When staining a piece of panelling or a door, the panels are first attended to, working across from one side to the other in parallel strokes, taking the brush well into the corners and into the quirks. Any inner members of the framework are stained and then the rails, finishing off with the stiles. By this means the treatment of each successive portion of the work will clean off any stain inadvertently overlapping at the joints, as the brush can be drawn cleanly in a line with the joints in the same direction as the grain. The mouldings are finally stained, using a small brush and being careful to avoid touching the panels, especially when working on mouldings running transversely with the grain of the panels. The brush should be sparingly charged to prevent the accumulation of stain in the quirks and corners.

If a particularly dark colour is to be applied to a light wood, it is generally advisable to give two or more coats of a weaker stain rather than one heavy coat, as the latter is apt to dry unevenly and show brush marks. Each coat must be allowed to dry completely before any further staining is attempted. Full directions for varnishing are given in the article on varnish.

Staining a Floor. Oil stains are preferable to water stains for this purpose, as they are more durable and not so likely to tread out. The wax stain above referred to would be quite suitable also. Varnish stains are considerably used for floors, though better perhaps for small areas.

When staining a floor it is important first to clean it thoroughly and to remove any grease marks. The floor should be sized and allowed to harden. Any holes are filled in with putty, wax, or plaster, according to the medium used, and the whole lightly glass-papered and dusted. It may then be stained, working towards the door, so that it is not necessary to tread on the finished work. When using varnish or a varnish stain it is essential to avoid dust, as once this has settled on the wet surface it is impossible to remove it.

STAIN: How to Remove. If due to grease, ink, fruit juice, or any other cause, prompt treatment is always advisable, for the older a stain becomes, the harder it sets. In addition, it frequently causes holes by easing away the cloth.

Discretion must be used in applying remedies, however, for many agents that are suited to cotton goods would have disastrous effects on silk, and what may with safety be used on thick dark-coloured materials would only produce fresh stains on delicate fabrics or cause the colours to fade. In all cases the fibre must be considered, and some knowledge of the different kinds of cloths is essential. Thus, acids have an injurious effect on vegetable fibres, and need to be neutralized by some other agent. Stains that are not obstinate enough to require special treatment may be rubbed with a cloth ball. The latter, being partly composed of fuller's earth, acts as an absorbent and is therefore specially effective in removing grease spots. Various patent preparations are sold for removing either acid or grease stains, but before using them on delicate materials they should be tested on an odd piece of the same colour and texture.

Preparations of benzine, though labelled 'improved' or 'non-inflammable,' still require care in use, and should not be applied near a naked light. The article treated should be aired by an open window until the smell of the cleansing has disappeared.

Stains on alabaster ornaments can be removed with a paste made from whitening, soap and water. The paste is left on till quite dry and then removed with a soft cloth. A little powdered pumice is sometimes effective for the removal of obstinate stains. Stains on marble slabs, chimney pieces, etc., are best treated with half a lemon, dipped in salt. Wash off thoroughly and polish with a soft cloth.

Grease Stains. Stains on clothing caused by the spilling of gravy, oil, etc., should be sponged immediately with hot water, or rubbed with a benzine cleansing preparation. If the fabric is coloured, the affected part may be placed over a cloth and rubbed well with turpentine. Begin at the outer edge of the stain and work to the centre, so that the grease may not spread. Continue rubbing until the damped portion is dry, and then hang the garment in the open air.

Grease stains may also be removed with the aid of some blotting paper and a warm iron. Place the stained part between two layers of blotting paper, and continue pressing with the iron until all the grease is absorbed. Table linen stained with grease should be rubbed with soap in hot water, but this must be done before the linen is put to soak previous to the usual wash. Marks on white materials caused by machine-oil need special treatment, for they will not yield to washing. Dip the stained material when dry in benzoline and rub it well with a clean linen rag.

Calcined magnesia is useful for the cleansing of silk, ribbon, or cloth that has become greasy. The material should be placed on a piece of cotton wadding, and the calcined magnesia sprinkled over it. Lay another piece of wadding over it; then pass a moderately warm iron over the surface. The wadding should absorb the grease almost immediately. White of egg will remove grease spots from leather chairs, etc., if allowed to dry in the sun. Obstinate grease stains on rugs may be sponged with improved benzine or covered with powdered magnesia and brushed off 24 hours later.

A stiff, creamy mixture of pipe clay and water will remove greasy patches from wallpaper, etc. It should be left on for a whole day and night. Practical directions for removing grease from plain wood are included in the general article on the cleaning of floors.

Ink Stains. An ink stain on a white fabric should be sprinkled with salt at once, and then rubbed with a cut lemon. Rinse and wash off both cleansers at once. This method should not be used for coloured things as it may shift the tint; instead, try the following method:

Soak the stained part immediately in slightly warm milk. This should remove the mark if it is a fresh one, and the marked area can be rinsed, dried, and smoothed with a warm iron.

Another method is to rub the stain with half a ripe tomato, then soak it in cold water, and the remains of the mark will disappear entirely after the next laundering. Tomato juice is satisfactory on dark woollen material if afterwards well sponged with cold water.

Old ink-stains which have dried in can only be removed from white fabrics with care, as the strong remedies necessary will spoil coloured goods. There is also always a risk of the cleanser eating a hole through delicate fabrics. Spread the stained part over a shallow dish or bowl half full of boiling water. Moisten the mark with water, and place a tiny pinch of salts of lemon over the stain. The latter must be carefully handled, as they are very poisonous. Leave the salts about a minute, then pour a thin stream of boiling water through them and the stuff. Repeat if necessary, rinsing off all trace of the acid immediately.

When ink is spilt on a carpet, take up the moisture immediately with blotting paper, then rub the place with a rag dipped in milk, preferably boiled, and dry with a dry cloth, rubbing hard. Or salt may be sprinkled on the stain, and rubbed with a cloth moistened in warm water.

Tea and Coffee Stains. For obstinate coffee stains on linen or cotton, a bleaching liquid made from ½ lb. chlorinated lime, ½ gallon boiling water, and 2 tablespoonfuls ordinary washing soda is

effective. Turn the lime into a clean basin, pour the boiling water over it and then add the soda. Stir the whole with a wooden spoon, breaking up any lumps, and working vigorously to help the water to draw out the chlorine. Careful straining is then necessary to remove all the powder and leave the liquid clear.

The latter should on no account be used stronger than one part of bleaching liquid to 4 parts of hot water, and in the case of old or fragile materials, one part of liquid to 6 parts of hot water, or an even weaker solution, is advised. The article should be soaked in this for a short time, and taken out as soon as the stains disappear. A soaking in cold water and a thorough washing to remove all trace of the chemical are then necessary.

This bleaching liquid should never be used on silk or wool. Tea stains may be removed in the same way.

Grass Stains. Grass stains on fabrics which are too delicate to be washed should be treated with methylated spirit dabbed on with a clean cloth. If the material can be laundered, however, the stained part should be soaked in cold water, then covered with a little cream of tartar and left in the sun. Finally rinse with more cold water, and if the marks have not disappeared, repeat the treatment. For grass stains on linen or cotton goods, javelle water (q.v.) will be found effective. *See Cloth Ball; Clothes; Dry Cleaning; Floor; Irons; Mildew; Paint; Petrol.*

STAINED GLASS. The introduction of stained glass in a window for hall or landing depends for success on architectural features, the design and shape of the window and its useful purpose. When there is an ugly outlook, or one on to a blank wall, a well-chosen stained glass window may be a charming piece of decoration, which screens without seriously obstructing the light. The best effects are usually obtained by concentrating the design to a border and a top panel or central motif, and using rippled or muffled white glass for the rest of the window. This is a successful treatment when it is made up from special pieces of glass put together with calms or lead strips to form leaded light panels as described in the article on Leaded Lights.

Stained Glass: its decorative use in the home. Fig. 1. Two examples of roundels and reproductions of 15th. century quarries introduced into the leaded light panels of a living room window.

A cheaper method for the small window is to have it glazed with opal or some translucent glass and to apply a design by means of prepared strips of lead, as explained in the article on Lead Art Craft, colouring the required portions with specially prepared stains.

Quarries and Roundels. Decorative effects can be obtained by the use of small panels or roundels reproduced from 15th and 16th century designs. These are most suitable when introduced into leaded lights. The window gains in beauty and colour and where clear glass is used for the rest of the light there is no obstruction either of view or of daylight.

In the 15th century small panels and roundels with pictorial subjects were inserted amongst plain quarries (rectangular or lozenge-shaped pieces of glass), while quarries with sacred emblems, monograms and heads or figures of saints were also used for church windows. These painted glass decorations were adopted in the windows of ordinary houses as well as of public buildings, and the

subjects of the roundels became frequently secular while personal initials and heraldic devices were used for the quarries.

Fig. 2. Lozenge-shaped quarry with H and K, the initials of Henry VIII and Katherine of Aragon, flanking the Tudor rose surmounted by a crown.

Beautiful roundels were painted with pictorial designs in black and white, often against a background of silver yellow stain. This style of painting is known as grisaille and dates from the Gothic period, though it was not apparently employed for roundels until the 15th century, when many magnificent panels and stained glass windows were painted in England. Henry VIII patronized German and Netherlandish refugee glass window designers and their influence is noticeable in some of the English work of this style in the 16th century.

The decorative use of quarries and roundels for the home window is seen in Fig. 1. In this instance the shapes of the patterned pieces do not correspond to those of the plain glass, but break the uniformity of the leaded light panel by the pleasing manner of their insertion. Fig. 2 shows a lozenge-shaped quarry with the initials of Henry VIII and Katherine flanking the Tudor rose surmounted by the crown. In Fig. 3 the charming effect is seen of two rectangular quarries set in panels made up of glasses of similar shape. Again royal emblems are chosen of the lion, unicorn, rose and standard.

The heraldic shield which is seen in the lozenge-paned light on the left of the picture is another pleasing example of the discreet use of coloured glass. Reproductions of quarries and roundels can be obtained to order at the Victoria and Albert Museum. They can also be sometimes picked up in antique shops.

While large panels of old stained glass are expensive, small quarries have been bought for a few shillings, and finely reproduced roundels are obtainable for about thirty shillings. Panels and roundels with good geometrical or conventionalized patterns have been introduced successfully into sash windows, but require to be specially designed for the style of furnishing in use. Lighting effects can often be improved by tinting white glass panels in fittings with amber or red glass stain. *See Glass; Lead Art Craft; Leaded Lights; Window.*

Stained Glass. Fig. 3. Discreet use of stained glass by the inclusion in a charmingly designed window of two rectangular quarries and an heraldic shield.

STAINED GLASS: OLD AND MODERN EXAMPLES OF INTEREST TO THE COLLECTOR

1. Royal Arms in a window of Westminster Abbey (15th century). 2. Scrollwork, East Window, Canterbury Cathedral (12th century). 3. Diaper, Rouen Cathedral (13th century). 4. Arms of Henry VIII and Jane Seymour, from Nonsuch Palace, Surrey (16th century). 5. Memorial window to 60th London Division in St. George's Cathedral, Jerusalem. 6. Rose window, South Transept, Westminster Abbey (Memorial to the Duke of Westminster, 1902). 7. Memorial window to the Northumberland Fusiliers in Cathedral of St. Nicholas, Newcastle. 8. The Annunciation, Church of St. Ouen, Rouen (14th century). 9. Figure of St. Stephen in York Minster (14th century). 10. The Angel in the clerestory of the Apse of Notre Dame Cathedral, Chartres (13th century). 11. The prophets Joel and Zephaniah in Fairford Church, Gloucestershire (late 15th. century).

STAIR CARPET. Whatever the individual choice of colouring and pattern may be, it is poor economy not to put down a type of stair carpet that will yield lasting wear. Good qualities of velvet pile and hair carpet are always suitable, and for the country cottage coconut matting has much to be said in its favour, as besides its durability it does not retain the dust. Thick felt pads should be placed under the carpet on each tread and an extra yard of carpet should be allowed for each flight to enable the carpet to be shifted at least two or three times a year.

Stair carpet is usually stocked in three widths, 18 in., 22½ in., and 27 in. In a few makes, colours and patterns it is obtainable in 36 in. width. When deciding on colour, and whether the carpet is to be plain or patterned, the width and lighting of the staircase, the wallpaper and the hall should be taken into consideration. Where a number of persons use a staircase it is often considered better to have a patterned carpet.

Where an oriental rug is placed in the hall the pattern of the stair carpet should blend in tone and be of the same type of design a small conventional pattern is satisfactory with a tiled hall, the ground of the carpet repeating a note of colour in the tiles. Where it can be used, the patternless carpet is easier to bring into an effective decorative scheme. It may be all of one colour, possess a plain contrasting border, or show a narrow line of colour a few inches from each edge. The last two varieties are usually to be found in hair carpet. Hints on the economical laying of stair carpets will be found in the article on Carpet (q.v.)

STAIRCASE: PLANNING AND DECORATION

With a Survey of its Architecture at Various Periods

This contribution deals with one of the essential features of the house, and is therefore discussed to some extent under such headings as Cottage; Hall; House; Landing. See also Baluster; Colour; Dado; Floor; Panelling; Stain, etc.

Few parts of a house require more careful planning than the staircase, which provides a means of access from the ground floor to the floors above, and at the same time offers great scope for decorative effect. It will almost always be found that a house with a well-designed staircase is easier to manage from the housewife's point of view than one in which the stairs are badly lighted, too narrow, or in some way out of keeping with the style of the house.

Economy of space is another leading consideration, and the location is very important. The severely geometrical designs essential to the construction of staircases admit of little variety in form, but in the materials used and in decorative details there is scope for original treatment. Some of the principal types of staircase are dealt with in this article, which also describes the component parts and constructional details of a simple form.

The materials used in stairmaking are generally either wood, brick, concrete, stone or iron. The stairs are made up of the following parts, strings, risers, treads, nosings, winders, landing, newel, handrail, balusters. The strings are the side members that receive the ends of the treads and risers, the latter two being housed and wedged into the former. If the stairs are fixed against a wall, that nearest to it is called the wall string, the other the outer string.

The risers are the vertical members which are placed across the stairs to receive and support the treads. They are housed into the immediate lower tread. The treads are the horizontal members which rest upon the risers and receive the wear and tear of the stairs. The nosing is the front of the tread. As a rule it is rounded off or moulded, and projects beyond the riser about ¾ in.

Winders are those steps or treads that form an angle, if such exists, on a staircase. Their shape on plan is similar to that of a kite. Winders should be avoided if possible, and be substituted by a quarter landing, that is, a rectangular space the same width as the stairs both ways. The rise of the stairs is the vertical height from the surface of one tread to the other, and the going is the name given to the horizontal distance between the faces of the risers.

Staircase. Fig. 1. Diagram showing positions of the various parts that make up a flight of stairs.

The newels are pieces of timber generally 4 by 4 in. in section. They are placed at the bottom, top, and at any change of direction of the stairs. The head and the pedestal of the newel are generally worked. The newels receive the handrail, the latter being tenoned into the former and pegged. The handrail is the member that spans between the various newels. It is rounded or moulded. If fixed over the outer string, balusters are placed between them, tenoned into the string and handrail respectively. They are placed about 4 in. apart, two balusters being generally allotted to each tread. The handrail is fixed about 2 ft. 9 in. above the string.

In addition to the strings, the treads and risers should be supported by carriers; 4 by 3 in. stuff is generally used for these, and they are so arranged that each step is supported by either one or two carriers.

Rules to Determine the Pitch

The pitch of the stair is governed by the available space and height. It should generally be arranged so that the rise multiplied by the tread will produce 66 or thereabouts, e.g. 11 by 6, or 9 by 7. These proportions give very good results in practice. The former would be used in the best class of work, while the latter would be applicable to the ordinary dwelling-house.

When the amount of rise and going has been determined, a gauge or pitch-board is made. This is a triangular piece of wood, the two sides forming the right angle being the gauge of the rise and tread respectively. By the assistance of the pitch-board and the plan of the stairs the newels and the strings are set out.

The housings for the treads and the risers are cut on the taper, in order that wedges may be driven to complete the fixing together of the strings, treads, and risers. The tenons and mortises are prepared on the newels, these latter being pinned to the strings during the fixing of the stairs. The width of the stairs should not be less than 3 ft. outside measurement. Stairs are often narrower than this, but it is undesirable, and in many instances very inconvenient.

Although in some of the newer small houses metal and concrete are utilized for staircases having steps of white or coloured composition, with rail and supports of metal tubing, the most common type is the timber staircase. Of these the two forms most used are the well and the dog-leg staircase. The latter consists of two or more flights so arranged that the outer string of each successive flight is immediately above that of the preceding one, the bottom newel of the upper flight acting as the top newel of the lower one. This form is chiefly used to economize space, and is seen in many terrace town houses. It is also the cheapest form of simple staircasing. Fig. 2 shows an elementary type of such a staircase.

Fig. 2. Open type of dog-leg staircase, simple form chiefly used to economize space.

Fig. 3 is an example of a well staircase. This type of stairs is probably the most dignified in appearance and consists of two or more flights built so as to enclose a space. The example given is constructed round three sides of a well, each of the flights being straight and having two quarter space landings, thus obviating the necessity of using winders. The handrail is of heavy proportion, but being in combination with the bold newels it does not appear out of place. The upward curve to be seen at the head of each rail is known as a ramp and is used to bring the rail up to the required height for the beginning of the succeeding member.

Staircase. Fig. 3. Well staircase of modern construction; a simple and dignified arrangement.

Tudor and Jacobean Staircases. In the early Tudor buildings the most used type was known as the solid newel, and consisted of a central upright or newel from which the treads and risers radiated in a spiral fashion. These were usually of stone and of crude construction, and were dangerous, owing to the treads necessarily tapering to a point towards the central newel. With the advent of the Renaissance, although stone stairs were still constructed, wood stairs arranged in straight flights came into use, these being the forerunner of those in use in modern times. The earlier specimens were often composed of a series of solid blocks built into strings of similar heavy formation, but these were later superseded by a lighter form of separate treads and risers housed into the strings. A notable feature of Elizabethan staircases is the treatment of the newel, which was carried above the

handrail and was usually surmounted by a capping or carved finial. This treatment is found in many later oak stairways and in adaptations of Tudor and Jacobean styles.

Fig. 4. Beautiful 17th century staircase in Ashburnham House, Westminster School, with Ionic columns, carved balusters and panelled walls. Fig. 5. Georgian staircase with gracefully turned balusters and carved mahogany rail. (Courtesy of Country Life)

time.

The later Jacobean staircases were of similar formation to the Elizabethan, except that they were rather lighter. The turnings, in place of the heavy bulbous type, were slighter, the handrailing of smaller proportions, and during the first half of the 17th century the newel was still carried above the handrail. This feature is probably a development of an earlier form, when the newel was continued from floor to floor in one continuous line, a style also found partially adapted to the modern stairway, as may be seen in Fig. 6.

Fig 6. Modern staircase in a two-storey country cottage; it has been planned to make a charming feature in a lounge hall. (Humphrey & Vera Joel)

Our next illustration, Fig. 4, shows a 17th century London staircase of unrivalled beauty. This is situated in Ashburnham House, now part of Westminster School, the building of which has been assigned to Inigo Jones, between 1633-1640, or to his pupil Webb in the period between 1660-1670. This staircase is considered to have been planned and designed with consummate ingenuity and art. Its wide, shallow treads, carved balusters, fluted Ionic columns, and its elliptical dome (not seen in the illustration) supported by a series of twelve columns, give an effect of great dignity and spaciousness. The lovely 17th century panelling should be noted.

Staircases of the 18th Century.

For the more intimate and cosy type of house which came into fashion in the reign of Queen Anne staircases were planned of much lighter construction. The heavy balusters and massive handrails disappeared in favour of a lighter and more elegant style. Three finely twisted balusters were sometimes found on each wide tread, and carving was discreetly limited to a delicate newel at the

bottom of the staircase, and sometimes to brackets below the treads on the outer side which enriched the appearance of the flight when seen from the hall.

In other 18th century staircases a railing of scroll work in bent iron was utilized in place of wooden balusters. This is yet another style adopted to day, in some cases all the iron work being painted to tone or contrast with the walls, in others the handrail only being coloured.

Fig. 5 illustrates a staircase in mid-Georgian style with turned balusters painted white and carved and polished mahogany handrail. The lighter construction can be noted here. The handrail is shaped round the lower end in the form of a scroll, and is superimposed on the newel. Handrails of this period, and on, were often of such a light pattern that they were strengthened on the under side by the insertion of an iron core. The lighting of this well staircase—an important feature in the construction of all staircases—is particularly good from the admirably proportioned and situated windows.

Modern Staircases. Economy of detail is characteristic of many modern stairways in small houses, but often a charming effect is produced by the planning. An example is shown in Fig. 6. Nothing could be simpler and yet more harmonious in a modern cottage type of building. In the small terrace house the stairs usually have to be arranged within the entrance hall or passage, but in a detached or double-fronted house there is often opportunity for a stairway to be a characteristic feature of a hall sitting-room. In Fig. 6 this is the case. The interest lies in the slightly raised newels at the bottom, the continuation of the newels at the turn of the stair to the upper floor, the well-proportioned moulded handrail and square balusters, and the small window in the solid timber partition on the left.

Fig. 7. Painted staircase planned for a labour-saving house. The solid construction of the wooden balustrade does not harbour dust. (Humphrey & Vera Joel)

A completely different effect is achieved by the treatment of the wooden staircase in Fig. 7. With the addition of a nursery gate in corresponding style, such a staircase would be ideal in construction for a house where there are small children, as its solid balustrade would obviate accidents. It also has the merit of harbouring no dust, unlike the open type of banisters. Interest is given to the design by the panels and the raised newels surmounted by balls. The staircase is painted to match the skirting, doors and window frames. Another interesting departure from convention seen in a modern staircase is to replace upright balusters with two thin, square rails between the handrail and stairs, and having only one or two matching

supports at intervals between the newels. All the woodwork was stained light oak colour. Concrete is occasionally used as a balustrade in the form of an unbroken wall surmounted by a metal handrail and terminating at the bottom in a scrolled formation or pillar, while metal tubing has been employed for banisters in place of wood on other staircases.

Decoration and Finishing. The importance of selecting a suitable colour scheme for the staircase cannot be overstressed. Brilliant colour is attractive in some houses, but it is advisable to remember that a neutral shade is far more likely to blend harmoniously with all the rooms which open off the

staircase. The hall and staircase should unite the whole colour scheme of the house and no discordant note should be permitted in their decoration.

Wallpapers and carpets with very pronounced patterns are, therefore, not a good choice. The modern liking for varnished paint and varnished marbled papers in pale tones of yellow, beige, green or grey for hall and staircase is to be recommended for two reasons. The first is that a pale, shiny surface reflects the light, and the second that such surfaces, especially when mottled, do not show dirt or marks, a consideration on a family stairway.

Sometimes the balustrade is accentuated by being painted in a darker colour to stand out against light walls, as in Fig. 7; in other cases, as in Fig. 6, the woodwork is of the same colour as the walls. In the latter example the dark rich tones of the stair carpet are particularly valuable. A good effect has been also obtained by painting the treads and handrail black, while the risers and rest of the woodwork were painted white. A grey-green carpet with a deeper toned border and pattern, and the green marbled wallpaper treatment, with the applied landscape motif, completed an inexpensive scheme for a town house. Another staircase was decorated in shades of grey. The walls had a dark grey dado with dove-grey paper above, and all other woodwork, including staircase doors, was in two medium shades of grey. The stair carpet was also grey, but colour was introduced by rugs, window curtains, and a set of flower prints framed in lead (see Lead Art Craft).

While paint is most usual on a staircase, stained woodwork has much to recommend it. It is permanent, neutral in colour, and costs little to maintain in good order. For the type of staircase shown in Fig. 3, brown woodwork has an excellent effect, and renders carpeting unnecessary if the treads and risers are of oak. Deal does not stain very well for this purpose, but British Columbian pine has a beautiful grain and, though dearer than deal, is worth the extra cost, which is comparatively little for the staircase and accompanying woodwork in a small house. The natural colour of the wood combines with a preservative stain to give a beautiful effect when wax polished. A scheme which included a dado of this wood, honey coloured walls and ivory ceilings would place no restrictions on the decorations of the rest of the house, and yet would be warm and inviting in itself. Such a scheme is, however, only possible for new woodwork when the choice of decorations rests with owner or leaseholder. Stains, especially those of a preservative kind, which give the best effect besides preserving the timber, not only penetrate the wood (unlike paint, which merely coats the surface) and are difficult to remove, but also have a destructive effect on paint should it be wished afterwards to make a change in the decorative scheme.

Staircase. Fig. 8. The cupboard under the stairs in some houses is a dark hiding-place for unwanted things. Not so in this case, where an electric light reveals its useful contents at a glance.

Stair Cupboard. In many houses there is a cupboard under the stairs which can be most convenient if its contents are easily seen and properly arranged. When used as a housemaid's cupboard and not as a hiding place for unwanted things it can be fitted with shelves, a broom rack and space left for the vacuum cleaner, etc It is also a good housing place for gas and electric meters. Where electricity is installed a light which reveals the contents of

the cupboard at a glance is well worth the extra point. Fig. 8 shows a stair cupboard fitted in this way. Note the wall socket at the foot of the stairs for radiator or vacuum cleaner.

STAIR ROD. The long, thin rod placed in the angle between the tread and riser of stairs to secure the carpet or linoleum is generally made of wood or metal. In selecting stair rods, it is well to bear in mind that those which are made of polished metal call for constant attention to keep them bright and in good condition, whereas only an occasional polish with furniture polish is needed for wooden rods. The good effect of oak stair rods is illustrated in Fig. 6 of the previous article. An oak rod with an oxidized metal eye or bracket is a useful fitting. The brackets are simply screwed to the tread and riser respectively.

To keep any type of brackets used at a uniform distance apart, it is a good plan to cut a stick or piece of wood of sufficient length to fit neatly between the two sides of the staircase or stringers of the stairs, and to cut two notches in one edge of the stick exactly where the metal brackets are to go. By using this stick as a guide and placing the brackets according to the notches, uniformity in fine is ensured.

Instead of rods, clips or holders are often now used. A simple switching of the holders is all that is necessary to release or fix the carpet. There are no loose parts to be taken away and replaced. Such holders are finished in oxidized brass, copper or silver.

STAKING: In a Garden. This is an important detail in the cultivation of trees and plants. Standard trees must be supported by strong stakes or the head of branches may cause the stems to break.

Suitable ways of supporting herbaceous border and other plants are shown in the accompanying diagrams. Plant supports ought to be as unobtrusive as possible, and they must be inserted in good time, for if the stems become bent the flower display will be spoilt. The metal coil stakes are commonly used for carnations; they are of spiral shape and tying is unnecessary. See Beans; Carnation; Fruit; Peas; Sweet Pea.

Staking. 1. Good knot for garden work: a, details of tying. 2. Same knot incorrectly tied at b. 3 and 4. Two useful supports of wood and string. 5. How to stake a tree securely: a, stakes; b, twisted ligature; c, knot as shown above. 6. Stake tarred or creosoted above and below ground. 7. Method followed in staking a pot plant. 8. General utility stake for border purposes. (By special arrangement with Amateur Gardening)

Stammering. *See* Speech.

STAMP: On Documents. Certain documents, in order to be valid, need stamps, the value of which varies with the value of the transaction for which the document serves. For instance, a contract note for the sale or purchase of any stock or marketable security must bear a stamp. This is 6d. for contracts between £5 and £100 in value: 1/- for those between £100 and £500; 2/- for those between £500 and £1000, and so on, until a stamp of £1 is needed for sums in excess of £20,000.

Stamp duties are also payable when land or houses or other property of that kind is conveyed or is sold. These are at the rate of one per cent. When the value of the transaction does not exceed £500, the rate is one half per cent. The stamp duty on a mortgage is 2/6 for every £100, or fractional part of £100, with smaller amounts for those below £100.

A promissory note must bear a stamp. If it is for less than £10 the stamp is 2d. It rises to 1/- for a note between £75 and £100, and is 1/- for every £100 or part of £100 above that amount. Stamps must also be put upon all life insurance policies. This is 1d. if the sum does not exceed £10. From this the scale rises by 6d. for every £50 or part thereof until on policies exceeding £1000 in value it becomes 10/- for every £1000, or part of that amount. All agreements except (1) an agreement in some matter under £5; (2) an agreement for the sale of goods; (3) an agreement for the hire of any servant, and (4) certain agreements relating to hire of sailors on board ship, must bear a 6d. stamp. An adhesive stamp may be used if it is affixed and cancelled at the time of the agreement, or a stamp may be impressed at Somerset House without penalty within 14 days of the agreement. An agreement may be after-stamped at any time on payment of a penalty. *See* Land; Mortgage.

STAMP COLLECTING

Practical Advice on a Popular and Educative Hobby

Devotees of other collecting hobbies will find in this work articles on the various subjects in which they are interested, e.g. Brass Collecting; Butterfly; China; Coins; Pewter Collecting.

Whether he intends ultimately to specialize or not, the beginner should make himself thoroughly acquainted with the wider aspects of the hobby in the realms of geography and portraiture, cartography and industry, transport and navigation, history, currencies, languages, and many other subjects. A collection comprising one or more of these groups will be a source of constant interest to its owner and to his friends, whether they are stamp collectors or not.

Whether the tiro intends to be a philatelist or to remain a stamp collector only, he should start on general lines, laying the foundation of his collection either by means of the gift of specimens, by the exchange of duplicates with other collectors, or by purchase from dealers.

Except in the case of the commonest examples, stamps have a recognized "catalogue" value, that is, the price at which they are quoted for in the dealers' annual lists; but it is not necessary for the beginner to buy them separately. Many firms make a speciality of packets ranging in price from a few pence to £50 or more, according to quantity and quality. Whole series of these are available, the contents so graded that no stamp is duplicated, the whole forming a nucleus for a general collection. Each stamp, no matter how common, should be studied carefully, both as to its design and philatelic components and its status and value according to the catalogue. The purchase of mixed variety packets from different firms will, of course, result in the accumulation of duplicates; these will be useful for exchange purposes.

After a groundwork has been achieved by the packet system, the beginner is recommended to build up his collection by means of the sets of various countries. These sets may be representative of the whole output of the country in question, or they may be of one series only, and are sold in great variety from a few pence upward. The next step is to write to dealers for selections on approval. These are the speciality of many firms, who invariably offer a discount off the catalogue prices. Approval selections are mounted on sheets or in small books, with the price for each stamp clearly indicated. Such selections should be handled carefully and, after retaining any specimens required, should be returned as soon as possible, together with the cash for those that are retained. A standing order may be left with a dealer for selections to be submitted from time to time, according to one's specific requirements, clearly stated on what is technically known as a "want list."

Stamp Collecting: some of the requisites. Right, star perforation gauge with sixteen variations, each in a space, of 2 cm. Above, left to right: tweezers with rounded ends; same with pointed ends; pocket magnifier.

If the collector intends to concentrate on the stamps of a certain country or issue, he should keep his eyes on dealers' announcements in the philatelic press, wherein specialized collections are occasionally offered for sale intact. If, on the other hand, he prefers to collect on general lines, and wishes to keep his album up to date, he cannot do better than join one or other of the several new issue services which exist for his convenience. Through their agency, and on payment of a specified premium over the face value of the stamps, it is possible to obtain unused examples of new postal issues soon after their appearance. This is one of the most popular forms of modern philately, and many stamps which are now very rare and costly have been supplied originally to collectors in this way.

Stamp auctions by reputable firms are a familiar feature of the trade; they are held every week from early September to the end of the following July. Many bargains can be picked up in this way, and when the collector has gained a working knowledge of market values, etc., it would be worth while applying to one or other of the auctioneers for a sale catalogue, in which the lots to be disposed of are listed in single stamps, sets, or collections according to scarcity.

Exchange Clubs. These provide another means for the economical extension of the collection, while also being a useful channel for the disposal of one's unwanted duplicates. Numerous clubs are in existence, their primary object being the circulation of a monthly packet containing sheets of stamps submitted for sale by members, each of whom has the opportunity of seeing the packet in rotation in accordance with a postal list supplied by the club secretary, who is charged with the settlement of the sales and the return, in due course, of unsold stamps to the owners.

The stamp collector must learn to buy wisely if he hopes to sell to advantage. Condition is of vital importance. Each specimen must be examined to see that it is not damaged or defective, that its colour is true. If it is a used stamp, it should be refused if the postmark is very heavy, unless it is a really rare example. If it is a perforated stamp the perforations must be intact, unless it is a bona-fide variety such as that termed partly perf. On no account should a damaged stamp be mounted in an album unless it is a very rare specimen.

In the ordinary way the collection should be limited to adhesive postage stamps. Nonadhesive stamps printed on postcards, envelopes, letter-cards, and wrappers are seldom included, nor fiscal or revenue labels, unless they have been used for postal purposes. Stamps available for both postage and revenue fiscally cancelled should be rejected altogether. Railway, telegraph, and local stamps should also not be mixed up with the ordinary postal issues in the album.

Necessary Accessories. Apart from the album there are three essential accessories which the collector should obtain at the outset, viz. a box of mounts (small strips of thin, transparent paper, gummed on one side for folding in the form of a hinge), a pair of tweezers, and an up-to-date catalogue. As he progresses with the study of stamps he will need a magnifying glass, a perforation gauge, and a watermark detector. Several sorts of magnifiers are made expressly for stamp collectors, with specially powerful lenses.

