserve border in April, and the seedlings are planted out in summer at $2\frac{1}{2}$ ft. apart. *See* Kitchen Garden.

Scotch Pancake. This is another name for the tea-cakes known as girdle cakes (q.v.).

Scotch Terrier. *See* Aberdeen Terrier.

SCOTCH WOODCOCK. The savoury that is called by this name is prepared by mixing 1½ teaspoonfuls flour to a smooth paste with 1 tablespoonful milk and putting what remains from a gill of the latter into a pan with 1 oz. butter. When these are hot, stir them on to the flour, mix all together, and boil them up.

Simmer them for a few minutes, keeping them well stirred, draw the pan to the side of the fire and let its contents cool slightly before stirring in one by one the yolks of 2 eggs. Continue stirring the whole over gentle heat so that the eggs may cook, then add salt and cayenne to taste, and a teaspoonful of chopped parsley. Have ready some small rounds or squares of hot, buttered toast, spread them first with some anchovy paste, and then with the hot mixture. Send them to table at once, garnished with narrow strips of anchovy laid across the egg.

SCRAP BOOK. Brown paper makes an effective book. Sheets cut to the required size and stitched together with strong thread, or fastened at the corner with a piece of ribbon run through, make an excellent background for all kinds of pictures. Books for hospitals, especially for sick children, can be made out of coloured and glazed calico, pink or blue, with the edges pinked and a piece of silk cord or ribbon threaded through to keep the sheets in place. If the calico will not take paste satisfactorily, a little seccotine or fish glue will serve the purpose equally well. The great advantage of such books is their lightness.

For the pictures themselves there is no need to seek far. Coloured advertisements cut out and pasted up neatly without the printed matter, and illustrations from bulb catalogues, or those distributed by seed merchants are useful. Such pictures should be cut out in silhouette if the best effect is to be obtained. Old Christmas and birthday cards, scraps from crackers, and the covers of magazines all help to provide colour and variety. Flour paste is usually sufficient for this work, though for thick cards something stronger may be needed.

SCRAPER: For Boots. In one sense this word refers to an article used for removing dirt from boots and shoes. Such are usually placed just outside the door of a house. *See* Boot Scraper.

SCRAPER: The Tool. The scraper is a tool for giving a better finish to an article already machined or worked. The type for woodworking, illustrated, consists of an oblong strip of sheet steel about 6 in. by 3 in. and in thickness about 1/16 in. This tool is largely employed in cabinet making. The method of using is to hold it in both hands a few degrees out of the perpendicular away from the operator. The two thumbs are placed in the middle of the scraper on the side nearest the user, while the fingers grip the other side. Pressure now applied by the thumbs will give the scraper a bend in

the middle and away from the operator. The lower edge is put upon the work and a strong forward motion imparted by the upper arm.

Scraper. Oblong strip of steel being used as a finisher in woodwork.

In the majority of cases the scraper is used in the same direction as the grain of the wood; but experience is the only guide in this respect. Very often the wood will come up woolly after scraping; this can be cured by scraping with the grain but from the opposite direction. It is sometimes useful to approach the scraper to the wood in an oblique

direction, this having a decided tendency to keep the grain in place, but it has the disadvantage of making a slower cut.

The method of sharpening represents a radical departure from the standard practice of tool sharpening. The scraper is set firmly in a vice between two pieces of wood, the top projecting a little. A fine file is then run over the top, and the burr thus created removed with a fine oil stone rubbed on the top and sides. When both edges are sharp a round rod of hard cast steel or similar material is pressed on the edge of the scraper at an angle of about 45° with it. The sharpened edge is thus destroyed and another burr created. This burr is the scraping edge of the tool.

Scrapers are extensively employed in metal fitting. Such a tool can be made from an old file, the teeth of which have been ground away on the grindstone and the edges ground sharp and smooth. Such scrapers are durable and efficient. *See Cabinet Making; Metal Fitting.*

SCREED. A projecting strip known as a screed is employed in plastering and rendering as a guide in the preparation of a flat surface. It may be of wood or metal or of the same material as the surfacing of the wall.

Wooden screeds are fixed to the face of the wall or other surface with the aid of rough grounds or thin packing pieces. The face of the screed is levelled, or brought into line with the desired face for the work. Two screeds are set vertically and two horizontally, then all four are adjusted until their faces truly represent the outer surface of the wall covering. Lines are stretched from one screed to another and any additional screeds added wherever they are requisite.

The wall surface is thus divided into a series of cells, the screeds being usually about 2 to 3 ft. apart. When this preliminary work has been done the covering material is then applied, and afterwards levelled with a long batten. When the plaster has set sufficiently the screeds can be removed and the spaces filled in with plaster, etc., or more generally are embedded in the second and finishing coats when these will be of sufficient thickness.

In other cases screeds are made in the form of little walls of cement or plaster and their faces levelled, the spaces between being subsequently filled in with the same material. *See Lath; Plaster; Rendering.*

SCREENS: USEFUL AND DECORATIVE

Their Choice, Construction and Renovation

For further information on the work suggested below consult *Marquetry*; such entries as *Embroidery; Fire Screen; Inlaying; Lacquer; Lead Art Craft; Leather Work; Moulding; Mitre Joint; Painting on Textile Fabrics; Patchwork; Plywood; Tapestry; Veneer.* See also *Nursery; Queen Anne Style*

To be decorative and practical is the twofold object of the screen. Styles which, by reason of spindle-like legs or of openwork carvings on their panels, let through draughts, are only useful where they hide something unattractive; if not required for this purpose they should be admitted to rooms only on the same principle as pictures—by right of intrinsic beauty.

When choosing a screen it is worth while taking thought and trouble to secure the right type, as it presents such a large surface to annoy or please the eye, and however beautiful in itself it can mar a room by being out of key.

Reproductions of rare and artistic screens can be obtained at a variety of prices, and for durability those in leather have everything to recommend them. In brown, antique finished hide with no trimming but brass nail heads, they look their best in an oak-furnished dining room or hall, while

the embossed or lightly modelled heraldic device style of ornamentation supplies variety to the same type of screen. The quaintly patterned and coloured leather screen, with its conventional fruit and floral motifs is, when placed against a plain wall, a joy in mellow richness of tint, and the same may be said of those panelled with grouped figures after the style of various schools of painting.

The most beautiful type of leather screens are painted and lacquered. The illustration with a Chinese design might have graced a Queen Anne room (though screens were then often six-fold), or have been seen during the middle 18th century period when Chippendale and other great designers were influenced by Chinese styles. Copies of such screens look beautiful in rooms which suggest 18th century furnishing. With certain severe types of modern interior decoration, plain gold lacquered screens may look more effective.

For the living-room tapestry screens are often suitable, and panelled with needlework tapestry are highly decorative. Drawing room screens may have Chippendale style mahogany frames, glass-topped and with lower panels of brocade. Sometimes beautiful old needlework is utilized under glass for this type of screen, or in combination with a gilt scroll-designed frame in the French style. Cheap Oriental screens are not to be recommended, as the paper backing under the embroidered gauze is so easily split and torn.

All-glass panelled screens are decorative in suitable rooms, and are useful where it is desired that

draughts but not light should be excluded. Mirror glass is used in sectional designs, and such screens tend to make a room look larger. As a general rule, glass of any kind is more suitable when confined to the upper panels of a solidly constructed wooden screen.

For a bedroom plain-coloured canvas, silk or cotton material repeating an established tone in the room is restful and pleasant. A different patterned cretonne or chintz to that already draping the room should be avoided. Some people like a gathered washing material merely tied with tapes on to one of the wooden frames sold for the purpose, so that the whole thing can be washed. The objection to this type of screen is that it is not a draught preventer.

Screen. Wooden screen with mountain landscape design inlaid with coloured marquetry and with inlaid line at the edges of the panels. (Courtesy of Rowley Galleries)

Decoration of Screens. For the nursery or living-room a wooden screen can be most decorative, light and yet durable. The white enamelled example illustrated is most practical, as it is washable; the other wooden screen shown has a mountain landscape design inlaid with marquetry of coloured woods. Less ambitious designs in marquetry could be confined to the upper panels of a screen constructed after the style of Fig. 1. This screen could also be enamelled and decorated like the nursery screen illustrated. The animal pictures can be drawn freehand, traced, or stencilled and painted in oil colours. Ideas for the suitable decoration of the upper panels of this screen will also be found in the article on Lacquer Work, and that on Enamel should also be consulted. Floral designs can be selected, a pretty idea being to copy flowers from a cretonne used in the furnishing of the room. A beautiful effect can be achieved by treating the upper panels with poker-work in colours, staining the lower panels and framework with marquetry stains. Wood carving can also be effectively introduced in low relief and incised designs.

Another form of decoration is by means of glass and lead art craft. A screen for a hall looks well with glazed upper panels treated in this manner, the rest of the screen being stained or lacquered a bright colour, if canvas is used to cover the panels, a conventional design may first be stencilled on the fabric (*see* Stencilling), or designs may be embroidered in coloured wools.

Screen. Four-fold hide screen with antique gold lacquer design on a cream-coloured ground. (Courtesy of Waring & Gillow. Ltd.)

Making a Screen. The three and four fold screen can be made by the amateur in many different patterns. The plain form illustrated in Fig. 1 will serve as a guide to their construction. The plain screen can be given a decorative effect by means of the panels, which can be of ornamental wood, and many kinds of plywood are of value. Canvas in artistic shades can be stretched on plywood and used as panels.

The construction of the framework of a screen is straightforward, but the material must be well seasoned to prevent warping, and planed quite straight and true. For a full-size screen the wood should be at least 2 in. by $\frac{3}{4}$ in., but $2\frac{1}{2}$ by 1 in. is advised. The extra thickness will make the screen heavier, but this is not a disadvantage. Before the joints are marked out, the method of securing the

panels should be determined. Two methods are suitable; in one the panel is let into a ploughed groove, as in Fig. 2, and in the other the panel is held in position by strips of beading, as in Fig. 3. The haunched mortise and tenon joint for the corners of the grooved frame is shown in Fig. 4; the grooves should be ploughed to fit the panelling and carried to a depth of $\frac{3}{8}$ in. The same joint should be made at the corners in the case of a plain frame, but the tenon will be flush with the inner edges of the frame. The choice of material depends on the panelling. If a canvas-covered panel is fitted, the frame can be of deal, pine, or whitewood stained to match the material; if a decorative wood is used the framework should match the panels. The uprights and rails should be placed together in marking out, so that the position of the mortises, tenons, and shoulders can be quite accurately indicated.

Screen. Enamelled wooden screen for a nursery, with animal scenes stencilled and painted in bright colours.

In the present design the uprights are 5 ft. 6 in., and the rails 2 ft., with a $2\frac{1}{2}$ in. by 1 in. framework, and the top panel should be 1 ft. 5 in. high. The frames should be cramped up and carefully tested for squareness, and it should be noted that any carelessness in cutting the joints may cause the frame to warp. As much of the surface finishing as possible should be done before the frame is glued up if the panels are let in the framing, the final cleaning up and subsequent polishing being done in the usual way, either wax or oil being preferable. The canvas-covered panels are very effective; the material should be pasted on, or if it has been embroidered or stencilled in a coloured pattern it can be stretched and tacked carefully to the edges of the panels.

If beading is used it should have a rounded edge, and be secured to the frame with panel pins, the corners being mitred. An alternative design can be made to the same proportions with plywood panels of Oregon pine, a centre upright being fitted, and the panels secured with $\frac{1}{4}$ round beading. Made with deal framing and stained either brown or green, the screen is both effective and inexpensive. The divisions can be hinged with the simple hinge shown in Fig. 5, or the usual form of screen hinge in Fig. 6. The latter enables the divisions to be folded in either direction, and keeps them close together. They are both easy to fit, slots being made to take the thickness of the material.

Renovating a Screen. A canvas or other plainly covered screen that has become shabby need not be discarded as useless, for it can be easily renovated. If the framework is stout, glazed calico can be used to cover it, being fastened round the edges by brassheaded nails, and in the folds by tacks.

By means of fish glue, scissors, and some bright-coloured pictures, the screen can be transformed into a gay and attractive piece of furniture for the nursery. Suitable pictures can be obtained from book wrappers, magazines, and old children's books. The pictures should be cut out neatly, brushed over with a thin coating of glue, special attention being paid to the corners, and stuck on to the screen.

One fold should be finished before another is begun, and the top row should be done first.

It is generally best to start at a corner not in the centre. It does not matter whether the pictures are the same size or not, but as they must fit exactly into the width of the screen and they should not be overlapped, it will probably be necessary to have a very wide one, or one, or two narrow ones at the end of the row. Thin white varnish, as used for lamp-shades, should be brushed over the pictures to complete the work.

Screen. Fig. 1. Easily made wood and canvas three-fold screen.

A screen frame can be covered with furnishing satin and decorated with shaped pieces of embroidery at the top of each panel framed by a gimp trimming, which in a wider form edges each fold of the screen. This method has been used successfully for covering an old screen, and depends on careful measurement, the neat stretching of the material over the frame and the skilful manipulation of the edging gimp. Hand embroidery or appliqué work can be used instead of bought pieces if more time can be devoted to the manufacture of the screen, or the scheme lends itself to all sorts of combinations of materials and colours in forming panels of pictorial patchwork. Painting on satin provides one of the most effective ways of renovating panelled screens. The frames themselves must be in good condition, and the satin of a colour that will harmonize with the wood. Embroidery and painting may be happily combined. Designs may also be outlined in coloured beads. If white or some pale shade of artificial silk or satin is used, a glass covering that will protect

it from dust and yet show the work to the best advantage is essential. Worked and painted panels can be made up into screens, the cost depending on the size and style of mounting.

SCREENING: In Wireless. This is a method of preventing interaction between two adjacent circuits by interposing a metal shield. The screening should be arranged so as to minimize both magnetic and capacity couplings, otherwise instability is liable to occur.

In simple sets a single metal sheet (usually of copper or aluminium) may suffice, but in sensitive multi-valve receivers it is sometimes necessary to enclose the adjacent amplifying stages in metal boxes. In sets employing up to five valves the screening is normally confined to the high-frequency stages. Inductance coils should be carefully placed in relation to the screening, since if the coils are mounted too close to the metal shields a marked loss of efficiency may occur. The metal work comprising the screening is normally joined to earth, and therefore to low-tension negative. It is essential to insulate from the screens all wiring not at earth potential.

SCREW: For Wood and Metal. The screw is a cylindrical piece of metal or wood having a spiral groove cut along the whole or a considerable portion of its length. At one end provision is made for imparting a turning motion to it.

The wood screw has a tapered shank, which taper varies according to the nature and the application of the wood with which the screw is used. The thread resulting from the spiral groove cut along the shank is deeper, thinner, and spaced farther apart in the wood screw than in the metal screw. The former terminates at its lower end in a sharp point. The metal screw, on the other hand, has a fine thread of little depth and in many patterns the thread is formed along the whole length of the shank. The shank is parallel and does not terminate in a point.

In principle the screw represents an inclined plane moved by a force up or along another inclined plane. These are represented by the screw thread and, in the case of the metal screw, the thread of the screwed hole. The wood screw makes its own thread as it advances. Metal has such solid properties that only a hole of the correct diameter and shape, tapped out with a cutting tool having an identical pitch, allows the screw to be turned into it. The angle of the inclined plane is known as the pitch angle of the screw, and the spacing of the threads as the pitch. The difference of type between the two classes of screw is necessary owing to the entirely different natures of wood and metal.

Screw. Diagram illustrating process of screwing in wood.

The countersunk wood screw is designed to sink flush with the wood, and is used where an unbroken surface is required, as in a table top. The round-head screw is useful where the material is too thin to permit countersinking, and this type is also used for its more decorative appearance. It is often japanned and used with rim locks, barrel bolts, and thumb latches.

Where a good appearance is desired iron screws may be blued, tinned, or finished to match any particular work with which they will be afterwards associated. Screws for outside work can be had with a galvanized finish. Raised-head screws are a combination of the countersunk and round-head pattern. These are often employed with a small brass cup, or socket, for use in hardwood, where they may be removed from time to time without

the risk of damaging the surrounding wood.

To enable a screw to be introduced into wood, it is necessary to bore a hole somewhat smaller in diameter than the screw. This is most conveniently accomplished with a gimlet. After the hole has been made, the screw can be driven with the aid of a screwdriver, or with a screwdriver bit in a carpenter's brace. If two pieces have to be screwed together, the screw can only bite properly into one of them, which should preferably be the thicker if there is any difference. What is known as a clearing hole is drilled in the first piece, and the termination of the hole on the face of the work should be properly countersunk. The head should draw the one piece towards the thicker or outer piece, ensuring a close, tight joint. If the work is not done in this way, the screw bites into both pieces of wood and will not draw the joint up tight. The plain shank will tend to jam in the hole, unless a proper clearing hole in which the shank can just turn is provided.

Driving screws into plaster is a difficult operation; either it will be necessary to fix a wooden plug or to employ one of the patent fibre plugs. The method is described and illustrated in the article Plug (q.v.).

Screws for Metal. The thread and pitch of metal screws vary with particular requirements, two standard threads much in use being the Whitworth and British Association sizes. The former is the thread most commonly used in machinery, and the latter for model work and small screws generally. Except for special purposes, the thread of a metal screw is taken to the head of the screw.

Metal screws can only be driven into material after a hole has been drilled and tapped to receive them. The tapping process consists in making a screw thread of the same size and shape as that on the screw which is to be screwed into it. *See Hand Screw; Stocks and Dies.*

SCREW CUTTING. So far as the amateur is concerned, there are two ways of cutting a screw thread, namely, by the use of stocks, dies, and taps, or in a lathe. The first of these methods is described in the article on Stocks and Dies.

Screw Thread. Fig. 1. Standard Whitworth. Fig. 2. International standard (metric system). Fig. 3. Acme standard. Fig. 4. Buttress thread. Fig. 5. Common type of square thread. Fig. 6. Double thread.

In using the lathe there is far more to be considered than a mere operating of the tool rest and the lead screw control nut of the lathe saddle. Some makes of small lathes are provided with a dog clutch on the lead screw instead of a split nut on the saddle. The first thing to do is to set the change wheels in accordance with the table of changes provided, selecting, if possible, a pitch that has an even multiple of the pitch of the lead screw. In other words, if there are 8 threads to the inch on the lead screw, then 16, 24, 32, and so on are even numbers, and the dog clutch or split nut that governs the travel of the saddle may be engaged at any point without fear of the tool failing to come up in register with the partly cut thread.

If an unequal number of threads per inch must be cut, it will be necessary to stop the countersunk and round-head pattern. These are often employed with a small brass cup, or socket, for use in hardwood, where they may be removed from time to time without the risk of damaging the surrounding wood.

To enable a screw to be introduced into wood, it is necessary to bore a hole somewhat smaller in diameter than the screw. This is most conveniently accomplished with a gimlet. After the hole has been made, the screw can be driven with the aid of a screwdriver, or with a screwdriver bit in a carpenter's brace. If two pieces have to be screwed together, the screw can only bite properly into one of them, which should preferably be the thicker if there is any difference. What is known as a clearing hole is drilled in the first piece, and the termination of the hole on the face of the work should be properly countersunk. The head should draw the one piece towards the thicker or outer piece, ensuring a close, tight joint. If the work is not done in this way, the screw bites into both

pieces of wood and will not draw the joint up tight. The plain shank will tend to jam in the hole, unless a proper clearing hole in which the shank can just turn is provided.

Driving screws into plaster is a difficult operation; either it will be necessary to fix a wooden plug or to employ one of the patent fibre plugs. The method is described and illustrated in the article Plug (q.v.).

Screws for Metal. The thread and pitch of metal screws vary with particular requirements, two standard threads much in use being the Whitworth and British Association sizes. The former is the thread most commonly used in machinery, and the latter for model work and small screws generally. Except for special purposes, the thread of a metal screw is taken to the head of the screw. Metal screws can only be driven into material after a hole has been drilled and tapped to receive them. The tapping process consists in making a screw thread of the same size and shape as that on the screw which is to be screwed into it. *See Hand Screw; Stocks and Dies.*

SCREW CUTTING. So far as the amateur is concerned, there are two ways of cutting a screw thread, namely, by the use of stocks, dies, and taps, or in a lathe. The first of these methods is described in the article on Stocks and Dies.

In using the lathe there is far more to be considered than a mere operating of the tool rest and the lead screw control nut of the lathe saddle. Some makes of small lathes are provided with a dog clutch on the lead screw instead of a split nut on the saddle. The first thing to do is to set the change wheels in accordance with the table of changes provided, selecting, if possible, a pitch that has an even multiple of the pitch of the lead screw. In other words, if there are 8 threads to the inch on the lead screw, then 16, 24, 32, and so on are even numbers, and the dog clutch or split nut that governs the travel of the saddle may be engaged at any point without fear of the tool failing to come up in register with the partly cut thread.

Screw Cutting. Fig. 1. Diagram showing where chalk marks should be made on the lathe. Fig. 2. Correct shape of blank. Fig. 3. Plan view showing one edge of tool cutting.

If an unequal number of threads per inch must be cut, it will be necessary to stop the lathe at the end of each cut and line up at the chalk marks previously made at two points, the first on the mandrel and the second on the lead screw, corresponding marks being made on the body of the lathe.

As soon as all four marks line up the saddle may engage with the lead screw on no account before. This is illustrated in Fig. 1.

The work to be screwed is first turned to the required diameter, and a small extension, left on the end, turned to the root diameter of the thread, so as to avoid the possibility of cutting the thread too deep (Fig. 2). The work should then be placed in the lathe, either between centres or in a chuck, according to its shape.

Next set the tool, ground to the correct angle, in the tool rest on a level with the centre of the work, and at an angle of 90° to the lathe bed.

Now approach the tool close up to the outside diameter of the work, so as to get the first position and reading of the hand-feed index. If one is not fitted, chalk a mark on the hand wheel, then withdraw the tool a little way and place it, by means of the tool rest, about $\frac{1}{4}$ in. from the work towards the tail stock. Then return the tool about one-sixth of a revolution of the hand wheel nearer the work, as indicated by the position of the chalk mark just made.

Start the lathe, having first engaged the back gear and the lead screw clutch, and make the first cut, withdrawing the tool smartly when the end of the cut is reached, at the same time throwing out the lead screw clutch. Then return the tool towards the tail stock to its original position and set about 5° deeper than the one-sixth just given: throw in the clutch and make the next cut.

This process is repeated until the thread is of the correct depth. In the case of work that is held in a chuck, it is an easy matter to test the progress of the thread with the part into which it is to be screwed. The chuck may even be unscrewed off the mandrel without fear of upsetting the register of the tool with the thread. Where the work is placed between centres great care must be taken, if the work is removed, to see that the arm of the carrier that is in contact with the driving stud on the face plate is again the driving arm when the work is replaced; otherwise the work will be half a revolution out by the time the driving stud makes contact with the other arm, and this will bring the tool out of register with the thread.

Great care must be taken in depthing the tool at each cut, and it must be borne in mind that the nearer the thread gets to completion, the greater will be the edge contact of the tool; therefore the depth of cut must be reduced gradually as the thread nears completion.

If this precaution is not taken it is probable that the point of the tool will wedge up and break off.

If the above points are noted little trouble will be experienced when cutting fine threads, but for coarse threads, after the first 3 or 4 cuts, the tool should be very slightly moved by means of the tool rest across the thread, so as to cause it to cut on one face only, reversing the process so that the next cut is on the opposite face (Fig. 3) The depthing of the tool is carried out as previously explained. When cutting a square thread this procedure is absolutely necessary for both fine and coarse threads. Plenty of thin oil or soap and water should be used.

Screw Threads. There are two classes of screw thread, the triangular and the square. The former is used where grip and maximum security are required, and the latter where progressive movement is necessary with as little binding or frictional effort as possible. The lead screw that operates the saddle of a lathe is a notable example; in fact, the screws of all forms of high-class machinery that are a part of the various controls are of square thread section.

The most common type of V thread is the Whitworth, which varies in pitch, i.e. in the number of threads to the inch, in relation to the diameter of the bolt. The shape of the thread is shown in Fig 1. One-sixth of the full depth of the thread is rounded off at the top and bottom to facilitate the cutting of the thread, and to render the exposed thread of the male member, the bolt, less liable to injury.

Where threads are formed by the use of stocks and dies, the shape of the thread will obviously be correct, but when the thread is cut in a lathe, such would not be the case unless great care is taken to see that the screwcutting tool is ground to the angle of 55° on the cutting faces.

Other standard screw threads are B.S.F., British Standard fine; B.A.S.T., British Association screw threads, the various sizes of which are stated in millimetres; B.S.P., British Standard pipe, used for all barrel work, such as gas fitting, etc.; and the I.S.T., International Standard thread (Fig. 2), better known as the metric thread. With this type the angle of the thread is 60° , the top of the thread being flat and the bottom rounded. The American Standard (the Sellers thread) is practically identical with the International in regard to shape of thread, but the pitch corresponds very nearly to the Whitworth table.

Two other types are the Acme and Buttress thread. The former, Fig. 3, is a modification of the square thread, used chiefly in machine tool work where a disengaging nut is required. Owing to the fact that the thread is wider at the bottom for a given pitch than the square thread, it is much stronger.

The Buttress thread (Fig. 4) is sometimes used where a screw has to resist a force acting always in one direction. It has one surface normal to the axis of the screw, like the square thread; the other, as shown, is at an angle of about 45° .

The square thread in Fig. 5 cannot be produced satisfactorily by dies, and has to be cut in a lathe. More than one thread may be cut on the same bar, if desired, i.e. 2, 3, or more separate threads, termed leads, may go to make the complete screw, the pitch remaining the same in each case, as seen in Fig. 6. *See Metal Turning; Screw; Stocks and Dies.*

SCREWDRIVER: How to Use. A good screwdriver for general use is that known as the London pattern, which has a flat blade (Fig. 1, A). The cabinet screwdriver (B) with a cylindrical shank and oval or spherical handle is also a favourite. A long driver as used by electricians (C) is handy for many awkward jobs where the screw is difficult of access. In D the blade and handle are forged from one piece of steel, the handle being made up to a comfortable grip with wooden scales riveted on.

Ratchet screwdrivers (E, F) permit the blade to be kept in engagement with the slot of the screw during the whole operation of driving or withdrawal. Right or left-hand motion is secured by moving up or down a slide on the ferrule, and a centre position gives a neutral position, with the ratchet out of action. In another type the shank is spirally grooved like the shaft of an Archimedean drill, and revolves automatically when the handle is pressed down. A spring in the working sleeve causes the handle to return ready for another stroke.

For heavy work a screwdriver bit may be used in a brace, as shown in Fig. 3, the ratchet being brought into action. If too much pressure is used, however, the bit is apt to walk off the screw head. When driving a screw, say, vertically downward, it is started in the hole by taking it in the right hand and screwing it into hole as far as it will go easily, without risk of cutting the fingers on the sharp edge of the head. The point of the screwdriver is then put in place in the slot in the head of the screw, the screwdriver being vertical, the palm of the right hand resting on end of the handle, and the thumb and fingers lying along the handle.

The process of driving the screw consists in turning the screwdriver to the right, while keeping a considerable pressure on it to prevent it from jumping off the head of the screw (Fig. 2). This pressure is liable to make the screw fall over to one side if it is excessive or directed out of the true line before the screw is half-way home. The fingers of the left hand are, therefore, placed loosely round the blade of the screwdriver a little above the point, so that they can act as a check on obliquity.

When the screw is right home it must not be over-tightened, since this may cause the screw threads to break the timber round them, which destroys the hold of the screw, and is particularly liable to happen with short or thin screws in soft woods. If it is found quite impossible to drive a screw it must be removed and the hole deepened or enlarged before the screw is re-driven. With small screws in hard timber, the screw should be withdrawn and the hole enlarged if the effort of driving becomes too great, or the screw may break.

Screwdriver. Fig. 1. A. London pattern, which has a flat blade. B, cabinet screwdriver. C. long-shanked driver for electricians for electricians. D, screwdriver with blade and handle forged from one piece of steel. E and F, ratchet screwdrivers.

Screwdriver. Fig. 2. Showing double-handed grip necessary for a large screwdriver. Fig. 3. Using screwdriver bit in brace.

A screwdriver seldom requires any attention if it has been correctly hardened and tempered in the first place. After a lot of hard service, however, the point may get rather bruised and rounded, when, it can be restored in a few minutes by filing with a smooth file on the two long flats and right across the point, being careful to keep the actual flat point square with the length of the tool and as thick as will enter comfortably into the size screw for which the tool is meant. *See Plumbing.*

SCREW PINE. The screw pine, also known as Pandanus, can be successfully reared in Britain in a hothouse, if grown in a moist and sunny position in ordinary potting soil in the intermediate house. It is best propagated by means of shoots or offsets. It will attain a height of 3 ft. or more. Pandanus Veitchii is most frequently seen.

SCREW PLATE. Used for cutting small sizes in screw threads, a screw plate is obtainable in two forms. One to hold dies consists of a flat frame of steel with an adjusting thumb screw at one end; the other is a flat plate of steel containing a number of graduated holes forming dies. The latter tool is only serviceable for the smaller sizes, since no proper clearance is possible for the chips. *See Stocks and Dies.*

SCRIBER: The Tool. The scriber is used for marking purposes in every kind of metal work. It is made of steel hardened and sharpened to a fine point. The double end scriber in Fig. 1 is used by art metal workers, and is convenient to hold on account of the twisted centre. The pocket scriber in Fig.

2 is provided with a steel point which is contained in the handle when not required; the handle is knurled so that it can be held firmly. The engineer's scribe in Fig. 3 has a loop handle and one point.

Although a marking knife is generally used for woodwork, a scribing point is sometimes necessary, and both are incorporated in a marking tool, as in Fig. 4. *See Metal Work; Repoussé.*

Scriber. Fig. 1. Pattern used by art metal workers. Fig. 2. Pocket scriber with removable point. Fig. 3. Engineer's scriber. Fig. 4. Marking tool.

SCRIBING. This is the term used for the process of scratching a gauge line on wood or metal work. In fixing a dresser against a wall, it is found that the skirting board must be allowed for and the legs of the dresser cut back to permit the fixture to stand in close to the wall. This means that a line must be marked on the dresser leg showing how much stuff ought to be cut out for an accurate fit. Again, when fitting a skirting board on an uneven floor, if the board is to fit close and its top edge be horizontal, the inequalities of floor surface must be compensated by giving a suitably shaped lower edge to the skirting board.

A pair of dividers is set to the distance between wall and dresser leg, and the points locked. Then the dividers are used as a gauge, being drawn along with one leg in contact with skirting and the other, in line, touching the dresser leg, so scratching a line on the latter showing the amount of material to be removed. When scribing the pilasters of a cupboard over the skirting, or to the wall, or when scribing a skirting board to the floor, the dividers are set to the greatest distance between the edge of the board and the wall or floor, as the case may be. *See Cupboard; Dresser; Skirting Board.*

SCRIBING GAUGE. This instrument is used to obtain measurements from any flat surface of predetermined accuracy. In the testing and marking off of engineering components of all kinds, the surface plate or table is the basis of all measurements.

The surface is a specially prepared casting, ribbed up at the back so that it forms a rigid base for any work laid on it, and with a top surface finished off to a high degree of accuracy. The smaller plates used on the fitter's bench are surfaced to $1/10000$ in. by hand scraping in comparison with another plate, or by a patented grinding process. Work of all kinds can be mounted on the surface table and with the scribing gauge surfaces may be marked out and tested, or machining and centre lines drawn on the job according to the requirements. A sheet of plate glass is sufficiently true for amateur use.

The diagram, Fig. 1, indicates how the bench surface plate and scribing gauge may be employed to mark out the levels of various lugs forming part of a casting. These lugs have to be planed off to the level shown by lines A, B, and C, which are all exactly the same height from the underneath side of

the casting resting on the surface plate. The drawing at the same time shows the simplest form of surface gauge that can be made. This comprises a block of metal, the under surface of which is machined flat, and a steel arm pivoted to the block with a screw which will make it work so stiffly that it will remain in any position to which it is set. This is best accomplished by fitting a double spring washer under the head of the screw. The end of the arm should be bent over, pointed, and be made of a steel that can be hardened and tempered.

Metal work requires to be locally chalked where the scriber is to make a mark. To preserve the marks, should the chalk be rubbed off, centre-punch dots are lightly hammered along the marked lines.

Figs. 2 and 3 illustrate a scribing block of a more elaborate kind. A V-slot in one of the vertical faces of the base block is useful for working against shafts and other round objects, while for obtaining scribed lines parallel to the edge of the surface table, or from any other straight edge, two pegs may be fitted in holes in the base. The steel pegs should be a push fit, so that they may be made to stand up or to project below the base and overhang the edge of the table or work being operated on, as illustrated. The scriber is held in a universal joint clamp permitting of movement in horizontal and vertical planes.

SCRUBBING BRUSH. The scrubbing brush used in the ordinary household consists of a plain solid stock, usually of birch, set with knots of bass, bassine, white fibre, or mixture.

In a machine-made scrub, a short piece of steel wire is punched crossways into each hole in the stock, pulling down with it a portion of the material used, and doubling it up to form the knot, the ends of the wire being forced into the wood at the bottom of the hole. It should be noted that the knots tightly fill the hole, otherwise there is little to prevent in use. Although a brush made by this

process is not to be compared with a hand-drawn brush, it answers very well, providing the holes are well filled.

SCRUPLE. This weight, used by chemists, consists of 20 grains, troy weight. Three scruples make a drachm and 24 scruples go to the ounce. *See Apothecaries' Weight.*

SCULLERY. In small houses and flats the scullery is often combined with the kitchen. Sometimes where the kitchen is also used for meals, a scullery adjoins, which is provided with a sink and a useful cupboard fitted for brushes, brooms, etc., and also with shelves for cleaning requisites, and pots and pans, so that washing up, the preparation of vegetables, and rough work may not have to be done in the kitchen. A neat little scullery of this type is shown in our illustration.

In larger houses the scullery equipment is necessarily more comprehensive. There are usually two or even three sinks, and various labour-saving devices may be included, such as an electric clothes washer, mangle and dishwasher. Furnishing and fittings for sculleries are on the same lines as for kitchens. *See Cupboard; Kitchen; Pantry; Sink.*

Scullery provided with sink and cupboard. The walls are painted and there is a tiled surround to the glazed stoneware sink. (Humphrey & Vera Joel)

Scurf. *See Dandruff; Hair.*

SCURVY. It has long been known that scurvy, or scorbutus, can be prevented by including fresh food, especially vegetables and fruit, in the diet, and the disease is now rare, apart from war conditions.

It has been found that the difference between fresh and preserved or dried food, as regards the liability to cause scurvy, consists in the absence from the latter of a complex substance called water-soluble vitamin C. Infantile scurvy, sometimes called Barlow's disease and scurvy-rickets, although it has no connexion with rickets, has occurred in infants fed exclusively on boiled or preserved milk or patent foods.

Scurvy begins insidiously with a gradual loss of weight and strength and increasing pallor. The breath becomes offensive and the gums are soft and bleed easily, while teeth may loosen and drop out. Numerous minute haemorrhages occur into the skin.

In infantile scurvy there is great tenderness in the long bones, first in those of the legs. The tenderness is caused by bleeding beneath the covering of the bones, and this also causes definite swelling of the limbs.

The treatment of scurvy consists in giving food containing a sufficiency of vitamin C. Under the heading Diet will be found a list of foods classified according to their vitamin content. The juice of two or three lemons should also be given daily. An infant should be put on fresh milk and have a teaspoonful of orange juice three or four times a day. *See Diet; Vitamin.*

SCYTHER. The scythe is a garden implement which has been superseded to a great extent by the lawn mower. It is still necessary to employ a scythe, however, when grass has been neglected, or allowed to grow beyond its usual length. The blade consists of a long, curved steel, with a back of considerable thickness, set in a bent handle, with two hand pieces.

The scythe should only be used when there is plenty of room to swing it, and it should be sharpened with a scythe stone before any attempt is made to use it.

Scythe: two movements in using this tool. Fig. 1. Beginning of the stroke. Fig. 2. The end.

The correct manner of using the tool is shown in Figs. 1 and 2. The small handle, projecting from the main handle, or snaith, nearest the blade is grasped in the right hand, and the upper handle is grasped with the left hand. The legs are placed about a foot or so apart, and the scythe is drawn back to the right, the blade being rested on the ground.

To begin the cut, the scythe should be swung around with the arms, to the left, keeping the blade resting lightly on the ground, and slightly pulling the tip of the blade inward (Fig. 2).

The scythe is then swung back to the right and the operation repeated, moving the feet forward slightly, and taking another cut of about 6 to 9 in. of grass, according to the length of the grass to be cut. It is convenient to begin on the left of the work, and work down the grass in a straight line, then returning to the starting point and again cutting to the right, as the tip of the scythe will be found always to come out into the space already cleared by the original cut.

Owing to the moisture in the grass the edge of a scythe rapidly loses its sharpness, which is renewed by the application of a stone, specially prepared for the purpose, shaped like the round of a ladder.

SEA HOLLY. The name of a group of hardy flowering plants (eryngium) which are generally of thistle-like appearance: the flowers, when cut, are useful for indoor decoration and last a long time. The beauty of the plants lies, in the blue or grey-blue colouring of the stems and thistle-like flower heads. The sea hollies are easily grown in ordinary well drained soil in a sunny place. Some of the best kinds are alpinum, 2-3 ft., blue; oliverianum superbum, 3 ft., blue; planum, 3 ft., small blue flowerheads; and the new variety named Violetta, 3 ft., violet-blue. Giganteum has pale grey-blue stems and flowers. The plants may be propagated by division in autumn or raised from seeds sown in a box of soil placed in a frame in spring.

SEAKALE. A vegetable valued for the young blanched succulent shoots in winter and spring. It may be raised from seeds sown in spring in shallow drills drawn at 2 ft. apart, but the roots will take two years to reach a serviceable size. The usual method of propagation is to plant small side roots in March, in deep, rich soil, their tips an inch or two below the surface, in rows 3 ft. apart. Side shoots which appear during the summer must be removed, and the soil between the rows should be hoed frequently. In the autumn when the leaves have died down, the roots may be lifted and forced into growth under cover. Later supplies are obtained by covering the soil over the roots out of doors, with heaps of sifted ashes or sifted soil and cutting the new shoots as soon as they begin to pierce the covering.

Seakale may be forced by lifting crowns from the beds out of doors, and placing them in a frame or house from which all light is excluded, in an average temperature of 60°. The young plants should receive liberal soakings of tepid water, and in about six weeks the seakale will be ready for cutting. If the house is not quite dark the kale will be yellow or purple in colour, and coarse in flavour.

Seakale. Blanched heads of this popular winter and spring vegetable.

Seakale: the best treatment. 1. Typical crown. 2. Prepared for planting. 3 and 4. Off-cuts or thongs trimmed and stored in pot of sand. 5. Thong developed for planting; two buds to be retained. 6. Forcing under manure: a, box; by lid over sight hole; c, manure.

7. Indoor forcing in pots; a, plug for vent. 8. Outdoor culture: a, fine rich soil; b, manure; c, subsoil; d, blanching box. (Courtesy of Amateur Gardening)

How to Cook. Seakale is in season from February to June. It may be boiled and dished on toast with sauce poured over it, stewed or made into savouries.

To cook it, wash and trim it, then tie the heads into small bundles and plunge into fast boiling water. Boil the seakale quickly from 20 to 25 min., then drain it, untie the bundles and arrange them on a slice of toast. The sauce may be poured over or handed round.

Good melted butter sauce, Hollandaise or béchamel sauce, is most suitable.

Seakale may be boiled in stock and served with brown sauce, but the brown sauce must be well flavoured and be enriched by the addition of 1 oz. butter and a good squeeze of lemon juice. If

seakale is stewed in stock it is better first of all to parboil it in water. Seakale may also be cooked according to any of the methods that are suggested for celery. *See Celery; Sauce.*

SEAL:For Sealing. Seals used for stamping hot sealing wax into a design are found in three main forms: Signet rings, fob seals, made originally to be attached to the fob and then worn on a watch chain, and the seals made for standing on the writing desk.

The design that is to be transferred to the wax may be a crest, a monogram, simple initials, a device, or a figure similar to that seen on a cameo. Old Roman signet rings were frequently engraved with such figures. The design is engraved in a circle or oval, usually of cornelian, onyx, agate, or bloodstone, but sometimes also of steel, brass, or gold, and occasionally of such semi-precious stones as amethyst or garnet. *See Postage; Ring.*

SEA LAVENDER. These hardy and greenhouse plants yield panicles of small flowers, some of which are useful when dried for vases indoors. The finest of the perennials are *latifolia*, 2¾ ft., lavender blue; *gmelini*, 20 in., violet-purple; and *incana*, 12 in., pinkish.

These sea lavenders thrive in ordinary well drained soil and need a sunny position. Propagation is best carried out by seeds sown in spring in boxes of soil in a frame.

Of the annual kinds, a popular one is *sinuata* with blooms in various colours, which provide the everlasting flowers sold by florists. *Suworowi* is particularly showy; it gives the best results when grown as a biennial from seeds sown in boxes of soil in July, the seedlings being potted subsequently and kept under glass safe from frost in winter.

Sea Lavender. Tiny flowers of this hardy plant, useful, when dried, for indoor decoration.

SEALING WAX: ITS DECORATIVE USES

Brilliant Effects that Can be Obtained by this Medium

This article belongs to the group of those describing art crafts, which includes, among many others,
Enamelling; Gesso; Italian Renaissance Work; Lacquer Work;
Repoussé Work; Stencilling

Sealing wax may be used to decorate candlesticks, boxes, vases, etc., and to make smaller articles, such as beads and pendants. It can be obtained in every colour, from delicate shades of rose, mauve and blue to black, and also in bronze colour's, silver and gold.

Surfaces coated with sealing wax are of pure colour, smooth and brilliant. The composition is a fine coloured lacquer, and for this reason oriental designs are particularly good carried out in gold or silver wax on a ground of vermillion or black wax. The drawback to the craft is that the wax, being brittle, is easily chipped. The advantage is that such chips can be repaired by holding the broken surface over a spirit flame and allowing the edges of the crack to run together. When working, if not satisfied with the result the wax can be re-melted and the process started again. The materials needed for sealing wax craft are inexpensive, and requisites for the work are stocked by most stationers and at handicraft studios where materials for art crafts are sold. All that is required is a spirit-lamp, a broad-bladed knife, a wax spatula and a moulder, steel knitting-needles of various sizes, methylated spirit, and sealing wax of various colours. In addition to these, a piece of soft rag

should be handy for wiping the melted wax off the tools and drying the cooled beads and pendants; a tumbler of cold water is needed, in which to cool the beads, etc., and the table-top should be protected by a marble slab or small sheet of plate glass.

Making Beads. Beads can be made with sealing wax in the following manner. Heat a knitting-needle in the flame of the spirit-lamp, and press it into a small piece of the wax. After deciding on the colour of the beads, or on the foundation colour if they are to be multicoloured, the wax of this colour should be broken into pieces of an appropriate size.

Having got the bead on the needle, allow it to cool; then return it to the flame and rotate slowly. The bead will gradually become oval in shape, and the shaping may be assisted by the knife. A little nicety of judgement is required at this point to tell exactly the moment at which to take the bead out of the flame. If it becomes too hot the wax will drop off, and, on the other hand, unless it is sufficiently heated the bead will suffer in shape. Very little experience, however, is needed to judge this point correctly, and the bead may be cooled by dipping it into a tumbler of cold water, if the heating goes too far before exactly the right shape is obtained.

To blend other colours, two methods may be employed. The sticks may be heated one at a time and a little placed on the shaped bead. This is heated carefully and rotated slowly until the colours mingle with the foundation colour. After that it is cooled in water, dried, and passed quickly through the flame again to restore the lustre. As an alternative method sealing wax of the desired colour is dissolved in methylated spirit to the consistency of cream, and the solution is painted on the shaped bead. This method is used when designs are painted on beads to obtain something of the effect of Venetian glass.

The bead must now be removed from the needle. Heat the needle just above and below the bead, slide the bead backward and forward a few times to ensure a good hole for threading, and finally let it drop off the needle into a glass of cold water, which will set the shape. The special silk prepared for stringing heavy beads is suitable for threading, and any shape, round, flat, oblong, oval, etc., will do for the beads. Pendants or a central plaque for the necklace are made on a piece of stout cardboard cut to shape, a hole bored at each side, and supported on a strong hairpin, the whole of the plaque covered with wax of any colour. Let the wax spread evenly over one side first by holding the plaque over the flame once or twice. When this side is dry coat the other in the same way. When the plaque is quite dry, paint or stencil a design in colours, using wax dissolved in spirit.

Decorating Small Articles. One method of ornamenting candlesticks and wooden cases for match boxes, comb cases, bridge pencils and other small articles suitable for a bazaar stall is to warm whatever has been chosen to be decorated, and at the same time heat the tip of the stick of sealing wax.

Then, beginning at the top, dab the wax on in spots leaving a space between each spot, and every now and again hold the article over the flame, rotating slowly and always in the same direction, until the spots of wax have melted and run smoothly over the surface. Repeat these operations until the entire surface is covered.

It must be remembered that this method of decoration must not be applied to any celluloid article.

Colours may be blended by melting a second or a third colour over the first and blending all together over the flame. Silver or gold wax may thus be used to fleck the background in an attractive manner over blue, green or black.

When a raised motif is required to decorate the corners or centre of a small article, or to make a border, the spatula and moulder may be used. Wreaths, baskets of flowers and tiny designs found on flowered china are specially suitable for this work. It is best to make a few trials with the hot sealing wax on a piece of cardboard and experiment on one or two flower shapes. Roses are easily modelled.

Mark a place with a pencil on the article where the raised work is to come. Heat the wax in the flame of the spirit lamp and let a tiny drop fall for each flower. Use two shades of pink for a cluster of roses and put several drops one over the other. Then, while the wax is still plastic, press with the spatula round the centre and make little separate dents to form petals and a dent in the middle of these for the rose centre. Heat the tool a little if the wax becomes hard. The tiny leaves may be made of green, silver or gold wax and consist of a drop of wax, the spatula being drawn quickly through to make a central vein and shape the leaf.

Enamelling with Sealing Wax. The most artistic effects in sealing wax decoration are obtainable by using solutions of the different coloured waxes in methylated spirit. This inexpensive craft has the appearance of fine enamel work and can be used on a ground of sealing wax to decorate beads, or on wooden articles covered with the wax, or on pottery and glass.

The first step is to choose the article to be so enamelled, and to decide upon the colouring. Then break up a stick of sealing wax and place it in a small bottle, covering it with methylated spirit. Cork tightly and leave overnight to dissolve. Shake it up well. Use in the same way as liquid enamel; a small sable brush is the best tool to employ.

Sealing Wax. Left, fig. 1. Brown vase decorated with apple blossom.

Right, top and bottom fig. 2. Vase of crackle ware ornamented with a design of anemones. Fig. 3. Powder box in alabaster, with decorated lid.

Colour the design, attempting no shading, and working quickly and evenly. Practice is required to prevent the work from being patchy. The pressure on the brush must be even, and the sealing wax must be kept

stirred. If it is too thick dilute it with methylated spirit. Keep the bottles well corked, and clean the brushes in methylated spirit. The shading is added when the first coat is dry.

One section must be done at once and allowed to dry, as the work is ugly if the enamel is thicker on one side than another. As the work is dry in a very short time, it should appeal to those who have nowhere to put things during the drying process.

The illustrations give a good idea of the possibilities of this form of handicraft. Fig. 1 is a useful flower vase. Its colour is dark brown, and it is decorated in white sealing wax shaded with fawn, the design being a ring of conventional apple blossom. Fig. 2 is a vase of white crackle ware, its decoration being done in sealing wax enamel representing multicoloured anemones. Fig. 3 is an alabaster powder box. The design on the lid, which was outlined entirely in black, shows brightly

coloured flowers and leaves painted in sealing wax enamel. Geometrical designs and the Greek key pattern are also suitable.

SEALSKIN. The beauty and the durability of sealskin make it one of the most valuable furs in existence. It is usually made up into coats, but is also used for coat collars and cuffs.

Musquash is often treated to resemble sealskin, but may usually be recognized by its size. A large number of musquash skins are needed to make a coat, so that the seams are numerous compared with those on a genuine seal. Coney and electric seal, made from rabbit skins, are other substitutes. Those who find it difficult to distinguish between genuine and imitation skins should examine the leather. In real sealskin this is never dyed, while in musquash and other imitations it is invariably of the same shade as the fur itself.

Sealskin is also imitated in a special kind of silk plush. This seal plush is generally dark brown or black, and is used for making winter coats, for trimmings and for travelling rugs. *See Fur.*

SEALYHAM. This type of terrier is a breed of small dog that has, during the 20th century, become very popular and fashionable. Founded upon a hybrid between the Jack Russell and Welsh terriers by later crossings with the Dandie Dinmont and the Cheshire terrier, its characteristics have become fixed and it breeds true to type.

It has short legs, a long body, strong neck, deep chest, and the short tail is carried vertically. The coat is short and hard, with crinkly, broken upper coat on the back. The drop ears lie close to the face; the powerful muzzle appears broader than it is owing to the long moustaches. The colour is uniformly white, or there may be patches of black or liver colour. Occasionally it is brown marked with black.

*Sealyham Terrier. Favourite breed of small sporting dog.
(Photo, Thos. Fall.)*

The smaller specimens are the more desirable. The Sealyham is affectionate and faithful, playful, and of quick intelligence; intruders are greeted with continuous barking. A first-class dog for the home, it is withal a splendid ratter. As a sporting dog, he is esteemed for badger-hunting, for which his short legs and pluck fit him, whilst his steady baying enables the hunters to locate him and his quarry. The name is derived from the Edwardes estate, in Pembrokeshire, where the breed originated. *See Dog.*

SEAMS FOR PLAIN SEWING

Some Helpful Directions for the Needlewoman

This article suggests reference to such entries as Dressmaking; Mending; Pattern; Sewing Machine, and also to various stitching operations, e.g. Hem; Herringbone-Stitch; Overcasting, etc.

The plain seam is the one most commonly used in needlework. To make it, lay together the two pieces of material to be joined, with the right sides facing and the two edges exactly level, and tack along the two thicknesses where the permanent stitching is to be put in. It is a good plan, when a garment is being cut out with the aid of a paper pattern, to mark the material round the pattern edges with chalk, so that, after the pattern is removed, there is a guide to the amount of material that

should be taken up in seams, etc. After tacking, carefully stitch the seam by machine; or, if small light articles are being made up, run the seam by hand if preferred, as in Fig. 1.

The stitching of all seams of garments should be commenced at the top, i.e. the waist of a skirt, shoulder of a sleeve, and so on. If one of the two edges is on the cross or bias of the fabric, it should be laid uppermost, as it is apt to stretch out of shape. When stitching a shoulder seam, always ease in the back shoulder-edge and stretch the front, in order to get a better fit over the shoulder blades.

It is the custom, when stitching seams of dresses or coats that take a concave curve at the waist, to stretch this part of each seam, so that it will still more follow the curve of the figure. Seams that take a convex curve are held in, so that they will not stretch, otherwise the shape would be spoiled. In stitching the seams of a 2-piece coat sleeve, commence by stitching the shorter or inner seam, and do the longer or back seam afterwards, easing in the elbow part of the wider or upper portion to the elbow part of the narrower portion, so as to give it more play at the bend of the arm. After any plain seams are stitched, remove tackings, and iron the seam edges open flat. If the seams are curved, however, be careful to snip the turnings here and there, evenly and regularly, as in Fig. 2, otherwise it will not be possible to iron them flat; the material under the seam edges will become dented or cockled up. Many seams have their edges notched or snipped out in this way, even if they are not curved, merely to give a better effect and to prevent the edges fraying out too rapidly.

Unless the raw edges of these plain seams are to be covered with a lining, they have to be finished off. In dresses it is usual to overcast the edges, as in Fig. 2. In unlined coats or wraps, the edges are bound with lute ribbon or Prussian binding, the binding being folded double, so that the seam edge can be stitched between. In some silken materials that have little tendency to fray, such as taffetas, the edges are merely pinked out; in heavier materials of this nature, such as velours, they are often pinked out or herringboned down.

Overlapped Seam. This seam is applied in the making of outer garments, and also on underclothes, pyjamas, etc. It may be used to make skirt seams, to set in yokes, and to attach strappings. It is easily made. Turn in the edge that is to be uppermost, to the amount of turning allowed, and tack along; then lap it on to the remaining edge, and again tack down, as in Fig. 3. Machine as far within the fold as desired, taking care not to go beyond the edge of the turning. The raw edges can be neatened in any of the ways previously mentioned.

French Seam. A seam often employed on delicate materials, such as lawn, muslin, crêpe-de-Chine, net, lace and georgette is the French seam. To make, set the two layers of material together, with the wrong sides facing and raw edges level, and run or machine as close to the raw edges as possible. If it is not easy to stitch as near to these as is desired, cut the turnings away quite narrow afterwards. Now turn the material to bring the wrong side outside, and the seam lying along the top of the fold; then stitch the two layers together again, close up to the raw edges, as in Fig. 4, so that these are enclosed in a little tube.

Flat Seam. The stitch and fell seam is employed for flat seams. Lay together the two pieces to be joined, with right sides facing and one edge nearly $\frac{1}{4}$ in. below the other; then tack along an $\frac{1}{8}$ in. below the narrower edge, and afterwards machine, run, or backstitch along this line. Fold the whole seam flat over on to the material, so that the narrower edge lies underneath, fold the edge of the wider turning under, and neatly hem down, as in Fig. 5.

Oversewn Seam. The top-sewn or oversewn seam is used when it is desired to join the selvages of longcloth, calico, cambric, and similar cotton materials. Tack together the two selvages and neatly oversew, working from right to left, as in Fig. 6, and making the stitches of an even slant. No

knotted ends of cotton should show. Leave a generous end of the cotton, and push it down on to the edges towards the left, so that the stitches can be made over it, at the same time not letting it drop below the position at which the needle passes through the edges. When the seam is completely oversewn, open out the two thicknesses and lay them flat on the table, and press the stitches down with the thimble to make the seam flat.

Counter Hem Seam. A counter hem figures largely in the making of men's and boys' shirts, in which a specially strong, flat seam is wanted. Turn under one edge to the wrong side about $\frac{1}{8}$ in. and turn the other edge over to the right side to match. Lap one edge over the other so that the raw edges face, and run a line of tacking down the middle; then machine both edges down as close up to the folds as possible. If desired, hemming may be resorted to, instead of machining, as in Fig. 7.

Seam. Fig. 1. Plain seam run by hand. Fig. 2. Notched and overcast edges of a curved seam. Fig. 3. Overlapped edge. Fig. 4. French seam. Fig. 5. Flat seam. Fig. 6. Oversewn seam for calico selvages. Fig. 7. Counter hem. Fig. 8. Seam in flannel with edges herringboned down. Fig. 9. Beading seam for underwear. Fig. 10. Openwork seam.

Flannel Seam. On flannel materials, it is usual to use a stitch-and-herringbone seam. The edges are first stitched by hand or machine in a plain seam, which is then pressed open flat with the fingers, and has the raw edges herringboned down, as in Fig. 8, the material being too bulky to permit of turning the edges under, as for hems.

Whipped Seam. When the edges of fine underwear or baby clothes are to be joined to lace, insertion, or beading, a whipped seam is generally employed. Take the material in the left hand, with the wrong side towards you and raw edge upwards, and roll this raw edge over towards you as a very tiny roll, with the thumb and first finger of the left hand, doing about 1 in. Let the roll rest over the first finger, with the beading or lace above, and whip them together as shown in Fig. 9, drawing the two edges together.

If the material is to have fullness, as in the case of a skirt part that is to be joined to a bodice by a band of insertion, the skirt edge must be rolled and whipped separately from the trimming, pulling up the cotton as the work proceeds in order to get the requisite fullness. After the edge is completely rolled and whipped, it is oversewn to the trimming exactly over the first stitches, so retaining the neat effect of the seam. This rolling and whipping can be used to apply a frill to an edge, the frill, if full, being rolled and whipped and drawn up, while the garment edge is afterwards rolled, and whipped to the frill as explained for beading.

Openwork Seams. Many blouses, summer dresses, baby clothes, etc., show open-work seams, which often have the effect of real hem-stitching. It is usually necessary first to hem or roll and whip the two edges that are to be joined, though in some cases a mere turning in of the edges will suffice. After the two edges are neatened, tack them down on to a strip of stiff paper, with the desired space between, and make the openwork stitchery, with embroidery silk or embroidery cotton, according to the nature of the fabric.

One type of hand-worked seam is shown in Fig. 10; but there are many others, simple herringboning being one that is much favoured, while another popular method is faggoting. In all cases the needle should be slipped along one of the hems to bring it out to the right side in the position needed for making each stitch or group of stitches. After the stitchery is worked, the tackings are snipped and the paper removed. Openwork can also be used to attach lace to the neatened edges of underwear, etc.

SEA PIE. For this popular dish the following ingredients are required: 1 lb. buttock steak, $\frac{3}{4}$ lb. flour, 5 oz. suet, a carrot, an onion, a small turnip, and pepper and salt to taste. Cut the meat and the vegetables into thin slices and place these in layers in a saucepan, seasoning them with salt and pepper and covering them with cold water.

Let the whole simmer for $\frac{1}{2}$ hour, and then remove the meat from the pan. With the suet, flour, and some water make a light crust and roll it out on a floured board. Roll the meat in this crust, return it to the saucepan with the vegetables and the liquor, and let it simmer for an hour.

Sea Pink. This is an alternative name for the plant more usually known as thrift (q.v.).

SEA SICKNESS. The effect of the up and down motion of a ship in the water is comparable to that produced by swinging, and in many people it produces a feeling of nausea and sickness, which culminates in vomiting and complete prostration. The scientific explanation of this troublesome malady is that it is due to a disturbance of the circulation in the brain and in the labyrinth of the ear.

While serious results are very rare, there is always some danger to those who are of apoplectic tendency, to sufferers from heart disease or rupture, and to pregnant women.

For three or four days before starting a voyage care should be taken that the food is readily digestible. The bowels should be regulated if necessary. At the same time, a dose of 20 gr. of the bromide of ammonium may be taken three times a day, in a wine-glassful of water after meals. This treatment may be continued during the first few days of the voyage. If the voyage is a short one, a single dose of this drug (30 gr.) should be taken about two hours before starting. Chloretone is often a preventive. A light meal should be taken 1 ½ to 2 hours before the voyage. A firm bandage worn round the abdomen often acts to some extent as a preventive of sickness.

A person who is apprehensive of being sick should sit in a low deck-chair, either facing or with the back to the bow of the ship. The chair should preferably be on deck, but in a sheltered part. A safer position still is to lie down, preferably on the right side, and bring the knees well up towards the body. Above all it is essential to keep comfortably warm. If sickness threatens, it is best to abstain from solid food, to suck chips of ice, or to take a glass of iced champagne in sips. When there is much nausea, but no vomiting, the stomach will be relieved by taking a pint of warm water to which a pinch of bicarbonate of soda has been added. This will empty the stomach and make the traveller more comfortable. When vomiting has continued until the stomach is empty, and distressing retching ensues, a little light food should be taken, if possible, such as gruel, arrowroot, warm milk and water, or milk and sodawater. If the sickness continues for some days other treatment will be required from the ship's doctor.

SEASONING. Every variety of spice or herb which imparts a relish, or brings out more distinctly the flavour of ingredients used for culinary purposes, is a seasoning. The term does not always imply mere salt and pepper, although salt may be reckoned to be seasoning of the first importance. Next in order would come the various descriptions of pepper and herbs, such as are used in forcemeats.

Seasoning is largely a matter of individual taste, therefore quantities given in recipes should not be too strictly adhered to. The safest way is to taste while cooking until the correct amount of seasoning has been added. *See* Flavouring; Ginger; Nutmeg; Pepper; Salt; Sauce; Soup; Spice; Stuffing, etc.

SEAWEED: Its Uses. There are several kinds of edible seaweed, but few of them are eaten except in the neighbourhoods in which they are found, and even then only in limited quantities. The most valuable of them is known as Irish or carrageen moss. It contains certain medical properties and is recommended for invalid diet. Another kind of seaweed, found along the Welsh coast, is sometimes used as food, and in Scotland some varieties of seaweed are also edible. *See* Irish Moss.

SEBORRHOEA. Certain conditions of the fat-producing glands of the skin cause an abnormal amount of secretion. This is known as seborrhoea or pityriasis, and is of an oily or a dry character, the latter taking the form of greyish or yellowish scales. The condition always begins on the scalp, from which it may spread downward to the face, neck, and other parts of the body.

The local treatment for dry seborrhoea of the scalp is given under the heading dandruff. Where the scurf attacks the non-hairy portions as well as the scalp, a mild sulphur ointment such as the following may be lightly rubbed in once or twice a day:

Precipitated sulphur	24 gr.
Benzoated lard	1 oz.

Local treatment of oily seborrhoea consists in washing the surface several times a day with soap and warm soft water, and then dabbing on the following lotion:

Tannic acid	20 gr.
Methylated spirit	2 oz.

SECATEUR. The pruning instrument known as a secateur has two cutting blades fastened together by a rivet, and actuated by a spring after the manner of clippers. It is invaluable for pruning purposes in the garden. *See* Pruning; Scissors.

SECRETAIRE. For all practical purposes the secretaire is identical with the bureau or the desk, but the name is retained by certain pieces of furniture, mainly those of French make.

Secretaires in which the influence of French models is seen were made by Sheraton. Some of these were shaped somewhat in the style of a cabinet. *See* Bureau; Marquetry; Sheraton; Writing Table.

SEDATIVE. Any drug used to calm an excited nervous system, to relieve restlessness, to quiet an overstrung heart, or an irritable stomach or bronchial tubes, etc., may be termed a sedative. As most of the so-called nerve sedatives have a greater or less depressing action on the heart, they should be used with caution, and never taken except under a doctor's supervision.

SEDGE. Under this name are included hardy perennial grasses, one or two of which are useful for the purpose of decorating moist spots in gardens, or by the sides of marshes in the wild garden. They are propagated by division of the plants in spring. Pendula, 5 ft., is one of the best. Those with variegated leaves, i.e. *Acuta variegata* and *Gallica variegata*, are attractive. *See* Japanese Garden; Wild Garden.

Sedum. This is the botanical name of stonecrop (q.v.).

SEED: For the Garden. Every seed is really a plant in miniature, containing the embryo, together with the food required to assist early development. To stimulate its growth, warmth, moisture, and air are necessary. Given these conditions the plant sends forth its radicle, or young root, into the earth, whilst the young stem bursts through the seed covering, gradually lifting the soil and making way for the seed leaves. After this has occurred, true leaves form and hair roots develop.

Seed should not be sown during very cold or frosty weather, but from February onward, when there is gentle warmth from the sun and while the soil is in a friable condition without excess of moisture. Seeds always germinate best in darkness, and consequently sowings made in pans, pots, or boxes should be covered with glass, over which is spread a sheet of paper to exclude both sunshine and light, as well as to conserve moisture and maintain some degree of warmth. As a general rule seeds should not be more than a year old, as their vitality becomes weaker with age, and slower germination results; some even become quite sterile.

Plants may be raised from seed in various ways e.g. sown broadcast, in drills, in prepared beds, in cold frames, on hotbeds, and under cover of a greenhouse. Some seeds possess a hard covering and, consequently, are more difficult to germinate speedily; this may be facilitated by slightly notching the hard coat, taking great care not to cut deeper than the outer covering, or testa as it is termed botanically. Another method is to soak the seed for a few hours previous to sowing.

Depth of seed sowing depends upon size, and to some extent upon weather conditions. Some tiny seeds need hardly be covered at all, whilst large seeds like beans and peas must be sown deep to

ensure the greater degree of moisture requisite for their germination. Our diagrams show sowing methods in detail.

Seed. How to prepare a seed bed. 1. Autumn preparation: a, ridged top soil; b, manure; c, well dug bottom soil; d, sand or exhausted manure. 2. Bed prepared: a, ridges and sand incorporated. 3. Sowing: a, seed covered in; b, rain channels. 4. Hardy and tender seedlings in one bed: a, top soil prepared as in Fig. 1; b, pockets of extra manure under tender seeds; c, manure; d, bottom soil; e, glass-covered shelters propped up and facing south.

Seed Bed. A properly made-up seed bed is of great service in the garden for raising seedlings of flowering plants and vegetables to be afterwards planted out. The soil must be dug and the surface pulverized; the addition of sand and sifted leaf-mould is beneficial on heavy land.

Draw drills to the required depth with a stick or hoe, setting the line carefully to ensure straight drills. After sowing seed, and before removing the line, label each row according to its contents, including date and weather conditions. Labels are made of planed wood painted with white flatting.

Seed Testing. In Great Britain an Act of Parliament passed in 1920 made it obligatory for a seller of seeds to give to the buyer a written statement of the variety, purity, and germination of the seeds in question. Seeds must not contain more than a certain minimum percentage of injurious weeds. There is an official seed testing station at Cambridge. *See Seedling; Sowing.*

SEED CAKE. This cake derives its name from the caraway seeds that are added to a plain cake mixture.

Seed rock cakes are made by adding 2 or more teaspoonfuls caraway seeds to every $\frac{1}{2}$ lb. flour used, as in making ordinary rock cakes. *See Cake: Rock Bun.*

SEEDLINGS: Their Care. After seedlings have formed their first true leaves they require special attention. In the open ground transplanting should be performed as soon as seedlings can conveniently be handled, whilst those raised in the greenhouse must be placed close to the glass. Great care is essential at this stage to avoid over-watering, giving the tiny plants just sufficient water to keep them moist; over-watering is one cause of damping-off (q.v.). Showery weather should be chosen for thinning and transplanting, as disturbed plants quickly recover if lifted and replanted without delay.