A watermark detector is a small black tile or japanned tray, on which a stamp, the watermark of which is undecipherable when held up to the light, is placed face downward, and a spot or two of pure benzine applied to its back. Used in this way, benzine is quite harmless for all ordinary philatelic purposes, but it is advisable to procure the rectified brand. A few issues do not lend themselves to this treatment, being printed in fugitive colours, some of which disappear when plunged in the benzine bath.

In cases such as this, where the watermark is not apparent on ordinary scrutiny, risk of damage can be avoided by recourse to a simple photographic process, in which the stamp is used as the negative.

Other Requirements. Less important accessories include a surcharge measurer, which is a device like a pair of dividers, opening and closing with a screw adjustment, a chalky paper tester, and a mount damper or fountainbrush for moistening stamp hinges. The testers consist of a fine silver point held pencil-wise, which, if the paper be chalky, will leave a slight black mark. The determination of the question of a stamp's surface, as to whether or not it is on chalky paper, frequently affects its value. Any piece of clean silver will serve as a test, which should be carried out in the margin of the stamp, if possible, rather than on the stamp itself.

Peroxide of hydrogen is useful for restoring the original freshness to oxidized colours, but no attempt should be made to expunge postmarks by means of chemicals. A pocket collecting-book and a supply of transparent envelopes are practically indispensable components of the outfit of even the most humble philatelist.

Varieties in the perforation of such stamps as were not issued imperforate must be represented by separate specimens in a specialized collection, but they need not concern the general collector. One of the principal objects in the philatelist's outfit is a perforation gauge. This is a printed card bearing a scale of dots of various sizes, ranging from 7 in the space of 2 centimetres (20 millimetres) to 17 in that width. By passing the edge of the stamp over the dots, it will be found that one or other of the 20 lines of holes will fit these, the figures at the side of the row indicating the gauge of perforation.

A stamp which has more than one gauge of perforation is said to be compound perforate, and in classifying such a combination the measurement of the top row of holes is placed first. Thus the current postage stamps of Great Britain will be found to be perf. 15 by 14. If the perforation varies on all sides, which seldom happens, the sequence of naming is top, right, bottom, left—that is, the direction of the hands of the clock.

Apart from measurements, there are a good many kinds of perforation, as well as of roulette, all of which are separately classified by the specialist, but need not concern the general collector. The main difference between perforation and roulette is that, whereas the former punches out the holes, the latter merely cuts the paper but does not remove any portion of it.

Mounting the Stamps. Before mounting stamps in an album, any pieces of paper or old hinges adhering to their backs should be carefully removed. This can be done by floating the stamps face upward on tepid water, or by moistening between damp sheets of clean, white blotting paper, a dry sheet being laid out ready to receive them, face downward, on removing them from the water. Stamps printed in aniline inks should not be immersed in water, nor should those on enamelled or chalksurfaced papers, which would quickly suffer if damped. Stamps should not be kept in a very warm place, as they are apt to curl up.

In the early days of the hobby it was the practice to fasten unused stamps into an album by means of their own original gum, and to gum or paste on the used ones. This has robbed the world of specimens which would have been well-nigh priceless to-day had they been mounted by the method now in use. The modern method is as follows: Take one of the special hinges referred to above, fold back about $\frac{1}{8}$ in. of one end, gum side outward, lay the stamp face downward, slightly moisten the turned back portion of the hinge, and fix it to the back of the stamp just below the top. Then moisten the other fold of the mount and attach it to the album in the place chosen for it.

Do not use stamp edging or ordinary gummed paper for the purpose, as this will probably ruin the stamps.

Peelable mounts are easily obtainable, the advantage of these being that they can be readily removed from the stamp or the album, or both, without damage to either.

It should be borne in mind that occasion may arise, from time to time, to examine the back of the stamp as well as the front, and the use of the special hinges makes this a simple matter. There is no need to wet the mount all over; a mere-touch on both the folds is sufficient to make it adhere safely and to simplify its instant removal when required.

In mounting or unmounting, sorting or classifying, always use the tweezers; there is never any necessity for the collector to touch his stamps with his fingers.

Arrangement and Annotation. If using a printed album, the stamps should be arranged in catalogue order, that is, chronologically, spaces being left for specimens which it is hoped to acquire later. If a blank album is used, due regard should be had to the artistic arrangement of the collection. Single stamps look well when arranged in straight, horizontal rows, varying in length in order to obviate monotony.

The stamps should be equidistant one from the other. This is facilitated by the faint ruled squares of the blank album pages. Each row should have the tops of the stamps level. Where blocks, pairs or strips are being mounted, a different plan must be adopted. A block of four or more look best at the top.

Completing the Album. Whether the collection is a general or specialized one, the pages of a blank album should be embellished by brief, neatly written, historical notes appertaining to the various issues displayed, showing the date of their appearance, the artist responsible for their designs, the engravers, printers, mode of production, kind of paper, water-mark and perforation, if any, and any other relevant notes of special interest. "Writing up" is an art in itself, and in highly specialized collections it may be elaborated considerably.

In such collections each issue, perhaps even one value of an issue, occupies several pages of the album, illustrating various stages of its career, shades, varieties, etc., and including examples of original sketches, essays, proofs and colour trials, and so forth. Used copies should not be mounted on the same page as unused ones, and separate pages should be reserved for those on entire, i.e. the original letter.

As a safeguard against damage by friction transparent envelopes, made of mica, may be had from many stamp dealers. These envelopes are as clear as glass, and add to, rather than detract from, the beauty of an artistically arranged album page. They are made in various sizes, for the accommodation of a single stamp, small or large, a pair or a block of four, fitting over the enclosure like a sheath.

Collectors, having decided in what country or group they intend to specialize, a contingency which is naturally governed by their capacity for acquiring specimens, must learn all about the subject, by reading all the available literature regarding it, or by taking advantage of the displays and papers by other specialists which are arranged by philatelic societies from time to time.

Every collector, specialist or not, should subscribe to at least two stamp journals, one to keep him up to date with the philatelic news of the day, and the other as an aid to the extension of his scientific knowledge. In any event, a current catalogue should be his constant companion.

Advanced Specialization. Specialization may be extreme, that is, calling for every possible variety in all colours, shades, papers and perforations, or it may be modest, in which the very minor trivialities are rejected.

It is open to every specialist to introduce individuality into his collection, and this is often done by the process of "graingerizing," in which the collection is enriched by a variety of evidential matter and extensive notes such as postal decrees, originals of and essays for stamp designs, etc. The practically unlimited scope of the hobby is one of its chief charms.

Plating, that is, reconstructing a sheet of engraved or lithographed stamps in the form in which it was originally issued, is the most advanced phase.

A knowledge of the various processes involved in the production of stamps is very desirable; indeed it is essential if the hobby is to be pursued on scientific lines. Generally speaking, stamps are produced either by line engraving (intaglio), lithography or surface printing, the last-named being by far the most commonly used.

When the philatelist has mastered the rudiments and technicalities of his hobby, it should be comparatively easy for him to separate line-engraved stamps from lithographed or surface printed specimens.

A Useful Test. The following is submitted as a test for determining an engraved stamp. Take a thin sheet of tinfoil and place it over the stamp.

Rub it gently with the finger, and in a few seconds the raised design on the stamp, if it is a line engraving, will force its way into the foil, and a distinct raised positive of the design will show on the surface of the metal.

Surface printed stamps show a distinct, though usually very slight, impression of the lines of the design in the paper. A lithographed stamp, on the contrary, has no trace of ridges of ink, and the impression is never very clear the outlines being more or less ragged. The first issue of Hungary and many of the so-called New Europe stamps are characteristic examples.

The first postage stamps ever issued—a page from the collection of F. H. Vallancey, showing method of annotation. (By courtesy of F. H. Vallancey)

Enlarged reproduction of penny red stamp of 1858-1879, showing plate number 177 at sides. This plate is common and must not be confused with the rare plate 77.

STANDARD FRUIT TREES. A standard fruit tree is one with a clear stem of 6 ft. or more high. The apple, pear, plum, damson and cherry are grown in this form for planting in orchards or large gardens. They come more slowly into fruit bearing than bushes or pyramids, but eventually they develop into large trees. Standards of apple and pear ought to be planted at 20 to 25 ft. apart and those of cherry and plum at about 15 ft. apart. If standard trees are planted in grass land it is most important that an area about 4 ft. from the stem be kept clear of grass and weeds.

The pruning of standard trees is directed chiefly to thinning

out superfluous shoots and branches to prevent overcrowding and is carried out in winter. *See* Apple; Fruit; Grafting; Pear; Plum; Stock, etc.

STANDARD LAMP. In the article on Lamps, and in those on Electricity, Electric Light Fittings and Gas, some general information is given about standard lamps. Floor standards are now usually adapted for gas or electricity, but occasionally an oil lamp is fitted with a stand. The drawback to this type is that it is more easily knocked over than a lamp placed on a firmly made table or bracket fixture. Whether wired for electricity, gas or oil, a standard lamp should be provided with a solid, well-balanced base. About 5 ft. 6 in. is a good average height.

Gas standard lamps with flexible metallic tube connexions are obtainable in good designs. An example is shown in Fig. 1 of a wooden floor standard with a fringed and dome-shaped silk shade. The wood is painted with brush cellulose lacquer picked out with silver metallic paint. Placed in the position indicated in the illustration there is little likelihood of a sudden pull on the lamp by anyone tripping over the flexible connexion.

Standard Lamp. Fig. 1. Floor lamp fitted for gas. The supply is obtained from the plug point in the skirting through the flexible metal tubing. Fig. 2. Handsome standard lamp of gilded wood fitted for electric light. The carved decoration is of eastern design.

Electric floor standards may be either severely plain in construction or highly decorated like the example seen in Fig. 2, a handsome gilded wooden lamp carved in an Eastern design and carrying a beautiful shade correspondingly ornamental. Equally beautiful lamps can be decorated in lacquer work.

Polished wooden standards in oak, walnut, or mahogany either suggest enlarged wooden candlesticks with twisted, fluted or baluster stems and heavy round or square bases, or are frankly modern in design, with base and stem formed of cubes, or of oval and square shapes combined. Metal is often utilized, either oxidized brass or copper, chromium steel or

untarnishable white metal, or older styles are reproduced in iron work. *See Bent Iron Work; Lacquer Work; Lampshade.*

STANDARD ROSE. There are three types of roses usually included under this heading, the half-standard, standard, and weeping standard. They are budded on the common wild briar or dog rose, or on the Japanese briar (*Rosa rugosa*); the latter is being used increasingly as a stock for standard roses. The stem of the half-standard is about 2 ft. high, that of the standard 4 ft., and of the weeping standard from 5 to 7 ft. high. Rambling and climbing roses are used to form weeping standards, and tea roses do exceptionally well as half standards. *See Rose; Rose Garden; Stock.*

STANLEY PLANE. This is a combination plane extensively used by practical workmen, and it has many different uses. It is supplied with a large number of cutters. By using the various parts and adjustments, the plane can be used for rebating, ploughing grooves, beading, reeding, and fluting, for rounds and hollows, for making all shapes of moulding, for matching, chamfering, sash and dado, as a fillister, and a slitting cutter. *See Plane.*

STAPELIA. Possessed of quaint, fleshy flowers, which emit a strong, disagreeable odour, the stapelia, in its native habitat in S. Africa, attracts carrion flies, hence its alternative name of carrion flower. The stapelia is suitable for culture in the greenhouse, the species *grandiflora*, shown in the illustration, being probably the finest. It should be potted in sandy loam.

Stapelia. Curiously shaped flower of this greenhouse plant, sometimes known as the carrion flower.

STAPHYLEA. This is a hardy summer-leaving and flowering shrub, from 4 ft. to 10 ft. in height. Staphyleas are suitable for sunny borders and shrubberies, in any ordinary soil. The flowers are white and are borne early in summer. The best is *S. colchica*, an early flowering sort, which may also be forced for greenhouse purposes. Propagation is by cuttings in autumn.

Staphylea. White blooms and pointed leaves of a summer flowering shrub.

STAPLE. This name is applied to a U-shaped fastening device. Another application is to the loop shaped fastener used in conjunction with a hasp and padlock. The small staples in common use, which are known as netting staples, are made of tinned or galvanized iron wire, and may be purchased for household use in the form of packets containing about a gross. Various sizes are available, ranging from ½ in. to 1¼ in. long. The gauge of wire generally employed in their manufacture is No. 17 to No. 14.

A stronger kind is the fencing staple used for attaching wires to fence poles. These staples are generally from 1 in. to 2 in. long, and are made from bright wire of No. 10 to No. 6 gauge. Very strong staples are made with a pair of long thin points. Usually a thick gauge of wire is used, and such staples are handy for attaching a chain to a wall. Electric or telephone staples are made from flat

wire, and when protected by a thin piece of fibre are known as insulating staples. See Gate; Latch; Padlock.

Staple. Left to right: Type for the support of straps around a box; strong wire staple with finely pointed ends; fencing staple for attaching wire to poles.

STARCH. Laundry starch is made from potatoes or, in better qualities, from rice. The potatoes are pulped and water run over them to carry off the starch, which is then washed and dried. Rice is treated with caustic soda to burst the starch cells, and when the starch is freed it is washed, dried and ground, washed again with soda, and finally with clean water. Starch is insoluble in cold water. It improves the appearance of certain fabrics by making them smooth surfaced, the better to resist dirt, and stiff to avoid a limp, untidy look. It is used with hot water for muslins, linens and cotton materials which require slight stiffening, and with cold water for collars, cuffs and shirt fronts which are to be heavily starched. For the former purpose $\frac{1}{2}$ teaspoonful of borax and a few shreds of wax are added to 2 tablespoonfuls of starch, which has first been smoothly mixed to liquid form with cold water, and boiling water is stirred in until the starch and other ingredients become semi-transparent. If boiling water is added to dry starch the result is lumpy.

For cold water starch 1 teaspoonful of borax is dissolved in a little boiling water and added to 2 tablespoonfuls of starch, already mixed with cold water, and a few drops of turpentine. The last named improves the gloss and the iron runs more smoothly on the fabric. The mixture is strained, left for a few hours and well stirred before it is used.

In laundry work the process of starching follows blueing. The strength of starch varies with the article and its required stiffness. For laces, muslins and cottons, boiling water starch is used of about equal parts of the made starch and water. For slight glazing rather than stiffening, about 1 part of starch to 15 parts of water is required and for table linen about 1 to 8. Cretonnes and coloured prints should be starched in equal quantities of starch and cold water used to preserve the colour. A slighter stiffening for lace or muslin can be obtained by using water in which rice has been cooked. Collars and cuffs are steeped in cold water starch, and then it is well worked into the fabric, wrung out and rubbed from the surface.

The articles are rolled in a clean cloth and left for about an hour before being ironed; they are then spread wrong side up on the ironing sheet and any loose starch is removed before a hot iron is passed lightly on the wrong side to set the starch. When starching a shirt, the starch must be well rubbed into the front, neckband and cuffs, while care is taken not to starch the body of the shirt, which should be ironed first.

Medicinal Uses. As a food starch belongs to the group known as carbohydrates. Its value lies in the fact that it is easily converted into a readily digestible form of sugar. The starchy foods are digested by the ferments contained in the saliva and in the pancreatic and intestinal juices. Any starchy food should be cooked thoroughly to swell and rupture the granules and should be well chewed.

In medicine starch is largely employed as a basis for dusting powders and insufflations. Mucilage of starch is also employed to suspend insoluble oils or powders. For inflamed skin surfaces the following powder is suitable: Zinc oxide powder, 1 dram; boracic acid powder, 1 dram; starch powder, 1 oz. To be thoroughly mixed. The powder should be placed in a cardboard or metal box, over the mouth of which a piece of gauze is stretched as a dredger.

The making of a starch poultice is described under the heading Eczema. *See* Diet; Food; Ironing; Laundry.

STAR OF BETHLEHEM. This is the popular name of a spring flowering hardy bulb (*Ornithogalum umbellatum*). It should be planted in autumn, will thrive in shady places and bears greenish white flowers. Other kinds bloom in summer and should be planted in sandy loamy soil in autumn in a sunny place. Some of the best are nutans, greyish green; pyramidale, white; and pvrenaicum, greenish yellow. These bulbs may also be potted in autumn for spring flowering in the greenhouse.

Star of Bethlehem, or Ornithogalum, spring and summer flowering bulbs of great fragrance.

STARTER: For the Motor Car. With all types of internal combustion engine some form of starting device is required to transmit the initial movement to the crankshaft. In motor car design the starting handle is fitted for this purpose. It consists of a cranked handle, with about a 10 in. leverage, mounted below the radiator in front of the car, and engages with a short extension of the engine crankshaft. Fig. 1 below shows the general design and principles of the old-established handle, also right and wrong ways of working.

There are three points to bear in mind when using the starting handle. The first is to see that the ignition is not too far advanced. The second is to let the handle lie snugly in the hand, as at B in the illustration; the third point is to see that all the control levers are correctly set and the petrol turned on.

On no account should the starting handle be gripped tightly with the thumb over the top, as shown at C. To hold the handle incorrectly is to court disaster should the engine backfire. A broken wrist or a dislocated elbow is an accident by no means unlikely to occur.

Starter. Fig. 1. A, principle of design; and B and C, right and wrong ways of holding the handle.

Before switching on the ignition, revolve the engine three or four times slowly. Switch on the ignition, engage the starting handle, and turn it slowly until the compression is felt just before bottom dead centre is reached. Then swing the handle past the bottom lead centre and finish with a very smart pull up. If the engine fails to start, engage the handle again and repeat the process. The greatest effort should be applied during the pull-up period only, because should a backfire occur it will only result in the handle being pulled out of the operator's hand.

It is a dangerous practice to attempt to revolve the starting handle barrel-organ fashion, unless one is abnormally strong or the engine is easily turned over on compression. Unless the speed is fairly high, there is always the likelihood of a backfire, and should this occur during the down stroke of the handle the consequences might be very serious.

As all modern cars are equipped with some form of self-starter, the starting handle is detachable and is carried on the car as a unit of the tool kit. This frequently means that the self-starter is employed as the starting medium for the engine from cold, which is a bad practice since a serious strain is placed on the battery. The proper method is first to give the engine a few turns by hand, before switching on, thus overcoming the resistance caused by the cold oil and allowing a charge of gas to enter the cylinders.

Electric Starters. These are of two main types. In the first the apparatus serves a dual purpose, functioning as a dynamo to generate current for the batteries, or as a motor to supply the initial impetus to the engine for starting, current being taken from the batteries in the latter case. In the second type of apparatus, shown in Figs. 2 and 3, an independent starting motor is used and brought into engagement with the crankshaft when necessary.

The type of starter motor that is a combination of charging dynamo and motor is called a dynamotor. The unit is permanently driven off the engine crankshaft or somewhere else in the engine line, usually by silent chain gear, and is controlled by two switches, charging and starting. With the charging switch on, the unit works as an ordinary dynamo, but with the charging switch off and the starter switch on, the unit becomes a starter motor, thus rotating the crankshaft. An advantage of the dynamotor is silence. This type, however, is seldom employed.

Starter. Fig. 2. Typical method of mounting an electric starter motor. Fig. 3. Showing quick-pitch screw, pinion and buffer spring.

Of the independent starter motor little need be said. Current is supplied from the accumulators to the windings of the armature, thus causing it to rotate. The chief point of interest lies with the automatic means by which the pinion mounted on the armature is caused to engage and disengage itself with the toothed ring on the flywheel of the engine. This is carried out as follows: Cut on an extension of the armature shaft is a quick-pitch square thread, on which the pinion is loosely screwed, and retained when out of use at a definite position against a coiled spring. When the armature is caused to rotate, the pinion, being a free member, is drawn along the threaded portion of the shaft, thus bringing it into engagement with the toothed ring of the flywheel. The duration of time between the commencement of rotation of the armature and that of the pinion is just sufficient to cause the pinion to screw itself along the shaft far enough to engage the teeth of the toothed ring. The moment this occurs, the pinion, by being held stationary, is readily drawn into full engagement.

To disengage the pinion the order is reversed. Current is switched off from the armature, causing it to stop, and the toothed ring on the rotating flywheel, now being turned by the engine, drives the pinion, thus unscrewing it off the armature shaft and out of engagement. Owing to the large gear reduction that must be used to avoid the necessity of employing a big, heavy starter motor, the pinion is thrown out of engagement with considerable force, and brought to rest without damage by the buffer spring.

With the ordinary electric starter motor the rapid acceleration causes considerable noise as the pinion teeth come into engagement. Moreover, the full power is applied on the teeth before they are right home. To overcome these drawbacks some types of starter motor effect the engagement of the

pinion before it is caused to revolve, or while it is rotating slowly, the full current being switched on by a further movement of the control.

Faults with electric starters are very rare, and for this reason the carbon brushes, the commutator, and the various connexions are liable to be neglected. All these should be looked to occasionally and kept perfectly clean. What is of most importance is to see that the carbon brushes are clean and working freely, and that the commutator is perfectly smooth and free from any deposit of carbon and oil. A breakdown from any other cause in the majority of cases will be a job to be dealt with by the makers or an experienced man.

Starting Difficulties. Although, when the engine is warm, there is no harm in a limited use of the starter, such is by no means the case when starting from cold, because the gummy nature of the oil renders the engine very stiff, thus calling for considerable effort from the starter motor to turn the crankshaft at a sufficient speed. First of all, before switching on, revolve the crankshaft by means of the starting handle. A few turns, given slowly, will very considerably reduce the amount of current drawn from the accumulators during the starting process. If this precaution is not taken, it is probable that the efficiency of the accumulators will suffer. Serious damage, such as a buckling of the plates and loosening of the paste from the grids, can often be traced to inconsiderate use of the starter.

Should the engine be properly warmed up and yet refuse to start, do not persist in the use of the starter, but make sure all is in order, petrol turned on, ignition switched on, carburetter flooding properly, and extra air shutter closed, if one is in use.

Trouble experienced in starting the engine in cold weather is generally attributable to faulty carburation, assuming of course that the ignition is in order and that there is nothing wrong with the engine mechanically.

The proper grade of lubricating oil recommended for winter use should be employed, the sump being emptied of the summer grade and recharged on the approach of cold weather. Other likely sources of trouble are incorrect tappet clearances, worn valve stems or guides, and anything producing an air leakage into the induction system. Thus a leakage may be brought about by wear on the throttle valve bearings. The sequence of tests given in the fault-finding chart under heading Motorcar should be carried out.

When starting from cold the throttle should first be opened a little more than is needed with a warm engine. If, however, the carburetter is flooded to excess and the engine raced, the surplus petrol washes away the oil film from the piston, cylinder walls, and other parts, and impoverishes the oil supply by dilution. When the engine starts from cold the oil, owing to its viscosity and the resistance it offers to movement, is not circulating properly, so that the working parts are almost dry. It is not until the oil gets warmed up that it can reach and effectively lubricate the different parts of the engine. It is clear, therefore, that for the first few minutes at least the engine should be run slowly, until it warms up. *See Carburetter; Motor Car; Tappet; Valve.*

Starwort. This is another name for the Michaelmas daisy (q.v.) or perennial aster.

Statics. *See Valve; Wireless, etc.*

Statys. Name sometimes used for the plant popularly known as the sea lavender (q.v.)

STEAK: Howto Cook. The term steak usually implies beefsteak, but in a general sense it may be applied to any thick slice of fish or meat. Beefsteak, which is boneless, is cut from the best parts of

the animal, and includes rump steak, fillet steak, buttock steak. For grilling the steak should be of the finest quality.

The largest steaks are cut from the round, but are less likely to be well flavoured and tender; therefore they are best stewed in a casserole. Fillet or tender loin steaks are from the undercut of a sirloin.

A steak which looks like a large chop, about $\frac{3}{4}$ in. thick, taken from a sirloin of beef with an undercut, is known as a Porterhouse steak. It should be flattened with a cutlet bat, trimmed, brushed over with melted butter, and seasoned with pepper, and then allowed to stand for half an hour before being grilled over a clear fire. The grilling should take about 15 min.

Rump Steak. This is a thick slice cut from a large three-cornered joint of beef known as the rump. The latter is that portion which lies behind the sirloin at the end of the back and reaches a short way down the leg in a slanting direction. It is seldom cooked whole, being usually cut into small joints. Rump steaks are generally grilled, but may also be included in meat pies and puddings. For grilling, they should be at least $1\frac{1}{2}$ in. thick. The middle and end cuts are best.

Stewing is a popular method of cooking steak. The directions given for stewed beef under the heading Beef should be followed.

Steak is also excellent when minced, made into rissoles, or, with the addition of kidney, into a beef steak pudding.

Grilled Steak. Steak à la Française provides a good dish, but before the steak is grilled the garnish of carrots should be prepared. To do this, scrape and wash a carrot, cut it into small squares, and cover it in a pan of boiling salted water until it is tender. Then strain off the water, melt 1 oz. butter in a saucepan, and toss the carrot in it.

Split 1 lb. thick fillet steak into 2 or 3 slices, each about $\frac{3}{4}$ in. in thickness. Make the slices into neat rounds, trimming off the fat, flatten them with a cutlet bat or a large knife, sprinkle them with pepper and salt, and pour over half teaspoonful of salad oil and 2 teaspoonfuls of vinegar. Let them soak for about 15 min. Press 1 oz. butter out on a plate, work into it $1\frac{1}{2}$ teaspoonfuls chopped parsley, and 2 teaspoonfuls chutney, cut into small dice and leave in a cool place.

Grill the steak for about 10 min., turning it frequently, and at the same time grill some of the fat that was trimmed off, first cutting it into small rounds. Arrange the fillets down the centre of a hot dish, with some of the grilled fat between each, and garnish them with small heaps of carrot and a few dice of the prepared butter.

A simpler way of grilling a rump or fillet steak about $1\frac{1}{2}$ in. thick is first to trim it and beat it a little to make it more tender; then rub each side with a little butter. Grill it on a well-heated gridiron, allowing 5 min. to each side of the steak; then turn it again and give it 5 min. more. Put a small pat of maître d'hôtel butter on the top, just before serving. Serve it garnished with small baked tomatoes or a little watercress.

Beef steak is less digestible when fried, though this particular method of cooking is often more convenient than grilling. To fry, heat a little butter in a frying-pan so that the bottom is just covered, and put the steak in this, frying both sides as rapidly as possible. When brown, continue the cooking more slowly, and turn the meat frequently. Serve the steak either with a little butter spread over the surface, or with gravy. Fried onions, cut into rings and cooked in butter or dripping, are a favourite accompaniment. *See* Beef; Beef Steak Pudding; Casserole; Diet; Food; Mince.

STEAK AND KIDNEY PIE. To make this very popular dish, take $1\frac{1}{2}$ lb. buttock steak or topside of beef, also about $\frac{3}{4}$ lb. bullock's kidney. Remove any skin from the meat and cut the lean into neat slices about $\frac{1}{3}$ in. thick; cut the fat into dice and lay on one side. Trim the kidney, removing skin

and hard part, and cut into neat pieces. Mix on a plate some pepper, salt, and flour, dip each slice of steak into this, and roll it up with a portion of kidney inside. Arrange these pieces in a pie-dish and scatter over them a chopped shallot and parsley, also add the pieces of fat. Almost fill the dish with water or stock, and then cover with a rich short crust rolled thick. Make a hole in the centre of the lid to allow the steam to escape, brush over with egg, and bake from 1½ to 2 hours in a good oven. *See Pastry.*

STEAMER: For Cooking. The most satisfactory way of steaming food is to cook it in a patent steam cooker, but if this is not available, a plate placed on top of a pan of boiling water, or a double cooker, such as that used for porridge making, can be utilized instead. Steamed puddings are usually-cooked in a basin or mould placed in enough boiling water to reach about two-thirds of the way up the sides.

A special steam cooker is obtainable in which a pudding can be mixed and cooked at once without a pudding cloth. Fruit can be cooked in this way without water and thus the juices are retained.

Another small steamer which is on the market is divided in half by an adjustable compartment so that two vegetables can be cooked in it at once. The compartment can be removed should it be desired only to steam one vegetable or other article of food.

Steamers can be bought in several sizes, but for family use the larger kinds with three or four containers are the best. The lowest container holds boiling water, and from it a pipe conveys steam to the vessels above. The steam can be regulated by means of a controlling valve. The strongest steamers are of tinned sheet steel with copper bottoms, but cheaper kinds can be had in aluminium.

The illustration shows an electric steamer in which four dishes can be cooked at once. Steamers are especially useful in flats and small houses, since a whole dinner can be cooked over one pan of boiling water. *See Pressure Cooker.*

Steamer. Electric steamer with four containers in which a whole dinner can be cooked.

STEEL: Grades and Uses. Made from iron in a variety of ways, steel is used in many forms in the house, and it is employed in nearly every craft. Steel is classified into three grades, mild, medium and hard, depending on the amount of carbon, which varies from 0·15 per cent to 1·5 per cent. It is made by melting the iron, driving from it by various processes its contained carbon and impurities, and then adding pure carbon. The softer steel contains less carbon than the harder varieties.

Soft steel is used for the manufacture of articles requiring a ductile metal, which be beaten or pressed to a desired shape; medium steel for constructional purposes where comparative hardness is required; hard steel is employed for all cutting tools, for fire irons, and every purpose where great strength is needed. Chrome steel contains a small percentage of chromium; it is intensely hard and is used for safes. Nickel steel contains a small percentage of nickel, which renders it very ductile. Manganese steel, containing a large percentage of manganese and carbon, is very hard but ductile, and cannot be softened by heat.

Steel can be hardened by heating it to a red heat in a clear fire, and then dipping it into cold water or oil. Steel is tempered by first hardening it and then polishing the surface quite bright with emery cloth. It is then heated up again until it assumes a certain colour and again cooled. Methods of hardening and tempering are fully dealt with in the articles Case Hardening and Hardening.

The difference between iron and steel is not readily apparent without some knowledge of their properties. The easiest test is to drop the metal on a stone floor. Cast iron has a dull, dead sound; wrought iron has a higher tone and a dull ring. Mild steel is similar, but it has a slightly higher tone. Tool steel has a much higher tone and a well-toned ring, and the harder the steel the higher the tone. The best tool or high speed steel cannot be filed, and ordinary carbon steel is not in any way affected by the file when it has been hardened.

The difference between mild steel and wrought iron can be seen if a strip is bent over on itself and hammered; the steel will not break, but the iron will. If fractured, the grain of wrought iron is of a fibrous nature, the outside being of a dull black with a reddish scale. Cast iron has a dull grey granular appearance. Mild steel is somewhat granular in appearance, but it is a greyish white intermixed with bright sparkling grains. The outside is brightish black in colour. Tool steel is similar, in appearance, but the grain is finer and the outside is a bright blue black.

Oil and soapy water are used as a lubricant in turning or shaping steel, and also to prevent the cutting edges of lathe tools from getting too hot; the lubricant is also used when cutting threads by hand.

Stainless Steel. Containing a percentage of chromium, this is used not only for table cutlery, but for many purposes where a hard cutting edge is not required. Saucepans and other kitchen utensils, dish covers, trays, hot-water jugs, spoons and forks are all obtainable in chromium steel, while excellent use is made of this stainless metal for door furniture and bathroom fittings. Tungsten steel is hard, and is employed for metal cutting tools. Mild steel can be hardened by the process known as case hardening, which leaves a hard outer surface with a soft interior. *See* Brazing; Forge; Hardening; Labour Saving; Lathe; Metal Turning; Metal Work.

STEEL: For Sharpening. This name is given to an instrument used for sharpening knives, especially carving knives. A steel is usually sold with carving knife and fork, the handles and finishings being alike. *See* Carving.

STEERING GEAR ON MOTOR VEHICLES

Principles of Operation and Method of Handling

Other articles that deal with allied subjects will be found under the headings Differential Gear; Front Axle; Gear; Live Axle. *See* also Motor Car; Motoring.

From the point of safety, apart from the brakes, the steering gear is the most important mechanical part of a motor vehicle, and the principle of its operation should be thoroughly understood.

There are two classes of steering gear, namely the adjustable and the fixed. The former term denotes that the steering wheel is adjustable for height, sometimes carried out by mounting the steering box on a swivelling bracket. In another type the wheel is attached to a telescopic mounting arranged at the top of the steering column. With the fixed type steering, a specially shaped bracket is cast as a part of the steering box and bolted to the chassis side member.

In the majority of cases the steering gear is designed on the irreversible principle, which means that, although the front wheels may be easily turned by the steering wheel, a reversal of movement from the wheels to the steering wheel is not possible. In actual practice this is only carried out up to a point, and in most cases, if considerable effort is applied against the front wheels, the steering wheel is caused to rotate.

This is as it should be, otherwise the castor action of the wheels that tends to straighten out the course of the car after a turn has been made would be lost; also the slightest movement of the steering wheel would definitely deflect the car's direction.

Apart from steering gear design the castor action of the front wheels is of great importance to easy steering, as it tends towards keeping the car on a straight course. Castor action is provided by either setting the stub axle behind the centre of the steering head, or by very slightly canting the steering head backwards. The result is to bring the projected point of contact of the steering head slightly in advance of the wheel's point of contact with the ground, as shown in Fig. 1.

For the 4-wheel motor vehicle the steering gear lay-out is commonly on the Ackermann principle, shown in Figs. 1 and 2, a rigid axle being fitted with a swivelling steering head at each end. These heads carry the stub axles on which the wheels revolve, and are connected to each other by a track rod, usually adjustable for length. The steering wheel controls the movement of the steering heads via the steering box and the steering arm. Movement of the steering arm must be provided for in all directions. Therefore, ball and socket joints are always fitted, and in the case of steering heads that are set outward at the bottom, i.e. are not parallel to each other, it is necessary to employ some form of universal joint at each end of the track rod as well.

Fig. 1. Diagrammatic lay-out of the Ackermann steering gear. On the left two methods of supplying castor action for the front wheels.

Owing to the fact that when the car is turning through part of a circle the outside wheel will be moving through a larger radius than the inside wheel, it is necessary to set the steering arms so that the correct angle is given to each wheel at all points between their limit of movement. This is carried out by setting the steering arms so that their ends cross imaginary lines drawn from the centre of the steering heads approximately to the centre of the back axle, as shown by the dotted lines in Fig. 1. The same rule applies whether the steering arms are fitted in front or are fitted behind the axle.

The steering box is very strongly constructed, as the whole of the road shocks imparted to the wheels have to be withstood by this unit. Fig. 3 shows the type in common use. It consists of worm, mounted on the end of the steering column, that engages a worm wheel on the shaft on which is mounted the drop arm. The latter, by means of the steering arm, controls the direction of the wheels. Reference to the diagram shown in Fig. 2 will make this clear.

Although some makers still fit a worm segment, it is common practice to fit a full wheel as shown. As wear takes place the wheel can be turned a quarter revolution, thus bringing fresh teeth into engagement, it being understood that only one quarter of the worm wheel is ever engaged for a full movement of the steering gear. Plain bearings are employed for the worm, and single thrust bearings at each end, the latter being adjustable to take the load.

The screw and nut type of gear is characterised by simplicity of construction and saving of weight. A screw on the lower end of the steering column works in a nut, the latter engaging two levers attached to the operating shaft. As the nut moves along the screw the shaft oscillates and so operates the drop arm fastened to its outer end.

In the cam type of steering gear the specially cut worm engages and moves a pin set in the end of a short arm connected to the operating shaft and thus to the drop arm, causing the latter to oscillate in accordance with the movement of the steering wheel. Another type is shown in Fig. 4. Here the worm on the steering column engages and swings a rotating ring mounted on the forked end of an arm fastened to the operating shaft. In order that the ring throughout its swing shall be properly engaged by the worm, the diameter of the latter increases towards its ends.

Steering Gear. Fig. 2. General arrangement of steering mechanism on the Ackermann principle. Fig. 3. Worm gear employing complete worm wheel. Fig. 4. Another type of gear in which the worm on the steering column swings a rotating ring mounted on an arm fastened to the operating shaft.

Care of the Steering Gear. A periodical overhaul should be given to all parts of the steering mechanism. It cannot be too much emphasized that all the bearings must receive regular and sufficient lubrication. The steering box and its attachments should be looked to first in the case of noticeable slackness, because it may be found that the fixings have worked slack owing to vibration and shocks transmitted from the wheels. The ball joints connecting the drag link to drop arm and steering head respectively should be examined, as they are equally affected by any strains imposed. The joints should be well packed with grease, and the same applies to the joints connecting track rod and steering levers. The track rod can be adjusted if it becomes necessary to correct the alinement of the wheels. Wheel wobble is a condition in which the wheels get into a state of side to side vibration; in shimmy, another similar trouble, rapid vibrations are set up in the steering gear, and so transmitted to the driver's hands. Wheel wobble occurs at fairly low speeds, whereas shimmy arises when the car is travelling at high speed. Both conditions are a source of danger, as even a small deflection of the wheels from the straight-ahead position may bring about a disaster when running at high or even moderate speed.

On modern cars, especially those having independently-sprung front wheels, shimmy and wheel wobble seldom develop. When these troubles do appear, however, attention should be directed to lubrication and alinement, and any excessive slackness in the mechanism must be corrected. In some cases the fitting of a steering damper, which introduces a certain amount of frictional resistance to the movement, will afford a remedy, though this can be regarded only as a makeshift and not sound practice from an engineering standpoint. Wheel wobble can sometimes be stopped temporarily by a sharp turn of the hand wheel. *See Motor Car.*

STENCILLING AND ITS POSSIBILITIES

A Decorative Medium Affording Scope for Originality

This article belongs to a group that describes various ornamental handicrafts. Others are Lacquer Work; Painting on Textile Fabrics; Pattern Printing; Pokerwork; Raffia Work.

See also Frieze; Lampshade; Lettering; Monogram; Screen

A stencil is a plate made either of metal or cardboard on which a design has been traced and cut out for the purpose of transferring it to linen, cloth, or other material. The transfer is accomplished by brushing over the stencil with oils, water-colours, waterproof inks, or stain.

Almost any material can be stencilled. The best fabrics are probably casement cloth, velvet, satin, Arras cloth, and hessian. Chiffon muslin, and similar thin fabrics can be treated successfully, but they must be stippled and not rubbed. Glass, china, wood, leather, imitation vellum, and cardboard all lend themselves to stencilling. The process is also employed in house decoration for friezes and panels, and other forms of ornament. The outfit required consists simply of the colours and brushes together with a piece of plate glass or marble for cutting plates, oiled manilla paper, a stencil knife, and a drawing board or table. Any good oil-colours may be used, but there are special stencil watercolours, and liquid oil-colours are sold in small bottles. No medium is required with watercolours, but for oils a stencilling medium is used. Inexpensive outfits are obtainable in any good art department.

When working in several colours on a one-plate stencil, it is advisable to use a piece of blotting paper or oiled manilla to cover up the design where the colour is not to go. This is called masking. The piece of paper is moved about to form a screen as the work proceeds. In doing very large quantities of any design a plate is generally cut for each colour, as one can work quicker, but for ordinary use a small mask is sufficient.

A separate brush should be kept for each colour, if possible. In working, the brush should be of a size suitable to the design that is to be transferred. If it is too small it makes the surface streaky, while too large a brush is apt to cover more of the design than is desired, and to necessitate masking. In Fig. 1, a hog-hair brush, a knife, and (lowest) a Japanese stencil brush are illustrated. Before using a new brush soak it in cold water. After the work is finished clean the brushes with a little turpentine on a rag and then wash them with soap and water.

Cutting a Stencil Plate. Many people prefer to buy stencil plates, but it is not difficult to cut out the designs at home, and in this way original work can be designed or attractive patterns copied. The beginner should choose a simple design first. If a copy is desired, make a tracing or rubbing of the design on a suitable piece of oiled manilla, which is the best paper for the purpose, leaving at least 1 in. margin all round for small things, and 2 or 3 in. for large plates, or finely cut ones.

Place the plate on a piece of marble or glass, and, holding a well-sharpened stencil knife at an angle of about 45°, cut out the design, working from the weak part of the plate towards the stout (Fig. 2). Never cut towards any part of the work if there is risk of breaking the ties, which are the portions of the plate left in to hold the design together.

In cutting a flower the centre should be cut out first, then the petals cut from the centre outwards. Always cut the side of the petal next to the one already cut. Do not cut the opposite side and then attempt to cut the petal after both sides are weakened. When a corner is reached, cut across it both ways, so that the piece comes out; never pull the pieces out, as this will make the edges of the plate rough and untidy. Stencil plates must be clean cut. A very sharp knife is the only instrument for this purpose.

Stencilling. Fig. 1. Tools used in the process: top, hog-hair brush; centre, knife for cutting stencil plates; bottom, Japanese brush for thin materials.

For stencilling on ordinary materials such as canvas or casement cloth, for china, glass or wood, oil-colours are most suitable. Waterproof inks are excellent for lampshade work as they are transparent.

Barbola colours (see Gesso) are good for stencilling on leather or suede articles. Bronze colours may be used and these are particularly effective on satin or velvet; patterns worked in silver and gold without other colours are most successful.

Stencil water-colours are used on parchment or for wallpaper decorations. For china and glass lacquer composed of sealing wax dissolved in methylated spirit may be employed. Break the sealing wax into small pieces, barely cover with spirit and leave for 24 hours (see Sealing Wax).

Stencilling. Fig. 2. When cutting a stencil, hold the plate firmly with the left hand, which should be above the knife to avoid any risk of cutting the hand should the knife slip. (Courtesy of Winsor & Newton)

Stencilling with Oil-Colours. Take a palette and squeeze out a little of each colour required, then shake up the medium and pour a little into a small saucer. If necessary, pin the material out on a board, then fix the plate in position and fasten the top corners with drawing-pins. The lower part of the plate is left

free, so that it can be lifted up at intervals.

Dip one side of the crown of the brush into the medium, then, holding it almost upright on the palette, gradually work the necessary colour all over the crown. Rub the brush on an old rag or piece of blotting paper to remove any superfluous colour, use an up-and-down movement (Fig. 3) for all thick materials, working as much as possible away from the edges of the plate. Working against the edge of the design often makes a thick, hard line all round the edge, which is very ugly. A round flower should be worked in the centre first, round and round, gradually working in this way until all the petals are coloured in.

Fig. 3. Showing the correct way to hold the brush for stencilling with oil colour on thick material.

The prettiest effects in stencilling are obtained by working one colour over the other. For leaves, use yellow on the tips, green from the base, and draw the two together with a little brown, blue, or red according to the leaf that is being coloured. When stencilling on a woven fabric is finished, allow it to dry, then place a slightly damp cloth on the right side, and iron on the wrong side of the material. Remove the cloth and press well. This is only necessary for fixing the colours, and need not be done otherwise.

Velvet must not be ironed. If necessary, cover the iron with a damp cloth, and pull the velvet over it. When working on a dark material it is necessary to kill it first, otherwise light colours will not show on it. It is possible to remove colour from the background with a preparation called Jarello. The design is stencilled in the ordinary way with this and then put aside and washed. The design will

then be bleached and pale colours may be stencilled on top of it. For a material which is unwashable, paint the whole design in white or a very pale shade of the colour to be used. When this foundation tint is dry, the stencilling is done over it in the ordinary way.

Fig. 4. When stencilling on thin materials use a Japanese stencil brush and stipple the colour. (Courtesy of Winsor & Newton)

When stencilling on thin materials, do not work up and down, but stipple and gently pat the designs, holding the brush upright, as in Fig. 4. Use blotting paper underneath, and work with the brush as dry as possible. Lift the material off the blotting paper now and again, and it may be found that most of the colour is on the blotting paper, and very little left on the fabric. This usually means that the brush is

either too wet or too hard. A Japanese brush, such as that illustrated, is best for very thin materials.

Stencilling on China. When stencilling on china, place the vase, bowl, or other article in a large pan of cold water, and the latter must be brought slowly to the boil. This process serves not only to temper the china and render it less likely to break, but also removes any stains that might disfigure the result. Once the water has boiled, take the pan from the fire and leave the china in it until it is cold; then dry it thoroughly, and, in order to guard against the possibility of a greasy surface, wipe it with a rag dipped in methylated spirit. The presence of grease will not only make the application of colour very difficult, but will also affect its permanency.

In working round any curved article it will be found necessary to snip the stencil plate top and bottom. Use the brush very dry and the colours sufficiently thick to prevent any white patches from showing through. Stippling is the best method, as the plate is difficult to fix and will be inclined to slip. When the design is finished, take off the plate, and with a clean rag wipe off any surplus colour. Begin drying the work in the open air, or, if this is impossible, in a cool oven, and when it is almost dry hold it in the steam of a fast-boiling kettle. This fixes the colours so that washing does not affect them.

When stencilling on glass use oil tube colours with quick drying medium or special colours for painting on glass.

The article to be decorated must be polished with methylated spirit to remove all grease. Hard surfaces such as wood, metal, china, or glass require a dry brush, as all the colour remains on the surface. Wood stains may be used for stencilling unpainted wooden articles. When finished and dry, the work may be varnished or wax-polished.

Florescan Stencilling. A very attractive form of stencilling which resembles the Florentine work of the 17th century is known as Florescan stencilling.

Handsome cushions, blotters, fans, curtains, etc., can be made by stencilling suitable designs on velvet, satin, leather, suede, gauze, or georgette. Florescan colours are sold in tubes and used with a medium. If required to wash or when painting on leather, the washable medium must be used. Japanese brushes should be employed.

Stencilling Curtains. Casement cloth for short curtains takes the colours very well, and has a matt appearance when finished. In working stencils on curtains or covers the corners must always be

taken into account. If possible work all the corners first, and then arrange the centres of the sides. The other way is to place the centre of a design in the exact centre of one side and then arrange the corner. Never work up to a corner or the centre without finding out whether the plate will fit. If not, it will be necessary to find some portion of the design which can be repeated to fill in any space.

A good example of stencil work for a curtain is seen in Fig. 5. In this particular case the corner was stencilled first and made to lie well inside the hem. The latter may be used as a guide, provided that the edges of the stencil-plate are true. The use of a skirt-board is an advantage, because it allows a good deal of the curtain to be pinned down at once. Stencil up the whole length of one side and along the bottom, arranging the medallion in the corner.

To get the best results the stencilling should be done before the top is gathered. The material will then lie flatter, and can be more easily ironed. Any colour scheme can be used so long as it tones with the room in which the curtains are to be hung. As soon as the stencilling is finished, cover it with a slightly damp cloth and iron first on the right side and then on the wrong side. This makes the curtains washable, and also fixes the colours. Thick stencilling should be avoided, for thin material hangs badly if much colour is used.

Fig. 5. Part of a curtain ornamented with a stencilled design around the hem and a stencilled medallion in the corner.

Decorating Cork Mats. Cork table mats may be successfully stencilled. The three examples shown in Fig. 6 are typical of the possibilities in this direction. The first is a dish mat, painted orange with gold border on which lines are drawn with outlining ink, using a fine sable-hair brush. The design is carried out in jade green, purple and black oil-colours and stencilling medium.

A monogram is an attractive feature introduced into a set of table mats as suggested in the second example illustrated. Colouring should match the dinner service in use. The third design portrays a peacock stencilled in blue, gold and green. If a dark colour is used for the groundwork of the mat, a coat of white should be applied to the bird and allowed to dry before stencilling with the proper colours. The design may be outlined in gold if desired.

Many other uses for stencilling will be discovered in connexion with other art crafts. In conclusion the following points may be stressed: All bottles of medium should be well shaken; liquid stencil colours should be kept stirred while in use; brushes must not be too heavily charged; superfluous colour should be removed on a piece of blotting paper before the work is touched. All stencil plates should be cleaned as soon after use as possible.

Rub them with a piece of paper or rag, then clean them with turpentine. Hang them up to dry, or lay them between pieces of newspaper.

STENCILLING: SIMPLE FORM OF DECORATION WHICH CAN BE APPLIED IN MANY DIFFERENT DIRECTIONS

1. Design for dining room frieze, with bunches of conventional Cape gooseberries. 2. Frieze for a nursery or child's bedroom, with pictures of nursery rhymes. 3. Border for tablecloth, carried out with a single stencil plate. 4. Stencilling on wood, and a Dutch design on a cushion cover. 5. Powder bowl, decorated with two-plate stencil of conventional butterfly. 6. Leather shopping bag ornamented with Egyptian design.

STENOSIS. Derived from a Greek word meaning narrow, the word stenosis is used to describe the narrowing of any of the natural apertures of the body.

Mitral stenosis means narrowing of the mitral opening, that is, the passage between the left auricle and left ventricle of the heart. It is a serious form of heart disease liable to follow acute rheumatism. Pyloric stenosis affects the lower opening of the stomach, or pylorus, usually as a result of ulceration in the neighbourhood, or as a functional disorder in infancy. As a consequence the stomach is unable to empty itself properly and becomes dilated.

Stenosis, in general, results from one of three circumstances. An obstruction may lie in the opening itself; it may be due to disease attacking the edges of the opening, as in the two examples cited; or it may arise from a tumour outside the organ exerting such pressure as partly or wholly to close its aperture. *See Heart.*

STEPHANOTIS. The hothouse evergreen climbing plant called stephanotis bears fragrant and beautiful white flowers nearly all the year round. Stephanotis can be grown in pots, or it may be planted out in a well-drained bed consisting of turfy loam, one-third each of decayed manure and peat, and sand.

Very little water is needed in winter. An average temperature of about 70° is the most suitable. Weak growths should be thinned out from time to time. A limited number of strong, thinly-disposed shoots are best. Propagation is by cuttings of the previous year's shoots in the propagator in spring.

Stephanotis. The fragrant white flowers of an evergreen greenhouse climber.

STEP LADDER. The difference between a step ladder, often referred to as a pair of steps, and an ordinary ladder is that in the former the feet rest upon flat pieces of wood, or treads, and in the latter upon rounded ones, or rungs. Another difference is that the step ladder is made in two pieces, a front and a back, which are hinged together so that when opened out it will stand alone. An ordinary ladder, on the other hand, must lean against something before it can be ascended. As step ladders are much safer to climb and usually much smaller in size than ordinary ladders, they are much used for household purposes, such as hanging pictures and curtains, cleaning windows, and the like.

Step Ladder for household purposes, provided with a tray for a bucket, etc. The treads fall flat automatically when the ladder is closed, as shown on the right. (Courtesy of J. H. Heathman & Co., Ltd.)

Step ladders are made in a number of sizes, and into some of them various contrivances are introduced. They range in height from 2 ft. to 16 ft., but probably the most useful sizes are those between 5 and 8 ft., with 6, 7, or 8 treads. Some are made so that the individual steps will fold up when they are put away and others have a hand pole at the top. Some are double, having steps on both sides, while others have

a special platform on which a bucket may stand while cleaning operations are in progress. Other steps, again, are so made that the worker can sit thereon in comfort.

The steps most commonly used are those with a hinged back and rope stays. They are made of deal, and are obtainable at a low price. When purchasing, it is advisable to examine the wood, particularly in the treads, to see that the grain is fairly straight and free from large knots. The treads should be set well in the sides, and if possible provided with iron bolts top and bottom. Chain is preferable to rope, as it is not liable to stretch and lasts longer.

The user of a step ladder should make sure that the legs are firmly placed on the ground before it is ascended. Now and again the rope that connects front and back should be examined, as this may become frayed and so give way.

Repairing a Ladder. The step ladder occasionally needs repair, especially if it has not been very well made or has been left outdoors exposed to the weather. The joints may become loose, the ropes may rot, and the hinges get rusty and break. Frequently, too, the top step is knocked off or loosened. To repair a ladder that has reached the state described the steps should be extra nailed with 2½ in. oval wire nails, and, if possible, glue should be run into the trenched joints. There will usually be room for two new nails at each joint. The heads should be punched down and the holes filled up with putty. The top step should also be extra nailed, as should the back hinged board. Care should be taken when nailing into the edge or straight grain of the wood, which is likely to split; holes should first be pierced with a bit.

If one of the treads is damaged, it can be renewed without disturbing the others. Saw the old tread in two places with a tenon saw well away from the nails, and then pull the end portions away from the groove. Tap the points of the nails and withdraw them with pincers. The new tread should be planed up from a piece of straight grained sound wood, and cut to the exact length between the two grooves. The groove and the ends of the tread should be coated with glue, and the piece pushed into its place. In nailing, use new positions on the outer piece.

The mortise and tenon joints of the back strut frame should, if loose, be reglued and wedged. If the tenons are broken it is best to make a new rail. A less satisfactory way is to glue the pieces together and fix a new rail across both joints with glue and fine nails on the outside. The hinges can be replaced by a new pair. The rope should be of strong window sash cord, and care should be taken that it is the correct length to give the right spread to the ladder, making it stand firm and level on the floor. The knots should be on the outer side of the wood. A step ladder should be painted to keep it in good condition. *See Ladder.*

STEPS AS A GARDEN FEATURE

Viewed from both Practical and Ornamental Standpoints

The construction of a flight of steps is by no means a difficult task for the amateur worker.

For further information he should consult the articles on the various materials, e.g. Brick; Cement; Concrete; Stone. See also Crazy Paving; Garden; Path; Paving; Pier; Rock Garden

Where the garden slopes gently a very pleasing arrangement of steps, as illustrated in Fig. 1, can be adopted, which combines the function of a path and that of a flight of steps. The whole is constructed of crazy paving, and the steps are comparatively low and the breadth considerable. Fig. 2 shows a method useful in small gardens and positions where there is a drop from the garden level to that of the ground floor or sub-basement. The steps here illustrated are made partly with crazy paving, but the nosing or edge of the treads is finished with hewn flagstone.

When it is possible to use rough-hewn stone of the type generally known as rubble masonry, a very handsome type of steps can be constructed somewhat as shown in Fig. 3. Retaining walls are built at the sides, and the steps are formed of roughly hewn flagstones set in rough masonry and embedded in cement mortar on foundations of broken brick.

Steps. Fig. 1. Picturesque effect achieved by the use of crazy paving for a path which rises gradually in shallow steps. Fig. 2. Steps connecting different levels in a small garden; they are of crazy paving finished on the edges of the treads with hewn flagstone.

Fig. 3. Showing the charm of a flight of shallow steps made of flagstone and rubble masonry flanked by retaining walls.

Flight of Brick Steps. Fig. 4 shows a flight of six steps with brick wing walls and brick piers. The path from the top step to the doorstep is laid with brick. The doorstep is flanked on either side by low piers of brickwork, those at the entrance being topped with capping stones.

The difference in level between the approach to the house and the carriage drive is 27 in. This height or its equivalent

on any other job has to be divided between any number of steps that can conveniently be built with bricks, plus the difference in level due to the fall of the path. In this case a fall of 2 in. is allowed from the door to the uppermost step. Each of the five treads of the steps has a fall of 4 in.; the five brick courses of bricks set on edge are each 4½ in. high, thus making up the required total, namely 27 in.

When details of this kind have been settled for any particular job a drawing of the steps should be worked out, such as that shown in Fig. 4, taking particular care to dimension the courses properly, according to the number of bricks used. Commonly, the dimensions for measuring purposes can be taken as 9 in. long, 4½ in. wide, and 3 in. thick. When the plan has been settled satisfactorily, the

ground should be marked out with pegs and lines, and a trench excavated on each side to receive the foundations for the wing walls. The excavation need not be carried down beyond the point at which the ground is firm and solid, so long as a depth of about 4 in. of concrete can be laid as a foundation. This should be placed on another foundation of broken brick or stone. A trench should be dug to receive the foundations for the bottom step. This should also be filled with concrete and roughly levelled off with a shovel, as in Fig. 5.

Steps. Fig. 4. Sectional view showing method of construction of a flight of six steps with brick wing walls and brick piers. Below.

Making a flight of brick steps as shown in the diagram left. Fig. 5. Laying concrete foundations. Fig. 6. Laying course for lowest step.

Fig. 7. How side walls are bonded together. Fig. 8. First two steps completed. Fig. 9. Heading course set on side wall and steps nearing completion.

The first proceeding is to lay a bed of mortar on the foundations for the front step and the two entrance piers, and commence by laying three courses of bricks at each pier. The bricks which are to form the step are embedded in mortar and should exactly fill the space between the two piers; they should fit

tightly and may be driven home with the handle of a heavy hammer, as in Fig. 6. Six more courses of bricks are set on each of the piers, and the side walls built up. These may be laid in the ordinary Flemish bond, the arrangement of the bricks by this method being clearly shown in Fig. 7, where the headers and stretchers are clearly distinguished. The worker should refer to the article Brick for further details of the method of bonding.

It should be noted that as the normal surface of the ground rises, the trench, with the levelled concrete in it for the foundations of the side walls, need not be kept in one main level, but may be stepped up. This result can best be achieved, by the amateur worker, in first preparing the foundations for the lower part of the wall at a reasonable level, placing a couple of bricks on end on the concrete, and laying in a bed of concrete to the level of the top of the top brick. This forms the stepped foundation, the height of the step being proportional to the height of the bricks, thus avoiding much cutting and making up with mortar.

Care should be taken to plumb up the piers and the walls as the work proceeds, and to drive up the bricks by tapping them with the end of the trowel. The second step should then be laid with bricks as before, well embedding them in cement mortar. The ground between the walls is cleared away level, some hard core rammed into it, and the foundations for the next step made by filling in with concrete to the level of the previous step, as is visible in Fig. 8. The work then proceeds in a similar manner as before, by laying another step in brickwork, giving the bricks a gradual fall to ensure that water does not lie on them, and driving them well home.

After the third step has been laid, the earth between the walls is again excavated, the concrete foundation prepared, and another step laid in brick. When within two steps of the upper surface, a header course of bricks should be set on the side walls as shown in Fig. 9. This gives a finish to the work.

The last remaining steps are then laid, and if the work has been properly done the top flight of steps will be exactly the same level as the top of the header course on the two side walls. This result is only accomplished by the constant checking of the level between the two side walls, by resting a batten across them and then testing with a spirit level.

The brick path is laid in the usual way, two small piers built by the doorstep, and the entrance piers completed in readiness for the capstones. These can be obtained from a mason's yard, or may be moulded in concrete.

STERILIZATION. The process of making certain substances free from germs of all kinds is usually called sterilization. A large number of different methods are used, the choice depending in any case on the materials of which an object is composed and also upon the uses to which it is to be put, etc.

One of the simplest means is to raise the material to a high temperature at which no germ life can exist. For example, the boiling of milk is the most thorough and reliable method of destroying any germs which may be contained in it. Pasteurising is a useful method which will destroy almost all the germs likely to be found in milk. It has an advantage over boiling in that it has a less marked effect on the taste of the milk. The process consists of raising the milk to a temperature of 145° to 150° and keeping it there for not less than half an hour. *See* Antiseptic; Bottling; Disinfectant; Milk; Pasteurisation.

STERNBERGIA. These hardy bulbs bear yellow, crocus-like flowers. They are suitable for planting in sunny places in the rock garden or at the foot of a house wall. The winter daffodil, or lily of the field (*lutea*), which blooms in September, should be planted in July, and *Fischeriana*, which is in flower in April, ought to be planted in October.

STETHOSCOPE. An instrument known by the name of stethoscope is used by doctors for listening to sounds produced within the body, e.g. the noises produced by breathing and by the action of the heart. In disease these sounds are modified or added to, each change having a diagnostic significance.

STEW. A stew can be made with either beef, mutton, or veal as the main ingredient, and directions for making such stews will be found under the respective headings. The ingredients needed for a mixed stew are $\frac{1}{2}$ lb. beef kidney, $\frac{1}{2}$ lb. pork (not too fat), $\frac{1}{2}$ lb. mutton, $\frac{1}{2}$ lb. veal, $1\frac{1}{2}$ lb. potatoes, $1\frac{1}{2}$ lb. onions, and 1 lb. carrots. Green peas might be used instead of the carrots when in season. The vegetables are first sliced and the meat cut up into neat pieces, then all should be put in layers, in a stewpan, vegetables making up both top and bottom layers. Season plentifully with salt and pepper and a little sweet herbs, if liked, and pour over it $\frac{3}{4}$ pint water. Simmer for about 3 hours, shaking the pan occasionally to prevent burning. Turn out on to a dish to serve. *See* Beef; Irish Stew; Veal.

STEWING: In Cookery. One of the most economical methods of cooking is stewing, which consists in slow boiling in a covered vessel, generally with very little added liquor. By this method tough portions of meat are rendered eatable, and very little heat is required to maintain the proper temperature after the food has been boiled. None of the juices of the meat are lost, and the food can be kept hot without deteriorating.

A stewpan, a casserole, or an earthenware jar may be used, and it is placed in the oven or on the top of the stove. Before starting the slow process, meat to be stewed must be well boiled up, or it will sour. A stew is nearly always thickened, and meat stews should be made with fresh not cooked, meat. The stew may be white, as in the case of Irish stew, or brown, as in stewed ox-tail or skirt of beef. Vegetables are usually stewed and served with meat. Fish may also be stewed; trout or eels make excellent stews.

Stewed Fruit. Stone fruits are much more digestible when stewed, and if served with some accompaniment of a milky nature they are less likely to disagree with children or those persons whose digestions are weak or impaired. For this reason it is the custom to serve cream or custard with stewed or cooked fruit, and sometimes milky puddings or blancmange. One advantage of stewing fruit consists in being able to cook any that is not actually ripe or is in the green stage. Gooseberries, for instance, when quite unripe, are excellent for stewing, but are not fit for this purpose when ripe. Certain kinds of plums stew well, also apples and a hard sort of pear.

The simplest method for stewing fruit is to put it in a stewpan with sugar and a little water, and cook it gently over the fire or in the oven until it is quite soft, and the sugar and water have thickened. The fruit must be in sound condition; before stewing it should be picked over, and all damaged portions rejected, then it should be rinsed with cold water in a colander.

The amount of sugar necessary is about the same quantity that would be required for making the fruit into a pie. Fruit must always be amply sweetened while cooking, as no amount of sugar added afterwards will avail to remove the tart taste. The quantity of water to be added also varies with the kind of fruit; for very juicy fruits the drippings of water after washing should create sufficient liquor for the stew.

A second method is to prepare a syrup, and, after heating it to boiling point, drain the fruit until no moisture is left, and turn it carefully into the syrup. About 1 gill syrup should be enough for each lb. fruit, and it must be strong, as it will be thinned considerably when the juice boils out of the fruit. Cook all until the fruit is tender, shaking the pan occasionally to prevent the contents from burning. The heat employed must only be moderate.

Another method is to lay each piece separately in the stewpan in a single layer, pour a strong syrup over it, and cook gently on top of stove or in oven until soft. Each portion or whole fruit will then be found entire, and can be properly arranged in a dish. The syrup when cool should be ladled over and round.

Rhubarb, if possible, should be treated by this method, and will make a superior dish, especially if a little syrup from a jar of preserved ginger is added while stewing. Strawberries are not suitable for stewing by any method, although they may be heated and softened in syrup for the purpose of filling tartlets and flans. The same applies to oranges, all pips and pith being removed, and also to fresh pineapples and bananas, and tinned fruits, such as cherries, peaches, pears, etc. One dessertspoonful of lemon juice should be added to the syrup made with a 2 lb. tin of peaches or apricots. Many varieties of dried fruit are excellent when stewed.

Stewpans. Except for size, stewpans are in most instances identical with ordinary saucepans, and in the average household the latter are used as substitutes. Pans used for stewing should have tightly fitting lids and the power to retain heat. Casseroles and other earthenware utensils have this latter property, and are therefore specially well adapted to this method of cookery.

Tinned copper, tinned iron, and enamel pans are also excellent for stewing, but care should be taken to see that the lining of copper pans is undamaged, otherwise poisoning may result. Double saucepans, such as those used in making porridge, are also suited to stewing, for they minimize the danger of burning. *See* Beef; Casserole; Dried Fruit; Pressure Cooker; Saucepan; Steamer.

Sticking Plaster. *See* Adhesive Plaster.

STIFF NECK. Muscular rheumatism, or fibrositis, may result in a stiff neck. It is more common among children than adults. Generally the stiffness is confined to one side, the muscles in front and at the side of the neck being most often affected. Persons subject to this painful affection should take the greatest possible care to avoid draughts and exposure to cold.

Usually the only treatment required is the rubbing in of some warming, stimulating liniment, and then covering warmly with a pad of cotton wool to prevent chilling. The following are two prescriptions for liniments that are suitable for external use in cases of stiff neck:

(1)

Camphor	1 part
Soft soap	2 parts
Water	10parts
Methylated spirits	12parts

(2)

Methyl salicylate	2 drams
Olive oil to make	1 oz.

See Fibrositis; Rheumatism.

STIFFNESS: Of Muscles. The painful stiffness in over-used muscles may be removed by a hot bath and sufficient massage; stiffness remaining after a night's rest is generally dissipated by brisk exercise.

Painful stiffness is a feature of muscular rheumatism or fibrositis, and here, also, heat and massage are good remedies. Stiffness and rigidity of the muscles of the abdominal wall are found when there is underlying inflammatory mischief, as, for example, appendicitis. *See* Fibrositis; Massage.

STILE: In Carpentry. This is the term used for the outer upright pieces of a frame into which the rails are tenoned. In cabinet and other double doors, the two inner stiles are known as meeting stiles, and the meeting edges are either rebated or one stile provided with a projecting beading to cover the space. *See* Cabinet Making; Door.

STILETTO: For Needlework. This is a small, sharp-pointed instrument used for piercing eyelet-holes. Stilettoes can be bought cheaply from all art needlework shops. Care should be taken to keep them free from rust. *See* Eyelet.

STILL BIRTH. When a child is born dead the occurrence is spoken of as a still birth. It is important to remember that still births, as well as others, must be notified to the medical officer of health within 36 hours in districts where the Notification of Births Act has been adopted.

Sometimes a child is born very pale or blue in the face, making no attempt to breathe or move, but with the heart beating faintly. The nurse should sprinkle the child's face and chest with cold water; this stimulates it to breathe. If that does not succeed, she should raise the child by its heels and tap its body smartly.

Should this be unsuccessful, artificial respiration should immediately be practised.

STILL ROOM. In large houses there is often a housekeeper's pantry or still room, as it is called. Though apart in its uses from the butler's pantry, it is furnished in much the same way with cupboards, shelves, and sink, and there is usually a gas stove or range and large kitchen or cook's table. Where a great deal of confectionery is made in the house a special still room maid often assists in this branch of cookery.