Seedlings should be carefully thinned out, and in due course transplanted to form sturdy plants for garden and greenhouse. Very tiny seedlings, like those of the gloxinia, should be handled by means of a small stick, notched V-shape at one end, as shown in our diagrams, which also indicate other ways of dealing with young and fragile plants. The smaller seedlings often produce the finest mature plants.

Seedling. 1. Sturdy seedling. 2. Attenuated specimen: a, where damping off begins. 3. Seedlings pricked off into pan. 4. Notched stick for lifting tiny seedlings. 5. Effective protection against birds: a, nails in wood triangles; b, black cotton. 6. Seedlings under frame on hotbed: a, plunged pots; b, box of seedlings; c, light. 7. Soot protection against slugs. 8. Sun protection. 9. Planting for protection against frost. 10. Planting in depression to conserve moisture. 11. Same earthed-up during bad weather. 12. Seedling lifted with a ball of soil.

SEIDLITZ POWDER. The effervescing powder of sodium tartrate is commonly called a seidlitz powder. It is a valuable saline purgative.

SELAGINELLA. This family of greenhouse fern-like plants thrives in a mixture of loam, leaf-mould and sand. They require a shady position, and may be propagated by means of cuttings at any time of the year.

The plants are evergreen, of erect, dwarf, or trailing habit, and are differently known as tree, club or creeping moss. They succeed best in a temperature varying from 50 deg. to 55 deg. from September to March, and from 55 deg. to 65 deg. for the rest of the year. Erect growers are *involvens*, *martensii*, and *caulescens*. Dwarf species include the excellent *densa*, whilst trailing kinds are *caesia* and *kraussiana*. All these are desirable plants for a greenhouse.

Selaginella, or Resurrection Plant, an evergreen pot plant needing greenhouse cultivation.

SELECTIVITY. In wireless reception this is the ability of a receiving set to discriminate between desired and undesired broadcast transmissions. In considering the question of selectivity attention must be given also to sensitivity and quality of reproduction (or fidelity), because all three factors are interrelated.

The selectivity of a receiver is directly proportional to the number of tuned circuits, and may be increased by adding an extra tuned circuit between the aerial and the input to the set. This procedure may have an adverse effect upon the sensitivity, and in practice one or more high-frequency amplifying stages are usually employed in order to provide at one and the same time a gain in selectivity and sensitivity. The high-frequency amplifier more than compensates for any loss in sensitivity occasioned by the use of selective circuits.

The degree of selectivity is largely affected by the efficiency of the tuning inductances. A coil having high losses due to the use of too thin wire, an unsuitable ratio of diameter to length, large self capacity, etc., will cause damping, a factor which flattens the tuning and so reduces the ability of the receiver to separate stations. Circuits containing coils with relatively large inductance and condensers of small capacity are desirable from the point of view of selectivity, because weaker couplings between the stages can then be employed without any appreciable loss in signal voltage.

A long aerial-earth system is detrimental to selectivity. A short single wire outdoor aerial or a small indoor aerial or frame is, therefore, indicated. The earth lead should be taken to its earthed point by the most direct route. A good earth and an aerial which is free from high resistance joints are absolutely essential.

The aerial should be loosely coupled to the grid circuit of the first valve, either by way of a tapping point along the grid coil or by using a separate small aerial coil inductively coupled to the grid coil. An equivalent effect may be obtained by inserting a small fixed or variable condenser in series with the aerial lead, a suitable value for the medium broadcast waveband being $\cdot 0001$ mfd.

Reaction, when intelligently employed, greatly improves the selective properties of a set. One of the difficulties in designing a receiver to give high selectivity is the possibility of high note loss. If the tuned circuits have very low losses, so that the tuning at resonance causes cutting of the side bands, there will be a decrease in the high note response, the magnitude of which will depend upon the extent of the side band cutting.

This can be remedied by employing a bandpass filter, comprising ganged tuning circuits prior to the first high-frequency amplifying valve, the high-frequency stage or stages being either choke coupled or coupled by flatly tuned circuits.

The band-pass filter can be designed to pass a predetermined band of frequencies, such as a band of nine kilocycles in width. An alternative is to use a number of tuned high-frequency stages having each tuning circuit comparatively flatly tuned, the required degree of selectivity thus being achieved gradually. This entails a multi-valve receiver. It will therefore be seen that in the case of small wireless receivers the degree of selectivity is a compromise involving sensitivity and quality of reproduction. Thus in a two or three valve set operated in the vicinity of a powerful broadcast transmitter, if the selectivity is sufficiently high to ensure the elimination of the nearby transmission within a few degrees on the tuning dial or dials, the sensitivity on distant transmissions may be decreased.

In general, a well-designed receiver provided with high-frequency amplification will be both selective and sensitive, whereas the degree of selectivity obtainable in a small set without high-frequency amplification is mainly limited by sensitivity and fidelity. The use of the superheterodyne principle is a method by which high selectivity may be obtained with the retention of simplicity in operation. *See* Superheterodyne; Wireless.

SELF HEAL. The common name of *Prunella*, a low-growing hardy plant suitable for poor soil in odd corners. *Prunella vulgaris* is a troublesome lawn weed. The best of the cultivated kinds are *grandiflora*, purplish, and *Webbiana*, rose purple.

SELF-STARTER: On Motor Cars. Unlike the steam engine and the electric motor, which can be started by the opening of a valve or the use of a switch, the internal combustion engine must be rotated first before it will commence to operate. The name self-starter has been applied to the electric starter, now a standard fitment on practically all classes of motor vehicles. *See* Starter.

SELF-TONING PAPER. Self-toning paper is a photographic printing-out paper, the film of which contains the chemicals necessary for producing a pleasing tone. All that is required with most brands of self-toning paper is to wash it for about 5 min., and fix and wash again in the ordinary way. Gelatino-chloride self-toning papers, such as Ilford Intona, do not require the preliminary washing. Collodio-chloride, or collodion, papers require the initial washing. All self-toning papers have to be printed much darker than ordinary P.O.P., as a good deal of depth is lost in the fixing bath, which is really a combined toning and fixing bath. This applies particularly to the collodion papers.

For all self-toning papers a plain hypo bath of 2 oz. to 3 oz. of hypo to 1 pint of water will give good brown and warm sepia to purple tones according to the brand of paper used. See that the prints are properly fixed, and the instructions as to time for fixing which are given with each paper carefully followed. The hypo bath should not be too strong for collodion papers, 2 oz. to 3 oz. to the pint, while variations in the strength of the bath do not affect the colour of the print. The normal bath preceded by washing gives a pleasing brown tone, but cold purple tones can be obtained by washing before fixing in a 10 per cent solution of common salt (1 oz. salt in 9 oz. water) and rinsing the prints in fresh water.

All baths, whether salt or hypo, must only be used once with self-toning papers. Not more fixing solution than is necessary to cover the print properly should be used, since the gold toning chemicals are on the face of the print itself. If too big a bath is used they will be diluted too much.

Fixing baths for self-toning prints must not be acid; to make certain of this a few drops of ammonia, or 10 gr. of sodium carbonate, may be added to each pint of the solution. Self-toning prints, as P.O.P., must be well washed after fixing. One hour in running water or 5 min. in each of 12 changes of water is necessary. *See* Toning.

SELTZER. Originally this was the name of a mineral water obtained from Selters in Germany, but to-day the word is used for certain artificial preparations that resemble, more or less, the natural water. Seltzer is a highly aerated alkaline water that contains bicarbonate of sodium, calcium, magnesium, sulphate of potassium, and similar salts. It is valuable in cases of chronic indigestion and disorders of the respiratory organs. *See* Mineral Water.

SEMOLINA: As a Food. Being a product of wheat, semolina contains considerable nutritive qualities and makes excellent milk puddings, but unless flavoured is rather insipid. The flavouring, such as lemon, nutmeg, or cinnamon, should be added when boiling the semolina with the milk so that it may be equally distributed.

To make a semolina pudding put 1 pint milk into a stewpan with a strip of lemon rind and a pinch of salt, and bring to the boil, then sprinkle in 2½ oz. semolina, and stir over the fire for about 10 min. to cook the grain. Beat together the yolks of 2 eggs with ¾ oz. castor sugar. Remove the pan from the fire and take out the lemon rind; when slightly cooled add the yolks of the eggs and sugar, and lastly fold in the whipped whites of the eggs. Turn into a greased pie-dish and bake for 15 to 20 min. in a moderate oven. For quite a plain pudding omit the eggs, and add the sugar just before putting the pudding into the oven.

Semolina Blancmange. Boil up a quart of milk, then sprinkle in ¼ lb. semolina, and stir well until the latter is cooked and the mixture thick and creamy. Add the grated rind of a lemon and 3 dessertspoonfuls castor sugar, and when the latter is thoroughly dissolved pour the mixture into a wet mould.

When the blancmange is set, turn it on to a dish, heap a small tinful of cherries round it and pour the syrup round. Cream should be served separately.

Semolina Blancmange, a delicious and decorative party sweet.

Semolina Cheese. For this savoury take 3 tablespoonfuls semolina, 2 oz. each butter and grated cheese, a little milk, and pepper and salt to taste. Boil the semolina with the butter and half the cheese in a very little milk, and season it with pepper and salt.

When cooked, turn out the mixture into a pie-dish to cool, and then cut it into small, round cakes. Arrange these on a well-greased dish, sprinkle them with the rest of the cheese, and bake them for about ten minutes in a hot oven.

Semolina Soup. Strain 1 quart white stock into a saucepan and bring it to the boil, adding a few peppercorns tied in a piece of muslin. When it reaches boiling point, sprinkle in 1½ dessertspoonfuls semolina. Continue cooking until the latter is soft and then draw the pan to the side of the fire, allowing the soup to cool a little.

Beat up the yolk of an egg, mix it with $\frac{1}{4}$ pint cream, and then strain it into the soup, stirring the whole until the egg is cooked. The peppercorns may then be taken out, a little salt added, and the soup served, accompanied by diced croutons. *See* Blancmange; Croûton.

Sempervivum. *See* Houseleek.

SENECIO. This is the name of a group of annual and perennial plants, some of which are valuable in the garden, while others are weeds. The most familiar of the latter is the familiar groundsel. *Senecio* (*Jacobaea*) *elegans* is a very pretty annual which may be sown under glass in March, the seedlings being planted out in May or potted for summer decoration in the greenhouse. Or seeds can be sown out of doors in April where the plants are to bloom in summer.

The daisy-like flowers are of many bright colours, carmine, crimson, purple, etc., and the plants, which grow about 18 in. high, last long in beauty. *Senecio multibracteatus* is a showy greenhouse perennial, 18-24 in. high, with rose-coloured blooms. Of the hardy perennial senecios the best are *pulcher*, 2 ft., reddish purple, which is suitable for the herbaceous border, and *clivorum*, *Wilsonianus* and *tangutica*, vigorous, rather coarse-looking plants, 4 ft. high, with large bunches of yellow flowers in summer, suitable for the wild garden or waterside.

SENEGA. Preparations of the dried root of *Polygala senega* are used in medicine for their stimulating effect on the lining membrane of the bronchial tubes. Senega is usually prescribed in chronic bronchitis where the expectoration is profuse and sticky, but is contra-indicated in acute bronchitis.

SENNA. The dried leaves of the senna plant are largely used in medicine on account of their mild purgative action. Common preparations and the dose of each are:

Confection of senna, 60 to 120 gr.

Compound mixture of senna, or black draught, 1 to 2 fluid oz.

Compound liquorice powder (containing senna). 60 to 120 gr.

Senna is commonly used for habitual slight constipation. The compound liquorice powder, which owes most of its purgative effect to its contained senna, is a common household remedy. *See* Aperient; Constipation.

SENSITIVE PLANT. This name is given to *Mimosa pudica*, the leaves of which close together when they are touched by hand. This is a hothouse perennial plant and flourishes in sandy soil in a sunny part of the house. It is often treated as an annual, and grown from seeds sown in spring.

SENSITIVITY: In Wireless. This is the ability of a receiver to respond to weak transmissions. A set which gives loud signals when tuned to a very weak distant transmission is said to possess good sensitivity, whereas a receiver which gives weak signals when tuned to a very powerful nearby transmission possesses bad sensitivity.

A set designed for high sensitivity normally incorporates one or more high-frequency amplifying stages.

SEPARATION: Of Husband and Wife. A husband is bound to support his wife in his home and a wife is bound to live with her husband. If the parties wish to put an end to these marriage obligations without putting an end to the marriage itself by a divorce, or if one of them has behaved in such a way that the other is entitled to refuse to live with him or her, they may either

(1) enter into a separation agreement, (2) obtain a decree of judicial separation; or (3) obtain a separation order from a court of summary jurisdiction.

Separation Agreement. By this the parties agree to live apart and not to interfere with one another, and the husband provides for the support of the wife and any children. The wife agrees not to make her husband liable for her future debts. The agreement must be made in contemplation of an immediate separation, and if a husband and wife who are still cohabiting enter into a deed whereby the husband promises that if at any future time the wife shall separate from him he will make her such and such an allowance, the agreement is bad. Immediately after the agreement the parties must cease to reside together, and merely ceasing to cohabit is not enough. If after a separation spouses decide to live together again they enter into a deed of reconciliation, and in this they may make provision for the possibility of their again being separated. A separation agreement is put an end to by the resuming of cohabitation between the parties. In cases where spouses have agreed to separate, neither can complain of desertion.

Judicial Separation. Whereas a separation agreement may be entered into at the will of the parties and without any special cause, a judicial separation is a decree of the High Court and can be obtained on proof of (1) desertion for two years; (2) any ground for a divorce; or (3) failure to obey a decree for restitution of conjugal rights.

Cruelty may be mental as well as physical. Desertion occurs when one spouse refuses to live with the other without some reasonable cause, such as the exigencies of business. If one spouse deserts the other, a decree for restitution of conjugal rights may be obtained at once, and, if not obeyed, the other spouse may obtain a judicial separation without waiting two years. The court may also make orders for the custody of any children and for the payment of alimony to the wife. This is usually such sum as will make the wife's income equal to one-third of the joint incomes of husband and wife. Thus, where the husband's income is £1,000 and the wife's £200, alimony from the husband would be £200, making the wife's income £400 in all.

Separation Order. A married woman may apply to a magistrate's court for a separation order

(1) if her husband has been convicted of an aggravated assault upon her or has been convicted upon indictment of any assault upon her and sentenced to a fine of more than £5 or imprisonment exceeding two months;

(2) if her husband has deserted her or has been guilty of persistent cruelty or wilful neglect to provide for her or her children. Either husband or wife may obtain an order if the other has committed adultery or is known to be an habitual drunkard.

The separation order may make all or any of the following provisions: that the husband (or wife) shall no longer be bound to cohabit; some provision for the legal custody of any children (this does not include illegitimate children); that the husband shall pay a weekly sum not exceeding £2 for the maintenance of the wife and a sum not exceeding 10s. a week for each child. Before the husband can be ordered to pay anything, there must be evidence that he has means, or is able to earn more than sufficient money for his own maintenance. The wife's means are also taken into account. If any change takes place in the means of either of the parties after the order, the husband may apply to have the amount reduced or the wife to have it increased, as the case may be.

A husband deserts his wife either if he leaves her or if he shuts her out of his house. A woman who has been guilty of adultery cannot obtain a separation order, and if a woman commits adultery after an order has been obtained, the order for the allowance cannot be enforced. The separation order is not enforceable while husband and wife are residing together, and the order comes to an end if they

continue to reside together for three months after it is made, or if they resume cohabitation. Neither a separation agreement, a judicial separation, nor a separation order puts an end to the marriage.

Separation Allowance. This term is used in two distinct senses. In one it is the allowance that a husband makes to a wife on their separation. It may be quite voluntary, but it is often the result of legal proceedings and is linked with a separation order. When an order of this kind is made the husband is usually ordered by the court to pay a certain sum towards maintaining his wife.

This amount varies according to circumstances, the main, but not the only consideration, being the means of the husband. A weekly wage earner will be ordered to make a weekly payment, while a richer man is ordered to allow his wife a larger sum of so much a year.

The court, in fixing the sum, will take into account the wife's habitual standard of living and also any income which she may possess in her own right.

The maintenance of the children, in cases where there are children, is a very important matter in fixing a separation allowance.

If the wife is to bring up and educate young children she will obviously be granted a larger allowance than if she is not. The court may fix a distinct amount for a child or for the children which the husband must pay, this being in addition to the separation allowance made to the wife.

Allowances in the Fighting Services. In the other sense, a separation allowance is the money paid by the state to the wives and dependents of soldiers, sailors, and airmen on active service. These allowances are very numerous and prominent in time of war, but there are comparatively few of them in time of peace. The amounts are altered from time to time according to variations in the cost of living and other matters.

Such a separation payment takes the form of an allowance of so much a week for a wife and so much for each child. A certain amount of the allowance is deducted from the man's pay, out of which he can, if he wishes, add to the allowance. Allowances to father, mother, and other relatives are only made if they are dependent, either wholly or partially, upon the soldier or sailor. *See Allowance.*

SEPARATOR: For Milk. This is a dairy appliance used for separating the cream from new milk. The principle upon which most of these instruments work is that of centrifugal force. The milk is led into a chamber where disks of tin or similar metal are caused to rotate at high speed. This churns up the milk and causes watery ingredients to be thrown out to the outside of the bowl, while the cream rotates near the central axis of the disks. By various forms of mechanism the cream and what is known as the skim milk are separated and led off through different channels to separate collecting vessels. A small type is manufactured as a hand-power machine, but other kinds are available which are driven by electricity, thus giving a more regular rotation of the disks, with consequent better separating effect.

SEPTEMBER

What to do in the Garden

Flowers

Plant hyacinth, daffodil and other springflowering bulbs in bowls of fibre indoors.

Place spring-flowering bulbs in pots of sandy loamy soil, put them out of doors and cover with old sifted ashes for 6 weeks.

Transplant conifers and other choice evergreen shrubs.

Prune rambler roses by cutting out old stems and tying in the new shoots.

Plant bulbs of daffodil, crocus, snowdrop and Spanish and English irises.
 Clip evergreen hedges for the last time before winter.
 Take cuttings of summer bedding plants and insert in pots or boxes of sandy soil in a frame.
 Place pot-grown chrysanthemums under glass so that the blooms may develop perfectly.
 Insert cuttings of roses, lavender, rosemary and other shrubs in sandy soil in a frame.
 Pot bulbs of freesia and lachenalia for spring flowering under glass.
 Sow sweet peas out of doors if the soil is light, otherwise in pots or boxes.
 Plant violets in a frame to provide winter flowers.

Fruit

Gather apples and pears which are ready for eating in October.
 Place greasebands on the stems of fruit trees to trap wingless female moths.
 Prune raspberry and black currant bushes.
 Plant a new strawberry bed. Remove diseased leaves from old strawberry plants.

Vegetables

Plant spring cabbage. Pot cauliflower plants and keep them in a frame for the winter.
 Lift and store late potatoes.
 Lift and store onions Select "seed " potatoes for planting in spring and store in a cool place.
 Earth up celery and leeks.

Food in Season

Fish

Bream; brill; eels; flounder; grey mullet; gurnet; haddock; hake; halibut; herring; lemon sole; perch; pike; plaice; red mullet; salmon; skate; sole; trout; turbot; whiting.

Shellfish

Crab; crayfish; lobster; mussels; oysters; prawns; scallops; shrimps.

Meat

Beef; lamb; mutton; pork; veal; venison.

Poultry and Game

Black game; capercailzie; capons; chicken; ducks (wild and tame); fowls; geese; grouse; hares; larks; leverets; moor-game; partridges; pigeons; plover; pullets; rabbits; snipe; turkey; turkey poults; teal; widgeon; woodcock.

Vegetables

Artichokes (globe); aubergine; beans; beetroot; broccoli; cabbage; carrots; cauliflower; celery; cress; cucumber; endive; horseradish; leeks; lettuce; mushrooms; onions; parsnip; peas; potato; red cabbage; spinach; sprouts; tomatoes; turnips; vegetable marrow; watercress.

Fruit

Apple; apricot; banana; blackberries; bilberries; cherries (morella); cranberries; damsons; figs; grapes; greengage; medlars; melons; mulberries; nectarine; orange; peach; pineapple; plum; quinces; nuts (various).

Notes for the Month

Sept. 1.—Partridge shooting begins.

Sept. 29.—Quarter Day.

Septicaemia. *See* Blood Poisoning.

SEPTIC TANK. A septic tank is employed in a particular process of sewage purification. It is used in certain towns, also in institutions and large houses in the country, as a considerable amount of land is needed for the treatment of the liquid passing out of the tank. The tank makes use of certain germs which split up and liquefy the solids that are suspended in sewage.

The tank is merely a chamber dug out of the ground and lined with brickwork, several feet in depth and roofed in, and of such a size that it takes the sewage 12 to 24 hours to pass through it. In some of these tanks there is no roof, but in either case the inlet and outlet pipes open below the surface of the sewage. A thick scum forms on the surface of the sewage, and this helps the germs by keeping them warm and protecting them from the air. Gases are produced which are highly inflammable, and these gases are sometimes collected and used as fuel.

After passing through the tank, a considerable amount of the solids in the sewage have been digested. The sewage is purer but, nevertheless, so black and offensive that further treatment is necessary by filtering through clinker or coke; or, in some cases, by distributing the sewage over a tract of land and allowing it to percolate through the soil. Some solid matter settles on the bottom of the tank, and has to be cleaned away every twelve months or so. Disinfectants, in any amount, added to the sewage prevent the septic tank from working properly.

Owing to the nuisance from smell, these tanks should be placed at an adequate distance from a house. They are satisfactory in their results but require careful and skilled supervision, and are of no value for small domestic establishments.

The Semi-Septic Tank. This is a variation of the septic tank, for in this type the work of purification is not completed in the tank itself, and only the primary process of disintegration goes on there. The breaking down of the solids is only partly carried out, and so the semi-septic tank is made on the small size, so that the partially treated sewage passes out to another stage for treatment. In this class of tank, therefore, the sewage is settled and partial liquefaction of the suspended matter takes place, besides the equalization in the strength of the sewage by its brief stay in the tank.

The second stage is to pass this effluent out for oxidation. This is accomplished in several ways. If there is plenty of suitable land available, it can be fed on the land, but the commonest way is treatment in one of the many forms of contact or filter beds now in use. These consist of a variety of materials of an indestructible nature. The essential feature is plenty of surface area to ensure the growth of bacteria. Probably the commonest material is a hard clinker, gauge one to three inches. For small systems one contact bed may be found sufficient, but in the large several beds are used *See* Cesspool; Sanitation.

SERGE: The Dress Material. Most serges are inclined to become shiny after long wear, and, on the whole, those which feel hardest to the touch take on a polish first. Serges such as chevots, with a short nap of fibre on the surface usually do not shine until the nap has worn away, but the wearing-off of the fluff lends a threadbare appearance.

Botany serge is fine, soft, and warm, and the best cloths of the sort show a neat and even twill. Serge shrinks less than flannel, and if white serge is washed and dried with care and bleached occasionally, it will be prevented from turning a dingy yellow. It is a useful material for sports wear and for children's coats, etc.

SERPENTINE LINE. In furniture this is a line used in design. The front of the piece is convex in the centre, whence it sweeps in wave-like form towards the wings, which become concave. It was much used by Hepplewhite for sideboards, dressing tables, etc. *See* Fender: Sideboard.

SERVANTS AND THEIR DUTIES

Hints Towards Comfort and Contentment for Employer and Employed

Shorter entries, e.g. Butler; Chauffeur; Cook; Housemaid; Nurse; Parlourmaid, deal with the various duties of various classes of servants. *See also* Character: Employers Liability: Housekeeping; Insurance; Kitchen

When servants are engaged through the medium of advertisements or a registry office, or in any other way, a personal interview should be arranged if possible. The smaller the household the more the mistress and servant or servants come in contact, and personality must count if the best results are to be obtained. It is also important for servants to see the style of the house or flat. Should a servant have come from a larger establishment, he or she may show at once that the new place will not suit; if from a smaller one, the mistress may feel that too much training will be required before the servant is up to the standard of the home and of the other servants kept.

After a satisfactory interview it is well to arrange for a personal reference. If the employer who is parting with the servant will give this, a better idea of the work and character is obtained both by the answers of the employer to the questions, which should be clearly thought out beforehand, so that nothing essential is missed, and by the aspect of the house. If a personal reference is unobtainable, it is never wise to accept from the servant a written reference. The late employer should be asked for a direct character, and this will be a better guide as to the servant's suitability for the new place.

Outdoor servants are almost entirely men, the two largest classes being gardeners and chauffeurs. They live in their own houses, or sometimes in houses on the estate of their employer, and, like other workers, receive a weekly wage. With domestic servants may be classed charwomen, jobbing gardeners, and others who work for more than one employer, doing a day's work here and there. They are paid so much a day.

Men servants classed as indoor servants are not very numerous. In larger houses a butler and perhaps one or two footmen are kept, and in some cases a valet. Men servants, like the women, receive board and lodging as part of their pay. A manservant does not now require a licence.

Where only one maid is kept she is known as a general servant. Two maids usually divide the duties of cook and house-parlourmaid. Bigger households may have in addition, a parlourmaid, between-maid, kitchen-maid and scullery-maid. A housekeeper may superintend the other women servants and there may be a lady's maid.

Nurses and under-nurses are kept in houses where there are children. In the larger houses their duties are strictly confined to looking after the children, but in the smaller ones a nurse-housemaid may be kept to do the work of a housemaid as well.

While it is impossible to keep to a hard and fast set of rules, a certain number are essential to order and comfort. If more than one servant is kept it is important to assign duties at the outset with even more decision than in the case of one experienced maid, who may be allowed to have some views of her own.

If a servant is to be put on board wages when the family go on holiday, this should be explained to her. The term board wages means the servant's ordinary rate of pay plus an allowance for food, and also for lodging if the house is shut up, the amount varying according to circumstances. When the maid accompanies the family, the question of board wages does not arise, but there may be friction if servants find themselves treated in this way without having been informed of it when they came. Another matter to be decided when engaging a servant is whether her friends shall be allowed to visit her. This is a question that must be settled in every case in accordance with individual wishes.

Comfort Essential to Good Work

Good or bad servants can make or mar the home. They should be well treated and, if good, their work should be respected and appreciated, and a real interest taken in them. Perhaps the most frequent causes of complaint are uncomfortable bedrooms, badly furnished, more than one maid in a small room or more than two in any room, insufficient or poor quality of food, and the matter of outings. In newer houses a small sitting-room or recess off the kitchen makes for comfort.

It is impossible to expect good work from anyone who cannot sleep in comfort. If the house is too small to accommodate the desired number of servants, it is best to have daily help.

Good food, without waste, is essential. The mistress should retain complete control of the larder and, unless she has an experienced cook, herself solve the problem of left-overs so that they shall not be wasted or eaten under protest in the kitchen. Where a servant asks for some special inexpensive article of diet, it should be provided for her.

Outings. In this matter hard and fast rules cannot be laid down. One afternoon and evening a week and every second Sunday afternoon and evening are the usual minimum. The hour of return in some places is fixed at 10 p.m. With a young servant this hour should be late enough, but if permission be occasionally asked to go to a theatre or other entertainment, it should not be withheld without good reason. Where there are several maids it may be difficult to arrange extra outings for all, and favouritism should be avoided.

In the case of the general servant, if she gets through her work, she should be encouraged to have as much time as possible to herself. In a small family an only servant is often lonely, and the kind and sensible thing to do is to allow her to invite a friend or relative to the house. A special sitting-room is not possible in the small house, but if the kitchen cannot be comfortable, owing to its size, it can sometimes be arranged for her to use the dining room after the evening meal. A good servant commands, and is worth, high wages. When a maid is young and inexperienced a mistress must expect tactfully to train her if the home is to be well run.

Where three servants or more can be kept their work is so clearly defined in the kitchen, sitting-rooms, and bedrooms that a well-organized household becomes a simpler matter than where all the duties have to be performed by a cook-general and house-parlourmaid, or a general alone. Where only two maids are kept, it is essential that they should get on well together, and that any housework which the cook is expected to do should be clearly understood on engagement. It is usual for her to be responsible for cleaning the dining room, breakfast room, should there be one, hall and steps. Sometimes she takes in the breakfast, and usually clears it away and washes up while the house-parlourmaid is busy in the bedrooms.

The cook assists in making the beds, and after that her duties are confined to the kitchen, except on the occasions when the other maid is out. The house-parlourmaid combines the duties of parlourmaid with that of housemaid, and should be dressed for luncheon. A simple dinner is usually arranged, with which she can cope, on the days when the cook is out. Where there are children a nurse-housemaid is sometimes kept as the second servant and the parlourmaid side of her duties require to be simplified.

Some people solve the two-servant question by engaging a husband and wife. They may both be trained servants, in which case the woman acts as cook-housekeeper and the man undertakes the duties of butler. When engaging a husband and wife the highest personal references are advisable, as it is a more serious matter if they have to be dismissed than is the case when a single servant proves a failure.

Maid's Uniform. The question of uniform sometimes presents difficulties, especially in the case of the general servant. Should she object to uniform she can usually be persuaded to wear an overall in the morning with a coarse apron for rougher work, and a dark dress in the afternoon with muslin apron, collar and cuffs. Very often if the mistress helps with the purchase of a smart uniform any difficulty in getting it worn is overcome.

Where a parlourmaid and housemaid are kept some mistresses like to provide the afternoon uniform so that both maids, if required to wait at table, or to assist in pouring out the tea at an "at home," present an attractive appearance. Black dresses need not necessarily be worn; brown, blue, claret colour or bottle green are sometimes preferred, with a pretty style of cap, apron, cuffs, and collar. In the morning parlourmaids and housemaids wear cotton dresses. Small patterns are more useful than plain colours. The house parlourmaid should wear a clean apron under her coarser one, so that the latter can be quickly taken off should she have to answer the door or a sitting-room bell in the morning. A rubber apron is a convenience to protect the maid's afternoon uniform when washing up. Neat shoes are important.

Cooks wear dresses with short skirts and either large linen aprons or overalls in the kitchen. Caps are optional. Where there are stone floors to kitchen and scullery boots are more comfortable than shoes.

Where one manservant is kept he does not wear livery. Black coat and dark trousers is the customary uniform. In many houses where no regular servant is kept, the housewife is relieved of the more laborious domestic duties by hiring the services of a daily girl. She may be engaged for the whole day, in which case she will probably wear uniform in the afternoon, or for the forenoon only, or for a couple of hours, according to requirements. Her wages are paid weekly and she may get her meals or not, as agreed upon.

Insurance. One of the duties of an employer is to see that his or her servants are insured under the national health insurance scheme and that the cards are regularly stamped. Outdoor servants, such as a gardener, now come within the unemployment insurance scheme, but private indoor servants do not. It is desirable to insure them against any accident that may happen to them in the course of their employment. The best way of doing this is to take out a combined insurance policy which covers risk from fire and burglary and also insures the servants against accident.

SERVICE HATCH. As a general rule a service hatch is an opening about 2 ft. square provided with a door or doors, forming a means of direct communication from the dining room to the adjoining kitchen or pantry. It is particularly helpful in a house or flat where only one maid is employed, as the meals can be handed through the service hatch from time to time as requisite, while the plates and dishes after use may be returned by the same means, thus obviating the necessity of the maid entering the dining room.

In most cases the service hatch consists merely of a door, which may be hinged or arranged to slide sideways or upward in grooves. The sides of the hatch are generally lined with wood, in the same manner as a door or window opening, and are also provided with a wide window board or shelf.

To prevent odours from coming through from the kitchen two doors or two sets of double doors can be provided, and the hatch made a couple of feet deeper. One set of doors will be hung on the dining room side of the wall, and the other on the kitchen side.

Service Hatch in which one set of doors closes automatically as the other set opens.

The articles as they are prepared for table are placed in the hatch, and the doors closed on the kitchen side. Those on the dining room side are then opened whenever the articles are needed, and the dirty plates replaced, the doors being closed afterwards on the dining room side.

In the case of the hatch illustrated, one set of doors is automatically closed when the other is opened and no view through into kitchen or dining room is

obtainable. No noise, sounds of talking, or smell of cooking can penetrate. Hatches are sometimes arranged to open above built-in dressers, or form portions of the backs of sideboards. *See Dining Room; Kitchen; Pantry.*

SERVICE LIFT. In houses with a basement kitchen the installation of a service lift saves the labour of carrying trays up and downstairs and also prevents food from getting cold during the transit from kitchen to dining room table. Before proceeding with plans for installation inquiries should be made to ascertain if there are any landlord's restrictions that preclude it. In some cases the local authority has requirements which must be met.

When the dining room is immediately over the kitchen the lift can be planned to rise in a corner of the room. Sometimes such a lift is of the disappearing type and is operated from below ascending through a hole in the floor. When the cage descends the floor boards on top return to their usual position. In other cases a built-in cabinet conceals the lift.

A service lift can be operated by electricity or by hand power. In the former case it can be worked from either the upper or lower floor. In the latter case the hauling rope must be adjusted so that it is not loose enough to rattle against the casing, or too tight so that it grates. If a self-sustaining gear is used, the cage is locked into position as soon as either the winding handle or the hauling rope is released. The lift may be fitted with a brake worked by a foot pedal; in this case the lift is moved when the foot presses the pedal and the brake comes into operation when the foot is removed. *See Dining Room.*

SERVICE PIPE. This name is given to a pipe conducting the principal supply of water or gas to a building, made of lead or galvanized iron, respectively. Generally there is a stop cock in the run of the water service pipe in any convenient position in or just outside the building, so that the water can be entirely cut off if necessary. A draw-off cock should be placed on the house side of the stop cock so that the entire system can be drained.

In the case of the gas service pipe, this is usually the property of the gas supply company, and runs from the gas main to the gas meter. *See Gas; Pipe; Water Supply.*

SERVICE WAGON. Known also as dinner wagons, service trolleys, tea wagons and table wagons, service wagons may be obtained in oak, walnut or mahogany, and also in enamelled or plain white

wood for nursery use. They are made with two or three tiers or trays, and in some cases are so constructed as to be readily convertible into tables.

The small two-tiered kind is most useful when an aid to service is required from ground-floor kitchen to dining-room or garden, and obviates the carrying of heavy trays. As such a wagon is table height it can be arranged and laid as an afternoon tea table, cakes, etc., being placed on the lower tier.

The wagon illustrated can be converted into a rigid table at which four people can be seated for luncheon or dinner. Slight pull on a small button enables anyone instantly to change the wagon while loaded into a table or vice-versa. When laid in the kitchen, the table is converted into the wagon shown on the left, wheeled into the garden or dining room, and converted into the table shown on the right. The cellulose finish resists damage to heat; if hot liquids are spilt and removed at once they will not stain the surface. Wagons with three tiers are obtainable, which swing into position and form a table at which six people can sit.

Service Wagon. Two views of a two-tiered wagon which can be laid in the kitchen, wheeled into the dining room and there converted into a rigid table.

Making a Trolley. The simplicity of this dinner or service wagon, made throughout in oak, commends it immediately. The overall height is 31 in., length 26 in., and width 16 in., 2 in. of the total height being accounted for by the rubber-covered castors screwed to the four uprights. The uprights are of $1\frac{1}{4}$ in. square wood, the fronts, backs, and sides of the trays or shelves being $1\frac{1}{2}$ in. by $\frac{3}{8}$ in. thick. The shelves or tray-bottoms are of 5-ply oak, each $24\frac{7}{8}$ in. long by $14\frac{7}{8}$ in. wide.

Service Wagon. Fig. 1. Wagon made in oak. Fig. 2. Detail of jointing. Figs. 3 and 4. Tray bottom and method of attachment.

Dowel joints are used throughout. The three tray-fronts are first dowelled and glued to the front uprights, the bottom tray-front being 4 in. up from the bottom, the middle one 12 in. higher, and the top one 12 in. above that. Proceed in exactly the same manner

with the back. When the glue has set perfectly, join front and back together as shown at Fig. 1, the jointing being shown in detail at Fig. 2.

The 5-ply shelves or tray-bottoms (Fig. 4) rest and are glued upon $\frac{1}{4}$ in. square strips of oak glued to the inside lower edge of each tray-front and side and back (Fig. 3), the tray-bottoms being notched out at each corner to ensure a neat fit. Fitting the rubber-covered castors completes the wagon, which may be polished or left in its natural colour. *See Dining Room; Dowel.*

Serviette. *See Napkin.*

SETSCREW. This name is given to a small, usually headless screw used to affix one part to another. Setscrews are employed for fixing a small pulley or gearwheel to a shaft, a knob to a spindle and for like purposes. As the name suggests, the screw is used to set or fix the position of a movable part on another part.

SET SQUARE. This name is applied to an instrument used for testing or marking out rectangles. Carpenters and engineers use squares when working in wood and metal, but the term set square is more correctly limited to the squares used by draughtsmen. In a simple form it may consist of a thin, flat piece of pear wood triangular in shape. Two of the sides form a right angle, and the third is at an angle of 45° or 60° to one of the other sides.

In almost all cases it is necessary that one of the edges of the instrument should rest upon a T-square or batten, which is set in position parallel with the base line or principal horizontal line. By sliding the set square along the batten or T to the desired spot and drawing a line against the edge of the square, the angle formed between this line and the horizontal or base line will be 90° .

As a test for accuracy of the square portion of the instrument, turn the square over without moving the batten. If the square is correct, a second line drawn from the same point as the first will exactly coincide; but if the square is incorrect, the lines will be tapered, and the amount of taper at the extremity of the square will be the amount of error in the instrument.

Squares should always be kept clean and in a dry place, preferably hung up on the wall. Celluloid or ivory set squares are best cleaned by washing them in soap and water. Wooden squares may be cleaned with a linen rag moistened with petrol, and then polished. *See Drawing; Measurement; Rule; T-Square.*

SETTEE. The settee is a long seat, usually upholstered, and having arms at either end. It thus differs from the sofa, being rather a development of the settle. It appeared in England about the end of the 17th century, and some splendid pieces, notable for their upholstery, were made at that time. The example illustrated is in walnut, with six cabriole legs, and high-backed seat covered in beautiful brocaded silk. Later the upholstery was left out from the back and sides, and the settee became in effect two or three chairs with a single back.

Chippendale designed settees with open backs, carved with ribbon work and C scrolls. Chinese frets occasionally form the backs, and the square legs are connected by rails. Hepplewhite became famous owing to his wheel-back settees, made of satinwood and painted. In general his settees have the crest rail in the form of a wave that flows gently into the arms at either end. The fully upholstered ones have in some cases no wood showing on back and seat, but in others a neatly moulded frame is visible all round. The legs are often round and straight, but cabriole legs are sometimes found.

The chair-back settee was favoured by designers of Regency furniture. *See Chair; Hepplewhite; Queen Anne Style; Regency Style.*

THE SETTEE BED AND ITS CONSTRUCTION

A Convenient Piece of Furniture for the Flat or Small House

This contribution describes the making of an article that will serve as a seat by day and as a bed by night. To make it, the amateur needs a knowledge of the various processes that are described under such entries as Dovetail; Joint; Mortise. See also Chair; Chair Bed; Divan; Upholstery.

A settee bed, as it is called, is a piece of furniture that will serve as a settee during the day and as a bed during the night. Such beds have to a great extent been replaced by divans, but are suitable for bungalows and bed-sitting rooms. There is only one main type of settee bed, but they are made in various sizes and patterns, and in various materials and qualities of material.

The settee bed shown in Fig. 1 will be found comfortable and inviting, and the extra cushion shown at the back can be transferred to the seat for those who prefer it. As a bed the appearance of the settee will be as in Fig. 2, the opening out being of the simplest description and speedily effected. The main dimensions, excluding cushions, are: height of seat over framings, 9 in.; height of arms, 1 ft. 11½ in.; height of back framing from ground, when vertical, 3 ft.; length of seat over upright, 4 ft. 2 in.; length over arms, 4 ft. 4 in.; width of sides over uprights, 2 ft. 4 in.; length of arms, 2 ft. 11½ in.; length of back, seat and foot frames, 3 ft. 10 in.; width of back and seat frames, 2 ft. 3 in.; width of foot frame, 1 ft. 11 in. net; and with stop extensions as required.

Settee. Queen Anne walnut settee with silk brocaded covering. (Courtesy of M. Harris & Sons)

Probably the best wood to select for general purposes is oak, stained to a rich nut-brown colour and bright polished. The legs or uprights (A, Fig. 4) require 4 pieces of 2 in. by 2 in., the length given in the cutting list allowing a shade for paring in finishing to include a stub tenon at the top end to enter the arm. Mortises should be cut for the seat and lower rails, and the legs may be mounted on castors, making an allowance of 1½ in. in height when setting out the working

drawing.

The arms (B) finish 3¼ in. by ⅞ in., and have the edges slightly rounded away for comfort. When fitted in position they project 1 in. on the outer side and ¼ in. on the inner, and 1 in. in front, which would allow 6½ in. net for adjustment projection of the arm at the back when finished. Just behind the back upright the arm is reduced to 2¼ in., as in Fig. 6.

The seat rail (C) takes two pieces to finish 2½ in. by ⅞ in., tenoned or dowel led to the legs, and similar rails (G, Fig. 3) are fitted to the legs at the same level front and back. A stretcher rail running between the front and back rails may be dovetailed in if desired. The underframing rails (D) and corresponding rails (H, Fig. 3) fitted to the sides and front respectively may finish 1¼ in. by ⅞ in. net.

The panels (E, Fig. 4) between the arms and seat rails have a visible height of 13½ in., and are fitted into position with ½ in. stub tenons top and bottom, the net finished width being 4½ in., using ⅝ in. or ¾ in. thickness as preferred. The panelled effect can be of applied mould glued and pinned on. If

this main framing is carefully put together a substantial and lasting result will be obtained. The separate framings for the back, seat and foot ends forming the cushion rests may next be dealt with, and a nicely smoothed finish with the edges slightly rounded away will give the best effect.

	Long ft. in.	Wide in.	Thick in.
4 legs (A)	2 0	2	2
2 arms (B)	3 0	3 $\frac{1}{4}$	$\frac{7}{8}$
2 rails (C)	2 4	2 $\frac{1}{2}$	$\frac{7}{8}$
2 rails (D)	2 4	1 $\frac{1}{4}$	$\frac{7}{8}$
2 panels (E)	1 2 $\frac{1}{2}$	4 $\frac{1}{2}$	$\frac{5}{8}$ or $\frac{3}{8}$
4 uprights (F)	1 2 $\frac{1}{2}$	2 $\frac{3}{4}$	or $\frac{7}{8}$
1 front rail (G)	4 2	2 $\frac{1}{2}$	$\frac{7}{8}$
1 back rail	4 2	2 $\frac{1}{2}$	$\frac{7}{8}$
1 front rail (H)	4 2	1 $\frac{1}{4}$	$\frac{7}{8}$
1 back rail	4 2	1 $\frac{1}{4}$	$\frac{7}{8}$
BACK FRAME.			
3 stiles (J)	2 3	1 $\frac{7}{8}$	$\frac{7}{8}$
2 rails (K)	3 10	1 $\frac{7}{8}$	$\frac{7}{8}$
8 slats or laths (L)	2 1	1 $\frac{7}{8}$ or 3	$\frac{3}{8}$
2 strut legs (M)	1 0 $\frac{1}{2}$	1 $\frac{1}{4}$	$\frac{7}{8}$
1 strut rail	3 9	1 $\frac{1}{4}$	$\frac{7}{8}$
1 clutch (N)	2 2	1 $\frac{7}{8}$	$\frac{7}{8}$
2 bolts and nuts	3	$\frac{3}{8}$	
1 adjustment rod	4 3	1 $\frac{1}{2}$	1 $\frac{1}{4}$
SEAT FRAME			
3 stiles	2 3	1 $\frac{7}{8}$	$\frac{7}{8}$
2 rails	3 10	1 $\frac{7}{8}$	$\frac{7}{8}$
8 slats	2 1	1 $\frac{7}{8}$	$\frac{3}{8}$
FOOT FRAME.			
3 stiles	2 0	2	$\frac{7}{8}$
2 rails	3 9	2	$\frac{7}{8}$
8 slats	1 10	2	$\frac{3}{8}$
2 stop fillets	2 3	2	1 $\frac{1}{4}$
2 strut legs	1 2 $\frac{1}{2}$	1 $\frac{1}{4}$	$\frac{7}{8}$
1 strut rail	3 9	1 $\frac{7}{8}$	1 $\frac{1}{4}$
1 clutch	2 0	1 $\frac{7}{8}$	1 $\frac{1}{4}$
2 ledges for seat frame	2 0	$\frac{7}{8}$	$\frac{7}{8}$

Reference to Fig. 5 shows that the whole back frame is hinged to the back edge of the seat frame, and supported at a convenient angle by an adjustment rod behind in the slotted arm, as in Fig. 6. Two outer stiles (J) and one centre stile will be required to finish $1\frac{7}{8}$ in. by $\frac{7}{8}$ in., and also 2 rails (K) to finish 3 ft. 10 in. by $1\frac{7}{8}$ in. by $\frac{7}{8}$ in. This allows for jointing and clearance between the arms so that the framing may fold down between for portability. The stiles and rails should be mortised and tenoned together and pinned. The slats or laths (L) may be anything between $1\frac{7}{8}$ in. and 3 in. wide, and finish $\frac{3}{8}$ in. thick, stubbed into the top and bottom rails and equally spaced.

Settee Bed. Figs. 1 and 2. Useful piece of sitting-room furniture which can be unfolded and used as a bed in an emergency.

This should result in a firm but light rectangular framing; when lowered to seat level it will be supported by strut feet which fold between the inner edges of the stiles in the manner indicated at Fig. 7. These strut supports (M, Figs. 5 and 7) take 2 pieces of hardwood $12\frac{1}{2}$ in. by $1\frac{1}{4}$ in. by $\frac{7}{8}$ in. and are bolted right through J and M with $\frac{3}{8}$ in. round-headed bolts. The heads are sunk and the bolts are nutted on the inside so that they pivot freely without play. A section at O (Fig. 5) shows how the bolt is entered.

Fig. 3. Front elevation of settee bed. Fig. 4. Part side view. Fig. 5. Framework. Fig. 6. Arm. Fig. 7. Back frame showing struts and supports

The stretcher rail between may be of the same substance as the legs, tenoned and pinned in. When the strut support is lowered and bearing the frame it is held in position by means of a clutch (N, Figs. 5 and 7) which is of $1\frac{7}{8}$ in. by $\frac{7}{8}$ in., or $1\frac{1}{4}$ in. by $1\frac{1}{4}$ in. thickness in the length and with a $1\frac{1}{4}$ in. projection at the extremity to pass over the stretcher rail of the strut and grip it. This clutch is hinged to the lower rail of the framing and is of a length to butt closely between the rails. The position, approximately, for bolting the strut to the framing will leave a space between the framing and the top of the strut leg of $2\frac{1}{2}$ in., or $4\frac{3}{8}$ in. from the outer edge of the framing; this indicates a position which should be suitable for allowing the clutch to overlap and grip the strut rail.

The seat frame is of the same dimensions as the back. It may be made with 3 in. by $\frac{3}{8}$ in. laths, which will be sufficiently thick to give a bearing, whilst wide enough to be comfortable. Seven laths are indicated in the illustration, and the centre and thicker stile is omitted, but the finished effect of the whole will be better if the frame is fitted with an equal number of laths to the back frame, with an extra one to replace the centre stile.

The foot-end frame itself is 1 ft. 11 in. wide only, but otherwise it is put together with stiles, rails and laths in a similar manner to the back. This foot-end frame lies loosely under the seat frame, and when home is flush with the front of the seat frame.

When extended it drops into position level with the seat frame. The latter rests upon two stop-fillets 2 ft. 3 in. by $1\frac{7}{8}$ in. by $1\frac{1}{4}$ in., screwed to the underside of the stiles (Fig. 5) and with a similar projection to that indicated for the clutch, which will stop against the seat rail (G, Fig. 3) and prevent the foot frame from dropping out of position. The frame is supported by a strut and locked with a clutch similarly to the back frame. The total length of the frames when let down horizontally will thus be 6 ft. 5 in. In Fig. 7 the strut support is shown in action with the clutch indicated.

In Fig. 1 the foot-end frame is omitted to show more clearly the position of its entry. When being drawn out or pushed home it travels on fillets screwed to each of the side rails (C) in a similar manner to a drawer runner. A cutting list is given on the previous page, with the lengths slightly on the full side, in most instances, to allow for finishing; widths and thicknesses are net.

The Cushions. Much of the comfort of a settee bed depends on the cushions, especially when they are used as mattresses. Unless they are well upholstered they will wear thin and provide little, if any, protection from the hard laths. The ordinary flock filling employed for mattresses can be used if it is properly packed in the inner casing, but as it is liable to wear limp and so become uncomfortable, the better plan is to use well curled horsehair.

The most satisfactory method of making the cushions is to use springs, and in this case they should be about 6 in. thick and fitted with 4 in. springs set at close intervals. For the amateur the best method of making them is to cut out oblong pieces of stout canvas, and sew the springs to two pieces, each spring touching the other. The sides should be fitted in with narrow material, and then each in turn covered with flock or hair to a thickness of 2 in. or so, and then with tapestry or repp. The two sides should be buttoned together so as to give rigidity and also to keep the two surfaces parallel.

SETTER: The Dog. The English setter is one of the handsomest of dogs, but, unlike the retriever, he is not greatly kept for show purposes. Several beautiful colours are recognized, such as black and white, lemon and white, liver and white, etc. The long silky coat is slightly wavy.

The shoulders should be well sloped, the loins wide, slightly arched and muscular, the brisket deep, and the ribs widely sprung. The legs should be strong and muscular; the feet close and compact. The head should be long and lean; the skull oval from ear to ear, allowing plenty of room for the

brain. The muzzle should be moderately deep and fairly square; the nostrils wide. The neck should be rather long, muscular and lean. The tail should be carried almost on a line with the back.

The colour of the Irish setter is a rich golden chestnut, entirely devoid of black. The Gordon, or black-and-tan, is the rarest of the three. He is somewhat more strongly built than his English cousin, and his head is much heavier. *See Dog; Kennel.*

Setter. Young English setter, a beautiful silky-coated sporting dog. (Ralph Robinson, Redhill)

How to Construct a Useful and Decorative Hall Seat

The reader may also consult the articles on Ingle Nook; Jacobean Style; Tudor Style; while references for the constructive side of this contribution include Cabinet Making; Chest; Corner Seat; Halved Joint; Wood Carving

Beautifully carved old oak settle with box seat; 17th century. (Courtesy of T. Edwards, Harrogate)

This word is used for a kind of wooden bench or seat. Most settles have arms and a high back and will hold three or four persons. Made of oak and heavy in style, settles appeared in England perhaps as early as the twelfth century. The high back was a protection against draughts, and some had in addition a canopy. Gradually they became more elaborate, and some examples of the Tudor and Stuart periods are

beautifully carved. In some the fronts are divided into panels around which is finely executed carving. A number of settles were made in the 16th and 17th centuries, but early in the 18th the piece went out of fashion. In the 19th, reproductions of the old settles made their appearance.

Strap work ornamentation is found on many British settles. They had inlaid chequer board decoration on the stiles and rails, and occasionally the arms were inlaid. In some, as shown in our illustration of a beautifully carved 17th century settle, the bottom of the piece was constructed as a chest.

Settles are made to-day in reproductions of the old styles, and are suitable in halls or living-rooms furnished in oak period styles. Loose velvet cushions, fringed or tasselled, are permissible, but a settle is never upholstered.

Making a Monk's Bench. A type of settle with a movable back and box seat was made in Tudor and Jacobean times. The back was adjustable to form a table and the piece is often known as a monk's bench. Copied to-day for hall furnishing, this is a useful and picturesque style of seat, which combines not only a table, but also a rug chest.

Settle. Fig. 1. Monk's bench type of settle, combining seat and table.

The monk's bench provides suitable surfaces for incised carving. The suggestions given in Figs. 1 and 2 are taken from old English carvings, and they may be executed with a few simple tools without any previous experience of wood-carving. By the method of construction shown in Fig. 3 there are no mortise and tenon joints, the lapped halving joint only being used. Oak is the correct wood, but the carving will be easier if seasoned yellow pine is used, and finished by wax polishing only or by staining.

Fig. 1

Fig. 2

Fig. 2. Front and side elevations.

The upright sides, A, are 2 ft. 5 in. by 1 ft. 3 in. by 1 in. But if machine-planed wood is used, the thickness will be nearer $\frac{7}{8}$ in. Two pieces are glued together for each upright, and the top curve is drawn to a radius of $7\frac{1}{2}$ in., 2 in. from the end. The curve should be reversed on

one side to give a flat portion of about 2 in. The curved line is sawn with a bow-saw, and finished with a spokeshave, and the small piece cut off, as shown at B, should be placed on one side for use on the under side of the top board.

Fig. 3. Details of fitting.

The back may be in one piece, glued up with 3 or 4 lengths and finished to 2 ft. $11\frac{1}{2}$ in. by 2 ft. 5 in., or formed with one 2 ft. $11\frac{1}{2}$ in. by 1 ft. 1 in., with a lower length, 1 ft. 5 in., of plywood. The back is fitted in a rebate cut in the upright sides, as shown. Two frames, D

Fig. 3

and E, are prepared from 2 in. by 1 in. wood (deal will do for this) to 2 ft. 10 in. by 1 ft. 1 in. The ends may be screwed or halved together, and then screwed to the sides and back. The frame, D, is flush with the bottom, and the top of E is 1 ft. 5 in. up. The top of D frame should be covered with a piece of plywood measuring the same outside-size as the frame.

A length of 2 in. by 1 in. wood is fitted at the back on top of E, as indicated at F, but two end pieces, G, the same width and thickness, should be joined to it with the halving joint and project 1 in. in front, the ends being rounded as shown. A 2 ft. 10 in. by 1 ft. 5 in. frame, shown at H, is made from 2 in. by 1 in. wood, halved at the corners, and a rebate cut at the back to take a panel, K, measuring 2 ft. 6¾ in. by 1 ft. 1¾ in. by ½ in. This framed panel should be fitted under the projections at G and screwed up from the front lengths of D and E.

The hinged seat flap giving access to the locker at the bottom of the bench is 2 ft. 6 in. by 1 ft. 1 in. by 1 in.; the front edge is rounded and two battens of 2 in. by 1 in. wood screwed under at the ends, so as to fit inside the rail E and prevent the wood from warping. The top board, which forms a table when resting on the arms is 3 ft. 6 in. by 1 ft. 6 in. by 1 in., and is hinged 1½ in. away to the back C. In order to allow the board to tilt back slightly when upright, a chamfer should be planed 1½ in. wide and ½ down at the hinge side. The pieces B, neatly cleaned with a spokeshave, are screwed to the top board, as shown.

Carving the Panels. The carved decoration may be drawn direct, or on paper and transferred. The border lines, as well as the curves, are cut with a veiner and enlarged with a quick gouge as indicated at M. Slight recesses are worked with a flat gouge as shown at N, and finished as indicated at O. The tool cuts at P are done in a similar manner. The effect gained by the simple incising of all lines with a veiner is quite effective; but, if thought too difficult, the gouge work may be omitted.

SÈVRES. The richly decorated porcelain characteristic of the famous French factory at Sèvres is rightly admired for its unique qualities of form and colour. Only the longest of purses could hope to acquire examples worth having, and the lover of antique china must usually be content to study old Sèvres in public galleries.

Started in 1756, Sèvres has always enjoyed royal or state patronage. For the first 13 years it produced soft-paste porcelain of the St. Cloud type. In 1769 a new era opened with the introduction of hard-paste, similar to that of China and Dresden. Since then practically all French porcelain has been made with china-clay and felspar, and hard-paste Sèvres is therefore distinguishable from the English reproductions made in bone porcelain at Coalport and elsewhere. It now became possible to turn out enormous vases, as well as plaques for painted scenes. During the Louis Seize period many of these plaques were set in ormolu mounts on rich marquetry, and a delightful cornflower-blue was introduced. The important class of biscuit figures, by great sculptors, is quite distinct from the homelier groups emanating from Dresden and Chelsea. Since the new factory was erected in 1876 there has been a revival of soft-paste porcelain, but it has not the delicacy and charm of the old Sèvres.

The mark of the double L, established in 1753 at Chantilly, with A to represent the year, was continued at Sèvres from 1756 to 1777. That year was indicated by Z, W having been omitted. The second cycle began with A A, and reached 1795 with RR, when the dating was varied for a time. Since 1818 the year has been expressed by its last two figures. From 1810 to 1848 imperfect pieces bore no mark, whereas since that date they have had a wheel-cut through the main mark. From 1854 to 1870 a crowned N stood for the emperor, and a T meant that the piece was soft-paste. After 1888 the mark became a potter at the wheel, with the word Sèvres and the two-figure date.

The fact that during the 19th century white biscuit pieces were freely sold has been a fruitful source of mystification. Large quantities were bought for decoration either in Paris or in England, so that the only part of them which was of genuine Sèvres origin was the body. It is estimated that of all the so-called soft-paste Sèvres in collections nine-tenths were decorated elsewhere. *See China; St. Cloud Ware.*

Sèvres. Left, trembleuse cup, cover and saucer, painted with medallions of children and a wreath of flowers on cover. Centre, flat-shaped gros-bleu vase and cover with white and gold scroll handles. Right, large gros-bleu cup and saucer painted with pastoral landscape and figures and with gilt scrolls and wreaths of flowers.

SÈVRES PORCELAIN: IMMENSE VARIETY IN COLOUR AND DESIGN

1. Louis XVI clock of light green oeil de perdrix Sèvres china with ormolu mounts. 2. Pierced goblet, 1854. 3. Inkstand presented by Louis XV to one of the royal princesses about 1770. 4. Vase, about 1768. 5. Porcelain clock with ormolu mounts, 1770. 6. Perfume-burner, about 1758. 7. Bottle-shaped vase decorated with mythological subjects, 1768. 8. Jardinière on pedestal. 9 and 10. Covered basin and stand, 1766. 11 and 12. Covered basin and stand decorated with paintings. 13. Vase, about 1755. 14. Louis XVI candlestick. 15. Casket mounted in silver, about 1754. 16. Louis XVI clock with ormolu mounts. 17. Jewelled cup and saucer, 1814-24. 18. Candlestick vase with elephants' heads, about 1757. 19. Louis XVI candelabrum for three lights. 20. Inkstand, 1761. 21. Pierced vase, about 1756. 22. Rosewater ewer and dish, about 1765. 23. 18th century biscuit china vase decorated with figures in high relief. 24. Covered basin and stand, 1759. 25. Cassolette from service made for Catherine II of Russia, about 1776-79.

SEWAGE. This describes the refuse from a house. In towns it is carried away through the drain pipes, in connexion with which an elaborate sewage system provides for its removal and disposal. In country districts residents have often to make their own arrangements for its disposal, and one way of doing this is by means of a cesspool.

Some of the contents of sewage have a high manurial value. The processes carried out at sewage works in connexion with the water carriage systems of towns remove the greater part of this value, as neither the solid part of the treated sewage, the sludge, nor the watery effluent is of much use. Where a cesspool is used for a country house, the action of bacteria reduces the solid constituents of the sewage to a soluble condition and the liquid can be drawn out for distribution in a garden.

A cesspool should be lined with cement, otherwise the contents soak out into the surrounding soil at a depth where nitrification processes do not go on, and the sewage may make its way in the ground water and so into shallow or surface wells. In this way typhoid fever, diarrhoea, and other diseases may be propagated. Even if it has a cement lining, a cesspool should be at a lower level than a well used for drinking water, and at least 100 ft. from any well, spring, or stream.

There is much to be said for the disposal of excreta by using an earth closet and burying the contents of the pails in the upper layers of the garden soil, where nitrification will go on and thereby promote plant growth. Where such a system has been tried plentiful crops of vegetables have been obtained, and have been consumed without causing diarrhoea, typhoid, or any other filth disease. The earth which is used in the closets should preferably be garden soil, and it is important that it should be collected on a dry day and stored in a dry place. Peat, which removes offensive odours effectually, may by its antiseptic effect interfere with the desired bacterial action. The excreta disappear as such in about a month, and with proper care the process can be carried out without being in the least degree offensive. An arrangement of pails has been devised whereby the liquid excreta are strained into a lower pail and disposed of separately. It has been pointed out by experts that urine diluted to 1 in 20 with water, and carefully applied to certain vegetables, promotes very vigorous growth, and that in the case of carrots it destroys one of their most common pests. Slop water on such a system would have to be disposed of separately, but could be utilized for watering, either by irrigation or by spraying. *See Cesspool; Drains; Earth Closet; Sanitation; Septic Tank; Water Closet.*

‘S’ RECIPES: A FURTHER SELECTION SHOWN IN COLOUR

Sponge Cake Mould: Prepare a pint packet of cherry jelly with $\frac{3}{4}$ pt. of hot water and use some of it to mask a fancy mould. When set, decorate the bottom with glacé cherries and angelica dipped in jelly, and leave these to set also. Cover them with more jelly and, while this is setting, make $\frac{3}{4}$ pt. custard and add to it 4 crumbled sponge cakes, 2 oz. castor sugar and a little vanilla flavouring. Set it to cool. Fold in stiffly whisked whites of 2 eggs and $\frac{1}{2}$ - $\frac{3}{4}$ oz. French leaf gelatine dissolved in $\frac{1}{2}$ gill water. Pour mixture into mould and leave to set. Strawberry Cakes: Sieve together $2\frac{1}{2}$ oz. flour, $\frac{1}{2}$ teaspoonful baking powder, 2 small packets or 3 oz. strawberry blancmange powder. Cream 3 oz. each of margarine and castor sugar, stir in an egg quickly and beat mixture for 10 min. Fold in flour, etc., together with a little milk to mix, add a few drops cochineal and turn the whole into small, greased, fluted cake tins. Bake in hot oven for about 12-15 min. and place on sieve to cool. Just before serving put $\frac{1}{2}$ teaspoonful jam on top of each. Strawberry Salad: Fresh strawberries served with either tinned or fresh peaches, flavoured with good Bordeaux wine or kirsch, and with strawberry syrup poured over. Sunflower Sweet: Split open 7 small sponge cakes, spread cut sides with apricot jam and mashed banana and put together again. Arrange in star pattern on glass dish, leaving small circle in centre. Dissolve $1\frac{1}{2}$ pt. packet lemon jelly in a little hot water and make quantity up to $1\frac{1}{2}$ pt. with syrup from tin of peaches. Soak sponge cakes with jelly and pour remainder round. Leave until jelly is almost set. Then cut some tinned peaches to resemble petals of sunflower and arrange one on each sponge cake. Leave to set. Sweeten 1 gill cream, whisk and put into centre, sprinkling with grated lemon rind. Strawberry Foam: Dissolve $\frac{1}{2}$ oz. sheet gelatine in 1 gill water and stir in 2 oz. sugar and 1 lb. strawberries crushed to a pulp. Add beaten whites of 3 eggs, whisk the whole until it stiffens and pile pyramid fashion on a glass dish.

SPONGE CREAM. Boil up $1\frac{1}{2}$ gills milk. Split a sponge cake shaped like a toast rack in half and put lower half into dish, cut side upwards. Soak with some of boiling milk and a little sherry, spread with glacé fruits cut into thin slices, and replace top half of cake. Soak this with remainder of milk and more sherry, and cover top with whole glacé fruits. Make some vanilla-flavoured custard, and when cool pour round sponge cake, without covering fruit decoration. Leave until quite cold. Whisk a gill of sweetened and vanilla-flavoured cream until it thickens, and then shake on to the custard.

SPONGE BASKET. Prepare some sponge cake mixture. Bake in a deep greased sandwich tin lined with greased paper that reaches 2 in. above top of tin. When cold, cut into rounds about 2 in. diameter. With smaller cutter mark out circle in centre of each and cut out to about half-way through cake. Warm a little red, stone-less jam, rub through a sieve, and brush it over sides and top outside rim. Then coat with chopped nuts or desiccated coconut and fill hole in centre with jam. Cut some long, thin strips of angelica to form the handles.

SEWING MACHINES AND THEIR CARE

How the Busy Housewife can Save Time and Money

In connexion with this article that on Oiling should be read. See also entries on various needlework processes, e.g. Dressmaking; Seam.

The earliest type of sewing machine, still used for children's machines, is that known as the chain-stitch, which uses only one thread. The machine in general use is the lock-stitch. In this there are two threads, one attached to the needle and the other to a spool enclosed in a shuttle. The needle carries the thread through the material, and, in rising, causes the thread to form a loop. The shuttle passes through the loop, which, in its passage to the top of the material, carries with it the thread from the shuttle. The tension caused by the thread attached to the needle forming the next stitch pulls up the lower thread tight (Fig. 1, A).

Sewing Machine. Fig. 1. A, stitch correctly made. B and C, stitches which result from faulty tension.

There are two methods of moving the shuttle in general use, one being known as the reciprocating and the other as the oscillating shuttle. The former will be found on some of the older machines, and it is therefore briefly described here. In the reciprocating shuttle machine there are two shafts to convert the rotary motion from the wheel. One

runs horizontally into the interior of the arm at the top of the machine, carrying at one end the heavy balance wheel, and at the other end the disk and roller for imparting the upward and downward motion to the needle-bar, together with a bevel gear wheel. The other spindle is vertical, with a similar bevel gear wheel at the top and the cam at the bottom for operating the feed lever and a balanced crank, this giving the reciprocating movement to the shuttle carrier, by means of a straight connecting rod.

The shuttle movement is at right angles to the direction of the sewing, and the shuttle slides in a shallow recess. The whole of the movement is directed towards obtaining an exactly corresponding movement of the needle and the shuttle, and the operation of adjusting these two disconnected parts is called timing. The timing is effected by adjusting the two bevel gear wheels, so that when the needle-bar is at the bottom of its stroke the shuttle must be in such a position that it can pass through the loop formed by the thread directly the needle commences its upward stroke.

The action of the lock-stitch is assured by this adjustment, but there are other points to be considered in order to obtain a good stitch. It is necessary to have the thread in the shuttle correctly threaded and at a suitable tension, and the thread in the needle adjusted in connexion with the take-up lever, so that when the needle-bar descends it carries the lever with its attached thread and then allows it to spring upward with the ascending stroke to gather the surplus thread used to form the loop and not required for the stitch.

Leading Types. A vibrating shuttle machine is illustrated in Figs. 2, 3 and 4. In this the top spindle is formed with a crank which produces a swerving movement in the vertical lever A. This lever is connected at B to an arm C attached to the crank D of the shuttle carrier E. The feed movement is

obtained through the cam at F (Fig. 2). which is attached to a crank at G (Fig. 4), operating the bar H, and imparting a back ward and forward movement.

The needle-bar movement is shown at Fig. 3. The presser foot, indicated at P, presses the work down on the feed and also prevents the work being pulled up with the ascent of the needle. The pressure produced by the spring can be regulated by a screw at the top of the bar. It is lifted up by a lever at O working on the principle of an eccentric.

The internal mechanism is the same for both hand and stand machines, the only difference being in the method of turning the balance wheel. In the hand machine a gear case is attached to the framework of the machine, and contains a large-toothed wheel provided with a handle which engages with a small-toothed wheel. The latter is connected with a movable arm, which can be attached to the balance wheel and easily removed to place the handle out of action. The stand machine has a driving wheel of large diameter, turned by a connecting rod attached to a treadle. A belt from the driving wheel transmits the power to the pulley, which forms part of the top balance wheel.

There is a type of machine in extensive use in which an oscillating hook-shaped shuttle carries the lower thread in a circular bobbin. This shuttle may work in a horizontal plane, or in a vertical one. There are several other kinds of sewing machine in use, as, for example, those having a circular container for the lower thread in the form of a rotary hook. Instead of moving backward and forward, the hook continues to revolve, and it is so arranged that when the needle is at the bottom of its stroke the point of the hook is a little behind it and carries the thread with it to form the lock of the stitch.

One of the best methods of operating a sewing machine is by means of an electric motor. This is attached to the back of the table. In some cases the motor is started and the speed regulated by means of a treadle or foot controller; in others a switch-lever is fitted on the table by the side of the driving-wheel and acts as a starter, regulator, brake and stop.

Care of the Machine. The machine which is regularly used and frequently oiled will not, as a rule, go wrong; it is irregular use and improper oiling that usually cause trouble. There are certain oiling points in every machine in which the spout of the oilcan should be placed, but from time to time the underneath mechanism and that portion covered by the frame should be attended to. The main causes of stiffness in running are clogged or gummed up oil and dust, small particles of fibre and grit. A machine that is in regular use is subject to trouble caused by dust and fibre, and it is necessary to examine the unexposed parts and clean them up occasionally. Only the finest mineral oil should be purchased and a very small quantity used at a time, all the oil holes being noted so that the oiling is thorough.

It is in the shuttle race that dust is likely to congregate, and this portion of the mechanism must be kept quite clean; it can be wiped over with a soft rag soaked in paraffin, the connecting bars and other parts being wiped over at the same time. If the machine has been neglected and the oil has gummed up, it will be necessary to use a stiff brush with plenty of paraffin, which should be wiped off before the new oil is applied.

The regulation of the tension should be carefully attended to, for the success of the stitching mainly depends on it. Referring again to Fig. 1, the correct stitch is shown at A; but if the tension is not enough, the thread from the needle will not do more than hold the thread from the shuttle loosely. If the tension is too tight, the shuttle may find a difficulty in passing through the loop, which is also liable to break, and, in addition, the shuttle thread, when it is pulled up, will be drawn through the material. The tension plates are fitted with a spring and an adjusting screw, so that different tensions can be given to the thread when sewing different materials. When the machine makes a good stitch

with both the upper and lower tensions fairly slack, there is nothing wrong with the other adjustments.

Using the Machine. Faults in sewing are more generally the result of careless use than of defective mechanism. A bent or imperfect needle, which is a frequent cause of missed stitches, may be due to the needle not being set straight in the needle-bar, or the needle-bar being bent. Other reasons may be that the needle is incorrectly set or unsuitable for the size of the cotton. The take-up spring may be set too long, or the hole in the needle-plate too large. All these faults can be adjusted, with the exception of the latter, when a new plate should be fitted.

Special care should be given to the choice of the needle; makers usually give a table showing the size required for various thicknesses of cotton.

The correct position is generally marked by a fine cut on the needle-bar, and when the eye of the needle is centred on the needle-plate the mark on the bar should coincide with one on the frame. The easiest way of centring the needle is to place an ordinary needle flat on the needle-plate and run the point of it into the eye of the machine needle, and let it remain until the screw is tightened up on the bar. The alinement of the needle should be frequently noted, as the careless handling of the material before the needle is entirely raised will often cause a bend, and if this is allowed to remain it may not only cause missed stitches, but also damage the needle hole or the shuttle.

As a rule, the hand machine is easily worked, but the treadle machine is found difficult at first. In order to become well accustomed to the movement of the treadle, the balance or hand wheel should be loosened by raising the small catch so that it will turn without moving the other parts of the machine. The presser-foot should be raised, both feet placed on the treadle, and the balance or handwheel revolved towards the machinist, never in the opposite direction. The feet are so placed that the toes and heels can be used with equal power, and have so much control over the treadle that the fly-wheel can be used slowly or quickly.

Sewing Machine. Fig. 2. Interior view of vibrating shuttle machine, showing cranked spindle which produces a swerving movement in the vertical arm.

Fig. 3. End view of the same machine, showing needle and presser bar, and also oiling points. See text for lettering.

Fig. 4. Underneath view of vibrating shuttle machine, showing the positions of the various parts and oiling points.

Practice should next be gained in guiding the material. For this the needle is raised, some material placed under it, and the presser-bar let down. The shuttle should not be used, and there should be no thread in the needle. The handwheel should

be turned forward and the material guided as the feed carries it along. The presser-bar should be lifted to turn the material which on no account must be pulled, as this action will bend and perhaps break the needle: and on no account should the machine be worked unless there is some material between the foot of the presser-bar and the feed.

The action of the stitch regulator should be tested, and in those machines fitted with a reversible feed this should be noted and its action practised.

The method of winding the cotton on the bobbin is more or less automatic, but if the winding is not perfectly even the adjustments should be noted and, if out of order, put right. The shuttle should be fitted with a bobbin, and correctly threaded so that the cotton runs out freely. The needle is threaded and the tension tested, and then the actual sewing commences.

In all modern machines there are a number of attachments for use in various kinds of work. These include, amongst others, a straight guide which serves to direct the material in a straight line, and which can be adjusted in various distances from the stitch-hole. The quilter guide is used for quilting padded materials in straight lines and squares. It is attached to the presser-bar and is easily adjusted. An automatic method of hemming can be arranged by the use of the hemmer, an attachment fitted to the presser-bar in place of the ordinary foot. The corder is a similar attachment, having a groove underneath to allow the cord to pass directly under the needle. The gatherer is a useful attachment adjusted by the length of stitch. It allows the lower of two pieces of material to be pleated or frilled, while the upper is straight and firmly stitched.

SHAD: The Fish. The several salt water fish of the herring tribe known as shad may be cooked in various ways, but perhaps the best methods are to broil it, or else to stew it in white wine, as in France.

To broil shad, scale, clean, and wash the fish, which should weigh from 2 lb. to 2½ lb., then cut off the head and score each side. Put it into a dish and sprinkle with salt and pepper, then pour over it enough oil to steep it and let it soak all night. The next day broil the fish very gently for about $\frac{3}{4}$ hour, turning it over during the operation. It is important to score it before putting it to soak, so that the seasoning may work into the flesh. Cook it each side about 20 to 35 min. Dish it very hot, and serve it with maître d'hôtel sauce.

To stew shad, scale and cleanse the fish and dry thoroughly, then bind it together with tape to prevent it opening where it has been gutted. Put it into an oval stewpan with 3 shallots, a clove of garlic, 1 blade of mace, 15 black peppercorns, a bouquet garni and salt to taste. Cover the fish with $\frac{1}{2}$ pint white stock and $\frac{1}{2}$ pint white wine. Stew gently for 35 min., basting the fish occasionally, then dish it up and remove the tape. Strain off the liquor and add $\frac{1}{2}$ pint of it to the same quantity of béchamel sauce. Mix well over the fire and pour over the fish.

It is better to fillet the shad if it is to be fried. Dip each fillet into well-seasoned flour and fry gently in boiling fat. Garnish with fried parsley. The roe of the fish may be separated from it, floured and fried at the same time as the fillets, and served with the fish. *See Sauce.*

Shaddock. This is an alternative name for grape fruit (q.v.).

SHADE: For the Eye. These shades may be classified under two headings. One type, generally for one eye only, is for holding in place boracic wool or other dressing which may be necessary. These shades are usually made of celluloid, being flesh colour on the outside and green on the inside, and are held in place by an elastic band which slips around the head.

A reading shade for both eyes is made from stiffened cloth or card with a brass wire, which fits around the outer edge of shade and above the ears. It is used for keeping oblique light off the eyes, and in cases of inflammation to protect them from bright light. *See Eye.*

SHAGREEN. The fine grained parchment made from the skin of the shark is termed shagreen. It was formerly used for the cases made to hold tea caddies and similar articles. The word is also used for untanned leather with an artificially grained surface, usually dyed pale green, with which various fancy leather goods are covered.

SHALLOT. The shallot is a very useful and easily grown vegetable of the onion family. The bulbs may be set during winter or early spring at about 6 in. apart in rows 10-12 in. from each other. Deeply dug and manured soil is necessary to ensure good results. Late in July, when the leaves have turned yellow, the bulbs should be lifted, cleaned and stored for use. Old professional gardeners advise planting the bulbs on the shortest day and lifting them on the longest day. If large bulbs are wanted the giant or Russian shallot should be grown. Shallots are excellent for pickling.

Shallot, an easily grown vegetable of the onion family which is largely used for pickling.

Use in Cookery. Shallots are used in cookery for flavouring purposes, and also for pickling. They resemble garlic, but are milder, and are often used as a substitute for the latter when a strong flavour of onion is objected to. To store shallots, hang them up in strings, but do not keep them in the pantry. *See Garlic; Onion; Pickle.*

SHAMPOO: For the Hair. Shampoo can be bought in liquid, powder or even cream form. Powder shampoo is the most commonly used, and different kinds can be bought for different kinds of hair. Rinses can also be bought cheaply, but the following recipes may be used, if preferred:

For white hair, a rinse of one part ordinary washing blue to four parts water. For golden hair, put Camomile flowers in a muslin bag and pour on boiling water. Rinse the hair with this infusion when the lather has been removed. Medicated and brightening shampoo preparations should be allowed to remain on the hair in lather long enough for the chemical ingredients to operate, 5 to 10 minutes being the usual time.

Coconut oil is the basis of various oil shampoos which produce a good lather.

Dry shampoos, though injurious to the hair if used too frequently, have advantages that give them a ready sale. They can be safely used by people suffering from colds, and their action is so rapid that they make excellent emergency shampoos. The powder should be applied to the hair with a pad of cottonwool, and removed later with a stiff brush. If the subsequent brushing is sufficiently thorough to remove all traces of powder, ill effects rarely follow.

Children's hair needs washing oftener than that of adults. Soap containing a little formalin makes a good cleansing shampoo, but the following recipe may be used: 1 oz. shredded soap, $\frac{1}{4}$ oz. carbonate of soda, 1 teaspoonful borax.

Dissolve the soap in a pint of boiling water, then add the other ingredients. Use as much as is required, preferably warm. *See* Egg Shampoo: Hair; Henna.

SHAMROCK. The name is vaguely applied to all sorts of trefoils and clovers. The true shamrock is either the white-flowered clover, *Trifolium repens*, or the yellow-flowered suckling clover, *Trifolium minus*.

SHANDYGAFF. This consists of a mixture of bitter ale and ginger beer, half and half; "rich man's shandygaff" is a mixture of champagne and ale, served usually in a pewter tankard and regarded as a great restorative.

SHANTUNG: The Silk. The crisp, hard-wearing, pale fawn coloured silk stuffs known as shantung are made by hand from the cocoons of the uncultivated silkworm. The threads are somewhat irregular, thick threads here and there not being regarded as blemishes. This material dyes well and is much employed in printed designs for dressing wraps.

Plain shantungs in natural or dyed shades wash and wear well. They are therefore suitable for children's clothes. Shantung should be ironed while it is dry or it will lose its gloss.

SHAVING. The requisites for shaving are a razor, a brush, some soap, and some water. Most men use a razor of the safety type and a special brush. Ordinary soap can be used, but shaving soap is much better, as it makes lathering easier. It may be in stick form, in a powder or a paste.

Hot water is best for lathering the face, as it expands the skin and helps the lathering properties of the soap. Thoroughly moisten the brush and rub lightly on the soap, then commence to work up the lather by a circular movement. If a soap powder is used, sprinkle a little on the wet brush. If a paste is used, it is best to smear a little on the chin before applying the hot lather brush. A very stiff and stubborn beard requires longer lathering than when the growth to be removed is only moderate. Stiff beards shave more easily with a moist rather than with a thick lather.

Shaving Soap. Soap employed for shaving generally contains an emollient such as lanolin or spermaceti, which has a softening effect on the skin. The chief object of a shaving soap is to provide a good lather, and also to soften the skin and so facilitate the work of the razor. *See* Chest of Drawers; Razor.

SHAWL. Shawls may be divided into four classes: the knitted or crocheted, the woven woollen, the woven silk, and the lace variety. Those in the first class are mainly utilitarian. Good patterns for knitted or crocheted shawls with full instructions can be obtained from wool shops and fancywork departments in stores.

Three oz. of white Shetland wool, $\frac{1}{2}$ oz. of pink or blue wool of a similar thickness, and a medium-sized bone crochet-hook are needed to make the baby's head shawl shown in our illustration. Commence with the white wool in the centre of the shawl by making 8 chain and joining to form a

ring. For the first round work 3 chain to form the first treble, 23 treble into the ring, and join with a slipstitch to the 3 chain at the beginning of the round. The second round consists of 3 chain to stand for a treble, 1 more treble into the same place, 2 chain, 2 more treble into the same place, * miss 2 treble of the previous row, 2 treble into the next, 2 chain, 2 more treble into the same place, miss 2 treble of the previous row, 2 treble into the next, 2 chain, 2 more treble into the same place, 2 chain, 2 more treble into the same place; repeat from * all round and join with a slipstitch.

The third round is worked thus: Slipstitch into the space between the treble of the previous row, * 3 chain to stand for treble, 1 more treble into the same place, 2 chain, 2 more treble, 2 chain, 2 more treble, and into the next space between the treble of the previous row work 2 treble, 2 chain, 2 treble all into the same place. Into the next space between the treble work 2 treble, 2 chain, 2 treble, all into the same space, and repeat from * all round, joining with a slipstitch. Continue in this manner, always making one extra pattern between each corner pattern, until the shawl is the right size.

Begin the edging by working 7 treble into each space between the treble of the previous row. Then between each pattern work one double chain; then another 7 treble into the next space between the treble of the previous row. With the coloured wool work all round the edge of the treble in double chain and the shawl is done.

Shawl. Baby's head shawl knitted in Shetland wool.

Woven Shawls. Many of the woven woollen shawls are also merely useful, being made in quiet colours with border of deeper tone and plain fringe, or in checks and tartans; but there are, in addition, hand-woven shawls which are carried out in brightly contrasted stripes or with floral borders, while gaily embroidered woollen varieties are often picked up as souvenirs when abroad, and can be utilized in a number of ways.

The finest woven all-over patterned or embroidered shawls come from Kashmir, and are made of the soft under wool of the special shawl goat. These shawls are highly valuable possessions when made at the best period. Similar shawls of inferior quality were made in India and have been imitated in France, and the Paisley shawl was modelled on them.

Shawls of several different patterns, chiefly oriental, are made in Paisley. The best known design is the pine or cone, woven generally on a red ground, with yellow, blue, green and other threads. A black centre is a characteristic of some of these shawls.

The richness, harmony and brilliance of the colours are as remarkable as the permanence which leaves shawls 100 years old as beautiful as ever. Their soft wool is attractive to moths, and they should be protected by wrapping in newspaper in storage. They can be washed and cleaned, but it is advisable to keep them out of the way of dirt.

To the woven silk class belong the most beautiful of all shawls: Chinese varieties, hand embroidered on heavy crepe, some in self colour, others with flowers and birds in many brilliant hues on a black or coloured ground, fringed with knotted silk. Less expensive are plain silk and crêpe-de-Chine shawls, relying on beauty of colour and fringe for their decorative value. Such shawls can be made with four squares of crêpe-de-Chine, each a yard square, joined together with faggot-stitching, a hand-made tasselled fringe in self-coloured silk trimming the edge. Other evening shawls are of tinselled brocades with woven coloured borders.

Lace shawls are usually Spanish lace, black or white silk blonde, or Limerick needle-run or appliqué, and though more often square, are occasionally triangular in shape. There are also the Egyptian shawls of tinselled net and the silk embroidered net Rumanian shawls.

SHEARER: The Style. The work of Thomas Shearer as a designer is largely associated with that of Hepplewhite. In general it was in the direction of simplicity, and a reaction from the more ornate designs of Chippendale. The two assisted in bringing about a revival in the use of turning, and are considered to have done more than any other designers to develop bedroom furniture.

Some of Shearer's pieces, notably his tables, of which new types were introduced under his influence, possess considerable distinction. Mention may also be made of his tea caddies. Square, oblong, or round in plan, these were delicately inlaid or painted with fans, ovals, or circles upon their tops.

Shears. Fig. 1. How a pair of garden shears should be used for small patches of grass. Fig. 2.

Using small shears to clip the edge of a curved border.

SHEARS: For the Garden. An ordinary pattern of garden shears is illustrated in Fig. 1, which is typical of a variety of similar implements ranging in size of blade from 4½ to 10 in. long. A convenient size for ordinary use has blades 7 to 8 in. long. The handles, which are usually longer than the blades, are made of hardwood and very securely fixed to the tangs or ends of the blades.

As a good cutting action depends upon the correct manner in which the two cutting edges close over one another, it is imperative

that the joint shall be a close one, and keep the faces of the blades in contact with each other during the cut. In the better patterns contact is effected by tightening up the pivot pin, which takes the form of a bolt with a fly nut and spring washer. This may be correctly adjusted by tightening the nut as occasion requires. The joints should be lubricated with ordinary light machine oil.

To clean the blades, the nut is unscrewed, the spring washer removed, and the two parts of the shears separated any dirt which prevents the blades working freely being cleaned away with a greasy rag or with one saturated in paraffin. This cleaning process should be followed by a liberal application of lubricating oil, and, if necessary, the cutting edges should be sharpened on an oilstone and the shears reassembled. The cutting edge forms an angle with the flat or under side. This angle must be maintained, and on no account should the flat side be touched with the stone.

Different types of shears are made with straight handles or with a cranked handle. The object of the latter is to enable the shears to be operated over a flat grass lawn without the necessity of knocking the knuckles on the ground, the crank enabling the blades to be kept parallel with the ground and to cut over the whole length of the blade. Either type of shears may be used for grass cutting or for trimming privet, yew, and similar hedges.

Shears are invaluable for working round odd corners and places where it is not possible to use the lawn mower. They are employed also for trimming the edges of lawns, and to keep the grass edge straight; it is as well to stretch a garden line along the edge of the bed or path, and to cut the grass accordingly.

For cutting round curved borders and in awkward corners, the grass shears illustrated in Fig. 2 are useful. These are formed of a single piece of metal, the two ends forming the blades, with a U, or bend: more or less circular in shape, acting as a spring. This implement is operated with one hand by squeezing the blades together and then releasing them.

When any considerable length of grass edging or border is to be trimmed, it is desirable to use a regulation pair of edging shears. So far as the blades are concerned, these are shaped like and operate upon the same principle as ordinary garden shears, but the shanks of the blades are turned up nearly at right angles and in the same plane as the blades. They are provided with hardwood handles, about 3 ft. in length or more; they should be of such a height that they can easily be operated by the hands while the gardener carries on his work in an upright position.

There is a certain knack in handling these shears which can only be acquired by experience, but, in general, the left hand should grasp the handle that is attached to the bottom one of the pair of blades. Consequently, this handle should be kept more or less stationary, so that the bottom blade glides along the ground, while the right hand manipulates the other handle.

Shears of all kinds should be smeared with petroleum jelly when putting them away, as this will prevent rusting and keep the edge in good condition. *See Osier.*

Shed. Fig. 1. Diagram showing a substantial lean-to workshop, built in the angle formed by two walls.

Full particulars of construction, together with the quantities and material required, are given in the next page.

SHED. A light structure, generally made of wood, the shed is seen in many shapes and sizes. Its main use is for the storage of materials and tools, but it is also used for potting plants or for a smaller amateur workshop. Particulars of a larger and more substantial structure to house a motor cycle combination will be found in the article on Garage (q.v.). An excellent shed may be constructed along the lines indicated for a garage, varying the doors and lighting to suit individual needs.

Lean-to Building. A shed or outhouse intended as a permanent erection may quite conveniently take the form of a lean-to built into the angle formed by two walls, as shown in Fig. 1. The shed is 10 ft. long by 8 ft. wide, and the height to the eaves is 7 ft. The following material is required:

150 ft. run 2 in. sq. deal.
 56 ft. run, 3 in. by 2 in. deal, for framework.
 1 ledged and braced door. 6 ft. 6 in. by 3 ft. 6 in. wide.
 1 pair 18-in. cross garnets, lock and key.
 80 sq. ft. 1 in. tongued and grooved flooring.
 9 8-ft. lengths of 3 in. by 2 in. for floor joists.
 5 windows (casements) glazed, with butts, handles and casement stays.
 1 10-ft. length batten, 2 in. by $\frac{3}{4}$ in. for the flashing.
 5 sheets of corrugated galvanized iron, 9 ft. by 2 ft. 2 in.
 1 roll of roofing felt.
 15 yd. of 2-in. galvanized wire netting, 2 ft. wide, or alternatively 1 square (100 sq. ft.) $\frac{3}{4}$ -in. T. G. and B. match lining.
 86 sq. ft. 1-in. rebated weatherboard for the walls.
 70 ft., 1 in. by $\frac{1}{4}$ in. architrave for door and windows.
 7 lb. paint.
 1 gall. creosote.
 Nails and screws.

No allowance has been made for a foundation, as it is presumed the yard has already been cemented over or paved. If not, this will have to be done, either with cement, concrete or asphalt. In either case the framework and joists should rest upon bricks, placed about 1 ft. apart, so as to allow free circulation of air and prevent damp rising. The ground being prepared, proceed by making up the front of the building in one section. Then make the end section. Fig. 1 shows the general idea of the work, while details of the different joints are given in a separate diagram (Fig. 2).

Shed. Fig. 2. Principal joints used in building the lean-to shown in the previous page. A, mortise and tenon. B, halved joint and how it fits together. C, mortise and tenon for top and bottom of uprights.

Having made the two frames, erect them on their site and bolt the corners together with 5 in. by $\frac{5}{16}$ in.- coach bolts and nuts. Secure the framework to the wall of the house with staples and screws. The weather boarding can then be added, nailing it to each upright with 2 in. wire nails. The windows can either be made or purchased ready for use. Horticultural or "greenhouse" glass will be quite good enough for the glazing. The roof is most conveniently covered with corrugated iron, but

it should be lined inside with tarred felt supported on galvanized wire netting or, alternatively, may be boarded with match-lining.

Shed. Fig. 3. Exterior view of a sectional span roof workshop or tool shed. Fig 4. The same partly erected, showing method of assembling the sections. Fig. 5. Useful lean-to shed made up on the same principle. (Courtesy of Alfred Turrell & Sons)

When walls and roof are complete, lay the floor joists, and securely nail the flooring with 2 in. floor brads. The joists and the underside of the flooring should be coated with creosote as a preservative. A strong and rigid floor is very necessary, especially beneath the legs of the work bench and any other heavy tools. A gutter and drain-pipe may be added if desired. Make a good watertight connexion between the corrugated iron and the walls, by

means of proper flashings fitted as indicated in Fig. 1. A lean-to built in this way might become a landlord's fixture, but if a framework is made for the end and back of the structure where they abut on the existing brick wall, and the roof is supported at its juncture with the walls by battens screwed to blocks let into the brickwork, the fixture will be a tenant's fixture, and therefore will be removable.

Sectional Building. We illustrate representative types of shed which are sold made up in sections ready for erecting. The ends and sides are bolted together and the roof frames are fixed on top. There is a great deal of competition in this class of product, and some very cheap stuff is to be met with. It is least expensive in the long run to buy a good substantial building, since the first cost is then the only one, for some years at least. If the covering material is weatherboard, then the purchaser should specify that it be either the rebated or the tongued, grooved and moulded variety ($\frac{3}{4}$ in. to 1 in.), which presents a flat surface to the interior. If vertical boarding is employed the material should be T. G. and B. matchboard, not less than $\frac{5}{8}$ in. and preferably thicker. Unless a bricked or concreted site has been prepared, a flooring will be needed, laid on 3 in. by 2 in. joists,

which in turn rest on sleeper plates supported preferably by low brick piers. The floor boards should be $\frac{3}{4}$ in. to 1 in. thick, and should be tongued and grooved.

Legal Points. If a tenant erects a shed on his premises for temporary use during his occupation he will ordinarily be able to remove it at the end of his tenancy. If, however, the shed is in the nature of a permanent structure and cannot be removed without material injury to the property, the tenant must leave it as the landlord's property. Thus a conservatory entirely detached from the house could probably be removed, but one fixed to and communicating with the rooms would belong to the landlord and be irremovable.

The erection of some sheds is controlled by regulations as to the position of the structure and the materials of which it may be built, and inquiry as to these should be made of the local authority.

Where premises are insured against fire, a shed added later will not be covered by the policy unless an arrangement to that effect is made and an additional premium paid if required. The presence of a wooden shed near to a house may increase the premium on the house itself. If the shed is of any particular value, or if it adds to the value of the house (as would probably be the case if a garage were erected), the rates on the house will probably be increased.

SHEEP. The main article of food that is obtained from the sheep is known as mutton, but other parts of the animal make nourishing and economical dishes.

Sheep's Head. To make a good broth procure a sheep's head ready dressed from the butcher. It must be soaked in warm water for an hour to finish the cleansing. The head should be split open and the tongue and brains removed. Place the two halves of the head in a large saucepan with 3 qt. cold water, bring to the boil and carefully remove all scum. Add $\frac{1}{2}$ oz. salt, 2 onions, 2 carrots, 2 turnips, $\frac{1}{2}$ a head of celery, and a bouquet garni. Simmer gently for 3 hours, then take up the head, cut off the flesh and shape in neat pieces. Strain the broth, return it to the saucepan with the pieces of meat, add a few freshly boiled vegetables cut in shreds, and 3 oz. well-washed rice. Simmer it for half an hour and pour into a tureen in which two tablespoonfuls of chopped parsley have been scattered.

The tongue and brains may be used for some other dish as a garnish, or they may be cooked and served covered with tomato or piquant sauce. Two ounces of pearl barley make a very good thickening for this broth in place of rice. Blanch the barley for 10 min., then tie it loosely in a muslin bag and add it to the soup with the vegetables. When the soup is strained, untie the bag, and stir the barley into it. Sometimes the vegetables first added to flavour the soup are cut small and served with it; if this is done the soup need not be strained, and the barley, after being blanched, may be added loose when the soup is half cooked. The meat from a boiled sheep's head may be pressed into a mould and filled up with jellied stock. Cover and press with a weight and turn out when cold.

Sheep's Heart. A sheep's heart is first washed in two or three successive lots of warm water, freed from pipes, etc., and then soaked for $\frac{1}{2}$ hour in cold, salted water. Dry it in a clean cloth, stuff it with sage and onion stuffing, and sew up the hole. Roast it in an iron pan in which a lump of dripping about twice the size of a hen's egg has been melted. Let the pan stand at the side of the fire, and baste the heart frequently with the fat. The cooking should take about 1 hour. Serve the heart with red currant jelly and some sauce made by thickening some of the fat with a little flour, mixing them smoothly, and adding some stock.

Sheep's Tongue. This dish may be prepared in several ways. Frying is perhaps the simplest, and may be done in the following way: Soak 2 tongues in cold salted water for 3 hours, then wash them

in clean water and put them into a pan containing enough stock to cover them. Cook them very slowly until they are tender; then skin and trim them and slice each lengthways into halves. Season the pieces to taste, coat them with flour, then brush them over with egg and roll them in fine breadcrumbs.

Fry them in a pan of smoking hot fat, and when they are golden brown on both sides lift them out and serve on a bed of mashed potatoes. A little gravy may be poured round them.

Sheep's Trotter. To fry, prepare 4 trotters by washing and scraping them, boil them up in a pan containing just enough cold water to cover them, and then strain off the water and rinse the pan. Wash the trotters for the second time, and put them back in the pan with enough white stock to cover them.

Cook them gently at the side of the fire until they are tender, then take them out and bone them, finally pressing them between two plates with a weight on top. When they are quite cold cut them into pieces of a convenient size, season to taste, brush them over with egg, and coat with breadcrumbs. Fry them in a pan of smoking hot fat, and serve garnished with parsley and cut lemon. Any suitable sauce may be served separately.

For baking prepare the trotters as directed in the previous recipe, cooking them in stock until they are tender, and then cutting the meat into neat pieces. Put some of the latter into the bottom of a greased dish, cover them with some sliced tomato and seasoning to taste, and on the top put a layer of fine breadcrumbs. Continue in this way until the dish is full, and on top of the last layer, which should be of breadcrumbs, place a few small pieces of butter. Pour in about $\frac{1}{2}$ gill stock, and bake the whole in a warm oven until it is of a golden brown colour. *See Brains; Brawn; Mutton.*

SHEEPDOG. The old English sheepdog is a most attractive animal. His shaggy coat, in which there is no curl, coupled with a closely docked tail, gives him a quaint appearance, and at the same time affords ample protection against the worst of weathers. If he is groomed every day there is no reason why the coat should become matted or untidy. The colour may be any shade of grey, grizzle, blue or blue merled, with or without white markings. What is termed a pigeon-blue is much esteemed. The forelegs should be heavily boned and dead straight, and, as they are clothed with hair to the feet, they look enormous. *See Dog; Kennel; Lurcher.*

Sheepdog. Thoroughbred specimen of the attractive breed known as the old English sheepdog.

Sheep Laurel. *See Kalmia.*

SHEEPSKIN. Sheepskin is used a great deal for bookbinding, but its wearing qualities are not of the best, and its use is confined to the cheaper class of work. It is more suitable for ladies' handbags or hats, or such goods as are not glued or pasted on to a hard substance.

In covering books or other articles with sheepskin, care must be taken to preserve the artificial grain. Glue is generally used in preference to paste for this purpose. This applies more to split skins than to those of full thickness. To prepare the leather for gold tooling or lettering, it should be washed with paste water, which is thin paste about the consistency of milk, and afterwards with two coats of glair (white of egg), or, better still, with glue water and one coat of glair. *See Bookbinding; Leather.*

SHEET. There are two standard sizes of sheets, namely, for double beds and single beds. In cheaper makes single sheets are sometimes too small for comfortable use on a bed 3-ft. wide and of full length. All sheets are usually bought in pairs, and the length should be judged by the length of the bed, allowing for a good turn over at each end.

Materials vary according to the taste and means of the purchaser. A heavy linen sheet wears better than any other, and is preferred by most people, especially in the summer. As linen is colder than cotton because of its smooth surface, some people prefer not to use it in the winter. The cotton materials range from coarse twill to a smooth and strong union. A good union, while not as expensive as real linen, is satisfactory in wear, and feels pleasant to the skin. Sheets may be quite plain, embroidered at the tops, ornamented with hemstitching, or with wide crochet edging.

An embroidered initial in the right-hand top corner is almost essential to the housewife who prides herself on her house-linen. If the name is marked in ink, it should be at the extreme end of the top hem, and so arranged that when the sheet is turned down the name is hidden underneath. The initial, on the contrary should be arranged so that it is plainly visible. Some people like an elaborately embroidered monogram in the very centre of the top, this serving instead of other embroidery.

Sheets should be aired when they come back from the laundry. If the house has a good hot cupboard, it will be enough to put them away in their places, and when they are used again they will be sufficiently aired. *See* Initial; Linen; Marking; Mending; Pillow Case.

SHEFFIELD PLATE FOR THE COLLECTOR

With Particulars About its Marks and Decorations

Various articles in this Encyclopedia deal with the collection of articles for beautifying the home, the aim of each being to indicate what is possible to the average householder. Such include Brass; Pewter; Silver. *See* also Candelabrum; Gadroon; Jug; Taperholder; Wine Cooler, etc.

Much of the plated Sheffield ware of to-day is really B.M., i.e. Britannia metal, an alloy which was instrumental in killing the pewter trade, as the various articles made in it could be covered over with a deposit of silver. Much, too, is E.P.N.S., i.e. electro-plated on nickel silver, a useful combination of decorative silver with a hard-wearing metal, the silver being deposited by the aid of electricity.

The credit for discovering a method of thinly coating a base metal with silver is due to Thomas Bolsover, or Boulsover, presumably but not certainly a native of Sheffield; but the practical developing and perfecting of the new process is due to another Sheffield man, Joseph Hancock, a cutler, who died in 1791. Sheffield plate of value to collectors was made during the latter half of the 18th and the early half of the 19th century.

The manufacture of this plate consisted in the overlaying of an ingot of copper alloy with a thin sheet of silver, both absolutely, i.e. chemically, clean and level. By means of a borax flux, applied to the edges of the silver, adhesion at the edge was secured when the fusion of the silver began in the furnace. The ingot, when removed from the furnace and cleaned, was rolled out to the thickness required, or to that suggested by experience. Later the process was extended to silver-plating on both sides of the copper alloy. This necessitated much care in preparation of the ingot, as the sandwich of copper and two silver sheets required two outer protecting sheets of silver, mechanically treated to prevent adhesion to the under sheets.

The branched candlestick illustrated in Fig. 1, which dates from about 1780, shows the popular gadroon ornament. This type of added edging was either in fine silver, or else copper alloy much more thickly cased with silver than the rest of the article; and in many cases the copper shows

through the thinner plating while the ornamental borders remain unimpaired with repeated cleanings.

Sheffield Plate. Fig. 1. Branched candlestick, c. 1780, an example showing fluted decoration and gadroon edging. A holder for a third light is filled by a stopper.

The ornament on Sheffield plate will be found to be chasing of the kind known as flat surface chasing, or else what is now called repoussé work, and in some pieces both methods are combined. In flat surface chasing the design is carried out with a blunt punch, which is held vertically in one hand and hit by blows from a special hammer. Nothing is removed from the surface of the metal, as would be the case in engraving it with a burin or a scorper. In repoussé the raised portion is worked from the back. In the case of circular and oval articles, the border is made separately and secured by means of solder. An example of such a border is illustrated on the wine cooler shown in Fig. 2. Many articles are ornamented with a geometrical or strapwork pattern with the field or background punched out in a press. It was found that better results were obtained in this way than by piercing, i.e. cutting with a saw and finishing with a file, as was done by silversmiths. The sugar basket illustrated in Fig. 3 is a beautiful example of such work.

Sheffield Plate. Fig. 2. Wine cooler, c. 1780, with decorated handles and border. (All photographs by courtesy of Chapple & Mantell)

Fig. 3. Sugar basket dated 1784, ornamented with geometrical open-work design, chasing and beaded edges.

The marks on Sheffield plate are many in number considering the short period, just over a century, during which the ware was being made. They generally consist of the maker's name and sometimes a device before and

after it. The Sheffield plate makers do not seem to have followed the example of the pewterers and deliberately to have used marks which were colourable imitations of the silver hall-marks. Some ware has the name of the firm only, some has a device or devices only.

As the best styles in decoration of Sheffield plate coincide with the Robert Adam period, the most desirable pieces to collect show classical influence and ornament. In addition such pieces are to be preferred because they are practical and more easily kept clean than the heavily chased and embossed style of ornament which came into fashion later in the 19th century. Utility is the best guide as to which pieces to collect. The classical vase shape with very little decoration beyond beading, is beautiful for a hot-water jug (Fig. 4), for coffee pot and milk jug. With such pieces and

two pairs of candlesticks, a plain tea caddy, a cake basket, which is equally useful for fruit, and an oval tea-tray with a pierced work rim, would make a representative and useful collection. Sheffield plate is occasionally picked up at auction sales for comparatively small prices, but is worth obtaining in good shapes with restrained ornament.

Sheffield Plate. Fig. 4. Hot-water jug of classical Adam design, c. 1784.

Inkstands are useful of the simple type with decorated edge and look particularly well flanked by candlesticks of Adam design, or in the company of a wax-jack taper holder such as that illustrated in Fig. 5, with ornamented border.

Right. Fig. 5. Wax-jack, c. 1800, with ornamental border and handles.

The best way to display Sheffield plate is to use it in the home. It must be carefully cleaned and handled, and if it should require repairs it must go to an expert. For the cleaning of Sheffield plate where the copper does not show through in places, good plate-powder is quite safe. Where the copper is exposed none of the polishes that contain oxalic acid is to be used, as the acid eats slowly into the base metal. Pieces in this state are unsuitable to hold food unless they are relined.

SHELF: How to Fix. In fitting up shelves it is generally preferable to use shelving board, which is simply good quality white or yellow deal in a prepared form. One surface is machine planed to a good finish, the edges and sides are clean and square, and the material is uniform in thickness and width.

Shelving board is obtainable in various sizes; those chiefly used by the amateur are known as 6, 7, 9, and 11 in. boards, and range from ½ in. thick up to about 1 in. These sizes are nominal, and the actual diameter will measure somewhat less than those mentioned. When planning shelves, it is well to bear this in mind, and also to make the width of the proposed shelves appropriate to the stock widths of the shelving board, as this obviates the necessity of ripping several lengths of timber and planing the edges up to obtain the requisite width, generally it is possible to provide most ordinary shelves by using a single-width board, and the most handy width for an ordinary shelf is 9 in.

When it is desired to use a width of, say, 12 to 14 in. or thereabouts, 2 ordinary, straight-edged boards can be used and the edges held together with cross battens screwed to the underside of the shelves, or the edges may be properly planed up and glued together. Another native is to use tongued and grooved floorboard. When 2 or more pieces of board are placed edge to edge, the tongue of one board fits into the groove of the next and so on. Consequently as one surface of the floorboard is prepared nicely finished up, it can conveniently be used for the wider varieties of shelves.

All that is necessary is to remove the tongue from one side by chiselling it off and, if necessary, cleaning up the edge with a small plane. If the boards are arranged so that the tongue is on the face or visible side of the shelf, there will be no need to remove the grooved portion of the board which adjoins the wall. For spans up to 3 ft. or 4 ft., tongued and grooved floorboard will answer perfectly,

if supported by battens or bearers of some kind at each end, and in cases where they are fitted against the wall or in a recess they may be supported on the inner side by a long batten or fillet secured to the wall. Shelves are preferably secured to the bearers with screws, as they can then be removed when desired without damage either to the boards or to the wall. It is necessary that they should be fixed, otherwise the joints will separate. Alternatively, the boards may be united with battens of wood screwed to the undersides of the shelves, as above described.

With regard to the thickness of material, it can be taken as a basis that the ordinary 9 in. shelving, 1 in. thick, will be satisfactory for spans up to 3 ft. or 4 ft. From 3 ft. to 2 ft. a $\frac{3}{4}$ in. shelf should be used, and for less than 2 ft., $\frac{1}{2}$ in. shelving is generally satisfactory.

The method of supporting the shelves is determined by their location. If it is practicable to fit battens or bearers to the walls, this plan is to be recommended. The battens may conveniently be secured with fibre plugs and screws. When the shelves are not near a return wall on which the ends may be carried by bearers, the best method is to fix vertical battens to the supporting wall at suitable intervals, and to carry the shelving on brackets screwed to these uprights. The shelves should be notched round the verticals to fit close to the wall.

When movable or adjustable shelving is wanted, the home worker can utilize slotted iron strips of the kind described in the article on Bookcase (q.v.). *See Dresser.*

SHELL: Collecting Specimens. Without going out of the British Isles, about 350 different kinds of shells may be found, the colour and pattern of each varying within wide limits. Every country walk or seaside ramble may therefore yield a new specimen for the collection.

The land shell which will be met with most frequently is the snail, since there are about 40 different types. They may be found all the year round, although the months from April to December yield the largest harvest. The evening, and especially the evening of a damp day, is the best hour during which to search for snails, since this is their usual feeding time. At other times search may be made under rubbish heaps, among tree roots, under fallen logs, stones, and leaves.

The snails most frequently found are the following: the common snail, with dark brown bands on an olive shell; the shrub and garden snails, which are similar, but both classes vary in colour; the girdled snail, with a yellowish-green shell not unlike the prettier and more rare green snail. In addition to these there are the pale green heath snail and the greyish bristly snail, the gored snail, found where chalk and lime abound, and the black-tipped snail, frequently mistaken for it.

As regards salt-water shells, any stretch of beach will prove a veritable treasure trove. Many of the shells will be broken, and therefore of no value, but any bunch of seaweed or small rock pool may be searched with profit. A pocket lens should be included in the shell hunter's outfit, since many shells, especially those found in sea-water, are extremely small, and only a lens can decide the difference between two shells which may look alike to the naked eye. If the shell is boiled in order to clean it, the inmate will be killed in the process. It may then be removed by means of a wire or pin. The boiling removes dirt, salt, etc., from the shell. Each shell should then be dried and painted over with white of egg, or a thin solution of gum arabic, before being added to the museum.

The small white cardboard boxes used by jewellers make excellent cabinets in which to store the shells, although larger boxes will be required for larger shells, such as oysters, mussels, scallops and the like. First put in a layer of cotton wool and then arrange the shell on this, using white cotton wool in the case of dark-coloured shells, and vice versa. This done, label each box with the name of the specimen and the date and place of finding. If any of the specimens cannot be identified, a visit to the nearest reference library, where the coloured plates of books on shells can be consulted, will soon solve the difficulty.

SHELLAC. Shellac is a fine resin, found in Indian trees, and is due to the action of the lac insect. The larva punctures the bark of the tree twigs, feeds on the gummy or resinous sap, and exudes a secretion which embeds the insect. The female secretes a red fluid known as lac dye.

The lac includes the twigs 2 or 3 in. long, on which it is formed in nodules, and is known as stick lac. For export to England it may take the following forms: seed lac, shellac, button lac, or garnet lac. Seed lac consists of the small lumps of natural lac broken off the twigs and washed.

Shellac is melted out of seed lac in rough bags held near a charcoal fire, the bags being wrung to squeeze out the molten resin. It is spread on cylinders, allowed to cool, and scraped off in flakes. The best quality of shellac is of a bright pale orange colour, quite transparent, and free from dirt and grit. Button lac only differs in that it is melted into larger pieces. Garnet lac is moulded into thick, flat pieces.

Shellac is soluble in methylated spirit and spirits of wine, and in this form is used as a french polish. It is also employed to make lacquers, or spirit varnishes, in various degrees of clearness. Although lacquers may be made up from the raw material, it is better to obtain prepared solutions from a reputable firm, specifying the colour or absence of tint required. *See* French Polishing; Lacquer; Polish; Resin; Varnish.

SHELLFISH. People with delicate digestions can more often eat oysters than any other kind of shellfish. If tinned shellfish are used, the contents of the tin when opened should at once be turned out into an earthenware bowl and carefully examined.

Many people suffer from a peculiar idiosyncrasy which causes the development of a digestive upset of greater or less severity after eating shellfish of any kind. With others these symptoms only develop if the shellfish have not been perfectly fresh. The symptoms in these cases resemble those of ptomaine poisoning, and the same treatment is to be carried out. *See* Crab; Fish; Lobster; Mussel; Oyster; Prawn; Ptomaine Poisoning; Shrimp; Winkle.

SHELL STITCH: In Crochet. The shell stitch forms a solid or all-over pattern in crochet work. The original stitch is a cockleshell shape, as seen in the sample illustrated, but there are many modern variations of it with spaces between the shells, and alternate rows of open stitches and solid shells. It is used where a close pattern is required.

Shell Stitch. The appearance of this crochet stitch when finished.

The number of chain stitches on the foundation row should be divisible by 3 with 2 stitches over. To work the first row, put 1 treble in the fifth chain from the hook, then 3 more trebles in the same place; * miss 2 stitches, 1 double crochet in the next stitch, miss 2 stitches, 5 trebles in the next stitch, and repeat from * to the end of the row, finishing with a shell of 5 trebles.

For the second row slip-stitch over the first 2 trebles of first shell, and work 1 double crochet into the centre treble of the same shell, putting the hook into the back loop of the stitch throughout the pattern. * 5 trebles in the next double crochet, 1 double crochet in the centre treble of the next shell and repeat from * to the end of the row, finishing with 1 double crochet in the centre of the last shell, turn with 4 chains.

For the third row put 4 trebles in the first double crochet over which the turning chains stand, then 1 double crochet in the centre of the next shell and repeat shells and double crochet alternately all along. Take note that a shell is always worked over a double crochet, and a double crochet in the middle of a shell of the previous row. Repeat the last 2 rows for the amount of pattern required if a straight piece of the same width all the way up is wanted.

Where a sloped edge to narrow the piece is desired, the decreasing is made on the shell by working 3 trebles only in the end shell, and also where the shell begins the row at the opposite side. Then, on the return row, this decreased shell is not worked into. By this method of working a gradual slope is given to the piece. *See Crochet.*

SHEPHERDS' PIE. Mash 2 lb. cooked potatoes, add to them 1 oz. melted butter, seasoning to taste, and a little milk if the mixture is too dry. Put a layer of these potatoes at the bottom of a greased pie-dish and a little round the sides, fill the dish to within an inch of the top with 1½ lb. diced cooked meat and one or two rashers of bacon also diced.

Pour over some gravy made by melting 1 oz. butter in a pan, stirring in ¾ oz. flour, and cooking the latter, together with 3 tablespoonfuls finely chopped onion, until it is lightly browned. Add ¾ pint stock, stir the gravy until it boils, then season it to taste. After pouring it over the meat, cover the pie with the remainder of the mashed potatoes, smoothing the top with a knife, brushing it over with beaten egg, and then sprinkling it with browned breadcrumbs. Bake the pie in a moderate oven until it is heated through and lightly browned on top. *See Mince.*

SHERATON: The Style. Thomas Sheraton, one of the great cabinet makers of the 18th century, made a few remarkably beautiful pieces which are to-day highly valued. He is chiefly, however famous for his designs. His book, *The Cabinet Maker's and Upholsterer's Drawing Book*, published in 1791 contains several hundred designs for furniture. His style reflects the sedate influence of Robert Adam, and was a reaction from the scroll and rococo work associated with exaggerated French styles in vogue before the Empire style and with some of the more ornate and less successful Chippendale designs. Sheraton was influenced to some extent by the new French style which developed from the Directoire into the Empire with its offshoot the English Regency style.

The *Drawing Book*, which gives a great number of his designs, reveals many instances of his skill, not only in fashioning beautiful pieces of furniture, but in introducing into them features that, without in any way marring their grace, add greatly to their accommodation and allow them to be used for more than one purpose. It gives also designs for such articles as work tables, shaving tables, fire screens, and clock cases. The library received a good deal of attention from him. Tables, suited to its special needs, and steps are shown therein as well as bookcases in considerable variety of design.

Satinwood, which came into use about this time, was greatly favoured by Sheraton. He had a special liking for the E. India variety, with its delightful figure and fine straw colour.

Harewood and amboyna were also adopted from French styles, and applied in veneers over cheaper and more easily worked woods.

According to one authority, the chief characteristics of Sheraton furniture are the use of the straight line in design and a perfect combination of proportion and constructional bulk.

Dual Purpose Pieces. Sheraton's designs have a very wide range, wider than that of any other of the great English cabinet makers. Many of his ideas find expression in space saving furniture of to-day. He was without a rival in the invention and construction of dual purpose pieces, such as a table which could be opened out to serve as a writing table and a dressing table with concealed mirrors and other features. In his day the bedroom was used to some extent for entertaining, so his folding

furniture was extremely useful, an example being a dressing table which could serve also as a card table. Beds suitable for alcoves and sofa beds were also designed by him, and the latter he developed into the sofa of the drawing room of his period with its white and gold effect. He also designed many graceful four poster and state beds.

His cabinets, which resembled bookcases, were very popular. In them the upper part formed the bookcase proper, while the lower, which projected, contained drawers. Between the upper and the lower divisions he fixed a writing table. This was covered by a sloping lid that fitted down to enlarge the surface of the table. The lid also covered sets of small drawers, between which were the divisions known as secret drawers, which are frequently seen in the bureaux of to-day.

Sheraton. Fig. 1. Mahogany bow front sideboard with inlaid satinwood lines; one cupboard contains a cellarette, the other, drawers. (Courtesy of Gill & Reigate, Ltd)

Use of Marquetry. Sheraton made excellent, because restrained, use of marquetry as a decoration. His designs for this were often scrolls of satinwood and festoons of drapery, or husks and shell ornaments with a fan pattern in the spandrils of his arches. This was usually upon a groundwork of mahogany, but if the piece itself was of satinwood the inlay would be in different coloured veneers to give a

pleasing contrast. Sometimes he introduced trophies of musical instruments, wreaths of flowers, and figures with foliated scroll extremities. Another feature was inlaid lines of veneer.

Sheraton did not himself make a great number of pieces, but many cabinet makers carried out his designs, and these laid the foundations of Sheraton furniture. In general its lines are very graceful. He favoured square, tapering legs for his pieces. The sideboards designed by him generally had serpentine or bow fronts. That illustrated in Fig. 1 is typical of the plainer type of sideboard, and is a good example of the combination of that grace and utility for which his work is noted. Secretaires veneered with satinwood are characteristic pieces.

He designed many tables after this style, including pier, card and sofa tables. The latter had sometimes only two legs spreading out into yoked feet. Other tables were in satin wood with painted tops.

Sheraton's designs for chairs were particularly graceful. The high-water mark of English chair making was reached at the close of the 18th century and his Drawing Book exercised a powerful influence on contemporary chairs. The cane backed bergère chair, illustrated in Fig. 2, is an example of the beauty of line and proportional value of his designs for this type.

Sheraton. Fig. 2. Cane-backed bergère chair with fine inlaid lines of veneer on the square tapering legs.

One point worthy of notice is that the ornamental backs of his chairs do not rise direct from the seat as they do in Chippendale's designs, but rest on a narrow plinth or rail 1 or 2 in. above the back of the seat. See *Antique Furniture; Chair; Marquetry*.

SHERBET: The Drink. This cooling, refreshing drink had its origin in the East. There are many different methods of preparing sherbet, but the most approved is a mixture of fruit juice, sugar, and water, cooled on ice. A variety of this drink is made from a bought powder, but prepared at home with fresh fruit as the main ingredient it is a far more wholesome and refreshing summer beverage.

To make this drink with strawberries, red currants, etc., allow 1 lb. fruit, 10 oz. loaf sugar, 1 tablespoonful orange-flower water, the strained juice of a lemon, and 3 pints cold water. Let the fruit soak in the water for 6 hours, then strain it through muslin into a jug or basin in which has been placed the sugar, strained juice of lemon, and the orange-flower water. Cover the vessel over and let all stand one hour, stirring occasionally till the sugar is dissolved. Ice before serving.

Sherbet may be made entirely with lemon juice. To each quart of water allow the thinly pared rinds of 4 and the strained juice of 9 lemons, also 1½ lb. loaf sugar. Put the lemon rind and sugar with 1 quart cold water into a stew pan, and bring it slowly to the boil. Then strain it into a basin and cool. Add the juice of the lemons and a little fruit essence and set it on ice before serving.

SHERRY: The Wine. Sherry is made from white grapes grown in the Jerez district in the province of Cadiz and other vineyards in the south of Spain. There are several types, ranging from the Fino, a light-coloured delicate wine of the Amoroso type, to the Oloroso, a rich, full-bodied wine. Very Old Solera and Fine Solera are commonly used as descriptive terms. These if blended wines, have no right to the title. Soleras consist entirely of natural wines and are always pale. The word Solera means foundation, and applied to the wine it means an old wine kept in casks which are never moved so long as it exists as a foundation on which younger wines are reared.

There are old golds, old browns such as the Old East India Brown, and pale straw-coloured Vino de Pasto. The name of the last, like that of Amontillado, is often taken in vain, Vino de pasto (wine for repast) is often applied in England to a superior dry sherry in Spain it may mean a very cheap wine. Good sherry has a well-developed bouquet and pale amber colour, and a fine delicate taste. It is not only the purest but also the most wholesome of wines, and can be taken by the gouty without ill effects. It has value as a restorative, and is prescribed by Spanish physicians instead of brandy. The alcoholic qualities develop considerably by keeping. Sherry will improve in the decanter, and will keep its excellence unimpaired for several days.

Dry sherry alone or with vermouth is a good appetizer, and mixed with soda water or Perrier is a refreshing summer drink. The wine is served with soup and fish, and at the end of dinner with dessert, either instead of or as well as port. *See Wine.*

SHETLAND WOOL. The strong but finely spun natural-coloured wool obtained from the sheep of the Shetland Isles is made into shawls and underwear of a lace-like texture.

A substitute for Shetland wool, sold under the same name and obtainable in a variety of colours, is now extensively used. It is considerably cheaper than real Shetland wool, and can be bought by the ounce from most wool shops.

SHIELD FERN. This is the popular name of a group of hardy evergreen ferns known botanically as aspidium or polystichum. They flourish in shady places in soil with which leaf-mould and thoroughly decayed manure are mixed. Planting may be done in autumn or spring. Propagation is by spores sown in boxes of soil in a frame in spring or by division at that season. There are numerous beautiful varieties of the hard shield fern (aculeatum) and the soft shield fern (angulare).

SHIN: Of Beef. The lower portion of the foreleg of the bullock is known as the shin.

It makes excellent soup, but is not so satisfactory as steak or some portions of gravy beef for beef tea. *See Beef; Stew.*

SHINGLE: For Roofing. As a roofing material shingles are thin strips of oak and other wood, about 12 in. by 4 in., which are used in the same way as tiles on roofs of a fairly high pitch. Although quite common in America, their use in Great Britain has been practically confined to the S.E. counties, and then for church spires and such structures as lych gates.

Oak shingles are split or rent from the block, and are thus uneven in surface. In roofing they are laid to an ordinary tile gauge, and generally fixed with copper nails to thin boarding covering the rafters. Hips and valleys are close cut and fitted with soakers, a variety of lead flashing. Hips may be close cut and mitred, or oak hip pieces may be cut out of the solid and used to course with the rest.

Shingles may be laid on laths where the roof is not open, but they should not be used to cover a roof laid with a pitch of less than 30°, as the rain is sure to work up between the courses and cause leaks. As shingles are apt to curl up under the heat of the sun they should be laid with not more than 4 in. of their 12 in. length exposed, and in this connexion it is important to lay the shingles on the right side. This is essentially a matter of direction of grain, the tendency of the wood being to curl towards the centre.

A shingled roof should be coated with a wood preservative if the separate pieces are not first dipped in creosote or some other suitable preservative; where the supply of water is dependent on that from the roof it is advisable to leave them plain. Shingles are imitated in asbestos and cement, and although more expensive they are fireproof and easily laid, and form an excellent roofing for bungalows. *See* Bungalow; House; Roof.

SHINGLES: A Skin Disease. Shingles, or herpes zoster, is an affection in which small blebs or blisters, like those of herpes, form along the course of one of the skin nerves; but while in simple herpes there is rarely more than slight tingling or burning, herpes zoster is often an extremely painful complaint. Exposure to damp and chill, and injury to a nerve or nerves: as after an accident or operation, are the chief causes.

Beyond protecting the blisters by covering with some simple dusting powder and a pad of cotton wool, little local treatment is required. The following powder may be mixed and dusted lightly on the blisters.

Zinc oxide 2 parts

Boracic acid 1 part

Starch 3parts

Where the pain is very severe, the doctor will prescribe other general sedatives over the blisters.

Ship. Model vessels are described and illustrated in this Encyclopedia under the headings boat (q.v.) and yacht (q.v.).

SHIRLEY POPPY. This favourite hardy annual blooms in summer from seeds sown out of doors in autumn or spring. It was raised from the wild field poppy by the Rev. W. Wilks, formerly vicar of Shirley. *See* Poppy.

SHOCK. After a severe injury or an operation, a condition of extreme prostration may result in which there is pallor, a sub-normal temperature, a rapid, feeble pulse, blunted mentality, and great muscular weakness. This condition is spoken of as surgical shock.

The treatment of shock consists of warmth, quiet in a darkened room to promote sleep, morphia, saline inactions into veins and into the bowels and, if possible, blood transfusion. Fluids are given by the mouth if the patient can take them, even tea and coffee being useful in this connexion.

SHODDY: The Material. Real shoddy is even better and more expensive than some kinds of new wool, and is made by pulling woven or knitted cloth to shreds and using the fibre for the same purposes as virgin wool. Inferior sorts, however, are also used. Shoddy enters largely into cheap costume cloths, boys' tweeds, etc. Shoddy is very difficult to detect with any certainty, although sometimes its presence can be inferred from the flabby feeling or dingy colour of wool cloths.

Shoe. *See* Boot.

SHOOTING BOARD. A shooting board is used by wood workers for preparing the edges of timber. It consists of a guide for the plane and a stop, or support, to rest against the work that is being prepared. An example of a shooting board is given in Fig. 1. The base consists of an ordinary piece of board 9 in. wide and about an inch thick. To the outer surface of this another board about 6 in. wide and 1 in. or more in thickness is to be glued and screwed. These two boards must be very carefully planed up on all four sides. The two parts may then be glued together and cramped up, and while the glue is setting the battens may be prepared.

Shooting Board. Fig. 1. Shooting board ready for use. Fig. 2. Planing the way of the grain.

If the shooting board is about 4 ft. in length it will be found convenient for most purposes, but it may be increased or decreased as required. Three battens will be needed for the under side, and these should be about 8 in. long, 2 in. wide, and 1 in. thick, glued and screwed to the shooting board, and arranged one at each end and one in the middle.

If the shooting board is used on a kitchen table or an extemporized work bench, it will be found convenient to screw a strong stop block to the under side of the board on the left-hand end. Make this block about 2 in. square and 8 in. long and fasten the ordinary batten at this end next to the block, inside. The purpose is to enable the board to be placed on the top of the table with the block overhanging the left-hand end, so that it will act as a stop and prevent the board moving while the planing operations are in progress.

The next step is to prepare a similar piece of batten; it should be equal in width to the narrower of the two pieces of timber forming the shooting board. This batten should be securely glued and screwed to the right-hand upper side of the board.

To use such a board the piece of timber to be planed on the edge is rested on the upper part of the board, one end against the stop. A jack or similar plane, with parallel sides, is laid on its side on the lower board and pushed up and down with the right hand, as in Fig. 2. The work is held with the left hand, and so positioned that when the plane is pressed against the edge of the upper part of the board it is just able to cut the timber.

Another use to which the shooting board can be put is in planing up the ends of comparatively narrow pieces of timber, such as battens and mouldings. These are simply held up against the stop on the end of the board, while a plane is worked across the end grain. It is necessary to make a small bevel cut on the opposite side of the work to that which is first reached by the plane iron;

otherwise the grain will split and the work be spoiled. When not in use, the board should be hung up from a nail on the wall. *See* Mitre; Picture; Plane.

SHOOTING STAR. The best known species of this hardy perennial is *Liatris spicata*, a handsome plant with lance-shaped leaves and spikes of purplish flowers, 2 to 3 ft. high, in late summer. Another species is *L. pyenostachya*, which bears rosy purple flowers in long racemes in August. It is short-lived, although nominally a perennial, and should be sown in a frame in summer to flower the following year.

The liatrises like well-drained or sandy soil, but they do well in any fertile, friable ground. It is an interesting peculiarity of this plant that the flowers begin to open at the top of the spike. Other names for liatrises are snake root and blazing star.

SHORING: Of a House. The process of supporting a structure, such as a dwelling house, that has become unsafe, until such time as it can be repaired or made secure, is known as shoring. *See* Underpinning.

SHORTBREAD. Shortbread that is made with egg can be prepared thus: Cream together 5 oz. butter and $\frac{1}{4}$ lb. castor sugar, then stir in an egg quickly and beat the mixture for a few minutes. Sieve 10 oz. flour, work it into the fat and sugar, shape the dough into a small ball with the hand, and roll it out to about $\frac{1}{4}$ in. thick. Cut it into small shapes with a fancy cutter, place half a glacé cherry in the centre of each or a small piece of angelica, and bake on a baking-sheet in a moderately hot oven for about 20-30 min., or until the cakes are lightly browned. Leave them on a sieve to cool. To make Scotch shortbread, sift into a basin $\frac{1}{2}$ lb. fine flour with $\frac{1}{4}$ teaspoonful salt, and add $\frac{1}{4}$ lb. fresh butter and 2 oz. castor sugar. Turn on to a floured board and knead until the ingredients are perfectly amalgamated; then shape into a firm ball of paste. Roll this out into an oblong or round about $\frac{1}{2}$ in. thick, pinch the edges to make a pattern, and prick the surface with a fork. Place the round on a baking-sheet and bake in a moderate oven till the shortbread is a light brown. This will take about 35 min. It may be decorated with comfits and with a thistle and leaves cut out of candied peel.

SHORT CIRCUIT. The term short circuit is employed to describe a direct path of very low resistance between the poles of a supply of electromotive force. Short circuits are seldom met with in modern homes, the preventives being adequate insulation of the conductors and proper proportioning and disposition of any exposed metallic conductors of electricity.

When a short circuit occurs in an electric lighting circuit the sudden rush of current flows through the wires or conductors of any apparatus in the circuit affected, and continues to do so either until some part of the conducting wire is fused or melted or the supply of electricity is cut off. To obviate the danger of fire, a fuse of soft metal wire, or its equivalent, is introduced into some part of the wiring. Its function is to melt at a low temperature and thus interrupt the circuit before the latter becomes dangerously overheated. In any well-designed house-lighting system sufficient fuses (q.v.) of proper value are incorporated for this purpose. *See* Electricity.

Short Sight. *See* Myopia.

SHORT WAVE: In Wireless. The name given to that band of wavelengths lying between the medium waves and the ultra-short waves upon which the television service operates. "Short-wave" transmissions can be heard over great distances owing to the fact that their space waves are reflected down to earth by the Heaviside and Appleton Layers of ionised air which exist many miles

above the earth's surface. However, where reception is practical only because of this reflection, and that applies at any distance beyond the range of the ground waves, it tends to be inconstant owing to the liability of the surfaces of these layers to shift.

The effect is noticeable by a fluctuation in the strength of the received programme known as "fading." To compensate for this, modern wireless receivers incorporate Automatic Volume Control, which renders the set more sensitive as signals diminish in strength, and vice versa. Complete compensation by this method when fading is severe is not always possible. Commercial short-wave systems use special aerial systems of a highly directional nature in addition.

Also short-wave broadcasting stations employ directional aerials so that their programmes can be transmitted with the greatest effect to selected distant zones. Nevertheless, "short-wave" broadcasting cannot provide wavelengths over restricted areas. There will inevitably be sound distortions and an exaggeration of "background" noises as the sensitivity of a receiver is automatically increased to offset bad "fading," and when this reaches a certain point the signal will be lost.

"Short-wave" broadcasting can be received on comparatively simple receivers, but the tuning and reaction controls are liable to need delicate adjustment, some experience being required to obtain satisfactory results. Further, an effect known as "hand-capacity" may render the operation even more difficult.

With a simple heterodyne receiver incorporating Automatic Volume Control, and a high-ratio tuning mechanism the reception of broadcast programmes from distant continents becomes a practical proposition for the ordinary listener who is not intolerant of periods of distortion or complete loss of stations due to "fading."

SHOULDER: Its Dislocation. The great range and freedom of movement at the shoulder joint necessary for the proper functioning of the upper limb is such that dislocation here is of great frequency as compared with other joints.

Dislocation of the shoulder joint commonly results from a fall on the hand or elbow, or a violent twisting of the arm. First-aid treatment is to support the limb in a sling and apply cold applications. *See* Bandage; Dislocation.

SHOVEL. A type of shovel that can be adapted to many uses in the home has a D-shaped end handle, but patterns may be obtained with a T-shaped end. The blades in some patterns are placed at different angles to the handles, and have a greater depth, with the sides formed higher above the level of the blade, to permit of a greater carrying capacity. As a general rule, however, for moving earth and the like, the sides are not raised to any great extent, and the tool has to cut into the earth to get the material. Too large a shovel should not be employed, as its continual use will soon tire anyone not accustomed to such work.

SHREWSBURY BISCUIT. This is a rich biscuit without aerating powder. The ingredients are 8 oz. soft flour, 4 oz. butter, and 4 oz. castor sugar. Dough is made firm with one small egg and a little orange juice. Work the egg and sugar into a soft paste, then gradually incorporate the flour into which the butter has been already rubbed. It is rolled out to a sheet about $\frac{1}{8}$ in. thick and baked in a hot oven. A few currants may be worked into the dough or the pieces may be washed over with milk and variously dipped on to finely chopped almonds or grated chocolate.