STILTON CHEESE. In the true stilton the milk with which it is made is enriched by a certain proportion of cream, added when making the curd. The cream is first scalded by a small quantity of boiling water being poured upon it. The best season for making stilton is from July to October, giving the cheese time to ripen for Christmas fare. Although the outer crust has a rough, pitted appearance, the interior is milky white with streaks of dark green.

Stilton should be cut in half to be served, and the half sent to table with a dinner-napkin folded round it. It is never cut in slides: portions are dug out of the top with a cheese scoop, and in the hollows which are made wine or ale should be poured. By degrees, if this process is carried out, the cheese will acquire a more matured flavour, while it will be kept sufficiently moist inside. *See* Cheese.

STIMULANT. A stimulant means any drug or agent which increases the activity of any organ or tissue; thus there are heart stimulants, brain stimulants, skin stimulants, and so on. Popularly, the word is used for something which invigorates the body, generally alcohol.

As a matter of fact, the stimulating effects of alcohol are transitory, and the main effect is narcotic. Small doses of alcohol, repeated if necessary, ought to be given instead of large ones in the treatment of collapse.

Ammonia is a good general stimulant, and may be given in the form of the aromatic spirit or sal volatile, in doses of a teaspoonful in a wineglassful of water. Tea and coffee are also good general stimulants.

STING: How to Treat. The poison introduced by an insect sting is usually formic acid. A solution of ammonia is the best remedial application, but solutions of bicarbonate of soda or of potassium permanganate are also useful.

Fresh tobacco ash is a simple remedy for stings. It should be applied to the affected part with moisture to form a paste, and then rubbed in gently.

A few drops of oil of geranium rubbed behind the ears and over the neck and ankles will generally afford protection against the stings of midges and other summer pests. Babies and children should be especially protected, as insect stings are not only painful, but may be dangerous when they occur on the lips or eyelids. If the oil is not rubbed on the skin, it may be used to soak small pads of cotton wool sewn to the clothing. *See Bee Sting.*

Stipa. This is the botanical name of the ornamental grass known as feather grass (q.v.).

STIPPLING. A flat effect is obtained with ordinary paint or distemper by the method known as stippling. The stippler used for paint is shown in Fig. 1, and Fig. 2 shows a larger brush for use with distemper. Both are made from hog-hair, and after use should be washed in lukewarm water if used with distemper, or with turpentine in the case of paint.

Stippling. Fig. 1. Stippler for paint. Fig. 2. Larger brush for use with distemper.

Stippling should be done while the paint is wet. The method is to apply the paint or distemper evenly; the direction does not matter as long as the surface is evenly covered. The stippler is then dabbed on the wet surface. The surface to be stippled should not be more than 1 sq. yd. at a time. Broken surfaces require considerable care, and it is often necessary to use a small sash tool as a stippler.

It is more difficult to use the stippler in applying a flatting paint. Only the tips of the hair should be used, and the brush must be kept clean by dipping it from time to time in turpentine and cleaning it on a piece of paper. Care should be taken not to drag the stippler over the surface, but to apply it with the hairs at right angles to the surface, and with a light touch. *See Brush; Paint.*

STIRRUP. Steel or nickel-plated stirrups are a necessary part of the rider's equipment, though not essential when learning the rudiments of horsemanship.

The use of stirrups is to assist balance and to form a support. Some riders drive their feet right home into the stirrups, but the disadvantage of doing this is counterbalanced by a lighter grip with the sole about its middle. The adjustment of stirrup leathers is always a matter of prime importance. If they are too long the rider does not get the requisite support, and sore back may result. The best method is for the rider to sit in the saddle and test the length by putting his feet into the stirrups.

There is another use for the stirrup, and that is the left stirrup iron serves to receive the left foot during mounting, aided by the grip of the hands of the pommel and cantle of the saddle.

Cleaning. Stirrups and stirrup leathers require cleaning after use; the former with metal polish and the latter with saddle soap. As the leathers are liable to perish with use it is necessary to examine them frequently, and replace worn portions. *See Horse.*

STITCH: In Needlework. Of the various kinds of stitches used in needlework, running is employed for gathering, and also for joining materials, and hemming for turning down raw edges, while tacking, which is a temporary stitch, holds the fabric in position while the permanent stitches are put in. There are also fancy stitches, such as cross-stitch and herringboning, which are employed for decorative purposes. *See* Appliqué; Basting; Cross Stitch; Dressmaking; Embroidery; Feather Stitch; Hem; Hemstitch; Herring-bone; Laid Work; Needlework; Overcasting; Running; Seam; Sewing Machine; Smocking; Tapestry Needlework.

STITCH: In the Side. The sharp, stabbing pain felt sometimes at the side of the chest, and popularly referred to as a stitch in the side, may result from running or any violent exertion after a meal, or from prolonged laughing, coughing, or sneezing. It may be due in these cases to a cramp-like spasm of muscle fibres in the midriff or the chest wall, and no treatment is necessary, as the pain passes off almost at once on resting.

Sometimes, however, this form of pain is a symptom of a broken rib, or lobar pneumonia, of pleurisy or of some disorder of the liver. The application of a hot bag is a useful temporary measure.

STOCK FOR SOUPS AND SAUCES

Recipes for Clear, White, Bone and Vegetable Varieties

This article is in close connexion with those on Sauce and Soup. *See* also Beef; Bouquet Garni; Gravy; Mutton; Veal, etc.

The foundation of most soups, sauces, and also of gravies used for made up dishes is stock. Impoverished stock will make a very poor soup, and no added flavour of vegetables or herbs will successfully disguise its original weakness.

Scraps of food, trimmings of meat and bones, which would otherwise be thrown away, can be added to the stockpot and turned into useful material. Almost any oddment, provided that it is suitable to augment or clear the stock, may be added from time to time. Egg-shells assist in clearing the liquor, and even hard crusts have their use in helping the scum to rise. Stock requires careful skimming when it boils up and whenever scum collects.

The more continuously the stock is allowed to simmer the better and richer it will be, but it is advisable to strain it out at night into an earthenware pan to prevent souring, especially in summer. Vegetables, particularly turnips, if left in the stockpot are liable to sour the liquor. Potatoes should not be put into the stockpot. Meat bones can be boiled again for a second and third stock, but vegetables should not be used a second time. Stock should not be left in the larder after the second day without being boiled up, and in stormy weather it should be boiled daily. A thundery condition of the atmosphere is alone sufficient to spoil the stock entirely.

If fresh meat is added to the pot, skimming must take place as soon as the scum rises, for if the scum is allowed to boil down in the liquor it will be impossible to clear it properly, and a thick and cloudy appearance will result. Never place a pan of hot stock on a slate or stone slab, or it will cool too rapidly; if obliged to set it away hot, place under the pan 2 or 3 pieces of wood to support it.

Chickens, rabbits, or meat intended to be served as a boiled dish may be cooked in the stockpot and will add to the strength of the stock, and they will be flavoured and enriched by it. Chickens should be wrapped in buttered paper or a loose cloth, which will prevent sediment or small pieces clinging to them.

Fish stock is made from fish or the bones and trimmings of fish, boiled with or without vegetables. A recipe is given in the general article on Fish.

First Stock. Clear soup is always made from first stock. This is composed of fresh meat or bones and flavoured with vegetables.

Mutton is difficult to clear on account of its tallowy fat, and pork is too fat for any stock. Beef, veal, calf's head, ox-tail and ox-cheek make the best first stock. Vegetable and bone stocks can also be used, but must be carefully strained, and clarified with white of egg if necessary. Peppercorns should be used for first stock, as ground pepper would make it cloudy. The salt should be added to the water when cold, as it helps the scum to rise, and care should be taken to remove the scum just as the stock is on the point of boiling, to prevent it sinking into the liquor. Before the vegetables are added all scum must be removed, and the vegetables should be put in by degrees to prevent dropping the temperature of the stock too suddenly. Never add marrow bones to stock intended for clear soup, as marrow fat cannot be entirely skimmed away.

There is no occasion for concern if stock made principally with beef does not make a strong jelly. For clear soup a meaty flavoured stock is more necessary than one which is very gelatinous, and the meaty stock will be bright as well as clear.

White Stock. White stock for white soups and sauces is always made with white meats. Knuckle of veal, carcasses of chicken, or an old hen are the most usual meats for this purpose. The flesh of the hen need not be wasted, as it can be worked up into some side dish.

The ingredients for a good white stock are a knuckle of veal weighing about 2 lb., $\frac{1}{4}$ lb. lean ham, 2 onions, 2 sticks celery or $\frac{1}{4}$ teaspoonful celery salt, $\frac{1}{2}$ turnip, 18 peppercorns, 1 blade mace, bunch of herbs, 4 in. lemon rind, 2 teaspoonfuls salt, 3 quarts water.

Chop bones and meat small and put into stockpot with salt and cold water, bring to boiling point, skim carefully, then boil for three hours, skimming frequently. Add vegetables, carefully cleaned and peeled and chopped small, together with the flavourings, and simmer for two hours. Strain through a hair sieve, and remove fat when cold. Use bones and meat for second and third stock.

Brown Stock. For this use 2 lb. shin beef, $\frac{1}{2}$ lb. knuckle of veal, $\frac{1}{4}$ lb. raw ham, 1 oz. dripping, 1 teaspoonful salt, 2 onions, $\frac{1}{2}$ turnip, 2 sticks celery, or $\frac{1}{4}$ teaspoonful celery salt, a bouquet garni, 2 quarts water.

Put prepared meat and bones in the stockpot with cold water and salt, bring slowly to the boil, being careful to remove all scum in the process. Simmer gently for three hours. Slice onions finely and fry in the dripping until brown. Drain well, add to stock with remainder of ingredients and simmer for two hours. Strain through a hair sieve and remove all fat when cold. Reserve meat and bones for second and third stock.

Bone Stock. A good recipe for bone stock requires the following ingredients: 4 lb. raw or cooked bones, 1 carrot, 2 onions, $\frac{1}{4}$ of large turnip, 2 stalks celery or $\frac{1}{4}$ teaspoonful celery salt, $1\frac{1}{2}$ teaspoonfuls salt, bouquet garni, 3 quarts water.

Chop bones small, place in stockpot with cold water and salt and bring to boiling point, skimming carefully all the time. Boil for three hours, skimming frequently. Clean and cut up vegetables, and add to stock with the herbs, boil gently for 3 hours, then strain. Remove fat when cold.

Vegetable Stock. Vegetable stock is made from mixed vegetables. To 1 quart water allow 1 lb. mixed vegetables. Carrots, turnips and onions are the most used, and, if liked, celery, tomato, leek, and a little parsley can also be added. Four peppercorns are used for seasoning, and 1 or 2 cloves

can also be added. The vegetables are washed and cut into small pieces, and then fried gently in about 2 oz. fat for about 15 min. in a covered pan. The water, herbs, and a sprinkling of salt and the peppercorns are added to the vegetables, and the whole brought to the boil. The stock is then left to simmer for about 2 hours in a covered pan and strained. Variety can be given to any of these stocks by the addition of other vegetables, small piece of cooked meat, poultry, game, or macaroni, vermicelli boiled rice, sago, or semolina.

Vegetarian stock is sometimes made by boiling bran with water for 1½ hours, then straining off the liquor and letting it settle. Oatmeal also is used for this purpose.

Straining Stock. When straining stock remember that pressure should not be resorted to if the stock is desired to be clear. The liquor should be allowed to drain until all is through, then the sieve is lifted off with the solid portions. By straining liquid stock it can be rendered free from grease, although it is usually more difficult to clear this stock from fat than that which is in a jelly. When perfectly cold pass the stock through a hair sieve or piece of muslin stretched over a basin, after removing solid fat with a broad flat knife. The hair or material will effectually retain any particles of fat, but the stock must be really cold; if merely lukewarm the fat will be liquid enough to pass through very fine meshes. Jellied stock may be cleared by the fat being taken off in a cake and the top washed with warm water.

Stockpot. Any pan or vessel reserved for the preparation of stock may be described as a stockpot. In the home, a large saucepan is generally reserved for this purpose, but pots specially designed for stock-making can also be bought in a variety of metals.

Some of the larger kinds are fitted with taps. An example is illustrated below, which is made in aluminium. When its contents have been heated, the tap allows the stock to be drawn off quickly.

Stockpot made in aluminium. The tap allows the liquid to be drawn off quickly after the stock has been heated up.

Unless the stockpot is of earthenware, stock should never be allowed to remain in it overnight, neither should it be left standing at the side of the fire for an indefinite time. Stockpots should be scoured and dried thoroughly immediately after they have been in use.

STOCK: The Flower. The stock is a delightful fragrant garden flower of which there are several types. By cultivating a suitable selection the plants will supply flowers during the greater part of the year. Ten week stocks are raised from seeds sown under glass in March, the seedlings being planted out of doors in May; they bloom in summer and autumn, and bear flowers in many beautiful colours. The Brompton stock is grown as a biennial, seeds being sown in June to provide plants that will flower early the following summer. If the garden soil is clayey and becomes sodden in winter it is wise to pot the plants in autumn, keep them in a frame and plant out in spring.

Intermediate, stocks raised from seeds in summer are very useful for greenhouse decoration in spring. If raised in a warm greenhouse in January they will bloom out of doors in late summer and early autumn. The East Lothian is a favourite strain of the Intermediate stock. Winter flowering stocks are splendid plants for the greenhouse. Seeds are sown in a frame in August. The seedlings are potted in small pots and subsequently into others 5 or 6 in. wide and brought into a slightly heated greenhouse in autumn. Favourite varieties are Christmas Pink, Beauty of Nice, All the Year

Round, and Empress Elizabeth. The night-scented stock (*Mathiola bicornis*) is a hardy annual raised from seeds sown out of doors in April; the flowers are very fragrant in the evening. See Night-Scented Stock.

Stock. Queen stock, a bushy variety with white, crimson or purple flowers.

Stock Cultivation. 1. Seedlings sown in box ready for transplanting. 2. Suitable transplanting. 3. Brompton stocks sown in pot; a, drainage; b, broken turves; c, fine rich soil 4. Good type of seedling potted in small pots. 5. Type of seedling which often produces single flowers. 6. Plants pushed on in frame: a, ashes; b, decayed manure or leaf-soil; c, ordinary soil; d, fine rich loam; e, block for ventilating. (By special arrangement with Amateur Gardening.)

STOCK: For Trees. The named varieties of fruits and roses are invariably budded or grafted on stocks, i.e. closely related trees or shrubs. Well developed trees are obtained more quickly in this way and in some cases the growth of the tree is controlled by the stock. For instance, standard apple trees are budded on the crab stock; they come slowly to maturity, but eventually form large trees. Apples budded on the broad-leaved paradise stock make less vigorous growth and bear fruits earlier. Thus the choice of stock on which a tree is budded is one of importance.

Similarly, pear trees on the pear stock grow more vigorously and come to fruit bearing later than others on the quince stock. Those whose gardens are restricted in size should plant apple trees budded on the broad-leaved paradise or other dwarfing stock and pear trees on the quince stock. Rose trees are budded chiefly on wild briar and the Japanese briar. The first named is considered the best for dwarf or bush roses, and is also used for standard roses, but, owing to the difficulty of obtaining suitable briar stems, the Japanese briar, *Rosa rugosa*, is now often used instead. Stocks for roses and fruit trees are raised by nurserymen or imported annually in large numbers. They are planted in autumn and budded the following summer.

As stocks for plums, the most popular are the Mussel, the Brompton, the St. Julien. For the cherry the most popular stocks are the mahaleb and the gean, or wild cherry.

STOCKS AND DIES FOR SCREW CUTTING

How to Form External and Internal Threads on Metal

This contribution explains the method of cutting an external screw thread by the use of a die, and also the tapping of holes. The mechanical process of screw cutting in the lathe is dealt with in an earlier article on Screw Cutting. See also Lathe; Metal Turning; Screw Plate.

In choosing stocks for screwing purposes the first consideration should be the nature of the work. For small diameter screws, a stock for use with circular dies is suitable. Such a stock would measure about 8 in. in length, and contain a circular socket or aperture for the small size die measuring $13/16$ in. diameter. This is suitable for screwing in brass up to $3/8$ in. diameter or thereabouts, and rather less on steel.

For work from about $1/4$ in. to $1/2$ in. diameter one of the engineer's type of stocks should be used, with a pair of adjustable (two-part) dies. For gas-fitting purposes, larger stocks employing separate dies are generally used.

External Threads. The function of a screwing die being to cut a screw thread upon the outside of a circular piece of metal, the interior of the die is fashioned in the form of the screw thread. Parts of the diameter are cut or ground away to form a cutting edge, and the threads themselves are ground away at the front or entering edge, to facilitate starting the screw thread.

Stocks and Dies. Fig. 1. Small circular die stock used in cutting a screw thread. Fig. 2. Adjustable circular dies. Fig. 3. How large die in stock is employed for screwing gas barrel.

Most circular dies have a small set screw which, when screwed in, expands the die slightly and thus increases its effective diameter. Two-part dies are adjusted for diameter by means of a set screw or screws in the body of the die stock. It is important that the die be adjusted to cut to the desired diameter. Screw it on to a clean piece of metal that has already

been threaded to the proper size, then adjust the die until it is stiff to move by hand. For steel set the dies a shade closer, and for copper or aluminium a shade slacker.

Plenty of lubricating oil or soapy water should be used while cutting the threads, and the die should be worked down gradually. Give it half a dozen turns, then reverse the direction for a turn; this clears the chips, frees the dies, and often avoids stripping the threads. Do not force the die beyond its cutting powers, which can be judged by the chips coming away cleanly and freely. If the chips clog and bind, reverse the motion. Screw the die back from the work, clear the cutting edges by wiping away the chips, and apply the lubricant freely. Proceed with the work by giving the die a half turn, and then backwards a quarter turn, and so on, gradually coaxing the die.

Internal Threads. Taps provide the simplest method of forming the screw thread in a nut, or in the end of a length of cylindrical tube. Three or four flutes or grooves are formed longitudinally on the tap, cutting away portions of the screw thread. The shape of the flutes is designed so that one of its walls forms a cutting edge. The opposite end of the tap is usually left plain, and finished with a square-shaped portion. The tap is turned by a lever or bar, known as a tap wrench, which may consist of a piece of metal with a square hole through it of a size to fit the square on the tap. A more convenient pattern is adjustable, having a pinching screw which clamps the shank of the tap.

The cutting part of the tap is shaped in various ways apart from the ordinary fluting. A set of taps for any particular size includes a taper, second, and plug or bottoming tap. In the case of the taper tap the screw thread portion is ground away for about $\frac{2}{3}$ of the length of the screwed part, so that it becomes tapered. In the second tap the tapering is restricted to a very slight amount at the end, the bulk of the screwed portion being of full diameter. In the plug, or bottoming tap, no part of the thread is ground off.

Whitworth		Gas.		B.A.	
Size	Drill	Size	Drill	Size	Drill
$\frac{1}{8}$	No. 38	$\frac{1}{8}$	11/32	0	9-11
3/16	No. 25	$\frac{1}{4}$	29/64	1	15-17
$\frac{1}{4}$	No. 9	$\frac{3}{8}$	19/32	2	24-25
5/16	$\frac{1}{4}$	$\frac{1}{2}$	47/64	3	28-29

$\frac{3}{4}$	41/64	2	2 5/32	8	48-51
$\frac{7}{8}$	47/64	2 $\frac{1}{2}$	2 25/32	9	51-53
1	27/32	3	3 9/32	10	53-55

Before the hole can be tapped it must be drilled out to a certain size, dependent upon that of the screw thread which is to be formed within it. Suppose, for instance, the screw which is to be inserted into the tapped hole is $\frac{1}{4}$ in. diameter. The hole will then have to be drilled out about $\frac{3}{16}$ in. diameter. The correct size of drill to use is most quickly determined with the aid of a drill and tapping gauge, an instrument consisting of a metal plate with a series of numbered holes through it. The hole marked $\frac{1}{4}$ in. (tapping size) will actually measure less than $\frac{1}{4}$ in., and denotes the correct size of drill to employ to prepare the tapping.

Stocks and Dies. Fig. 4. Three taps for forming the screw thread in a nut, left to right, taper, second and plug tap.

Fig. 5. Showing tap rotated by hand.

Gauges are generally based on the assumption that the Whitworth system of screw thread will be used. With other systems of screw threads, such as the B.A. or British standard fine, or the gas threads, the correct size to drill the hole can be ascertained from the tables of tapping sizes which are given in engineering text books. Some of those most likely to be required by the amateur are given in the accompanying table. It should be noted that in the gas thread system the sizes for the taps are based on the bore of the tube, and not the diameter, as in the case of a rod.

When the hole has been drilled through a piece of metal, the taper tap should be inserted into it, and if both are correct the end of the taper tap should just fit in the hole. The tap should be given 2 or 3 half turns to the right. It should then be turned backward a half turn and forward for 2 or 3 more half turns, then back again, and so on until the tap has nearly screwed right through the hole to its full diameter.

It is then unscrewed and the hole finished by tapping it out afresh, either with the second or the plug tap. The second is the best to use when the tap can be passed right through the hole. In the case of a blind hole—that is, one that is drilled for a certain depth into a solid piece of metal—a start has to be made with the taper tap to the maximum depth, following with the second and finishing with the plug tap. In this case the greatest care is needed to avoid breaking the tap by forcing it too harshly into the hole, or by jamming it on the bottom of the hole. When tapping iron or steel the tap should be well lubricated with light machine oil.

It is important that the tap should be rotated about its own centre line; if allowed to swing from side to side in even the slightest degree the hole or the threaded portion will be enlarged or distorted. Special care is needed when starting the tap.

Whatever size of tap is used, the same method is followed in all cases likely to be met with by the amateur. It is exceedingly important to use a tap of the correct diameter and thread form for the screw which is to be fitted into the hole. This, however, presents very little difficulty in practice, as bolts and screws mostly used in the home, for such work as the repair of a stove, mangle, garden implements and the like, are generally screwed on the Whitworth system. Small work, such as that in wireless receiving apparatus, scientific instruments, and the like, is generally screwed on the B.A. system, as regards the small size, up to about $\frac{1}{4}$ in. Larger sizes are often cut in a lathe.

Threads used in the home for screwing iron pipe, either for gas or hot water purposes, are always screwed on one of two systems. Iron pipes are screwed with gas threads, while copper and brass pipes are usually screwed with brass gas threads. Taps and dies for this work are obtainable at most tool shops. The size of the tap wrench varies according to the size of the tap.

As taps can be purchased separately, the amateur will be well advised to buy those needed for any particular job, and gradually accumulate a stock as circumstances necessitate. To prevent them becoming rusty they should be wiped over with a greasy rag.

STOCKFISH. Large fish, such as cod or hake, were at one time extensively cured by being split open and dried in the air until very hard, no salt being used. The fish before being cooked was beaten with sticks in order to soften it. The name is now often applied to salt cod, ling, hake, etc., and is a term of commerce. *See* Cod; Fish.

STOCKINETTE. A wool or silk knitted fabric of elastic texture, stockinette is employed to make frocks, cardigans, and other sports wear, and underwear.

Stockinette needs the same care in laundering as other knitted materials. No wringing or rubbing should be done, the dirt being removed by squeezing the garment in warm soapy water. It should be

pulled gently into shape while still damp, left to dry on a flat surface and ironed with a cool iron. When holes appear in stockinette they should be darned at once, otherwise they will form ladders.

STOCKINGS OF SEVERAL TEXTURES

With Directions for Knitting Two Standard Types

Other articles in this work that describe the various items of footwear include Bootees; Boot; Mocassin; Sock. See also Artificial Silk; Knitting; Silk; Wool.

The correct choice of stockings for women and girls depends chiefly on footwear and costume, silk being worn with light shoes and silk and wool, lisle thread or all wool textures being selected for sports or country wear with a heavier type of shoe.

In choosing silk stockings the hand should be run through inside from top to toe to see that the fabric is clear of flaws. Stone rings should be removed before doing this, or they may ladder the silk. Attention should also be paid to the fashioning, whether full or slight, of the leg and the width round the top. A top which is too narrow cuts in an uncomfortable way, and if not full enough the stocking will split or ladder at the back seam. In some makes the heel piece runs up to a fine point or twin points at the back of the ankle, insuring a better fit.

Stockings of a lighter shade than the shoes worn make the feet appear smaller, but they are not helpful to thick ankles. Very dark brown or gunmetal grey silk stockings have the most slimming effect. With gold and silver shoes the silk stocking should match as nearly as possible in tone. Grey shoes and stockings should match exactly. Sports stockings for winter wear are smartest when hand-knit in thick silk or fine wool. Some display patterns of contrasting shade up the leg instead of ribs. Such patterns generally have a thickening effect on the ankles.

The usual sizes for women's stockings are 8½ in. and 9 in. for sizes 3 and 4 in shoes, 9½ in. for sizes 5 and 6, and 10 in. for sizes 6½ and 7. Some people reinforce the toes and heels of new silk stockings by cutting out pieces of fine mesh of silk veiling to fit the required size and invisibly catching them on the wrong side of the stocking foot.

Woollen stockings can be lightly darned in the same places with fine wool of the exact shade before being worn. Hand-knitted stockings can be strengthened by using a finer wool, in addition to that used for the rest of the stocking, knitting the two together for heel and toe.

No stockings can equal in durability those that are made by hand, whether they are knitted with wool, coarse or fine, or with silk. There are many patterns and styles, one of the most popular being the plainest of all.

For closer fit there are the ribbed hose, which are even stronger than the plain, and are specially suitable for sports wear. By way of a standard, a plainly knit stocking has been illustrated and fully described so that when once the making is thoroughly understood others can be modelled in a different style and with slight variations in size.

Plain Knitted Stockings. To make the stocking shown in Fig. 3, 8 oz. of 4-ply fingering are required and four steel needles. No. 14. Some workers will like to rib the top of the stocking with needles No. 16, as the finer knitting affords a closer grip. The model is planned for wear with suspenders. Should garters be worn, the leg should be about 3 in. longer to allow for rolling over.

The wool must be wound very loosely, 2 or 3 fingers being taken in with every 16 or 18 windings round the ball. A quick knitter will like to have several yards of the wool pulled off the ball at once to lessen the number of unwindings.

For this stocking, cast on 80, arranging 26 on one needle and 27 stitches on each of the other two needles. Make the welt by knitting 2 and purling 2 alternately all round for 30 rounds.

An excellent and durable top for a stocking to be worn with suspenders takes the form of an ornamental hem. After casting on, knit 11 plain rounds. 12th round: Make 1 by bringing the wool round the needle, knit 2 together. Work thus all round. Work 11 plain rounds. Take an extra needle and with it pick up the cast-on stitches opposite those on the working needle. Fold the work so that this needle is at the back and those last knitted are in front. Knit a plain round, taking up a stitch from each needle, and work them off together as one stitch. Continue thus all round.

Take care that the stitches are exactly opposite one another, or the hem will be twisted. The 12th round forms a series of tiny scallops at the edge of the stocking. The 25th and 26th rounds are purled. For the 27th round make 1 and knit 2 together all round. Purl the 28th and 29th rounds.

Now begin the leg. In the next round raise an extra stitch in the middle, and purl this as a seam-stitch in every row till further notice. Knit plain for 80 rounds—that is, as many rounds as there were stitches cast on.

Stocking. Left. Fig. 1. Turning the heel of a plain knitted stocking. Fig. 2. Joining up the toe. Fig. 3. Finished plain knitted stocking which can be used as a standard.

In the next round, begin to decrease to shape the calf. Knit as usual to within 3 stitches of the seam-stitch, * slip 1, knit 1, and draw the slipped stitch over it, knit 1, purl the seam-stitch, knit 1, knit 2 together, knit the rest of the round plain. Knit 8 rounds without decreasing. Repeat from * 8 times, thus reducing the number of stitches to 63. Knit 63 rounds plain for the ankle, that is, as many rounds as there are stitches on the needles.

Divide the stitches ready for the heel. Place 31 stitches on one needle with the seam-stitch in the middle. Put 15 stitches on to each of the remaining 2 needles. Leave these stitches for the present, as later on they will be wanted for the instep. Work in rows backward and forward (purl at the back and knit in front), always slipping the first stitch of a row. When 24 rows are done, decrease exactly as in the leg, and purl back. Repeat this row twice.

Knitting the Heel. The heel is now ready to be worked off thus: Knit to the seam-stitch: knit that and the next together, knit 1. Turn, slip 1, purl 2 together, purl 1. Turn, slip 1, knit till the little hole is reached that was made by the decreasing of the preceding row, knit 2 together (the stitches on each side of the hole), knit 1. Return in the same way, purling instead of knitting. Continue thus till all the stitches are worked off.

The following directions make an excellent heel, with rather more spring in it than the former. When the flap is finished, knit to the seam-stitch, then purl 1, knit 5, knit 2 together. Turn. Slip 1, purl 11, purl 2 together. * Turn. Slip 1, knit 11, knit 2 together. Turn. Slip 1, purl 11, purl 2 together. Repeat from * till all the stitches have been taken up.

Next, the stitches must be arranged for the instep. Pick up and draw the wool through the double loops that run down the side of the heel flap. After every third stitch increase by knitting and purling 2 in the edge of the work. When all have been picked up, slip 3 stitches on to this needle from the instep pin. Work across, and slip the last 3 stitches on to the needle with which the loops up the second edge of the heel-flap are to be picked up exactly as before. Knit with this needle to the centre of the heel where now future rounds are to be begun. Knit all round to get the stitches arranged in their places.

Shape the gussets next. At the end of the first needle, when 3 stitches are left, knit 2 together, knit 1. On the instep needle, knit 1, slip 1, knit 1, and draw the slipped stitch over, knit till 3 stitches are left, knit 2 together, knit 1. On the next foot needle, knit 1, slip 1, knit 1, and draw the slipped stitch over, knit plain to the end of the round, which is the beginning of the sole. Knit the next round, with no decreasing. Repeat these 2 rounds till 61 stitches are left. Work plain knitting for 50 rounds, counting from the end of the gusset. Some ways of finishing the foot require fewer, others more rounds for the foot, according as the shapes of the toes are longer or shorter. This round toe takes up 2½ in., others are little more than ½ in. deep.

Shaping the Toe. For the toe, knit 2 together to get an even number of stitches, then knit 6, knit 2 together all round. There will be about 3 stitches left over, but these will not interfere with the look of the toe. Knit 6 plain rounds. For the next round knit 2 together and knit 5 all round. The next 5 rounds are plain. For the next round knit 2 together and knit 4. Knit 4 plain rounds. Continue thus, gradually lessening the number of stitches, till the round in which it is knit 2 together, knit 1. Then work 1 plain round.

This shape of toe is most successful when joined into a circle at the tip by running a large needle threaded with the wool through the last stitches. Turn the stocking inside out, draw up the stitches closely and run the end of the wool in and out of the back of the toe till it is firmly secured. Cut it off closely.

Should a square toe be preferred, proceed as follows when the foot is finished: Take one half of the stitches on to the instep needle and divide the rest on 2 foot or sole needles. Begin on a line with the seam-stitch, which can easily be traced down from the heel. ** Knit till 3 stitches are left, knit 2 together, knit 1. On the next needle, knit 1, slip 1, knit 1, and draw the slipped stitch over, knit the remainder till 3 stitches are left, knit 2 together, knit 1. On the last needle, knit 1, slip 1, knit 1, draw the slipped stitch over and knit to the end of the needle.

Knit one plain round. Repeat from ** till about 20 stitches remain. Keep 10 of these on the one needle, and slip the other 10 on to a single needle. Close the opening by turning the stocking wrong side out, take the stitches alternately from the 2 needles with the end of wool and a rug-needle. Fasten off by darning the wool on the wrong side. If grafting is preferred, proceed thus with the end of wool threaded on a large rug needle.

Put the two needles together; for the front pass the needle as if to knit through the first stitch and slip it off the needles, put needles into the second stitch, as if to purl, but only draw the thread through without slipping it off. For the back purl and slip off, then put the needle into the next stitch as if to knit, but keep it on and draw the thread through. As the stitches are slipped on to the wool, draw this up closely, to make the seam invisible.

When finished the woollen stockings should be laid wrong side out on an ironing board covered with a thick blanket. A damp cloth should be spread over them, and pressed with a moderately hot iron till dry. The stockings will then look like well-finished woven hosiery.

Boys' Stockings. A popular type of stockings for men and boys are those with turn-over tops. A pair of ribbed stockings of this kind suitable for a boy of 10 to 14 years of age can be knitted from the following directions. These include a turn-over top in three colours, as shown in Fig. 5, as well as a turn-over in a different ribbing from the stocking, but in the same colour of wool, as in Fig. 4.

Stocking. Fig. 4. Pattern for a boy of 14 years. The turn-over top can also be knitted in three different colours, as shown in Fig. 5.

Stocking. Fig. 5. Turn-over top for a boy's stocking, which can be knitted in three different colours by following the directions in the text.

The stocking measures $24\frac{1}{2}$ in. from the top to the bottom of the heel flap, including $3\frac{1}{2}$ in. on the turn-over. The foot is 9 in. long from the back of the heel to the point of the toe, but the length of the latter can be varied in the centre of the foot before shaping the toe. The length of the leg can be altered in two places, either between the welt and the first decrease, or between the last decrease and the heel flap. The materials required to knit a pair are 6 oz. of 4-ply White Heather Scotch fingering wool in grey, with a set of 4 No. 12 steel knitting needles. For the 3-colour top 1 oz. of Lovat mixture and 1 oz. of green or cardinal wool will be required as well as the grey.

To begin the work cast 26 stitches on each of 2 needles and 28 on the 3rd needle, to make 80 stitches in the round, and if making the turn-over in one colour do $3\frac{1}{2}$ in. of single rib, that is, knitting and purling a stitch alternately all round. For the 3-colour turn-over begin with the grey wool, cast on the same number of stitches, and work 12 rounds in rib of knit 4 and purl 4 alternately. Here take the Lovat mixture, and, leaving the grey wool hanging, work 2 rounds in the new wool.

In the next round do 2 stitches in grey and 2 stitches in Lovat mixture, letting the wool not in use pass behind loosely so as not to contract the work. Work another round the same as last round, keeping the respective colours over each other so that a dark square is formed, then work 2 more plain rounds of Lovat mixture. Take the cardinal wool, and work 1 plain round, then 1 grey round, 2

cardinal, 1 grey, and 1 cardinal, and fasten off the latter colour. From this point 3 rows of check are worked in grey and Lovat mixture.

For the 1st row of checks do 4 stitches in one colour and 4 stitches in the second colour alternately. Do 3 more rounds as the last one. For the next 4 rows reverse the colours, then do 4 more rounds as the 1st 4. Join on the cardinal wool again and do 1 plain round, then 1 grey, 2 cardinal, 1 grey, and 1 cardinal. Fasten off the cardinal securely, as this is not required again, and complete the turn-over with 2 rounds of Lovat mixture. Fasten off the latter colour and resume with the grey for the rest of the stocking.

Now turn this top inside out so that when the stocking is completed the right side of the turn-over will be uppermost.

Knit the next round plain, as this will form the turning-edge of the top, and in that round increase 7 stitches by knitting in the front and back of a stitch at equal distances in the round to make 87 stitches. Having fewer stitches on the stocking top will give a firm grip and keep the stocking in place.

Decreasing the Leg. The stitches should now be arranged 30 on each of 2 needles and 27 on the 3rd, so that each needle ends with a completed rib, as the rib continues in the pattern of knit 2 and purl 1 alternately all round. Continue in this pattern for 14½ in. from the 1st round, when the work will be long enough to begin the leg decreases, thus: * knit the 1st 2 stitches together, continue in the rib up to within 3 stitches of the end of the round, then knit 2 together through the back of the stitches, and purl the last stitch. Knit 6 rounds without shaping, but taking care to keep the continuity of the rib after the decreasings. Repeat from * until 9 stitches are decreased at each side and 18 stitches less in the round.

Continue ribbing on these stitches until the stocking measures 2½ in. from the top, counting the turn-over. This brings the work to the top of the heel-flap, so more rounds can be worked here for a longer stocking before beginning the heel. In the last round knit together the last 2 stitches.

To work the heel knit the first 17 stitches of the round on to one needle, slip the last 17 stitches of the same round on to the other end of the same needle, making 34 stitches for the heel. Divide the other stitches equally on 2 needles, and leave them for the instep. On the heel stitches purl and knit a row alternately until 33 more rows are worked, always slipping the first stitch; the last row will be a purl row.

To turn the heel knit 20, knit 2 together, turn. Always slip the 1st stitch after the turn. Purl 7, purl 2 together, turn; knit 8, knit 2 together, turn; purl 9, purl 2 together, turn; knit 10, knit 2 together, turn. Continue in this manner until all the heel stitches are knitted on to one row again, then knit back 10 stitches and leave the heel stitches on 2 needles. Slip all the instep stitches on one needle, so releasing one as a working needle.

For the 1st needle knit the remaining 10 stitches of the heel, and knit up 17 stitches at the side of the heel. For the 2nd needle knit the instep stitches, and on the 3rd needle pick up and knit 17 stitches on the other side of the heel and the remaining 10 heel stitches. Knit one round plain, then decrease for the instep in the next round thus: Knit to the last 3 stitches of the 1st needle, knit 2 together, knit 1. Knit the 2nd needle without shaping. On the third needle, knit 1, knit 2 together, through the back of the loops, knit to the end of the needle. Repeat the last 2 rounds until only 17 stitches remain on each of the 1st and 3rd needles, working the rib pattern on the 2nd needle only.

After the instep shaping is finished, work one more round, increasing 2 stitches on the 2nd needle to bring the stitches up to 70. Then continue on these stitches, ribbing only the 2nd needle, for 58 rounds, or until the toe is reached. The heel, sole, and toe will be in plain knitting. Extra rounds can be worked here before shaping the toe if a longer foot be desired, allowing for nearly 2 in. more to finish the toe.

The toe proceeds in plain knitting, and in the 1st round the 9th and 10th stitches are knitted together, then 2 rounds are worked without any decreasing, and these 2 plain rounds are worked after every decrease round. In the 4th round knit every 8th and 9th stitch together; in the 7th round every 7th and 8th stitch; in the 10th round, every 6th and 7th stitch; in the 13th round, every 5th and 6th stitch; in the 16th round, every 4th and 5th stitch.

Run a double thread through all the remaining stitches, and darn in the end very securely. An alternative method for finishing a toe is by the process known as grafting.

STOKESIA. This is a hardy perennial, 18 in. high, with large aster-like blue flowers in late summer. It should be planted in well-drained or light soil on a sunny border. Propagation of stokesia is by division in spring or by seeds in the spring or summer.

STOLE. To make a fur scarf or stole from several skins, first arrange the latter so that all the fur lies in one direction, and number each skin in order on the back before starting to join them. The careful matching of the skins, not only in colour, but also in both texture and length of fur, is most important.

Having matched the skins, cut a paper pattern as large as the largest oblong that can be contrived from the smallest of the pelts. Cut them all out by that, placing each pelt fur downward on a deal table and marking round the pattern in pencil or ink upon the leather side before proceeding to cut through the lines. Holding the skin taut between the fingers, cut it with a very sharp penknife. To join them, place the cut edges back to back, fur inside, and threading a special 3-sided fursewing needle with stout No. 30 cotton, overcast them together, firmly and strongly enough to hold the skins side by side, but not so closely or tightly as to draw the cut edges up into a ridge. In sewing smooth the fur down and away from the cut edges which are being joined by means of passing the needle between them.

When the skins have all been joined line the stole with silk or satin or brocade that matches or tones with the fur, with or without an interlining of domet or flannel, or a thin layer of wadding. Any interlining should reach barely to the edges of the fur, while the lining proper should be cut at least 1 in. wider all round, to allow for a good turning. The interlining should be attached with a few invisible stitches to the fur, before starting to line it.

STOMACH. The shape of the stomach varies according to the degree of distension, but is somewhat like a pear, with the large end to the left just below the heart. Hence, when the stomach is distended by gases in indigestion, the action of the heart is often interfered with, and there may be difficulty in breathing.

The capacity of the stomach in an adult is roughly from 3 to 5 pints. In the feeding of children it is important to know how much the infantile stomach can comfortably hold. At birth the quantity is very small, and even when at the age of 12 months a child will be made uncomfortable if it gets more than $\frac{1}{2}$ pint of milk at one time.

The duty of the stomach is to digest protein matter and to help in pulping the starchy material of bread and vegetables. It contains a variety of glands, which manufacture pepsin, the ferment which digests meat, eggs, cheese, etc.; a fluid that clots milk immediately it is swallowed; and hydrochloric acid. This last substance serves to prevent fermentation of the food, and is necessary for the action of the pepsin. The muscles keep the stomach in constant movement after a meal so as to chum up the food and mix it with the digestive juices. When the mass is ready for discharge into the intestine, the muscular wall contracts and forces it through the communicating valve in little spurts, repeated until the whole meal is passed through. The spasm of dyspepsia is a violent contraction of these stomach muscles.

Diseases of the Stomach. One of the commonest of the disorders and diseases of the stomach is atony, or loss of power in the muscular wall. The food remains too long and fermentation occurs, causing flatulence.

Inflammation of the stomach lining, or gastritis, and gastric ulcer are treated under their own headings.

Cancer of the stomach occurs mostly between the ages at 40 and 70, and is sometimes preceded by a chronic ulcer. It has been pointed out that its most frequent site is the spot likely to be affected by hot liquids, and by alcohol when this is swallowed raw.

The size of the stomach is increased by dilatation, which in an acute form may come on suddenly with a troublesome hiccough. Chronic dilatation is of two kinds. In one the outflow of the stomach's contents is obstructed; the cause of the other is atony, often the result of eating very large meals or drinking a great deal of fluid habitually, such as beer. The chief symptoms are flatulence, constipation, vomiting, sleeplessness, and occasionally cramp in the calf of the leg. In the atonic cases rest in bed improves the condition, but the cure is slow. Efforts should be made to improve the general health and so restore the tone of the stomach muscles. In the cases arising from obstruction an operation is necessary for complete relief. *See* Acidity; Digestion; Gastric Ulcer; Gastritis; Indigestion.

STOMATITIS. Inflammation of the mouth, or stomatitis, is of several varieties. Simple stomatitis may arise from smoking hot tobacco, drinking raw spirits, and other causes. Aphthous stomatitis, in which small white blisters form, chiefly attacks ill-fed children.

In thrush patches of white membrane form on the soft palate, tongue, and elsewhere in the mouth. In the ulcerative form sores form on the gums about the teeth. Gangrenous stomatitis is practically limited to children who are underfed and live in squalor.

The diet must be confined to bland liquids, which must not be given hot. Keep the mouth clean by washing it out with solutions of boracic, potassium chlorate, etc.

STONE AS A BUILDING MATERIAL

Durability and Grace in Domestic Architecture

Related information will be found under such headings as Crazy Paving; Steps; Sundial; Wall. See also Building; Concrete; House; Path; Paving; and other entries that deal with constructional matters

The stones used in building are sandstone, limestone, slate, and granite. All stones are porous, some to such an extent as to render them unfit for domestic purposes. A very porous stone absorbs much rainwater, especially when the face of the building is exposed to the prevailing wind and weather. Granites should not absorb much more than about 1 per cent, of their volume of water, limestones 17, and sandstone 10, after 24 hours' immersion. The weight of the stone has also to be considered. Heavy stones may be used for buttresses or quoins, but lighter stones are required for vaulting and similar work.

In selecting stone for building, the colour is often attractive, but some highly coloured stones are not so durable as those of a duller colour. The best stones are those which are free from bands or spots of colour, and are of a uniform colour in structure. This, of course, does not apply to marble. Stone when freshly quarried contains a certain quantity of moisture, known as quarry sap. The stone is preferably cut to size and shape as soon as possible after quarrying, as it is more easily worked, but it is then set aside to season, gaining considerably in hardness and durability. Artificial stone is a

term applied to slabs of concrete, with differing forms of aggregate, often sold under proprietary names.

Stone. Beautiful 17th century stone-built house at Broadway, Worcestershire, showing the steep gabled roof and mullioned windows which are typical features of the Tudor style of architecture.

The stone employed in building work may be one of the many freestones that can be tooled readily, but generally the choice is governed by the material available locally. On this material will depend to a great extent the style of the work and the nature of the ornament. For example, in certain districts a soft and easily worked stone is associated with fine tracery and delicate carving, whereas when a hard and intractable stone is

available the nature of the building is quite different. When a coarse sandstone has to be used, the mouldings are bold and large, but on granite the style is broad and simple.

In the article on Loggia, is illustrated the stone-built loggia of a Wiltshire house. This is carried out in local stone. We show in this and the following pages other pictures of typical stonework, indicating different methods of surface finishing.

The amateur constructor should ascertain the kind of stone available in his district, the cost of transport, and the amount of work that will have to be expended on the stones before they are fit to use. Some of the extensively used grades of stone are stocked by merchants, such as York stone for paving, and some of the West of England stone for general work in rock gardens and the like, otherwise the supplies have to come direct from a stone quarry. Should it have to be drawn by road, the cost per ton, inclusive of handling, should be agreed at the outset with a contractor equipped for the work.

As turned out by a country quarry, the stone is split into thin slabs or sawn to shape in pieces suitable for building. It is possible to obtain stone in a rough form, comparatively small in size, but thick and solid, such being suitable as regards size for walls and constructional work of an elementary character. Thinner pieces generally of larger size are used for paving purposes, and also for some walls and roofs, and the stone can also be obtained cut to any reasonable shape and size.

York stone is largely used for crazy paving in pieces about 2 in. thick and of random shape. It is quite admirable for paths, steps, and the floors of outbuildings. When the material is delivered, the best plan is to sort out roughly those pieces which have at least one edge straight or nearly so, and to set these pieces aside for the edges of the steps or for other similar work.

Methods of Walling. The chief structural difference between one class of stonework and another lies in the arrangement of the stones, which is known as walling. This is either carried out in courses like brickwork, or in a more or less indefinite manner known as random rubble. Walls of rubble are built of thinly bedded stones of irregular shape, generally 9 in. deep or less. Varieties of rubble include coursed and squared rubble. Block stone masonry is composed of squared blocks set in regular courses, or random formed of different shaped blocks.

The easiest walls for a novice to build are those of random rubble set dry, as seen in Fig. 1, where the wall is composed of substantial blocks of rough stone set without mortar. The foundations may be of concrete, or a course of stout stones set with the greatest width across the wall and bedded to

the solid earth. For the sake of security two courses breaking joint should be employed, and the walls erected upon them. The stones are roughly selected for height and width, and arranged to fit into each other as tightly as possible. They are kept in line by setting them by a cord stretched from end to end of the wall. The top is finished with stout stones set upright, and often bedded on earth to keep out rainwater.

Stone. Fig. 1. Random rubble wall set without mortar. Fig. 2. Rubble walling with lacing course of brickwork and top finished with vertical stones. Fig. 3. Cutting a groove before severing a stone. Fig. 4. Preparatory levelling of a block of sandstone. Fig. 5. Simple test for chisel drafting.

Another type of wall consists of several courses of stonework and then a few courses of brick, as shown in Fig. 2, finishing with other stones and upright pieces on the top.

The lacing course of bricks adds longitudinal and transverse strength to the wall. When this is done, the

stones are preferably set in mortar, and the wall is often composed of smaller stones worked with the smoothest and straightest faces set outward. The spaces between the two sets of stones are filled in with small pieces and grouted with mortar.

Another method, particularly applicable to buildings, is to set rubble stones in front of a backing wall of brickwork. This has the effect of providing a smooth and durable inner face. Each course is set in mortar, and the stones are arranged to break joint. Usually only the face stones are set in

mortar, the spaces between the irregular stones and the brickwork being filled in with hearting or small stones, and grouted in with liquid mortar poured from a pail. The mortar should not be allowed to run on to the face of the stones.

All the foregoing wallings can be put up by the amateur if reasonable care be taken to bed the stones well and to work a bonder or through stone about every yard square of the wall surface. The bonder is a stone of sufficient proportions to pass through the wall from face to face, and act as a stiffener to tie the whole together.

Gutting Stone. The preparation of bonders will probably necessitate cutting the stone, which is by no means easy until the knack has been acquired. One way is to score a shallow groove along all four faces of the stone by chipping a line with a cold chisel and hammer, as shown in Fig. 3, afterwards striking it a few blows with the mallet, delivering the blows through a board set vertically over the groove. A stone severed in this way would be sufficiently smooth and straight for random rubble work. The working or tooling of stone and the arts of the mason are hardly to be acquired by the amateur, but a few simple exercises in trueing a stone will aid in the completion of such work as the cutting and shaping of capstones for walls, etc.

In order to produce a flat surface on a block of soft sandstone, the method shown in Figs. 4 and 5 may be followed. The first step is to cut the stone roughly to shape and size, and to select the flattest surface or bed. The comers of this part of the stone are chipped away with a chisel to form two flat surfaces at the front side; one such place is formed similarly at the back. Blocks of wood of uniform height are placed on the front flats and a batten rested on them. The purpose is to raise the batten above the level of the rough parts of the stone. A block is also placed on the one flat at the back, and another on the untouched back corner. The second batten, as shown in Fig. 4, is rested on the blocks at the back, and the last corner is cut away as much as necessary until the top of both battens appear level or parallel when viewed by looking across them. The same test is applied after the front and back edges of the block have been chiselled in order to make them level (Fig. 5).

There are thus two level surfaces along the front and back edges respectively, which are known as chisel drafts. The intermediate stone between these drafts may be cut away with the chisel and hammer, or the stone may be finished with chisel-drafted margins. The method is applied to the preparation of capstones for the top of a low garden wall. Capstones may be used for decorative effect as well as for protection of the brickwork or other walling material, such capstones being set preferably in cement mortar.

When stone is used for building purposes the walls have to be much thicker than they would be if made of brickwork, and, unless built in random rubble set in mortar, will have to be well fitted together, and secured where necessary by means of dowels, cramps, or other fasteners.

Stone. Fig. 6. Part of an old Sussex house with a picturesque roof consisting of thin slabs of Horsham stone.

Stone has been largely used for roofing purposes, and a roof covered with Horsham shale is illustrated in Fig. 6. This is a thin stone of good weathering qualities, and is set on massive oak roof rafters. The stones are laid in random courses, decreasing in size from the eaves upward. The slabs are hung on oak pegs driven into holes in the head or narrow part of the stones. In modern work the stones are often set on a boarded and felted roof covering, and secured with brass nails or screws. Another plan is to cover the rafters with expanded metal lathing, covering this with a bed of mortar, setting the stones thereon and pointing the joints as the work proceeds.

Left. Stone. Wing of stone-built house showing both tooled and rough surfaces. Windows are stone mullioned and gables finished with sawn coping stones.

Circular window, an interesting combination of tooled stone with rock-faced stonework.

Any attempt at rigid regularity of shape robs the stone roof of much of its charm. Roughness and unevenness in the stones also assists the drying out of moisture, which is important, as any dampness in the roof, by admitting frost, accelerates splitting of the stones. The valleys are generally swept, and the ridges finished with a half-round ridge tile or by sawn stones. A hipped roof is rare, and calls for great skill in cutting and fitting the stones.

STONE: The Weight. This useful measure of weight consists usually of 14 lb. avoirdupois, although there are stones of other kinds. The Smithfield stone for dead meat is only 8 lb.; that of wool is 24 lb., and of hay 22 lb. *See* Avoirdupois Weight.

Stone: The Disease. *See* Calculus; Gall Stone.

STONE CROP. These hardy flowering plants are chiefly suitable for the rock garden and the wall. One, however, the Japanese stonecrop (*Sedum spectabile*), is a valuable border plant, 15 in. high, with grey succulent leaves and large flat bunches of carmine-rose blooms in September which attract the butterflies and bees. It thrives in ordinary border soil, and is easily increased by division in spring. Low growing stonecrops suitable for the rock garden flourish in sunny places in soil with which sand and old mortar rubble have been mixed.

They are increased by division in early autumn or spring. The common yellow stone-crop is *Sedum acre*; it is a creeping plant with yellow flowers in summer. Choicer kinds are *Ewersii*, rose purple; *kamtschaticum*, yellow; *lydium*, pink; *middendorffianum*, yellow, and *spathulaefolium*, yellow.

STONE MARTEN. This fine fur is obtained from a species of marten (a genus of carnivorous mammals of the weasel tribe) which derives its name from its liking for rocky places. The best skins come from Asia, and are of a soft, fine texture, the underfur being almost white and the tips resembling sable in colour. In some respects stone marten bears a great likeness to the latter fur, and is sometimes dyed to imitate it. It has the advantage of being both hard-wearing and attractive. *See* Fur; Marten.

STONE WARE. This term is used for a certain kind of pottery. It is less fine than chinaware, and is widely used for domestic crockery. Stoneware was first made in Germany, and later in England, where certain districts, e.g. Staffordshire, earned a reputation for it. After a period of decay its

manufacture was revived, chiefly by the firm of Doulton, whose artistic stoneware was a notable contribution to English pottery. *See* China; Doulton Ware; Nottingham Stoneware; Pottery.

STONING: Of Fruit. Many varieties of stone fruit when made into jam or marmalade are stoned. To do this the fruit should be split in half and the stone removed without tearing the fruit. Special cherry stoning devices for domestic use can now be obtained, which may also be used for olives and damsons. The seeds of raisins should be extracted before this fruit is added to puddings or cakes. When large quantities are to be stoned the operation is done by means of a machine, but for smaller numbers the seeds are removed by hand.

Stool. Walnut stool with carved cabriole legs and splay feet, covered with woolwork. Early 18th century. (By permission of the Director, Victoria & Albert Museum, South Kensington)

It is well to have a small basin of warm water on the table when starting to stone raisins, but recourse should be had to this as little as possible, as the added moisture detracts from the flavour and richness of the fruit. To stone, split the raisin in half lengthways with a sharp cook's knife, but do not actually divide it. By pressing the knife against the stones which are exposed they will rise, and can be removed without wasting the pulp. If the fingers become sticky, dip them lightly in the water and wipe them on a damp dish cloth before again commencing operations.

When using sections of oranges for jellies or pastries the seeds should be removed. This is best done by feeling for the pip and pressing it out with a quill, in order to avoid injuring the appearance of the fruit or allowing the escape of the juice.

STOOL. A stool is almost the oldest form of seat. Early examples are of the milkmaid's stool type on three legs, but in the 16th century they were made with four, and a certain amount of decoration was introduced into the simple design. Sometimes they possessed a box seat with hinged top. In the late 17th century they were upholstered, but about the same time they began to lose popularity owing to the greater comfort afforded by the chair. Specimens, however, continued to be made, and the legs of these were cabriole, and showed the carved knees and the claw, lion's paw and claw and ball terminations of the period. Queen Anne stools were often covered with petit-point embroidery. An example of one with a tapestry needlework covering is illustrated in the previous page.

The stool most valued by collectors is one of the joint stools, as they are called, of the 16th century. They are of oak and rest on four legs, which are joined together by stretchers. The legs are turned, and in some examples there is carving on the sides of the seat. Many of them are inlaid with box and ebony in alternating triangular pieces, placed in the rails just below the seat. *See* Camp Stool; Chair; Dressing Table; Jacobean Style, etc.

STOOL OF REPENTANCE. To play this round game one person is sent out of the room and the others then decide what shall be said about him or her, these criticisms being noted down by the leader. A stool is set for him in the centre of the players, and he is called in to occupy it. When he is seated the game proceeds.

The leader reads out each criticism in turn, thus: Somebody says you are irritable, or conceited, or good-natured, and the victim has to guess the name of the critic. If he guesses a sufficient number correctly he is released from the stool of repentance and allowed to take his place in the circle, while another player goes out to endure the ordeal; but as the game would cease to be amusing if the same person were dealt with twice running, he is usually considered to have earned his release whether he guesses correctly or whether he does not. *See Children's Party.*

STOP: In a Camera. The amount of light which passes through the lens of a camera is controlled by a stop or diaphragm placed behind a single lens or between the components of a compound lens. On the size of the stop used depend both the length of the exposure required and the degree to which sharp definition of detail can be obtained throughout the picture.

The most usual form of diaphragm or stop in the modern camera, known as the iris diaphragm, consists of a series of thin metal tongues working on points in a ring in the lens mount.

Each tongue has a curved slot cut in it, so that as the ring is rotated the metal tongues move uniformly towards or from the centre, making an adjustable circular aperture as seen in the photograph. The apertures at which the stop or diaphragm works are indicated on the lens mount and are known as F/numbers.

The larger the stop which can be used with any particular lens the shorter the exposure, while the smaller the stop the greater is the effective depth of focus of the lens, and the sharpness of detail. The process of using a smaller stop, which is known as stopping down, is used far too frequently by the amateur photographer. In doing so, he not only lengthens the exposure unnecessarily and thereby destroys the principal quality which makes a lens both good and expensive, but also produces photographs that are lacking in artistic quality.

Stop. Iris diaphragm, for controlling light passing through a camera lens.

The whole tendency in modern photography, and this is particularly the case in landscape, figure study, and portrait work, is so to increase the aperture of the lens, and therefore the size of the stop which may be used with it, as to shorten more and more the period of exposure, while producing softer and more artistic photographs in which the different planes of vision are separated. Many of the better quality modern roll film cameras are fitted with f/4.5 lenses, and full advantage should be taken of the opportunities they offer. It is chiefly a matter of knowing what

stops to use and when to use them.

The amateur should not be misled by instructions which he may find on inexpensive fixed-focus cameras as to using different stops for different subjects. These instructions are a necessary compromise, due to the lack of focussing adjustment, and also to the fact that the shutter has only one speed. With a fixed-focus, single-speed shutter camera it will be necessary to stop down to get foreground subjects into focus (since stopping down deepens the field of focus), and also to cut down the light passing through the lens when shorter exposures are required, since the shutter speed cannot be increased.

The larger the aperture of the lens the shallower is the field of focus. This means that while objects in the foreground may be sharply defined those in the middle distance will be softened, while those in the background may be so far out of focus as to be unrecognizable. This gives the photographer

considerable opportunities for artistic work, especially when differential focussing is employed, by which the object that is of principal importance in the picture is more sharply defined.

For portraits and similar studies the largest stop available should be used, but with landscapes, which include a wide field of view, a medium stop, such as $f/6.8$ or $f/8$, may be required. At the other extreme the smallest stops are required when copying prints or in photographing specific objects, such as furniture.

The effect of using different stops is best studied carefully on the focussing screen before rather than after exposure. For this purpose it is essential that the screen should be well shaded. In general it may be said that the proper use of lens stops indicates the skill of the photographer. Always bear in mind that the exposure varies according to the square of the stop used, $f/11$ requiring twice the exposure of $f/8$, and $f/16$ four times. *See Camera; F/Number; Focus; Lens.*

STOP COCK. In its most general application a stop cock is any principal tap used to cut off the supply of liquids or gas to a building or to some section thereof. In the home the term is restricted to the main water or gas tap that is fitted in the run of the main supply pipe.

The water company generally fits a stop cock of substantial pattern at the nearest point to the main water pipe where the branch is taken to the building, and generally it is operated by a long-handled metal rod or key. It is an advantage to have another stop cock fitted inside the house on the rising main, e.g. beneath the sink in the kitchen. *See Pipe.*

STORAGE BATTERY. This is an appliance which acts as a reservoir for electrical energy. Usually it consists of a series of cells or accumulators, and is intended to yield a higher voltage or greater volume of energy than is feasible from a small portable accumulator.

For house-lighting purposes the units are usually fitted with open-top glass cells, and, instead of having the ordinary type of terminals, the lugs terminate with a bolt and nut, and are connected by means of lead strips which are bolted to the lugs on the plates. The cells are usually arranged on a wooden stand so as to raise them from the ground and permit of inspection and necessary attention. Any unit or cell composing a storage battery holds nominally not more than 2 volts. Actually, however, this figure rises slightly when the cells are fully charged, and may drop slightly below 2 volts when they are almost discharged. Consequently, if it is required to provide a nominal voltage of 25 volts, it is necessary to have at least 13 and preferably 14 cells, with some means of controlling the voltage, such as by a resistance or by temporarily disconnecting one of the end cells. In other words, to find the number of cells required the voltage is divided by two and one extra cell added to the total.

In arranging for the erection of a storage battery it is desirable to choose a cool, dry place, well ventilated, and situated where the fumes given off by the cells cannot affect the surroundings. A small brick-built outbuilding with a ventilated roof, and used only for the storage battery, is the best, but if the battery has to be housed indoors it should be located away from the foodstuffs and as far from the living-rooms as possible. It must be partitioned off from the rest of the room and provided with some independent and direct ventilation to the open air.

Charging and maintenance instructions are issued by the makers of the battery, and the information contained therein should be carefully followed. *See Accumulator.*

STORAX. The white-flowered, deciduous and hardy shrub storax requires a dry position in light ordinary soil, preferably under the shelter of a south wall. It is worth some attention, and will benefit by incorporation of peat in its root run. The most suitable planting period is from October to February. It is propagated by layering of shoots. Two good species are japonica and obassia, natives of Japan.

STORE ROOM. In some larger households, the accommodation provided for holding food stores, etc., in the larder, kitchen and pantry is supplemented by a special store room.

This room should have a north or eastern aspect, and the nearer it is to the kitchen the better. It is essential that it should be thoroughly dry and airy, and have at least one window covered with perforated zinc or wire gauze, the walls and ceilings being whitewashed or coated with sanitary paint. The floor can be left with plain, well-scoured boards or covered with linoleum. Every little crack in flooring or walls should be carefully filled to prevent the entrance of mice, beetles or other vermin.

The store room must be well fitted with shelves, preferably of graduated sizes. If all are very wide, there will be a tendency to pack each with several rows of articles instead of a single row, and so small objects may easily be hidden behind large ones and overlooked. Each shelf should be neatly covered with oilcloth held in position by drawing-pins. The stores must be grouped according to their character, i.e. all the jams together, all the seasonings in another group, different kinds of sugar together, etc. Cereals are best kept on one shelf, each stored in a separate tin. There should be a few shelves set apart for soaps and cleansing materials, not too near foods such as flour. Soap can be kept in bulk, as it hardens with keeping and is thus rendered more economical. Certain stores such as cheese, coffee, etc., impart their flavour to other foods, and therefore should be stored in airtight tins. Tea also tends to lose its aroma unless kept in an airtight container.

A slate and pencil or writing tablet is generally kept hanging in the store room for noting down any supplies that need replenishing. If preferred a store indicator can be bought for a few shillings. This gives a printed list of stores and a system of removable pegs to indicate which are needed.

Storing crops and plants. 1. Potato clamp. 2. Suspended pears. 3. Parsnips or carrots in box of sand. 4. Suspended onions. 5. Geranium in winter. 6. Winter radishes in sand: a, turves, grass uppermost; b, soil. 7. Storing dahlias. 8. Apple or pear rack in section: a, fruit; b, trays; c, tray supports.

STORING: Of Vegetables, Fruits, etc. Beetroot, carrot and turnip should be lifted in autumn when growth is complete and stored at the foot of a wall or fence. A covering of earth, sand or old ashes will provide protection from frost. Or they may be stored in boxes containing one of these materials and placed in a shed. Potatoes are lifted when the tops have died down, and after having been exposed to the air for two or three hours to dry the skins they are placed in boxes or tubs or in heaps

in a frost-proof shed. Care should be taken to store only sound tubers, and it is wise to scatter a little lime on them.

Parsnip, salsify and scorzonera are dug as required. To enable the roots to be lifted in severe weather the soil should be covered with bracken or straw to prevent its being frozen. Onions when fully ripened should be tied in bunches, as in Fig. 4, or made up into "ropes" in an airy shed or even on a sunny wall. Savoy and other cabbages, kale and Brussels sprouts are very hardy, but broccoli, when fully developed, should be lifted and hung, heads downwards, in a shed.

Roots and Bulbs. Flower roots of a tuberous nature which cannot be left in the open ground during winter should be lifted as soon as the first frost has touched their foliage. Their stems should be cut down. After they have been in a cool place under cover for excess sap to drain away, they should be stored in boxes of sand, as in Fig. 7, in the shelter of a frost-proof shed. Bulbs such as daffodils and tulips should be left in the soil until their foliage has become yellow, drying them slowly in a shaded, airy place, and storing in boxes away from frost; the foliage must be thoroughly ripened before storing.

Gladioli corms and others should be lifted before winter sets in, tied in bunches, and suspended in a cool place until their foliage has withered, when they may be stored in boxes of sand. Geraniums and other bedding plants must be taken indoors in autumn, potting them up after trimming. A simple and common method of dealing with geraniums in the winter months is illustrated in Fig. 5.

Apples and Pears. Apples and pears should be graded according to size and quality, storing them, if possible, in a rack of trays, as shown in the diagram. Where the quantity is small, separate fruits may be suspended to beams or rafters in a cool and airy place, as in Fig. 2. Grapes will keep in bottles of water containing a few pieces of charcoal, the bottles being fixed at a slight angle in a dark and cool place. Nuts must be gathered when fully ripe and should be stored in boxes of sand which are set in a cool, dry place. Apples keep best if wrapped in special oiled papers sold by horticultural dealers for the purpose.

Storage cupboards constructed as explained below are probably the best solution of the problem, since the fruit is stored on single shelves and can easily be examined, any which show signs of deterioration being removed for immediate use.

Ordinary packing cases or Tate's sugar boxes may, for the sake of cheapness, be used, but it is better to make the boxes a certain standard size, so that all shelves are interchangeable. Ordinary cheap white-wood may be used 4 ft. by 2 ft. 6 in. by 2 ft. 6 in. The boxes themselves are made from 1 in. by 8 in. tongued and grooved wood, and the sides may be joined together by a simple dovetail. At suitable distances inside each box, six ½ in. grooves are cut, into which 1½ in. strips of wood are screwed. The inch which projects into the box forms convenient runners along which the trays slide.

Stork's Bill. *See* Pelargonium.

STOUT. A dark brown malt liquor, stimulating and nourishing, stout is a superior kind of porter. It is brewed in much the same manner as ale, with roasted malt to give it colour. Oatmeal stout is also made.

Stout is a drink which blends very well with cheese or a cheese savoury. It is also good with oysters. On account of its somewhat heavy qualities some people prefer it mixed with bitter beer, half and half. It should be served in a pewter or silver tankard.

From a medical standpoint really good pure stout, like other good beers, is certainly the most nourishing of all alcoholic drinks, but still it contains only a very small quantity of nutritious

material. With some people flatulent indigestion is a very common result of drinking it, and when nursing mothers take it their babies may have their digestions upset. *See Beer; Diet.*

STOVE: For Solid Fuel. A stove differs from a fire because the fuel and heat are enclosed in an iron or some other kind of casing.