SHRIMP. There are two kinds of shrimp, the brown and the red, the latter being the best and most expensive. Shrimps are usually ready boiled when bought, but if boiled at home they should be put

into a pan of boiling salted water and cooled rapidly until they change colour. Freshly boiled shrimps are firm, of a bright colour, and have their tails turned stiffly inwards.

The dish known as creamed shrimps can be prepared in the following way: Stir together in a chafing dish, 1½ gills milk, the yolk of an egg, and a teaspoonful of anchovy sauce, then add ½ pint shelled shrimps, and salt, pepper and cayenne to taste. Heat the mixture well, but do not let it boil, or the egg will curdle. Keep stirring all the time, and serve the whole on buttered toast.

Shrimps in aspic make a good cold dish. To prepare it, line some small moulds with aspic jelly, putting a fairly thick layer at the bottom. When the jelly has set, put 2 or 3 shrimps in each mould, and fill it up with more jelly. If one large mould is used, the shrimps and aspic may be used in layers. When set, turn out the jelly and garnish it with cress, chervil, slices of hard-boiled egg or beetroot.

A very good stuffing for baked sole is prepared by mixing lb. shrimps with 5 or 6 tablespoonfuls of breadcrumbs, a dessertspoonful of finely chopped parsley, and a little anchovy essence, binding the whole with some beaten egg, and then adding salt and pepper to taste.

SHRUB: The Drink. This drink can be made from the juice of lemons, currants, or raspberries with the addition of spirits such as rum or brandy.

SHRUB: The Bush. So many beautiful flowering shrubs have been introduced that the shrubbery can now be made most attractive, and if a careful selection is made one or another will be in bloom throughout the year. These are some of the best now available. *Hamamelis mollis* (Chinese witch hazel), yellow, fragrant, winter; *laurustinus*, pink buds and white flowers, winter; *erica darleyensis* (Mediterranean heather), 12 to 24 inches, reddish, winter; the almond, blush, early spring; *forsythia spectabilis* (golden bell), April; *berberis Darwinii*, orange yellow, and *berberis stenophylla*, yellow, April-May; ornamental cherries, plums and crabs, April-May; *rhododendron* and *azalea*, May-June; *Viburnum plicatum* (guelder rose), June-July; *philadelphus* or mock orange, June-July; hardy fuchsia, August-September; *ceanothus Gloire de Versailles*, blue, August-September.

Special mention should be made of the leaf-losing barberries, which bear a profusion of brilliantly coloured red fruits in autumn, e.g. *Wilsonae*, *aggregata*, *polyantha* and *sub-caulialata*; *buddleia variabilis*, mauve flowers in summer, a vigorous shrub; *cytissus Dorothy Walpole*, crimson, a showy broom; *philadelphus* (mock orange) *Virginal*, double white; *prunus cerasus Kanzan*, double pink cherry; *pyracantha rogersiana*, with yellow fruits; *pyrus Eleyi*, crimson-flowered crab; *ribes King Edward VII*, a crimson flowering currant; *symphoricarpus laevigatus* (snow-berry), with unusually large white fruits, and *viburnum fragrans*, white fragrant flowers in early spring.

Shrubs suitable for shady places are *mahonia* (*berberis aquifolium*), butcher's broom (*ruscus*) St. John's Wort (*hypericum calycinum*); *laurustinus*; laurel, box and *aucuba*.

Beautiful shrubs for house walls are *wistaria*, summer and winter jasmine, *ceanothus Veitchianus*, *ceanothus Gloire de Versailles*, *pyrus japonica*, *pyracantha*, *cotoneaster horizontalis*, *chimonanthus fragrans*, *clematis* in variety, *escallonia macrantha*, *forsythia suspensa*, *hydrangea scandens* (climbing hydrangea) *kerria japonica fl. pi.*, *magnolia stellata* and honeysuckle.

SHUTTER: For the House. Shutters for windows may be classed under three heads: louvered, lifting or sliding, and box shutters. Louvered shutters open outward on to the external walls, a half of the shutter folding on either side of the window; if the window is a wide one each half shutter may again fold in halves by arranging rebates and butts. This type of shutter permits air to enter freely although the shutters are closed.

Lifting or sliding shutters are arranged so as to slide vertically in front of the window on the inside. Their working is similar to a double hung sliding sash.

Box shutters are arranged to close across the window. They are usually hung at right angles to the window, and sometimes the walls at the sides are splayed so as to provide for better light when the shutters are out of use. Box shutters are so named because they fold and hinge back into a box or recess on either side of the window. *See Blinds; Louvre.*

SHUTTER: Of a Camera. The purpose of the shutter is to expose the sensitive material to light for a predetermined time, which can be accurately known. The ideal shutter should expose the whole picture area and the whole lens aperture simultaneously, remain open for the required time, and then instantaneously close. Mechanical considerations make these ideals impossible to attain. There are two possible positions for the shutter: close to the lens (lens shutters), or close to the sensitive layer (focal-plane shutters). When the shutter is close to the lens diaphragm the whole of the picture is exposed instantaneously, but the lens aperture is opened gradually; while with shutters near the focal plane, the whole of the lens area comes into operation practically instantaneously, but only over a small area of the picture at a time.

Lens Shutters: (1) Blade Type. Lens shutters are of three types: in the first (and commonest) type a number of thin blades (from one to five) are caused to rotate in their own plane about a pivot outside the lens aperture, as close as possible to the lens diaphragm.

Shutter. Left, the "N.S." shutter with lens in Sinclair "Una" camera gives speeds from 1/2 t o 1/100 sec. Middle, Ensign between-lens, Compur type, with escapement mechanism. Right: "Luc" silent 5-blade shutter; clamped over lens.

The greater number of blades there are the more quickly is full aperture reached, because each blade is smaller and has a shorter distance to travel. It is, however, found advisable not to increase the number of blades beyond five owing to the increased number of parts. The blades can be made so thin that even a five-bladed shutter occupies very little axial space. Thus this type can be mounted close to the lens diaphragm, and there is no cutting off of light at the corners of the picture (vignetting).

There are three methods of speed-regulation in use today. In the first, the sector ring is attached by a pivoted lever to a piston moving in a cylinder. When the shutter is in motion the piston moves, compressing the air in the cylinder, which thus acts as a brake. The disadvantages of this method of braking are that the viscosity of the air alters with temperature, so that speed cannot be guaranteed; secondly, lubricating oil between piston and cylinder causes irregular action. In the other two

methods clockwork mechanism is used: in one case causing a wheel with vanes to rotate rapidly, the friction of the air causing the damping; in the other case the gearing is applied to a crown wheel with an escapement. This is probably the most popular type of reliable shutter in use to-day. Speeds up to $1/500$ sec. are obtainable.

(2) **Roller-Blind Type.** The second type of lens shutter is the roller-blind; an opaque fabric blind having a rectangular opening is made to travel, under spring action, close to the lens at a speed which may be varied by adjusting the tension of the spring, which is housed inside the lower roller on to which the blind moves in making the exposure. It is set by winding the blind on to an upper roller by pulling a string, and released by freeing a detent on a toothed wheel.

The aperture is made rather larger than the lens, so that as the blind moves the lens aperture is gradually uncovered from one side, remains fully open for a while, and then is gradually closed from the same side. As the shutter is not at the diaphragm, the top and bottom of the image receive less light than the centre. It is necessary to use a dark slide with this type of shutter because the lens aperture is uncovered in setting the shutter, and the slide must therefore be withdrawn only after the shutter is set.

With the Louvre type this article does not concern itself, as this shutter is at present only fitted to aircraft cameras.

(3) **Focal Plane Shutters.** The focal-plane shutter works on the same principle as the roller-blind lens shutter, except that the opening, which extends the whole width of the picture area, is variable as well as the speed of travel, so that very short exposures are possible (up to $1/1250$ sec.). Obviously, the quicker the shutter the shorter the exposure. Suppose that the slit is as wide as the height of the picture and that it travels across in $1/50$ sec., then the exposure of every part of the plate will be $1/50$ sec. If now the slit is narrowed to only $1/20$ the plate height, then each part of the image will receive light for only $1/20$ the time, so that the effective exposure is $1/1000$ sec.

Efficiency. Efficiency is defined as the percentage ratio of the total light received by the sensitive surface to the amount that would have been received if the full beam had operated for the whole time of exposure. For a lens shutter it is generally about 70 per cent, the five-bladed shutter being the most efficient; with a single blade efficiency may be as low as 50 per cent. Focal plane shutters have a somewhat higher efficiency—generally from 80 to 85 per cent.

Characteristics of Different Shutters. Lens shutters occupy small space, and are therefore especially useful on the small folding cameras.

They can be made cheaply for inexpensive cameras; thus the one-blade type is fitted to box-form and other cheap cameras, and is made to give one time exposure and one instantaneous exposure (usually about $1/25$ sec.). A little better type has two or three blades, and yields about three instantaneous exposure speeds: $1/25$, $1/50$ and $1/100$ sec. Naturally these speeds cannot be guaranteed. More expensive shutters are capable of giving a considerable number of speeds from 1 to $1/500$ sec. and are reliable in action, and their speeds will be found to be not greatly different from the nominal ones.

The focal-plane shutter has the highest efficiency, and can give the shortest exposures ($1/1250$ sec.), and is thus eminently suitable for high-speed work. It is therefore almost exclusively fitted to press cameras, reflex cameras, and the precision miniature cameras. Its advantages with the last arise not only from the possibility of high speed, but also from the ease with which it can be coupled with the film wind and the facility with which different lenses can be used on the same camera.

The focal-plane shutter suffers, however, from one drawback—the distortion produced with rapidly moving objects. There are also various kinds of silent shutter, particularly suitable for the portrait studio. *See Camera; Exposure.*

SHUTTLECOCK. A shuttlecock or shuttle is used in the child's game of shuttlecock and battledore, and also in badminton. It is very light in weight, being essentially a rounded cork, around the flat top of which a number of small quill feathers have been stuck. While a child's shuttlecock could easily be improvised in the home, the weight and balance are of such importance to it in badminton that a home-made one would be of little use. For outdoor badminton, heavier shuttlecocks are provided, the bases being made of rubber instead of cork. *See Badminton; Battledore.*

SIBERIAN CRAB. This is the popular name of a handsome hardy tree (*Pyrus baccata*). It is beautiful when in blossom in spring and again when in fruit in autumn. It flourishes in ordinary soil. The fruits make excellent jelly.

Sibthorpia. *See Moneywort.*

SICILIAN BUTTERCUP. This fowl is one of the light or non-sitting breeds, lays white eggs, which average 8 to the lb., but its record does not entitle it to be recommended on its laying properties only. The cockerel is red in colour, wing bows orange red, primaries black with the outer web bay; secondaries, outer web reddish bay, inner black and bay, tail a mixture of black and reddish bay; comb, face, wattles and lobes red, legs olive green. The pullet is buff on breast, free from markings; back golden buff finely marked with black; tail black except two uppermost feathers, which are mottled with buff. In these birds the comb is the most distinctive feature in both sexes. It is like a buttercup, the two leaves of which it is formed meet, and the spikes stand up all round the comb, the centre forming a hollow or cup. *See Fowl; Poultry.*

Sicilian Buttercup. Cockerel of this handsome and distinctively combed breed.

Sick Headache. *See Migraine.*

SICKLE. For cutting grass in odd corners of the garden or trimming hedges, a sickle is often useful where it is impossible to employ the scythe. It consists of a curved blade of steel, with either a sharp or serrated edge, and a round wooden handle, the cutting edge being on the inside. The cutting edge should be kept very keen by sharpening on a coarse stone, or carborundum scythe or hook stone, known in some districts as a rubber. The tip of the tool is sharpened first, then the rest of the blade is sharpened by placing the tip of the tool on the ground, holding the hook firmly with the left hand and manipulating the rubber with the right, rubbing on either side of the cutting edge alternately. *See Grindstone; Scythe; Shears.*

SICKNESS. In a particular sense the term sickness means nausea, with or without vomiting. It may indicate gastritis or some other stomach complaint, or may be due to other definite causes. The fact that an infant returns some of its milk after a feed is not necessarily vomiting, but usually means that it has taken too much. Vomiting in a child may often be benefited by $\frac{1}{2}$ to 1 teaspoonful of castor oil, which is retained more often than might be expected. *See* Biliousness; Gastritis; Morning Sickness; Nausea; Sea Sickness; Vomiting.

SIDALCEA. These beautiful hardy herbaceous plants are 3 or 4 feet high and bear mallow-like flowers in summer. They flourish in ordinary garden soil and are increased by division in autumn or by sowing seeds in spring in a frame. Of the older sorts *Listeri*, carmine rose, and *Candida*, white, are the best; many new varieties with flowers of various shades of rose and crimson have been raised.

SIDEBOARDS: ANTIQUE AND MODERN

How to Choose Them and How to Make a Light Modern Type

A great number of articles in this Encyclopedia are connected with this subject. Such include those on allied pieces of furniture: e.g. Cupboard; Dresser; on the various furniture styles, e.g. Hepplewhite; Sheraton; and on the woods employed, e.g. Mahogany; Oak. *See also* Dining Room; French Polishing; Furniture; Inlaying; Polishing. The maker of a sideboard should consult the various woodworking entries in this work.

Sideboards may be broadly divided into two classes: those showing the original table construction of this piece of dining-room furniture, consisting of a board placed on trestles at the side of the room and used for service at meals, and those of threefold construction which incorporated the two pedestals often found as separate adjuncts to the sideboard proper early in the 18th century.

Sideboard. Tudor example, dating from early in the 16th century, and illustrating the first development of this piece from the board placed on trestles at the side of the dining hall. (By permission of the Director, Victoria & Albert Museum, South Kensington)

Beautiful mahogany sideboard, veneered with Spanish mahogany, showing the influence of the Adam style and the threefold development of this piece accomplished by incorporating two pedestal cupboards. (Humphrey & Vera Joel)

Cupboards were fitted into some of these pedestals, and others might perhaps have accommodation for bottles. In others drawers were fitted, and the tops were used as stands for knife urns or candelabra. When some furniture designer made these three pieces into, one the second class of sideboards was evolved.

Our first illustration shows an example of the older pattern dating from Tudor times. This style of sideboard, reproduced for period furnishing in oak to-day, was the immediate successor of the board on trestles. Many beautifully carved examples of Jacobean side-boards are still extant, some having backs and fitted with drawers under the table surface.

Some of the Queen Anne period sideboards, made in oak or walnut, stood on turned legs connected by gracefully curved stretchers, while others (in walnut) had cabriole legs and were usually without backs, but fitted with drawers.

The Threefold Pattern. Sheraton describes the sideboard of his period as often made without drawers of any sort, having simply a rail a little ornamented, and pedestals, on which were vases, at each end. Some sideboards had hollowed fronts, and under them it was customary to place the wine cooler. Sheraton, however, soon improved on these existing pieces. His sideboards are in the main straight, but with curved or serpentine fronts, and most of them designed without backs. They were made in mahogany, and some were inlaid. One beautiful example typical of his work is illustrated in the article on Sheraton style.

Sheraton's Drawing Book shows designs for several sideboards. Three comparatively simple ones are each provided with a rail at the back. One of the three is furnished with holders for candles. A secret drawer, which opens by means of a spring, is fitted into one of them, while another is flanked by pedestal cupboards on which knife urns or other articles may stand.

In another he introduced a rail at the back in which was framed a small round mirror, thus starting a style which developed into the huge mirror backing of the sideboards of the mid-Victorian period. Sheraton's pedestals were rounded in shape, and the knife urns were placed within them, while on the tops, where the urns stand in most sideboards, he placed something resembling a round, two-tiered stand, surmounted by a candelabrum. In another piece he replaced the rail at the back by a wooden strip.

In pieces designed by Hepplewhite the right-hand drawer was fitted with partitions for bottles, and behind it was a place for cloths or napkins. In the left-hand drawer were two divisions: the back one was lined with green cloth to hold plate, and the front one lined with lead to hold water for washing purposes. His standard sideboard was from ft. to 7 ft. long, about 3 ft. high, and from 28 to 32 in. wide. Hepplewhite made good use of the serpentine line to give grace to his pieces.

Chippendale did not make sideboards, although he designed pedestals for the Adam brothers, and these were incorporated into the beautiful sideboards that bear their name Chippendale's Cabinet-Makers' Director, however, contains several designs for the pieces of furniture known as sideboard tables, one or two of which anticipate the modern sideboard.

Adam sideboards have usually two cup boards and a drawer between them, the space beneath being open. The front shows the graceful lines associated with this rime, and the cupboard doors are often beautifully ornamented with oval panels. The board proper is below the level of the cupboard tops, thus continuing the idea that they were once separate pieces of furniture, and the back is formed by a rail. Regency sideboards showed the same features associated with mounts of bronzed metal or brass. A development of these was the chiffonier.

Our second illustration is an example of a beautiful sideboard which shows the Adam influence and clearly displays the threefold construction. It is of mahogany veneered with Spanish mahogany and the pedestal cupboards have side doors at either end of the piece.

As the sideboard became more popular, it was made in a greater variety of styles, but the threefold arrangement was retained in Victorian pieces. Some were made without legs, the space beneath the drawers being fitted with cupboards. In many the centre cupboard was made to hold a cellarette. Another change was the introduction of the large mirror into the back, flanked by bracket shelves and heavy carved and scrolled side pieces. The Victorian sideboard assumed vast dimensions in keeping with the great display of silver plate which was considered necessary in the dining room of the period.

Modern sideboards are of light construction and usually of small size. Mahogany, walnut and oak remain the favourite woods, and some are beautifully inlaid. They show the development of the threefold idea by having cupboards at either side and a drawer or drawers in the middle, but many of the smaller pieces go back to the original type as far as the table top is concerned, adding merely a back rail. The piece for which constructional details are given also shows the modern use of the stretcher, a correct and pleasing feature in an oak sideboard of otherwise simple design.

Making an Oak Sideboard. In most modern houses a length of 4 ft. is ample for a sideboard. It gives reasonable accommodation without occupying too much space. A sideboard of this size in modern style is shown in Fig. 1. It has two handy cutlery drawers and capacious cupboard space. In addition the doors have a useful shelf arrangement. The latter need not be followed exactly, but can be adapted to suit individual requirements.

Sideboard. Fig. 1. Useful 4-ft. sideboard in oak which can be constructed by following the directions given in the text and the working diagrams below.

Although a somewhat massive item the construction is comparatively simple because use is made wherever practicable of readymade furniture parts, thus avoiding most of the difficult work. For instance, legs ready-turned and grooved can be obtained. The various rails, too, are grooved, and the same applies to the mouldings. Again, the doors, instead of being framed up, are formed of pieces of thick veneered

plywood. The virtue of this is that, apart from the elimination of a good deal of Work, the plywood will stand without danger of shrinkage.

The leading dimensions are indicated in Fig. 2, and Fig. 3 shows how the main carcass is put together. Deal first with the legs. These are usually sold in sets of four, two legs having a single groove, and two having two grooves each. The double-grooved ones are put at the back. Another leg with no grooves at all is needed for the centre.

To ensure the joints being all marked out alike, the legs should be fixed together temporarily and the marks squared across the whole. All the rails are tenoned into the legs, with the exception of the top front rail, which is dovetailed. They all stand upright, except the first and second front rails, which lie flat (Fig. 3). If we except for the minute the stretcher rails, which are plain, all the back and side rails are grooved. A special grooved moulding can be obtained which requires simply to be cut to length and the tenons formed at the ends. The second back and side rails must be grooved at both edges. All the front rails are plain.

Those to whom simplicity is all-important can omit many of the mortises in the legs. This is done by cutting short tenons on the rails to fit into the grooves in the legs. For a stronger job deep mortises must be cut, and corresponding tenons formed on the rails. In any case mortises are necessary where the front rails and stretchers are fixed. When all the joints have been marked out the legs can be separated and the joints cut.

Fig. 2. Front and side elevations of the oak sideboard shown above. Fig. 3. How the main carcass is put together.

The same plan of fixing together the parts can be adopted in the case of the rails. The shoulders of all front and back rails are the

same length, so that it is an advantage to cramp these together and square the marks across. The same thing applies to the side rails. If it is decided to cut short tenons, the length of these is fixed automatically by the depth of the grooves. In any case remember to allow for the tenons when cutting the rails to length.

A close-up view of the front joints is given in Fig. 4. Note specially the dovetail joint at the top. The shoulder length of this is the same as that of the other rails. Notes on the actual cutting of the various joints used are given under their respective headings in this work, and the article on Joint may usefully be consulted. The centre leg joints are similar to those of the others except that there is no dovetail at the top. Instead, the rail here runs right through and a joint like that shown in Fig. 5 is formed.

The various panels are of 3/16 in. plywood. Those at the sides are oak veneered. For the back a cheaper birch plywood is good enough. Allowance for the part projecting into the grooves must be made when cutting out. As a rule the grooves are 1/4 in. deep. This means that 1/2 in. must be added to the sight size in both length and breadth.

When assembling the main carcass the two sides should be put together independently and the glue allowed to set before the remaining rails are added. This saves the necessity of dealing with many joints in one operation. Lay one leg on the bench, glue in all the rails, and slide in the panels. When the other leg has been put on the whole can be cramped up. Test for squareness before putting the unit aside to set.

Fig. 4. Close-up view of leg joints. Fig. 5. Detail of top of centre leg. Fig. 6. Useful shelf arrangement at back of doors; it is put together first and added to the door as a complete structure.

It is advisable to have assistance when adding the front and back rails. The back should be put together as far as possible first; that is, the centre uprights and the panels should be assembled. When this has been done the whole back should be fixed to the sides and the job stood upon its feet. If only one cramp is available nails can be driven into the joints to prevent their springing apart.

Next add one set of front rails to one leg, glue in the centre leg, and put in the remaining set of rails. This necessitates slightly straining the sides outwards. The top front rail is glued in last. Test for squareness in both plan and elevation.

Drawer runners and guides are fixed as shown in Fig. 4. The groove in the runner is necessary when a dustboard is desired. Screws are used to fix the runners. The guides, which prevent the drawers from rocking from side to side, are glued and nailed above. An extra wide runner is needed in the centre to support both drawers. Plain squares of wood are fixed to the rails to hold the cupboard bottom, which can be made of plywood $\frac{3}{8}$ in. or $\frac{1}{2}$ in. thick. The sectional view in Fig. 2 shows how the top is made. A special rebated top moulding is mitred together and a piece of veneered plywood glued in the rebate. This saves having to joint up several pieces to make the width.

It has already been mentioned that thick plywood is used for the doors. Fig. 6 shows how the hanging shelves are made up. The complete shelf structure is put together first, and this added as a whole to the back of the door. The middle shelf rests in grooves, and the bottom tits in rebates in the uprights. The small inset sketch shows how the whole is fixed to the door by pocket screwing. One important point is that the uprights of the shelves must stand in from the door edges, otherwise the door will bind when opened. The decorative mouldings on the doors and drawers are simply glued and nailed. The corners are mitred. Use the usual dovetail or lap joints for making the drawers.

SIDECAR. It is possible, though not advisable, to fit a sidecar to any motor cycle of 175 cc. or over. The main objection to using a sidecar with small engines is that the average pace of such a combination is well below the speed of traffic streams on the open road. The presence of a comparatively slow vehicle in a fast traffic stream creates dangerous eddies, necessitating frequent overtaking, and is therefore to be discouraged on the ground of public safety.

Moreover, the occupants are uncomfortable because they are forced on to the camber, and much larger vehicles constantly rush by them at higher speeds. An engine of 500 cc. should be regarded as the minimum from this point of view a larger engine being preferable, though a 350 cc. sidecar combination is satisfactory on other grounds. Moreover, when a sidecar is drawn by an engine of 750 cc. or 1,000 cc. the running costs approach very closely to those of a small car, so that the 500 cc. sidecar thus represents the best compromise. The maximum regular load for a sidecar combination consists of two people and a quite small child. It is not economical to carry a woman

and one or two children in the chair and a pillion passenger on the carrier behind the driver, as is often attempted at holiday times. The heavy load makes the machine slow, with the disadvantages described above, and imposes stresses on the mechanism which are reflected in the cost of upkeep. The novice should not take a sidecar on the road without receiving instruction from a practised driver. When the peculiar steering is once mastered the machine is entirely controllable, and can be turned in a smaller space than any other vehicle, but the novice is extremely likely to upset it on left-hand corners until he has been instructed how to corner. He will also experience difficulty on cambered roads until he realizes that the front wheel is used solely to steer the machine and not to balance it, for he is probably accustomed to a bicycle, with which the front wheel is used to balance as well as to steer.

Sidecar. Diagrams in plan and elevation, showing the correct method of lining up sidecar to motor cycle.

Where storage space is limited, a folding sidecar chassis is recommended. The entire outfit when folded then occupies little more width than a motor cycle; when extended, the frame is as safe as a rigid pattern. It is usually best to buy the sidecar chassis from the maker of the motor cycle, as it will then be designed to fit special lugs brazed into the frame the sidecar can easily be set in proper alinement and the connexions will not shift, as might occur with bolted joints.

It is not possible to provide weather protection for the driver, though wind screens and leg shields are obtainable to keep off wind and rain in some degree; the sidecar, however, should always have a hood and screen. If ample engine power is available, a boot for luggage should be formed in the tail of the chair. It is cleaner and more convenient than a grid. Sidecars are sold having brakes on the side wheel, but these are not recommended except to the expert driver. The standard motor cycle brakes are adequate for ordinary purposes, and on precipitous hills further retardation can be obtained by descending on bottom gear. The diagram indicates the proper method of adjusting the sidecar on the frame of the motor cycle.

Owing to the extra load punctures are more common with a sidecar than with a motor cycle. It is easy to store a spare wheel on the tail of the sidecar, and it is unwise to buy such an outfit without detachable and interchangeable wheels. *See Motor Cycle.*

SIEVE: Its Uses. A sieve or sifter is really an appliance for separating the finer from the coarser particles of any loose material. It consists generally of a framework with a number of strands stretched across it; the diameter and distance apart of the strands determine the size of the particles which can pass through the sifter.

The ordinary household sieve has a hardwood rim with a very fine gauze or mesh stretched over the lower part of it and secured by a second or outer rim, and is useful for sifting sugar and many other ingredients used in the kitchen. Fine sieves for culinary purposes have meshes of hair, muslin, and wire gauze.

Sieves for grain and chaff have wooden rims and cane bottoms and vary from 15 in. to 28 in. diameter.

The potato sieve, with a diameter of about 24 in., has an oak rim about 3½ in. deep and a very wide mesh, varying from ¾ in. to 2 in. It is employed to sort out the small potatoes from those of sufficient size to be suitable for seed purposes or for ordinary consumption. *See* Cinder Sifter.

Sifter. Wood used for a kind of sieve for sugar, etc. *See* Flour Sifter.

SIGHT. This word means, in one sense, the faculty of seeing. As a general rule persons whose sight is not normal suffer either from myopia or short sight, or from presbyopia or long sight, the latter being usually due to increasing age.

Sight Testing. It is quite impossible for anyone who is not an oculist or a qualified optician to test vision with any degree of accuracy, and to obtain spectacles except on an expert's prescription is fraught with danger.

For example, hypermetropia, or long sight, and astigmatism may both be present, but may be concealed by muscular action; either of these conditions may be responsible for a large degree of eye strain, and may be productive of severe headache. An error of vision may always be suspected if headaches are frequent when the eyes are subjected to any strain, as in reading or writing, or especially when visiting a theatre or cinema.

Persons over 40 years of age are very liable to suffer from presbyopia. In this condition, the distant vision may be normal, but glasses are required for all near work and will need to be strengthened at intervals of about five years. *See* Astigmatism; Eye; Myopia; Spectacles.

Signal. The recognized traffic signals are illustrated in the article on Motoring (q.v.).

SIGNATURE: In Law. When the law requires a signature to be affixed to any document, as a rule it is sufficient to sign with the ordinary signature, not necessarily with the full name, but anything which is intended for a signature is enough in law. It has even been held that a printed name at the top of a billhead, invoice, etc., is a sufficient signature. Except in the case of a will, where the signature must be placed at the foot or end of the will, the signature may be placed anywhere. It may also be made by initials or even by one initial or by a typed or stamped signature. *See* Cheque; Will.

SILENE. This group of hardy perennials and annuals is known as the catchfly or campion. The favourite annual kind is *Silene pendula*, which is largely grown as a groundwork for flower beds; it becomes a mass of rose-pink blooms in late spring. It is raised from seeds sown out of doors in June, the seedlings being planted in the flower beds in October. The perennials are chiefly rock garden plants. *Silene schafta*, 6 in., rose coloured flowers in July-August; *alpestris*, white. July; and *maritima*, 6 in., with double white flowers in summer, are some of the best. *Silene acaulis* is of moss-like growth, and needs very gritty soil. Propagation is by seeds sown in spring in a frame or by division.

SILICA. Many materials contain this substance; rock crystal quartz, and flint are practically pure silica. Chemically silica is an oxide of silicium with silicon as its base. Silica is the chief substance of which glass is made; in a pulverized state such as sand, it is an essential ingredient in strong

mortar. Plate glass and window glass or, as it is sometimes called, crown glass, are silicates of soda, and flint glass is a similar compound with a considerable addition of lead silicate.

A proprietary brand of paints with a zinc oxide base is known as silicate paint. A preparation known as silicate petrifying liquid is sold for treating damp or porous brick or stone walls, cement and plaster surfaces, etc. *See Damp.*

SILK. The quality, texture and sheen of silk vary considerably, according to the kind of silkworm that produced it. The strong, natural coloured silks called tussore or shantung are obtained from a so-called wild silkworm. Finer silks, bright yellow and white in colour, are produced by the mulberry silkworm.

Chiffon, crêpe-de-Chine, ninon, velvet, satin, taffeta, georgette, stockinette, and brocade are but a few of the fabrics that are composed chiefly of silk. It is very suitable for clothing, as it is a bad conductor of heat thus keeping in the heat of the body. Being light, and not bulky or clumsy, it is particularly useful for under-garments, as the surface is smooth and soft, and does not irritate delicate skins. Silk is very durable, and absorbs moisture, although not so readily as wool.

Plain silk, poplin, and velvet are still sometimes made into curtains, whilst silk damask and tapestry are employed for upholstery. Hand-woven materials in silk are particularly beautiful and give good wear. Fine silks are suitable for cushion covers, as feathers do not easily work through. The use of pure silk for furnishing fabrics has been largely superseded by artificial silk mixtures.

As silk is not a cheap fabric it is more adulterated than any other material, the object being to give weight and generally to improve the appearance of silks of poor quality and uneven texture. Coloured glacé silks are frequently loaded with mineral salts. These weighted silks wear badly, splitting after being in use a short time. Other common fillings are clay, starch, ultramarine and size. Although it is beyond the power of the housewife to determine the actual quantity of such adulteration, some idea of it can be obtained by rubbing and shaking a small piece of silk over a sheet of paper, using black paper for bright-coloured silk, and white paper for dark silks. If the fabric is heavily loaded, a little of the filling will come out as dust, and the silk will feel thin and look poor after the treatment.

Another simple test is to soak a pattern of the silk in warm water for ½ hour, and then wash it carefully, using ordinary soap. If the character of the fabric is hardly changed, this proves that the silk has not been adulterated to any extent. A thread of pure silk when heated in a flame shrivels and forms a little bump or knob at the end; silk containing tin salts does not do this but forms ash similar in length to the thread burnt.

Mending and Washing. As a rule it is not advisable to spend much time on mending silk garments that have commenced to wear. Unlike cotton materials, silk threads, when once they show serious signs of wear, rapidly break down and the fabric is of little use. Should a perfectly sound garment become torn or burnt it can be mended by inserting a neat patch or by placing a piece of silk under the rent and darning it to the garment. Woven silk underwear and stockings can be darned in the ordinary way, but to avoid straining the fabric it is advisable to use silk thread similar in texture to that employed in manufacture. It is worth taking good articles to be mended invisibly by an expert.

The appearance of some of the more elaborate varieties, especially ribbons, corded and glacé silk, is spoiled by washing with soap and water. These can be dry cleaned at home (*see Dry Cleaning*), or sent to the cleaners.

Washing silks are strong, and require little skill in getting up, but the more delicate silks, such as crêpe-de-Chine, ninon, and foulards, need careful treatment. Alkalis, such as washing soda, strong soaps and soap powders, are actually harmful to any silk fabric, and ammonia should be used

judiciously for dark-coloured silks only. Silk, being an animal product, must not be boiled, nor must it be washed in very hot water.

How to Wash Silk Articles.

Before commencing to wash, sort all silk articles into three distinct lots, white silks, coloured, and black. The white silks should be washed first, commencing with the least soiled and finest fabrics. Prepare sufficient warm soapy water for the amount of washing to be done; the lather can be obtained by using soap jelly or soap flakes. Soap flakes are made by shredding yellow soap, and drying and storing it ready for use. When required, put about two tablespoonfuls of flakes into the bath, and pour on a little boiling water, adding warm water or more soap as may be found necessary. It must be remembered that no cleansing whatever takes place unless there is a lather on the water. The amount of soap that is necessary to do this entirely depends on the nature of the water, whether hard or soft. When dissolved soap is required quickly, place a cake of yellow soap in a wire cage soap-saver and pour boiling water over it.

Wash silk garments by kneading and squeezing. A little hard yellow soap can be rubbed on to any specially soiled parts such as collars, cuffs or bands. When the garments are quite clean on the right side, turn them and wash them on the other side; it is generally advisable to have a second washing water. Hard rubbing should be avoided, especially for loosely woven silks. When clean, rinse first in warm water, then in cold. this removes the soap and clears the fabrics. The appearance of white silk is enhanced by careful blueing, which counteracts the yellow tinge that white silks invariably acquire after having been laundered several times.

Stiffening and Ironing. Silks that require stiffening should be immersed in gum water. To make gum water, dissolve 2 oz. best white gum arabic crystals in $\frac{1}{2}$ pint of water; strain the solution through muslin and bottle. When required, 1 to 4 teaspoonfuls of this solution should be added to $\frac{1}{2}$ pint of cold water. For large articles, such as dresses and curtains, the quantities must be increased proportionately. Thick silks, such as corded shantung and tussore, are better not stiffened. The appearance of glossy silks is improved by adding a dessertspoonful of methylated spirit to the stiffening water. Small silk articles, after being wrung out, can be rolled down tightly in a clean cloth. On no account should silk be completely dried and damped down but should be ironed when half dried out.

The finished appearance of washed silk depends on the ironing. The object should be to iron it in such a way that the finished appearance resembles as closely as possible the material when new. Therefore, some silks should be ironed on the right side and some on the wrong. The following look better if ironed on the right side: Jap, glacé, foulard, tussore and shantung.

Any patterned silks, embroidered or corded, should be ironed on the wrong side, also silk lace, crêpe-de-Chine, ninon, georgette and stockinette. Coloured silks can be successfully got up by following the same directions, but the colours are improved by adding 1 tablespoonful of both salt and vinegar to the last rinsing water. Salt sets, and vinegar brightens, the colours that have been faded by the soap. The colour of black silk is improved by steeping for a short time after rinsing in deep blue water.

Removing Stains. Stains are not so easily removed from silk as from cotton and linen, and some stain removers, such as chloride of lime or eau-de-javelle, must not be employed. When using a bought stain remover, notice carefully if it is suitable for silk fabrics. Use oxalic acid with care to remove rust and ink stains from silk. Turpentine should not be employed to remove paint from silken fabrics, but instead a mixture of one part benzine to two parts of methylated spirit should be used.

Silk for Needlework. Spun silk is used in knitting, crochet, and embroidery of all kinds. It is divided into two main classes, real silk and artificial. Real silk washes and wears well, and can be re-dyed at home. For knitting and crochet and all needlework purposes it is the more satisfactory to handle, as it is soft and the stitches stay in position, while artificial silk is springy, and requires careful handling, particularly in knitting when there are a lot of stitches on the needle. For some decorative purposes the brilliant gloss of artificial silk thread is valuable.

Knitting silks consist of very fine strands very loosely twisted, while crochet silks have a decided twist, to prevent the crochet hook from piercing the silk and dividing the strands. A fine artificial silk is also made for crochet, which is about half the thickness of the standard twist. Crêpe twists are also made in both classes. These silks are usually sold in hanks and balls of 2 oz. and 4 oz., while embroidery silks are made up in small skeins.

Tests for Silk. Though in dyeing properties spun silk differs considerably from the artificial products, the housewife may find it difficult to differentiate between the fabrics in their bleached state. The burning test may be helpful, though not always conclusive. Real silk fibre is practically non-inflammable. When ignited the flame does not run, and the ash forms a knob or globule, a smell as of burnt feathers or hair being given off. Some kinds of artificial silk do not flare, but the substance melts back into globules, and the characteristic smell of burned animal feathers is absent. Another type of artificial silk flares up and burns away, with an odour like that of burning paper. The tests are made more difficult by the practice of combining the different materials in the yarn. *See Bag, Candlesshade; Curtain; Embroidery; Painting on Textile Fabrics; Patchwork; Ribbon Work; Stockings; Weaving.*

SILKIE FOWL. Quite distinctive in the shape and colour of its comb, the colour of its lobes, face, wattles, and legs, and in the texture of its plumage, the Silkie fowl is unique amongst poultry. It is not a great layer, nor is it a table bird; owing to the fact that it is so small; its bones are dark purple, the skin also is dark. The plumage is very soft, fine and without web, so that the bird appears to be clothed in a coat of down.

Silkies are bred in four colours—white, black, buff, and partridge. The only utility claim that can be put forward on their behalf is that they are most trustworthy mothers, and no fowl can beat them as a broody. Some exhibitors use half-bred Silkie-Wyandottes for incubation purposes with good results. *See Fowl; Poultry.*

Silkie Fowl. A curious and distinctive breed notable for its sense of maternal responsibility.

SILL: In Building Construction. A sill is the horizontal piece of stone, brickwork, concrete, or timber at the base of a framed opening, such as a door or window. Ground sills are the lowest pieces of timber which support the posts and superstructure of a timber building, while the term also refers to the lowest member of a studded partition.

Sills for door frames should be formed of oak; they may be 4 in. by 3 in. or 6 in. by 3 in., and weather on the external side. The sills of window frames may be of oak, but in many instances similar material to that with which the frame is made is used. External door sills are formed with York stone, cement, bricks, etc., the former being the most expensive. The first essential for any

external door sill is a good foundation of Portland cement concrete. External window sills are formed of stone, brick, cement, concrete or tiles bedded in cement.

Provision should always be made to deal with the water that is liable to be received during rainfall. With an ordinary window sill this is accomplished by cutting a throat or groove on the underneath side about $\frac{3}{4}$ in. from the front edge. In the case of a door a piece of iron usually 1 in. by $\frac{1}{4}$ in., is placed on edge into a prepared groove between the wood sill and the brick or stone sill on which the former rests. It is called a water-bar and should be bedded into place with red and white lead. A door sill is liable to wear hollow, especially if made of wood. To remedy this a slot is cut to include the worn portion and a new piece of wood let in. *See Door; Window.*

SILVER: Medical Uses. In the form of the nitrate or lunar caustic silver is often used in medicine as a caustic where a limited and superficial action is required. Lotions of silver are sometimes used on account of their astringent and styptic action.

A very weak solution. 1 to 2 gr. of silver nitrate to the oz., dropped in the new-born infant's eyes, after they have been first thoroughly cleansed with weak warm boracic solution, is an efficient protection against ophthalmia neonatorum.

SILVER WARE: BRITISH “PERIOD” STYLES

Pieces that Lend Grace and Beauty to Domestic Life

The reader should further consult the entries on the various silver articles, e.g. Cream Jug; Muffineer; Porringer; Punch Bowl; Spoon; Tankard; Teapot. See also Cutlery; Glass Ware; Pewter; Piercing; Repoussé; Sheffield Plate and the subsequent article on Silver Work.

Fine examples survive of English silver work done during early Tudor times, especially pieces for church use in the form of standing mazers or communion cups. In a prosperous household a large salt container of hour glass shape, and beautifully proportioned, might be found in daily use with silver cups and silver-mounted drinking horns, some odd spoons, a basin and ewer, one or two dishes and candlesticks in silver. In the 16th and 17th centuries tankards, dishes, and other articles were often made in silver gilt or parcel (partly) gilt.

The discoveries of silver in America and its importation in the 16th century placed it well within reach of the affluent. The result was a great increase of domestic plate and the distinction between rich and poor at one time was marked by their uses of silver or pewter for eating and drinking vessels.

Much of interest can be learned about silver ware from the copies that were made by the pewterers. All through the history of the two crafts it is found that when the shape of a spoon was modified by the silversmith, the brass or latten spoon makers copied it and so did the pewterers. When the silversmiths evolved a new candlestick for table use, the pewterers, ever on the watch for something new, copied it, making it a little thicker and sometimes a little more clumsy to compensate for the greater softness of their alloy.

Later the silversmiths were copied by the Sheffield plate workers, but the silversmiths themselves were affected artistically by any art inspiration that came to them from without. The influence of the work of such great designers as the brothers Adam, Chippendale, and Josiah Wedgwood upon the craft of the silversmith can be seen in countless little details which, not in use before their time, must therefore be attributed directly to these influences. Much beautiful silver ware was made during the 17th and 18th centuries in Scotland and Ireland, and bears the Edinburgh, Glasgow and Dublin marks, while some early pieces were marked at Cork.

Drinking Vessels. From church plate to everyday domestic ware, the silversmith's craft has been largely concerned with articles for the service of drink and food. Silver drinking vessels are known by various names, and the line of demarcation between one and another is not always precisely drawn. Prominent among them are the cups used for wine, which are represented to-day by the wine glass, and the challenge cup, given to successful athletes. A main feature of these cups, except in the case of the loving cup type, with two handles, is the absence of that accessory.

Goblets are usually, but not always, bellied, and are supported on a straight stem which may be square, but is more commonly rounded. The vessel known as a steeple cup, made in the reign of James I, is not unlike the goblet. It has a cover which either fits like a cap or does not rest directly on the brim, but is raised therefrom by three or four slender balusters. The cover terminates in a spike which suggests a church steeple.

The beaker is another type of drinking vessel. Like the cup and the goblet, it is without a spout and a handle, but unlike them it has no foot, resembling in this respect the modern tumbler. As a rule, beakers are severely plain, with straight sides and surfaces decorated with a chased design or a raised pattern. The sides taper and the diameter is nearly always larger at the top than at the bottom. The beaker dates from Tudor times. The hanap was a large standing cup also of early date, and richly ornamented.

Fig. 1. Silver tankard, period George II, with domed lid, thumb piece and graceful handle. (Courtesy of Chapple & Mantell)

The silver mug was made in a variety of styles, although in essentials one differs very little from another. They may be quite plain or they may have a bulbous body. A scroll or a bow handle is seen on some examples, and the decoration includes reeding.

Early tankards have straight sides, and are decorated elaborately with chasing and repoussé. In the middle of the 17th century they were designed in plainer styles with flat lids, but in the 18th they were made with domed lids. Fig. 1 shows a typically shaped tankard of the time of George II. More ornamental pieces of later date showed chased designs and raised patterns on the bellied bodies and decorative knobs on the lids. The flagon is very similar to the tankard except that it is of even earlier date. Porringers, posset cups, and caudle cups, all popular vessels from the collector's point of view, may be linked with drinking vessels.

Silver. Fig. 2. Left, beautiful example of large, covered porringer, dating from the time of Charles II, having bellied body decorated with lion and unicorn design. Right, smaller porringer without cover, dating from the reign of George III.

The porringer of the time of Charles II possessed a cover and usually was of the shape illustrated on the left of Fig. 2, about 6 to 8 in. high being the size of these pieces. Later porringers were made

without lids and with straighter sides, as seen in the example on the right of Fig. 2, dating from 1764. Caudle cups in the 18th century were made after the style of the earlier covered porringers.

Liquor Service Vessels. The silver jug has developed along more than one line, according to the use for which it was intended. The cream jug is one form of it, while the hot-water jug of to-day is not unlike the wine jug of two centuries ago. The jug may also be regarded as the ancestor of the chocolate pot and the coffee pot, two pieces of some interest to the lover of old silver. Of these the chocolate pot, in use in high society in the time of Queen Anne, has its spout fixed almost at right angles to the handle. The latter is sometimes quite straight like the handle of a saucepan, not bowed and fixed at top and bottom to the body, as is the handle of a teapot.

Silver. Fig. 3. Coffee Pot, of conical shape, dating from Charles II; London mark, date 1681-2. (By permission of the Director, Victoria & Albert Museum. S. Kensington)

The earliest silver coffee pots resembled truncated cones with a straight spout and a wooden handle. Fig. 3 shows one of these dating from Charles II. They were next made with an octagonal body, and later with a bellied one and a curved spout, the decoration becoming gradually more elaborate. A vessel very like the coffee pot, and used for the same purpose, is the biggin. The difference is that the latter had a very small spout, this being little more than a lip. Both chocolate pots and biggins are rare, but coffee pots of the early 18th century are more frequently seen. The teapot came a little later than the vessels just mentioned. There exist a few

in the Queen Anne style, which has been much copied, but antique examples are mainly of Georgian date. The early ones were without feet, and for them stands to match were often made. Some George I teapots are of octagonal plan with domed covers and faceted tapering spouts.

The tea urn and the kettle may suitably be mentioned together. The kettle in silver with a lamp under it was made early in the 18th century, the urn coming a little later. The early kettles were usually spherical in shape, and a few of them were in a gimbal on a tripod frame, thus enabling the contents to be poured out by tilting the vessel. Others had a pair of snuffers attached to the stand and the spout of the kettle was fitted with a hinged lid. Shell work and scroll work are found on 18th century kettles. The most beautiful urns are those that show the Adam influence and follow the classical model by having the body shaped like a Greek vase and add to this chasing and other graceful decoration.

Fig. 4. Punch Bowl with hollow flutes and straight gadroon edge; Irish mark, maker Robert Calderwood, 1732. (Courtesy of the Goldsmiths' and Silversmiths' Co., Ltd.)

Of the other silver vessels that were used for holding liquor, two of the most coveted are the punch bowl and its near relative, the monteith. An example of a punch bowl dating from the time of George II is illustrated in Fig. 4. The ladles which were made for these bowls with handles often of whalebone or a hardwood, are also prized by collectors.

The best-known kind of sauceboat has a long lip, a scroll handle, and is supported on three feet; but perhaps more prized is the oval one with both ends pinched to form lips. The feet, rims and handles lend themselves to graceful treatment which they received from the craftsmen of the 18th century.

Tureens are round or oval, a gadroon border and scroll feet being seen on some fine examples.

Two vessels allied to those mentioned are the pipkin and the argyle. The former is a kind of saucepan which was used for warming food in a living-room or bedroom when a formal meal was not required. They are usually bellied at the base and diminish in diameter from the waist to the brim, where there is a small lip at right angles to the handle. The argyle was used for holding gravy at the table. It has a jacket, wall, or other contrivance for holding hot water, the idea being to keep the gravy warm. With a handle and a short spout, the argyle is not unlike a teapot.

Silver Dishes and Baskets. A fruit or cake dish known as a tazza was originally used and described as a drinking vessel. The rimmed dish is supported on a short stem having a round or square foot.

Silver dishes and plates were frequently seen on the tables of the rich in the 17th and 18th centuries, and the former have popular representatives in the entree and other dishes of to-day. Occasionally they were part of a silver dinner service.

Dishes used for meat are generally oval, and some are provided with a cover. Those used for vegetables have sometimes three or four divisions, while others have a wooden handle straight out from the side. Of all dishes, the entree or breakfast dish lends itself most readily to graceful treatment, and good examples fetch high prices. Some are provided with a second tray for holding hot water, and many have detachable handles, so that the cover can, if necessary, be used as an extra dish.

Fig.5. Cake Basket with feet formed of satyr masks and terminating in scrolls, the sides of the basket being pierced and engraved; London mark, dating from 1739.

Silver baskets, which were and are used for holding bread, cake and fruit, form a popular class of silverware. Bread baskets date from the 17th century, the earliest being without feet or handles. In the 18th century occasionally handles were on either side. The example illustrated in Fig. 5 is on feet formed of satyr masks and terminating in scrolls. The handle has caryatid supports, the sides of the basket are pierced and engraved with fruit and conventional scrolls. It was made in London and dates from 1739. Later these baskets took the form of an oval tray on a short stem, and a shaped foot. For these piercing was a usual kind of decoration, and chasing was occasionally combined with it.

Sugar basins, known at one time as sugar baskets, fall into the same category. The earliest were quite plain, but later they were embossed and fluted, and later still piercing and other decorative effects were introduced. A glass lining was essential for the pierced pieces, which have often a foot and a bale handle. Others have feet of the ball, lion's paw, or ball and claw pattern.

Sugar basins, known at one time as sugar baskets, fall into the same category. The earliest were quite plain, but later they were embossed and fluted, and later still piercing and other decorative effects were introduced. A glass lining was essential for the pierced pieces, which have often a foot and a bale handle. Others have feet of the ball, lion's paw, or ball and claw pattern.

Castors and Condiment Sets. Sugar was also placed for use in castors or dredgers, of which there exist some charming examples of 18th century work. These castors were made in a variety of shapes. The body, for instance, may be straight or cylindrical, oval or octagonal. Others are shaped like a vase with a bulge just above a short stem. The top or dome was at first quite small, but in time

it became larger and was ornamented in a variety of ways, some pieces very elaborately indeed. This ornamentation took the form, in addition to graceful and regular patterns for the holes, of chasing, engraving and embossing.

Castors of this kind were not used for sugar only. They are very often seen in sets of three, the largest being for sugar and the two smaller, which are equal in size, for pepper, white and black. Vessels in which pepper was contained were known not only as castors or dredgers, but as muffineers. Salt cellars succeeded the big trencher or bell-shaped salts which usually stood in the middle of the dining table. The bell salts which were made from 1590 to 1613 were made in 3 tiers, the 2 lower having the receptacle for salt and the top one being pierced for pepper. Early examples of salt cellars date from William III, when they were circular in shape and supported on feet, and also in the same shape from Queen Anne's day. Afterwards they became fashionable in oval, octagonal, and, at the end of the 18th century, in boat shapes.

Mustard pots in silver date from about the middle of the 18th century. The majority of examples are glass lined and agree in styles with the salt cellars of the same periods. Oil and vinegar frames usually have a flat tray on ball or claw feet, with ring frames for two silver mounted bottles. Soy frames were similar in construction. There are two distinct types of 18th century cruets. The boatshaped tray with end handles, and the frame with a central lifting handle and the cut out plate fastened to the handle for the purpose of supporting the bottles.

Other beautiful pieces besides spoons, forks, etc., connected with table service and which are copied to-day include butter dishes, tea caddies and canisters, chafing dishes, sweet dishes, coasters or decanter stands, and a variety of candlesticks. There are also a large number of trays and salvers, the former dating from Commonwealth times. A George II salver is illustrated in Fig. 6, having finely moulded edges: other types have borders decorated with gadroon ornament, or relieved with raised scrolls, masks and foliage designs.

Fig. 6. Silver salver with moulded border and engraved centre ornament, dating from 1730. (Courtesy of Chapple & Mantell)

Many handsome silver articles were made for other domestic purposes, such as the writing table accessories, including inkstands with taper holders or wax jacks, sand bottles and wafer boxes. There were also candle snuffers on trays and all the toilet service pieces, such as silver framed mirrors, mounted bottles, pomade boxes, vinaigrettes and a variety of snuff boxes in silver.

By the practical worker and by the student in decoration and antiques much can be learned from the electro-type reproductions in the Victoria and Albert Museum, South Kensington, and from the manuals and handbooks published by the museum authorities.

But besides these there are many books dealing with the silversmith's craft and particularly with hall marks.

Hall Marks. In the early days of the guilds, when pride in the work done was the rule and good work was insisted upon by the master, it became necessary to have a mark which was a ready means for the identification of the worker. To this was added a place mark to show the town of origin, a date mark to show the year of manufacture and a quality mark as a guarantee of the quality of metal used.

Of all the old English silver still in existence nine-tenths at least bear the mark of the Goldsmiths' Hall in London. The symbols used in London for gold are the carat mark, which is 22, 18, 15·625, 12·5, or 9·375: the standard mark, a crown, which is placed on the 22 or 18 carat standard only the town mark, a leopard's head, crowned until 1823, but uncrowned since; the date letter; and the makers' mark, usually their initials, and always impressed by themselves. On silver the sterling standard of 925 parts, or 11 oz. 2 dwt. out of 12 oz., is denoted by a lion passant instead of the crown. The higher standard of 958 parts, or 11½ oz. out of 12 oz., which was the compulsory minimum for plate from 1697 to 1720, and is still permissible, is distinguished by a figure of Britannia and a lion's head erased instead of the lion passant and the leopard's head. This so-called new standard is not, however, marked in Ireland.

London hall marks from 1300 to present day.

The standard marks at Birmingham and Chester, as well as for Sheffield silver, are the same as above. Edinburgh and Glasgow replace the crown and the silver marks by a thistle and a lion rampant respectively, although since 1914 Glasgow also uses the thistle alternatively. The lower gold standards in Scotland are 15, 12, and 9. In Dublin the 22-carat gold and the silver standard have a crowned harp, the 18-carat a unicorn's head, and there is an intermediate 20-carat Irish standard, with a plume of feathers.

The present provincial town marks, and their earliest dates, are: Birmingham, anchor, 1773; Chester, sword and three sheaves, 1701; Sheffield, crown, 1773; Edinburgh, castle, 1457; Glasgow, tree, fish, and bell, 1819; Dublin, Hibernia, 1638. The London date mark is indicated by the letters A to U, omitting J, each cycle of 20

years being distinguished by the style of the letter and the shape of the shield. From 1438 to 1558 there were 7 cycles, during which the shields followed the outline of the letter. From 1558 to 1738 the shields resembled a rectangle on a triangular base. After 1738 the shield's base was usually curved to a cusped point at the middle.

Method of stamping hall marks.

STANDARD		DUTY MARK
 1300-1697	 1544-1697	 1784 1786 1786 1820
 1697 TO 1720		 1821 TO 1830
 1721 TO 1822		 1831 TO 1836
 Since 1822		 1837 TO 1895

In the 1876-1895 cycle the shield's chief was a double concave line, and since 1896 the shields have had three lobes to the base. The cycle now in operation runs to the year 1935.

The date-letters of the provincial offices are in different styles, shields, and cycles. They are 25-year cycles at Birmingham, Edinburgh, and Dublin, and 25-year alternating with 20-year cycles at Chester and Sheffield, J being invariably omitted. The only 26-year cycle is at Glasgow.

Silver. Standard hall marks of the provincial offices, both closed and active, are given, in addition to the London hall marks shown above. (Courtesy of Herbert Jenkins. Ltd.)

Care of Silver. The best kinds of modern silver are simple in design and rely for beauty on graceful shape and fine workmanship. Most of the plain classical types of table silver are copied, but very highly decorated designs are considered unsuitable for two reasons: they are not strictly hygienic owing to the difficulty of removing particles of food from the interstices, and they take too long to clean. The price of modern silver articles varies in a way out of all proportion to the intrinsic value of the metal used and is almost entirely dependent on quality of design and workmanship.

For cleaning purposes some housewives prefer rouge, which is used by jewellers, and mixed with water containing ammonia it is a good cleanser. Others may prefer jeweller's soap, which gives most excellent results. Some, again, put their faith in plate powders, while others always use polishing fluids.

A good cleansing agent is precipitated chalk, and the finer the better, applied with ammonia and water, or with sal volatile if expense is not to be considered. Do not use whiting as it is sold in the rough, but either precipitate the chalk or buy it ready-made. After cleaning remove all traces of the rouge, paste, chalk, or other cleaning and polishing medium by means of a brush.

It is a popular fallacy that washing has an injurious effect upon silver, causing it to become discoloured and destroying its polish. The truth is, however, that if silver is to be kept in good condition, it should be washed immediately after use, and then cleaned in the usual way. Warm soapy water, to which a little ammonia has been added, should be used. If rubbing is necessary, choose a soft sponge small enough to be passed inside the necks of jugs, etc.

Filigree silver is sometimes difficult to clean because dust collects in the crevices and seldom yields to sponging. For this an old toothbrush will be found effective. The bristles should be fairly stiff, but not hard enough to produce scratches. Silver ware should be dried thoroughly after it is washed, and if it does not require cleaning rub it well with a chamois leather. This will restore its polish.

Silver inkstands that are disfigured by ink splashes of long standing are sometimes difficult to clean, though stains that receive early attention can always be washed away with hot soapy water. A paste made from water and chloride of lime is often effective in obstinate cases. It should be applied with a soft rag, and allowed to dry on the stains before being rubbed off.

The storing of food in silver utensils is never attended with risks, because silver, unlike copper and brass, is a metal that is not acted upon by food acids.

When not in use, silver cutlery is best stored in a large piece of baize. Each knife, fork, and spoon should be rolled up separately, and the baize then tied securely with string or tape. This method of storage keeps out the air and thus obviates the need for constant polishing.

If silver has to be repaired it must go to a working silversmith, not to an ironmonger. Silver will stand a vast amount of hard usage, and in repairs it will stand the fire necessary for hard soldering. If silver has once been soft soldered and later on requires repair with hard solder, all traces of the previous soft solder repair must be removed. Repair can be done quite easily by a qualified silversmith, and good silver should on no account be entrusted to anyone else.

SILVER BEET. Also called seakale beet, this is a vegetable of striking appearance, grown for the sake of its edible stems and midribs, which are cooked in the same way as seakale, and for the leaves which are treated as spinach. It is raised from seeds sown out of doors in April and May. *See* Seakale; Spinach.

SILVER BELL TREE. The snowdrop or silver bell tree, of the family Halesia, is one of the most beautiful of summer-leaving trees when in bloom, its white flowers bearing a marked resemblance to snowdrops. It does not often attain a greater height than 15 ft. It is therefore suitable for a small shrubbery, or for a lawn. The best kind of this tree is *Halesia tetraptera*.

SILVER FOX. Perhaps the most expensive of all fox furs, silver fox derives its name from the long silvery white hairs that provide such an attractive contrast to its rich, glossy black coat. In firmness it is unequalled, yet it has a remarkable softness that gives it a foremost place among good furs. *See* Fur.

SILVERING: Of Mirrors. In the production of mirrors one surface of the glass is coated with a mixture of silver, and this process is known as silvering.

A method that should give satisfactory results is as follows: Prepare a solution of nitrate of silver in the proportions of 90 gr. of the silver to 4 oz. of distilled water. Prepare a solution of pure caustic potash in the proportions of 1 oz. of potash to 25 oz. of distilled water, and a third solution consisting of 1 oz. of milk sugar in powder form to 11 oz. of distilled water.

The half of the first solution is placed in a clean tumbler or other glass vessel, and pure ammonia (sp. g. 0·880) added to it very slowly, drop by drop, until the precipitate is just dissolved. Twice the quantity of the second solution is added, and ammonia again added to the solution until it just becomes clear. It is then further diluted with distilled water, the proportions being 1½ times that of the combined solution. The next step is to add gradually some of the first solution until a slight grey precipitate is formed which does not redissolve. It is then allowed to settle, and after that some of the third solution is added and well stirred.

The plate glass to be silvered has now to be properly cleaned. This can be done by washing in a solution of ammonia water, following this by washing in a solution of hydrochloric acid, in the proportions of 1 part of the acid to 100 parts of distilled water. The glass is then rinsed, dried, and polished with a perfectly clean cloth. The plate must now be placed on a dish and carefully levelled until the surface of the glass is perfectly flat and horizontal when the solution is poured very gently on to the glass so that it will cover the whole plate.

The operation must be carried out in a warm room, which must be quite free from dust, and the glass allowed to remain for several hours. At the end of that time the solution is poured off the plate, the latter again set level, and a fresh supply of solution poured upon it, and left there until the silver has deposited. The plate is well rinsed in distilled water and set aside to dry. It is then given a coat of varnish, following this by a coat of good paint made up from finely ground red lead and a little turpentine.

Every vessel used for the solutions for the separate steps in the various processes must be chemically clean, and the processes carried out in a cleanly manner.

SILVER LEAF: The Disease. This malady attacks plum trees chiefly, but several other fruit trees, as well as laurel and some other shrubs, are liable to it. There is no cure, and diseased branches should be cut off and burnt. Silver leaf is easily recognized by the silver-grey colour of the leaves. The Victoria plum is particularly liable to this disease. The law requires all dead branches on diseased trees to be cut off and burnt in summer. The disease is believed to make more rapid headway on heavy soils and in damp situations. Any improvement, therefore, in the drainage of an orchard will help the trees.

SILVERSIDE: Of Beef. That portion of the round of beef which is known as the silverside is considered, when salted, to be a prime boiling joint; it is also economical, as there is little bone and practically no fat attached to it. The round is divided into two, cut downward, one part being called the topside and the other part the silverside; but the latter is most usually salted or pickled. Silverside also may be boiled, braized or stewed without salting, and sometimes it is roasted. It is usual to obtain it ready pickled from the butcher, but it may be prepared at home by directions given for salting, and will take about 10 days to pickle properly.

When about to cook, wash the meat free from brine, wipe and weigh it, but if it appears very salt when sent home it is better to soak it for an hour in cold or tepid water, changing the water several times. If too much salt is left in the meat it will be hard when cooked and the liquor from it will be unfit for culinary purposes. This liquor, if strained off, makes very good stock for pea or lentil soup. The butcher should skewer the silverside together neatly, adding a small lump of fat. The skewers must be removed when dishing the meat. It must be carved in very thin slices, a small piece of fat being served with the lean. *See Beef; Salting.*

SILVER WEDDING. This term is used for the 25th anniversary of a wedding day. It has become a custom that the presents given on such occasions shall be of silver.

SILVER WORK FOR THE AMATEUR

Ornaments for the Home and for Personal Adornment

The metal worker who is interested in this subject should turn to the articles in this work under the general heading of Metal; also to Drilling; Riveting; Soldering; Wire. Those on Bowl; Spoon and other articles made may also be consulted, while kindred operations are described under Enamelling; Repoussé, etc.

The working of silver, as dealt with in this article, falls into three main divisions. The first is confined to the manipulation of the flat metal and includes riveting, silver soldering, repoussé, and chasing. The second deals with beaten work, such as the shaping of bowls and other round shapes worked from the flat metal. Another form of silver work comprises the use of the metal when it has been drawn out in the form of wire in any section. It can also be cast and used with enamel, but these operations are beyond the scope of the present article.

Silver is generally sold by the oz. and measured by the metal gauge, but the thicknesses mentioned will be in S.W.G., and it should be obtained rolled ready for use from a silversmith, or a dealer in art metal working materials. The various tools required for each stage are enumerated as they are required, and the essential ones are illustrated.

Silver Work. Fig. 1. Piece of silver marked out for making a simply designed cigarette box: A, base and sides; B, top; C, angle pieces. Fig. 2. A, bending up sides on hardwood block; B, edge of back turned over steel plate; C, round closed over steel rod; D, corner piece; E, lid; F, edges of lid folded back; G, sectional view of edge turned over steel rod; H, cuts made for hinge; J, box ready for lid.

Fig. 1

Fig. 2

Above. Fig. 3. Two silver pin bowls which can be made by following the instructions given here. A shaping block is also shown.

A Cigarette Box. A simple piece of work for the beginner might consist of a cigarette box, with corner angle-plates forming feet and a hinged lid. Suitable gauge is 20 S.W.G., and a piece measuring $9\frac{1}{2}$ in. by 7 in. will be sufficient for the whole of the box. Mark out the piece of metal as in Fig. 1. A forms the base and sides, B the top, and C the angle-pieces. The small squares surrounding A are waste, but they will be found useful for making various small articles. The parts are cut apart with a pair of shears and the edges trued up with a file. The next step is to bend up the sides on a hardwood block, as in Fig. 2, A, fitted in the vice or firmly attached to a table, using a mallet and working very lightly so as not to bruise the metal. The back is

turned over on a piece of steel measuring $\frac{1}{8}$ in. thick, as at B, the top edge being rounded and made perfectly smooth with emery cloth.

Having folded the metal on to the face of the stake, place a length of $\frac{1}{8}$ in. steel rod in the hollow and carry the metal around it to close it in, as in C. The corner pieces are bent in the centre at right angles, as at D, and the holes for the rivets drilled. These pieces are placed in position one at a time, the holes marked through and corresponding holes drilled in the sides.

The lid is cut to the shape shown at E, and the edges first turned over at right angles and then folded over quite flat, as at F. The back projection is turned over on the narrow stake and the round completed as at G, in the same way as the bottom. The two rounded portions are placed together to mark out the cuts to form the hinge; these are then made with a piercing saw, as at H and J, and trued up with a file. A length of brass or copper wire is then cut to the length of the side and fitted in.

If the hinge work has been neatly done there is no need to solder the round in a small piece of work, but in making a larger casket on similar lines it is safer to solder the joint, especially with a heavy lid. Considerable variety is possible in the design of small boxes, and a pleasing effect is to use hinges (either pierced or in repoussé) soldered or riveted to the lid and back. Hairpin boxes jewel caskets, and stamp boxes are suggestions for this type of work.

Hollow Work. The second division in silver working is that of forming bowl shapes from the flat metal, and this can be done by three distinct methods. The commonest is that of forming the shape by beating it into a depression on a block of wood, or over the edge of a block. The simplest article to commence with is a pin bowl, as in Fig. 3, made from a piece of 18 S.W.G. silver from 1 in. to 4 in. in diameter. With a compass draw the size of the base inside a 4 in. circle: it should be about 2 in. in diameter leaving 1 in. all round to form the sides. Next provide a stake of the necessary shape (Fig. 3). This is made from a piece of hardwood about 3 in. square and 6 in. long. Place the block upright in the vice, mark a 2 in. diameter circle in the centre, and then with a gouge cut out a concave depression to a depth of $\frac{1}{2}$ in., finishing the hollow as smoothly as possible.

Fig. 4. Blocking hammer being used on a hollow block.