The principle on which many stoves work is that known as slow combustion. There is an enclosed furnace in which the rate of fuel consumption can be controlled by regulating the quantity of air supplied to the fire.

Left. Stove. Fig. 1. Slow combustion coke-burning stove, with piping passed through roof. (Courtesy of Smith & Wellstood, Ltd.)

Fig. 2. Stove fitted to an existing fireplace. It burns anthracite nuts or coke, and is fitted with automatic ventilating check valve and gas tube. (Courtesy of Smith & Wellstood, Ltd.)

A stove of useful and simple type is shown in Fig. 1. It consists of a cylindrical iron casing lined with fireclay, and the fire is laid on the solid clay bottom at the base, there being no fire bars. Though sometimes a little troublesome to light, stoves of this type are efficient and economical in use. The kindling wood and other lighting material should be dry, and the stove should not be filled until the fire has taken hold. Coke or anthracite is suitable fuel. Stoves of this kind are commonly fixed in school-rooms, halls, or workshops. It is best to keep the stove pipe inside the building, if a brick flue is not available, as condensation sometimes causes trouble when the pipe is taken through the wall and carried up outside.

Of the many patterns of coal stove, the varieties that burn anthracite or similar fuel have many advantages, and are readily fitted to a fireplace in place of an existing grate.

To take full advantage of this class of stove it should be kept burning continuously during the cold weather, so that the room is always at a comfortable and equable temperature. Figs. 2 and 3 show representative patterns.

Fuel Consumption. The fuel consumption of a stove suitable for use in a room 20 ft. by 12 ft. would be approximately 1 cwt. anthracite per week (continuous burning). This is based on the maintenance of an average indoor temperature of 62° to 64° F., with a minimum outdoor temperature of 32° F. Coke can be used, the kind known as washed nuts No. 2 being suitable. Owing, however, to its tendency to choke and hang up in the stove, and its greater ash deposit, coke is not so good for continuous service as anthracite.

Stove Brush. For cleaning the fireplace in the home a strongly made brush is required, with stout grip-handle screwed on to the back, and there is a varied selection of oval and oblong shapes. The chief consideration should be a well-filled bristle surface with the knots securely drawn into the stock with wire.

The hair is trimmed level, which with a curved stock means longer knots at the ends than in the middle; some have distinct wings or tufts at the ends to facilitate getting into corners, and negotiating uneven surfaces. Very stiff bristle is not necessary, but a brush of pure bristle, or a good mixture of fair length, will outlast several inferior articles. *See Anthracite Stove; Boiler; Brush; Burner; Cooker; Oil; Range.*

Stove. Fig. 3. Slow combustion stove which fits into a fireplace recess. It has an ashpan regulator, and a slide damper in the flue at the back. (Courtesy of Smith & Wellstood, Ltd.)

STOVE HOUSE. A stove house or hothouse is a glazed structure in which a high temperature can be maintained, thus permitting the forcing of fruits and the cultivation of plants native to tropical climates. Such structures require skilled attention and maintenance, and are only suitable for market growers, specialists in exotic plants and ferns, and amateur gardeners of ample means. For the average gardener a cold or warm greenhouse will be found more economical, and, within limits, will be of greater all-round utility. The construction of a stove house for amateur purposes can follow very largely on the lines described for greenhouse and conservatory building. Usually the temperature is kept at 60° to 65° at night. Consequently the arrangements for heating the stove house must be fully adequate to the demands made on the system.

Stove House. Fig. 1. Sectional view of a simple type of forcing house, showing heating pipes. Fig. 2. Method of setting stone side table into brickwork.

The section of a simple stove house is shown in Fig. 1, partly cut away to reveal details of construction. The lower part of the walls is built in 9 in. brickwork with ventilating or air bricks at intervals. There are skylights or openings in the roof, and by control of the inlet and outlet the desired temperature and ventilation are maintained. The air bricks can have shutters to close them,

and these are controlled by a long handle or rod, the end reaching to the front of the tiers of hot-water pipes.

The pipes will have to be of adequate capacity to maintain the heat, and may be in one continuous system, or in two or more distinct sets, each controlled by separate valves. The average size of these cast-iron pipes is about 4 in. diameter. The heating surface of such a pipe can be reckoned roughly as 1 sq. ft. per foot of length.

Heating Capacity. Thus, if a stove house were to be, say, 18 ft. wide and 50 ft. long, with 6 pipes a side, there would be roughly 1,344 sq. ft. of pipe area if the pipes were set on the three sides of the house, leaving one end free for the door and entrance. The boiler would therefore need a heating capacity equal to about 1,300 ft. run of pipe 4 in. diameter, and would probably measure about 5 ft. long, 2 ft. wide, and 3 ft. high. These sizes are approximate and vary with the make and type of boiler.

The side staging can be made of wood or preferably of stone or slate, which may be set into brickwork as shown in section in Fig. 2. The stages or tables can be covered with a layer of coarse sand or other material to a depth of 2 or 3 in. whereon to stand the pots. The purpose is to absorb moisture and give it out again for the proper development of the plants. *See* Conservatory; Greenhouse; Orchid.

STRAIN. Muscular strain is particularly common in people who go in for games and exercises without the necessary preliminary training, as may be noted at the beginning of the cricket, football, and other sports seasons. In most cases of severe strain some of the muscular fibres are torn, and unless proper care be taken the muscle may remain weakened for a long time. Rest is the cure, while cold, heat, or other anodyne applications will be useful at first. Slings, bandages and strapping help to secure absolute rest.

Heart strain is a popular name for dilatation of the heart, usually caused by excessive muscular exertion. It may come on suddenly from a single great effort, as in lifting a heavy weight, or the heart may dilate more gradually in consequence of repeated efforts beyond the person's strength. Cycling up hills is a common cause, being especially injurious to growing boys and girls. Week-enders who lead a sedentary life from Monday to Friday, and then start on a long walking tour, hillclimbing, rowing, etc., are frequent sufferers from heart strain.

When this occurs the patient may feel considerable pain in the region of the heart, he suffers from palpitation, may faint from slight causes, and is liable to sleeplessness. For sudden or acute heart strain absolute rest is necessary. In more severe cases, rest in bed with mustard plasters to the feet and legs, and ice over the heart, will usually give relief. A very important factor in predisposing the heart to strain is some temporary weakness due to recent influenza or some other infection. A day's rest in bed is the best means of allowing an overworked heart to recuperate. People who have difficulty in getting through the week should therefore make a habit of taking such a rest periodically, and this applies not only to those with damaged hearts but to the aged. *See* Exerciser; Heart; Sprain.

STRAINER. The shape of a strainer for culinary purposes may be round or conical. The round strainer in appearance is somewhat similar to a metal pan with slightly sloping sides, the base being perforated or composed of metal wire. The conical pattern is perforated all round the sides with the exception of a broad band of plain metal encircling the top. A handle extends from one part of the edge, in both shapes, by means of which the strainer can be held in place over the receptacle into which the liquor falls. In larger round strainers two short handles, one on either side, replace the one in the smaller.

An excellent strainer may be devised by using a piece of muslin. The material should be held or fastened over a bowl and the liquor poured through it. Hair or wire sieves and colanders may be used as strainers. A very small strainer shaped like a tiny bowl and perforated or fitted with fine silvered woven wire is often used to retain the leaves when pouring out tea. Some lemon squeezers are fitted with strainers which keep back the pips and portions of pulp, leaving the juice clear.

Strainer. White enamelled strainer suitable for use with vegetables.

Gravy strainers are convenient for small quantities of soup, for finishing sauces or for coating purposes, and also for pouring sauce or custard round a dish. For this purpose the conical form of strainer should be used. When

larger quantities of stock have to be dealt with a sieve is inverted on a bowl on which it will rest firmly and the stock is poured through quickly. A hair sieve should be used for the more delicate varieties of stock, but a wire sieve is suitable for any ordinary kind. For straining completed soups, if only a small quantity has been made, a conical strainer is best, but larger quantities must be strained through a sieve into a bowl and then re-heated.

To strain sauces, use a hair sieve and pass through as much of the solid matter as will be absorbed by the liquid. No acid sauce should be passed through a sieve fitted with brass wire.

There are many liquid or semi-liquid cookery ingredients which require straining. Milk is better strained before being used and sometimes it is necessary to strain it after it is boiled. Eggs when beaten should be strained to remove the thread. This hard piece will be quite apparent in a pudding or custard if not strained out. Strain the eggs when sufficiently mixed but before they are entirely beaten, and continue the whipping after straining. When using yeast and after the liquid has been added to it, let it be strained, using a fine conical strainer. *See* Fish Kettle; Jelly Bag; Labour Saving; Soup; Stock; Vegetables.

STRAINING POST. A particular type of post is adapted to take the strain of fencing material. In a wire fence, for example, the wire must be at a good tension, and this is ensured by specially braced posts being placed at intervals in the fence so that the slack of the wire may be drawn up tightly. *See* Fence; Post.

STRAMONIUM. The dried ripe seeds and the dried leaves of the thorn apple furnish the preparations of stramonium, which has an action closely resembling that of belladonna. Stramonium is chiefly used to relax the spasm of the bronchial tubes occurring in asthma.

For this purpose the drug may be given internally in the form of the tincture, or cigarettes made of the leaves may be smoked, or the fumes of a burning powder containing the dried leaves mixed with powdered nitre, etc., may be inhaled. Tincture of stramonium is given in doses of 5 to 15 minims. Stramonium sometimes has a slight effect on the heart, rendering its beating less regular and even producing palpitation. *See* Asthma.

STRAP. Odd straps may be bought from leather stores, and it is worth while buying a good one, for cheap leather wears rapidly and sometimes stretches. When it becomes necessary to make new holes in a strap, use a sharp skewer, holding the leather over it and pressing the point through. This is more satisfactory than cutting the strap with a penknife.

When straps have been laid aside for some time, and are to be used again, make certain that the buckle is firm. If the leather has become hard, soak it in hot soapy water for a few hours, and then hang it up in an airy place to dry. Finish by rubbing it vigorously with a soft rag dipped in linseed oil. *See* Harness; Leather.

STRAPPING. A few strips of adhesive plaster may be applied to an injured or diseased part for the purpose of giving support and securing rest. In some cases ordinary adhesive plaster suffices, in others something stronger will be required and calico plasters are employed. *See* Adhesive Plaster.

STRAP WORK. This is the name of an ornament used on furniture and metalwork. It is formed by narrow strips of wood or metal, as the case may be, crossed to form a lace-like pattern. *See* Guilloche; Jacobean Style; Tudor Style.

STRATHSPEY: The Dance. This Scottish dance is a type of reel, the difference lying more in the time than in the actual steps. In common with the reels the Strathspey tunes are divided into two parts of 4 bars each, but Strathspey music is played more slowly, the steps being energetically rendered and with jerky effect, in contrast to the more gliding movements of the true reel. The jerkiness is due to the fact that the notes of most Strathspey tunes are alternately a dotted quaver and semiquaver, the bar frequently terminating in a crochet. In the modern Scottish reel part of the dance is often in Strathspey time.

Typical steps include the setting step, in which the right foot is placed behind the left; the dancer sinks and hops on it and then the same movement is repeated with the left foot behind the right. Another step is known as cross passes. The dancer springs to one side with the right foot, immediately passing the left across it, hopping, and crossing again, which finishes one step. It is repeated, beginning the spring with the left foot.

A constantly recurring step is the open step; beginning with the feet in the second position and then with straight knees the dancer makes a smart spring upon the toes to the fifth position and does a like spring, being careful to let the foot which was before in the first spring be behind in the second. *See* Reel.

STRAW. Consisting of the dried stalks of wheat and other grain, the uses to which straw is put are manifold. In building it is employed for thatching roofs; in the home it is seen in the form of baskets, bags, and matting; and it is made into hats of all colours and shapes, as it dyes and bleaches well in both fine and coarse varieties.

STRAWBERRIES AND THEIR CULTURE

And Various Ways to Cook and Serve Them

The directions given here on growing this fruit are followed by information about serving it, after which come recipes for various strawberry dishes. *See* Layering; Netting./

This fruit is grown most successfully on well-tilled land which does not dry out in summer; it is not satisfactory on very light sandy soil unless old turf and manure are dug in freely. The best time to plant is in August or early September, using small plants which were layered in pots of soil in June and July. If this practice is followed there will be a fair crop of first-rate fruits the following summer, an abundant crop of good fruits the second year, and a heavy crop of smaller fruits the third year. It is the usual practice to destroy the strawberry bed after it has borne three crops and plant a fresh one, but the old plants may be left for another year or two if desired, though they will

produce only small fruits. Strawberry plants should be set from 18 to 24 in. apart according to the vigour of the variety.

Strawberry, Fine fruit of the variety known as Bedford Champion.

In late summer dead and diseased leaves should be removed together with all weeds, and a dressing of manure put on the soil. Before the blossoms open in spring, straw should be spread among the plants; it will keep the fruits clean and free from soil splashed up during rain. The mats specially sold for this purpose are now used in many gardens instead of straw. The plants must be covered with fish netting to prevent the fruits being damaged by birds.

The best flavoured strawberries are Dr. Hogg, Countess, British Queen, and The President. British Queen needs to be layered every year, the bed being replanted each autumn. These varieties are rarely grown nowadays; they have been superseded by others of less delicious flavour but better constitution. Royal Sovereign, Tardive de Leopold, Fillbasket, Sir Joseph Paxton, The Duke, Givon's Late Prolific and King George are favourite sorts. Viscomtess de Thury, which bears heavy crops of rather small fruits, is an excellent strawberry for jam-making. The perpetual-fruiting strawberries St. Fiacre and St. Antoine de Padoue bear fruits both in summer and autumn.

To obtain an early crop of strawberries under glass in May, runners layered in small pots of soil in June should be repotted in 6-in. pots in August, in a compost of loam with which a little decayed manure and sand have been mixed. If placed in a slightly heated glasshouse in December and January, they will yield a succession of fruits in late April and May.

Strawberry Cultivation. 1. Good runner plantlet. 2. Poor sample. 3. Runner rooting in sunk pot. 4. Correct planting. 5. Planted too deep. 6. Planted too high. 7. Pegging down plantlets. 8. How to support the fruit. 9. Pot-layered plant transferred to fruiting pot.

Strawberry Pests. The chief pest of the strawberry is mildew. This fungus attacks both old and young fruit, covering it with a white mildew, and causing the older fruit to decay. Though often observed only on the

fruit, it develops first on the under surface of the leaves, a point which should be noted, as it is only in the early stages that remedial measures can be satisfactorily applied. The mildew usually appears in May.

As soon as it has been discovered the plants should be dusted with flowers of sulphur or black sulphur, and the treatment repeated if necessary. A small pair of bellows, called a sulphurator, may be used for this purpose, but if one is not available the sulphur may be shaken out of a loosely woven bag attached to a stick.

Leaf blight, in the form of red spots which run and spread on the leaves, also occurs, usually after the fruiting period is over, but with a weakening effect upon the subsequent health of the plant. Another pest, which can be dealt with in the orthodox way, is green fly. The fruit may also be attacked by slugs, which are best combated with soot or lime or with traps of brewers' grains. Red spiders may attack plants grown under glass if the air is allowed to get dry, but proper syringing will keep this under.

An insect known as the strawberry tortrix moth is at times very destructive. The damage is done by the caterpillar, which eats the foliage in May and June. The only satisfactory treatment is to pick over the plantation by hand on the first appearance of the pest. To keep the plant clear of another destructive insect, the strawberry blossom weevil, all dead leaves, waste straw, and the like, should be removed from the vicinity of the beds, as the adult weevils dwell therein in the winter, whence they issue forth when the strawberry blossoms are beginning to open.

How to Cook. Freshly picked strawberries may be served with cream or included in fruit salads, compotes, trifles, and other sweet dishes. They are also made into jam, wine, ices, flans, and pies. If fresh berries are not obtainable, the bottled or tinned kinds may be used instead. Those preserved in tins are sometimes lacking in flavour and almost always lose their bright, attractive colour. For the latter reason they are unsuited for garnishing, but for other purposes the colour may usually be restored with a little cochineal. Strawberries combine well with raspberries and several other kinds of soft fruit, and make an excellent filling for fruit shortcakes.

Strawberry Charlotte. Either fresh or tinned fruit can be successfully used to make this sweet. Prepare it by dissolving a pint packet of lemon jelly in $\frac{3}{4}$ pint hot water, then pour a little of it into the bottom of a mould and leave it to set. Stalk and wipe a few small strawberries, dip them in jelly, arrange them in a ring in the mould, and in the centre put a few diamond-shaped pieces of angelica, also previously dipped in melted jelly. Leave these to set, then cover them with a little more jelly. While this layer is setting, cut the ends from a few sponge fingers so that they will stand upright, then place them round the sides of the mould, standing them on the jelly. They should reach just to the top of the mould, and if they are too long they should be cut. Mix a few biscuit crumbs with 2 tablespoonfuls of melted jelly, and if there are any cracks between the sponge fingers, fill them up with this paste. Set the whole aside in a cool place.

Strawberry Charlotte, made with fresh or tinned fruit, lemon jelly and sponge fingers.

Make $\frac{1}{2}$ pint of strawberry purée by rubbing some fruit through a hair sieve. Add 3 oz. castor sugar and 1 teaspoonful lemon juice to the purée and mix them well. Whisk 1 gill cream until it thickens, then add the fruit purée to it gradually, and lastly strain in $\frac{1}{2}$ oz. French leaf gelatine dissolved in $\frac{1}{2}$ gill hot water or strawberry syrup. Stir the mixture over ice until it begins to thicken, then turn it into the mould and leave it to set.

When ready, turn it out on to a dish and garnish it with a few strawberries. If tinned fruit is used, the garnish should consist of strips of angelica, and glacé cherries.

Strawberry Fool. Wipe and stalk 1 lb. strawberries and then rub them through a hair sieve, adding to the purée 3 oz. castor sugar and 2 teaspoonfuls lemon juice. Mix with a pint of rich custard and whisk well.

Strawberry Fritter. Only the large, firm strawberries are suitable for fritter making. Dredge them well with sugar, sprinkle them with kirsch and leave them in a cool place for about ½ hour. Then dip them in batter and fry them for a few minutes in a deep pan of smoking hot fat. Drain them thoroughly, dish them on lace-paper and serve them sprinkled with more castor sugar.

Strawberry Jam. In making strawberry jam, ¾ lb. to 1 lb. sugar should be allowed to every lb. of fruit. Stalk and wipe the strawberries, put them into a preserving pan and cook them slowly until some of the juice has been extracted. Then add the sugar and continue cooking slowly until it has dissolved. The jam should then be boiled steadily for an hour, when it may be put into pots and tied down.

Strawberries and gooseberries together make an excellent jam. To prepare it, top and tail 6 lb. gooseberries and pick over an equal quantity of strawberries. Put them into a preserving-pan with 1½ pints water, add 10 lb. sugar and cook the jam slowly until the sugar has dissolved. Then bring it to the boil, boil it for about 1 hour, and turn it into pots.

Strawberry Jelly. A tin of strawberries in syrup, ¾ pint hot water, a pint packet of strawberry jelly, and a few pieces of angelica are needed to make this sweet. Dissolve the jelly in the hot water and add to it a gill of strained syrup from the tin of strawberries. Rinse out a mould with cold water, set a little of the jelly in it, and then decorate it with the angelica dipped in jelly.

When these are set, pour over a little more jelly, let it set, and then add a layer of strawberries. Continue with these strawberry layers until all the fruit and jelly are used; then leave the whole to set. Whipped cream may be served with it.

Strawberry Jelly, made with tinned strawberries, and decorated with small pieces of angelica. Whipped cream can also be added.

Strawberry Pie. To make this, line a greased pie-dish with some short-crust pastry, then fill it with strawberries, strewing these thickly with castor sugar. Put on a top crust, make two or three slits in it with a knife, so that the steam may escape, and bake it in a hot oven till it is lightly browned. When it is done, dredge the top of the pie with some more castor sugar. It should be served quite cold, accompanied by whipped cream.

Strawberry Pudding. A cold strawberry pudding can be made by fining a pudding-basin with sponge cakes, filling up the centre with strawberries, gently heated in syrup, and then covering them with more sponge cakes. Cover the pudding with a weighted dish, and leave it to get cold before turning it out and serving with cream.

STRAWBERRY-RASPBERRY. This plant is often wrongly described as a hybrid between the two fruits, but it is a bramble or rubus. The plant is very attractive with its bright green leaves, white blossoms, and red fruits, but the latter are most palatable in a cooked state. *See Raspberry.*

STRAWBERRY TREE. The hardy evergreen strawberry tree produces white or blush-coloured flowers in spring and summer, followed by globular reddish fruits somewhat resembling strawberries. *See Arbutus.*

STRAWBOARD. Strawboard is a form of cardboard commonly brown in colour which is chiefly used in the home for packing purposes, as, for instance, in sending pictures or other articles through the post.

STRELITZIA. This striking plant is suitable only for a large heated greenhouse. It has broad leaves and the blue and yellow flowers are on stems 5 ft. or more high. Owing to their brilliant colouring the strelitzia is commonly known as the Bird of Paradise flower. It may be grown in large pots or in a bed of soil; a suitable compost consists of loam with sand and decayed manure or leaf-mould. Propagation is by division.

Strelitzia. Curiously shaped blossom of the greenhouse perennial plant that is sometimes given the name of Bird of Paradise flower.

STREPTOCARPUS. This is the name of a family of dwarf, greenhouse perennial plants that bear comparatively large flowers of many colours—blush, crimson, purple, rose and so on. They are raised from seed sown in early spring in pots or boxes of loam, leaf-mould and sand, and kept in an average temperature of 50° with plenty of moisture during the months of summer and autumn. Young plants may be placed in a cold frame during the summer. As soon as the seedlings are large enough they should be shifted into 3 in. pots, and a further shift may be made later on, if the young plants thrive and are sturdy. Flowers are produced, as a rule, about 6 months after sowing. *See Greenhouse.*

Streptocarpus. Greenhouse plant with petunia-like flowers in pink, white or blue.

STRETCHER: How to Make. A stretcher may be improvized by taking two poles, broom-handles, or something of the sort, and rolling each up in a side of a blanket till they are about 2 ft. apart. The blanket is fixed in this position, and two pieces of wood are tied across the poles, one at the head and the other at the feet, to prevent the poles coming together. Instead of a blanket two sacks will serve if the poles are pushed through the bottom corners, or coats buttoned up and with the sleeves turned in could be used in the same way. Where it

is available a light door or gate, which can be taken off its hinges easily, makes a good stretcher in an emergency.

Stretcher: how it may be improvised. Two poles about 8 ft. long are rolled into the sides of a rug or blanket till they are about 2 ft. apart. The corners of the rug are then tied to the poles and cross-pieces of wood are fixed on to prevent the poles being drawn together by the patient's weight.

In carrying a sick or wounded person on a stretcher, certain rules should be observed. The bearers do not keep step, the front man

stepping off with the left foot and the rear with the right. The object of this is to diminish the swing of the stretcher. The patient is carried feet foremost except when going up a hill or up stairs. If, however, a leg is broken it should always be carried level with or higher than the trunk. A stretcher must never be carried on the shoulders or over a high wall, as one of the bearers may stumble and the injured person thrown off. *See Bandage; First Aid.*

STRETCHER: In Woodwork. In woodwork a stretcher is a piece of wood joining two rails which is used for strengthening the framework of cabinets, tables, chairs, and other forms of construction. *See Cabinet Making; Chair; Sideboard.*

STRING. There are so many uses for string in every household that it is generally a good plan to keep a ball of medium thick twine in a box, or in a canister with a hole in the lid.

Many housewives keep a string bag, often hanging it on the back of a hall or kitchen cupboard door, in which they place lengths of string removed from parcels.

If parcels of some weight have to be carried any distance it is a convenience when tying them up to make a handle. The string is passed twice round the longest side and several inches apart, and around these two a length of string is passed across and across three or four times. The loose end of the string is then twisted round the strands, and between them and itself to form a handle, closely covered with buttonhole stitch.

With a heavy parcel it is best to start as above, but to twist the string round a number of times. A piece of stout, pliable cardboard as wide as the handle should be wound over the strands and made fast with gum.

Kitchen Uses. In the kitchen fine string is most needed for tying down jam jars, trussing fowls and preparing joints for the oven. For tying down the cloth over a pudding basin a stouter string will be required, also for tying together the feet of a turkey, goose, etc., that it may hang in the larder. Small ends of string can be utilized to make loops with which to hang up kitchen utensils to hooks, etc. A piece of fine string will cut a bar of soap.

The use of string in mending is usually merely temporary. In mending a broken cup, for example, string or tape is frequently tied around it to keep the pieces together until the cement sets. The same use is made of string in glueing together a box, the leg of a table, etc. For mending or for making

sacks, string threaded through the eye of a specially large needle is used. See *Macramé*; *Netting*; *Parcel*.

STRING BAG: How to Make. A string bag is fairly easy to make. To make one that will hold six tennis balls, the only requisites are a ball of string, white string, strong but not too thick, being the most suitable, a netting needle, and a piece of wood, resembling an ordinary rule, i.e., about 12 in. long and 1 in. wide.

The netting needle should be of wood or bone. The needle, or mesh, as it is called, should be 5 or 6 in. long and about $\frac{1}{2}$ or $\frac{3}{4}$ in. wide. It is forked at both ends so that the string can be wound upon it. This should be tied very tightly and only a little at a time so that the needle will slip easily through the loops.

The work consists of netting, which is a series of loops knotted evenly. To begin with, the worker should make a foundation loop with a separate piece of string. This should be about 10 in. long, and its ends knotted together. It should then be slipped over the knob of the chair, or on a nail, or anything else that will allow it to be pulled at a height convenient to the worker. Having arranged the foundation loop with an ordinary knot, the worker should fasten it to the end of the string that has been wound on to the needle.

Then, taking hold of the mesh with the left hand, he should wind the string, marked A in the diagram, from the needle once round the mesh and pass it through the foundation loop. He next draws the mesh up to the foundation loop, and places the first finger of the left hand upon the string B, at the point C. He next casts a loop of the working thread and passes the needle to the right of the foundation loop, between it and the mesh and through the loop which has just been cast. This enables the worker to form a knot which he can then draw tight against the first finger, which should be kept on the string B until this is done. It is important to bear in mind that the string is drawn towards the worker, not upward.

Fifteen stitches or loops should be cast in this way on to the foundation loop. The mesh may then be slipped out and removed, while a complete turn is given to the foundation loop on the nail. The work is turned over so that the work is begun on the left-hand side again, but at the same point at which it was finished off on the right. This strip, ready turned for the first stitch on a new row, will be seen on the bottom of the diagram. The next row is continued in the same way, but a separate loop instead of the foundation thread should be taken up.

The whole bag is made in this way, row after row of knotted loops being worked from left to right. The work must be turned on the nail after each row. After about 25 rows it will be found that the strip of netting, when it has been doubled in half and joined up at the sides, will be long enough to make the bag required. To finish it off slip the mesh out of the last row and neatly cut off the needle string. Then take out the foundation loop and join up the sides as though they were being sewn, using the fingers as the needle, poking the string through the loop, and joining with a knot top and

bottom. The bag is then complete except for the draw-string at the top. This should be threaded through the loops which form the mouth of the bag. It should be about 20 in. long and of stouter string than the bag itself. The ends should be knotted after it has been threaded through the loops at the neck of the bag. *See* Netting.

STRING BOX. For holding string, boxes are obtainable in wood and metal. The wooden box is turned from hardwood, generally provided with a cutter. Metal boxes are composed of two half-spheres hinged together; some are provided with a ring for hanging and others have a metal base to stand upon. Boxes in wood pulp and papier mâché are obtainable which can be decorated by stencilling or other forms of painting. *See* Italian Renaissance Work; Lacquer Work; Pattern Printing, etc.

STRINGING. Stringings mean very thin lines of inlaid wood put round panels and the edges of constructional parts of furniture. Satinwood stringing on mahogany is used to give a light line on dark wood, and ebony to give the opposite effect. Stringing was much used by Sheraton and other makers at the end of the 18th century. *See* Inlaying; Parquet; Sheraton.

STRIPPING KNIFE. The knife used for stripping off old wallpaper and paint consists of a broad blade with a straight handle, the blade being so tempered as to give slightly when pressure is brought to bear upon it. After first wetting the wallpaper the knife is inserted under it and the paper peeled off in strips. With old paint this knife can only be used on large areas, when a good deal of ground can be covered in a short time. The paint is scraped off with the knife after it has been burnt with the blow lamp. The stripping knife must be used in the direction of the grain of the wood. *See* Painting; Paperhanging.

Stroke. *See* Apoplexy; Paralysis.

STROKING: In Needlework. This process consists in placing side by side, in even folds, the little flutes made in material by gathering, thus giving a much neater effect. Before stroking can be done, the gathering thread must be drawn up fairly tight and wound round a pin inserted in the material at the left end of the gathering. The cotton must not be broken off, as the gathers are afterwards released to the size required.

Take the material in the left hand, with the right side of the fabric towards you; then take a needle in the right hand, with

the point upward. Beginning at the left hand end of the work, raise each gather gently with the point of the needle, and stroke down into the little ruck which lies between, moving it gently to the left, so that it is placed under the thumb. Repeat this process until all the gathers are stroked under the thumb; then release the cotton at the left end, to make the gathering the desired size, and fasten off.

bottom. The bag is then complete except for the draw-string at the top. This should be threaded through the loops which form the mouth of the bag. It should be about 20 in. long and of stouter string than the bag itself. The ends should be knotted after it has been threaded through the loops at the neck of the bag. *See* Netting.

STRING BOX. For holding string, boxes are obtainable in wood and metal. The wooden box is turned from hardwood, generally provided with a cutter. Metal boxes are composed of two half-spheres hinged together; some are provided with a ring for hanging and others have a metal base to stand upon. Boxes in wood pulp and papier mâché are obtainable which can be decorated by stencilling or other forms of painting. *See* Italian Renaissance Work; Lacquer Work; Pattern Printing, etc.

the point upward. Beginning at the left hand end of the work, raise each gather gently with the point of the needle, and stroke down into the little ruck which lies between, moving it gently to the left, so that it is placed under the thumb. Repeat this process until all the gathers are stroked under the thumb; then release the cotton at the left end, to make the gathering the desired size, and fasten off.

Care must be taken to stroke the portion of the material above the gathering thread, as well as below it, and in order not to scratch the material, it is best to use a blunt-pointed tapestry embroidery needle for the stroking. *See* Gathering.

STRYCHNINE. The action and the medical value of *nux vomica*, the dried seed of an East Indian plant, depend almost entirely upon the strychnine which it contains.

Strychnine is one of the ingredients of Easton's syrup, and is valuable in many tonic digestive mixtures, acting as a stomachic and carminative. It is largely employed in the treatment of chronic heart disease and is an ingredient of expectorant mixtures in inflammation of the lungs or bronchial tubes. Strychnine should never be taken except under a doctor's immediate supervision.

STUARTIA. Growing up to 10 ft. in height, the beautiful shrub *stuartia* has nearly oval, toothed, pointed leaves and large white flowers in summer. It thrives out of doors, but should be planted in a sheltered sunny position. Ordinary soil can be made suitable by adding leaf-mould and peat. Propagation is most easily carried out by sowing seeds, but layering may be done in late summer. The best kind is *Stuartia pentagyna*, which bears large white flowers stained slightly with red.

STUCCO. This term has been applied in a general sense to the plastering of walls with any material designed to produce a finished the present day it is mainly calcareous materials with a mixture of sand.

Stucco was once used extensively for internal decorative plastering, such as for forming cornices or mouldings, and decoration of ceilings. It was composed of pulverized marble and gypsum, mixed with fine sand and clean water, and it hardened gradually, thus giving opportunity to work it into the design, which the plasterer did with the aid of small steel tools.

This kind of stucco has been superseded in Great Britain by stick and rag work. Mouldings are cast into the shape required and kept rigid with the aid of canvas; after these are placed in position, the joints are made good with plaster of Paris, in a mastic state.

The materials used for trowelled stucco, that is, the kind that is used as a finishing for 3-coat plastering, are lime-putty mixed with clean washed sand. Such materials form a setting coat, having a smooth and hard surface, and should always be used in the case of ceilings that are to be treated with distempers. Where a rough surface is desired, the stucco may be brushed over with a wet distemper brush just before it sets. It is not advisable to use this kind of stucco externally. *See* Cement; Plaster.

STUD: In Engineering. A stud or stud-bolt is a headless bolt with a screw thread formed at each end and an unscrewed portion between. It is screwed tightly into some fixed member, and the projecting end, in conjunction with a nut, serves to hold in position some other part, e.g. the detachable cylinder head in an internal combustion engine. *See* Bolt; Nut.

STUDY: Its Fittings. When it is possible a light, airy room on the quiet side of the house should be chosen for the study. There should be a good heating arrangement and convenient artificial lighting, as it is difficult to do the best mental work when handicapped by any degree of discomfort.

With regard to the treatment of decoration and furniture most people would wish to aim at harmonious repose for the former and comfortable efficiency for the latter. Some would feel keyed up to work in a bright but austere furnished study, while others would prefer the more conventional style illustrated in Fig. 1.