Silver Work. Fig. 5. Tools necessary for making the silver pin bowls shown in the previous page, and for other hollow work.

Place the metal over the depression on the block, and, as shown in Fig. 4, beat down the metal into the hollow with the ball end of the hammer, or with a bossing mallet (A, Fig. 6). These tools are shown in Fig. 5. A series of blows should be struck all round the metal, and the result will be as shown at B, Fig. 6. The bowl is tilted up a little as at C, and another round of blows is given; this will bring the sides up higher, as at D. The next stage is similar with the bowl still higher, as at E, and when this round is complete the sides should be nearly upright, as at F, and it will be somewhat difficult to proceed further with the hammer. The final stage calls for

the use of a stake: but as this is rather expensive, the beginner will find the round end of a poker quite as good for small work. Before the final shaping is done the silver must be annealed by placing it on top of a shallow bowl filled with charcoal or small coke, and playing a blow pipe flame over it until it is red hot. The alternative is to place the bowl over a gas flame, but the greatest care must be taken not to overheat the metal. A good earthenware bowl should be provided to hold the pickle of equal parts of sulphuric acid and water, and the annealed metal is then dipped in it and left until it becomes frosty white, when it is washed and dried in sawdust.

Silver Work. Fig. 6. Various processes in making bowls: A, beating hollow in metal with bossing mallet; B, result of striking a series of blows round the metal; C, bowl tilted for another round of blows; D, result of second round; E, third round of blows; F, its result, sides nearly upright; G, beating edge round a poker head; H, resulting shape; J, shape with out-turned edge; K, method of turning edge; L, out-turned edge flattened; M and N, methods of forming a fluted edge; O, notched block for fluted edge; P, panelled shape achieved by flattening rounded sides.

The bowl is now placed on an appropriately shaped stake and the edge beaten over, or the same process followed with the poker head, as at G, Fig. 6, and this will result in the shape as at H.

Planishing. The bowl at this stage should be quite even in shape, but to give it the desired finish, the surface must be planished after being again annealed. A stake is almost a necessity if the planishing is to be done in a workmanlike manner, but if a conical shaped poker head can be obtained and the end filed off, it will be possible to get close to the inside corner. The regular and even hammer marks on handmade silver work give it a beauty and charm that is impossible to produce in any other way: but the real effect of the planishing is to true up the surface and stiffen the shape. It is possible to spoil the work with careless planishing, the hammer blows must be

evenly spaced and weighted, and if the hammering is heavier in one part than another the bowl will be uneven and difficult to true up.

Another method of forming a bowl requires no other tools than a hammer or mallet and an anvil, or very hard wooden block. It is done by placing the metal on the anvil and, commencing in the centre, hammering in concentric circles to the outside. The success of this method depends on accurate hammer work. Full directions are given in the article on Bowl (q.v.), where the shaping of a copper one is illustrated.

Fig. 7. Using the raising hammer in coursing.

Once having worked out a simple bowl shape by either of the above methods, it will not be difficult to form this into other shapes. It is just as easy to turn the edges out as in. For example, the shape at J, Fig. 6, can be worked on a stake as at K, and the edge flattened out as at L by hammering the edge on a bick iron. Fluted forms can be formed by using a raising hammer as at M and N, on a notched block as at O and panelled shapes can be worked by flattening the round sides as at P.

Fig. 8. Shape for a vase, shown in section, which can be made from a circular piece of silver.

Coursing. This process consists of hammering the metal against a stake, as shown in Fig. 7. The metal is held in contact with the stake about 1 in. below where the hammer is struck in order that the metal is hammered on to the stake. To make the shape shown in the section at Fig. 8, a piece of 16 S.W.G silver should be cut in a circle a little larger than the contour of the section, as shown by the dotted lines. Next draw a number of concentric circles commencing 1 in. from the centre, each one increasing in radius to the outside, in order to guide the hammer blows. The metal is now beaten into a rough bow shape with a mallet, by driving it into a hollow stake. The stake shown in Fig. 7 is then fixed in the vice, and the hammering commenced, the blows being carried completely round; a second course follows $\frac{1}{2}$ in. higher up; and each succeeding course is followed out in the same way as before.

The metal has a tendency to work into wrinkles. These must not be allowed to increase in size, but must be flattened out at once; if these wrinkles are allowed to form it is probable that the work will split at that point. The advantage of this form of shaping is that all kinds of shapes can be beaten out, but owing to the initial difficulties and the expense of silver compared with copper, the beginner will be well advised to undertake some preliminary raising with the latter metal. A selection of suitable tools is shown in Fig. 9. The necessity of frequent annealing must not be forgotten.

Soldering. The worker cannot advance very far without silver soldering. This requires the use of a blow pipe and a spirit lamp. A small piece of work suitable for a first attempt is a napkin ring which has been made up from the flat and has to be joined.

Silver Work. Fig.9. Tools used in the process known as raising. (Courtesy of C. J. Plucknett & Co., Ltd.)

The method of using the mouth blow pipe is as follows. The portions surrounding the joints are freshly scraped or filed, fixed in place with binding wire, and touched with borax, which is rubbed down with a little water, and applied in the

form of a thick cream. Small snippets of silver solder are placed close up to the joint, which is now ready for the application of the flame.

The lamp flame is directed around the work first to warm it, and presently the borax will boil up and then run into a fluid state, carrying with it the solder. The parts to be united must be kept in close contact till the work has cooled. *See Soldering.*

SIMMERING. The cookery term simmering consists in keeping any liquid in a heated condition just below and never actually reaching boiling point.

SIMNEL CAKE. This cake, eaten in Lent, is made by creaming 6 oz. each butter and sugar and then beating in four eggs, adding each one separately. Mix in 9 oz. flour, 1 lb. cleaned currants, 5 oz. mixed chopped peel, 2 oz. shredded almonds, and $\frac{1}{2}$ teaspoonful mixed spice. Lastly, add 1 tablespoonful milk.

Turn the mixture into a tin lined with buttered paper, and bake it in a moderate oven for about 2 hours. Leave it to cool on a sieve, and when it is cold cut it into two rounds. Divide $\frac{3}{4}$ lb. of almond paste into two, roll it into two rounds of the same size as the cake, put one round between the pieces of cake and lay the other on top. Mark a trellis pattern on the latter, brush it over with beaten egg, and put it into the oven so that it may become lightly browned. *See Almond Paste.*

SINGEING: In Cookery. Poultry and game are singed, after being plucked, in order to remove long hairs and down without risk of tearing the skin. Singeing is best done with a long, loose spill of white kitchen paper. The bird is held in the left hand by the scaly part of the legs, and the lighted paper is applied quickly and just long enough to burn off the hairs. The bird is then wiped free from any particles of paper. Pigs are singed after scalding to remove long hairs or bristles.

SINGING GAMES. The traditional singing games are still popular among small children, and are hard to beat for charm and variety. They have also a distinct educational value, combining singing, dancing, and rhythmic movement.

A pretty entertainment may be given by children of from four to ten years of age simply by the joyous performance of a dozen or so of these games. They involve little rehearsal, since the effect would be largely spoiled by a lack of spontaneity, but the organizer of the entertainment should be careful that the children know the correct tunes and that the games are played with the proper actions. If all the small players are dressed in similar costumes, such as the Kate Greenaway style, the effect will be doubly charming. Books can be obtained which offer a large choice of these

games, giving the music and describing the actions. Some of these singing games will be found under their own headings in this work, e.g. Nuts in May.

SINK. In every house the sink is a necessary sanitary fitting, whether in the scullery or the kitchen, for the cleansing of domestic utensils and other purposes. One of the best and most serviceable sinks to use in the small house is made of glazed stoneware. The deep pattern has many advantages over the shallow one, and is usually fitted with a washer and plug, so that the sink itself can be filled with water for washing up purposes.

Sink Brush. The brush used for cleaning a sink is usually flat with rounded end set with stiff bass knots and a short handle. The knots should be drawn in with wire, as hot water would melt the pitch if they were stuck in. Bass does not depreciate by use in water, and the open spread of this material in a sink brush enables it to be kept free from the waste which is prevented from going down the sink drain. *See* Brush; Draining Board; Drains; Gas; Kitchen; Scullery; Washing Up.

SIRLOIN: Of Beef. The sirloin is that portion of the ribs which lies between the rump and the wing, or fore-ribs. It corresponds in position to the loin in a carcass of mutton. Sirloin is a prime roasting joint and should be cooked with the bone left in it. If it is boned the flavour will be spoilt. Attached to the rib bone underneath is a very delicate portion of flesh called the undercut or fillet. This part is better eaten hot, and should always be carved off first. It should be cut down to the bone in slices, about $\frac{1}{4}$ in. thick, but the slices carved from the top portion of the joint must be as thin as possible. *See* Baking; Beef; Carving.

Sisyrinchium. *See* Satin Flower.

SITTING-ROOMS AND THEIR FURNISHING

Distinctive Ideas for the Odd Reception Room

Suggestions for the arrangement of family reception rooms are given in the articles on Dining Room; Drawing Room; Living-Room; Lounge. Readers are also referred to the entries on Attic; Colour; Cottage; Decoration; Flat; Fireplace; Furniture; House; Panelling; Rugs.

Sitting-room. Fig. 1. Comfortably furnished sitting-room with charming tiled fireplace and built-in bookcases. The floral design of the loose covers unites the colour scheme of the room. (Humphrey & Vera Joel)

In many houses there is a room which is furnished as an odd sitting-room with a jumble of pieces which have seen better days and no particular colour scheme to bring them into harmony. Sometimes this room is called a morning- or breakfast-room, and is in the basement or semi-basement next to the kitchen and on a level with the garden. Such a room usually possesses a window with charming possibilities, and this can often be taken as a starting-point for the housewife's plans for redecoration. These plans can be quite inexpensive if carried out with a sense of colour and good taste. In other cases the room is upstairs and perhaps is chiefly used by one individual or by the younger members of the household.

To begin with, take the basement or ground-floor back room as an example. Even if there is a pleasant view into the garden, such a room is unlikely to be well lit, especially in the winter, and it is therefore necessary to keep walls and ceiling a pale colour and have bright accessories such as a mirror over the fireplace or opposite the window, one or two pieces of lacquered brass or copper, and some pale tinted or white glazed pottery to reflect or catch the light. In a small room the plainer the wall surface the better, but distempered walls will not have the same durability of surface as a faintly marbled or patterned paper.

An inexpensive oriental carpet is a good choice for such a room, as it can be obtained in bright, light colourings which at the same time do not show marks. In a small room a dark fawn shade of hair carpet and wool handworked rugs, designed in colours to match those in the cretonne selected for the window curtains, will prove a delightful scheme with beige or old ivory ground to the wallpaper and faint pink or ivory washed ceiling.

A window seat upholstered in the same cretonne as the curtains is attractive where there is a bow window. A boxpleated or gathered valance for both seat and curtains is the appropriate finish. Glass curtains are not always necessary, especially when the ground of the practical curtains is light in colour. If required, inner curtains may be made of a plain cream net with a border of stripes needle-run with wools to match the colours of the patterned rugs and hangings. Such a border gives a distinctive note, which can be also picked up in the stencilled patterns on imitation vellum lampshades and on hand-painted washable door plates of a cellulose composition. These latter items are obtainable for a few shillings each. A still better idea is to paint designs copied from those on the cretonne curtains, on the back of plain glass door plates. It is these small things which count so much in interior decoration.

With regard to the style of the furniture, having surrounded it with such an agreeable setting, it really does not matter vitally in a room of this type. Naturally it is nicer if of good simple design and excellent workmanship, but with the absence of drab accessories and in particular of all ornaments which do not give or reflect light or enrich colour, and the resolute banning of rubbish, the room will be both homely and charming. Wicker or cane chairs should be enamelled the same colour that is chosen for the woodwork of the room, or, if this is stained brown then to match the ground of the carpet. Upholstered Victorian chairs are best given loose covers. If new small chairs have to be bought, those with ladder backs and rush seats have much to commend them as they are neither old nor modern in style and harmonize with other furniture of odd periods and with cretonne, linen or chintz hangings.

In a typical upstairs town sitting-room of medium height and about 12 ft. square, perhaps a feature which has to be reckoned with might be the sitting-room tiles. These may be, for example, leaf-green, the woodwork and mantelpiece being already enamelled the usual ivory shade. In order to achieve brightness, height and warmth in a room with a cold aspect, the walls could be painted a pinky beige and the ceiling distempered the same colour.

The floorboards are best stained oak-brown and wax polished. The carpet might have a darker brown ground and be unobtrusively patterned in beige. Brown furnishing satin or velvet would be used for the curtains, lined with fadeless green poplin, while the glass curtains would be of string-coloured net. A printed linen or glazed chintz chosen for the loose covers should have a leaf-green ground and be patterned with dull pinks, lavender and soft yellow. Plain cushions should repeat the darker notes of colour.

A charming sitting-room of this type is shown in Fig. 1. Good use has been made of the recesses on either side of the chimney breast by fitting them with bookshelves. The modern weathered oak writing-table and chair have nothing eccentric about their style. They would accord perfectly with any other plain pieces suitable in such a room. An alternative to the settee would be a well-upholstered divan, covered in plain brown velvet or furnishing rep, measuring 6 ft. by 3 ft., raised from the floor on a strong frame and piled with cushions against the wall. The cushions would repeat the colours of the patterned material used for the loose covers of the chairs. Three-piece suites are not to be had cheaply; they are not wise investments unless the frames are strong and well upholstered. Single armchairs can sometimes be picked up in reliable qualities for a comparatively low price at an auction sale.

For the same kind of room, but with a sunny aspect, the scheme could be worked out with pale green walls ivory-washed ceiling, and furnishing fabrics of different shades of grey with a printed linen having a brightly coloured conventional pattern in clear tones of lemon-yellow, coral, black fight blue and green on a grey ground.

Sitting-room. Fig. 2. Restful country sitting-room blending the old world with the new by the use of a few unobtrusively modern pieces of furniture. (Humphrey & Vera Joel)

Individual Tastes. In some cases a sitting-room can be decorated and arranged according to individual requirements. A pleasant room for one musically inclined is illustrated in Fig. 2.

This is in a country house, and the walls and ceiling are of parchment colour which enhances the overhead oak beams. There are two rounded niches which have been fitted with bookshelves, a delightful window with simple curtains which could be of velvet to tone with the plain carpet. There is a thoroughly comfortable chair for a privileged listener, an old oak chest and a modern oak writing-table, but otherwise the room is rest-fully empty of unnecessary furniture, and there are no pictures. Colour is supplied by the books, flowers and the garden view. In such a room the mantelshelf should not be overcrowded. A bit of coloured glass, an old spode or lustre dish or jug, or a pottery figure piece, to break the fine against the wall, are a good choice; there should be no small ornaments or fussy details to the furnishing accessories.

Our third illustration is of a delightful sitting-room particularly suitable for a man. The walls have a panelled effect obtained by applying moulded strips of wood on panel boards. The plain frieze and ceiling are cream washed. A specially good feature is the use made of a recess for a built-in

bookcase and cupboard with mirror glass door, a smaller cupboard and spaces for gramophone, etc., being fitted below. The brick fireplace with its pattern of mellow colour against the woodwork is enhanced by the white pottery book ends and jar. The fire is a gas one made to simulate glowing logs. The low book table suits the height of the chairs, which are most sensibly and attractively covered, one in velvet and the other in a furnishing oil baize. At the opposite end of the room (not seen in the photograph) is a beautifully made leather-topped writing-table designed on square, modern lines and an equally suitable modern cabinet with a drawer under the cupboard.

Fig. 3. Sitting-room for a man, with thoroughly comfortable chairs, charming brick fireplace and attractive built-in cupboards flanked with bookshelves. (Humphrey & Vera Joel)

Such a room suggests a colour scheme completing the harmony of tones in the woodwork and brick fireplace. To carpet it all over in brown velvet pile would look most comfortable and suitable at first, but would not be good in wear owing to marks from cigarette ash and footmarks.

The oriental carpet, or woven geometrically patterned rugs, would be again the best choice in subdued shades with a good deal of rust, dull reds and browns in their colouring. A fine shade of red that is between rust and crimson, which is particularly good in velvet, might be used for the curtains, and one of the armchairs might be covered in this fabric, while brown would be used for the other chairs. Instead of velvet, quite an excellent furnishing material is a fairly close-woven tweed. A flecked brown, beige and red mixture, piped with plain brown, would be most practical, comfortable and effective for covering the armchairs and for the window curtains. The last should be lined with fadeless brown casement cloth.

If linen or cretonne curtains are preferred they should have conventional patterns; either a checked or geometrical design of reds, browns, greens and wine colour on a beige ground would be suitable. Another good fabric for covering the chairs would be plain and checked mohair. An effective style with this material would be to use a plaid mixture of brown and tan for the seats of the chairs and a plain brown for the back and cushion. Alternatively a plaid mohair could be used entirely to cover one chair and a plain mohair to cover the other. The ground of the plaid must match the plain fabric in colour.

SIZE. Size is a glutinous substance commonly made from the parings of leather, hoofs, parchment, etc., after prolonged boiling in water, and purification by straining. It may also be made from common glue and potatoes. Painters use size in connexion with various kinds of work. Before a wood floor is varnished it should be sized, the size stopping up the pores of the wood and thus allowing an easy and economical application of the varnish.

Size is generally a constituent of good distempers; it has an adhesive effect upon the distemper after it is applied to the walls or ceilings of a building. Size may be purchased from any colour merchant in kegs; it is then in a jelly or viscous state; but it may also be obtained in a concentrated form in

small packets. To render it fit for use it is dissolved by boiling water and applied hot with a brush. Wallpapers are sometimes sized so as to obtain a smooth surface for the varnish. *See* Painting; Paperhanging.

SKATE: How to Cook. Skate should be kept at least one day, and should not be eaten directly after it is caught, but it must never be taken out of season, and is better in the late autumn and winter. The time for it is from August to the following April. It is advisable to buy this fish ready dressed from the fishmonger, as it is a difficult process to crimp it, and even if the fish is to be boiled whole it will need to be skinned both sides. The liver is usually removed and made into sauce, or served with the fish as a garnish. The directions given for crimping and cooking ray may be followed for skate. The wings or fins of the skate may be made into a breakfast dish. Dry the wings of a large skate, skin them, and cut them into fingers, then blanch them. Put the pieces on a tin and cook them in a moderate oven till quite tender. Then draw out the bones and rub the flesh through a sieve. Melt 3 oz. butter in a stewpan, add the fish, lemon juice, grated nutmeg, pepper and salt, mix well and dish on buttered toast cut into squares. Pour round it a thick egg sauce. Skate when crimped may be served with some piquant sauce. *See* Fish; Ray; Sauce.

SKATES: Their Care. For use on ice the skate is made with a steel blade secured to metal plates or a wooden block for attaching to the boot. The cheaper kinds are those with a wooden block, with straps in front and at the back, and a screw for the heel; they are suitable for children and beginners. To-day in Great Britain most of the skating is done on rink ice and takes the form of figure skating. Skating on natural ice is only available as a rule for two or three days in the year and sometimes not at all, except perhaps in the north of Scotland. Many persons, however, go to Switzerland or other countries where during the season there is natural ice in abundance, but there, too, figure skating is the more popular form.

Types of Skates. Of figure skating there exist two main schools, called the international and the English, and for each there is a particular kind of skate. A good skate of the international type is the Salchow-Meyer, seen in Fig. 1. This has a serrated toe and a narrow blade, which is hollow ground, the depth of the grinding varying with the condition of the ice, as natural ice needs a sharper edge than does rink ice. The point of this skate should touch the boot. The Acme has straps and expanding clamps to clip heel and sole.

For the English school of skating a good type of skate is the Club (Fig. 2). This is a skate with a broad obtuse-angled blade slightly hollow ground to a radius of 7 ft. for sizes up to 11 in. and 8 ft. for anything larger. It is the official skate of the English school and is sold in sizes from 9½ in. to 12½ in. Another good skate of the same kind is the Mount Charles, which is generally used for figure skating.

The Criterion (Fig. 3) is a good skate for skaters of the international school and it has the additional advantage of being made entirely of Sheffield steel. Somewhat heavier than the Salchow-Meyer, its footplates are bronzed, a feature which adds to its appearance. The fourth skate shown in the illustrations is the Junior (Fig. 4), one made specially for juniors and beginners. This is very near the ground and has no serrations on the toe.

For speed racing a different kind of skate is necessary. This is usually quite straight, lacking the curved end seen in most of the skates used for figure skating. The Ice King is a good example, but there are others.

Skates. Four kinds in general use. 1. Salchow-Meyer. 2. Club, official skate of the English school. 3. Criterion. 4. Junior, suitable for beginners. (Courtesy of Lillywhites, Ltd.)

Boots and Accessories. The skater's boots are important. Special boots are made and sold for skating, but ordinary laced ones can also be worn. They should, however, fit perfectly and should be provided with a moderately thick sole, flat straight heels and fairly stout uppers. They should fit tightly, but when they are first put on the ice it is advisable not to lace them up too tightly; the laces can be tightened after the first few minutes on the ice.

The skater should provide himself with covers for the blades of the skates. These may be of leather or rubber. The blades should be kept quite clean and should be covered with vaseline when not in use. The vaseline must be thoroughly well rubbed in, and a fairly thick coating left on. The screws and bolts must be taken out and thoroughly cleaned or they are liable to rust. Skates need grinding from time to time as the edges must be kept sharp. This can be done at home on an emery wheel or a grindstone, but many persons prefer to send them to the maker for this purpose. A skate sharpener that can be carried in the pocket is sold.

Skidding. *See* Motoring.

SKIMMER. This utensil is employed, as its name implies, to skim the fat from the top of soup, stews, etc., and also to remove the cream from milk when skimmed milk is required. It skims more quickly and thoroughly than, a spoon.

SKIMMIA. This hardy evergreen shrub is about 2 ft. high, and bears white flowers in summer and red fruits in autumn. Male and female flowers are on separate trees, and care must be taken to plant both kinds to ensure fruits. Fortunei, japonica and Foremannii are the best. These shrubs thrive in a mixture of loam and peat and should be planted in September or October or April. Propagation is most easily carried out by layering.

Skimmia japonica, a bushy plant bearing greenish-white flowers and, later, scarlet berries.

SKIM MILK. Milk from which the cream has been removed by skimming or separating is known as skim milk, and, although devoid of the natural fat possessed by new milk, it is used for many purposes in cookery. It makes good milk puddings if a small portion of finely chopped suet is added to enrich it, or it may be used in making batters, milk bread, biscuits, or cakes.

Despite the absence of natural fat, skim milk is a wholesome and strength-giving food, as it retains the casein, and a proportion of fat can always be added if desired. The finest variety of pork is that obtained from pigs which have been fed on skimmed or separated milk. *See* Cream; Milk; Separator.

SKIN: Its Care. The skin is tough and very elastic, so that it stretches when fat accumulates underneath and returns to its former state if the fat becomes reduced. As a person grows older this elastic property of the skin diminishes and causes wrinkles.

The skin consists of two layers, the cuticle without and the true skin within. The cuticle, also called the epidermis, or scarf skin, is sub-divided into layers; the outermost is the horny layer, while the innermost contains the pigment cells which give the skin its colour; the accumulation of this pigment causes freckles, chloasma, etc. The cells of the outer surface are continually wearing out and falling off. Blisters are accumulations of fluid under the outer layers of the cuticle, which have no nerves, so that the puncturing of a blister does not cause pain. Thickening of the cuticle takes place in a large number of skin diseases. Parts exposed to intermittent pressure may form callosities and corns. *See* Corn.

The cuticle, when undamaged, is impervious to water and microbes, but if abraded it admits microbes; some microbes and other fungi can thrive in its gland ducts and on its surface, giving rise to skin eruptions. The cuticle allows certain drugs to pass through when they are mixed with oils or fats and well rubbed in.

The dermis, also called the cutis vera, true skin, or corium, is very much thicker than the cuticle. It consists chiefly of interlacing fibres of connective tissue, together with bloodvessels, nerves, glands, etc. The glands are of two kinds, the sebaceous, or oil glands, and the sweat glands. The former manufacture an oily fluid which is poured out on the skin, and keeps it and the hairs soft and pliable.

The sweat glands consist of little tubes about $\frac{1}{4}$ in. long, coiled at the inner extremity and opening on the surface of the skin. The chief purpose of the sweat apparatus is to help to regulate body heat in the widely differing temperatures in which human beings live. The sweat glands are always active, pouring out water on the skin; this may evaporate at once, constituting what is called insensible perspiration; but when we go through exercise they become much more active, and the amount of sweat is greatly increased and forms sensible perspiration (q.v.). The same happens in hot weather or when one is in a warm room.

Certain conditions interfere with the function of the sweat glands. Thus on a damp, hot day the evaporation is checked, and we feel oppressed by the heat in consequence. Because it prevents evaporation, waterproof clothing is unhealthy. Alcohol increases both perspiration and the flow of blood to the skin. Consequently alcohol is a dangerous thing to take when one has to face extreme cold.

It is very necessary for health to promote the normal action of the skin by cleanliness, correct choice of clothing, and exercise. Many skin diseases arise partly from want of care of the skin. Coughs and colds, and diseases such as rheumatism, etc., find an easier victim in the person whose blood-vessels have no acquaintance with the tonic properties of cold baths.

There is no better means of preserving the elasticity and bloom of the skin than daily brisk exercise in the open air. Even more important is scrupulous cleanliness, not of the exposed parts alone, but of the whole body surface. For those in vigorous health a cold bath every morning and a warm bath once or twice a week are to be recommended. It is often recommended after the bath to rub the skin vigorously with a rough towel. This measure, however, may cause irritation and scratching of a tender skin, with a resulting crop of pimples.

Soft water should be used when available and cheap, harsh soaps should be avoided. The skin of the body requires a good quality soap as much as the face. For very irritable skins a superfatted soap may be used, or bran added to the water. The skin is irritated in many people by wool clothing. After a time in addition to the discomfort a crop of pimples breaks out owing to the constant irritation. In these cases the remedy is to wear silk, or cotton, or very fine wool next the skin. While clothing should be sufficient, the healthy action of the skin will be greatly interfered with if too much is worn. On the other hand, a person whose feet, or legs, or hands or arms are constantly cold cannot have a healthy skin.

In certain constitutional affections the skin is involved, e.g. in some of the fevers. In a large number of other instances, however, the skin itself is the original site of disease. For purposes of description, ailments which attack the skin directly may be classed as follows: 1. Inflammatory diseases, such as eczema, herpes, psoriasis, etc. 2. Affections of the glands of the skin, such as seborrhoea, blackheads, etc. 3. Affections characterized by overgrowth or wasting of the skin, such as corns and warts, and types of baldness following on atrophy of the hair-roots. 4. Nervous affections, such as itching of the skin, pruritus. 5. Parasitic diseases, such as scabies. *See Beauty Culture; Face.*

SKIN EFFECT: In Electricity. This is the property of a high-frequency alternating current whereby the current tends to flow along the surface of a conductor, in contrast to a direct current, which is evenly distributed throughout the mass of the conductor. The surface or “skin” effect increases with an increase of frequency.

SKIPPING. Skipping is admittedly one of the best forms of exercise, especially in cold weather stimulating the circulation and keeping the muscles firm and supple.

For ordinary purposes the skipping rope, when held in each hand, should be long enough to reach the ears of the skipper while her feet are resting upon it. This means that when the handles are included the whole should reach to the top of the ears. Unless the rope is this length, the skipper will not be able to keep her knees straight.

For plain skipping the rope should be held so that it almost rests on the ground behind the feet, while the arms are extended to their full width on a level with the shoulders. At a given word, or at the commencement of the music, the rope is twisted backwards, while the skipper springs lightly over it with each revolution. Music is a great assistance to good skipping. The feet should be kept together and the knees straight, while the arms must remain fully extended and the head well up. The arms should be practically still, the rope being turned by movements of the wrist.

Cross Skipping. For the cross skip the arms are folded across the chest, while the rope goes over as easily as if it were straightforward skipping. The arms, however, must not touch the body. It is generally interspersed with plain skipping, two plain and a cross, or three plain and a cross. The double cross is more difficult. For this the arms are reversed; that is, if the first cross is performed by crossing the right arm over the left, the second, which must follow immediately without any plain skipping in between, must be formed by crossing the left over the right. In a yet more difficult form the double cross is the same cross repeated twice.

Another difficult exercise is the double through or double under. To achieve this, the rope has to pass twice under the feet to one spring. Two things are necessary for a successful performance. The rope must be worked up to as high a speed as possible; and the skipper must spring very high in the air to allow the double passage of the rope. This is not as a rule possible with straight knees. If the knees have to be bent the feet should be flung backward, as though the performer were about to

kneel down, not forward as though she were about to sit. When well done the action should be a steady rhythm, with the double through performed every sixth step; but this can only be achieved with practice, and needs perfect balance as well as extreme agility.

Various dancing steps may be performed with a skipping rope, among which the ordinary gavotte step is popular. Some of the Scottish reel steps and the first of the Highland fling are also effective. The foregoing type of skipping should always be performed to music to ensure perfectly rhythmic movement, and with the rope going from front to back in order to keep the shoulders open and the chest expanded. This adds good breathing to the many other advantages bestowed by the movements.

SKIRT: Of Beef. This is an inner portion of the buttock, sometimes called the midriff, and is part of the diaphragm. When the skin is removed and the skirt is trimmed, it is cut into pieces and used in place of steak for making puddings and pies. Beef skirt is considered very suitable for this purpose because it is always tender.

The skirt is sometimes made into a stew, and if mixed with ox kidney an excellent dish is the result. Equal parts of beef and ox kidney are used and the procedure is the same as that described for stewed beef.

SKIRTING BOARD. In house-building this is a thin deal board laid along the foot of a wall to give a neat finish to a room, and to protect the face of the wall from damage. It is stained or painted to harmonize with the rest of the room. The usual width is 2 to 9 in., and thickness $\frac{1}{2}$ in. to 1 in. Other forms are made in different sections, as, for example, triangular, ground, and chamfered, these generally measuring about 2 by 2 in. Other patterns include those with a ground hollow, which gives a more or less coved effect to the angle between the wall and the floor.

In better-class construction, the skirting board is built up from several pieces or sections, properly jointed together, as in the diagram, which also shows how the skirting is fixed to the wall and the floor.

Skirting Board. Section of built-up skirting board, showing also method of fixing it to wall and floorboards.

The skirting in this example is composed of two pieces, the lower one being practically an ordinary board with a groove ploughed in its upper edge.

The upper part of the skirting is moulded at the top, the lower edge being tongued and fitted into grooves in the lower timbers. The skirting is attached to the wall by means of strips of rough wood known as grounds. These are generally about $\frac{3}{4}$ in. thick and 2 or 3 in. wide. The grounds are nailed to breeze bricks, wood blocks, or plugs, or even by driving the nails into the mortar joints between the bricks.

The edges of the grounds which adjoin the plaster work are planed up to an angle, so that when the plaster is applied it acts as a key and assists in holding the grounds and the plaster in position. The grounds are carried right around the room about $\frac{1}{2}$ in. or so below the upper edge of the skirting. To support the lower edge a rectangular or other sectioned strip of wood may be nailed to the floor to provide a stop or abutment for the skirting, which is then nailed to this rough strip.

When fixing skirting boards, the heart side should be used as the face, in order that the lateral tendency of the timber to warp will only cause the top edge to be forced more tightly against the face of the plaster. When a single skirting board is used, it should only be nailed along the top edge; the lower edge should be tongued and fitted into a groove cut in the floorboards, so that the skirting board is able to shrink and twist without splitting. The depth of the tongue should be sufficient to allow for shrinkage and expansion, without entirely coming away from the joint at the bottom.

Scribing a Skirting. Sometimes, in older houses, when it is desired to fit a new skirting board, it may be found that the floor has settled and is no longer flat. In such a case, the best procedure is to scribe the skirting board to the floor. To do this, it is placed in position and set with its upper edge horizontal. It will then be found to be resting at one or more places on the floor. A pair of dividers is set so that the distance between their two faces is exactly the same as that between the floor and the lower edge of the skirting board.

The dividers are then used as a scribe by moving them along over the surface of the floor, with the upper leg pressing on the skirting board, and keeping the points vertically above each other. By doing this, a line will be scratched on the surface of the skirting board, and its contour will exactly equal that of the floor. The board is then removed, accurately sawn, and finished, if necessary, with a spoke-shave or plane to this scribed line, when, on placing it in position, it should fit the contours of the floor exactly.

SKITTLES. For this game a skittle alley is necessary. This can be made by laying down a number of planks to form a stretch of level flooring, which should be about 12 yd. long and 3 or 4 yd. wide. The game can be played by two persons or by any other even number, provided there are not too many of them. In the latter case they are divided into two sides.

Skittles. Fig. 1. A, ninepin; B, flat-sided wooden ball called the cheese.

The game is played with a wooden ball and ninepins. The former, called the cheese, is flatsided, and should weigh about 10 lb. The latter weigh from 7 to 9 lb. each, and are set up as shown in Fig. 2. The player stands about 6 or 8 yd. from the pins and his aim is to throw the ball so that it will knock down as many pins as possible. They must be knocked down by the ball itself, or by a pin that it has caused to fall. Any pin knocked down by a rebound is not reckoned as down. The player is allowed one step

forward when throwing.

Fig. 2. Diagram showing dimensions of skittle frame and run, with places for the ninepins.

There are several ways of scoring. One is to make exactly 31 points in the fewest possible throws, each pin knocked down scoring one. If 31 is exceeded the number scored in the last throw is not counted, and another throw is allowed. Another way of scoring is for the players, in turn, to throw at the pins and each one to knock over as many as possible, the one with the highest score winning at the end of an agreed number of throws. Another form of the game is to allow each player three successive throws, his aim being to knock down all the pins in as few throws as possible. If he knocks down all the pins in one throw, he scores three points; if in two throws, he scores two points; and if in three throws, he scores one point. If the player fails to do this, he scores nothing. The scores are added up at the end of the game, and the individual or the side with the most to his or their credit is the winner.

There are other skittle games. Some play with only four pins, one at each corner. In Dutch skittles, as it is called, the ball is bowled along the ground, not thrown, grooves being made in the floor for it to roll in. A round ball is used for this game, and the rule is that the centre pin must be knocked down first. This is sometimes known as the king pin, and is often distinguished from the others by its make or size.

SKULL CAP: The Plant. These are uncommon plants of the sage family and bear somewhat helmet-shaped flowers in summer. They are 10 or 12 in. high, and are suitable for the rock garden or near the front of the flower border. The botanical name is *Scutellaria*. Some of the chief hardy perennials are *alpina*, purple and yellow, *albida*, white; and *baicalensis*, purple. Of the greenhouse kinds the best is *Scutellaria mocciniana*.

Skull Cap. One of the popular names of the perennial Scutellaria, a valuable plant for the rock garden or a sunny border.

SKUNK: The Fur. The dark brown glossy fur known as skunk is obtained from an animal of the same name, closely allied to the otter and weasel. It is of remarkable durability, and is of a soft, thick texture. *See Fur.*

SKYE TERRIER. Although it is naturally a sporting dog, the Skye terrier as a domestic dog shows strong affection, faithfulness and obedience. It has a quick ear and warlike readiness to meet any intruder, large or small. A long-bodied, short-legged dog, with a well-feathered tail, his other points are hidden by his long, hard upper coat, which is perfectly straight and falls to the ground or near it. The head is relatively large but its form and the face are screened by the long veil which parts only to reveal the black muzzle. The softly feathered ears may be either erect or drooping; the close-set hazel eyes are all but invisible under the veil. The colour should be either blue-grey—light or dark—or fawn with black points. The total length from muzzle to tip of tail is 40 in.; the height at shoulder is 9 in., and the weight 18 lb. *See Dog; Kennel.*

Skye Terrier. An active long-coated little dog. (Photo, Thos. Fall)

SKYLIGHT. A window or sash fixed in a pitched roof for the purpose of lighting a room, passage, or space below is known as a skylight. It must not be confused with a lantern light, which is used chiefly in connexion with a flat roof. *See* Flashing.

SLAT. This is a name given to a long, narrow and thin piece of wood wider than a lath. The pieces of wood forming a Venetian blind are called slats, as well as the movable or fixed strips of wood in an open window shutter. The name is given also to the pieces of iron which are fitted from side to side and from end to end on the framework of a bedstead to support the mattress.

SLATES AND SLATING FOR AMATEUR BUILDERS

A Practical and Economical Method of Roofing

Matters concerning the roofs of houses are dealt with under a variety of headings in this work, such including Corrugated Iron; Felt; Roof; Shingle; Thatching; Tile. *See* also Bungalow; Cottage; Garage; House; Scaffolding; and the articles on the various outbuildings.

Slates are used extensively for covering the roofs of buildings, and when properly laid they form a good covering, being comparatively light in weight and economical in use as compared with many other roofing materials, while their expansion is practically negligible. They resist fire well and their power of absorption is not great, which is an important consideration, because much wet absorbed on a roof means added weight. Good slates, as a rule, should not increase in weight more than during rainfall.

Slates are used more in towns than in rural areas, where tile»s are often a local product. A roof covered with slates does not need such large timbers as one covered with tiles, and the roof need not be given such a steep pitch as a tiled roof, which is an advantage economically. Slate used for roofing purposes is quarried principally in Wales, Lancashire, or Cumberland, and is split into standard sizes.

Slating. Fig. 1. Beginning of slating.

The varieties most frequently used are Duchess, 24 in. long and 12 in. wide; Countess, 20 in. long and 10 in. wide; and Ladies, 16 in. long and 8 in. wide. Allowing a 3 in. lap, it will take approximately 122, 180, 280 slates respectively to cover one square, which consists of 100 sq. ft. of roof area.

There are several methods of preparing a roof to receive the slates, the most inexpensive being to nail wood battens across the rafters to the required gauge, as in Fig. 1. A better method is to cover the roof with

boarding and then nail the slates direct on to the boards. A more costly method is to board the roof, cover it with tarred sheet felt, then nail the battens on to this, and fix the slates on to the battens.

Finding out the Gauge. It is first necessary to calculate the gauge, i.e. the width of slate exposed in the course. This depends to a certain extent on the kind of nailing that is to be used, that is, whether the slates are to be nailed at the top or in the centre. For example, if Duchess slates are to be used with head nailing, deduct from the length of the slate the lap (which is generally 3 in.) and 1 in.

besides, divide the result by 2, and that will be the gauge at which the slates are to be laid, which in the above example will be 10 in. For centre nailing the length of the lap only will be deducted from the length of the slates so that the gauge would be 10½ in. Thus, a slightly bigger area is covered when centre nailing is used; if the slates are to be fixed on to battens, the latter, too, will be nailed to the rafters to suit the gauge.

Fig. 2. Punching the holes.

The slates must have the holes punched into them, Fig. 2. The position of the nail hole has to be calculated as follows: Add to the gauge, previously ascertained, the estimated lap, and to this add another ½ in. making 13½ in. If the Duchess slate is used, that means the holes are punched 13½ in. from the bottom edge, or tail, of the slate. No matter what may be the size of slate, the method of calculation is the same.

Fig. 3. Top, slater's axe, for trimming and making holes in the slate; bottom, cutting iron. (Courtesy of Richard Melhuish, Ltd.)

Right. Fig. 4. Showing double eaves course.

To facilitate the marking of the slates for holing, a simple gauge may be made from a straight piece of batten to which a stop has been fixed at the proper distance from one end. The trimming of the slates when it becomes necessary, and also the punching for nailing is carried out by the use of very simple tools (Fig. 3). A cutting iron is fixed to a piece of timber on which to rest the slate. Another tool, the slater's axe, is like a chopper in appearance, but it has in addition to the chopping blade a spiked piece of metal, which is used for making the holes in the slates. In making the holes the slate should be struck from the under side. The top side, it will be noted, has the edges chamfered.

The slates may be fixed to the battens with copper, zinc, or composition nails; it is advisable not to use iron nails, because they will rust away and the slates will fall.

It is necessary to board or batten the roof before slating is commenced. Battens are fixed at the gauge calculated, so that the centres of the battens are the gauge distance apart. If boards are used, the gauge is marked with a chalk line.

Laying the Slates. The most important point is to start the slating correctly. Slates are laid beginning at the eaves, that is, the bottom edge of the roof. There must not be any straight joints, otherwise the rain will find its way through the roof. Experience has proved that it is necessary to have a double course at the eaves, as in Fig. 4. The first course of eaves tiles has to be cut specially to proper length, which may be arrived at by adding the length of the lap to that of the previously calculated gauge.

It is usual to fix under the first course of slates a tilting fillet, formed from a piece of 3 in. by 1 in. stuff cut across the diagonal, and forming one feather edge. This gives the slates a tilt so that their tails press on to it when they are securely nailed. Thus each successive course presses on to the former one, and the slates are kept firm and the roof sound.

Fig. 5. Correct placing of slates, so that successive courses break joint.

Fig. 7. How to remove old or broken slates with the tool shown above.

Fig. 6. Slate rip.

The second course completely covers the slates that have been specially cut, the tails of the two courses keeping the same line. Great care must be taken to see that the joints are broken, as in Fig. 5; straight joints will let the water in.

With the double eaves courses fixed there need be no further difficulty. The slates have to be cut at the verge or outer edges of the roof, also to fit the hip or valley should these occur in the roof to be covered. The successive courses of a simple job are illustrated in Fig. 5. It is good practice to put a tilting fillet against the side of any chimney or wall that the roof might butt up against, as this helps to throw the water on to the main roof. The ridge, valleys, and hips of a roof may be finished with lead, or with slates specially formed for that purpose. These are bedded on to their positions by the use of cement mortar.

When, owing to breakage, slates have to be removed the tool known as a ripper (Fig. 6) is used. It is thrust up beneath the broken slate and the sharp hook-shaped blade brought against the nail so as to sever it and free the slate. (Fig. 7).

Sledge Hammer. *See* Hammer; Forging.

SLEEP: Its Value. When the body is growing rapidly more sleep is required. A newborn child should slumber almost continuously for the first 6 days of its life, and up to the age of 10 years not less than 12 or 14 hours of sleep are necessary every 24 hours. From 10 to 15 years, an allowance of 12 to 10 hours should be given and up to the age of 25 it is best to sleep at least 8 hours. After that age the matter becomes a personal one.

Owing to the growing complexity and strain of modern life sleeplessness has become a very prevalent disorder. In many cases the remedy is simple, and the hints given under the heading *Insomnia* will be helpful.

A common form of sleeplessness consists in waking unduly early in the morning. In such cases the sufferer should get up directly he wakes; the hour of awakening will soon become later. The importance of darkness and quiet is well known, but it is equally necessary that any cause of irritation, such as a decayed tooth or a blistered heel, should receive attention. The commonest cause of insomnia is the stomach. Excessive tea-drinking, hurried feeding, and late meals of indigestible food account for many a bad night, although no discomfort is present. Finally, never, without medical advice, should drugs for inducing sleep be taken.

Sleeping Out of Doors. Many people, especially those who work indoors in large towns, realize the advantages of sleeping out of doors, not merely for an occasional camping holiday, but as a regular thing. Those who build their houses can plan for one or more sleeping porches opening from the upper floor; but there are many simpler ways in which outdoor sleeping may be satisfactorily arranged in an ordinary back garden.

Waterproof shelter is essential, and aspect is important. Outdoor beds should be protected from the east, whence come the bitterest winds and the morning sun, which is apt to wake the sleepers unreasonably early in summer. With a south-west or west aspect the roof must project several feet beyond the foot of the bed, or rain will drive in. A veranda opening out from one of the sitting-rooms makes an ideal improvised sleeping porch, though if exposed to the rainy winds it may need a roof extension. The east or north-east side of an outdoor bedroom, if open, should be filled with glass, wood, or removable screens of canvas, according to the nature of the structure.

For comfortable and regular sleeping out proper bedsteads are essential, and can be moved out from the house. Naturally, expensive ones should stay indoors, the cheaper, wooden, iron and camp beds being placed in sleeping shelters. For a veranda which is wanted in the daytime for lounging and afternoon tea, the best equipment is a camp bedstead or light make of divan bed supported on legs with castors.

In damp weather the person who makes the beds should throw right over them camping ground-sheets, waterproof covers, or a collection of old mackintoshes, to keep out the moisture. Particular care should be taken that the pillow is well protected, though experience has proved that even those who sleep out in winter as well as summer suffer in no way from damp bedclothes. Besides being extremely pleasant, regular outdoor slumbers have been proved to be particularly beneficial to nervy and anaemic people. *See* Hammock; *Insomnia*; *Nightmare*; *Sleepwalking*.

SLEEPING BAG. A sleeping bag is a useful article of equipment for campers out, yachtsmen, or even for those who sleep out in the garden during the summer, while for small children in their

perambulators it is invaluable. The first type can be procured from most athletic outfitters. It may be made of fur, camel hair, or some waterproof material, and usually has a flap which can be fastened down over the head of the occupant. This arrangement also enables the bag to be used as a valise when packing up for the next stage of the journey.

An adequate sleeping bag may be made by the simple expedient of folding a blanket in two and stitching it up at the side and one end. It is not necessary to cut the blanket for this, which means that it may serve its purpose as a bag for as long as it is needed, and may then be unstitched, washed, and returned to its normal use. For this purpose handstitching is recommended as being easier to unpick. The bag should be long enough to come well up to the sleeper's armpits, and, if required for really cold weather, only the head should extend beyond the bag. Some people prefer to have the top foot or foot and a half left unstitched, so that they can move their arms freely, or can turn the top edges down and over if they get too hot in the night.

SLEEPING DRAUGHT. A sleeping draught may be prescribed and obtained from the chemist made up ready for use, or the hypnotic ingredient may be prescribed and directions given regarding the preparation of the draught. It is often advised to give the draught in hot milk or gruel, except in the case of an evil-tasting substance like paraldehyde. No patient should make up his own sleeping draught, nor should hypnotics be within his reach, as a patient desperate from sleeplessness might easily take an overdose. *See* Hypnotic; Insomnia.

SLEEPING SICKNESS. The disordered condition known as sleeping sickness is the last stage of trypanosomiasis, or infection with some trypanosoma. This is a protozoal parasite which first exists in the blood but later finds its way into the cerebro-spinal fluid. The disease is found in West and Central Africa and in Brazil, and is transmitted by various species of tsetse flies.

African sleeping sickness must not be confused with encephalitis lethargica, the so-called sleepy sickness, outbreaks of which have been noted in Great Britain since 1918. *See* Encephalitis.

SLEEPWALKING. This troublesome habit is more common among children, and as a rule a child grows out of it; but in some cases it lasts on into adult life.

Sleepwalking resembles the hypnotic state. The somnambulist has no recollection of what he does when he walks in his sleep. The sleeper gets out of bed and moves about. In most cases he merely gropes around the room, and, partially awaking, returns to bed. Sometimes, however, he leaves the room, and, in rare cases, gets out of the window.

Among the most common causes of sleepwalking in children are over-pressure at school, and going to bed in a state of anxiety from this or another cause. Attention should be paid to the diet and to the bowels. These persons should not eat a heavy meal just before going to bed, nor go with an empty stomach. If there is any costiveness, a dose of aperient medicine should be given. Exercise in the open air is very necessary. The bedclothes should be light, and the room well ventilated.

When a person is found walking in his sleep it is better not to awaken him, but to lead him quietly back to bed. Danger in awakening a sleepwalker is largely a matter of where the sleeper happens to be at the moment of awaking. The bedroom door should be fixed so that it will not open sufficiently to let the sleepwalker pass through: the windows should be secured in such a way that they will not open wide. A good plan is to put a piece of cold oilcloth at the side of the bed, which may awaken the sleeper as he steps on it. When a child is much given to the practice it is always best to take him to a doctor. *See* Sleep.

SLICE. This word is used for the silver or silver-plated knife or server with a thin broad blade that is employed for serving fish. It is also frequently used to describe the kitchen implement employed

to lift fish, fried eggs, rissoles, etc., from the frying pan without risk of their breaking. Such a slice is usually of aluminium or enamelled metal and has a broad, thin blade perforated in order to allow surplus grease to escape back into the pan.

SLIPPERS. This term is now chiefly employed for bedroom slippers, including heelless leather, felt, quilted satin, woollen and raffia woven footwear and also the types of bedroom slippers known as mocassins, silk or satin boudoir slippers with heels, and the mule, which is simply a toe cap of material attached to a heeled and padded sole. The main thing about this class of footwear is that they should slip on and off easily and be held in place without fastenings. *See* Mocassin.

Slipper wort. This is the popular name of *calceolaria* (q.v.).

SLOE. This is the fruit of the blackthorn (*Prunus communis*), the progenitor of the garden plum. A double-flowered kind named *spinosa* is worth growing as an ornamental shrub.

Sloe Gin. This cordial can easily be made at home from the following recipe: To 1 pint sloes add 1 lb. sugar. Half fill a bottle with the sugared fruit and fill up with gin. If the sloes have been previously pricked, the liqueur should stand for 2 or 3 months before drinking, otherwise for 12 months. Properly matured sloe gin should be the colour of full-bodied port wine. A cocktail known as sloe gin rickey is made from $\frac{3}{4}$ gill sloe gin with ice and the juice of half a lime squeezed into it. Fill up the glass with cold soda water.

The following is another recipe: Take 3 lb. sloes, $\frac{1}{2}$ gallon unsweetened gin, 1½ lb. Demerara sugar, and $\frac{1}{2}$ oz. bitter almonds. Wipe and stalk the sloes, prick them well with a needle in several places, and put them into a large stone jar. Add the gin and sugar, and then the blanched and skinned almonds, cork the jar tightly, and then shake it vigorously. Shake it once daily for about 14 weeks, at the end of which time it may be strained and bottled for use.

SLOP BASIN. This is a basin placed on the table at breakfast and tea to receive the dregs from the cups. Slop basins are usually part of a breakfast and tea service.

SLOP PAIL. In bedrooms not fitted for running water, and where the ordinary toilet service is used, this may include a pail to match. Enamelled pails are used for the purpose of emptying slops. These pails are easily kept clean and are less fragile than china ones.

SLUG. This is one of the chief garden pests, and may do immense damage, especially among seedlings and young plants. It is invariably most troublesome in ill-cultivated land; soil which is kept in a good state of cultivation by digging, forking, and hoeing is not, as a rule, badly infested. This pest is most harmful in wet weather. It can be trapped by means of orange peel, bran, pieces of potato or carrot laid down on the soil, and examined frequently. Scatterings of lime, soot and alum are useful. Ashes placed round about plants when fresh growth is pushing through the ground will often keep away slugs. Zinc collars pressed into the soil are used to protect choice rock garden plants.

The best remedy is to dissolve one pound of commercial aluminium sulphate in one gallon of water and a double handful of lime in four gallons of water. The two solutions are then thoroughly mixed together and applied to the soil infested by the pests.

SLUG WORM. Often called the slimy grub, this larvae of a species of sawfly is destructive to leaves of the pear, and sometimes attacks the plum, peach, and cherry. The saw-fly itself is shining

black with dusky wings, and the larvae a quite small slimy black slug with a large head. Eggs are deposited on the upper surface of leaves during June, hatching out late in the month with grubs that are white, then yellow and filially covered with black slime. As soon as grubs are seen they should be given a dusting of powdered lime.

There is also the rose slug worm which destroys the upper skin of leaves, and these may be recognized by their colouring, pale yellowish green, orange head, and dark marking down the back. Two broods are produced, one in June and another in September, or earlier. The bushes should be sprayed with hellebore wash or a nicotine insecticide. *See* Insecticide.

SMALLPOX. One of the most contagious of all diseases is smallpox, or variola. It is an acute infectious disease accompanied by fever and an eruption of papules or pimples on the skin, which change into pustules and then into scabs. The great preventive is vaccination.

When the disease breaks out among people who have not been vaccinated it is always very destructive.

A smallpox patient is infectious from the onset of fever and other symptoms until convalescence. The most dangerous period is from the outbreak of the eruption until the scabs have dried up. The infectious material exists in the blood and secretions, in the exhalations from the lungs and skin, but chiefly in the pustules, which dry and fall off in fine particles. It is thus possible to become infected in a railway carriage or any public vehicle or place of public resort. Overcrowding favours the spread of the disease, and so does bad sanitation.

Mistakes are made in diagnosing smallpox because at the outset it often closely resembles chickenpox. If an epidemic is raging, smallpox may be strongly suspected when there are sudden severe pains in the head and back, with vomiting and high fever, following a shivering fit.

When an epidemic breaks out it is advisable that everyone should be vaccinated or re-vaccinated. Smallpox patients should be removed to special hospitals. *See* Vaccination.

SMELLING SALTS. The inhalation of ammonia has a stimulating effect of much use in the relief of faintness and headache. The ammonia is derived from ammonium carbonate or from strong solution of ammonia, and the preparation is made agreeable by the addition of perfumes. Sometimes carbolic acid or eucalyptus oil is added to obtain an antiseptic effect in influenza, common colds, hay fever, etc.

When liquid ammonia is used in the preparation it should be thoroughly soaked up by a piece of sponge, asbestos, or some other absorbent material, as the liquid, if spilt on some coloured fabrics, will stain them. The pungency of strong acetic acid serves the same purposes as smelling salts. *See* Acetic Acid; Fainting.

SMELT: The Fish. A small, delicately flavoured fish, the smelt needs to be cooked as soon as possible after it is caught, otherwise the flesh loses its firmness. To clean it, press out the inside through a slit made just below the gills, cut off the latter, and then wash the fish quickly.

Frying is the usual method of cooking smelts, but they may also be stewed, and in this form make a good dish.

To fry them, clean and dry the fish, then coat them lightly with seasoned flour. Brush over them a little beaten egg, roll them in breadcrumbs, and then fry them in a pan of smoking-hot fat until they are of a golden brown colour. Drain them on paper and then serve them hot, garnished with parsley and accompanied by plain white sauce.

For stewing, cut the heads off the fish and then lay the latter in a small fireproof dish containing enough white stock to cover them. Add seasoning to taste, put on the cover of the dish, and cook the fish in the oven for about $\frac{1}{4}$ hour. *See Fish.*

SMILAX. These are hardy and greenhouse evergreen climbing shrubs and plants. The long slender trails of smilax (*Asparagus medeoloides*), so much in demand by florists for decorative purposes, is a greenhouse plant. It is easily grown from seed, planted in a compost of loam, leaf-mould and sand and trained on string or wires. Of the hardy kinds the chief one is *aspera*, a vigorous climber, suitable for covering a rough fence.

Smilax. Greenhouse plant, the long graceful tendrils of which are much used for table decoration.

SMOCKING: In Needlework. Smocking is formed by gathers which are drawn into vertical pleats by running gathering threads at certain distances from each other. The latter depend on the design, and are used as guides for spacing, when the decorative part is begun. The stitches on the surface of the pleats are the ordinary sewing and embroidery stitches. They all appear on the surface of the work, except in honeycomb smocking, when only the stitches that connect the pleats can be seen on the right side, the rest of the stitch being run inside. This form of work is always useful, as well as decorative, on children's clothes, and its popularity never dies out. It is particularly useful on the wrists and at the necks of frocks and of small boys' suits, as it is elastic and will stretch easily over the head and hands. Smocks are also exceedingly serviceable as overalls, and for gardening work, when made in holland, linen or heavy Shantung silk.

Smocking. Fig. 1. Running the gathering threads along dotted lines.

Methods of Working. Mercerized cottons may be employed for smocking casement cloth and similar goods, embroidery cottons for nainsook and other white goods, linen embroidery threads for soft linens and twisted embroidery silk on washing silks.

Smocking transfers can be bought at almost any fancywork shop, and these consist of sheets of paper with dots marked in transfer ink, which are transferred to the material by means of a hot iron. These dots are spaced evenly, about $\frac{3}{16}$ in. apart, along the row and the rows about $\frac{1}{2}$ in. apart. If a transfer is not at hand, a card with holes at the correct intervals through which the point of the pencil is inserted makes a permanent marker. Before using either the transfer or a marker the material should be stretched on a drawing-board and secured with drawing pins.

To gather, begin at the top right-hand corner, and put a good knot at the end of the cotton; make a little backstitch here to prevent the knot from going through. These gathering threads are drawn out afterwards, as they only serve to hold the pleats together. Put the needle down through the material again half-way between the first and second dots, and out again at the second dot. This will result in

a flat stitch lying over the first half of the space between the first and second dots. Continue this to the end of the row. Fig. 1 shows two gathering threads completed and the third row with the needle in position. Repeat this gathering thread on all the rows of dots. When they are all finished draw up the top thread and secure the latter round the pin at the left side as for ordinary gathering. Fig. 3 shows three of the pins with the cotton twisted round. After drawing up the top row stroke the pleats into position. Draw up, secure and stroke each row, when the work will be ready for the smocking stitches.

Fig. 2. Four different stitches used, all worked from left to right.

When the work is begun the threads can be released a little but must still be fastened round the pins while working. It is necessary to draw the pleats up tight at first to set them in an even position. Fig. 2 shows specimens of four different stitches, from which many pretty designs can be formed.

The top row shows ordinary stem stitch completed and the second row the same stitch in progress, taking up the stitch on the top of a pleat, and bringing the needle out under the cotton. If the work is held sideways the thread is thrown over to the left of the needle. Note that the work proceeds from left to right. The third row shows crewel outline stitch pleated and the fourth row crewel stitch in progress. The only difference is that the loop of thread is thrown over to the right in working and the needle comes out above the thread. The fifth row of the same figure shows alternate stitch, that is outline stitch for the first stitch and stem stitch for the second one, repeating these two movements alternately across the row. The last row on the same figure is herringbone stitch, taking the first and second pleats together for the first top stitch, and the second and third pleats together for the next lower stitch; for the top part of the next cross take the third and fourth pleats together and continue across the row. For each new stitch take the second pleat of the last pair, together with a new pleat.

Smocking. Fig. 3. Honeycomb design shown in two sizes.

In the same way all the feather-stitching patterns can be carried out in this work, and the 3 stitches in Fig. 2 can be worked in zigzags or waves to form new designs. In Fig. 2 the gathering threads are fastened off at the back of the work for the purpose of illustration, but when they are cut out entirely the smocking expands, causing the pleats to stand up evenly and giving a much prettier effect. The gathering threads should not, however, be removed entirely until the work is completed.

Honeycomb Design. Fig. 3 shows the honeycomb design. After setting the pleats as described above, join the thread to the top left-hand pleat, as the work proceeds from left to right, and take a stitch through the second and first pleats. Insert the needle in the second pleat just where the last stitch was made, slip the needle down under the pleat and bring it out on the second line of dots for the big honeycomb or halfway between the two lines for the smaller honeycomb.

The two sizes are illustrated on Fig. 3. This long stitch running through the pleat must be entirely hidden. Take a back-stitch through the third and second pleats, slip the needle under the third pleat and bring it out on the first running line again. Take a stitch through the fourth and third pleats, and slip the needle down through the last pleat to the second line once again. Reference to Fig. 3 will show clearly how succeeding rows are formed, always taking the second pleat of the last pair with the new pleat in the middle row, to open the honeycomb. The third row is a repetition of the first row, which closes the honeycomb at the lower end. The needle is shown in position taking a back-stitch through two pleats.

Many pretty designs can be made with honeycomb stitch, such as Vandykes, gradually tapering the pattern off to a point, with only one diamond in the last row, and it only requires a little ingenuity for the worker to show individual taste, especially if she has a working knowledge of a number of embroidery stitches. *See* Embroidery; Feather Stitch; Herring-bone Stitch.

SMOKE TREE. Smoke tree is the common name for *Rhus cotinoides*, a hardy deciduous shrub, otherwise called sumach. It is suitable for the mixed shrubbery or for the lawn, and bears foliage which assumes a rich orange-crimson shade in autumn. There is a similar species, *cotinus*, known as the smoke bush and this is perhaps more beautiful. The smoke tree should be planted in good ordinary soil during autumn, and increased by layerings or cuttings of ripened shoots during the same period. *See* *Rhus*.

SMOKE WOOD. This is another name for *Clematis vitalba*, the Traveller's Joy of chalky lands and hedgerows. While it is useful for covering old tree-stumps, banks, and trellises, and is popular on account of its feathery, smoke grey seed heads, its main use is as a stock on which can be grafted choicer kinds of clematis (q.v.).

SMOKING. There are no certain rules as to the quantity of tobacco that should be consumed in a day or a week, as this naturally depends on the individual smoker. Factors to be reckoned with are the condition of his heart, nerves, and digestive organs, the nature of his occupation and the amount of physical exercise, particularly open-air exercise, which he or she is in the habit of taking. Generally speaking, a fair average for a pipe smoker is 4 oz. a week; many are satisfied with less.

Where smoking is indulged in to excess, it is most frequently in the form of cigarettes, and if inhaling is practised at the same time the danger to health is very real. Those who suffer from anaemia should be very careful to smoke in moderation, and to avoid inhaling, and if there is any weakness of the heart unlimited cigarette smoking will cause trouble. Cigarettes offer the cheapest form of smoking only to those who strictly limit the number they consume in a day.

Strong tobacco may contain as much as 9 per cent of nicotine, but the amount is usually less, and in a mild mixture it may be as low as 2 per cent. A person can only judge whether he is smoking too much by the effects produced. These are indigestion, generally acid indigestion with flatulence; reduced appetite, more or less mental depression, some reduction of the muscular strength and more fatigue than should be after exertion, and perhaps dimness of sight. Sore throat (smoker's throat), with huskiness of voice and a short irritable cough, is not infrequent.

If the tongue becomes sore, or the heart palpitates, cease smoking for a time. These are danger signals that should not be disregarded, and any dimming of the sight is another. People who should not smoke at all are those whose heart or nerves are weak, sufferers from relaxed throat, or a tendency to bronchitis or consumption. Smoking is specially injurious to growing lads.

All smokers should be careful to wash the teeth morning and night. The tobacco poison clings for a long time to the mouth, and if one goes to sleep without removing it he will swallow some portion of it in the night. The best mouth-cleanser for smokers is water in which bicarbonate of soda has been dissolved, the proportion being a teaspoonful to the pint.

Smoker's Heart. Nicotine in excessive quantities acts as a heart poison, and anyone who smokes immoderately may suffer from unpleasant symptoms.

In extreme cases the action of the heart becomes irregular, attacks of palpitation occur, there is giddiness, and in pronounced cases actually fainting. If the smoking be stopped the heart recovers very quickly, as a rule in a few weeks' time. No other treatment is required in the great majority of cases.

Smoker's Throat. A chronic state of inflammation of the pharynx, though not very severe, caused by the excessive use of tobacco, is sometimes called smoker's throat. Some forms of tobacco are more irritating than others. Pipe smoking is thought to be chiefly liable to produce it.

The symptoms are a husky voice, frequent hawking, and very often a short cough. The only cure is a reduction of the amount of tobacco consumed. Before going to bed every smoker should gargle the mouth and throat with a solution of bicarbonate of soda in water, $\frac{1}{2}$ teaspoonful to $\frac{1}{2}$ pint. *See* Nicotine; Pipe; Throat.

SMOKING: Of Meat. Whilst meat and fish may be cured by being merely dried after salting, they possess a superior flavour if the drying is supplemented by smoking them in the fumes from a wood fire. The best results are obtained by burning green birch, beech, or oak wood, oak sawdust or broom tops. Occasionally juniper wood is employed to impart a special aromatic flavour to hams and bacon.

When meat is to be smoked it must be well dried after removal from the pickle, by hanging it in a cool, well-ventilated place; there should be plenty of air, but no direct draught on the food. Salmon is sometimes pickled with a mixture of saltpetre, bay salt and coarse brown sugar before being smoked, but after pickling it must be rubbed with common salt and then dried. Haddocks and herrings are merely salted and dried before being exposed to the smoke.

The smoking of butcher's meat or bacon is usually done in places constructed especially for the purpose, but it is possible to smoke small hams and portions of bacon at home if a wood fire may safely be built on the stone or brick floor of an outhouse. The meat should be suspended sufficiently high above the fire to smoke without getting cooked. Ham and bacon take from 10 days to 1 month to be properly smoked.

Fish is easier to manage, as the curing may be accomplished in about 12 hours after exposure to the wood smoke. To smoke small fish a tank or cask with both ends open may be turned on end on the brick floor of an outhouse and a good layer of sawdust placed inside. Into the sawdust a red-hot iron should be inserted. The fish should then be slung on an iron rod across the top of the cask and smoked in the fumes.

SMOKING ROOM. In many modern houses where smoking is allowed in every room there is no special smoking room.

Where a sitting-room is reserved for this purpose, the chief characteristics should be cosiness.

Rugs may be preferred to carpets as they can be taken up and shaken frequently to rid them of tobacco ash. Suitable materials for upholstery would be leather, oil baize, or mohair. A wide, deeply padded angle seat covered with some dark material—narrow striped or plaid effects are good, the

stripes toning with the colours in the rugs—and a few large, plainly piped cushions to match, make a cosy treatment for a warm corner.

Smokers' tables should be solidly made; they stand more firmly, and are more useful if shelved after the fashion of a book table fitted with small cupboard sections. A cupboard or cabinet for drinks and glasses—in a panelled room this cupboard might be built in—a card table flat-topped writing desk, four small chairs of solid make and a bookcase or shelves according to requirements would complete the necessary furnishing. Lights should be shaded, and reading lamps are essential. Pictures are usually confined to a few etchings, engravings and sporting prints.

SMOOTHING: In Wireless. The process of eliminating irregularities from electric currents used in a radio receiver. Such irregularities would not interfere with the normal working of a domestic electric appliance or light, but even slight ripples can be magnified in the amplifying circuits of a receiver and heard as loud humming or crackling. In other words, the supply for this must be made very smooth. This is done with combinations of chokes and condensers. In the case of Alternating Current (q.v.) mains supplies the smoothing is carried out subsequent to rectification.