A restful room of this type could be treated with dove-grey walls and ivory woodwork and ceiling, a deeper grey carpet with purple border, and the windows curtained with purple velours and ivory net. Touches of dull pink and yellow could be introduced in the cretonne covers.

Study. Fig. 1. Spacious and well-lighted study with conveniently placed desk, roomy bookshelves and comfortable chairs for moments of relaxation.

A brighter room might have walls of duck egg green and furnishing fabrics in autumn leaf tints. A cretonne in old English needlework design would then be a good choice for curtains and any loose covers.

Some people prefer the bureau type of writing desk because of its more charming appearance in a room, but

the flat-topped desk is more comfortable to work at than a bureau.

In many cases the owner of a study requires more than one or two small shelves for the accommodation of his books, and a bookcase with glass doors, which keep out the dust, is added to the furniture.

Fig. 2. This dignified study with its solid mahogany desk and modern furnishing, exemplified by the two chairs in chromium plated metal tubing, belonged to the late Mr. Edgar Wallace. (Humphrey & Vera Joel)

Fig. 2 shows the very businesslike study of the late Mr. Edgar Wallace. Comfort and colour are supplied by the rich tones of carpet and rug, the floor cushion, and the velvet furnishing fabrics. The modern note is well emphasized in the two chairs with tubular steel frames, in the writing table and in the severely plain bookshelves.

There are well-designed tables and ornamental covers for typewriters to be had which will harmonize with most furnishing schemes. A tiling cabinet is often required and a cupboard with shelves in which to stow away stationery. The desk chair is a matter of individual taste, but a comfortable armchair in which to sit while reading, a fair-sized, solidly made table, and a good reading lamp may be considered essential.

Over a desk or low bureau, placed to the right of a window, near a corner of the room, an angle arrangement composed of two shelves which allow the requisite depth between them for reference books makes a useful corner treatment and a pleasing one if an attractive piece of china is placed on

the top shelf. A small cupboard let into the wall near the desk is convenient for the telephone. *See* Bookcase; Library; Writing Table.

STUFFING: In Cookery. Stuffing is a savoury compound which is combined with meat, game, or fish in order to impart a rich or special flavour. Stuffing may be used to fill hollows, it may be laid between two flat portions of food, or, on the other hand, it may be converted into a coating.

If meat is boned it is often stuffed, while if made into a galantine a certain quantity of stuffing is mixed with the other ingredients which help to form the filling. Stuffing also is added to meat and poultry served whole. Veal is accompanied by what is known as veal stuffing, or forcemeat, and pork by sage and onion stuffing; poultry and game may be stuffed with a large variety of forcemeats, flavoured and seasoned in a suitable manner, but always made very savoury.

In meat the stuffing is inserted by raising up the skin covering a hollow or convenient place for pressing in a sufficient quantity; the position varies according to the nature of the joint, but the stuffing must be so placed that there is a possibility of equal distribution when carving takes place. It must be entirely covered when in the joint and fastened in place securely, or it will escape in the dripping pan.

In poultry or game the stuffing is pressed under the breast from the neck end of the bird. Sometimes a portion of it is inserted through the vent under the lower part of the breast. Hares and rabbits are stuffed where the internal organs have been removed, and the hole should then be sewn up.

The practice of cooking stuffing apart from the food it is intended to flavour cannot be recommended, as the meat is prevented from absorbing the savoury ingredients while it is cooking. Stuffing made up into balls is added to meat pies to enhance the flavour.

Most varieties of fish may be stuffed. If the fish is whole the stuffing is inserted where it has been gutted, the opening is sewn up, and usually the fish is trussed round or in the shape of an S. Sometimes the stuffing is used as a filling for fillets, and often two small fish may be split open, boned, and one fillet placed on another with stuffing between. All stuffing for fish should be well seasoned and flavoured liberally with lemon.

Many vegetables are stuffed with highly seasoned forcemeats, to which may be added chopped or pounded meat and sausage meat. Vegetables usually are partially cooked before being stuffed. If stuffed savouries are required, a case of some description must be prepared beforehand in which to serve them. This may consist of tomatoes with the inside scooped out, the halves of hard-boiled eggs with the yolk removed, or some other cup-like device. Olives frequently are stoned and stuffed, and served as savoury or garnish.

Sage and Onion Stuffing. To make sage and onion stuffing mix 4 oz. fine breadcrumbs with three small chopped onions, two teaspoonfuls of chopped sage, and salt and pepper to taste. Bind these ingredients with 1 oz. butter and a beaten egg, and mix the whole thoroughly before inserting the stuffing.

Sage, apple and onion stuffing, which may be used for ducks, geese, and pork, is made thus: Peel three large apples and the same number of onions, put them into a pan with six sage and three lemon thyme leaves, and cover them with water. Cook them slowly over the fire until they are tender, then rub them through a sieve, and to the pulp thus formed add enough mashed potato to mix the whole to the desired consistency, and season it well. This should be sufficient to stuff an average-sized goose or two small ducks.

Chestnut Stuffing. This stuffing is particularly used with turkey, but is sometimes liked for fowls. About 24 chestnuts are sufficient for the usual amount required. They should be boiled until tender and then skinned. The stuffing is better when employed for chicken if it is enriched and the livers of

two fowls, parboiled, should be pounded with the chestnuts, and 4 oz. fat bacon, 1 oz. chopped parsley, a pinch of nutmeg, and a little salt and pepper added, and all well pounded together.

For turkeys a less rich forcemeat is required, and the liver and bacon are therefore omitted. The chestnuts are baked for about 20 min., skinned and then simmered until they are soft, in enough water to cover them. They are then rubbed through a sieve and mixed with a lump of butter about the size of an egg, and a sprinkling of seasoning. *See* Forcemeat; Goose; Turkey; Veal; etc.

STUPOR. In coma the patient cannot be roused by any means, but in stupor he may be roused by speaking loudly to him, or by some other form of stimulation.

A large number of causes may give rise to this condition, e.g. concussion of the brain, as a result of a blow or a fall; compression of the brain, by a fracture or a tumour; epilepsy, abscess of the brain, meningitis, asphyxia; poisoning by opium, chloral, alcohol, and other narcotic drugs.

One of the most difficult cases to diagnose is that in which a man is found in a state of stupor, and smells of alcohol. The tendency is to suppose that the man is very drunk, but he may have taken only a little alcohol, while his condition is due to some one of the causes enumerated above. Mistakes are sometimes made with serious consequences to the patient. When there is the least doubt the person should always be assumed to be ill, and be treated accordingly. *See* Coma.

STURGEON: How to Cook. The flesh of the sturgeon is solid, white, and not unlike veal. When fresh the veins and gristle have a blue appearance, and the grain of the flesh is even; if the veins are brown or dingy in colour the fish is not good. The roe is preserved, and in the form of caviare it is highly valued as hors d'oeuvres. The isinglass manufactured from the air bladder is superior to gelatine for the purpose of stiffening jellies and creams.

After cleansing, the skin of the sturgeon should be loosened with a sharp knife, starting from the backbone and dealing first with one side and then with the other. The skin is then laid over the fish again and fastened with string or tape. It is better thus to loosen the skin before cooking the fish, as it is not good served with it, and loosening facilitates dishing.

To boil sturgeon, take half a small fish and put it into a fish kettle, just cover it with water, add the rind of half a lemon, 20 black peppercorns, a small stick of horse-radish, and 1 gill of vinegar to each quart of water. Cook from 1½ to 2 hours very gently, then drain the fish, remove the skin and serve with a good piquant sauce.

A favourite method of cooking sturgeon is to roast it. Cleanse 3 lb. of fish and remove the skin, but do not replace it. Dust each side of the flesh with salt and pepper and then lard it closely or cover it with thin slices of fat bacon, which should be tied on. Butter a thick sheet of white kitchen paper and lay over it 2 prepared and sliced onions and 2 carrots, also prepared and sliced, 1 dessertspoonful sifted dried sweet herbs, and 1 tablespoonful chopped parsley.

Wrap the fish completely in the paper and secure it. If the paper is not very thick it would be best to use it double. Melt 3 oz. butter or good beef dripping in a baking tin, lay the fish in the tin, and bake it from 1 to 1½ hours, basting frequently. It must cook rather slowly. To serve the fish remove the fastenings and paper, and if it is not well coloured return it to the oven to brown, then brush over the top with glaze and serve it very hot. A well-flavoured brown sauce may be handed round.

Sturgeon may be roasted like veal, stuffed with a good veal forcemeat. Let it be well basted with butter and served with thick brown gravy. One way of dishing it is to pour over it when dished a good brown sauce. Garnish with cut lemon and little rolls of bacon.

Sturgeon is sometimes cut in small steaks, and these should be broiled. Prepare and cut the steaks, which should be about 1¼ in. thick. Cover each with egg and fine seasoned crumbs, wrap them in

buttered paper and broil them over a slow, clear fire. Serve them with anchovy sauce. A little chopped parsley may be added to the breadcrumbs.

For fillets of sturgeon prepare about 2 lb. of the fish and cut it into fillets. Melt 2 oz. butter in a sauté pan, put in the fillets and cook them very slowly. When done on one side turn them and cook the other side ; they will take about 20 min., but much depends on how thick they are cut. When tender, take them up and serve hot with a good brown sauce or Genevoise sauce. *See* Caviare; Force meat; Isinglass; Sauce; Veal.

STYE: In the Eye. Inflammation of a little gland at the root of an eyelash results in a hordeolum or sty. This is a painful swelling which soon suppurates, the matter, if it be left to itself, finding its way out, usually through the inner lining of the lid. It will shorten suffering, however, if the affected lash is pulled out and the little abscess opened as soon as matter has distinctly formed. Until then hot applications, for example boracic fomentations, should be made.

Not uncommonly one sty is followed by a succession of others. The eye should be washed regularly with boracic lotion for some time after a sty. A lotion or drops of sulphate of zinc is also sometimes required. The general health may be depressed and require tonic treatment, and constipation if present must be corrected, as a habit of this kind may be responsible for styes. *See* Conjunctivitis; Eye.

STYPTIC. A drug or other agent used to stop capillary bleeding by contracting the blood vessels and furthering clotting of the blood is called a styptic. Very hot water has the same effect. Amongst the drugs used in this way are perchloride of iron, tannic acid, the salts of copper and lead, calcium chloride, hazeline and adrenalin. Cobwebs applied directly to a wound act as an effective styptic, but should never be used in view of the danger of poisoning the wound. *See* Bleeding.

STYRAX. This hardy shrub thrives in well drained loamy soil with which leaf-mould has been mixed, and in a sunny sheltered place. One of the best kinds is *styrax japonicum*, 15 ft. or more high, with white flowers in summer. *Styrax Obassia*, a japanese white-flowered shrub, is also beautiful. The gum resin called storax is obtained from *styrax officinale*.

SUCKER. To the gardener a sucker is a shoot rising from the subterranean stem of a tree or bush. Such can be used for propagation purposes, as in the case of the raspberry. The suckers which develop on the stocks on which roses, fruit trees and certain shrubs are grafted or budded ought to be pulled up and destroyed. *See* Apple Sucker; Plum; Propagation; Pruning; Raspberry.

SUCKING PIG. Usually the pig can be purchased ready for dressing, but, if not, it must be thoroughly cleansed, particularly the nostrils and ears, as the head is served at table. Cut off the feet at the first joint, loosening the skin and leaving enough to turn under. The pig should then be stuffed with sage and onion stuffing as for roast pork. Sew the stuffing up inside the body of the pig, then roast it as for roast pork.

To cook this dish to perfection the flesh should be basted first of all with brine, then pour it away, and baste thoroughly and frequently with butter. Serve with rich gravy well flavoured with lemon juice, and hand round apple sauce.

The sucking pig should not be more than 3 weeks old, and it will take about 2 hours to cook. It is served split in half. And the snout and jaws should be trimmed off, leaving only the cheek and ears and the outline of the snout and jaw. Sucking pig is sometimes stuffed with the chestnut stuffing used for turkey. *See* Pork; Stuffing.

SUÈDE. Obtained from sheepskin dressed soft and finished on the flesh side with a very fine nap, suède can be sewn and worked for all purposes just as easily as velvet. Suède is utilized largely in the manufacture of gloves, shoes, handbags, belts, hats and sports coats. Artificial flowers are made from it, and it is dyed to many different shades.

Care of Suède Shoes. Wet suède shoes should be placed on shoe trees or stuffed tightly with paper and left to dry. They should not be dried in front of the fire, as this causes the leather to split. If they are mud-stained, they should not be brushed until they are thoroughly dry. Like all other suède goods, they may be cleaned with petrol, the latter being applied with an old toothbrush. The pile or nap may be restored with sandpaper or with a small wire brush which is sold for the purpose.

The best means of cleaning coloured suèdes that have become soiled in wear is by the use of the many coloured dry cleaners marketed for the purpose. Grease and other stains are best removed by rubbing briskly with a piece of suède, or a piece of chamois leather, used dry without any lubricant at all. Glass paper is also useful for removing obstinate stains. The employment of petrol, benzine, and other spirits is not advised for red and other brightly coloured suèdes. They will remove the stain, but may also cause the dye to fade and so give the leather a patchy appearance. Suède, so treated will need to be redyed in order to restore its original colour. *See Cloth Ball; Glass Paper; Gloves; Leather.*

SUET: In Cookery. The fat which lines the loins and kidneys of sheep and bullocks furnishes the suet which is indispensable in cookery for making puddings and for other purposes. The best is that which surrounds the kidneys, and is commonly called kidney suet.

When suet is received from the butcher it should be examined to see that it is free from taint, as the slightest defect of that kind will probably spoil a whole dish. To prepare it, the skin is first removed and the suet is sliced up into flakes. It has then to be chopped finely. The success of the cooking depends to a great extent on the skill and thoroughness with which the chopping is done. Suet graters can be bought and do the work more quickly than it can be done with a knife.

Suet should be firm enough to chop without the necessity of adding flour during the process, but if the weather is close and the fat seems unduly soft, flake it, then add the whole quantity of flour needed for the pudding and finish chopping. By adding small quantities of flour, as is often done when chopping suet, the fat is merely worked into a paste and cannot be successfully mixed. It should be remembered that extra flour added for chopping purposes destroys the proper proportions and takes away from the quality of the dish.

To keep suet for a few days the best plan is to remove the skin, chop the suet and put it into a dish, covering it with flour. The fat must be entirely covered, and an account must be kept of the amount of flour used. The practice of burying a lump of suet in the flour tub, unskinned, is not good. The skin quickly becomes tainted and it then contaminates the flour.

SUET CRUST. For making dumplings and roly-poly, and also for covering meat or fruit puddings, a suet crust is made as follows: Chop finely 10 oz. suet, and mix it lightly with 1 lb. household flour which has been sifted, with $\frac{1}{4}$ teaspoonful of salt. Work these ingredients into a fairly stiff paste, using about $\frac{1}{2}$ pint cold water. Some housewives add baking powder to suet crust (*see Apple Pudding*), others consider that any raising agent should be avoided in the making of this crust.

The pudding should be perfectly light if the suet is properly chopped the dough skilfully handled and not made too moist. A pudding may either be cooked in a greased pudding basin, covered with a greased paper, or as in the case of a roly-poly, tied up in a floured pudding cloth. The pudding is plunged into fast boiling water and kept boiling the whole time of cooking. When mixing, pour the

water into the centre of the basin and work in the flour round the sides as quickly as possible till all is mixed, but take care that the whole is smooth and the ingredients properly incorporated. The paste should be firm and no moisture should appear when it is cut or rolled. If a richer crust is desired the quantity of suet may be slightly increased.

The time required to cook plain suet or roly-poly puddings varies from 1½ to 2 hours according to size. Fruit puddings take about the same time. *See* Apple Roly-Poly; Dumplings; Plum Duff, etc.

Suffocation. *See* Artificial Respiration; Asphyxia; Drowning.

SUGAR: ITS USES IN THE HOME

Consideration and Comparison of Kinds and Qualities

This contribution is connected with a great number of other entries in this Encyclopedia, notably the cake, preserve and sweet making recipes in which sugar is used. *See* Chocolate; Diet; Food; Jam; Sweets; Toffee, etc.

For home consumption sugar generally consists of loaf or lump sugar, granulated, castor, icing, and the varied forms of yellow or brown sugars. The very first consideration when buying any of these should be to ensure quality; the purchase of an inferior article is no economy in housekeeping, as moist, sticky sugars, even if slightly cheaper in price, are heavier in proportion to the pure crystals, while their sweetening power is considerably lower. The white crystalline sugars are the purest, and usually are free from the impurities frequently found in loose or brown sugar. Loaf sugar is not often adulterated, and the quality is easy to detect from the appearance. It should be clean looking and sparkling.

One or two rules for distinguishing good sugar from inferior may be useful. A good white sugar should look very dry and highly crystalline, also when rubbed between the finger and the thumb it should be free from any feeling of stickiness, and should never appear clammy. Good cane sugar should be easily soluble, and may be tested with water. If dissolved in half its weight of cold water, and found to be free from sediment of dirt or pieces of foreign matter, it is absolutely pure.

White Sugar. Lump or loaf sugar may with advantage be employed not only for table use, but for all the most delicate kinds of cakes and sweets. For use in cookery it needs, unless it can be dissolved in liquid, to be pounded in a mortar and passed through a fine sieve, and the rougher portions which remain must be pounded again and sifted until the whole is a fine powder.

White sugar should always be used for making jams and marmalade ; not only is a greater degree of sweetening principle obtained from it, but the jams will be clearer and a better and brighter colour. In some country districts moist sugar is used for jam making, but the preserve then has a rough taste as well as looking cloudy. Of course, something depends on the quality of the sugar. Summer and invalid drinks, also home-made wines, should be sweetened with loaf sugar. The more delicate kinds of toffees should be made with this sugar, and jellies should be sweetened with it.

Granulated sugar is a purer variety of white sugar than inferior castor sugar, but for some cookery purposes, also for table use, it is rather coarse, and not so easily or so completely soluble as loaf sugar. It may be employed for sweetening fruit in pies, in puddings, for large cakes, and it is often used for making jams and marmalade. A large white crystal sugar is specially sold for use with coffee.

Castor sugar, which is a pounded form of lump or loaf sugar, should have a bright, dry appearance, and the tiny crystals should also be well defined and even, as in granulated sugar. It is most suitable for table use, and also for sweetening delicate cakes where a spongy consistency is needed. It is

likewise used in making meringues, custard and whipped cream mixtures, whips, some glazes, and is sprinkled over pastries for decorative purposes.

Another form of white refined sugar is icing sugar. This is white sugar pulverized until it resembles a fine powder, and the greater the extent to which it is pulverized, and the finer the powder, the higher the quality of the icing sugar will be, and the better the use which can be made of it for cooking cakes and for decorative icing. However good the sugar, it must always be treated by further sifting before it is used for cake icing. A fine hair, tammy, or silk sieve should be used for the purpose.

Brown Sugars. Of all brown sugars Demerara ranks the highest. It should be a golden brown colour, and the crystals should be dry and separate. It makes a good porridge sugar, and is sometimes used for coffee. It is useful for sweetening lunch, rich large cakes, and many varieties of puddings. Demerara is occasionally adulterated, a kind of yellow crystal sugar being sold as a substitute for it which is made from beet sugar and dyed.

Barbados is a rich moist sugar, brown in colour. It is, when pure, very good for mixing in with dark coloured puddings, or any description of gingerbread; it is also used for dark toffees, in the pickle made for salted and spiced meats, and in chutneys. It is not suitable for sweetening fruit when cooked, as it imparts an unpleasant syrupy taste, and also spoils the colour of the juice.

A cheap sugar called white moist is sometimes sold, but there is no economy in buying it, as the saccharine principle is very deficient and the quality altogether inferior. Foots' sugar is the moist syrupy sugar which lies at the bottom of the hogsheads of raw sugar. It was at one time used for toffee. A yellow crystal sugar, not unlike sugar candy, is preferred by some people to the white crystal sugar for sweetening coffee.

Food Value. From the medical standpoint sugar is one of the most valuable foods, because it is a source of body heat and energy. Cane and grape sugar are composed of carbon, hydrogen and oxygen. Cane sugar, although obtained chiefly from the sugar cane, is also manufactured from beetroot, carrots, and the sugar maple. Glucose, grape, and starch sugar are found in various fruits; they are prepared artificially from cane sugar, starch, and dextrin. Glucose has not the same dryness as cane sugar, and will attract and absorb moisture. When cane sugar is moist it is often due to the presence of grape sugar.

Milk sugar, or lactose, which is found in milk, and may be separated from it as a fine white powder, is much less sweet than ordinary sugar, but is readily digestible by infants, and has a slight diuretic and laxative effect.

Malt sugar, or maltose, is obtained by treating the starch of barley with the ferment diastase. It readily undergoes alcoholic fermentation. It is impossible to lay down any general law as to the amount of sugar which should be included in any particular individual's diet. A point to be remembered is that sugar has a cloying or satisfying effect, and therefore it should be eaten at the end of a meal.

A proportion of sugar must be maintained in the blood and, as necessary, glycogen is changed back into glucose and added to the blood stream. The proportion in animal blood is from 0·08 to 0·04 per cent. If the amount in the blood is too high sugar appears in the urine; but in the condition known as kidney diabetes sugar is apparently able to pass into the urine although the proportion of blood sugar is not raised. Sugar appears to take the place of alcohol and to diminish the tendency to build up a taste for the latter.

The handling of sugar sometimes produces dermatitis of the hands and forearms, a condition which among grocers is called grocer's itch. When unrefined sugar is being handled it is thought the

irritation may be due to the sugar mite, an insect which resembles the itch mite, and which occurs in such sugar. Fat children who take an excess of sugar may suffer from eczema, and symptoms of rheumatism are also sometimes a result of excessive use of this food.

SUGAR BASIN. The receptacle for sugar may be an ordinary basin, but it is usually more elaborate when sold separately or as part of a tea service. Sugar basins are made in glass, china, pottery, plated metal, or silver, in old and modern styles.

Sugar Basin. Right. Fig. 1. Example in pierced silver work, lined with blue glass, 1785. Fig. 2. Fluted sugar basin on ball feet. (Courtesy of Chapple & Mantell)

Often they are made in plated metal or in silver to match a milk jug and teapot in reproductions of Queen Anne and other classic styles. An early form of the sugar basin is the glass bowl sometimes found in a tea caddy. Sugar basins in antique silver and Sheffield plate are valued by collectors. Some early pieces are embossed. Others of a somewhat later date are adorned with pierced and fretted trellis work, a decoration which necessitated a glass lining. This was usually blue in colour, but occasionally crystal. An example of such a basin, or basket, is illustrated in Fig. 1. It has a swing handle and a bead edge. Under the heading Sheffield a round basket of the same period, but made in Sheffield plate, is shown. Some fine examples are supported on bail and claw feet, or on lion's paw or ball feet. Sometimes the basins were made with covers. Fig. 2 shows a fluted sugar basin, with gadroon border, scroll handles, And ball feet dating from early in the 19th century.

SUGAR CANDY. Being a pure and wholesome sweetmeat, sugar candy consists of sugar crystallized and dried in an even, hot temperature. The crystals are formed on strings, but as special vessels are necessary to do this, it is scarcely possible for an amateur to attempt making it.

SUGAR CASTOR. A sugar castor or sugar dredger is employed to sprinkle castor sugar over fruit tarts, stewed fruits, etc., after they are brought to the table. It is usually very similar in shape to a muffineer (q.v.) or pepper pot, though larger, and, like a muffineer, is provided with a conical or round, screwed-on, and perforated lid.

Sugar castors are frequently made entirely of silver or silver plate. Sometimes the lid alone is of silver, the rest of the castor being cut glass or china. Collectors' examples in silver date from the

end of the 17th century. Queen Anne shaped castors were often octagonal, the pierced top surmounted by an octagonal knob.

SUGAR SIFTER. This is a spoon used for serving sugar. The distinctive point about the article is the pierced bowl which enables the sugar to be sifted as it is put on to the food. Sifters, which are usually of silver or electroplate, can be purchased either separately or with a sugar basin.

SUGAR SOAP. This is the name given to a soap in powder form used for washing down paintwork before repainting. It can be had from an oil and colourman. *See Paint.*

SUGAR STICK. This sweetmeat can be varied by changing the colour and flavour, and needs to be stored in airtight bottles. Prepare the sticks by dissolving $\frac{3}{4}$ lb. granulated sugar in a little more than $\frac{1}{2}$ gill water, and then adding 3 oz. glucose. Stir the whole in a pan over the fire until the glucose has melted; then boil it up to 300° F. and pour it on to an oiled slab. Flavour with cinnamon, add a little saffron for colouring purposes, and fold the hot candy over and over with a flat wooden spoon, afterwards pulling it out with the hands until it begins to harden. It is then ready to be cut into sticks.

SUGAR TONGS. The pair of tongs which often accompanies a sugar basin is usually of metal, silver and electro-plate being freely used. They are made with a slight amount of spring, so as to grip the sugar when pressed. A shape often seen is one resembling two spoons fastened together.

SUIT CASE. The lighter types of suit cases consist of a plain frame covered with morocco cloth, vulcanized fibre, brown canvas, green drill or some other material of that kind. The heavier ones are of leather.

A very light weight case has a soft top. Such suit cases are lined with a fancy material or cotton moirette and are made of leather grained cloth or black or coloured oil baize. Expanding cases are serviceable in reliable and stouter makes. Another type is here illustrated. It is covered with vulcanized fibre, lined with strong material, and the top is fitted to hold six dresses. The bars come forward, for hanging them. The lower portion of the case is deep enough for shoes and other articles of clothing.

Suit cases are fastened by snaps or locks or both. They are made in a variety of sizes. Small ones are 18 in. long, $13\frac{1}{2}$ in. wide, and $5\frac{1}{2}$ in. deep, and they can be bought as large as 30 in. long, 17 in. wide, and 8 in. deep.

Suit Case in vulcanized fibre, lined and fitted with bar attachment, over which dresses and skirts may be hung and held in place.

SULPHATE: The Fertilizer. Salts that are formed with sulphuric acid are termed sulphates. In the garden, three sulphates, ammonia, lime, and potash, are of great value in fertilizing crops. Ammonia can be applied to all kinds of soil, except those containing chalk. It is particularly useful on cold, heavy ground. It should be applied to the soil before planting, but may be used as an after stimulant in liquid form in the proportion of $\frac{1}{2}$ oz. to a gallon of water.

Sulphate of lime, sometimes called gypsum, is an excellent fertilizer, its action being to liberate silicate of potash for the feeding of crops; it has the power of fixing ammonia, and is used on manure heaps for that purpose. Sulphate of potash is very soluble, and this quality, in conjunction with its feeding value, makes it invaluable for pot plants, flowers, etc.

One of the poisonous winter washes for the cure of black spot, mildew, scorch, and rust, is made with sulphate of copper, also called blue stone. It is mixed with water, in the proportion of 1 oz. to 2 gallons, and carefully applied with a syringe or pneumatic sprayer when growth is dormant. *See* Bordeaux Mixture; Lime; Potash.

SULPHIDE. Amongst the sulphides the one known as sulphide of potassium, or liver of sulphur, provides an excellent remedy for mildews in garden and greenhouse. It is simply prepared by mixing 3 oz. sulphide of potassium with 4 oz. soft soap, dissolving both separately in water, and adding further water to make up to 10 gallons. The solution must always be used when perfectly fresh. It is applied to mildewed plants during summer. *See* Mildew; Spraying.

SULPHUR: Medicinal Uses. Sulphur is widely used in medicine as a parasiticide. In scabies or itch sulphur ointment is a very valuable remedy; or the drug may be applied in the form of Vleminckx's solution. In the treatment of other skin diseases, notably acne and dandruff, it is also a valuable medicament. Internally, sulphur acts as a gentle laxative, and is often prescribed for children.

Compound liquorice powder, a useful and reliable laxative, owes its action partly to sulphur, which it contains. Sulphur lozenges, containing 5 gr. of precipitated sulphur, one to two at bedtime, are often taken in order to correct constipation, or by the subjects of chronic rheumatism.

The sulphur waters of the natural springs in various parts of the world are used inwardly and as baths for the cure of chronic rheumatism, skin diseases, and a large number of other conditions. A sulphur bath at home is made by dissolving 6 oz. potassa sulphurata in boiling water and adding to a full bath, that is to say, about 30 gallons of water.

SULPHURIC ACID. Oil of vitriol or sulphuric acid is a heavy, oily, highly corrosive liquid which will destroy any animal tissues and many other substances with which it comes in contact.

Sulphuric acid as used medicinally is always very greatly diluted. Externally dilute sulphuric acid is sometimes used to check slight bleeding. Internally dilute or aromatic sulphuric acid may be used to check acute diarrhoea. It is often given as a daily dose, well diluted, for those who work in lead, painters, colour grinders, etc., as the acid combines with any lead which has been taken into the system, forming sulphate of lead, which is insoluble and harmless. In general debility, diluted sulphuric acid, either alone or with other tonic drugs, sometimes acts as an effective alterative, improving the appetite and generally bracing up the system. It should not be allowed to come in contact with the teeth.

On account of its violently corrosive effect, poisoning by sulphuric acid is a most painful as well as highly dangerous condition. Violent burning pain, from the lips down to the stomach, with vomiting of blood and corroded shreds of tissue, and collapse, are the chief symptoms.

While awaiting the doctor, magnesia, chalk, or soda should be given at once, if obtainable, in water, milk, or olive oil. If these substances are not at hand, crumbled-up plaster from a wall, soapsuds, or mortar, mixed with water or milk, should be given. An emetic should not be given. For the pain, poultices or fomentations are applied to the abdomen. If breathing is difficult put cloths wrung out of hot water round the throat and moisten the air with steam by means of a bronchitis kettle.

Afterwards demulcents, such as white of egg, or olive oil, should be given to soothe the inflamed stomach.

SULPHUROUS ACID. On account of its strong deoxidizing action, sulphurous acid is used as an antiseptic, a deodorant, and a disinfectant. The acid is sometimes applied locally in parasitic skin diseases, e.g. ringworm. Sulphurous acid is sometimes given internally to prevent gastric fermentation. The dose is $\frac{1}{2}$ to 1 fluid dram.

SULTANA. A small seedless raisin with a thin rather light-coloured skin, the sultana is much used in cookery for adding to puddings, cakes and scones. It is considered to possess a delicate flavour, although it lacks some of the full rich taste of the larger seeded raisin. Sultanas give better results when mixed with other dried fruits except when a plain fruit cake is desired.

Sultana Bread. This is made by sieving together $1\frac{3}{4}$ lb. flour and a pinch of salt, rubbing into them 1 lb. margarine or butter, and then adding and mixing in 5 oz. picked and cleaned sultanas and $\frac{1}{4}$ lb. sugar.

Put 1 oz. yeast into a small warmed basin, mix it with 1 teaspoonful castor sugar until it is reduced to liquid and then add $\frac{3}{4}$ pint warm milk. Strain these into a well made in the centre of the flour, etc., mix in a little of the latter from the sides, then cover the basin with a cloth and let it stand in a warm place for 20 min.

When this is done, mix in all the flour, adding more warm milk if required. Turn the dough on to a slightly floured board, knead it for about 8 min., then put it back into the basin, cover it and leave it to rise in a warm place for about $1\frac{1}{2}$ hours. Turn it out and knead it again for a few minutes, then put the loaf of dough into a greased and floured bread tin.

For the third time, let it rise in a warm place for 20-30 min., then bake it in a hot oven for about $\frac{3}{4}$ -1 hour. When cooked, brush the loaf over with a glaze made from castor sugar and milk, putting it back into the oven for a few seconds in order to dry.

Another recipe, in which yeast is omitted, is as follows: Sieve together $1\frac{1}{4}$ lb. flour, $\frac{1}{2}$ teaspoonful each carbonate of soda and cream of tartar, and $\frac{1}{4}$ teaspoonful salt, then add 2 oz. cleaned sultanas and mix the whole with enough water to make a fairly soft dough. Turn this into a greased tin and bake it in a fairly hot oven for $\frac{3}{4}$ hour. The bread is improved if buttermilk can be substituted for the water.

Sultana Pudding. To make this pudding, take 6 oz. sultanas, 5 oz. each of margarine or butter and of sugar, a lemon, an egg, $\frac{1}{2}$ lb. breadcrumbs and some milk. Grate the rind of the lemon and stir this into the breadcrumbs. Wash, pick over and dry the sultanas and beat the sugar and the margarine or butter to a cream; to these add the egg, which should be stirred in quickly and beaten for a few minutes. Mix the breadcrumbs and sultanas, adding a little milk as required, and stir the whole well together.

Put this mixture into a greased pudding basin, cover it securely with a well-greased paper, steam it for about 2 hours, and turn it on to a dish. This pudding should be served with syrup sauce. To make this, take 3 tablespoonfuls golden syrup and one tablespoonful each of strained lemon juice and water. Place these three ingredients into a saucepan and boil them together for a few minutes. *See Bread; Cake; Scone.*

SULTAN FOWL. This is a quaint looking white-crested fowl with cheek mufflings and a beard. It is heavily feathered on the shanks, the feathering being carried right down to the toes, and is vulture hocked like the Brahma; it possesses five toes, and thus may be akin to the Houdan. The comb is

horned. The Sultan is not a large fowl, the males when full grown weighing 5 lb. to 6 lb. and the hens 3½ lb. to 4½ lb. The hens lay a white egg which weighs slightly under 2 oz. The chicks, which are creamy white, are very hardy, and show the leg and foot feathering immediately they leave the shell. *See Fowl; Poultry.*

Sumach. This is the popular name of a group of ornamental hardy shrubs, known botanically as *rhus* (q.v.).