SMOOTHING PLANE. The most usual type is about 8 in. long, which is enough for ordinary finishing purposes. The method of assembling and adjusting is much the same as for a jack plane, except that to loosen the plane iron the back of the plane is tapped with a hammer or mallet. No handle is required. The plane is grasped at the back with the right hand; the left hand is placed on the front, and is used at the end of the stroke to pull out long shavings. *See* Plane.

SNAIL: In the Garden. As a rule snails like green diet, i.e. living plants of all kinds, and are therefore enemies to the gardener. They usually feed at night or at dusk, but in damp weather, or after heavy rain, they may be found in numbers in the daytime.

Dry dressings of any irritant may be tried to kill them. Of these the best is a mixture of lime and caustic soda, 4 parts of caustic soda to 96 of lime, well mixed. Other dressings are soot and lime, salt and lime, and powdered coke. Two or three dressings should be given, the second some 15 or 30 min. after the first. These dry dressings, except powdered coke, should be applied after sunset, or else very early in the morning. *See* Lime; Slug.

SNAKE ROOT. The snake root is an attractive hardy herbaceous perennial. It grows 3 ft. or so high, and in July and August bears small white flowers on long, graceful stems.

They flourish in ordinary well cultivated land, do not mind slight shade, and are increased by division in autumn. The best are simplex, japonica and race-mosa. The botanical name of snake root is *Cimicifuga*.

Snake Root. White flower spikes of the species japonica.

SNAKE'S HEAD. This is the popular name of one of the fritillaries (*Fritillaria meleagris*), a charming spring bulb with beautifully chequered flowers. *See* Fritillary.

SNAP: The Card Game. This popular indoor game is played with specially prepared packs of cards. These are of various sizes, but the general principle is that they shall be in fours, each four bearing the same figure. No special number of players is necessary. Two can play, but it is better to have four, five, or six. The cards having been dealt, the players, holding them face downward in their hands, play in turn. Each places his played cards face upward on a heap in front of him. When two similar cards are exposed together any player can call snap, and the one who calls first obtains all the cards which lie beneath the two snapped ones. So the game continues until one player has secured all the cards.

In case a player calls snap when there is nothing to snap on the table, the cards in front of him go to a pool.

There they lie until a card similar to the one on the top thereof is exposed, whereupon, if a player calls snap pool, he receives those in the pool.

Special packs of cards may be bought for this game, or it may be played with ordinary playing cards. The former include cards made with a great variety of comic or artistic designs and are usually more popular with children than ordinary packs. They have an added advantage in that they save a good pack of playing cards from the rough usage which is almost inevitable in this game. If an ordinary pack is used the snapping will be between cards of the same value; for instance, one two and another, one king and another, and so on. If a more complicated game is required the snapping may be from one to two, two to three, and so on.

The game can be played without any calling of snap. In this case a small object—say, a shell—is placed in the centre of the table and, instead of calling snap, the player places his hand on this. This prevents any doubt as to the winner. In calling it may be difficult to say who called first, but only one hand can touch the shell at once.

Animal Grab. There are some amusing variants of the game, among which may be mentioned animal grab and grimace snap. In the former each player chooses to be some animal with a distinctive cry, e.g. a dog, cat, pig. When two players turn up similar cards, instead of saying snap, each has to make the noise of the other person, and the one who achieves it first wins the cards. As the tendency with most people is to make their own noise, while searching vainly in their memory for the one belonging to the other person, the effect is usually very ludicrous.

Grimace snap is extremely simple. Instead of snapping, the players are under contract to make each other laugh, to which end they may do anything except speak. In this way the player with the most mobile face stands to win.

SNAPDRAGON: The Plant. This is the popular name of *antirrhinum* (q.v.), a favourite garden flower grown in British gardens in quantities for summer bedding.

SNAPSHOT: In Photography. Snapshots may be described as amateur photographs of the more or less limited kind that are possible to the owner of an inexpensive hand camera with only one shutter speed. This is usually about 1-30th sec., though often marked, if marked at all, as 1-25th sec. It is possible, of course, to take snapshots with any camera that has a shutter working at one or more speeds in addition to time exposures, but the beginner in photography is generally limited to snapshots.

So long as the light is strong enough to give a fully exposed film or plate with an exposure of 1-30th sec., the amateur will have little difficulty on this score, but it is essential that he should recognize clearly this limitation. Only a proportion of subjects which the amateur usually wants to photograph are sufficiently well lighted to give good bright prints from snapshot exposures with cheap cameras

with moderately good lenses, although the faster films available permit somewhat wider latitude in exposure.

With a camera whose lens works at about $f/11$, sunshine, or sunlight with very thin clouds, in the summer is essential to good results. Winter or early spring sunshine is deceptively bright, as a test with an exposure meter will demonstrate. If the lens is marked $f/8$, bright midday winter sunshine or slightly dulled summer light will give reasonably good results. As the strength of the light is the prime factor in snapshot photographs, the amateur will be well advised to purchase an exposure meter.

The Watkins Fall Meter (Fig. 1), for roll films and other cameras, is inexpensive, and indicates by a simple test whether the light is strong enough for a snapshot. It is supplied with special dials suitable for particular Kodak and other cameras. If the meter shows that the light is too weak, it is a waste of film to attempt a snapshot. The Fall exposure meter is a modification of the general Watkins' meter. Full instructions for its use are given with the meter.

In snapshot work it is often of importance to know or be able to calculate the speed of moving objects in order to estimate the maximum exposure possible without showing movement or blur in the negative.

Snapshot. Fig. 1. Exposure meter for giving reliable indication whether light is strong enough for a snapshot. (Courtesy of Watkins (Hereford))

Movement relative to the camera's focussing screen is the fundamental consideration. If the object is approaching the camera from the front the movement of the image on the screen will be small relative to the actual movement of the object, while the image movement will increase in proportion to the angle that the object makes with the camera, the maximum obviously being when the object is moving straight across the front of the camera.

Thus it will often be possible to secure a good snapshot of a moving object if the photographer can get into a position at a small angle with it. In the diagram (Fig. 2) the moving object, A, is supposed to be a motor car travelling at 20 miles per hour, or about 30 ft. per sec. The camera being at B, 50 ft. away, the longest exposure possible with a V.P.K., if movement is not to show, is 1-100th sec. With the camera at C it would be, roughly about 1-50th sec., while at D, an D exposure of 1-25th sec. might give good results.

As a basis of calculations of this sort it is to be assumed that during the exposure the image must not move more than 1-100th in. on the focussing screen if it is not to show blur in the negative.

For a lens of 6 in. focus, which may be taken as the distance between lens and focussing screen, an object 100 ft. from the camera is 200 times the distance from the lens that the image of it on the focussing screen is from the lens, 100 ft. being 200 times 6 in.

Therefore a movement of 1-100th in. seen on the focussing screen is equal to an actual movement of the object of 2 in., and this is the maximum movement permissible during the time the shutter is open. Thus we can calculate maximum length of the exposure. At 20 miles per hour the object, say, a motor car, would move about 30 ft. in 1 sec., or 360 in. As it must not move more than 2 in. during the exposure, the time is 2-360th or 1-180th sec.

Snapshot. Fig. 2. Showing how the time of exposure varies according to the angle between the camera and the moving object.

As the longer the focal length of the lens the larger the image on the screen, and the greater its movement, a short focus lens such as is usually found on snapshot cameras will permit longer exposures. With a small camera of the vest pocket Kodak type where the distance between lens and film is about 3 in., the exposure in the example given will be doubled, i.e. 1-90th sec., or, to be safer, 1-100th sec. These

calculations assume that the object is moving across the line of vision, i.e. at right angles to the camera. If other positions can be taken up, as indicated in Fig. 2, the exposure times will be reduced accordingly.

Mr. Walter Kilbey in his book "Advanced Hand Camera Work" gives the following exposures for certain types of moving objects. With a lens of 5 in. or 6 in. focus the objects being not less than 20 ft. from the camera, for groups standing in the street, children at quiet play, etc., 1-50th sec.; for children actively at play, athletics and less rapid sports 1-200th to 1-600th sec.; for rapid games, cycling, racing, horse jumping, 1-500th to 1-800th sec.; for divers, football, etc., 1-700th to 1-1000th sec.

The exposures given are of course the maximum possible if movement is not to show and have no relation at all to the aperture of the lens, the strength of the light or the speed of the plate or film. If the camera lens is not fast enough, i.e. of sufficiently large an aperture, for the strength of light on a particular occasion, or the speed of the plate, then a snapshot is hopeless, because exposure will be insufficient in order to give a properly exposed negative.

Sneezewort. *See* Helenium.

SNEEZING. The process of sneezing is a provision of nature by which irritating substances are expelled from the upper air passages. Ordinary causes are the presence of irritating matters, such as snuff, pepper, dust, etc., in the air passages. In hay fever the pollen of grasses produces violent and distressing sneezing.

Sneezing is one of the earliest symptoms of a cold in the head, of influenza, measles, and hay fever. If measures be taken against a cold in the head as soon as sneezing occurs, further development may be prevented. When the affection is troublesome and prolonged, it may often be stopped by smelling camphor, sniffing menthol snuff, or fine powder of bismuth carbonate. Pressing the tip of the tongue against the back of the central upper teeth sometimes arrests sneezing.

SNIFE: How to Cook. This smallish bird is in season from October or November up to the following February.

To find out whether the bird is young, the feet should be examined, and if these are not soft and tender the bird is old. The long bill also will indicate whether the snipe has been kept too long, as it must not be moist. Like many small birds, snipe is best when dressed without removing the trails, but the gizzard should always be taken away before the bird is cooked. It is trussed with the head left on, and when it is plucked the head and neck feathers should be carefully removed, also the eyes must be picked out. The snipe is then singed and trussed.

To truss snipe, cut off the claws and then twist the legs so as to force the feet behind the thighs. Then run the sharp bill through the thighs and body as if it were a skewer. Fasten a noose of string round the bend of the leg joints, across the lower part of the breast; then bring both ends up to the head, pass round that and the tip of the bill and tie at the back. Cross the feet. Cover each bird with a slice of fat bacon tied on with string, and roast as described under the general heading Game in this work.

Snipe Pie. Prepare 4 to 6 snipe and cut them in halves. Chop very fine $\frac{3}{4}$ lb. rump steak and 6 oz. fat bacon, and pass twice through a mincer. Cream 3 oz. butter, season it, add $\frac{1}{4}$ teaspoonful grated nutmeg, the juice of half a lemon, and the same of orange. Work in 3 oz. fine breadcrumbs and 2 yolks of egg. Mix in with these the meat and bacon, and moisten to a paste with white wine.

Make this forcemeat into balls. Lay at the bottom of a pie-dish $\frac{1}{2}$ lb. rump steak and $\frac{1}{2}$ lb. bacon cut in strips and rolled; lay on these the portions of snipe, with the forcemeat balls arranged between. Season well, and three-parts fill the dish with stock. Cover over with good rough puff pastry, glaze, and bake $1\frac{1}{2}$ hours.

Snipe Pudding. Make a good crust with kidney suet and fine flour well salted, then prepare 4 snipe, and cut in halves. Reserve the livers and the trails. Sprinkle a little lemon juice over the birds and season them with salt and cayenne pepper. Peel and slice a Spanish onion, and fry it a light fawn in 2 oz. butter; stir in 1 oz. flour, $\frac{1}{2}$ lb. prepared and chopped mushrooms, 1 teaspoonful sifted sweet herbs, $\frac{1}{4}$ of a chive (chopped), a good pinch of grated nutmeg and seasoning to taste.

Stir all the ingredients in the pan for 2 min., then add $\frac{1}{2}$ pint of well flavoured stock to which 2 wineglasses white wine have been added. Simmer over the fire for 10 min., then add the liver and the trails. Pass the contents of the pan through a wire sieve into a basin. Line a pudding-basin with the suet crust, add the snipe and the purée, and a little more liquor if needed. Put a lid of paste over the pudding, tie it up and steam for $1\frac{3}{4}$ hours. The paste for this pudding must not be very thick. The pudding can also be boiled. *See Game; Pastry; Suet Crust.*

SNOOKER POOL. This game is played on an ordinary billiard table. It can be played by two or more persons, either as sides or independently, and is a game consisting of winning hazards, cannons being ignored.

The game is played with 22 balls, which are placed on the table in the following fashion: Fifteen red ones are in the form of a triangle, the ball at the apex being on the pyramid spot, and the base being parallel with, and nearest to, the top cushion. Black is on the Milliard spot; pink on the centre line of the table, touching the apex ball of the pyramid; blue on the centre spot; brown on the middle of the baulk line; green on the left, and yellow on the right hand corner of the D. The remaining ball is the white or cue ball. The values of the balls are: red 1, yellow 2, green 3, brown 4, blue 5, pink 6, and black 7.

Having arranged what number of points shall make a game, the players must decide upon the order of play. The first player must play from hand with the cue ball. This must strike a red ball, and if one or more of the red balls are pocketed the player scores for each one, and continues his break

until he fails to score. At his second turn he must strike one of the pool balls, these being the balls that are not red, and the game is continued by pocketing reds and pool balls alternately.

If the striker fails to score, the player next in turn plays from where the cue ball rests. If the cue ball is pocketed or forced off the table, the next player plays from hand. Each pool ball pocketed or forced off the table must be respotted before the next stroke. It should be noted that unlike the reds, two pool balls must not be pocketed by the same stroke, nor must they be struck simultaneously. *See Billiards; Pool.*

SNORING. The usual cause of snoring is sleeping with the mouth open, particularly when lying on the back. It results from the flapping of the soft palate between two currents of air, one through the mouth and the other through the nose. The cure is to keep the mouth closed and to sleep on the right or left side; perseverance is necessary.

In some cases the mouthbreathing which provokes snoring is due to an inflamed and thickened state of the mucous membrane lining the nose, due to chronic catarrh, which must of course be dealt with. Snoring in children is a very common result of adenoids. *See Adenoids; Breathing.*

SNOW. A fall of snow, especially if it should be heavy or continuous, will cause considerable damage to a house unless prompt measures are taken to deal with it. These include clearing it away from porch, steps, and paths; preventing it from stopping up gutters and falling on to low roofs and glass roofs. Newly fallen snow can generally be brushed away with a stiff broom, but if it has been allowed to get hard, use a spade or some form of scraper. A liberal application of salt is sometimes used to loosen hardened snow, but care must be taken to remove the whole, or a surface of icy smoothness may form instead.

Snow. Section through a roof showing position of snow guard.

Snow Guards. For the protection of low roofs or glass structures adjoining high ones, it is usual to provide a rack, or snow guard. This consists of a wooden rack or wire guard fixed at the edge of the roof. The guard supports the snow and prevents the guttering on the eaves from becoming clogged. It is necessary to provide very strong supporting brackets. The iron brackets should be at least $1\frac{1}{4}$ in. by $\frac{5}{16}$ in. in section, and although the single support, if placed at frequent intervals, will generally be sufficient, high roofs overhanging a greenhouse or a conservatory should be strengthened with iron brackets as indicated by dotted lines in the diagram.

The height of the snow guard need not be more than from 6 to 10 in., but the battens must be securely bolted on the brackets and the whole structure painted to preserve it. If the wooden guard is considered unsightly and wire guards are desired, they should be made from a stout gauge material and supported at more frequent intervals than in the case of wooden ones. If the wire is galvanized after it is made up it will be more durable.

Snow Ball Tree. This is another name for the guelder rose (q.v.).

SNOWBERRY BUSH. This name is given to a vigorous bush which bears attractive white fruits in autumn (symphoricarpus). It thrives in ordinary soil even in shady places. The best kinds are racemosus and mollis.

SNOW BLINDNESS. Long exposure of the eyes to the glaring light of snow causes inflammation of the conjunctiva. There is a gritty feeling in the eye, which begins to water, and there is difficulty in keeping the eyes open from the painful effect of light on them, more especially a bright light. The condition can be prevented by the use of smoked glasses.

SNOWDROP. This is one of the earliest spring flowering bulbs. It looks best when planted freely in grass. The bulbs should be set 3 or 4 in. deep in August-September; they flourish in ordinary soil, particularly that of a loamy character. The common snowdrop is *Galanthus nivalis*; others with larger blooms are *Elwesii*, *byzantinus* and *plicatus*. Snowdrops may be grown in pots in the unheated greenhouse or in bowls of fibre indoors.

Snowdrop. Dainty bell-shaped blossoms of one of the first spring flowering bulbs.

SNOWDROP TREE. This is a small family of hardy flowering trees belonging to the genus *Halesia*, and also known as the silver bell tree (q.v.).

SNOWFLAKE: The Flower. The snowflake is a beautiful spring and early summerflowering bulb, with drooping, white, green-tipped flowers. It thrives in ordinary soil and should be planted in September, 3 in. deep, preferably in the rock garden. The spring snowflake, *Leucojum vernum*, is 6 in. or so high; the summer snowflake (*aestivum*) reaches a height of 18 in. One named *autumnale* has white flowers slightly tinged with rose in early autumn. Snowflakes do not usually bloom freely until well established.

SNOW FLY. This tiny pest, often described as the white fly, is destructive to greenhouse plants, particularly tomatoes. The fly multiplies with great rapidity, crippling foliage by sucking its sap. If disturbed the flies ascend in cloudlike swarms. For amateurs, the best remedy is two or three fumigations with a good nicotine preparation, the first to kill mature flies, and others successively about three weeks later. White-fly vapour is a proprietary preparation that is also used. *See Insecticide: Spraying.*

Snow Fly laying its eggs on a tomato leaf. The insect is here enlarged about five times.

SNUFF. First said to have been used to ward off infectious diseases, snuff came into fashion as a sternutatory in the 18th century, a pinch being taken or snuffed into the nose and causing sneezing. As tobacco smoking came more and more into vogue, the practice of snuff-taking declined. Snuff is made chiefly from the stalks and mid-ribs of the tobacco plant, ground to a fine powder and flavoured in various ways. In the process of manufacture much of the nicotine is dissipated.

Alkaline salts, including carbonate of ammonia, are added. The essential oils used for scenting include cloves, cinnamon, cassia, oil of bitter almonds, bergamot and lavender.

Snuffs are of two kinds—dry; such as dark rappee and Prince's mixture; and moist, like the popular blend known as S.P., and the Scotch, Welsh, and Irish mixtures. Kendal brown and Lundy foot and other varieties have their supporters, and most dealers supply a special mixture of their own. Some snuff-takers buy small quantities of two blends and mix them together.

Although snuff-taking is generally supposed to be harmless, it may in time cause some chronic inflammation in the nose-cavity, with thickening of the mucous membrane, and a certain amount of obstruction of the breathing.

A pinch of snuff may be useful in causing the expulsion of a foreign body from the nose.

Snuff Boxes. Early snuff boxes are mostly of French workmanship, and are found either round, oval, or oblong in shape. High prices have been paid for specimens of the periods of Louis XV and Louis XVI, which were of gold with carved and chased decorations, or decorated in enamel and precious stones. One of the many different designs in Napoleonic boxes is illustrated in Fig. 1. A feature of many early snuff boxes was the addition of a small spoon and grater so that the user might grind his snuff for himself.

The custom of commemorating the misfortunes of the Stuarts, and of expressing loyalty to the house, was responsible for the production of many snuff boxes bearing on their lids portraits of Charles I, Charles II, and James II; but these were not necessarily made during the reigns of the monarchs portrayed.

Snuff Box. Fig. 1. Napoleonic example with embossed medallion. Fig. 2. Georgian painted box. Fig. 3. Scottish snuff box of the Georgian period. Fig. 4. Box of chased and engraved silver; 19th century. (Figs 1-3. courtesy of Fribourg & Treyer)

Early in the 18th century gold, ivory, enamel, and tortoiseshell were the materials used in England for presentation boxes. A charming painted box of the late 18th century is shown in Fig. 2, and illustrates the fashion for decorating the lids of snuff

boxes with miniatures. As the habit of snuff taking grew copper boxes coated inside and out with white enamel were made at Battersea after the middle of the 18th century in response to popular demand. Their shapes are often very odd, resembling boats, fiddles, books and animals. The snuff boxes decorated with plaids in imitation of the Highland tartans are frequently met with. An example of one, dating from late 18th century, is shown Fig. 3. Boxes of papier mâché were in common use in the late 18th and early 19th century in England. They are often decorated with mother-of-pearl, or Chinese characters in gold and black, or are made to imitate tortoiseshell.

Silver boxes were fashioned in a variety of shapes and with different styles or ornamentation. The specimen illustrated in Fig. 4 shows a well known type in use through a great part of the 19th century.

SNUFFERS. A pair of snuffers consists of a pair of scissors with a closed box to hold the charred wick which is cut off. Many of them have three small feet to enable them to stand on a specially shaped tray which often accompanied the snuffers. They were made in silver, Sheffield plate, brass, and also in plated metal and iron.

Some beautiful examples of snuffers, with trays to match, the trays being pierced and chased, date from the early 18th century. Snuffers are a useful accessory in a modern home if wax candles are employed to light the dining table. *See Brass.*

SOAKAWAY. A soakaway is a loosely filled cavity in the earth adapted to receive rain or surface water and allow it to percolate into the ground. It is useful in many gardens and in the vicinity of houses and outbuildings. The water is first collected and delivered to the soakaway through pipes, a channel, or some similar system, which may include the ordinary form of trapped gully. It is most conveniently located immediately beneath the delivering pipe. The size of the soakaway will depend upon the quantity of water of which it has to dispose. A convenient size is an excavation in the earth to a depth of about 6 ft., making the aperture about 3 ft. square.

In the case of good, solid earth the walls can be left in their natural state, but should preferably be cut or sided to a vertical face. The space is filled at the bottom with gravel, broken brick, clinker, or other hard core well rammed and consolidated. The whole of the cavity to a depth of about 4 ft. is filled with similar material, the top surface being covered with gravel to the level of the inlet pipe, which should normally be some 12 to 15 in. below the level of the ground. Large pieces of stone, broken brick, or similar material should be placed on the top of the gravel to allow the water to discharge freely from the pipe. The filling is continued on the top of this layer and the whole covered with soil and turfed or otherwise finished.

In the case of very light soil it may be necessary to erect temporary shuttering, wooden supports, or even to line the walls with concrete. If this is done, apertures must be left to allow the water to come through, especially in the lower part of the soakaway. Such holes can easily be cast by inserting short lengths of agricultural drain pipes prior to pouring the cement between the shuttering.

Where two or more soakaways are arranged in series, to handle a larger volume of water, the first should be filled with coarse material and the others with finer materials. *See Drainage.*

SOAP AND ITS VARIOUS GRADES

For Household, Laundry and Toilet Purposes

Reference is suggested to the articles on Baby; Beauty Culture; Face; Hair; Shampoo; and also to the many entries that deal with cleansing processes, e.g. Laundry; Spring Cleaning; Washing Up.

The quality of soap is an important matter, whether for household or toilet use, and though ingredients vary in different soaps, according to the purpose for which they are required, they should be free from adulteration.

A good scrubbing soap for household use is light in colour and has a fresh, pleasant odour when pure fat has been used in its manufacture. Extra soda in its composition is an advantage, because it cuts and extracts dirt and grease. Resin is present in yellow bar soaps: a small quantity as an ingredient produces a good lather and gives the soap a clean scent. In large quantity it is an adulterant to weight cheap soaps, and its stickiness prevents the soap from being a good cleansing agent. The darker in colour a bar soap is the lower the grade.

Wrapper soaps sold in bars of two stamped tablets are free lathering with a small proportion of resin. Disinfectant household soaps to which tar acids are added are strongly alkaline and only suitable for occasional floor scrubbing or for outhouses, etc.

It is economy to buy household bar soaps in quantity and stock them, as if thoroughly dry before use they last longer. Any scraps can be saved and put into a large earthenware jar and covered with water. As the soap jelly which forms is used, more scraps and water are added. Where there is much scrubbing to do one tablet of household soap dissolved in three quarts of water makes a satisfactory soapsuds solution.

Soap powders make a good lather. They are useful for washing down paint, and the result is good if care be taken to sponge the soap off at once with clean water. Soap powders are not economical when sold at the price of soap. They contain very little fat, which is the expensive ingredient, and a great deal of soda, which is comparatively cheap.

Laundry Soaps. Laundry soap should be firm, pale in colour and of a fine, even texture. For rough work it should not contain much resin, and for fine work this ingredient should not be present. The so-called white soaps do not contain resin, and the flaked soaps sold in packets or by the lb. are practically free from it. Resin combines with any lime in the water and in excess produces a yellow stain on the laundry when dry. Soap powders also are inclined to have this effect, and too much soda in any soap yellows white silk and fades colours.

Pure white Castile soap, which is mainly composed of olive oil, may be shredded and the lather used for washing lace and delicate fabrics. Marseilles and lower grades of white Castile, though cheaper oils are used in their manufacture, are also valuable cleansers for fine work.

Carpet Soaps. Solid soaps specially made for cleaning carpets have the ordinary yellow soap basis, with a proportion of ox-gall, ammonia, or benzine. These extra ingredients, being detergents, assist in removing grease and also revive the colours of carpets.

The paste form of carpet soap is made by mixing fuller's earth 4 oz., spirit of turpentine 1 oz., pearlash 8 oz., with sufficient soft soap to make a stiff paste. A liquid carpet soap is also employed which consists in dissolving $\frac{1}{2}$ bar of yellow soap in a pailful of hot water and, when nearly cold, adding $\frac{1}{2}$ pint of liquid ammonia.

In using any form of carpet soap the carpet is spread out evenly, preferably on a stone floor, and washed as one would clean a floor, but not employing water so freely, as it is only desired to wet the upper surface of the carpet.

Medicated Soaps. Medicated soaps are commonly employed for various affections of the skin. Their remedial effect is slight, however, unless they are allowed to dry on. Sulphur soap is used for scabies. Naphthol soap is used in conjunction with naphthol ointment in psoriasis. Carbolic, coal tar, and terebene (turpentine) soaps are also used in certain cases, as, for instance, after infectious fevers, for their antiseptic effects.

Soaps are also made containing resorcin, salicylic acid, ichthyol, and many other drugs. In acute eczema, or whenever the skin is greatly inflamed, soap of any kind is exceedingly irritating, and should not be used. The skin can be cleansed by rubbing olive oil on a soft cloth and wiping it off with a dry cloth. Special soaps for washing dogs contain either sulphur or creosote.

Toilet Soaps. As only the highest grades of fat and oil should be used in a super-milled toilet soap, it cannot be bought at a cheap price. Too much caustic soda added to the fats causes the soap to be too free in alkali, which has an irritating effect on delicate skin. On the other hand, soap is cleansing to the skin by virtue of the alkali it contains. When rubbed on the skin a little of the soda separates

and unites with the grease of the skin, at the same time it softens the superficial waste layers of the skin and allows of their removal by water.

It is important, therefore, that the fatty acids and alkali contained in a toilet soap should neutralize each other. Too much alkali can be detected by a simple litmus test. Having melted a small piece of soap in water and added a few drops of litmus, the colour should be mauve if the soap be properly neutralized; if free alkali be present the colour will be blue. Super-fatted soaps may contain glycerin or an excess of fat and oil, in which case they should not be stored for long as they may become rancid.

First-class toilet soaps are hard, highly polished, denoting the finest texture, and of a pale colour.

English soaps of this quality are unexcelled as complexion soaps. Strong perfumes are only desirable in the best quality of soap, as essential flower oils, balsams and animal scents such as ambergris, musk and civet are costly. Synthetic perfumes and substitutes are used in the cheaper qualities. Dark colouring often disguises a poor grade of fat. The presence of too much coconut oil, though a small amount is necessary to obtain a free lather, has an irritating effect on the skin and necessitates the use of a coarse perfume to disguise the strong odour.

The addition of resin in the composition of bath tablets increases their lathering quality, but these soaps should not be used for small children or for the face. Honey soap, which is yellow soap of a good quality, coloured and perfumed, and curd soaps are suitable for the bath, but are too strong in alkali for complexion soaps. Palm oil is used as an ingredient for cheaper violet soaps as it has the odour of violets.

Soaps having a good proportion of pure olive oil in their composition are the best for a baby's skin. If a child's face is shiny or rough after washing, the soap is too harsh or has been rubbed on in excess. Pure white Castile soap is usually a satisfactory choice.

Shaving soap should lather freely with a softening effect on the beard, and no irritating effect on the skin. Caustic alkali should not be present or any excess of coconut oil, though some is necessary for free lathering. A creamy lather may be induced by paraffin wax or gum tragacanth, and a considerable amount of superfatting makes it more emollient.

Soap Bubbles. Soap bubbles provide children with an amusement which seldom palls either in the nursery or out of doors. If played in the garden they are usually an even greater joy, because there is more room for the sport, and sun and foliage enhance the colouring of the bubbles. Clay pipes, with the ends well sealing-waxed, are the best implements for blowing bubbles, and the supply should be liberal, as they are very brittle. The soapy water should be warm, and the lather is best made with soap flakes or soft soap.

The pipe should be put into the water with the bowl downwards. If it is shaken gently up and down once or twice in this position enough of the water will have been collected to form a good bubble without a lot of unnecessary fluid. Each player will have his own methods and fancies; one may set out to blow very large bubbles without releasing them and letting them float in the air; another may like to blow many small ones and allow them to form a fleet.

Soapwort. Profusion of pink blossoms of the small species boissieri, a useful rock garden plant.

SOAPWORT. This group of hardy annual and perennial plants bears rose-coloured flowers in summer. Of the perennials *Saponaria ocymoides* is a charming trailing plant for the rock garden;

another good rock garden plant is *caespitosa*. Both flourish in well-drained rockery soil. A taller kind, which grows from 18 to 20 in. high, and has double rose-coloured blooms in summer, is an attractive border plant. The best of the annuals is *calabrica*, 6 in., with rose-coloured blooms, which is raised from seeds sown out of doors in spring.

SOCKS FOR ADULTS AND CHILDREN

Instructions for Knitting Standard Patterns

This article gives detailed instructions for knitting a pair of woollen socks for a man, a pair of woollen socks for a child, and a pair of bed socks. Other articles on knitted wear include Bootees; Gaiters; Stockings. See also Darning; Knitting; Mending; Wool.

With a heavy type of shoes or boots in cold weather, machine or hand-knitted ribbed woollen socks for men and boys are most suitable. A heavy shoe will quickly wear holes in a thin sock. For evening dress plain black silk, and for ordinary town wear, with shoes of medium weight, cashmere socks are worn by most men. These last should be guaranteed pure wool and of a firm but soft and even texture.

When buying woollen socks, whether woven or knitted, it is well to purchase a size too large. Even though guaranteed unshrinkable, however carefully washed they will shrink a little. Measuring round the closed fist to ascertain the length of a sock is not infallible. It is better to ask for socks that will fit a size larger than the shoes worn.

For country wear, well-knitted socks are the most comfortable for much exercise. Heels and toes may be strengthened by double wool or by knitting silk of the same shade. Knitting should be loose enough for the needles to pass through easily, and success depends on an even appearance and upon the skill in turning the heel and rounding the toe.

Babies' socks are usually made in the softest white wool, and may be knitted in a fancy stitch, or, if preferred, crocheted in a rib-stitch. This is ordinary double crochet, the ribbed effect being obtained by putting the hook into the back part of the foundation each time a stitch is worked, instead of into the front. For children, best socks are knitted in silk. Mercerized or fine crochet cotton may be used and also fine wool. Boys' socks are usually of a heavier make.

Men's Knitted Socks. A pair of men's woollen socks is illustrated in Fig. 1. They are of average size, and since the leg is not shaped, they can be made either longer or shorter without necessitating a change of pattern. The knitting is done at a tension to produce about 10 stitches to the inch in width: 4 oz. of 4-ply Beehive Soft Knitting wool and 4 No. 13 knitting needles are required to make a pair.

Begin by casting on 84 stitches, 28 on each of 3 needles, and work in rounds, in ribs of knit 2 and purl 2 until 4 in. have been worked.

Continue in plain knitting until the sock measures 11 in., and then commence the heel as follows: Knit the first 21 stitches of the round on to one needle, and slip the last 21 stitches of the round on to the other end of the same needle. These 42 stitches are for the heel, and all the others, which make up the instep, should be divided on to two needles.

On the heel stitches purl and knit a row alternately until 41 more rows are worked. The first stitch of each row should be slipped, and the last row should be a purl one. To turn the heel, knit 26, knit 2 together, then turn, purl 11 and purl 2 together. Turn, knit 12, knit 2 together. Turn, purl 13, purl 2

together. Turn, knit 14, knit 2 together. Turn again, and continue in this way until all the heel stitches are worked on to one row again. Then knit 13 stitches and the heel is completed.

Socks. Fig. 1. Man's sock in soft wool that can be knitted at home.

Slip all the instep stitches on to one needle, and on to the first needle knit the remaining stitches of the heel. Knit up 21 stitches at the side of the heel and the first stitch from the instep needle, and with a second needle knit all the instep stitches but the last one. With a third needle knit the last instep stitch; then knit up 21 stitches at the other side of the heel, and the other 13 heel stitches. Knit one round without shaping, and then decrease thus for the instep in the next round.

Knit to the last four stitches of the first needle; knit 2 together, knit 2. Knit the stitches on the second needle without shaping, but on the third, knit 2, knit 2 together, and through the back of the loops knit

to the end of the needle. Repeat the last 2 rounds until only 20 stitches remain on each of the first and third needles. If a 10 in. foot is required, work without shaping until the sock measures 6½ in. from the side of the heel where the stitches were knitted up; for a 10½ in. foot, work 7 in. from the side of the heel, and 7½ in. for a foot measuring 11 in.

Shape the toe thus: * Knit to the last three stitches on the first needle, then knit 2 together and knit 1. On the second needle, knit 1, knit 2 together, and then knit to the last 3 stitches; then knit 2 together, and knit 1. On the third needle, knit 1, knit 2 together through the back of the loops, and knit to the end of the row. Knit 1 round without shaping, and then repeat from * until only 24 stitches remain on the round. Knit the stitches on the first needle on to the third, and close the toe, by the procedure known as grafting.

To do this, place the two needles together, and having threaded the wool into the bodkin, work in the following way: Place the bodkin in the first stitch of the front row, as for knitting, slip the stitch off the needle, and draw the wool through. Then put the bodkin in the second stitch of the front needle as for purling, and draw the wool through, but do not slip the stitch off the needle. Pass the bodkin under the front needle, put it in the first stitch of the back row, as for purling, draw the wool through and slip the stitch off the needle. Then place the bodkin in the second stitch of the back row, this time as for knitting, and draw the wool through, but do not slip the stitch off the needle. By this it will be seen that the action of the bodkin is reversed on the back needle. Repeat until all the stitches are worked off, and take care not to draw up the wool too tightly. When the last stitch is reached, pass the wool through it and fasten it off securely on the wrong side.

Child's Socks. Woollen socks with striped coloured tops, Fig. 2, for a child of about 6 years of age, can be made according to the following directions. The socks measure 8½ in. from the top to the ankle and 7 in. from the back of the heel to the point of the toe, and the work is done at a tension to produce about 10 stitches to the inch in width. The materials required are 1½ oz. of Beehive 3-ply Scotch fingering wool in white or grey, and ½ oz. of the same kind of wool in any other colour for the turnover or striped tops, with four No. 14 steel knitting needles.

With the coloured wool cast 24 stitches on each of 3 needles, and working the top in a rib of knit 1 and purl 1, do 4 rounds in the coloured wool and 4 rounds in white, then 1 round in colour, 4 rounds in white, 4 rounds in colour, 4 rounds in white. This completes the top, and as both sides are the same it does not require turning if the socks are to be worn with a turnover top.

Knit the next round in plain knitting and increase one stitch at the beginning of the round by picking up a loop of the previous round and knitting it as an ordinary stitch. Now begin the shaping for the leg in the next round. * Knit 1 stitch, knit 2 together, knit to the last 3 stitches of the round, slip 1, knit 1, pass the slipped stitch over the knitted, knit 1. Knit 4 rounds without any shaping. Repeat from * 3 more times, then do another decrease round, making 5 decrease rounds and 10 stitches decreased away all together. Work 54 more rounds to reach the ankle. Extra rounds are worked here for longer sock.

Socks. Fig. 2. Child's sock hand-knitted in wool, with coloured turnover top.

Now begin the heel. Knit the first 16 stitches of the round on to one needle, slip the last 16 stitches of the same round on the other end of the same needle; these 32 stitches are for the heel flap. Divide the remaining 31 stitches on 2 needles and leave them for the instep. Now work on the heel stitches, always slipping the first stitch, purl 32, turn, knit 31, turn, purl 30, turn, knit 29, turn. Continue in this manner until 9 stitches are left at each side of the heel, the last now being purl 14.

Turn and knit 14, lift up the right-hand side of the loop just before the 15th stitch and knit the 2 stitches together to prevent a hole. Turn, purl 15, lift up the loop just before the 16th stitch and purl the 2 together. Continue in this manner, working one extra stitch on to each row till all the 32 stitches are on the one row.

The last row will be a purl row. Knit back 16 stitches and so complete the heel. Slip the instep stitches on to one needle.

Now on the first needle knit the remaining 16 stitches of the heel, knit up 2 stitches at the side of the heel, and knit the first stitch from off the instep needle. With the second needle knit the instep stitches; with the third needle knit up 3 stitches from the side of the heel and the other 16 stitches. Knit one round plain, then decrease for the instep in the next round as follows; Knit to the last 3 stitches of the first needle, then knit 2 together, knit 1, knit the second needle without any shaping, on the third needle knit 1, slip 1, knit 1, pass the slipped stitch over the knitted one, then knit to the end of the needle. Repeat the last 2 rounds 3 times. Now work 56 rounds without any shaping for the length of foot required before shaping the toe, allowing for the latter to add another $1\frac{3}{4}$ in.

Shape the toe as follows: * Knit to the last 3 stitches of the first needle, knit 2 together, knit 1; on the second needle knit 1, slip 1, knit 1, pass the slipped stitch over the knitted, knit to the last 3 stitches of the same needle, then knit 2 together, knit 1; on the third needle knit 1, slip 1, knit 1, pass the slipped stitch over the knitted one, knit to the end of the needle. Knit 2 rounds without shaping. Repeat from * until there are only 28 stitches in the round, then knit the stitches of the first needle on to the third needle.

Place the two needles together, and knit a stitch from each needle at a time, and when 2 stitches are on the right-hand needle slip the first one over the second stitch, and so on until there is only one stitch left, then cut the wool, draw it through the last stitch, thread the end in a darning needle, and fasten off very securely on the wrong side of the sock. Casting off the toe can also be done by grafting, which is a much neater method and more comfortable in wear.

Bed Socks. To make a pair of bed socks of average size for a woman, $2\frac{1}{2}$ oz. of some such soft wool as Baldwin & Walker's 3-ply Ladyship Flossella Wool will be required and also $1\frac{1}{2}$ yards of ribbon, and three No. 7 needles. Commence at the top by casting on 53 stitches, and work the first

24 rows in ribs of 2 plain and 2 purl, always knitting the first two stitches at the commencement of every row and purling the last three stitches of every row.

Now change and work in moss-stitch (1 stitch plain and the next stitch purl, alternately to the end of the row, then on the return row reverse the order of the stitches so that a plain stitch comes over a purl stitch of last row) for 4 inches, increasing 1 stitch at the beginning of the first row in order to bring the stitches up to 54.

To make the holes for the ribbon, work 2 moss-stitches, * make 1, take 2 tog., 4 moss stitches; repeat from * to the end of the work, ending with 2 moss-stitches. Now work again in moss-stitch for 12 rows, then the stitches will be divided for the foot.

Work in moss-stitch over the first 16 stitches, on the next 22 stitches work backwards and forwards in moss-stitch for 40 rows (always slipping the first stitch), then break off the wool and join to where the 16 stitches were left and with the same needle pick up 20 stitches along the side of the instep flap and also 11 stitches across the toe. With the spare needle work across the remaining 11 toe stitches and pick up 20 stitches along the other side of the instep flap, also the 16 remaining stitches on to the same needle. Work across all the stitches for 10 rows; then decrease 1 stitch at both ends of both needles for 5 rows. Then cast off or leave the stitches for grafting. Join up the seams and through the holes at the ankle thread the ribbon.

SODA. Soda is a valuable agent for quickly and thoroughly removing grease and dirt from pots, pans, and other kitchen utensils, accessories, and cloths. These should be thoroughly rinsed in clean hot water before they are dried. Soda should not be used for cleaning aluminium and enamelled vessels.

Household Uses. If the household water is very hard, common soda is frequently added to it when boiling green vegetables, or it is used for the purpose of restoring the colour of the vegetables when they have been closely packed and carried to market. It is, however, preferable to sacrifice appearance and omit it altogether, for on some constitutions it has a deleterious effect, particularly the common or washing soda. At all times the quantity should be strictly limited, and bicarbonate of soda should be substituted for the washing soda, as much as will lie on a sixpence being quite sufficient to soften each gallon of water.

Bicarbonate of soda is used as a raising agent in the making of bread, cakes, and scones, and for cakes it has almost superseded yeast. Sometimes cream of tartar is added to the soda in order to prevent it from darkening the flour. Bicarbonate of soda is the most important ingredient¹ of baking powder.

Uses in Medicine. Soda is largely employed for medical purposes in the form of various salts of sodium.

Sodium bicarbonate, 2 drams to the pint of water, is a useful lotion to apply to the skin in cases of mild itching. Made into a paste with a little water and applied to insect bites and stings, it often gives immediate relief, as also in burns and scalds before blisters have formed. Internally sodium bicarbonate is constantly prescribed in various kinds of indigestion.

The phosphate and sulphate of soda and tartarated soda are widely used purgative salts. Most of the natural purgative mineral waters such as Apenta, Rubinat, Hunyadi János, Carlsbad, etc., derive their characteristic action from one or more of these sodium salts.

Sodium chloride or common salt is one of the natural ingredients of the tissues, and therefore is an essential article of our dietary. In large doses it acts as an emetic.

Sodium citrate is often added to the milk of babies' bottles to make it more readily digestible. One grain of sodium citrate dissolved in a teaspoonful of water is added for each ounce of cow's milk in the bottle. The effect is to render the curds of the milk which form in the infant's stomach less tough. *See* Saline.

SODA CAKE. For making this economical cake the ingredients are 1 lb. flour, $\frac{1}{2}$ lb. sultanas, $\frac{1}{4}$ lb. chopped peel, 6 oz. butter or margarine, $\frac{1}{4}$ lb. granulated sugar, a little grated nutmeg, 2 eggs, 1 teaspoonful bicarbonate of soda, $1\frac{1}{2}$ gills milk, pinch of salt. Sift flour and salt together, rub in the butter, add the sugar and dried fruit. Put the bicarbonate of soda in the milk and add it to the eggs, which have been beaten. Pour this on to the dry ingredients and beat all thoroughly before putting the mixture into a baking tin lined with paper and baking it in a moderate oven for about $2\frac{1}{2}$ hours.

SODA WATER. The name soda water is rather misleading, for commercial soda water consists usually of water charged with carbonic acid gas. Occasionally soda is present in small quantities, about 5 gr. of bicarbonate of soda to the bottle. It should properly contain 30 gr. to the pint of aerated water. Soda water can be made at home, the aerating process being accomplished with sparklets. *See* Sparklet.

SOFA. Through its predecessors the day bed, courting seat, settee, and the couch of the Regency period, the sofa has a very long pedigree. As seen to-day it has a head at one end and sometimes a back. The frame is of wood, which may be mahogany, deal, or one of intermediate value. Many sofas are fitted with a loose cushion and a bolster for the head.

In Victorian days a sofa was made and sold as part of a suite of furniture, and these suites were seen in dining rooms, drawing rooms, and other living-rooms. To-day the sofa is less popular, its place having been taken to a large extent by the divan, modern versions of the settee, or the Chesterfield.

It may be remembered that, in common with many other pieces dating from the first half of the 19th century, well-made sofas increase in value and interest as people begin to collect furniture of this period.

Repairing a Sofa. The back of a sofa is composed of a shaped top rail as at A, Fig. 1, two ends B, a centre piece C, and a bottom rail D. These parts are generally secured together with dowels, as shown, and if loose they can be replaced and the joint glued up again. An alternative method of strengthening the frame is to screw on angle brackets at the corners as at E. This method should not be employed in the case of a badly damaged frame.

The frame itself is usually dowelled to the seat frame and screwed to the scroll ends. The seat frame shown at Fig. 2 is sufficiently strong to resist the strain of wear, but it is possible that the cross or end rails may have become loose or broken; in this case the method of repair is to fit a new rail across, as at F or G, the latter being additional, to strengthen the frame or remove a twist caused by a warped length.

The legs are usually secured with dowels, the repairing being generally a matter of fitting new dowels. It will be seen from Fig. 3, which shows a plan of the framing directly over one of the legs, that two of the dowels are fitted in the outer rail and one in the cross rail. In renewing them, a larger diameter dowel should be provided, and the old ones bored out; in addition the two flat surfaces should be scraped quite clean so that the glue will hold up tight. The leg with dowels is shown in Fig. 4.

Castors may have been replaced two or three times and worked loose again, or the wood may have split. In the former case it is advisable to fit a stout dowel in the leg as in Fig. 5; the end can be shaped so as to fit in the castor. If the leg has been split at the bottom, it will be as well to bind it

with wire, suitable grooves being cut as in Fig. 6. By using an ordinary wood filler the wire binding can be entirely covered and will not be noticed. The scroll ends are liable to work loose or break off at the tenon joints, as at H, Fig. 2, and K in Fig. 7. Although they can be glued up again, it is generally more satisfactory to cut the tenons off, fill up the mortises with suitable blocks of wood, and replace with a dowelled joint, as in Fig. 8. The dowels should enter both pieces for at least 1½ in.

If the ends are not very loose, the joint can be strengthened by blocks of wood screwed to the inside of the frame, as at L, Fig. 9, but it will probably be necessary to fit in thin blocks each side, as at M, to bring the inside of the scroll upright to the same distance as the seat rail. Further strengthening may be necessary in dealing with the scroll ends by renewing the rails P, R, and T. These are placed there as much for upholstery purposes as for strengthening the construction. As a rule, they are secured by glued blocks, as at N, but in better class work they are housed in the sides.

Breakages in the short grain of the wood are not unusual, either at the bottom, as at W, Fig. 7, or as in Fig. 10. In dealing with a break as at W, the best way is to screw on a suitable strip of hardwood, as shown. Breakages at the top are repaired with a narrow strip screwed on as in Fig. 10, but the broken edges, particularly if they are of long standing, must be thoroughly cleaned and glued together. Re-glued joints should have newly planed surfaces, but if this is impracticable, the surfaces must be scraped to remove old glue; where it is impossible to use a scraper, the wood should be cleaned with hot water and a stiff brush. *See Castor; Chesterfield; Divan; Dowelling; Settee.*

SOFFIT: In Building. There are numerous applications of the soffit in domestic architecture. Externally it is the covering applied to the underside of the eaves of a house: on internal parts of the building the term soffit refers to exposed ceilings such as those found beneath some forms of staircase.

The term is applied to the inner face of an arch and to some forms of ceiling formed into panels and otherwise treated, and often found on projecting or bow windows. Soffit lining is the covering on the underside of lintels for a window or door, or arch opening, or the linings covering the underside of an exposed flight of stairs. *See Ceiling; Eaves; Rafter; Roof.*

Soft Water. *See Water Softener.*

SOFTWOOD. The timbers that are classed as softwoods are those that are light in texture and are easily worked, the opposite kinds being the hardwoods. The chief of the softwoods are the coniferous trees such as the pine, fir, larch and yew. They abound in resin and yield turpentine and pitch. *See Deal; Hardwood; Larch; Pine; Wood.*

Soil. 1. Soil stack: turves interlaid with lime (a) and manure (b). 2. Lightening heavy soil: a, bottom spit well dug; b, manure; c, top soil with lime and sand forked in (d). 3. Improving light soil: a, subsoil; b, manure: pig, cow or vegetable refuse; c, top spit with lime (d); e, surface of clay or heavy loam. 4. How to burn clay: a, coal and coke fire; b, soil; c, soil and slack; d coal dust; e, leaves; soil; g, draught bricks. 5. Base for same: A, fire; b, draught passages; c, bricks; d, soil, etc. (By special arrangement with Amateur Gardening)

SOIL: The Varieties. The chief kinds of garden soil are heavy, loamy, peaty and light or sandy soil. The nature of each can be modified by artificial treatment to suit the conditions of the garden and the requirements of the plants that are to be grown therein.

Of the four chief kinds of soil, a heavy soil consists almost entirely of stiff clay, and must be lightened by deep digging and throwing the subsoil open to disintegration by the action of frost during the winter months. It may also be further lightened by the admixture of sand, wood ashes, burnt weeds, grass and other bonfire material. Road sweepings, where they can be obtained free from the taint of petrol refuse, are excellent for lightening heavy soils.

A loamy soil is the best for all general purposes, and is the one in which clay and sand are found naturally mixed. A peat soil is very dark in colour, due to the preponderance of decayed leaves in its composition. It is invariably found in the neighbourhood of woods and forests, and should be mixed with other soils to obtain the best results.

Sandy soil is easily recognized by its dry and powdery nature. It is composed chiefly of silica, and alone is unsatisfactory and unproductive. It is best improved by the addition of clay, animal manure, decayed vegetation, and anything that helps to bind the particles of sand together.

If the soil is sick, and grows moss and sorrel, it contains too much acid, and requires a good dressing of lime. In making a new garden liming is always necessary. About 10 lb. to a square rod will be sufficient.

Health and the Soil. The nature of the soil on which a house is built may have a great deal of influence on the health of the inhabitants. It often happens that a person who suffers from rheumatism, neuralgia, lung troubles, etc., finds himself much better on changing his residence to another neighbourhood. There may be other reasons, of course, for the improvement, but in many cases the chief cause is removal from a damp soil or low location to porous, dry, and warm ground.

The most porous or permeable soils are gravel and sand. Through these the rainfall percolates freely, passing down until it meets an impermeable stratum, such as clay or rock. The next most porous is a chalk soil. Any of these furnishes a dry site for a house provided it is situated on a slope. Limestone is only slightly porous; the water will flow away over it if the site is on a slope, but otherwise it is apt to keep the surface wet.

Hard rocks and clay soil are almost impervious to water. A rock site on a slope forms a very healthy foundation as the water flows away quickly. Clay is nearly always cold, and on a dead level, or in a hollow, it forms a very wet, bad site, both the ground and the air being damp. When sandstone or chalk is present in a mixture with clay, it is likely to be damp unless the slope is steep enough to allow the water to run away freely.

Two important points have to be considered in connexion with soil, namely, ground water and ground air. All soils except those that are quite impervious, contain water and air. The water consists of the rain which has passed through the upper porous layers, and, at a greater or less depth, is prevented from sinking further by an underlying impervious stratum. Thus if we dig down we always reach water. In some low-lying, wet places this ground or subsoil water comes up close to the surface in rainy seasons; in marshy districts it may be level with the surface; in other places it may be hundreds of feet down.

Above the level of the ground water the interstices of the soil are filled with air, the ground air. When the water level is close to the surface a great deal of it goes off into the outer air by evaporation, making the air around the house damp. The level is constantly varying, and each time the ground water rises it forces out the air contained in the soil above it.

If the soil is pure this air is harmless. If the soil is contaminated, the air will be impure, and when forced into the basement of a house it may cause injury to health. The soil may be contaminated by its contents of decaying vegetable matter, or by drainage from manure heaps cesspools, middens,

farm buildings, leaking drains, graveyards, etc. Not only does a rise of ground water force gases into a house unless there is a thick concrete foundation, but it may contaminate wells.

The points to consider in connexion with this matter are the nearness to the surface of the ground water and the greater or less fluctuations of level which take place. If the ground water is not more than ten feet below the surface, the site is not a good one for a dwelling-house; probably the level should be fifteen or twenty. Likewise, if there are great and frequent changes in the level of the water, danger arises from the gases forced out.

In Great Britain the building by-laws of most local authorities now require the provision of a ground layer. This usually consists of six inches of concrete over the site of the rooms, and effectually prevents any movement of ground air inside the house irrespective of the level of the ground water. It also protects the inmates of the house from contaminated ground air which is detrimental to their health. *See House; Ventilation.*

SOIL PIPE. This name is given to an impervious pipe connecting the w.c. with the manhole in a drainage system. The requirements of the local authorities must be strictly observed when putting in, repairing, or in any way dealing with soil pipes.

In most districts it is a requirement that these pipes be of good grade cast iron treated on the interior with Dr. Angus Smith's solution to render them immune from the attack of acids, water, and foul matter generally. All joints must be properly made and absolutely airtight. Customarily an air vent is provided from the highest point reached by the soil pipe and taken from that some distance above the roof.

The lower end of the soil pipe discharges into the first manhole adjacent to the house. This manhole has also to be ventilated with fresh air in common with other parts of the sewage system. The result in a properly devised system is that the soil pipe is normally empty and is ventilated throughout by a steady current of air. The exterior of the pipe should be kept in good condition by the frequent application of paint, and all ears, lugs, straps, etc., used to fix the pipe to the exterior of the building should be examined from time to time. *See Drains; Sanitation.*

Solanum. The winter cherry (Solanum capsicastrum), a greenhouse and window plant with orange-red berries in winter.

SOLANUM. This is the botanical name of a group of shrubs and plants which includes the potato and several kinds of ornamental value.

The bitter sweet of the hedgerows, of which the red berries are poisonous, is *Solanum dulcamara*. *Solanum melongena* is the egg fruit or aubergine which is raised from seeds under glass in spring and grown in large

flower pots or on a sunny border. The winter cherry (*Solanum capsicastrum*) is a favourite window and greenhouse plant which bears orange-red fruits in winter and is raised from seeds or cuttings under glass in spring. *Solanum crispum*, mauve, and *jasminoides*, white, are vigorous climbing plants suitable for a wall in mild districts, or for the greenhouse elsewhere. *Solanum Wendlandi*, which must be grown under glass, is a climbing plant with large mauve blooms.

SOLAR FLOWER. A flower that opens and shuts during the day about certain hours is known as a solar flower. Thus the goats-beard is open from 3 to 5; the dandelion from 5 to 6; the pimpernel

about 8; day lily from 10 to 11; and the tiger lily about 12. Closing times vary with particular plants. Solar flowers are sometimes used to compose a floral clock.

SOLAR PLEXUS. Lying behind the stomach and in front of the aorta, or chief blood vessel of the abdomen is that part of the sympathetic nervous system known as the solar plexus. It consists of two large ganglia, and of interlacing nerve fibres. It receives branches from the right vagus nerve and supplies branches to the liver, stomach and other abdominal organs. The disabling effects of a blow over the solar plexus are well known.

SOLDERING FOR THE METAL WORKER

Enabling the Handyman to Undertake his own Repairs

This process is necessary for a number of mending and constructional operations described in our work. The reader should therefore consult Aluminium; Bent Iron Work; Copper; Leaded Lights; Napkin; Piercing; Silver Work. See also Blow Pipe; Flux; Plumbing.

The process of joining metals together by means of another metal that melts at a relatively low temperature is known as soldering.

The requirements for amateur work consist of a soldering iron or copper bit (Fig. 1), some solder, flux, emery paper, an old file or two and an odd knife for scraping the metal clean. In addition there must be some means for heating the iron, and preferably some sacking or rough cloth with which to wipe it clean. The size of the iron and its type will depend on the nature of the work. For domestic use a plain bit weighing about $\frac{3}{4}$ to 1 lb. will suffice, and this may be the ordinary adjustable type of iron with a wooden handle. The term "iron" is misleading, for the actual heating element is a pointed or hatchet-shaped piece of copper. The most useful form of solder is tinman's solder in bars about $\frac{1}{2}$ in. wide and $\frac{3}{8}$ in. thick, sold by weight. Blow-pipe solder, which is harder, is sold in long, thin strips; this is best used with a large copper bit or a blow pipe. Tinman's solder also can be purchased in narrow strips.

Soldering. Fig. 1. Top, ordinary type of soldering iron, showing well-tinned bit. Centre, self-heating petrol blow lamp type of soldering iron. Bottom, electrically heated soldering iron in place on economy bracket; the weight of the iron automatically presses down the bracket and reduces the current consumed.

The soldering acid or flux may be powdered resin, killed spirits, that is, hydrochloric acid in which a number of small pieces of zinc plate have been dissolved, or one of the proprietary brands. A combined solder and flux in paste form is useful for small jobs, as the surfaces can be coated with the paste, held or

wired together, and united by sweating, using a blow pipe or lamp, as later described. In an awkward corner the point of the soldering iron can be introduced to heat the joint.

The heating medium for the soldering iron is preferably a gas heater of some kind, a regular soldering stove, or a powerful blowlamp when gas heating is not available. Irons are made that are self-heating (Fig. 1). Some derive their heat from a self-contained gas burner, and others from an electric heating device, or a petrol blow lamp forming a part of the soldering iron itself.

Mending a Kettle. As an example of the methods of soft soldering, suppose a leak is to be mended in a tin kettle. The first step is to clean the surface to be repaired. The best method is to scrape or polish the metal with an old file or knife, as in Fig. 2, and finish with rough emery paper. Then wipe the metal clean with a piece of clean cloth to remove the dust and chips.

The iron is heated over a gas ring or any clear, hot, bright fire until the copper is almost but not quite red hot. Now take the bit from the fire and wipe it quickly with a cloth to remove any surface dust. Next rub the tip of the copper with a file, as in Fig. 3, resting the iron on an odd bit of wood or metal to prevent scorching the bench.

The next step is to tin the bit, that is, to cause a film of solder to run on to and adhere to the point of the bit. If the bit has cooled in the cleaning process it must be reheated. Place a spot of flux on the centre of the clean piece of tinplate and dip the point of the hot iron into the flux for a moment. Then, holding the iron in the right hand and the strip of solder in the left, place the point of the iron on the tinplate and apply the solder to the edge of the iron.

The worker turns the iron over as the solder melts (Fig. 4), moving it about and rubbing it into the little pool of molten metal until the solder adheres to all the four sides near the point of the iron. The appearance of a well-tinned bit is shown in Fig. 5, and it is in this state that the iron is fit to use. The iron need not be reheated until it fails to melt the solder freely. When this point is reached, take care not to overheat the iron and melt off the tinning, as if this is done it will have to be cleaned and retinned as already described. If carefully used the iron should not need tinning except at long intervals.

Presuming the iron to be still hot, the next step is to take a small disk of tinplate and place it over the hole on the cleaned part of the work in hand, to which flux will previously have been applied, adding a touch of flux to the edges. Press the iron on the edges of the tinplate disk and apply the solder to the side of the soldering bit, melting off a few lumps or blobs as shown in Fig. 6, and proceed to flow the solder all round the edges of the disk. At the same time press the soldering iron on the centre of the disk to assist in heating it; and also to draw the solder well under the metal and ensure a sound joint. Finish by running the iron around the joint to make the surface of the solder neat and tidy, as shown in Fig. 7.

It is well, when the solder has been run round the patch, to press on the latter with the point of an old file or some similar object, so as to hold the patch firm until the solder cools. If the file is held upright on the centre of the patch the soldering iron can be worked round the edges of the patch to make a neat and even joint. The kettle should be firmly supported so that both hands are free.

Exactly the same processes are followed in soldering any tinplate article, the steps being to clean the surfaces, apply flux, see that the iron is well tinned and sufficiently hot. flow the solder round and under the joint, and finish by smoothing with the point of the iron. Any small lumps of solder are removed by the iron or can be filed away, the use of the soldering iron being preferable.

Tinning a Joint. For brass or copper the same procedure is adopted, except that it is necessary first to tin the surfaces to be united. This is accomplished by rubbing with the point of the tinned copper soldering bit and at the same time flowing on a further supply of solder. The surface is generally

made smooth and bright by wiping it over with a clean rag while the solder is still hot and molten. This ensures a better ultimate joint, as the two faces can then be brought into more intimate contact. Wrought iron and steel can be soft soldered by first tinning the surfaces; they are, however, more often brazed together, as there are few occasions for the use of soft solder when steel has to be employed, since this metal is used on the grounds of strength. A soft soldered joint is not naturally strong unless the parts to be joined are fitted into one another, or otherwise made secure against external stresses.

Soldering. Fig. 2. Scraping bottom of kettle with a file before soldering. Fig. 3. Cleaning end of iron before tinning it. Fig. 4. Tinning the bit by dipping it into molten solder. Fig. 5. Well tinned bit. Fig. 6. Soldering disk over a hole in a tin kettle. Fig. 7. Patch soldered in place on kettle.

Sweated Joints. Another method of soft soldering is known as sweating, and this does not call for the use of a soldering iron. The typical procedure can be illustrated by the case of a brass ferrule forming part of a pipe union for attachment to a gas fitting. The first steps in this case are to clean the surfaces thoroughly and then to tin them by holding the parts in the flame of a blow lamp; as

soon as the metal is hot, apply a trace of flux and press the end of the stick of solder on to the metal. It should then flow over the surface and partly adhere. The tinning is completed by wiping the surface with a clean rag.

The parts are then placed in position, the flame of the blow lamp directed on to the joint, and the solder melted into place. The end of the joint should be pressed against some suitable object, the heat being concentrated on the outer part of the joint, remote from the lip, as the solder will always run towards the heat. If the greatest heat is at the inner end where the joint begins, the solder will be more difficult to flow into place. Small jobs can be carried out by using paste solder combined with flux. Sometimes the objects to be united can be held over the flame of a gas ring, spirit lamp, or Bunsen burner.

Zinc is soldered in the usual way, but with the use of killed spirit as a flux. Aluminium can be soldered, but only with specially prepared solders and a suitable flux. There are several proprietary brands on the market, and they should be employed exactly as the makers direct. Methods of soldering lead are dealt with in this Encyclopedia under the heading of plumbing.

Hard Soldering. To carry out hard soldering, or silver soldering, a blow lamp or blow pipe (Fig. 8) is essential, or some other form of easily controllable heat giving a long clean blue flame. The soldering is effected with silver, the metal being alloyed with a small proportion of brass, to lower the melting point. Articles made of silver can thus be united with the solder without danger of fusing them. This method is used by silversmiths and jewellers, and has the advantage that the joints are particularly strong and durable for small work, being in many respects superior to brazing. There are several kinds of flux that may be used, but probably the best is borax in lump form, which is reduced to a paste with water by rubbing the borax on the surface of a slate. The solder is obtainable in several grades, melting at different temperatures. To use it, the metal is cut into strips of suitable size and fed up to the job while playing on it with the blow-pipe flame or the jet of a blow lamp.

As an example, suppose it is desired to solder in a boiler end to a model boiler, the barrel being formed of seamless tube, as described in the article on Engine. After the surfaces of barrel end and disk have been cleaned the borax paste is applied to the joint with the point of a small camel-hair brush. One or more of the strips of solder are bent around and placed on the borax flux. After this the flame of a blow lamp or gas blow pipe is directed on to the work. The clean part of the flame must be kept on the joint. This is generally a little distance from the tip, at a spot where the inner cone of flame is visible as a slightly different coloured cone. If the dirty part of the flame is used the work may be oxidized and the result prove a failure. As the metal is heated the borax will froth and turn white and finally melt. Soon the metal will appear to be red hot and the strip of silver will melt and flow around the joint.

The crux of the operation is to make the silver flow properly, and only experience can give the requisite skill to accomplish this. It is largely a matter of correct temperature and correct position of the flame; the metal will always follow the heat of the flame, and can be drawn, as it were, to the desired spot. If the work is at all delayed the flux may all be burned, but this can be remedied by application of a further supply from a spoon made from a piece of thick iron wire beaten to a spoon-like end. If this is placed near the flame of the blow lamp it will keep hot, and when dipped into the borax some of the latter will adhere, and it can then be conveyed to the desired spot.

When properly made, a silver-soldered joint is nearly as strong as the metal to which it is applied, and for all small work it is preferable to soft solder. The resulting scale on the work can be removed by filing and finishing with emery paper.

Should it be desirable to unsolder an article, the sweating process is perhaps the best when it can be carried out, the metal being heated, a small amount of flux applied, and the parts pulled asunder while the solder is molten. After any soldering process all traces of the flux or soldering acid must be removed by scouring the article in hot soda water or by the use of emery paper.

Soldering. Fig. 8. Implements used in hard soldering. A, bench gas burner. B, holder for small objects. C, gas blow pipe. D, mouth blow pipe. E, charcoal block. (Courtesy of H. W. Burn & Co.)

Some of the appropriate implements for hard soldering are illustrated in Fig. 8. The gas blow pipe (C) is used in conjunction with a small bellows. The gas burner (A) has a swivelling tube; when this is turned at right angles the flame is reduced to a tiny jet. The method of silver soldering jewelry and similar objects is somewhat different. The worker places the articles to be united on a charcoal block (Fig. 8, E), or a soldering "wig," and after applying the borax plays on the joint with a small blow pipe (D). The solder is cut into small pieces and placed in position with a pair of tweezers. The jobs are small, of course, and the heating source can be a spirit lamp or a Bunsen burner. The parts to be soldered are fastened together with binding wire. For quite tiny objects one can use a holding device (Fig. 8, B) consisting of a pair of clips mounted on a rod which is held in the hand or a vice. The clips have universal joints, so that the parts, when gripped by them, can be brought into contact and are held fast while being soldered.

SOLE: The Fish. A flat fish with firm, white flesh and an excellent flavour, the sole should be cooked as soon as possible after it is caught, but in cold weather may be kept for a few days without harm. There are two kinds of sole, known respectively as the lemon and the real sole. The latter is superior in flavour and therefore dearer. Steaming between two plates over a saucepanful of water is the best way of preserving the delicate flavour of fillets of sole. The fillets of the fish should be seasoned with pepper and salt and lemon juice.

Fillet of Sole. To bake fillets of sole, wash them well, removing the white skin, and roll each one into a round. Stand them in a greased pie-dish, add $\frac{1}{2}$ gill milk, and salt and pepper to taste, and place a small piece of butter on each fillet, using about 1 oz. in all. Cover the dish with a plate, and

bake the fish in a moderately hot oven for about 18 min. In the meantime prepare 1½ gills white sauce and brown some breadcrumbs. When the fillets are cooked, take them from the oven, roll them in the breadcrumbs, and then stand them in a line on a dish. Pour the sauce round and garnish the top of each fillet with a thinly cut slice of lemon.

Another method of baking sole is described in the following recipe: Skin and fillet a small fish, season it and then fold each fillet in two, doubling the thin end over towards the thick. Lay them on a baking-tin greased with butter, add a tomato, cut into quarters, then cover the whole with a piece of greased paper, and bake it for about 8 min. Serve the fish on a hot dish with the pieces of tomato placed round it.

Baked fillet of sole may also be served with white sauce to which two heaped tablespoonfuls of grated cheese have been added. Some more grated cheese should be sprinkled over the fish after it is cooked and then browned under a gas griller.

Either whole or filleted, sole may be fried as directed in the article on Fish.

Sole may also be grilled, and a pat of maître d'hôtel butter is a good garnish. Finely chop 1 teaspoonful parsley, add a squeeze of lemon juice and incorporate with sufficient butter to make a round pat. Place one on each portion of grilled sole when ready to serve. *See Carving; Fish; Lemon Sole; Sauce.*

SOLIDAGO. These vigorous herbaceous perennials bear yellow flowers in September and October. They flourish in ordinary soil and are easily increased by division in autumn and spring. The best kinds are Golden Wings, Shortii and canadensis, all about 5 ft. high. One, canadensis nana, is only 2½ ft. high.

SOLITAIRE. This game for one is played on a circular board containing 33 holes, each made to hold a marble. They are arranged in the form of a cross, each line containing 7, as shown in the illustration. Marbles are placed in the holes, except the centre one, and the object of the player is to remove them one by one until only one is left, and that one in the centre hole. The removing is done by taking one off the board when another is moved over it into an empty hole beyond, as in draughts. Moves can only be made in a straight line, not diagonally. It is by no means easy for the beginner to succeed in his task, as one false move will leave him with three or more marbles in such positions that they cannot be taken.

Solitaire Board, showing the thirty-three holes, arranged in the form of a cross, for the marbles.

SOLOMON'S SEAL. This is an excellent hardy plant for shady places. It grows 3 ft. high and has arching leafy stems bearing numerous greenish white flowers in May. It spreads rapidly and thrives in ordinary soil. Roots may be potted in autumn and placed in the greenhouse for spring blooming.

Solomon's Seal. Showing the rows of greenish-white bell-like flowers which hang from the undersides of the stems.

SOLO WHIST. This card game, generally known as solo, is played by three or four players with an ordinary pack of 52 cards. If only three play, either one suit entirely is omitted or only three hands are dealt, as the players agree. The cards are dealt three at a time to each player in turn, and the last round consists of a single card to each player, the final card, the dealer's, being turned up for trumps.

Each player either says "I pass" or make-a call. The lowest call is proposal, usually contracted to "prop." A player who props does so in the belief that his hand is good enough, if backed by a reasonably good one by another player, to make 8 tricks in the partnership. Any other player may take the proposal, pass, or make his own call.

The next highest call is solo. This is a call by a player when he undertakes to make at least 5 tricks, playing a lone hand against the other three. Above the solo call is misère. When a player makes this call he undertakes to lose every trick, despite every effort on the part of the other three players to make him take a trick. There is no trump suit in the misère call. Above misère comes abundance in any suit except trumps. A player declaring abundance undertakes to take at least 9 tricks, playing a lone hand against the other three. Abundance in trumps calls over abundance in a plain suit.

Above the last call comes open misère. When this call is made a player undertakes to lose every trick, his hand being exposed upon the table after the first trick has been played. The highest call of all is abundance declared, when the player, naming his own trumps, undertakes to win all 13 tricks against the other three players. A player making such a call has the right to lead.

When players are playing prop and take, or prop and cop, as it is more generally known, they may be sitting together or opposite one another, and in those positions they remain. No player may bid after once passing with the exception of eldest hand, who has the privilege of accepting a proposal.

In three-handed solo a player is sometimes allowed to bid a 6-trick solo, in which he names his own trumps and must take at least 6 tricks. Except in abundance declared eldest hand leads and players should follow suit. If not, a player may discard or trump. The winner of each trick leads for the next. *See Whist.*

Somnambulism. *See Sleepwalking.*

SOOT. In summer, when fires are infrequent, soot accumulates only in small quantities, but in winter it forms a thick coating inside the chimney and it is most important to have it thoroughly swept and to arrange for the periodical visits of a sweep.

Garden Uses. Soot which has been exposed to the air for a few weeks is an excellent fertilizer for plants and may be scattered on the soil round about them. If placed in a bag suspended in a barrel of water soot makes a useful liquid manure for ferns, chrysanthemums and other pot plants. Fresh soot either alone or mixed with lime is a good soil insecticide; it should be forked in the ground, not left on the surface.

SOOTHING SYRUP. The practice of dosing fractious and restless children with soothing syrups, soothing powders, and similar preparations is strongly to be deprecated. It may make things easier for the mother or nurse, but this may be at the expense of the child's welfare. If a dose of castor oil, or some other simple purgative, does not improve the child's temper, consult a doctor. *See Aperient; Child; Teeth.*

SOPHRO-CATTLEYA. This name is given to a bigeneric orchid raised by crossbreeding between *Sophranitis grandiflora* and *cattleya*. It flowers during winter, and may be grown in well-drained

pots, or hanging baskets. The cultural requirements of *sophro-cattleya* are very much the same as for *cattleyas*. *See* Orchid.

SOPHRONITIS. This is a small group of dwarf-growing evergreen orchids. The favourite is *grandiflora* with orange-scarlet blooms; it should be grown in pans or baskets suspended from the roof of the intermediate house. *Sophronitis* needs a mixture of peat moss, and charcoal, and flourishes in a temperature which may vary from 55° to 70°, according to the season of the year. *See* Orchid.

SORBET. This is a water ice flavoured with fruit and liqueur. General directions for the making of water ices and the serving of sorbets will be found in the article on ices (q.v.).

Sore Throat. *See* Laryngitis; Pharyngitis; Throat; Tonsillitis.

SORREL: The Herb. The leaves of this herb are used as an ingredient of salads and soups. Seed should be sown in March in drills 6 in. apart, and the rows thinned out during the following month. The name sorrel is frequently applied to species of the genus *Oxalis*. *See* Oxalis; Spinach.

Use in Cookery. Sorrel is used in cookery chiefly for a soup and a purée, the purée being employed as a means of dishing and also as a garnish for entrees. It is especially suitable for serving with lamb, veal, or sweetbreads, and also as a garnish for poached eggs in place of spinach.

Sorrel must always be thoroughly cleansed, and it is better to use a hair sieve for making it into puree. Soda should never be put with sorrel when cooking it, on account of the acid contained in the leaves.

Sorrel. Hardy evergreen shrub much used in cookery, sometimes as a substitute for spinach.

Sorrel Purée. To make the purée, pick and wash 2 lb. of sorrel and boil it in about ½ pint of water until quite soft, then drain it on a hair sieve until all the water is out of it. Clean the stewpan in which it was cooked, dry it and melt in it 1½ oz. of butter. In this fry to a light brown 1 peeled and sliced onion, then add 1 oz. of flour, 1 dessertspoonful of brown sugar, and ¼ teaspoonful of grated nutmeg. Stir all together for 2 or 3 min., then put in the sorrel and 1½ gills of brown sauce. Season well and pass through a hair sieve.

Sorrel Soup. Sorrel soup may be made as a clear vegetable soup or it may be thickened by mixing in the yolks of 2 or 3 eggs to each quart of soup. If it is to be served as a vegetarian soup water must be substituted for stock. For the thin soup clean and shred fine 2 lb. sorrel, the best part of a large lettuce, 12 sprigs chervil, and 4 or 5 sprigs parsley. Sauté these in 2 oz. butter in a stewpan, then add 2 pints well flavoured rich clear stock, 2 lumps sugar, and seasoning to taste. Boil up and simmer for 20 min., then clear the soup of fat, pour it into a soup tureen and serve with dice of fried bread. For the thickened soup proceed as for thin soup, but when the whole is boiling, whisk up 2 or 3 yolks of eggs and add to them by degrees about ¾ pint of the liquor of the soup. Stir these till all is

just ready to serve, then draw the pan back from the fire and stir in the thickening. Cook for 2 or 3 min. without allowing the soup to come to the boil, then add a good slice of fresh butter, stir this in and serve.

Souchong Tea. Souchong is a black China tea of a fine flavour suitable for everyday consumption or for blending. *See* Tea.

SOUFFLÉ. The meaning of this word is something puffed or blown up, and in cookery this condition is obtained through using the stiffly whipped whites of eggs and preparing the ingredients in such a manner that they rise upward as soon as the heat penetrates them. Baking powder is never added to give lightness, success depending on skill in preparation and the beating of the eggs. The delicacy of a soufflé renders it a most wholesome and favourite dish, and one which may be safely offered to invalids.

A soufflé is cooked directly it is mixed and served immediately before it has time to sink. It may be baked, in which case the oven must be exactly of the right moderate heat and kept at a steady temperature during the process of cooking; or it may be steamed, in which case the water must be boiling in the saucepan before the soufflé tin is placed in it. Baked soufflés are served in the dishes in which they are cooked.

Before serving a steamed soufflé it is usually turned out on to a dish from the tin mould with straight sides in which it has been cooked. The mould is prepared by brushing it over with pure salad oil or clarified butter. A double band of white kitchen paper deep enough to stand 3 or 4 inches above the top of the mould and long enough to fold right round and overlap should be also greased and tied round the outside of the mould. A round of paper is then greased ready to cover the top. The soufflé mixture should only fill three parts of the mould to allow for rising. The mould is then put in a pan of boiling water. See that the water only reaches half-way up tin.

For baked soufflés fireproof earthenware china or glass soufflé dishes are used. Oven table glass ware is an aid when making a soufflé, as the process of baking can be clearly seen. When serving, fireproof dishes are placed on another dish covered with a paper doily, unless the soufflé dish is provided with a plated or silver frame. Individual soufflés are baked and served in small paper or china cases. Any dishes or cases used must be first well greased. When three parts filled with a soufflé mixture, they are placed on a baking-tin and cooked until well risen and firm. Avoid any unnecessary opening of the oven door, as a sudden draught of air might cause the soufflé to sink. It should never be left in either steamer or baking dish after it has finished cooking.

Sweet flavourings are added for light soufflé puddings, while cheese or fish, game and white meats make this quickly cooked dish into a savoury, a light luncheon course, or entrée. The main ingredients consist of flour, milk or stock, and new-laid eggs. Any fish or meat used should be first pounded and passed through a sieve. Cheese should be grated. Fruit is not very suitable for sweet soufflé making, the best flavours being chocolate, vanilla, coffee, almond or a delicate essence. Sweet soufflés may be steamed or baked, cheese soufflés are baked- while fish and meat soufflés are steamed.

Cheese Soufflé. Melt 1 oz. butter in a saucepan over the fire, stir in ½ oz. flour, and when the mixture is smooth add 1 gill milk, stirring the whole over a gentle heat until it thickens. Then take the pan from the fire and mix in 2½ oz. grated cheese. When the mixture is slightly cooled stir in, one at a time, the yolks of 2 eggs. Season the mixture to taste, afterwards folding in lightly the stiffly whipped whites of 3 eggs. Half fill a greased and fireproof soufflé dish with the mixture, and bake it in a quick oven for 10 or 12 min. Sprinkle about 2 teaspoonfuls grated cheese over the top of the soufflé, and serve it immediately.

Chicken Soufflé. Make this by taking the flesh from a chicken and, after removing the skin and gristle, cutting it into small pieces and pounding them well in a mortar. Season them with salt, pepper, and a grating of nutmeg, and add 1½ gills good white sauce and the yolk of an egg before passing the mixture through a fine wire sieve into a clean basin. Then work in lightly, but thoroughly, 1½ gills cream, partially whipped, and the stiffly whisked whites of 2 eggs, pour into a prepared soufflé tin, and steam gently for about 50 min. Let the soufflé stand for a minute to shrink slightly, then remove the paper from the tin and turn out on to a hot dish. Serve at once with béchamel sauce. Game or rabbit can be used for this soufflé **in place of chicken.**

Chocolate Soufflé. This soufflé can be made from ¼ lb. breadcrumbs 2 oz. sugar, 1 oz. grated chocolate, 1 pint milk, ½ oz. butter, and 2 eggs. Boil the milk, chocolate and sugar together, then add the breadcrumbs and butter and stand the mixture in a cool place. When it is cool, add a few drops of vanilla essence and the yolks of the eggs, afterwards stirring in the whites, whipped to a stiff froth. Pour the whole into a well-greased glass or other fireproof soufflé dish, and bake it for 20 min. in a moderate oven until it is of a golden-brown tint.

Fish Soufflé. To make this soufflé melt 2 oz. butter in a saucepan, stir in the same quantity of flour, and mix them together over the fire for a few minutes. Then add 1 gill milk or fish stock and stir until the sauce thickens. Put it into a mortar with ½ lb. of any white fish and pound them well together, adding 3 eggs, one by one. Season the mixture carefully, rub it through a sieve, and mix it with 1 gill whipped cream. Put it into a prepared soufflé tin and steam for ½ hour, then coat it with some good white sauce and decorate top with chopped parsley.

Fish Soufflé. Dish made from any white fish.

Lemon Soufflé. This sweet soufflé may be steamed. It is made by rubbing together a heaped tablespoonful of castor sugar and the grated rind of a lemon. Melt a lump of butter about the size of a hen's egg in a small pan over the fire, add a heaped tablespoonful of flour, and mix the two smoothly. Cook them for a few minutes, taking care that they do not brown; then pour in a gill of milk and stir the whole over the fire until it leaves the sides of the pan. Move the latter to the side of the fire, add the sugar and rind, and a little lemon juice, and then beat in separately the yolks of 3 eggs. Whisk the whites of 4 eggs, together with a pinch of salt, to a stiff froth and stir them into the mixture, blending the two well together.

Have ready a prepared soufflé tin, and decorate the bottom of it with halved glacé cherries. Pour the mixture in and cover it with another piece of greased paper. Place the tin in a pan of boiling water and steam the soufflé for about ½ hour, or until it is well risen and firm to the touch; then turn it on to a hot dish and serve it with lemon sauce. Orange may be used to flavour the soufflé and sauce instead of lemon.

Liqueur Soufflé. Any kind of liqueur can be used to flavour this soufflé. Make it by melting a lump of butter rather smaller than a hen's egg and then mixing in a well-heaped tablespoonful of flour. Stir the two over the fire until they are smooth, but do not let them brown. Pour in 1 gill milk; continue stirring for a few minutes, and draw the pan to the side of the fire before beating in separately the yolks of 2 eggs.

Add 1 tablespoonful castor sugar, a pinch of salt, and enough liqueur to flavour the whole to taste. Just before turning the mixture into a greased soufflé dish, stir in the stiffly beaten whites of egg. Place the dish in a tin of hot water in the oven and cook the soufflé until it is firm and risen. If a sweet sauce is served, it may be flavoured with the same liqueur as that used for the soufflé itself.

Oyster Soufflé. To make this soufflé, blanch and beard a dozen oysters and cut each into three or four pieces. Melt 1 oz. butter in a stewpan, stir in smoothly 2 oz. flour, and mix them well together over the fire. Pour in 1 gill oyster liquor, and stir the whole until the flour loses its raw flavour and the sauce thickens. Take the skin and bones from ½ lb. whiting, then put it into a mortar with the sauce and pound the two together, adding the yolks of 3 eggs, one by one, and salt, pepper, and cayenne to taste.

Oyster Soufflé, coated with white sauce, and decorated with half slices of lemon.

Rub the mixture through a hair sieve, then stir into it the oysters and the stiffly whipped whites of 4 eggs. Pour the mixture into the prepared soufflé tin, and steam it gently for about ½ hour, or until it feels firm. Serve it with a good white sauce poured over it, and garnish it with lines of finely chopped parsley or slices of lemon.

Potato Soufflé. To make this dish, rub 1½ lb. cooked potatoes through a sieve, add to them 1 oz. butter, previously melted in a pan, and put in also 2 tablespoonfuls milk, the yolks of 2 eggs, and seasoning to taste. Mix these well, then take the pan from the fire and stir in lightly the stiffly whisked whites.

Turn the whole into a prepared soufflé mould and steam the soufflé for about 40 min. in a saucepan containing enough boiling water to reach half-way up the mould. Turn it on to a hot dish, pour some white sauce over it, and garnish it with chopped parsley or the yolk of a hard-boiled egg rubbed through a sieve. If preferred, the soufflé can be baked in a china soufflé dish in a moderate oven for about hour.

Rice Soufflé. An excellent rice soufflé can be made by washing ¼ lb. rice and boiling it in 1 pint milk to which has been added 6 oz. butter, and the same quantity of sugar. When these are cool, stir in the yolks of 4 eggs and add a little vanilla essence. Whisk the whites of the eggs very stiffly, then fold lightly into the rice, and pour the whole into a well-buttered mould decorated with angelica and cherries. Steam the soufflé gently for about ¾ hour, and serve it with jam sauce. *See Eggs; Egg Whisk; Entrée; Fireproof Ware; Ham; Mould; Omelette; Sauce.*

Soups: Clear and Thick Kinds

Many Recipes for the Staple Item of the Dinner Menu

This contribution, which describes the making of various kinds of soup, may be read in connexion with the articles on Dinner; Luncheon; Supper. See also the entries on Artichoke Soup; Beef Tea; Browning; Clarifying; Croûton; Menu; Mutton; Sauces; Scotch Broth; Stock, etc.

Soup is prepared by boiling meat or vegetables with water. It may be thickened by the aid of starchy substances or the admixture of beaten eggs. It precedes the fish and meat courses at meals.

To make nourishing soups good stock is essential and directions for preparing the various kinds are given in the article on stock. Directions for making roux to thicken brown and white soup are given in the article on Sauces. Soups may be divided into five classes: Clear Soups, Broths, Thick Soups, Purées, Vegetarian Soups.

Clear Soups. Clear soup or consommé is prepared from first stock, and if that is ready and made according to the rules laid down, all that is necessary is to provide extra seasoning, and a garnish.

The foundation of clear soup is always the same, the various names given to it on a menu being merely dictated by the garnish. Spring soup, for instance, is clear brown stock garnished with delicate spring vegetables, including asparagus points, green peas, forced French beans, or new carrots, the two latter cut small.

A good clear soup is made by the addition to any clear stock of minced beef and vegetables. An onion and a carrot, cut into small pieces, should be allowed to ½ lb. beef and 4 pints stock. These should all be put into a saucepan, with 1 or 2 peppercorns, a sprig of mixed herbs (parsley, marjoram, and thyme), and the white of 1 egg. The soup should be whisked over the fire until frothy. After it has boiled it is left to simmer for about 30 min., then strained through a scalded tea-cloth.

Consommé royal is made from brown stock with the addition of a savoury custard, cut into fancy shapes. To make the custard, 1 egg is allowed to 1 tablespoonful milk or white stock. The egg is beaten with salt and pepper to taste, and stirred into the hot milk or stock. The custard is then steamed in a small greased basin for about 15 min. and allowed to cool. When it is cold the custard should be sliced with a knife which has been dipped in hot water, and then stamped into fancy shapes. These should be placed in the soup tureen and the boiling consommé poured over.

Clear soup can be garnished with cooked vegetables, shredded very finely, or with cooked vermicelli or macaroni, or small forcemeat balls fried and well drained.

Julienne Soup. This favourite clear soup is made by the addition to 3 pints of clear brown stock of 1 carrot, 1 onion, ½ large turnip, 1 strip celery, 1 tablespoonful green peas (cooked), pepper, salt, ½ oz. butter. The prepared vegetables are cut into fine strips like matches. Melt the butter in a saucepan and fry the vegetables in this with the seasoning for a few minutes shaking them to prevent them from scorching. Drain them from the butter, add them to the hot stock, simmer for 30 min., keep well skimmed. The vegetables may be parboiled in salted water instead of frying in butter if preferred before simmering in the stock till quite tender. French beans, cooked and cut into thin strips, may be added instead of or with the peas.

Paysanne Soup. This clear vegetable soup is made by cutting into thin rounds about the size of a sixpenny-piece a carrot, a turnip, 2 leeks and a stick of celery. Fry these lightly in a saucepan containing a little butter; then add a pint of chicken or veal consommé, and let the whole cook gently until the vegetables are tender. Just before serving, remove any scum that may have risen to the surface, and add a little chervil.

Broths. For this class of soups the stock is usually made by saving the liquor from meats boiled whole for table. The liquor should be strained through a hair or tammy sieve, skimmed free from fat and well seasoned. It is generally thickened with rice or pearl barley and a few fresh vegetables cut

small and cooked in it. At the finish a small quantity of chopped parsley may be added. Sheep's head broth, mutton broth, Scotch broth or veal or chicken broth are some of the varieties of this description of soup or bouillon. Boil some vegetables in the liquor while cooking the meat to flavour the broth.

Pot au Feu. Pot au feu is the name given to the French national broth. To prepare it, put 1 lb. brisket of beef in a large saucepan with 2 quarts water, bring the latter to the boil, remove all scum from the top, and add salt to taste. Simmer all for ½ hour, and in the meantime prepare 2 carrots, 2 leeks, 3 sticks of celery, a cabbage, 2 turnips, and a parsnip.

Cut the cabbage into two, tying the halves together, and peel and slice an onion. Cut up the carrots, turnips, parsnips, leeks, and celery, using only the white portion of the two last-named, and at the end of the ½ hour add them to the soup, together with the onion, cabbage, 10 peppercorns, and a bunch of herbs. Simmer the whole with the lid on the pan for 1½ hours, then strain the soup and skim off the fat from the top. The soup should then be served in a hot tureen. This broth is often termed *Croûte-au-pot* when French bread is cut into thin slices and placed in the tureen just before serving, the meat and vegetables being served as a separate course at another meal.

Veal Bouillon. Take 2 lb. scrag of veal and cut it into small pieces. Then put them into a saucepan with 1 quart boiling water and 1½ oz. of well-washed rice, boil up, and simmer gently for an hour. Add an onion, carrot, and 3 sticks celery cut in neat pieces. Cook until these are soft, and just before serving sprinkle in two tablespoonfuls of picked chervil. Skim and remove all fat before adding the chervil to it.

Thick Soups. These may be either white or brown according to the white or brown roux employed to thicken them, or to the nature of the stock used. Thick brown soups should be made with good stock and flavoured with vegetable. They may be thickened either with a brown roux, or with rice. If rice is used as a thickening it should be cooked previously and boiled up in the soup.

All brown soups should possess a rich deep brown colour, whether made thick or thin. To improve the appearance of the soup it may be necessary to add a little browning, but this should be done with discretion.

In making either white or brown thick soups the quantities required for thickening are important, and the following may be noted: From 1 to 1½ oz. flour will thicken 1 quart liquor. About 2 tablespoonfuls rice, etc., should be allowed to 1 quart stock and 2 to 3 eggs and 1 gill cream will make a sufficient thickening for about 2 or 3 pints of white soup. When eggs are added as a thickening, the soup must only be simmered and not allowed to boil up again, or the eggs will curdle.

The garnish for thick soups should not be neglected. If vegetables are to be used they must be neatly cut and freshly boiled. If no vegetable cutter is available the roots may be shred or shaped evenly in dice. Small pieces of carrot take about 7 min. to boil, turnip 5 min.

Chicken Soup. A nourishing thickened white soup is made by cutting up an old chicken into small pieces, and putting the whole, together with the bones, into a saucepan containing enough cold water to cover it. Bring the bird slowly to the boil, skim the stock well, and add a carrot, a leek, two small sticks of celery all cut into small pieces, a bunch of mixed herbs, and ½ teaspoonful salt. Simmer the soup for about 5 hours, remove all traces of scum, and then strain through a fine sieve. Let the liquor stand in a basin till it becomes cold, then pound some of the chicken meat in a mortar, moisten it with a little stock, and rub it through a sieve. Make a smooth white roux by melting a

small lump of butter in a saucepan and mixing with it $\frac{1}{2}$ oz. flour, then add the liquor and pounded meat, and boil up the whole. Finally add $1\frac{1}{2}$ gills boiled milk and seasoning, and serve.

Giblet Soup. To make this thickened brown soup the giblets of a goose or turkey, or of a couple of chickens or ducks, are needed. Cleanse and cut them into small pieces; then melt 1 oz. butter in a saucepan, add the giblets, together with 1 lb. lean beef, and a small onion, $\frac{1}{2}$ a carrot, and a stick of celery, all cut into small pieces. Fry all these a pale brown, then add 3 pints stock or water, a bunch of parsley and mixed herbs, and salt and pepper to taste. Bring the soup to the boil, skim it well, then put the lid on the pan and let its contents cook gently for about 2 hours.

The giblets, etc., may then be strained out and the liquid poured into a clean saucepan. Mix $\frac{1}{2}$ oz. flour smoothly with the butter in which the vegetables were fried, brown and add half a glass of sherry or a little cold brown stock, add it to the soup, and boil up the whole. Put in 2 or 3 in. of cooked macaroni cut into thin rings, and stir it over the fire for a few minutes. Before serving the soup add more seasoning if desired.

Macaroni Soup. Boil 1 quart white stock, then add to it 2 oz. cooked macaroni and simmer for 5 min. Mix together the yolk of an egg and 1 gill unsweetened condensed milk, and add 2 tablespoonfuls grated cheese. Take the pan containing the macaroni away from the fire before adding the egg mixture, and then stir all over a gentle heat until the soup thickens. Season to taste, add 1 dessertspoonful of chopped parsley, serve with sippets of toast and then hand round grated cheese.

Mulligatawny Soup. To make this thick brown soup, fry 1 carrot, 3 onions, cut small, with a head of celery cut into dice, in 4 oz. fat or butter until the onion begins to look clear, then add 2 tablespoonfuls curry powder and the same of flour. Fry all till the onions brown then stir in by degrees 2 quarts good stock. Let all simmer till the scum has risen well and the vegetables are quite soft.

Pass the soup through a hair sieve, return it to the saucepan, adding a dessertspoonful of curry paste and seasoning to taste. Squeeze in a little lemon juice. The curry paste should be rubbed smooth with some of the liquor and dissolved before being added to the soup. Rice should be handed round with it.

Mushroom Soup. A quart of bone stock and $\frac{1}{4}$ lb. each of ox kidney and mushrooms are needed to make this brown soup. Cut the kidney into small pieces and roll them in flour, mixed with a little pepper and salt. Melt 1 oz. butter in a saucepan and fry the mushrooms, peeled and cut into small pieces. Add the kidney and the stock, and simmer for about 2 hours. Make a brown roux from a tablespoonful of flour stirred into a tablespoonful of melted butter and thicken the soup with this. Bring it just to the boil and serve it very hot.

Tripe Soup. For this white soup take $\frac{1}{2}$ lb. tripe, a turnip, a carrot, 3 onions, 2 tablespoonfuls cornflour, $\frac{1}{2}$ pint milk, 3 pints water, and a little sweet herbs, parsley, salt and pepper. Scald the tripe in boiling water and then cut it into small pieces. Having prepared and sliced the vegetables, put them in a saucepan with the tripe and water and simmer them for $1\frac{1}{2}$ hours. Mix the cornflour to a paste with a little cold milk, add to the soup, and stir all well together. Just before serving add the rest of the milk, the herbs, parsley, salt and pepper, and serve the soup hot with croutons of fried bread.

Turkey Soup. This soup provides an excellent method of using up any cold cooked turkey. To make it, cut up the remains into small pieces and put these, together with the chopped bones, into a stewpan. Add a bouquet garni and a small blade of mace, a small peeled onion, 2 quarts white stock or milk and water mixed in equal proportions, and seasoning to taste. Put the lid on the pan, simmer its contents gently for about 3 hours, then strain the soup, and after rinsing out the pan pour it back again. Mix oz. ground rice smoothly with a little cold milk, stir it gradually into the soup, then bring the latter to the boil and let it boil gently for about 10 min. Have ready 2 oz. freshly boiled macaroni or spaghetti, cut it into short lengths, and heat it up in the soup before serving.

Purées. This class of soups is made by rubbing the meat, fish, vegetables, etc., through a sieve after cooking. For vegetable purées, beans, carrots, peas, artichokes, potatoes, chestnuts, tomatoes, or celery are used. These are prepared and, if necessary, cut in small pieces. They are then tossed in butter for a few minutes and cooked in boiling stock. When done they are passed with the liquor through a sieve, then returned to the stewpan, boiled up, seasoned, and served in a tureen, with dice of fried bread handed round.

Vegetable purées are often white as when potatoes or artichokes are used. White stock must then be added instead of second brown stock and a small quantity of milk or cream must be boiled with them when finishing the soup in order to blanch it. White soups usually are seasoned still further with a dash of mace or nutmeg.

Carrot purée should be an orange colour and only the red parts of the carrot be used for it. Green pea soup may be made with second stock, and an economical version of it can be prepared by cutting up the pea shucks and adding them with the peas to the liquor, increasing the amount of stock in proportion to the quantity of shucks. The shucks will boil quite tender if the peas are young, and the flavour after the vegetables have been passed through the sieve will be found excellent. About 2 lb. fresh vegetables to 3 pints liquor is the average.

Dried pulse vegetables make good and nourishing soups, and water may in all cases be substituted for stock. The pulse is soaked overnight, then washed and picked. It should be stirred, with a few fresh vegetables to give it flavour, notably onions, in butter or fat for a few minutes over the fire; the water is then added cold, and the whole boiled up together and cooked until the pulse is perfectly soft. The soup should be passed through a wire sieve or colander, and afterwards returned to the saucepan in which it was boiled, well seasoned and thoroughly heated ready for serving.

A bacon bone or one or two rashers are often added to lentil soup. The bone is removed before the soup is sieved, but the rashers, if minced small, will pass through the sieve with the lentils. To pea soup ham or bacon bones are sometimes added and boiled with the peas; they must be removed as soon as the peas are soft enough to sieve. For soup made from split peas it is better to use the liquor from salt beef after it has been boiled, but first ascertain that it is not over-salted. The liquor from any boiled meat may be used, or a weak stock. Plenty of fresh vegetables must invariably be cooked with dried pulse to give the right flavour.

Haricot beans make an excellent white soup, but only celery and onions are suitable for adding as a vegetable flavouring. This soup should be finished with a small quantity of milk. The amount of pulse required for each quart of water is about $\frac{1}{2}$ pint; $\frac{1}{2}$ pint milk is the usual quantity for finishing 1 quart white soup. Fish purée is made with fish stock, thickened with white roux, seasoned and finished with milk or cream. The fish is cut up and flaked, all bones and skin removed, cooked in stock till tender, and then passed through a sieve before adding the cream.

Parmentier Soup. A good creamy potato purée can be made by slicing 3 large potatoes and the white part of 3 medium-sized leeks, frying them lightly in a saucepan containing 1 oz. butter, and then adding 1 pint veal or chicken stock. Cook the whole gently until the potato is tender; then rub

it through a fine sieve. Reboil it, and before serving add seasoning to taste 1 gill cream, 1 oz. butter, and a little chervil.

Parsnip Purée. The ingredients consist of 1 pint milk, 1 quart bone stock, 4 parsnips, 1 onion, 2 sticks celery, flour and seasoning. Clean and slice the vegetables, fry them in dripping, and then add the stock. Let the whole simmer until the vegetables are tender, then rub them through a wire sieve and return the puree to the stewpan. Add the milk, seasoning, and the flour mixed smoothly with a little milk, and cook the soup for about 5 min. Serve it with croutons of fried bread.

Spinach Soup. Cook the spinach, make it into a purée, then stir it in butter for 6 min., and add boiling white stock and a little cream. The quantities required are 2 lb. spinach, 1½ pints stock, 2 oz. butter, 1½ gills cream. Flavour with lemon and nutmeg, and add the stock to the purée by degrees.

Tomato Purée. Trim and wash three leeks, holding them under running water so as to rid the inner leaves of grit, then cut them into small pieces, and fry them gently without browning them for a few minutes in a pan containing 1 oz. fat.

Add to them ¾ lb. tomatoes previously wiped and cut into quarters; fry these also until they are tender, and then pour over them 1½ pints stock. A bunch of mixed herbs should also be added, and the whole boiled up rapidly. Then season it to taste, and after cooking it slowly for about ¾ hour rub it through a fine sieve.

In the meantime rinse out the saucepan, then pour the soup back, add a teaspoonful milk, and reheat the whole. Just before serving the soup add a lump of butter about the size of a hen's egg, and, if necessary, a little more seasoning.

Vegetarian Soups. The recipes for the pulse soups given may be adapted for vegetarian soups by using vegetable stock, milk and water or milk in place of meat stock. For other vegetable soups the vegetables are cut thin, fried in butter as for purée, before adding the liquor. Onion soup and leek soup should be thickened with white roux. For white soups the vegetables must only be stirred long enough for the butter to be absorbed; if the soup is to be brown they must be well fried. After they have been cooked in the butter, they are boiled and passed through a sieve. Onions, leeks, and a touch of garlic are necessary for these soups to increase the flavour. They are seldom thickened except with dried or baked pieces of bread.

Another class of white vegetable soup is made by shredding lettuce, the hearts of spring cabbages, cucumber, spring onions, and various salad herbs. These shreds are stirred in butter for 8 min. without colouring them. They are then moistened with vegetable stock, a little nutmeg is added, also seasoning, boiled up and simmered for 15 min. Just before serving the soup is thickened with a liaison of eggs and cream. Bonne femme soup is made much like the foregoing; 4 lettuces, 1 cabbage, and a good handful of salad herbs being required, and about 3 pints vegetable stock and 2 oz. butter.

Vegetable Bouillon. A purely vegetarian broth is made from the following vegetables prepared, cut up into small pieces and placed in 4 quarts boiling water to make 2 quarts soup after simmering for 4 hours: 8 oz. carrots, 1½ oz. haricot beans, ½ oz. lentils, 4 oz. potatoes, 4 oz. turnips, 3 oz. leeks or onions. Add salt to taste.

SOUR MILK: Medical Uses. Poisonous substances resulting from the putrefaction of protein food in the bowel have been blamed for causing or aggravating various disorders, such as acne, boils,

eczema, enteritis, neurasthenia, and arterio-sclerosis. It is often attempted by the use of soured milk to diminish or prevent this auto-intoxication. The lactic acid bacilli contained in sour milk multiply in the bowel at the expense of the putrefactive bacteria.

A pint of soured milk is taken daily, in two or three portions, at meals, or preferably between meals. The soured milk is taken for three weeks at a time, and should be persevered with even if constipation ensues, which it frequently does.

Ordinary buttermilk is sometimes used, but milk artificially soured by the Bulgarian bacillus is better, as this bacillus appears to be more active and more resistant than the ordinary lactic acid bacillus found in buttermilk. Solid and liquid preparations containing the Bulgarian bacillus are on the market, but it is better to use the products of a good dairy, when these can be had. It is very important, when undergoing the treatment, to avoid meat extracts of all kinds, white of egg, fat meat, and high game, as these form a good food for the putrefactive bacteria which it is desired to destroy.

Sour Milk Scones. To make these, take $\frac{1}{2}$ lb. flour, $\frac{1}{2}$ teaspoonful cream of tartar, $\frac{1}{2}$ pint sour milk, $\frac{1}{2}$ teaspoonful bicarbonate soda, 1 teaspoonful golden syrup. Add salt to flour, then mix in all dry ingredients. Add the syrup to the sour milk, pour into flour, etc., and mix lightly. Turn on to a floured board, and knead quickly until smooth. Roll out into a round $\frac{1}{4}$ in. thick, divide into four or six pieces, and cook in a hot oven or on a girdle until well risen and browned. The scones should be served hot.

Sour Milk Cheese. Allow the milk to become very thick and curdled, then put the solid curds in a piece of clean muslin. Tie this up and suspend it on a hook in a cool place where all the moisture can drip from it. When it is dry and crumbly take the bag and dip it quickly into boiling water. Do not let it stay in the water more than a minute or so. Let it dry again, then put the curds in a basin and beat up with salt and pepper to taste. Press into a mould or make into a pat, and cover with greaseproof paper. The cheese will keep several days in a cool place. *See Milk.*

SOUTHDOWN MUTTON. A fine special breed of sheep fed on the Sussex downs is noted for the quality of its meat, which is known as Southdown mutton. A leg of this mutton, in particular, is considered a delicacy, but the chops and cutlets are also esteemed. *See Mutton.*

SOUTHERNWOOD. This is a shrubby plant, *Artemisia abrotanum*, which grows 3 ft. high and bears fragrant greyish leaves and yellow flowers in late summer. It flourishes best in light or well-drained soil and is increased by cuttings in a frame in August. Other names for this plant are lad's love and old man.

SOWING: Of Garden Seeds. The commonest errors made in sowing seed are to sow too thickly or too deeply, and to allow insufficient drainage to seeds sown in pots, pans, and other receptacles. As to depth of sowing, it is a good practice to cover seeds about twice their own depth.

Vegetables as a general rule are best sown in drills shaped like a V to the desired depth by means of a hoe, but in the case of beans and peas it should be flat or saucer-shaped, as shown in the diagram. Other drills are also pictured. Always use a taut garden line when chopping out or drawing drills, to ensure straightness. Sufficient seed should be placed to provide good rows, an old garden maxim being one for pests, one for the weather, and one for the harvest crop.

The following quantities, in portions of ounces or pints, will be found ample for good rows of vegetables 100 ft. long: Broad beans. French beans, and scarlet runners, $\frac{1}{2}$ pint; broccoli, Brussels

sprouts, cabbage, cauliflower, leek, kale lettuce, onion, savoy and turnip, $\frac{1}{4}$ oz.; carrot, parsnip, radish, and swede, $\frac{1}{2}$ oz.; beet chervil, and spinach, 1 oz.; peas, 1 pint.

Hardy annuals are usually sown out of doors in March and April where they are to bloom in summer; many may be sown in August-September to provide late spring and early summer flowers. Biennials, e.g. sweet william and Canterbury bell, are sown in May; hardy perennials under glass in spring or out of doors in early summer. *See Frame; Hotbed; Propagation; Seed.*

Sowing. 1. Home-made drill rake. 2. Drills drawn and labelled. 3. Triangular drill. 4. Flat drill for beans, peas, etc. 5. Economical group sowing. 6. Seed-box with glass covering. 7. Drainage holes for same. 8. Seed-boxes and pots in frame. 9. Pot prepared for sowing: a, crops; b, soil fibre; c, chopped turf; d, good soil; e, fine soil and sand. 10. Soot sprinkler.

SOY. This sauce is usually bought ready prepared. Its chief ingredient is the soya bean, which is imported from China, Japan and Manchuria. Japanese soy, made from soya beans, coarse barley meal and salt in equal weight, is usually the most popular. It should be brown in colour, of a thick consistency and clear. Chinese soy contains varying amounts of sugar, mace, ginger and pepper, and has a sweet, treacly flavour. Japanese soy is largely used in the making of store sauces. *See Sauce.*

SPADE. There are several varieties of spade, and many fancy shapes, but the one with the simple, broad, straight edge is the best for general purposes in the garden. The handle grip usually fitted is of the type known as the eye handle, and is strengthened with a rivet through the gripped part. Another type (illustrated in use) is T-shaped, having a short length of rounded wood attached at its centre to the end of the handle.

Much labour is wasted in digging if the spade is not properly used. The spade should be held nearly vertically over the ground where it is desired to dig, the left hand being a good way down the handle. The right hand grips the end of the handle. A sudden downward motion follows this. Having pushed the spade as far as possible into the soil with this downward thrust, the left foot is planted on the blade on the left side of the handle. The weight of the body is used to sink the blade still lower into the ground. Using the unbroken ground at the back of the spade as a fulcrum, the earth is prized up on to the blade of the spade by a downward and backward movement of the right hand. If this operation is found very difficult the earth may be loosened by moving the spade backward and forward before attempting to prize the mass. To turn the earth over or to throw it to any desired place, the left hand is used for raising the blade end of the spade. The last operation consists of turning over the earth, the spade being tilted over to the left to free it from the earth. *See* Dibber; Digging.

Spade. Correct position in which to hold the spade before thrusting it into the earth.

SPAGHETTI. A particularly fine make of macaroni, spaghetti is easily digested and can be given with safety to invalids.

Savoury Spaghetti. To prepare savoury spaghetti, melt 1 oz. butter in a saucepan, and fry in it for a few minutes 1 lb. sliced tomatoes and a peeled and sliced onion. Then add $\frac{1}{2}$ pint stock and $\frac{1}{4}$ teaspoonful of mixed herbs tied in muslin; bring the whole to the boil, adding seasoning to taste, and then simmer it until the vegetables are tender. Break $\frac{1}{4}$ lb. spaghetti into small pieces, wash it well and cook it in boiling salted water until it is tender. Take out the herbs from the tomato sauce, rub the latter through a sieve and then put it back into the saucepan, thickening it with $\frac{1}{2}$ oz. cornflour previously mixed with a little cold water.

Boil the whole for a few minutes, keeping it well stirred, and then mix in the cooked and drained spaghetti. Grease a pie-dish, cover the bottom of it with 2 oz. grated cheese, then pour in the tomato and spaghetti mixture and over the top sprinkle another 2 oz. grated cheese. Heat the whole in the oven, and then brown the top beneath a griller before sending it to the table. *See* Macaroni.

SPAN. As a measure of distance this is 9 in., which is approximately the distance between the tip of a man's thumb and little finger when his hand is outspread. In architecture it is the spread of an arch between its abutments.

SPANDREL. A spandrel is the corner space between an arch and its surrounding frame. If the arch is in a colonnaded oak bedhead, there are two spandrels, one on each side of the arch. If a circular panel is used in a door, there are four spandrels, each roughly triangular, occupying the space between the ring and the enclosing frame. Spandrels are found in inlaid sideboards of the Sheraton and other styles.

SPANIEL. The generic name of spaniel is applied to seven of the most useful varieties of gun-dogs. They are the clumber, cocker, English and Welsh springers, field, Irish water and Sussex. The cockers and springers are most used, performing the dual function of springing and retrieving the game. They are generally docile and friendly of disposition, the exception being the clumber, who does not lavish his favours upon strangers. The spaniel's length of muzzle allows free olfactory

development, securing highest scenting powers. *See* Clumber; Cocker; Dog: Japanese Spaniel; Kennel; King Charles; Mange, etc.

Champion field spaniel, with close-up of head. (Thos. Fall; Ralph Robinson, Redhill)

SPANISH BROOM. This beautiful hardy shrub (*Spartium junceum*) bears slender, rush-like branches, and yellow flowers in summer. Spanish broom will thrive in ordinary garden soil, especially if light and sandy. It does not care for stiff, heavy soil. Propagation is by seeds, sown in the open in autumn or spring, or by

cuttings of young shoots raised in frames in the summer-time.

SPANISH CHESTNUT. This is a hardy, summer-leaving tree (*Castanea sativa*), 20 ft. to 50 ft. in height, which flourishes in ordinary soil and a sunny position. The nuts are ripe in late autumn. Propagation is by sowing the nuts in early spring, and transplanting the seedlings when they are one year old. The timber is of value to the woodworker, as it is hard and heavy and is sometimes used as a substitute for oak. *See* Chestnut.

Spanish Fly. *See* Cantharides.

SPANISH FOWL. One of the oldest breeds of poultry known to British breeders is the Spanish fowl, which is an excellent layer of large white eggs averaging 2½ oz. and in some strains even more. It is a moderately large bird, with a fair quantity of white flesh, and although it is a black plumaged bird its skin is delicately white.

A single-combed breed, the Spanish fowl carries large white lobes that spread over its face until they meet beneath the wattles. The comb and wattles are red, the plumage rich, glossy, green-black, legs and feet slate blue. *See* Fowl; Poultry.

SPANISH IRIS. The common name for *Iris xiphium* is Spanish iris. It is one of the most useful bulb plants for display in the garden, and for providing cut flowers of many shades of colour. It has been called the poor man's orchid. Spanish irises should be planted 3 in. deep and 6 in. apart in early autumn. *See* Bulb; Iris; Planting.

Spanish Iris, popularly known as the poor man's orchid and invaluable for providing cut blooms.

SPANISH OMELETTE. To make this, finely chop a shallot and a clove of garlic, fry them to a pale brown colour in 1 oz. butter, and then add 4 stoned olives cut into small dice. Beat up 4 eggs, add 2 tablespoonfuls sherry, and seasoning to taste, and pour them on to the mixture.

Stir the whole over a good fire until the eggs begin to set, then tip up the pan and shape the omelette to an oval form. The upper side may be lightly browned either by turning the omelette or holding it before a clear fire. Serve it with a little hot Espagnole sauce. *See* Omelette; Sauce.

SPANISH ONION. This is the name of a large variety of onion. Spanish onions are considered to be better than British ones for serving as a vegetable, but not for flavouring. They are also very useful as a cure for certain complaints. *See* Onion.

SPANNER: For Nuts and Bolts. There are two main kinds of spanner in general use. Within its limits the adjustable type can be made to fit almost any nut as occasion demands; the fixed or key pattern is rigid but can be obtained in various sizes.

Cycle spanners, or wrenches, are perhaps the most common of the first type. These can be adjusted by means of a nut, which is generally in the handle of the tool. The fixed size spanner is often double ended, the two ends differing in size by about $\frac{1}{2}$ inch. In box-type spanners the recess is capable of taking the whole thickness of the nut to be unscrewed, reducing considerably the risk of the spanner slipping off the nut. Some are tubular in form, with a T-handle, a cranked arm, or just a hole through which a loose “tommy” bar can be put to give leverage. The tubular type is usually supplied in sets, the smaller sizes nesting inside the largest one. Since they are often double ended, a complete set takes up quite a small space.

Ratchet spanners are handy and take two main forms. In one sort the spanner itself is box shaped, fitting into a holder to which is attached a ratchet handle. In the other kind the spanner resembles the ordinary flat double ended type, but the jaws are disk shaped, interchangeable, and formed with ratchet teeth on the periphery. There is a pawl in the handle which engages with a tooth of the jaw and forces it round as the handle is moved forward and backward.

The cone spanner is for tightening up cones, as on an ordinary bicycle, without removing the wheel. Being made of thin material the spanner can be placed on the cone, and the latter turned the required amount, if the spindle nut is slackened sufficiently. Another handy type for a cycle is the spoke spanner. It fits over the nut on the rim ends of the spokes, and can be turned without taking the spanner off the nut, thus adjusting the tension of the spoke.

In using an adjustable spanner the open end of the jaws should face in the direction of the turn. There is then less tendency for the spanner to slip over the nut. If the nut is exceptionally tight, it should be remembered that a sharp tap, or series of sharp taps, on the end of the handle of the spanner is more likely to effect a movement than prolonged pressure. In some cases it may even be necessary to heat the nut before it can be unscrewed. *See* Wrench.

SPAN ROOF. The common form of roof for a dwelling-house is the span roof. It is formed by roof plates fixed to the walls, common rafters and a ridge board, all framed together to cover the space between two walls. Such a roof can take a span of 12 ft.; if a greater span is to be covered, purlins will have to be introduced, or principal rafters in the form of a truss. *See* Purlin; Roof.

SPARAXIS. These bulbs, which bear brilliantly-coloured flowers on slender stems 15 in. high in early summer, may be potted in autumn or early spring and grown in the greenhouse, or they may be planted out of doors in well drained compost of loam, leaf-mould and sand, in a sunny sheltered position. In wet weather in winter a temporary glass covering is beneficial. The bulbs may be left undisturbed for several years. There are many named varieties.

Sparaxis, a gaily flowering bulbous pot plant.

SPARKING PLUG. In all types of petrol engine the high tension spark from the magneto or coil is conveyed to the inside of the cylinder by means of a sparking plug and caused to jump across a gap, thereby firing the mixture.

Sparking Plug used in an internal combustion engine.

Plugs can be purchased for long, short, or medium reach, the distance from the point of the central electrode to the seating of the plug varying according to the type of engine to which it is to be fitted. The end of the plug should be approximately level with the inside surface of the combustion head or the face of the valve cap, as shown in the diagram.

The sparking plug consists of a steel shell screwed into the body of the cylinder or the inlet valve cap. Inside this shell is fitted the central electrode, which is surrounded by a stout casing of some insulating material, such as porcelain, mica or steatite, and thus insulated from the outer shell. At the bottom of the outer shell is a small projection so placed as to be close up to, but not touching, the central electrode. The high tension current that flows from the magneto via the high tension lead and the central electrode jumps across this gap, returning to the magneto via the outer shell of the plug and the metal work of the engine.

In order to ensure a gas-tight joint between the insulation and the outer shell, a brass gland nut is generally employed. When a plug has been in use a considerable time it is often possible to tighten the gland nut down a little owing to the fact that the gland packing will have contracted. This adjustment should only be made while the plugs are warm, and it will necessitate also the checking or resetting of the gap or amount of space between the points of the plug.

The proper setting is highly important, especially in regard to the starting up of an engine, because the wider the points are apart, the stronger is the current required to jump across. Thus, with a magneto, a greater initial speed will have to be given to the engine before a high tension spark of sufficient intensity can be developed. The correct gap for magneto systems is 0.020 in. (1/50 in.); for coil ignition it is 0.025 in. (1/40 in.).

Spark Tester. Tube containing neon gas, a device for testing ignition which obviates removal of plug.

Testing Ignition. Sometimes a fault in the ignition is put down to the magneto, because a test of the plugs has been made by turning the engine over very slowly, while placing a finger on the terminal of the plugs and noticing whether a slight shock is felt. This procedure is wrong, because it in no way proves that a current is passing across the points. Further, it is possible for a plug to function properly at a low voltage, and yet to short badly on a high voltage through insulation failure, such as a cracked porcelain body.

One way to test for insulation failure is to take the plug out of the engine and lay it on some metal part with the high-tension lead attached. The metal shell must be touching some metal engine part, but care must be taken that the plug terminal is not in contact with, or too close to any metal. Then, by revolving the engine at a good speed by hand or by the self-starter, the sequence of sparks at the points can be noted. The spark should be

regular and of a uniform intensity, otherwise the insulation is at fault, assuming the plug is perfectly clean. A better method is to use a neon tester, consisting of a small tube containing neon gas.

With this device the plug need not be removed.

The tester is suitably protected, and has a terminal which is placed in contact with the terminal of the plug to be tested. If the plug is sparking a characteristic red glow is seen in the tube.

For other details about sparking plug troubles and their remedy the reader should refer to the article on Motor Car, especially pars. 1 and 2 of the section dealing with the care of the car. *See* Internal Combustion Engine; Magneto.

SPARKLET. Plain water can be converted into soda water by the use of metallic capsules known as sparklets. They are sold by chemists, and aerate the water or charge it with carbonic acid gas. *See* Aerated Waters; Carbonic Acid; Soda Water.

Sparling. The name is sometimes given to the smelt (q.v.). Occasionally a young or very diminutive herring is called a sparling.

SPATCHCOCK: In Cookery. Spatchcock chicken is prepared by splitting a young bird down the back, brushing it over with some warmed and melted butter, and then coating it with a mixture prepared from a little made mustard mixed with 2 tablespoonfuls Worcester sauce, a lump of butter about the size of an egg (previously melted), and seasoning to taste. Sprinkle the chicken with breadcrumbs, then coat it with some more melted butter, and grill it over a slow fire. Serve the bird with piquant sauce. The neat appearance of spatchcock chicken is gained by breaking the legs and wings at the first joints and fixing them in a flat position with skewers. *See* Chicken; Sauce.

SPAVIN. This is a disease affecting one or both of the hocks of horses, cobs and ponies, and it is exceedingly common. A swollen condition of the hock, especially after the animal has been standing in the stable, following upon active work, is spoken of as bog-spavin. The hock is swollen and puffy, imparting a soft or boggy sensation to the fingers when these are pressed upon it, particularly at the front and sides. This condition does not actually constitute disease, unless it amounts to a considerable degree of distension, thus interfering with freedom of movement of the hock. Apart from this, it does not render the animal in any way unsound. Bone spavin is regarded as constituting unsoundness. No one should purchase a horse without having it examined previously by a veterinary surgeon. *See* Horse.

SPEAR GRASS. Spear grass, which is sometimes called the bayonet plant, is the hardy rock perennial *Aciphylla*. There are three species in cultivation, *lyallii*, *colensoi*, and *squarrosa*, all about 6 in. high. Spear grass is best planted in rich sand loam, during spring or autumn, in an open part of the rockery. *See* Rock Garden.

SPEARMINT. The fragrant herb called spearmint is sometimes known as lamb mint, and has lance-shaped leaves of pungent odour. Other familiar kinds are peppermint and pennyroyal. Of the several kinds of garden mint, spearmint has the finest flavour.

Spearmint is sometimes used as a flavouring for milk or batter puddings, and can be regarded as suitable either for sweet or savoury dishes. *See* Mint.

SPECIAL LICENCE. This term is used for a marriage licence issued by the archbishop of Canterbury. It permits a marriage to be celebrated at any place, with or without previous residence in the district, and at any time, but the reasons given on application must be regarded as satisfactory

by the archbishop's advisers. The fee for a special licence is £25, and application for one must be made to the Faculty Office, 23, Knightrider Street, Doctors' Commons, London, E.C. *See Marriage; Wedding.*

SPECTACLES. The principal use of spectacles is to correct errors of vision. The particular type which should be worn is highly important. Much harm results from wearing spectacles or glasses of any kind which do not fit properly, or are not accurately suited to the purpose in view and the sight of the wearer.

The type of spectacles required can only be determined after skilled examination by an oculist or a sight testing optician. It is always false economy to obtain glasses without having the eyes properly examined, or to buy cheap which may cause eye strain or even more serious and lasting trouble.

The shape of the bridge of the nose often decides whether spectacles or eyeglasses should be worn. Nothing but spectacles should be worn by children, and the frame should be of steel nickel plated, or solid nickel, with curl sides which hook behind the ears. The bridge of the frame should not bear directly upon the bridge of the nose; the weight should be borne by attachments which bear only on the sides of the nose. The lenses should be of such a shape that the child cannot easily look over or under them.

Spectacles. Top, pair with round lenses in tortoiseshell frame. Centre, steel rimmed with curl sides. Bottom, rimless pair with gold bridge and sides.

For adults the frame may be of platinum, gold, rolled gold, tortoiseshell, or other material, or even without any frames around the glasses. Spectacles with curl sides are best adapted for those who require to wear their glasses continuously.

Where bright light irritates the eyes, spectacles made of Crookes' glass may be worn. It is made in four tints, the two paler ones being most beneficial for absorbing the ultra-violet rays; the two darker tints are suitable for bright sunlight and tropical climates. Deeply tinted glasses are also largely used in factories where there is a very bright light. These glasses are usually fitted up in the form of goggles, with fine gauze around the edges, to protect the eyes from flying particles of metal. Goggles of various forms are also used in strong winds and in sandy districts to protect the eyes.

Spectacles require great care in handling. They should not be put on or taken off roughly, and the greatest care should be exercised in closing down the sides lest the joints be damaged or the frames bent; when not in use they should always be placed in a case. When the frames become bent, the defective vision is not properly corrected, therefore it is essential that they should be straightened by an optician.

Glasses should be wiped with a piece of clean old linen, or with special cleaners, which prevent the glasses from steaming, and give a bright, clean polish. If they are much soiled, they should be washed in warm water with soap, to which a little ammonia may be added. *See Eye; Eyeglass; Sight Testing.*

Specularia. This hardy annual with purple, bell-shaped flowers is called Venus' Looking Glass (q.v.).

SPECULATION: A Card Game. This is a card game for any number of persons, and is played with the full pack of 52 cards, each player contributing an agreed number of counters to the pool. The dealer puts in twice as many counters as other players. He deals three cards face downward to each player and himself, and turns up the next card for trumps. This last card the dealer has a right to, as well as the three he has in his hand.

The object of the game is to hold the best trump among the cards dealt. If the turn up is an ace, the dealer automatically holds the best trump and takes the pool. If it is a court card or a ten it becomes an object of speculation, and any player may try to buy it, the price being agreed upon between him and the dealer, on the off-chance that the card is the highest trump and will take the pool. The dealer may elect to keep the card if he wishes.

Rules of Play. Beginning with the eldest hand, each player in turn turns up his topmost card. If any player turns up a better card than the exposed trump, this card may become an object of speculation. The holder of the highest trump for the time being is excepted from turning up any more of his cards. If all cards are turned up without it being beaten he takes the pool. If his card is beaten he continues with the other players to turn over his cards one at a time in his turn. Any player turning up the ace of trumps at once takes the pool.

Any player may buy any of the unexposed cards from another player, in the hope that they contain the winning trump. If any card in his hand is accidentally looked at by a player, save the actual card he is turning up, all his cards are immediately thrown face upward in the middle of the table, and the player must then pay a penalty into the pool.

SPEECH: Its Defects. Human speech may be affected more or less seriously by a large number of complaints. When there is any blocking of the air passages, as by chronic catarrh of the nose, adenoids, nasal polypi, etc., the patient pronounces the letter M as EB, and N like ED. Treatment is to clear out the obstruction so that the child may breathe properly. After this, lessons in correct pronunciation should be carried out. Lispings may be due to carelessness in teaching the child to talk; the defect is well within his power to control.

Deafness coming on after disease in childhood, before speech has been solidly acquired, may end in deaf mutism. Paralysis of nerves may be the cause of the defect. Another serious defect is aphasia, which is interference with the thought processes of speech and is due to some injury or disease of the brain.

Stammering and stuttering are not due to actual defect in the speech mechanism but to inability to control it on account of emotional disturbance. It is an expression of anxiety hysteria, and an attempt should be made to cure it by finding out the emotional disturbance that underlies the hysteria. Voice exercises, as in declaiming, and breathing exercises may be beneficial by giving the patient confidence. *See* Deafness Larynx; Tongue; Voice.

Speedboat. *See* Boat.

SPEEDWELL. This name covers a group of evergreen shrubs and hardy herbaceous plants of great garden value known botanically as veronica. They flourish in ordinary soil. The hardiest shrub is *Veronica Traversii*, 4 ft. high, with white flowers in summer. *Veronica speciosa*, of which there are varieties with purple, crimson, rose or white flowers, 3 to 5 ft., is less hardy: it does well in seaside gardens and in mild districts or may be grown in pots in the greenhouse.

Among the herbaceous border plants the best are gentianoides, 18 in., with pale blue flowers in May: longifolia and subsessilis, 2 or 3 ft., blue, in August, and spicata, 12 in., blue, in June. Veronica rupestris is a lovely low-growing blue-flowered rock garden plant. The shrubby kinds are increased by cuttings in a frame in July, the others by division, or seeds in spring.

SPERMACE TI. The fatty substance obtained from the sperm whale, and called spermaceti or cetaceum, is quite a common basis of ointments. The ointment of spermaceti is made up of spermaceti 10 parts, white beeswax 4 parts, benzoin 1 part, and almond oil 36 parts. These ingredients are heated for 2 hours. Spermaceti may be applied alone to inflamed, irritated surfaces for its emollient action. Pron. Sper-ma-see-te.

SPHAGNUM. Sphagnum moss, which is commonly found on peat bogs, is used extensively in the potting of orchids. Being extremely retentive of moisture, it keeps the fleshy roots of plants in sound condition, whilst its open, spongy character allows air to be admitted freely. Sphagnum does not decay like other mosses, a peculiarity that adds a good deal to its usefulness. *See* Orchid.

SPICE. Aromatic seasonings obtained from plants of tropical growth are used in cookery and as food preservatives, and some have certain medical properties. They are known as spices, those chiefly employed in cookery being cinnamon, cloves, ginger, mace, nutmeg, and pepper. Allspice or Jamaica pepper combines the flavours of cinnamon, cloves, and nutmeg.

In addition to their use in cookery, cloves are employed to flavour wine, cough mixtures, and confectionery, while cinnamon is a popular flavouring for liqueurs, and has certain properties that justify its inclusion in many tablets and mixtures sold to cure colds. Grated nutmeg is added to junkets and puddings, and ginger is a valuable stimulant. Various spices, such as turmeric, coriander, and ginger are contained in curry powders and pastes. Condiments such as pickles and sauces owe some of their piquancy to spices.

Spices should be bought in small quantities as they deteriorate rapidly if exposed to the air. They are best stored in special spice boxes. *See* Allspice; Cinnamon; Clove; Curry; Flavouring, etc.

Spice Bush. This is an alternative name for the plant known as lindera.

Spider. The crochet stitch which goes by the name of the spider pattern.

SPIDER: A Crochet Pattern. This all-over pattern derives its name from the solid centre-piece of double crochet, from which long chains branch out in different directions. The foundation chain on which the work begins should be a multiple of 14 with 5 stitches over. In the small piece illustrated there are 47 chain stitches, worked as follows:

1st row: 1 double crochet in the 11th chain from the hook, 1 double crochet in each of the next 2 stitches, * 5 chains, miss 5 stitches, 1 double treble in the next stitch, 5 chains, miss 5 stitches, 1 double crochet in each of the next 3 stitches. Repeat from * until only 6 stitches are left, then make 5 chains, miss 5 stitches, 1 treble in the end stitch, 7 chains. Turn.

2nd row: * 3 double crochet on 3 double crochet, 5 chains, 1 double treble on double treble, 5 chains. Repeat from * across the row ending with 3 double crochets, then 5 chains, 1 treble in the 6th chain of the loop at the end, 1 chain. Turn.

3rd row: * 1 double crochet on double crochet below, * 5 chains, 1 double treble in the centre double crochet, 5 chains, 1 double crochet in the chain before the double treble, 1 double crochet on double treble, 1 double crochet in the chain after the double treble. Repeat from * across the row, then 5 chain, 1 double treble on the centre double crochet, 5 chains, 1 treble in the 6th chain of the end loop, 1 chain. Turn.

4th row: 1 double crochet on the first chain, * 5 chains, 1 double treble on double treble, 5 chains, 3 double crochet on 3 double crochet. Repeat from * across the row, ending with 5 chains, 1 double treble on double treble, 5 chains, 1 treble on double crochet at the end 7 chains. Turn.

5th row: * 1 double crochet on the chain before the double treble, 1 double crochet on double treble, 1 double crochet on chain, 5 chains, 1 double treble on the centre double crochet, 5 chains. Repeat from * across the row, 1 double crochet on chain, 1 double crochet on double treble, 1 double crochet on chain, 5 chains, 1 treble in double crochet at the end, 7 chains. Turn. Repeat from the 2nd to the 5th rows inclusive, according to the length of pattern required, finishing the last pattern at the end of the 4th row to give a straight edge. *See Crochet.*

SPIDER WEB: In Embroidery. This pattern is used in two different forms of work, one as a solid white or coloured linen embroidery for decorative purposes, and the other to fill in an empty corner where threads have been drawn.

Spider Web, a pattern which is much used in solid embroidery, and also for filling up a corner in drawn thread work.

In the first case fancy canvases and coarse linens are used, where the threads can be easily counted to form sections. In the illustration coarse linen is seen, worked with coarse sylko cotton giving bold relief to the pattern. Here 40 threads are counted each way, and the next thread is drawn out at even intervals; this divides the linen into sections.

To work, secure the thread on the wrong side at one corner of a section, and cross in an

oblique line to the opposite corner, then put the needle down to the wrong side. Bring the needle up again at the bottom right-hand corner and down again through the top left-hand corner; there will now be 2 threads crossing each other from the corners. Now cross the square in the same way, but working from the 2 sides. Bring the needle up in the centre of this section and make a small stitch across the lines, then another stitch in the opposite direction, so that there is a small cross-stitch in the middle holding the long lines in position. If one colour is being worked, the weaving can be continued without a break.

To join on a new colour, pass the thread back through the centre to the wrong side of the material and fasten off very securely with a few back stitches. Join the new thread under the back stitches

and pass through to the right side at the centre of the design to the left of one of the spokes. Pass the needle from right to left under the same spoke and under the second spoke at the same time, and draw up the thread closely. It will be seen that the thread encircles the first spoke. Pass the needle from right to left under the second and third spokes, and draw the thread up. As the second spoke was worked under in the previous stitch, the thread will now encircle it.

The work proceeds in this way in rounds, always passing the needle under 2 spokes, so that the thread goes under and round a spoke each time. This causes the rolled effect on the finished web as seen in the third section of the illustration, with a web completed. The second section shows the web in progress, with the needle in position. Here the spokes are laid in one colour, and the little centre cross-stitch is made in that colour in the third section, giving a little spot of colour at the centre, while the web is woven in the second colour entirely.

For Drawn Thread Work. To work the spider-web on a drawn-thread corner, the working thread is secured to the buttonhole stitches that are usually worked on the edge of the linen after the threads are drawn. The spokes are attached to the edges in the same manner, but a cross-stitch cannot be worked at the centre, as there is not a material foundation underneath, so 2 drawn-thread knots are worked in opposite directions to hold the spokes at the centre. The latter are woven under and over as in ordinary darning, missing 2 threads at the beginning of each new round, so that the thread that was passed over in the previous round will be passed under in the second.

The change of round can be seen easily in the working, when the needle passes a second time under the same thread. To ensure an even weave, it is best to put the material in an ordinary round embroidery frame when working the corner pieces, that is, when the remainder of the work is being done over the fingers. *See Drawn Thread Work Embroidery.*

SPIDERWORT. This is the popular name of *tradescantia*, a group of hardy and greenhouse plants. The best of the hardy kinds is *Tradescantia virginica*, called Flower of a day, which thrives in shady places and bears purple-blue blooms in summer. Those suitable for a warm greenhouse are quick growing trailing plants with green and coloured leaves. They [are useful for planting beneath the staging, or if grown in pots make a suitable edging; they look well also in suspended baskets. They are easily increased by cuttings and thrive in a compost of loam, leaf-mould and sand.

SPILLIKINS: The Game. This game is played with a number of thin pieces of bone or ivory. These pieces, the spillikins, are cut into queer shapes and each has a number, the numbers usually running from 5 to 40.

The spillikins are taken in the hand of one of the players and dropped in a heap on the table. The players then take turns at trying to remove one of them from the heap without disturbing the others. This is sometimes done with the fingers and sometimes by means of two small hooks provided for the purpose.

When the game is over each player adds up the numbers on the spillikins he has taken, and the one with the largest number wins. Sometimes, instead of the players taking turns to remove one spillikin, one player continues to remove them until he disturbs another one, when he loses his turn.

SPINACH. There are four chief kinds of this useful leaf vegetable. Summer spinach is sown at intervals from February to April in drills 1 in. deep and 12 in. apart; rich deep soil is necessary to ensure quick growth. Winter spinach is sown in August-September in a similar way: the seedlings of both crops should be thinned to 6 in. apart. The round spinach is commonly sown in spring and the prickly spinach in August and September.

New Zealand spinach is a vigorous tender plant which should be sown out of doors in May, or raised in pots in a frame. The plants must be 3 ft. apart. The tips of the shoots are gathered for cooking. Perpetual spinach or spinach beet is a rather coarse, large-leaved vegetable which should be sown in spring and again at the end of July to provide a long succession of produce.

Spinach. Leaves of the round variety, the best summer spinach.

How to Cook. Spinach is one of the most wholesome and readily digested of vegetables. It is served either as a vegetable or as an entree. Spinach sometimes accompanies fried or grilled ham, and a favourite dish is poached eggs on spinach.

The leaves require very thorough and careful cleansing, as they are always gritty. They should be well picked over after being washed, and the stalks removed. Salt is required in varying quantities according to taste. No soda must be added to it while cooking, and no water is required save that which clings to the leaves after washing. One of the simplest methods of preparing a plain dish of spinach is to put about 4 lb. of the leaves in a large saucepan, sprinkle over them a tablespoonful of salt and a teaspoonful of white sugar. Bring slowly to the boil and boil them for about 12 min., or until they are soft, stirring them in case they cling to the bottom of the pan. When cooked, strain and press out the water until the spinach appears dry, then turn it on to a board, chop it, and return it to the saucepan with a little butter, lemon juice, pepper and salt. Dish it on toast.

Spinach. 1. Soil preparation: a, manured soil; b, fine soil. 2. Rows separated by rain channels (a). 3. Catch crops between peas or beans. 4. Winter spinach sheltered by heaps of bracken or straw. 5. Spinach beet between shrubs or under trees. 6. New Zealand spinach in pots: a, corks and rough stuff; b, decayed manure; c, fine rich soil. 7. Box similarly prepared. 8. Pots and boxes sheltered in cold frame or covered box.

For an entrée, prepare 4 lb. spinach, then boil it in the drippings from the leaves, adding salt. Stir frequently, and when it is cooked strain and press it free from moisture. Now immerse it in cold water and leave to cool, but do not separate it. When quite cold, drain, and once more squeeze out all water. Chop it fine, and pass it through a wire sieve. Melt in a stewpan 2 oz. butter, add the spinach, and stir it round, then season it with salt, cayenne, and $\frac{1}{4}$ teaspoonful of grated nutmeg. Pour in 1 gill thick cream and 2 tablespoonfuls white sauce, also 1 teaspoonful castor sugar. Serve it on round croûtes of buttered toast with a garnish of fried half-moons of puff pastry or of bread.

A savoury dish of spinach may be prepared in the following manner: Boil 3 lb. spinach as directed in the second recipe. Chop it slightly, and fry it in 2 oz. butter, with 4 anchovies, washed, boned, and chopped fine.

Add a good squeeze of lemon juice, seasoning of salt and pepper, a pinch of ground mace, and 2 oz. muscatel raisins, stoned and cut in quarters. Serve the spinach on a dish with a border of grilled tomatoes and croûtons of fried bread.

Spinach greening for colouring sauces is made by pounding 2 lb. well-washed spinach in a mortar until it is a pulp, then turn it into a clean pudding cloth and twist it one end one way and the other end the other way. Take care that the spinach is completely enclosed in the cloth and that a basin is placed under neath to catch the juice. The squeezing is done better if two people hold the ends of the cloth. Pour all the liquor squeezed out into a small saucepan, place it on the fire, and, as it curdles, scrape the curds out on to a sieve to drain off the water. After draining put the greening into a covered jar in a cool larder till the sauce is ready. Home-prepared greening is best for sauce or mayonnaise, but for colouring sweets it is more convenient to purchase liquid spinach green colouring. *See Kitchen Garden.* Pron. Spin-aje.

SPINDLE TREE. This is a small British tree (*Euonymus europaeus*) valued for its highly coloured ornamental fruits in autumn. It thrives in ordinary soil.

SPINE. The spine, or backbone, makes it possible for the body to assume and maintain an upright position and at the same time act as a protective covering for the spinal cord, which, with the brain, forms the main part of the central nervous system. It is made up of 24 vertebrae, which allow a certain amount of movement one on the other, and two terminal bones, the sacrum and the coccyx. The bodies of the vertebrae are separated by thin layers or disks of cartilage. These not only allow the bones to move without grating, but also act as shock absorbers.

When standing in the erect posture, the spinal column forms a series of natural curves from before backward. These curves balance each other, with the result that the general line of the spine is practically vertical.

Curvature of the spine is dealt with under that heading. Injuries to the spine by blows, twists, and other forms of violence may result in sprains or strains. There is local pain and tenderness, and perhaps slight swelling. Cold applications may relieve suffering, but it is often necessary to rest for some weeks. The result of an injury may, however, be much more severe than this. *See Curvature; Fracture.*

SPINET. Being smaller than the harpsichord, the spinet does not possess a double keyboard, and the tone was usually a fifth higher. The sound is produced by means of a piece of leather or quill which is attached to an upright piece of wood called jack, and plucks the string as it passes, when the further end of the balanced key is depressed by the finger. As it returns, a wooden tongue into which the striking-point is inserted allows the quill to repass the string without repeating the stroke, this tongue being kept in place by a string at the back.

Small pianos of the late 18th century were sometimes called spinets erroneously, as they possessed a hammer mechanism instead of the rising jack and plucking-point of the spinet. Dating from the 16th century, during the 17th the spinet was popular in England. It was usually set on a three-legged stand which gave it the appearance of a miniature grand piano. Any graduation of tone is impossible, as the spinet has but one string to each key. *See Harpsichord; Piano.*

Spinet of wood and ivory ornamented with jasper and other stones, made in Milan in 1577. (By permission of the Director, Victoria & Albert Museum, South Kensington)

SPINNING WHEEL: The Antique. Though first introduced into England about the 14th century, Dutch examples of spinning wheels made in the late 17th and 18th centuries were copied in most European countries, and the spinsters of England, Scotland, Wales, and Ireland used wheels which in design were very similar to those of Flanders. What is still known as the Dutch wheel is collected assiduously by interested people, though the name is used to designate one of Irish manufacture.

The wheels employed in English cottages for the purpose of spinning for a living were frequently of elm, ash, or birch. The fly-wheel of these was heavier, and the turning of the spokes, spindles, and legs much coarser in detail than was the case in the walnut and mahogany spinning wheels of more expensive make. Round the distaff, which is seen on the left above the wheel in the illustration, is loosely wound the raw fibre. This is spun off by the spindle. The fly-wheel is driven by the treadle, which is also clearly shown.

Spinning Wheel. Carved walnut spinning wheel; height with distaff, 4 ft. 4 in. 18th century. (By permission of the Director, Victoria & Albert Museum, S. Kensington)

A unique collection of spinning wheels is that of Mr. John Horner, of Belfast, where these old machines are housed in the Municipal Art Gallery and Museum. Various museums in Yorkshire, notably Hull, also possess examples showing local characteristics, and a few specimens are preserved in the Victoria and Albert Museum, South Kensington.

SPIRAEA. Both shrubs and herbaceous plants of decorative value in the garden are included in this group. Some of the shrubs are very handsome when in full bloom; they thrive in ordinary well-tilled soil. The best are *Thunbergi*, *arguta* and *canescens*, which bear white flowers in spring and early summer, and grow 4 ft. or so high; *Lindleyana*, *Aitchisoni* and *discolor*, which bear plume-like clusters of white or cream-coloured flowers in late summer and reach a height of 10 ft. or more; and *japonica*, *bumalda*. and *Anthony Waterer*, which have red flowers in July-August, and are from 2 ft. to 4 ft. high. Propagation is by cuttings or seeds. Of the hardy herbaceous spiraeas the noblest is *aruncus*, a vigorous plant 5 ft. or so high, with cream-white flower plumes in summer. *Filipendula* and *ulmaria* (the common meadowsweet), with whitish flowers, and *palmata*, red, are other useful kinds. They are all good waterside plants, for they thrive best in moist soil. Propagation is by division in autumn and spring. *Spiraea japonica*, white, is a favourite plant for the greenhouse. Pron. Spi-ree-a.

Spiraea. Spray of S. astilboides, a July blooming plant with long feathery spikes of white flowers.

SPIRIT LEVEL. A spirit level is an instrument for ascertaining the level or adjusting the level of an object in relation to the horizontal.

Spirit Level. Fig. 1. Testing level between two pieces of material.

Right. Spirit Level. Fig. 2. Use of spirit level in testing for the vertical.

Essentially, the instrument comprises a wooden or metal frame containing a glass tube closed at each end and almost filled with liquid. A small air bubble, however, remains visible in it, and when the tube is in a horizontal position, the bubble will always be exactly in the middle of the length of the tube, and at the top of it. A spirit level is calibrated and tested at the time of embedding the bubble tube in the frame, and thereafter should not be disturbed, otherwise the instrument may be thrown out of truth. To facilitate the reading and to increase the accuracy of the result, two lines are generally marked on the top of the tube, in such a position that when the air-bubble is exactly between them, the instrument is perfectly horizontal. As an example of its use, suppose that a floor joist has to be set in a horizontal position. All that has to be done is to place the joist approximately in position, rest the spirit level upon it, and raise or lower the ends of the joist until the air bubble is exactly between the two lines marked on the tube. The joist will then be level. For ordinary purposes the regular carpenter's level, shown in Fig. 1, will suffice. It is here seen in use to level two adjacent planks. These levels are available in various sizes, but one about 10 in. long is very convenient. Practically all levels with a wooden body, or frame, have a brass plate at the top and brass tips at the bottom, to strengthen the wood and increase the durability

of the instrument. For carpentry or building purposes a longer level measuring about 24 in. will be found to be preferable. A useful type has two tubes, one at right angles to the other. The second tube is set near the end of the frame in a vertical position, so that the instrument can be used for plumbing uprights. When the bubble is in the middle of the tube it indicates that the object which is being tested is perfectly upright, as shown in Fig. 2. *See* Plumb Bob; Plumb Rule.

SPIRIT OF SALT. This strong acid, known alternatively as hydrochloric acid, has valuable cleansing properties. It may be used to take stains from lavatory pans and washing basins and when diluted with 20 times its volume of water, it removes rust marks from clothes without damaging the material. Thorough rinsing is essential, otherwise the acid may cause the fabric to rot. *See* Hydrochloric Acid.

SPIRITS. This term is used for certain liquids used for drinking purposes that are obtained by distillation. Such include brandy, gin, and whisky. *See* Alcohol; Brandy; Gin; Rum; Whisky.

SPIT: For Roasting. A spit is a pointed rod with a handle at the end, and mounted so that the meat can be supported on the spit and rotated from time to time in front of the fire. *See* Roasting.

Spitchcock. This is a method of cooking eels. They are salted, then fried in batter and breadcrumbed. *See* Eel.

Spitting. *See* Expectoration.

Splat. This term is used for the broad, flat, upright portion of a chair back. *See* Chair.

SPLEENWORT. This is the common name of an extensive genus of ferns, hardy, greenhouse, and stove, botanically classified as *Asplenium*. Amongst hardy kinds the scale, maidenhair spleenwort, and wallrue are suitable for growing on old walls; the lady fern in moist shady corners or borders; whilst others are useful for planting in the rock garden. The bird's nest fern is extensively grown for market purposes. *See* Fern.

Spleenwort fern in a wall.

SPLINT. More or less rigid materials used as supports for a broken or otherwise injured limb form splints. Their purpose in cases of fracture is to keep the ends of the bone together and to keep the limb in a natural position to prevent deformity. Splints are most commonly made of wood, but a great variety of other materials are also used, such as poro-plastic, gutta-percha, metal, celluloid, and cotton, linen, or flannel, stiffened with plaster of Paris, starch, or gum. Straw matting rolled up and cut to a suitable length forms an excellent splint in an emergency. Other materials with which, in an emergency, splints may be made are laths, a broom-handle, a walking-stick or umbrella, a small straight branch of a tree, a few folded newspapers, a rifle, and a scabbard.

Padding must be done carefully, so that there shall be no lumps and that the splint shall fit evenly against the limb; extra padding should be placed over bony prominences, e.g. at the ankle. Probably the best material to use is sheep's wool, but cotton wool or tow serve very well. In emergency some old flannel, or a number of handkerchiefs, may be used. A splint should fit the limb accurately; for a

broken thigh bone it should reach from the armpit to below the ankle. For other broken bones it should extend far enough on each side of the fracture to afford good support and secure perfect rest. When first aid is being rendered one person should hold the broken limb in an extended position while the other ties on the splint. First tie above the fracture, then below. If a leg is broken, tie both legs together after the splint has been applied. Handkerchiefs may be used for tying if bandages are not available. The splint should be tied on firmly, but not too tightly, lest the circulation of the blood be interfered with. Make the knots over the outer splint. *See* Bandage; First Aid.

SPLINTER: How to Extract. Thorns, needles, and splinters of wood which penetrate the skin should be removed as soon as possible, for if allowed to remain until inflammation begins, they become more firmly fixed in the swollen tissues; needles also sometimes wander far from their point of entry. If the splinter is visible, the opening through which it entered should be enlarged with a carefully sterilized needle or a sharp-pointed knife. The sterilization can be done by passing several times through a spirit lamp flame. The splinter should then be worked out by pressure with the tips of the fingers. If the splinter lies deeply, it is better to consult a doctor at once.

SPLIT BALUSTER. This is the name of a form of decoration used on simple styles of oak furniture especially towards the end of the 17th century. It consists of a spindle which, having been turned between two points on a lathe, was cut lengthways into two or more parts and applied to ornament a frieze or border on a chest or dresser.

SPLIT PEAS: In Cookery. Split peas are amongst the cheapest and the most nutritious of vegetables. Their principal use is for soup-making, and they can be cooked in the same way as lentils. To be quite digestible they need long cooking after being soaked in cold water for 12 hours. *See* Lentil; Soup.

SPODE: The Ware. Josiah Spode was the founder of this firm of Staffordshire potters, which was one of the leading houses in the trade. After an apprenticeship to Whieldon and Josiah Wedgwood, Josiah Spode started a factory in 1770. His services rank next to Wedgwood's, and his black basaltes and jasper wares are in high esteem. He was the first to apply transfer-printing to the willow pattern and his printed ware was often hand with enamel colours. The improvements made by his son helped to establish the supremacy of English bone-porcelain and opaque china.

Spode. Beaker painted in colours and decorated with gilding in imitation of Japanese Imari ware. (By permission of the Director, Victoria & Albert Museum S. Kensington)

Spode porcelain is a translucent paste with a soft glaze and good printing. Dinner services were at first made with a medium-blue decoration, set off by solidly gilded handles and rims. The production of old Japan patterns, and also of lustre ware, was in the front rank. The earliest mark was Spode, stamped in the paste or pencilled on the glaze. The name was afterwards placed within a scroll, or across a square seal with the words stone-china beneath.

Partnership between the younger Spode and William Copeland led to the factory passing ultimately into the family of the latter. For a time the mark was Spode & Copeland, then Copeland & Garrett

late Spode, and afterwards Copeland late Spode, a mark which still survives. The present factory continues to produce many of the old Spode designs because of their popularity, but the modern ware is always distinguishable by the mark. *See China; Pottery.*

SPOKESHAVE: How to Use. A spoke-shave is a two-handed wood-working implement, consisting essentially of a stock or holder and a cast steel blade or cutter. Two typical examples are illustrated. The original and still extensively used spokeshave has a wooden stock. Into the middle portion is fitted a steel cutter having two tangs at right angles to the plane of the blade and located at each end of it.

Spokeshave. Right, pattern with wooden stock and tanged steel cutter. Left, type with malleable iron stock and a flat blade clamped to the stock.

The prongs of the spokeshave are pressed into holes cut in the wood, and as both hole and tangs are tapered, the blade holds firmly when tapped home. The other type has a malleable iron stock and a flat blade something like a plane iron. This is held to the stock by means of a clamped plate and a thumbscrew which goes through a slot in the blade. The cutter can be adjusted by pushing it in or out, and when in its correct position it is secured by twisting the thumbscrew. In the case of the wooden stocked spokeshave, the cut is regulated by tapping the cutter closer to or farther away from the working face of the stock.

The essential purpose of the spokeshave is to work curved surfaces, either externally or internally, so as to bring them to a correct and uniform curve. The work should be firmly held either in the vice or supported by blocks temporarily screwed to the work bench. The operator stands facing the work, and grasping the spokeshave in both hands, his thumbs pressed across the back part of the cutter, but clear of the work. The implement is pressed firmly on to the wood and pushed forward. The cutter must never be worked against the grain, or the wood fibres will be torn.

Some spokeshaves are provided with an adjustable fence or guide, and with variously shaped blades, so that some form of moulding and reedings can be produced. *See Plane; Router Plane; Rustic Work.*

SPONGE. The soft, porous article known as a sponge is a form of animal life brought up from the bottom of the sea by divers. For toilet use it is indispensable, and, on account of its absorbent properties, it is also employed to bathe cuts and other wounds. Sponges vary in quality and price, the cheaper kinds being liable to tear after a few weeks' use.

The finest sponges are the Turkish, which are much favoured for babies and facial use, because of their softness. All sponges should be soaked in cold water for 24 hours before being taken into use. This gets rid of any sand and enlarges the sponge, by about one-third, to its working size.

Sponges may be kept clean by occasional washing in strong, hot soda water. If allowed to hang in a sunny window, where the air has free access to them, they will last longer and require less washing. Old sponges are useful for washing paint work.

If sponges are used for washing wounds, or mopping up blood in operations, they should be sterilized by soaking them in corrosive sublimate before use. After use they should be washed in borax soap powder, and then kept in a 5 per cent solution of carbolic acid. A sponge should not be boiled. Sterilized gauze, it may be said, is a much safer and better material to use than a sponge for wiping wounds. *See Bathroom; Toilet.*

SPONGE CAKE. To make, break 3 eggs into a basin, whisk them with 6 oz. castor sugar for about 15 min., and then lightly fold in $\frac{1}{4}$ lb. sieved flour. Grease the inside of some small sponge cake tins, coat them with a mixture of sugar and flour, shaking out any that does not adhere, and then put in the sponge cake mixture. Shake a little castor sugar over the cakes and bake them in a hot oven for 10-15 min. Sponge cakes are used extensively in the making of trifles and other sweets.

Sponge Finger. Sponge cakes shaped like fingers, such as are used in making fruit charlottes, can be made from the same mixture as for sponge cake, using special finger-shaped tins for baking. Bake the cakes in a hot oven for about 7 min., but do not let them brown, and when they have been cooled on a sieve, put them together in pairs, using a little jam to stick them together.

Sponge Fingers fitted together in pairs and served for afternoon tea.

SPOONS FOR COLLECTING AND FOR USE

Their Development from Antique to Modern Shapes Illustrated

The reader is referred to the article on Dessert Spoon; Electro-Plate; Fiddle Pattern; Ladle; Pewter; Rat Tai; Silver; Table Laying.

The earliest form of spoon was a shell with a cleft stick as handle. The cleft was slipped over the edge of the shell and tightly bound behind the join. Wood, bone and horn spoons followed, and these materials are still in use to-day for salad, salt and kitchen spoons, while mother-of-pearl shell is also still employed for condiment spoons.

Spoon. Fig. 1. Roman spoon, 4th century, which was found in England. Fig. 2. Coronation spoon in gold, an example of 12th century work; it is part of the English regalia. (Fig. 1, courtesy of Spink & Son, Ltd.)

Fig. 1 shows a Roman spoon of about the 4th century, which was found in England. Fig. 2 shows the coronation spoon, which can be seen with the regalia in the Tower of London. The date of this gold spoon has been a subject for discussion; in general, however, it is accepted as an example of 12th century work. Silver spoons were made in this country in early Tudor times and designs were copied in base metals.

The chief source of information concerning spoons is gathered from inventories, wills, and other old documents. That spoons of silver must have been somewhat scarce is proved by the careful way in which they are described, and the probability is that among the lower classes of society they were practically unknown, spoons made of pewter, wood, or latten, a mixture of brass and tin, being in general use.

In Tudor times the bowls of spoons were fig-shaped. The handles terminated in various fantastic shapes, such as a whirled knob, a diamond point, an acorn, a kind of fir-cone knob, or knop, while some were made with a seal top end, as illustrated in Fig. 3. Others had a figure on the end, a representation of the Virgin Mary, being one of the earliest, known as the Maiden Head knop, followed by what are called Apostle spoons. These spoons bore at their ends representations of the twelve Apostles, each figure having its distinctive emblem, by which it can be recognized.

Fig. 3. Seal top end and fig-shaped bowl of a spoon of the Tudor period. Fig. 4. Apostle spoon, the figure bearing a distinctive emblem; Tudor period. (Courtesy of Spink & Son, Ltd.)

Accompanying a set of 12 spoons was the Master spoon holding an orb in the left hand and with the right hand held up in the act of blessing. A 14th spoon was added to the collection representing St. Paul. A specimen is illustrated in Fig. 4 carrying his

emblem, the sword. Complete sets of these spoons are extremely rare, and when a set comes into the market it usually fetches a high price.

Spoon. Fig. 5. Puritan spoon with stump end, made in London, 1653. Fig. 6. Charles II spoon with ornamented cleft handle and ovate-shaped bowl. Fig. 7. Silver spoon and fork with contemporary case; William and Mary period. Fig. 8. Early Queen Anne silver spoon. Fig. 9. Silver spoon, George II period, showing scroll instead of rat tail. (Courtesy of Spink & Son, Ltd.)

The transition from the knops to plain ends occurred after the reign of James I. In Commonwealth days the stump end (Fig. 5) was introduced, to be followed by the cleft-end and ornamented lobe ends in the reign of Charles II. In this new variety the stem end is more or less cleft into three parts, and the lower part of the stem is continued to a length which extends more than half-way down the back of the bowl. This continuation of the stem at the back of the bowl is the commencement of the rat tail form. Fig. 6 shows a spoon of this style bearing the London hall mark for 1680, and the back of the bowl bears the characteristic scroll decoration, also found on the front end of the spoon. Fig. 7 shows a spoon and fork of the William and Mary period and the case for holding them. Handles remained cleft and well spread. Fig. 8 is an example of a spoon of the early part of Queen Anne's reign, showing the trefoil-end handle, which was a transition from the cleft-end to the so-called Old English seen in Fig. 9. In both these spoons the elongation of the bowl is noticeable. Early in the reign of George II the rat tail disappeared, a slight thickening taking its place, which later became an ornamental scroll or shell on the back of the bowl as seen in Fig. 9, a typical example of this period. A favourite ornament at the end of reign of George II was the bead-edged handle, while a little later many handles were engraved. After the accession of George III new patterns of spoons were introduced, but these differed only in the manner of ornament, the main design remaining the same, until the fiddle pattern appeared in the Victorian era.

Modern Spoons. To-day, unlike our ancestors, who were often content with one single spoon, which was carried about wherever they went, we have in common use a wealth of spoons for particular needs. A table service contains table, soup, dessert, tea, coffee gravy, mustard, salt, pepper caddy, sugar, egg, salad, fruit, orange, and ice cream spoons.

Fig. 10. Modern orange spoon.

The orange or grape fruit spoon illustrated in Fig. 10 shows the bowl conveniently shaped and the handle of conventional Old English pattern, as seen in Fig. 9. Designs for spoons and forks are usually based on the old patterns. Bead or reeded edges are seen on some handles, on others ornamentation takes the form of shells and fluting. Plainer Puritan designs are liked, and the fig-shaped and ovate bowls are reproduced in modern soup spoons, and in fruit and salad service spoons with flat-shaped handles. The knop ends are often adapted to coffee spoons and to jam spoons. Salt spoons and mustard spoons usually match in style the containers they accompany. Egg spoons may be attached to a silver or plated stand or be bought separately to match the tea and other service spoons in use. Silver or plated ladles for sauce or soup generally match the tablespoons. Very ornamental spoons are seldom used, but fruit servers are designed in which there is a decorative connexion between the plain silver handle and spoon bowl characterized by fine workmanship and artistic form. Kitchen spoons include the ever useful wooden ones in various sizes, perforated aluminium spoons for lifting eggs, etc., from boiling water, sets of attached measuring spoons, of five different sizes, and teaspoon infusers for making single cups of tea.

SPORE. This is the name given to those cells or bodies which are found on the backs of fern fronds and other flowerless plants and by means of which propagation is effected. The spores are gathered when ripe by shaking the fronds over a sheet of paper; they are sown in flower pots or pans of sterilized soil in a propagating case under glass and kept moist and shaded.

Spot: On the Skin. See Blackhead; Pimple; Rash; Skin.

SPOT-LIGHT. In many modern professional portraits attractive and artistic results are obtained by use of a spot-light, an arrangement by which a beam of light, natural or artificial, is projected on to a face or profile or other part of the sitter, in addition to the ordinary illumination. By this means striking highlights are obtained, or parts which would be without detail in the photograph are given pleasing tone and balance.

Spot-light. Fig. 3. Spot-light connected up and alight, ready for making an exposure. (Courtesy of Ensign, Ltd.)

In taking portrait photographs by natural light spot-lighting effects can be obtained in a room lighted by two windows. especially if a bay window is available. One arrangement is shown in Fig. 1. Ordinary lighting is given by window A and the reflector. Spot lighting from above, or top-lighting, is given by window B, all but the top part about 12 in. or 18 in. square, being blocked up. This will give a soft and not too obvious lighting of the face from above. Other arrangements can be tried; these include leaving the centre of the blocked window open and

moving sitter and reflector about. An arrangement which may be tried in an ordinary square room with two windows is shown in Fig. 2. This also will afford basis for experiment which may conveniently be carried out on an inanimate object.

A more convenient and adaptable method of spot-lighting, such as is used on a large scale by professional portrait photographers, is the lantern form of light (Fig. 3) for use with electric lamps. It is fitted with a condenser lens mounted on a spring bracket which enables the light to be directed at any angle. The lamp-holder is adjustable to permit focussing with the condenser, and the light is controlled by means of a movable diffusing screen, and also a blue filter, used separately or together. The light must not be placed too near the sitter. Experiment will show the best positions for the light and the exposure to be given. As a basis the amateur should try the spot-light about 6 ft. or 7 ft. from the sitter. The lamp is also useful in getting effects with daylight portraits, in addition to or in place of a reflector. *See Portraiture.*

Spot-light. Fig. 1. Arrangement in a room in which the spot-light is given by the window B. Fig. 2.

Arrangement in a square room, with one of the windows partly covered.

SPOTTED FEVER. This is the popular name of cerebro-spinal meningitis, an inflammation of the covering membranes of the brain and spinal cord caused by a germ. These germs invade the throat in the first place, and are often found in the throats of people who have had the disease and also of others who do not themselves suffer from it, but who can communicate it to others. In any community there are always "carriers" of spotted fever, and this danger increases in a marked degree when people are crowded together. Epidemics of the disease are therefore liable to break out in barracks, camps, etc. Dirt and bad sanitation play a contributory part.

Children are most frequently affected. Severe headache and vomiting, followed by a painful rigidity of the muscles at the back of the neck, are early symptoms. The doctor should be called at once. This is a notifiable disease and the patient must be isolated. Those who have been in close contact with the patient should use antiseptic gargles.

SPOTTING: Of Negatives. Negatives frequently require spotting because of the presence of small holes in the film, called pinholes, due to dust on the plate before exposure, or somewhat larger holes due to bubbles of air adhering to the plate during development. These holes are transparent, and therefore print black. They are most noticeable in the high lights, i.e. the dense parts of the negative, and may spoil the appearance of the print or the enlargement.

Prevention is, of course, the best remedy, and will be achieved by taking great care to keep the interior of both camera and dark slides free from dust. Do not attempt to brush off possible dust with a camel-hair brush from the negative prior to development. In a dry atmosphere the brushing will slightly electrify the film of the negative, and attract much more dust than it removes. Glass negatives may be sharply tapped on the back with the thumbnail, or the edge tapped on the table.

When pinholes appear they must be filled by spotting with Indian ink or other pigment. The secrets of neat spotting are to use the pigment nearly dry and not to attempt to work it on the film. One touch in the right place is all that is required. More will only spoil the result. Spotting is a simple and effective process if a little care is taken. Lamp black or ivory black, mixed with water containing a little gum arabic or Indian ink, may be employed. Use a fine brush, preferably a No. 1 camel hair. Give it a good point by twisting on paper or between the lips, and take a very small quantity of pigment, mixed with sufficient water to make it of the consistency of cream.

Try the brush on paper, twirling it as when giving it a point until it hardly seems to mark. Then immediately touch the pinhole once, making a fine dot, and leave it. If the hole is a large one, a series of dots may be required, but they must not be allowed to run into one another. Allow the first to dry, if necessary, before making another. By this means, if care is used, spots in the prints will be entirely avoided, and with a little practice it will be found that a number of pinholes in a negative can quickly be spotted out. When a negative which is to be enlarged contains a number of very small pinholes, it will be found that by throwing the negative slightly out of focus the holes will be practically unnoticeable in the enlargement without reducing its quality.

To spot prints, a pigment or water colour to match the colour of the print is chosen, mixed with gum water, and spotting carried out as for negatives. Large black spots may be removed with a touch of Farmer's bleacher, as used for intensifying (potassium ferri-cyanide with plain hypo). A spot of the bleacher is applied with a camel-hair brush, left for a minute or two to set, and then sponged off. The resulting white spot is touched with pigment to match. *See Negative.*

SPRAIN. Whenever a joint is wrenched the bones may be displaced or fractured but when the injury stops short of this and consists merely of stretching or tearing of the ligaments and tendons it is called a sprain. Even this may do damage, cause pain, and hamper movements of the joint.

Bleeding takes place from torn blood vessels, and this is quickly followed by inflammatory reaction in the injured tissues. These things combined lead to more or less swelling and discoloration, and when in the course of a few days the shed blood breaks down, the familiar changes of colour from red or black to green and yellow occur.

Cold compresses should be applied at once. They relieve pain and help to diminish bleeding. Later hot applications may be used for the pain and to promote absorption. Rest at first is necessary, and splints may be used to this end, but early massage and passive movements are necessary to prevent stiffness. *See Ankle; Bandage; First Aid; Joint.*

SPRAT: How to Cook. The sprat is seasonable from November to March, and should be eaten very fresh. After being cleaned it should be rubbed in a cloth to remove the scales. The condition of this fish is easily ascertained by the appearance of the eyes; if these are bright it is fresh, also the skin of the fish should have a silvery look when washed. Dried sprats may be bought in bundles. As much as possible of the dried skin should be removed by placing the fish in boiling water and then wiping them dry on a clean cloth. The sprats are then heated in the oven in a greased baking tin.

After being cleaned and rubbed sprats may be dressed by being dipped in seasoned flour and fried in boiling fat, a frying basket being used to keep the fish together. The fat should be smoking hot or the fish will be sodden. If no frying basket is at hand the sprats must be fried in a frying pan, using

plenty of fat. The fat cannot be used again for anything except fish. Another method is to dip the fish in seasoned flour and egg and crumb them using very fine white breadcrumbs.

Pickled Sprats. Sprats may be pickled to keep. Clean the fish and boil them, just covered with water. When cooked drain off the liquor and pack them tightly but evenly in jars. Fill up the jars with equal quantities of strained fish liquor and vinegar. Set them by for a few days, and if the vinegar has become reduced fill up the jars. Tie down closely.

Sprats au Gratin. Prepare 2 lb. sprats and arrange them in a well-buttered fireproof dish. Season them with salt and cayenne pepper, and pour over them the following mixture $\frac{1}{2}$ lb. mushrooms, prepared, cut in strips and blanched in $1\frac{1}{2}$ gills stock, 2 good wineglasses sherry or white burgundy, 2 peeled and chopped shallots, and a grate of nutmeg. Pour this, including the liquor in which the mushrooms were blanched, over the fish, then place at intervals about 1 oz. butter in small pieces. Scatter over 1 tablespoonful chopped parsley and coat with browned breadcrumbs. Bake for about 20 min. *See Fish; Sardine.*

SPRAY: Medical Uses. In affections of the nose and throat the use of a spray is often preferable to other methods of applying medicaments. The liquid is converted into a fine cloud by means of a rubber ball which, when compressed, sends a current of air across the mouth of a tube that dips into the liquid. The spray is safer than the nasal douche for a cold in the head, and more effective than gargles for a sore throat. Cocaine, menthol, carbolic acid, iodine and other sedative and antiseptic drugs are used and the vehicle may be water or liquid paraffin. *See Douche.*

SPRAYER. For domestic purposes a sprayer can be used for scent and for fixing charcoal, pencil, and other drawing, by covering them with a finely distributed film of varnish. Larger forms of the same appliance are employed for spreading whitewash, distemper, and paint, and in the garden disinfectant and insecticide are sprayed on potatoes and on fruit and rose trees. The principle is quite simple and consists in passing a current of air over the top of a tube which is immersed in a liquid.

Sprayer. Portable paint spraying outfit suitable for home use. The pistol is shown enlarged on the right. (Courtesy of Richard Methuish. Ltd.)

The simplest form of sprayer consists of two lengths of glass tube fastened together with a hinged clip, so that they can be set at right angles. One tube passes through a cork and reaches almost to the bottom of a bottle containing the liquid to be

atomized. When air is blown through the horizontal tube the liquid is drawn up from the bottle and projected as a fine spray. The essential feature of the appliance is in the relative positions of the ends of the tubes, for the end of the horizontal or air tube must be so put that it directs the air across the top of the liquid tube.

In the scent spray for the dressing table the air is supplied either by a rubber ball or a piston, the former producing a continuous spray.

The common pump sprayer for insecticides has an action similar to that of the tubular sprayer described above. It consists of an air tube in the form of a pump, and similar in action to a syringe. A nozzle at the end is directly over the liquid tube, which is attached to and fits in a receptacle holding the liquid, this container being filled through an opening covered by a screw cap. This type is used also for spraying rose trees and fruit bushes.

The spraying of distemper, paints, cellulose finishes, etc., requires a more powerful air pressure. In commercial work a power driven air compressor is used, but a substitute for home use is available in the form of a foot pump in combination with an air reservoir. Machines suitable for garden purposes are described in the succeeding article.

SPRAYING: In the Garden. Various liquid mixtures which are administered by spraying are widely used for destroying insect and fungus pests on fruit trees, rose trees, and other flowers, as well as on certain vegetables; for instance, potatoes. Spraying is most effective in dry weather. If it is followed quickly by heavy rain it must be repeated as soon as the weather clears. Early morning and evening are the best times of the day for spraying.

A hand syringe with a spraying nozzle is usually sufficient for treating potato plants, small fruit trees, rose trees and flowers, but for large trees and stretches of potatoes a mechanical sprayer is advisable.

Spraying Machine. Where there are a good many trees concerned a machine sprayer is used. One of the best is known as the knapsack, being so called because it is carried on the back. This is suitable for spraying all kinds of fruit trees, as well as potatoes, and other vegetables.

In these machines the container, which holds about $3\frac{3}{4}$ gallons of the spray is usually made of plain or tinned copper. The former is less expensive, but it cannot be used for a lime sulphur wash, for which either a tinned copper one must be used, or one with a container made of an alloy that is chemically resistant. Fitted to the container is a short length of hose, and attached to this is a brass lance about 3 ft. long, the nozzle being fitted to the end of the lance. For spraying large trees a lance, 5 or 6 ft. long, can, if necessary, be fitted. All spraying machines are fitted with strainers. When it is necessary to spray an orchard of large standard trees, a type of small wheel manual machine is recommended.

Winter Spraying. For spraying fruit trees in winter the tar-oil washes are recommended; they not only cleanse the trees of moss, lichen and other impurities, but help to destroy hibernating pests among the branches. Lime-sulphur, nicotine and Bordeaux mixture are commonly used in early spring before the blossom buds open, and again at summer strength later on if necessary. Arsenate of lead paste, in solution, if sprayed on the trees as soon as the blossom has failed poisons the food of caterpillars. During the summer months one of the concentrated insecticides sold under various patent names will keep down aphids and other common pests. *See* Apple; Bordeaux Mixture; Fruit; Insecticide; Potato, etc.

SPRIG: In Lace. In lacemaking this word refers to one of the separate pieces of lace fastened on a ground in appliqué lace. Material embroidered with sprigs, or which has sprigs in the pattern, is known as sprig embroidery or sprig muslin. *See* Lace.

Spring. *See* Door; Lock.

SPRING: In the Garden. For the amateur gardener spring is the most delightful season of all, particularly in the open garden, and it is also a busy time. The results of hard work during the dark, cold, wet and frosty days show themselves by the arrival at perfection of many beautiful subjects, particularly flowering bulbs. First of all come the snowdrops, which are closely followed by crocuses, scillas, anemones, hyacinths, narcissi, daffodils, and tulips. Later on flowering cherries and almonds put forth their beautiful pink and white blossom, fresh young buds and foliage begin to appear upon trees, shrubs and perennial plants.

Strenuous work must be done out of doors in order to obtain the best results later on. This necessitates care in the sowing of seeds of hardy annual flowers, which, in small gardens, may be done safely in between the clumps of spring flowering bulbs already in bloom and the groups of established perennial plants which begin to indicate their presence for the season. Many questions of pruning, propagating, dividing, and other technicalities arise at this time of the year.

As the official period of spring is from March 21 to June 21, information regarding the constructional part of gardening work will be best derived from the tabulated information given in this work under the headings of the different months. *See* April; Autumn; June; March; May; Summer.

SPRING CABBAGE. This is a valuable vegetable which supplies produce in spring and early summer. Seeds are sown on a reserve bed during the third week in July and early in August in southern districts, and early in July in northern countries. In September the plants are put out where they are to remain at 15 to 18 in. apart. Some of the best varieties of spring cabbage are Harbinger, April, Ellam's Early, Flower of Spring, Mein's No. 1, and Emperor.

SPRING-CLEANING. The housewife who starts to spring-clean with a definite plan of action generally manages to renovate the home with the least possible amount of fuss or disturbance of its other inmates, and with the best and most economically accomplished results. The plan includes arrangements for essential repairs outside (in the case of the owner's house) and inside; also getting rid of rubbish, storing away winter things, making at home anything in the way of new covers, lampshades, curtains or cushions that are required, or getting them made, and sending away carpets and other soft furnishings which need professional cleaning or dyeing.

It is wise to make out the plan a good fortnight before the cleaning begins. Obviously any external repairs needed to roof, gutters, windows, etc., should be done first; then when the carpets are up any repairs to gas fires or other installations which may be required indoors. Should any room or rooms have to be redecorated it is advisable to remove everything portable, and have that work finished before proceeding with the other general spring cleaning. In the meantime small things can be attended to; cupboards can be thoroughly turned out, winter goods protected from moth by cedar chips, naphtha or lavender, stored away safely wrapped in newspapers, and rubbish disposed of; china can be mended and also rugs and carpets which need fresh binding or darning with rug wool. Any odd jobs of carpentry or putting up shelves, etc., should be done before cleaning starts. Mattresses or pillows which require re-making should be sent away, and stock can be taken of the linen, glass, china and kitchen utensils.

Method of Procedure. In the case of a house it is best to start from the top downwards. The sweep should be engaged to clean in turn any chimneys in rooms where there have been coal fires. Having decided the rotation of cleaning, prepare a room for the sweep the day beforehand by removing all hangings, etc., and covering the rest of the furnishings with dust sheets and newspapers.

An electric vacuum cleaner is a great aid to the housewife where electricity is installed; it is not only useful for cleaning ceiling, frieze, picture rail and walls, but also for mattresses, stuffed chairs, divans, settees and soft furnishings generally. Once the sweep has finished, the special attachment to the vacuum cleaner should be used for ceiling and walls, or, failing this aid, a long-handled soft ceiling broom. After this the floor is dealt with, scrubbed or washed over with soda water and repolished, if parquet, or if of stained boards which are worn, restained with equal quantities of Brunswick black and turpentine, giving as many coats as are required, leaving them to dry in turn and then treating with floor polish.

When linoleum, rubber or cork carpet is the floor covering, use a little disinfectant in hot, soapy water with a clean floor cloth, afterwards dry thoroughly and wax polish. Japanese or fibre matting can be scrubbed, using a little soap and water, and working the way of the weave. The matting should be dried with a soft cloth immediately. Paintwork is best lightly treated with a tepid solution of borax and water, dried and polished with a soft rag on which a few drops of paraffin are sprinkled. Windows should be thoroughly cleaned and blinds, if any, scrubbed with a brush wrung out so that it is merely damped with soapy water and afterwards the blinds must be well dried. All furniture and fittings are next cleaned. Polished wood that requires particular attention should be washed in tepid vinegar and water and then rubbed over thoroughly with linseed oil and left for a few days; after this it should be well polished with furniture cream. Other furniture should have the woodwork washed over with a damp cloth and polished, and any upholstery well brushed or treated with the correct vacuum cleaner attachment.

Cleaning Fireplace and Mantelpiece

All pictures and mirrors should be cleaned, all drawers and cupboard shelves washed over with a damp cloth wrung out of hot water with a little disinfectant added to it and, when dry, relined with clean paper. Brick fireplaces, which should be rubbed down weekly with warm water to which a little paraffin has been added, may be further cleaned with a preparation sold for cleansing unglazed bricks. White marble curbs and mantelpieces which are stained should be rubbed with half a lemon dipped in salt. Leave the application on for a few minutes, wash off and dry the marble thoroughly. China and glass, ornamental or useful, should be washed in soapy water with a little ammonia in it, using a hoghair paint brush for finely-modelled pieces and for getting the dirt out of crevices. Fittings of brass, copper, etc., and ornamental pieces should be cleaned and the opportunity taken to apply a transparent lacquer to any suitable pieces, which will save further cleaning for a considerable time. Piano keys and other ivory can be best treated with a paste made from sal volatile and olive oil, rubbing it on with a wash leather and leaving till dry, when the paste is polished off with a clean soft cloth. All books should be thoroughly dusted and old papers and magazines discarded if useless. *See* Brushes; Carpets; Clothes Moth; Labour Saving; Paint; Polishing; Vacuum Cleaner.

Springer. Champion of this breed of spaniel.

SPRINGER: The Dog. The breed of sporting spaniel known as the English springer is a very symmetrical dog, weighing on the average from 40 to 50 lb. He is possessed of a long head, square

muzzle, longish flat coat, long ears, straight front legs, good strong feet, and a general look of activity.

The colours are various. Among sporting dogs the springer's extra size gives him greater pace than the cocker, and he is able to retrieve a hare. *See Dog.*

Spring Mattress. *See Divan; Mattress.*

SPRING ONION. To prepare these for table, wash them well in cold salted water, so as to draw out any insects from the leaves, cut off the roots, and trim the green tops. The outside leaves, if withered, may be peeled off. Serve the onions either whole with salt, or cut them up and add them to a mixed salad.

Spring onions are sold in small bunches. The leaves should be upright; any tendency to droop being an indication that the onions are not fresh. *See Onion; Salad.*

SPRINKLER: For Clothes. Any vessel which has a perforated top that will serve as a sprinkler may be used to damp clothes before they are ironed. The large enamelled tins, with handle and detachable tops, sometimes used as flour dredgers, make good sprinklers, and enable the damping process to be done more evenly and thoroughly than would otherwise be possible. *See Ironing.*

SPROCKET: The Wheel. A toothed wheel of any diameter suitably designed for chain drive as distinct from gear drive is a sprocket. The shape, width, and pitch of the teeth will vary in accordance with the pitch and width of the chain to be used.

In its true form the sprocket wheel is always employed for pedal cycle work in conjunction with the block or roller type of chain, the roller chain being the most popular. A sprocket used with the silent chain is in appearance identical with the ordinary pinion, the teeth being much the same in shape. This pattern is always employed where chain drive is incorporated in the design of a motor vehicle. *See Bicycle; Internal Combustion Engine; Motor Cycle.*

SPRUCE: The Tree. This is the common name of a group of conifers among which are valuable timber and ornamental trees. Deal is the wood of the common spruce or Christmas tree (*Picea excelsa*). The blue spruce (*Picea pungens glauca*) is a beautiful lawn tree, and others of decorative value are the Himalayan spruce (*Picea morinda*); Engelmanni, the Servian spruce (*Picea omorica*); and the Sitka spruce (*Picea sitchensis*); the last-named is an excellent tree for wet land. Propagation is by seeds.

Uses of the Timber. Spruce or white deal is one of the cheapest and commonest woods, imported into Great Britain from N. Europe and N. America. It has a white, clean appearance, with distinct annual rings and with numerous small hard knots, the latter making it rather difficult to work, as they dull the cutting tools, otherwise the wood is fairly soft. It is light, elastic and resonant, the latter quality making it a suitable wood for sounding-boards and for violins.

As a tree spruce is tall and straight, yielding poles which are suitable for masts, spars, scaffold and telegraph poles, and for ladders when split. Builder's planks and temporary constructions are generally of spruce, and it is used for piles, packing cases, and similar rough work, and also for making paper pulp.

Its cheapness and clean appearance are reasons why spruce is employed for flooring, matchboarding, kitchen dressers and tables, and much other interior joinery. It is used also in boat-building and for oars. The Christmas tree is a small spruce. *See Wood.*

SPRUCE BEER. This is a beer flavoured with a decoction of the young shoots of the spruce fir. To make it, dissolve 4 lb. treacle in 2 gallons water by heating them in a large pan over the fire, then strain the liquor into a cask and add to it 2 gallons cold water and about 2 tablespoonfuls spruce essence.

Let the whole stand until it is just lukewarm, and then stir in $\frac{1}{2}$ gill fresh yeast. Place the cask in a warm place, and when fermentation ceases bung it closely and leave it until the following day, when its contents may be bottled. Spruce beer made in this way is ready for drinking in a week's time. Essence of spruce is made by boiling the tops of the black spruce in water, then taking them out and boiling the water again so as to concentrate the decoction.

SPUD: For the Garden. This is a long-handled tool with a sharp, straight, narrow blade which is used for digging out hard-rooted weeds such as thistles or burdock. Smaller types are convenient for eradicating lesser weeds on lawns, paths, and between cultivated crops. *See Spade; Weeds.*

SPUR: For Horses. Nickel or electroplated spurs are those in general use. Each spur consists of the branches for the heel, neck, and rowel, blunt or sharp, with a strap to go below the boot and one to fasten around the instep, with a leather pad to keep it in position on the boot and to prevent undue pressure on the foot. Spurs are used for enlivening a jaded horse or as an aid to guiding the animal in crowded thoroughfares, or to force a horse up to its bit when necessary. When applied with discrimination they are considered essential for breaking and making good hacks and hunters. After use the straps should be removed and the leathers carefully sponged. *See Horse; Riding.*

SPURGE. This is a large genus or group of plants, but few of them are of much value to the gardener; the botanical name is *Euphorbia* (q.v.).

SPUR VALERIAN. This is a useful plant (*Centranthus ruber*), suitable for sunny or shady borders, walls and the wild garden. It grows about 2 ft. high and bears rose-red flowers in summer. It spreads rapidly by means of self sown seeds. The variety *coccineus* is a better colour and the white variety is attractive.

Spur Valerian. Rose-red flowers of a hardy plant for a sunny or shady border.

Sputum. *See Cough; Expectoration.*

SQUAB PIE. To make, fill a pie-dish with alternate layers of fairly thin pieces of uncooked mutton, sliced onions, and sliced apples. Over each layer of meat and onions sprinkle salt and pepper and a pinch of chopped herbs, over the apple a little white sugar. If the mutton is very lean, a few small pieces of bacon fat should be added. When the dish is full pour over it about $\frac{1}{2}$ gill water, then cover it with a good thick short crust and bake the pie slowly. It should be served hot. *See Pastry.*

SQUARE MEASURE. This is employed for measuring land, walls, floors, and surfaces of all kinds, being essential in all building operations. It is as follows:

144 square inches = 1 square foot

9 square feet	= 1 square yard
30¼ square yards	= 1 square rod, pole, or perch
40 square rods	= 1 rood
4 roods	= 1 acre
640 acres	= 1 square mile

See Architecture; Bungalow; Measurement; Rule, etc.

SQUEEGEE. The simplest form of squeegee is the flat type, consisting of a strip of thick india-rubber mounted in a wooden holder. When passed over a wet sheet it drives out excess of water from both upper and under surfaces of the sheet.

Large flat squeegees mounted on broom handles are much more effective than a broom or mop for sweeping water off concrete or cement floors and paved courtyards.

Squill: The Bulb. Squill is an old-fashioned popular name for the spring-flowering bulb scilla (q.v.). *See* Bluebell; Hyacinth.

SQUINT: How to Treat. Strabismus or squinting is mostly due to errors of refraction, but may also be the result of paralysis of a muscle of the eye. Squinting from long sight or hypermetropia may appear at a very early age. When a child makes a strong effort to bring near objects to a focus there is undue contraction of the muscle, and a squint is produced. In short-sighted squint there is weakness in turning the eye. An inward squint is commonly due to paralysis of the muscle, which turns the eye outward.

For the squint caused by paralysis the treatment will vary according to the disease on which the paralysis depends. In the forms of squint arising from errors of refraction, the child should be at once taken to an oculist, who will prescribe suitable glasses. If this is done in time the squint may be cured in many cases. But if one eye is weaker than the other, efforts must be made to strengthen it. The usual measure is to cover the stronger eye with a shade, so that the weaker one may be strengthened by exercise. The same object is obtained if some atropine ointment is applied daily to the better eye. The treatment should be given a full trial for at least a year. *See* Eye; Sight Testing; Spectacles.

SQUIRREL: The Fur. Squirrel fur is grey in colour, the clear paler shades being most valued for making up into coats and wraps. It dyes well and the darker skins can be treated to imitate Kolinski or sable. Squirrel is also dyed to match mole and flat brown furs as a trimming. Unfortunately, it is not a durable fur. *See* Fur.

SQUIRREL PAINT BRUSH. To a great extent brushes of squirrel hair have taken the place of the camel hair brush for oil and water colour painting. They are made in a variety of sizes and are obtainable at artist's colour shops.

SQUIRREL'S FOOT FERN. This is the common name of *davallia*, a greenhouse fern. Its rhizomes are often trained round objects of various shapes and sold as fern balls. The most popular kind are the squirrel's foot fern (*bullata*) and the hare's foot fern (*canariensis*). *Davallias* are well suited to cultivation in suspended baskets. They like moist, warm, shady conditions. A suitable potting compost is two parts of fibrous loam with one part each of sand, peat, and charcoal, potting being performed in spring.

SQUIRREL TAIL GRASS. The ornamental grass known as maned barley or squirrel tail grass belongs to the genus *Hordeum*, and the only noteworthy species is *H. jubatum*. This is an annual growing about 2 ft. high, the bearded awns of which form a kind of mane. It may be sown in spring or autumn and will thrive in any open space.

SQUIRTING CUCUMBER. This is a curious half-hardy annual climbing plant with oblong, cylindrical fruit somewhat resembling small cucumbers. When ripe these fruits open and discharge their pollen. They should be grown in a heated glasshouse in a mixture of loam and leaf-mould and may be trained up the sides of a sunny greenhouse and on to the roof. Potting up must be done in early spring in large pots.

Propagation is by seeds sown in pots early in the year, in a temperature of from 60° to 70°. The flowers of the squirting cucumber are yellow in colour. The botanical name of the family is *Momordica*, while other popular names are balsam apple and apple of Jerusalem.

STABLE. In building a stable the points that must be principally borne in mind are that the horses should have plenty of light, plenty of air, and that the floor upon which they stand should be dry and well drained. A stable may be built of any material convenient, either stone, cement, bricks, or timber.

Stable. Stalls in a model stable, showing tiled walls, conveniently placed hay racks and feeding troughs, and a general effect of light and cleanliness. (Courtesy of Young & Co. (Westminster), Ltd.)

The stable walls should be 8 or 9 ft. high, so as to give plenty of head room, and the floor should be raised at least 9 in. above the surrounding soil. The common practice of building the hay loft above the stable is not a good one. It leads to bad ventilation and to dust and dirt in the stable beneath, while at the same time the ammoniacal vapours rising from the stable do not improve the hay.

Ventilation should be provided in the ridge of the roof and also in the walls, but the ventilators in the walls must be set above the height of the horse or horses' heads. If set lower, draughts will be caused and the horse will suffer. Stalls are frequently made too narrow; 6 ft. is the minimum width to be allowed for an ordinary horse. The slope of the floor should not exceed 1 in 50. There is nothing worse for a horse than to be compelled to stand on a steep slope, with the greater part of its weight upon its hind legs.

Points about the Floor

The floor of the stall or loose box is generally made of cement concrete slabs, which are roughened so as to give firm standing. Blue bricks grouted in cement make an excellent floor, but it is more costly than cement. Stone setts can be used if laid on cement and grouted with cement mortar. Cement alone will not stand the hoofs of heavy horses and asphalt is too slippery, while wood absorbs moisture and cannot be kept clean. Good drainage is all-important, for if a horse is allowed to stand on foul and wet bedding its feet will certainly suffer. Under-floor drains, like stone causewayed floors, are now out of date, the drainage to-day being usually carried out of the stall.

The modern hay rack is usually of iron, and set at a much lower level than the old wooden rack. The feeding trough is either of cast iron or of fire clay, and is set not more than 3 ft. from the floor of the stall. Water is usually provided in the stall, the water pot being set at a little distance from the manger, and provided with a supply pipe and tap. It should be of a shape easily kept clean, and water should not be left in it. The woodwork of the stall should be clean dressed and varnished, and all ironwork painted three coats.

The stall should be provided with suitable windows. It is cruel as well as foolish to keep a horse in a dark stable, and particularly when it is opposite a blank wall. The windows should be of the sash variety, and made to open and shut. The best for stable purposes are made with iron frames. A window in the wall must be protected with iron bars on the inside. It is well to remember that an ordinary 15-hand horse can reach up to a height of quite 7 ft.

The harness room is usually part of the same building as the stable, and is provided with fittings for holding harness and saddlery. These, as a rule, are made of iron, but wood is a preferable material. The harness room is provided with some method of heating it, either a stove or an open fireplace, for although there is no necessity to warm the stable itself, it is essential to have means at hand for drying wet harness, and for making hot gruel or bran mash for the horses.

Shelves are required for holding harness soap, oil, and polishes, and a few veterinary medicines can be kept in a small cupboard. In a small establishment the corn chests may be kept in the harness room. These are made of galvanized iron, and they are usually separated into two or more compartments, to hold oats, beans, maize, bran, etc.

It is necessary that water be laid on to the stable, and the tap must be one that will take a hose pipe. The manure pit should in no circumstances adjoin the stable. All manure should be removed each day to a pit in the garden, or at some convenient distance from the house and stable. *See Drainage; Groom; Harness; Horse; Manure; Roof.*

STAFFORDSHIRE CHINAWARE. The qualities which characterize this china, both in its useful and in its ornamental forms, are durability, whiteness, and translucency. It has had as much to do as the coarser pottery and stoneware with spreading the renown of the Five Towns, Burslem, Tunstall, Hanley, Longton, and Stoke, whose activity was greatly enhanced by their amalgamation into the county borough of Stoke-upon-Trent, which possesses five great public museums. Among outstanding names are Spode, Davenport, Minton, Neale, Mason, Ridgway of Cauldon Place, Adams, Copeland, Green, and Brownfield.

Collectors of old china regard the immature and uneven productions of William Littler, of Longton Hall, for a few years after the middle of the 18th century, as the beginning of Staffordshire china. The mark was made up of two L's crossed, and examples are now rare. But it was Josiah Wedgwood who introduced into the manufacture of fine earthenware those new methods of potting, firing, and decoration which revolutionized the industry.

Somewhere about the year 1800, Josiah Spode, the younger, adopted at Stoke-upon-Trent a mixture of china clay, felspathic rock, and bone ash, with a lead glaze, which resulted in a true porcelain. His example was followed not only in his own neighbourhood, but ultimately also in the great rival factories found elsewhere.

The result was to abolish the old 18th century distinction between hard paste, as represented by Dresden, and soft paste, as wrought at Sèvres, and virtually to establish a standard composition for English bone-china throughout the kingdom. As the proportion of bone-ash may be as much as $\frac{2}{5}$, the resulting body differs radically from that of the Chinese porcelain, and has become the chief model for modern china manufacture in all countries.

In the early years Spode and Davenport turned out tea and other services in old Japan patterns, sometimes on rose or celadon-green grounds, with gilt feet. Davenport also made at Longport vases and other pieces with raised floral ornaments enclosing delicate landscape panels.

After the mid-Victorian art revival, Mintons did some outstanding work, and the Crown Staffordshire Porcelain Co., Ltd., successfully rivalled the enamel tints used by Chinese potters in the famille verte, famille rose and powder-blue groups. Perhaps the highest achievements in this direction are the flambé glazes wrought by Bernard Moore. *See* China; Davenport Ware; Minton Ware; Pottery; Spode; Wedgwood.

STAG BEETLE. The visits of stag beetles to the garden on summer evenings often gives rise to unnecessary alarm. They are perfectly harmless, in spite of the formidable appearance presented by the antler-like development of the male beetle's jaws. These are neither offensive nor defensive in their function, being, in fact, mere ornaments. The smaller, inconspicuous jaws of the female are of a far more practical character; but they are used only for crushing soft shoots in order to suck up the sap. As the attack is made chiefly on oak trees, no appreciable harm is done. The grubs spend the full period of their existence feeding in the decayed wood of old stumps, and are in no sense garden pests.

Stag Beetle. Male and female of this harmless garden insect.

STAGE. When a stage is required for amateur theatricals or concert in house or garden, it

may either be hired from an entertainment caterer with its accessories of proscenium, curtains, and lighting arrangements, or else it can be made at home in a simple but satisfactory way.

Presuming that the performance is to be in the house, the size of the available room must be considered first, as the smallest stage requires a room not less than 14 ft. high, 20 ft. wide, and 30 ft. long. Of the last measurement 14 ft. is required for the depth of the stage and the remaining 16 ft. for the accommodation of the audience, who are too near the players unless 4 ft. be left between the stage and the first row of seats.

The bare stage floor measuring 20 ft. by 14 ft. seems a good size, but when the marginal space of 4 ft. has been allowed at each side, and at the back for standing room, exits, and entrances of the actors, the passing behind the scenes required during the performance, and the necessary support for scenery by stage braces, the acting portion of the stage is reduced to a 12-ft. wide opening and a depth of 10 ft. Though workable, it will be seen that this size somewhat limits the scope of the productions. If the entertainment be given with screens or drapery as a background instead of scenery, the same amount of marginal space would not be required on the stage, and a smaller room could be used.

Making the Curtains. The curtains may be made of dark coloured Bolton sheeting, and should part and fall easily. A simple plan is to sew rings on a tape running diagonally across each curtain on the side away from the audience. For a stage with a 12-ft. opening the rings would start from the upper right and left inner comers respectively, and be continued down to a point on the edge of the curtains, where they come together in the middle, 6 ft. from the top.

A line is threaded through these rings and over a pulley at each top corner, which will draw the curtains up into a festoon. Weights should be sewn along the bottom hem. This method requires a person on either side to raise or lower the curtains.

The Scenery. The scenery is usually hired from one of the scenic studios, where a speciality is made of small scenes for home entertainments to suit the size of stage described. Exterior scenes are usually formed by a back-cloth, wings, or side pieces, and borders of top pieces of trees or sky. Interior sets are, as a rule, made up of flats and ceiling borders. Flats are straight pieces fastened edge to edge by means of cleats and lines and held up by wood or iron braces heavily weighted with counter-weights.

A few details as to simple stage effects may be found useful, though most of them require practice, because if badly done they may spoil a serious scene. Horse-hoofs are imitated by two half coconut shells tapped against the wall. For wind, a special wind machine can be hired at a theatrical store. The effect of steam from a railway engine can be obtained by rubbing two pieces of sandpaper together in imitation of short or long escapes.

For lightning on a darkened stage a magnesium flash may be used. Thunder is suggested by blows on an iron sheet suspended by two ropes; the roll of thunder is suggested by holding the iron sheet at the bottom and shaking it. Rain effects are worked by pouring dried peas through a long wooden tube studded inside with nails; the slight or the marked tilt produces a shower or heavy rain. *See Amateur Theatricals.*

STAINS AND THE STAINING OF WOODWORK

Rules for the Application of this Decorative Finish

Useful both to the householder and the woodworker, this article deals not only with methods of staining but with the preparation of the varied surfaces so treated. See also Floor; Graining; Oak; Paint; Pokerwork; Varnish, etc.

The object of staining generally is purely decorative, but certain stains have preservative qualities and thus answer a double purpose. By the use of a stain inferior woods may be made to resemble those of a finer quality, and hardwoods may be darkened to any shade for the purpose of enhancing their appearance.

While painting forms a completely new surface upon the wood, thus hiding the grain, a stain percolates into the grain, changing its colour without forming a fresh surface. There are many different varieties of stains, the chief difference being in the medium with which the colouring properties are mixed. This may be water, spirit, oil, wax, or varnish.

A useful wax stain is sold under the name of Stainax. It is applied with a brush, dries in a few hours, and results in a durable wax finish which can be polished with a brush. It is obtainable in a number of shades.

Another method of staining is by the use of chemicals such as permanganate of potash, ammonia, and bichromate of potash. There is another class of chemical stain, the use of which involves two processes, a priming and a colouring coat. The solution combines with the wood to form pigments which are fast, and the colour may take a couple of days to develop.

Stains may be either purchased ready made in liquid form, or obtained in the form of paste, powder and crystals. They are usually named according to the woods they represent, as light and dark oak, mahogany, walnut, and ebony, or in direct colours, as blue or green.

For outdoor work it is necessary to obtain stains which are weatherproof, as ordinary types are apt to fade quickly and develop a patchy appearance. For cabinet work or indoor fittings the wood should be first planed smooth and flat, and then well glass-papered with, first, No. Middle 2, and finished off with No. 1½, using a cork rubber on which to hold the glass paper, and working it always in the same direction as the grain of the wood. If the glass paper is rubbed transversely to

the grain, this will roughen the surface and cause any such parts to become darker than the remainder when the stain is applied.

Where it is desired to stain existing woodwork, care should be taken to ensure its being clean and free from grease marks, as these parts will be lighter than the remainder when the stain is applied, and will give a spotted and patchy appearance. Such places should be treated by rubbing them with a rag soaked in benzine. Any dirty marks can be removed by the use of glass paper.

When staining wood of poor quality, it is sometimes advisable to dress the surface so that the stain may lie evenly. The dressing consists of a coating of size applied fairly thin and left to harden thoroughly before staining. Sizing is necessary before the application of varnish stains to new woodwork, as otherwise the porous nature of the grain will soak up the quick-drying liquid before it is possible to work it.

All nail holes and other indentations must be filled in before staining. If water stain is to be used, the stopping is made up of plaster of Paris, or of wax mixed with suitable colours. Ordinary oil putty is used if the work is to be treated with oil or varnish stains. Care must be taken to avoid marking the surrounding woodwork with the putty, as this may leave such places lighter than the rest when the stain is applied. The holes are rubbed down level with glass paper afterwards.

The brushes required vary according to the nature of the work. For intricate parts of the work, such as mouldings and carvings, a narrow flat brush is the most suitable. A too-fully charged brush is apt to give a streaky appearance to the wood, and there is the danger of the stain dropping from the brush on to the work.

The stain should be kept in airtight bottles, sufficient being made up to finish the whole of the work in hand, so that the colour will be uniform throughout. When required for use, it may be poured into a shallow vessel. Before applying the stain to the wood, it is advisable to test the colour on a spare piece of similar wood.

How to Use the Stain. The stain is applied by drawing the brush from one end of the work to the other in the same direction as the grain, working across from one side. It is essential that the edge of the colour should not be allowed to dry before the adjacent portion is stained, as this would result in a series of streaks; hence it is necessary to proceed smartly, especially when working on a large surface. A hot, dry atmosphere should be avoided, as one brushful will dry before the application of the next. It is a mistake to begin at the centre and work outward, as this necessitates working two edges of colour.

Stain. Fig. 1. In staining a floor the brush is drawn with, not across, grain, working from one wall towards the centre.

Stain. Fig. 2. Using a piece of muslin folded into a rubber in order to remove brush marks. It should be lightly held and an even pressure maintained over the surface of the wood.

Having covered the whole surface, the brush should be pressed out to remove all surplus stain and lightly drawn to and fro over the work in a series of parallel strokes in the same direction as the grain. This will have the effect of removing any excess of stain in any one part. Some workers prefer to finish off with a piece of muslin folded into a rubber, which gives a more even finish and removes all brush marks. Rub evenly and with only a moderate pressure, as otherwise the stain will be rubbed off in patches.