SUMATRA GAME FOWL. No fowl approaches the black Sumatra game fowl in the richness of its colour, which is dense black, with a glossy beetle-green sheen. The head is small and rather short, the eye large and bold, the comb small and pea shaped. The body is broad, with a full-round chest.

The body feather is close fitting, but the bird has long flowing saddle hackles, and the cockerels have a very long drooping tail, with immense side hangers and sickles, which almost sweep the ground. The hens have a large fan-shaped tail. The eye should be red, but is often brown or black, the face, comb and lobes are black, the beak and legs olive green. The bird often shows double spurs. The hens are layers of tinted eggs which weigh 1⅞ oz. to 2 oz. The Sumatra is a fairly good table bird, the flesh being delicate and having the flavour of game. It thrives best on free range. *See Fowl; Game Fowl; Poultry.*

SUMMER: In the Garden. Summertime for the gardener officially extends from June 21 to Sept. 29. It is during this period of the year that the fairest flowers, roses, carnations, and lilies, to mention only a few, are in bloom; turf is at its greenest, summer beds are at their brightest, the trees are at their leafiest, and many of the most delicious fruits and choicest vegetables are available.

The summer is also a period for observation. Errors in the lay-out of beds and borders, mistakes in colour schemes, and incongruities in the arrangement of plants should be carefully noted, and plans made for alteration or improvement when autumn comes. Plants, the flowers of which show any outstanding qualities in the way of size or beauty of colour or perfume, should be carefully noted for special care and attention when the season for propagation arrives. Indoors the chief trouble is with insect pests, various methods of battling with which are given under many headings throughout this work. *See August: Border: Garden; Insecticide; July; June.*

SUMMER CHAFER. This pest of the rose is similar to the common chafer or May bug, and it feeds in the evening, attacking both the foliage and petals of flowers. The only way of dealing with chafers is to seek the pests, during dull days and evenings, amongst the petals of blooms, immediately destroying all that may be found.

Seek also in the ground for their fat white grubs that feed on fibrous root-lets, as well as on the skin of large roots, applying a little sulphate of iron to the soil during late autumn and early spring. If beetles are seen in flight around trees, give a spraying with arsenate of lead wash. Regular warfare must be waged against all garden chafers and their white larva. *See Rose; Spraying.*

Summer Chafer, slightly reduced.

SUMMER HOUSES: RUSTIC AND FORMAL

Points to Remember in their Construction and Situation

The amateur is herein told how to construct a summer house, a choice of styles being offered. Other useful information will be found under such headings as Arch; Garden Furniture; Rustic Work; Steps; Thatching; Trellis.

In a variable climate a well planned and built summer house provides the necessary shelter for long hours to be spent in the garden. Many days, even in winter, can be thus enjoyed, especially if the summer house is of the garden-room type, with casement windows and glass panelled door. Where there are children the summer house forms a delightful playroom or nursery, in which they can have the benefit of fresh air in safety, and in hot weather the shelter may be fitted up as a sleeping room or serve as a dining room. Such a summer house to be practical should measure from 8 to 10 ft. square.

The furnishing of summer houses should be plain or rustic in character, according to the nature of their structure. Painted wood or cane, or natural teak wood furniture, fabrics which will not fade or deteriorate with damp, and cottage earthenware or rough pottery meal services are always suitable, while wicker and rustic wood benches, tables and seats are appropriate for the simple type of structure illustrated in Figs. 1 and 6.

The placing of the summer house in the garden is of great importance, not only from the point of view of getting shelter from north and east winds, but also because a pleasing structure of this kind can enhance the design of the garden. Fig. 1 illustrates the charming placing of a thatched shelter on a southern slope with a background of trees and a foreground of stone steps. The summer house is covered with wavy-edged elm boarding, is rustic in appearance, and in perfect accord with the rock garden which surrounds it.

Summer House. Fig. 1. Thatched summer house of rustic appearance, well suited to the rock garden which surrounds it and to the stone steps which approach it. (Humphrey & Vera Joel)

Delightfully chosen for its surroundings is the summer house pictured in Fig. 2. This is of serviceable size and solid construction, particularly suitable to the formal Dutch garden which it enhances.

The tiled roof is supported on stucco-coveted brick pillars, the side windows are glazed and the floor is bricked. A charmingly designed garden seat furnishes the interior, but there is plenty of room for other chairs and a table. Such a dignified type of shelter is suited for a town garden.

For a more open setting Fig. 3 shows another type of equally picturesque summer house, also of quite substantial construction, thatched with straw. The opening is framed by the rough hewn posts which support the front. The sides and back are filled in with rustic work. There is a brick floor, and the semicircular space in front is paved with rough hewn timbers.

Another summer house with an open front is shown in Fig. 4. It is built with a rebated framework to allow the weatherboarding to be nailed flush with the outer corners of the uprights, and is supported

on a suitable brick or concrete foundation. Hinged casement windows are fitted in front and at the sides. The roof is boarded to overhang in front and at the back and sides, and is supported by rafters fitted against a small ridge board and finished with a capping[^]planed on both sides to the roof angle.

The floor is boarded with 1 in. tongued and grooved boards, suitable joists being placed at intervals of not less than 18 in. The construction can be arranged in sections with a separate floor, to which the front, back, and the two ends, as complete sections, can be bolted. The roof in this case is made in two halves, and bolted to the top framing and joined on top with a capping.

Summer House. Fig. 2. Set in a Dutch garden, this formal summer house with its red-tiled roof, brick floor and stucco-covered pillars is an admirably chosen shelter for a town garden. (Humphrey & Vera Joel)

Stock Models. Fig. 5 shows a house which is built up on a square floor supported on a stout foundation provided with a revolving gear. The newest form of this is similar to that employed for locomotive turntables and does not stick through rust or wear. The whole building

can be easily turned to catch the sun or to avoid bitter winds. The revolving gear is to be found in the less expensive types of summer house, as well as in the larger structures. The roof of this example is thatched, but though this material is coolest and most picturesque to use, weatherboarding or oak shingles could be substituted. The front of the summer house is provided with two windows (shown shuttered) and a door with glazed upper panels. There are also windows at either side.

Above. Fig. 3. Summer house with thatched roof and heavy rough-hewn supports overlooking a sunk garden in Sussex. The sides and back are of rustic work and there is a brick floor. (Humphrey & Vera Joel)

Summer House. Left. Fig. 4. Attractive structure of stained weatherboarding, open at the front and with casement windows at front and sides.

Above. Fig. 5. Revolving summer house that can be turned round so that the front windows, here shown shuttered, may face the sun. (Courtesy of Boulton & Paul, Ltd.)

Fig. 6. Summer house constructed with ordinary poles roofed with a thatching of willow faggots.

Stock models can be obtained of shelters which will suit most gardens. Walls are made of deal or of wavy-edged elm boarding, or for a lighter type of shelter are of woven reeds. Some houses are made on a multiple unit system. By this means it is possible to order a shelter which will be of the exact size required when constructed. The units are obtainable in 4-ft. and 6-ft. lengths and in two heights. Each unit can be used as a plain wall, or with a window or door, and multiples or combinations of the units permit of putting up a structure to meet any requirement. Roofs also admit of a variety of treatment. Existing structures may be afterwards extended at small expense and with very little trouble by means of this unit system.

Rustic Summer House. A rustic shelter can be constructed with ordinary poles, such as may be purchased at small cost in most country districts. A simple structure is shown in Fig. 6. It measures some 7 ft. in width and 6 ft. in breadth, the height of the corner posts being 6 ft. 6 in. clear above the ground. It is roofed with thatching employing faggots made up from young willow. Alternatively the roof may be covered with straw or thatched with heather.

Rough drawings giving the leading dimensions are prepared and used as a guide while the work is in progress. The plan of the building is marked out on the ground with the aid of pegs and lines, after which seven upright poles are erected. These should be well embedded in the ground, and the tops finished off level. Cross-pieces are nailed to the tops of the three uprights on either side of the shelter. The cross-pieces should project about 9 in. beyond the corner posts. They are fitted by making little flats on the undersides of the cross-pieces, chipping away the round part and securing the cross-pieces with 4 in. or 6 in. nails.

Rafters for the roof can be fixed by first setting up tie bars across the back and front pairs of uprights, and erecting a temporary upright in the middle of them to support the ridge pole, afterwards nailing the rafters to the ridge. The horizontal members are nailed, one near the ends of

the rafters, and one in the middle of their length. The work is completed by fixing short uprights from the crossbar to the rafters at each end of the building.

The roof may be covered next. The faggots are most easily fixed with soft galvanized iron wire, wiring the bundles or faggots to the cross-pieces on the roof. The exact method of covering the roof will have to be modified according to the material employed, but if ordinary brushwood is used it can be laid with two layers of faggots. Each faggot is separately wired to the roof, and the whole secured with a further turn of wire. The end of the faggots should be trimmed off with shears or a bill hook.

The cross-pieces between the uprights are fixed at about the middle of their height, and pieces should be nailed from post to post on all three sides, leaving the front open. A crosspiece is fitted near the ground to act as a support for the lattice work which forms the walls or sides. This may consist of poles about 1 in. diameter, nailed to the uprights and cross-pieces with in. wire nails. They are set diagonally, each panel running in opposite directions, as shown.

Seats are provided on three sides by making gallows brackets. These are spiked to the uprights, one being fixed to each. The brackets in the angles of the building should be set at an angle of 45° to the side walls to form a support for the poles used for the seats. The top of these seats should be about 18 in. off the ground. The poles are nailed to the tops of the gallows brackets and overlapped slightly at the angles or comers to give the effect of a mitre.

The back and sides of the summer house can be completed in trellis work, set diagonally. The whole may be treated with wood preservative stain or varnished. In the latter case the bark will have to be stripped off the timber before it is erected. Some of the harder woods are quite satisfactory if the bark is left on them; with others it is desirable to remove it; but there is no hard and fast rule for this part of the work, and it is largely a question of appearance. Useful hints will be found in the articles Arch and Rustic Work. The same method of construction can be used for a more elaborate structure, taking care that the principal supports have the requisite strength.

SUMMER PUDDING. This is a pudding made from bread and stewed fruit. It is a good way of using up stale bread, and any fruit in season may be used. It is advised specially for those who are unable to eat pastry with fruit. To make it, cut some stale bread into slices rather more than $\frac{1}{4}$ in. thick. Trim off the crusts. Cut one of the pieces of bread into a round to fit the bottom of a greased basin. Measure the depth of the basin and cut pieces of bread to fit. Odd bits can be fitted into any spaces as may be necessary. Cut a second round to fit the top of the basin.

When the basin is lined with bread, pour in sufficient hot stewed fruit to fill it. Any kind will do, but it must be nicely sweetened and not too much of the juice used. Lay the second round of bread over as a lid and put a plate on the top of the basin with a weight on it to press the bread down. Leave it until it is cold, then turn it out on to a dish and serve it plain, or with custard or cream.

SUMMONS. The usual method of compelling a defendant to appear in court is to issue a summons, which he is bound to answer. It is usually issued by the magistrates' courts and county courts. Anyone who wishes a summons to be served upon another person to answer a charge should go before the magistrate and make a complaint, which may or may not be taken down in writing and required to be signed by the complainant.

The summons is served by a warrant officer, who is usually a policeman. It orders the defendant to be at the court on such a day at such an hour to answer the charge preferred against him.

A county court summons must be issued at the office of the registrar of the county court. It is procured by going to the office and filling in a form which will be there supplied, which states what the summons is to be in respect of. There are two kinds of these, ordinary and default. The ordinary summons is issued merely on request and is served by the bailiff of the court. If the bailiff says he is

unable to find the defendant, the plaintiff himself, or his solicitor, may ask to be allowed to serve it. *See Debt.*

SUN BLIND. Sun blinds are blinds fixed to the outside of a window and brought into use during days when there is a good deal of sun. They are also used for the same purpose to protect doors and in conservatories and greenhouses generally. Rooms, especially those that are exposed to an abundance of summer sun, need the protection of sun blinds, both to keep them cool and to protect their wallpapers, curtains, and other furnishings from becoming faded.

Wooden shutters are sometimes made to serve as sun blinds, and, though effective enough for this purpose, they shut out the light and make a room rather gloomy. Sun blinds also have the advantage of giving the house a bright appearance and can be fitted by an amateur.

The colour for sun blinds should be determined by the colour of the paint or brickwork of the house. Striped blind fabrics are the best choice, as they are obtainable practically fadeless and clean and wear well. If sun blinds are damped by rain, they should be left open until dry, otherwise they may rot.

The box-head spring roller blind is constructed on the same lines as ordinary indoor blinds, except that a boxing of some kind must be rigged up to protect the blind from the elements. A central cord is used to draw the blind down and secures to a cord-holder on the window sill, thus preventing the blind blowing about on a windy day. The blind can be made of striped or any other material that is strong and durable. It is attached to the blind roller as described for indoor blinds. Japanese rush blinds, in some shade of green, can be fitted in exactly the same fashion.

A sunk porch or entrance door is easily shaded, either with a plain or a spring roller blind attached to the top of the framework over the fanlight. The blind should be long enough to reach at an angle from the fanlight to the front of the porch, where it is secured by a crossbar of wood or metal, inserted through a pocket formed in the material. This rod slides into two eyes or staples let into the brickwork when the width inside the porch is greater than at the entrance. Otherwise it is secured with short lengths of light brass chain. The blind may hang down beyond this rod as much as desired. The rod must be at least 6 ft. above the ground so as not to inconvenience passers-by.

The term sun blind is also used for a rectangular piece of material that is hung in front of a door during hours of sunshine to protect the paint. For this a strong fabric should be selected, preferably one with green stripes, and the colour should be guaranteed not to fade in the sun. Having been cut and hemmed to the required size, it can be hung by fastening a ring at each of the top corners and placing these upon two hooks put in position above the door. *See Awning; Blinds; Window.*

SUNBURN. It is not the heat of the sun, but the chemical action of the violet and ultra-violet rays which causes sunburn. It has been found that the condition is most likely to result from the early morning sunlight or from the reflected light from water or snow-covered ground. A dry wind also favours its occurrence, as it deprives the skin of its natural moisture. Fair-haired people are affected more readily than dark people.

In the most common form there is nothing worse than browning of the skin, which acts as a protective from the heat of the sun. In severer forms the face becomes red, painful and perhaps swollen. There is tingling and itching, and a few days after exposure the skin peels off. In sunburn of a still greater degree blisters are formed. When people are daily exposed to the powerful rays of the hot sun for a long time the skin is likely to become dry and wrinkled.

For the redness and irritation cooling and soothing lotions should be applied. In the slighter cases a little eau-de-Cologne mixed with three times its quantity of water is very effectual. Rosewater and elderflower water are also used. Sometimes an astringent lotion, such as Goulard's water, dabbed on the face and allowed to dry is most serviceable.

The following will be found an admirable cooling application for the skin after returning from an outing in the sun. It should be dabbed on the face with a piece of lint or very clean rag:

Tincture of benzoin	1 dram.
Eau-de-Cologne	1 oz.
Almond mixture	2 oz.
Rosewater, enough to make	8 oz.

A simple but very efficacious cooling application for sunburn is freshly-sliced cucumber lightly rubbed on. *See* Complexion; Dermatitis; Face; Freckles.

Sundae. *See* Glassware; Ice.

SUNDEW. There are three native species of sundew, which is an insect-eating plant and a hardy perennial. Of these the best known is *Drosera rotundifolia*, a low plant with roundish, reddish, radical leaves covered with sticky, shining, glandular hairs, which glisten in the sun. It is found in parts of Great Britain, Ireland and the Channel Islands in boggy places.

Although hardy, it is sometimes grown in pots as an interesting greenhouse object. A compost of peat and sphagnum moss is suitable. Propagation is by seed or division. There are several other species.

SUNDIALS: HOW TO ERECT AND SET A Picturesque Feature for Gardens Large and Small

The earlier part of this article describes the building of a sundial, while in the latter our readers are told how one should be set. *See* Brick; Cement; Concrete; Stone; and other entries that deal with the tools and materials used by the amateur worker; also Flower Garden; Garden.

A sundial may be fixed vertically on a wall, as Fig. 7, but it is generally found in a horizontal position, mounted on a pillar or some form of pedestal like that illustrated in Fig. 1. This is set up in a sunny spot in the garden, in such a position that at midday the shadow of the gnomon falls exactly on the 12 o'clock mark on the dial.

Fig. 1. Skilful placing of a pedestal sundial in a long and terraced path.

Making a Brick Pillar. Brick is perhaps the best material for the amateur to use. First of all the foundation has to be prepared. If the site selected is in a grass plot, the top soil must be removed until firm ground is reached. This is made up with broken brick or hard core, and coated with concrete floated off to a level surface. The centre panel may be made up with crazy, or random flagstones laid in cement mortar, or the whole of the area can be covered with brickwork.

The crazy paving can be surrounded by a brick border. The centre of the site is ascertained by driving four pegs, one at each corner, and stretching a line tightly between them, the point of intersection of the two lines exactly marking the centre. A scale drawing should be made of the pillar showing the number of courses, the positions for the tile creases, and any other structural

details. The drawing given in Fig. 2 is that from which the pillar shown in the accompanying illustrations was constructed.

Fig. 2. Showing number of brick courses and position of tile creases in sundial pillar illustrated below

The worker should refer to the article on bricks for details of the making up of mortar, method of laying the courses, etc. The first course is laid and levelled, and the second course is then set upon the first, half a brick's width less in size, so as to form a stepping.

The bulk of the pillar measures 14 in. square, and is easily built up by arranging the bricks alternately, one brick lengthways and the next at right angles to it. This operation is repeated for three courses, and then the tile creasing is laid in a similar manner, consisting of two courses.

A further three courses of bricks are laid on the tiles, and another tile creasing course. The tiles should be tapped up level to the sides of the shaft by striking them lightly with the handle part of the trowel. They should be well bedded in mortar and pressed down firmly, as indicated in Fig. 3. Two courses of bricks are then laid, to complete this part.

The over-sailing course of bricks remains to be laid on the top of the pillar so that they project over 1 in. beyond the face of the shaft ; for this purpose it is necessary to cut a closer, that is, a short piece of brick, to fill the gaps between the whole bricks. The overhang can be measured with a rule or

gauged with a small wooden gauge having a notch cut in one edge to represent the amount of overhang. The bricks should be bedded in a thick bed of mortar and well tapped home with the end of the trowel, as shown in Fig. 4.

Sundial: stages in making a brick and tile pillar for mounting a sundial. Fig. 3. Second course of tiles being laid. Fig. 4. Laying over-sailing course of bricks at top of pillar Fig. 5. Use of spirit level when fixing capstone in position; this can be a thick, flat stone or be cast in concrete.

The capstone can be a piece of thick, flat stone or paving stone, 18 in. square and about 2 in. deep, or in its absence an excellent substitute is obtained by first preparing a rough wooden mould and casting a capping piece in concrete. To provide a means of attachment for the plate of the dial four rectangular pieces of wood are arranged in the centre of the mould before the concrete is filled in.

The mixture is poured into the mould box in a moist condition, and the surface should be trowelled off smooth. Instructions for moulding concrete are given in the article Concrete.

The concrete must remain in the box for a week or more until it has set thoroughly hard, after which it may be removed and placed upon the top of the column, first covering the latter with a thick bed of mortar. When placing the slab, it is important to get a uniform overhang on all sides of the shaft, and to lay the slab flat on top of the brickwork. The slab should immediately be levelled up, by laying a large spirit level diagonally across it, first from one side and then the other, as depicted in Fig. 5, tapping the upper surface of the slab and gradually working it home until it is quite level. It is highly important that the capstone should be perfectly level. The dial itself should be procured before dealing with the capstone, so that the correct position of the wooden fixing blocks can be determined. In the case of a brick or stone capping, lead or hardwood plugs are inserted for the fixing screws. Leave the plugs full large, so that there is room for adjustment.

Setting a Sundial. The dial is attached to the top of the pillar by screwing it down with four screws to the wooden blocks embedded in the concrete capping. The gnomon should point north and south, with the highest part pointing towards the north.

A sundial made for one particular place is quite useless for another place in a different latitude. Before setting a sundial it is essential to know whether the sun is fast or slow of the clock. Sundials show apparent time, whilst clocks measure equal or mean time, so that if a perfectly regulated clock were set to apparent solar time it would agree with the sundial only on four days of the year.

A solar day is the period which elapses between two successive returns of the sun to the meridian. The moment the sun reaches its highest point in the heavens, that is, the highest point above the horizon, it is true noon. Sometimes the sun is as much as 14 min. 28 sec. after the clock, and at others 16 min. 18 sec. before the clock, at XII o'clock noon. Mean time is that shown by clocks generally, the day of 24 hours being obtained by taking the average of all the solar days of the year. Place the dial upon the platform and move it about until the shadow cast by the gnomon on the dial shows the correct time within a few minutes.

Sundial. Fig. 6 (above). Sundial elaborately marked with cardinal points of the compass and ornamental engraving. Fig. 7 (right). Dial plane for a vertical wall surface

Fig. 6, courtesy of Francis Barker & Sons, Ltd.

To read the time by sundial, stand on its north side. The forenoon or morning hours will then be on the right-hand side of the dial, whilst the afternoon hours will be on the left. At noon the shadow of the gnomon will fall within the space between the two lines at XII o'clock.

When the dial is in the correct position mark the platform or capstone through the holes in the dial for the fixing screws. Finally adjust and fix the dial at XII o'clock noon. Of course it can be fixed at other times, but XII is the best. As before mentioned, the sundial and clock coincide only four times in a year, about April 15, June 14, Aug. 31, and Dec. 25, and it will be found convenient to fix the dial on or near one of these days, provided that the sun is shining.

Set a watch to the mean time of the place where the sundial is to be fixed, and ascertain on the day the sundial is fixed the difference between mean and solar time. Say the dial is to be fixed on April 10—the watch having previously been set to the correct mean time of the place, by adding the difference fast or slow of Greenwich—it will be seen that the watch is faster than the time shown on the sundial by 1 min. Move the dial about on its platform until the space between the two lines at XII o'clock is filled with the shadow cast by the gnomon and the watch shows exactly 1 min. past XII o'clock. When correct, firmly screw the dial to its platform.

If the dial is fixed during the period in which summer time is in force, it must be remembered to make the necessary allowance.

SUNFLOWER. There are both annual and perennial sunflowers of considerable value in the garden. The latter plants flourish in ordinary soil and spread rapidly. They ought to be lifted, separated into small pieces, and replanted every autumn to keep them under control. Some of the best are *Helianthus multiflorus*, 4 ft.; *rigidus* and its variety. Miss Mellish, 6 ft.; Golden Monarch, 6-8 ft.; and *Soleil d'Or*, double, 4 ft.

Sunflower. Left, dark-centred blooms of the common annual sunflower. Right, double perennial variety

The annual sunflower (*Helianthus annuus*), which bears enormous circular flowers on stems, 6 to 8 ft. high, is a familiar plant in cottage gardens, but the newer sorts, 3 or 4 ft. high, with smaller yellow and reddish flowers, which are more valuable, are less grown. The annual sunflowers are raised from seeds sown in spring. *See* Prairie Sunflower.

Sunlight: In Medicine. *See* Heat Stroke; Light; Rickets; Tuberculosis.

Sunstroke. *See* Heat Stroke.

SUPERHETERODYNE RECEIVER. It is the superheterodyne principle of reception which has made possible the inexpensive wireless set having a high order of selectivity and considerable range. It has also assisted in bringing the reception of short-waves within the province of the ordinary listener by eliminating the delicate separate reaction control.

A superheterodyne receiver is in a continual state of oscillation, as would be a set employing an ordinary tuning and reaction system if the reaction control were left turned full on all the time. This oscillation is combined with the energy received from the broadcasting station and the resulting "beat" effect is amplified and then rectified for passing to normal low-frequency amplifying circuits. The "beat" effect occurs when two sound frequencies are combined. The two engines of a double-engined aeroplane can often be heard to produce a low, throbbing note. This is a "beat" note.

The advantage of the principle as applied to radio is that a high frequency current of one constant frequency is derived from the energy of any broadcasting station by combining it with a "local oscillator" in the set. No reaction adjustment is needed, and subsequent high frequency amplification can be carried out with fixed tuning "intermediate amplifiers" that do not need tuning adjustments as with different stations. Also the H.F. amplification can be carried out much more efficiently at the lower frequency.

It is very advisable to have a conventional stage of high frequency amplification preceding the "first detector" or "mixing circuit," in order to reduce interference from atmospheric and other forms of electrical disturbance to which the "superhet" is otherwise rather susceptible owing to its sensitiveness.

A typical superheterodyne circuit is as follows: first, a normal high frequency amplifying stage using a high frequency pentode or screen grid valve. This is followed by a pentagrid valve which combines the functions of "oscillator," "mixer" and intermediate frequency amplifier. Further intermediate amplification may be provided by an H.F. pentode. There may be a double-diode triode valve for applying automatic control and for converting the H.F. current into L.F. current and amplifying at low frequency. The final valve may be an L.F. pentode or a triode output type. In a mains "superhet" there will also be a rectifier valve or a metal rectifier. In some cases metal rectifiers are also employed as "second detectors." *See* Heterodyne.

SUPERPHOSPHATE. In garden parlance this is the valuable manurial preparation superphosphate of lime. It is obtainable in three qualities, viz., ordinary, containing about 25 per cent soluble phosphates; concentrated, embodying up to 45 per cent, of the same essential plant food; and double, a grade in which soluble phosphates as high as 80 per cent often appear. For ordinary farm and fruit crops, the first named is quite suitable. The concentrated may be used for more exacting culture, but for special classes or specimen plants the double grade is best.

As superphosphate contains only phosphoric acid, other essential plant foods must be supplied by using potash and nitrogenous manures, and when used in suitable quantities the mixture gives the best results on general crops in most soils. A good average quantity to use is 2 to 3 oz. per sq. yd.

Unless required for immediate use superphosphate should not be combined with nitrate of soda, and it is not advisable to apply it to acid soil. *See Manure.*

SUPPER. In many households where a hot dinner is cooked in the middle of the day, and usually on Sundays, supper is served in the evening in place of a more formal meal. Except in warm weather, when all cold food may be preferred, soup and a hot fish or savoury dish are generally liked, with a cold joint, meat pie or galantine and a salad on a table or sideboard for those who want a more solid meal. Any cold sweet, such as a jelly, stewed fruit and custard, blancmange or pastry, is suitable for supper, with cheese and biscuits to follow, unless the savoury chosen contains cheese. Coffee is sometimes liked, or the usual cold family beverages.

Entertainment suppers are nearly always cold, unless hot soup in cups is served, or there are facilities for cooking special hot dishes as required. Mayonnaises, game, poultry, galantines and terrines, salads, cold savouries such as stuffed olives or caviare prawn croûtons, creams, fruit jellies and other sweets, all kinds of ices and every variety of dessert are suitable refreshments. When served at a big party, the dishes are placed down the length of the tables in the dining room in order that the guests may help themselves, servants, or waiters engaged for the occasion, standing behind the table to assist as required. Cocktails may be a feature at the opening of the party. Champagne and other wines are provided at a smart supper, and various cups, other iced drinks, and hot coffee.

Where a number of guests are entertained and the staff is small, the buffets and tables should be well arranged so that many people can help themselves at the same time without a scramble. A good idea is to have all the cutlery laid out on a first table with plates piled in their respective sizes. The guests take what they require and proceed to the buffet where the food is laid out within easy reach. Drinks and glasses are placed on another table, and service is further facilitated if there are a number of small tables and chairs placed well apart from the buffet to which people may retire to eat what they have chosen.

Small Suppers. More intimate, sit-down suppers for a small number of guests may be given after a theatre or on a Sunday evening. A prettily decorated table is an important factor. A summer supper for such a party might consist of grape fruit, salmon mayonnaise, galantine of chicken, cold veal and ham pie, strawberry trifle, meringues filled with ice cream, hock or - cider cup. A winter menu could consist of soup, oyster patties, hot cutlets and vegetables, or salmis of game or chicken en casserole, with some cold meat dish and celery salad, little fruit jellies and cheese straws. Any cold savoury or sweet should be prettily decorated and arranged on a suitable dish.

A chafing dish is an admirable aid at such a party, as it enables the hostess to cook a variety of appetizing little dishes at the table. Omelettes of any kind, various fricassées, scrambled eggs with anchovies laid across the top, and other savouries can be ready in a few minutes. If food has been prepared and cooked beforehand it can be kept hot on a food warmer, the necessary heat being supplied through a flexible tube connected to a gas point. An electrical contrivance is a table cooker which can be put over a large plate on which has been previously placed the sausages, cutlets or anything else of the kind which it is desired to cook. The current is then switched on to cook the food. When done, the food can be left under the cooker to keep hot for some time after the current has been switched off. The cooker can afterwards be inverted to stand on its insulated feet and the hostess can then boil a kettle on it for coffee.

Every evening suppers for children should be light. Party suppers—except for quite small children, when the simplest of the suitable dishes are usually selected—are served on the same lines, without the wines but with claret cup and iced drinks, as are those at grown-up entertainments. *See Chafing Dish; Cocktail; Salad; Sandwich; Table Laying.*

SURNAME. A surname is the name which a person has or adopts in addition to his Christian name which was given to him at his christening or which he was registered as possessing. Anybody may adopt any surname he pleases without permission, except an alien, who may not change his surname without the leave of the Home Office.

Nobody has any right to adopt a surname with intent to deceive. If he does, the true owner of the name, if able to prove damage or likelihood of damage to himself or his business, may obtain an injunction. *See* Name; Naturalization.

SURTAX. This is an additional income tax, and in Great Britain is levied on all incomes, whether earned or unearned, that are in excess of £2,000 a year. In estimating the total income of an individual for purposes of surtax, the amount taken is the full gross amount of the income without any deductions for earned income and other abatements, and before deduction of income tax proper. This means that a man with an income of £2,100 must pay surtax, although, owing to allowances, he is only liable to pay income tax proper on perhaps £1,700.

The rates of surtax in force for 1937-38 are given below. No changes have been made since the Budget of October, 1931. The tax is payable as a deferred instalment of income tax on January 1, following the year of assessment for which it is charged.

On the first	£2,000 of income	Nil	
„ „ next	£500 „ „	1s. 1½ d.	in the £
„ „ „	£500 „ „	1s. 4½ d.	„ „ £
„ „ „	£1,000 „ „	2s. 2-2/5d.	„ „ £
„ „ „	£1,000 „ „	3s. 3-3/5d.	„ „ £
„ „ „	£1,000 „ „	3s. 10-1/5d.	„ „ £
„ „ „	£2,000 „ „	4s. 4-4/5d.	„ „ £
„ „ „	£2,000 „ „	5s. 6d.	„ „ £
„ „ „	£5,000 „ „	6s. 0-3/5d.	„ „ £
„ „ „	£5,000 „ „	6s. 7-1/5d.	„ „ £
„ „ „	£10,000 „ „	7s. 1-4/5d.	„ „ £
„ „ „	£20,000 „ „	7s. 8-2/5d.	„ „ £

On all Income in excess of		
£50,000 a year	8s. 3d.	„ „ £

Thus a man with £7,500 a year pays £859 7s. 6d., supertax made up as follows:

£		£	s.	d.
500 at 1s. 1½ d.	of income	27	10	0
500 at 1s. 4½ d.	„ „	34	7	6
1,000 at 2s. 2-2/5d.	„ „	110	0	0
1,000 at 3s. 3-3/5d.	„ „	165	0	0
1,000 at 3s. 10-1/5d.	„ „	192	10	0
1,500 at 4s. 4-4/5d.	„ „	330	0	0
	Total	£859	7	6

See Income Tax.

SUSSEX FOWL. The most popular fowl among British poultry breeders is the Sussex, and it has gained its position by sheer merit. Sussex fowls have secured the chief awards in the dead table-fowl classes at the Dairy and Smithfield shows and in the principal laying competitions. There are four colours in this breed—light, red, speckled, and brown. The first-named are the most popular among both utility breeders and exhibitors. The browns are the largest of all, and with the speckleds are held in great esteem by those who breed and fatten for the market.

Sussex are large-bodied birds, broad in back and deep in breast, very white in skin and flesh, and carry an abundance of fine quality white meat. The hens are good winter layers and careful mothers; the chicks are hardy and grow quickly. Full-grown males weigh from 8 lb. to 10 lb., hens 6 lb. to 8 lb., the browns generally going 1 lb. or 2 lb. heavier. The eggs are brown and average 8 or 9 to 1 lb. *See Fowl; Poultry.*

Sussex Fowl. A typical speckled cockerel. (Courtesy of The Poultry World)

SUSSEX PIE. To make this, take 2 oz. sultanas, 2 oz. currants, 3 oz. sugar, 8 oz. cooked apples, and a pinch each of cinnamon and mixed spices. Make a little short-crust pastry and line a pie-dish with it. Having washed the sultanas and currants, put them, with the apples, sugar, cinnamon, and spice, into the dish, cover it with pastry, and bake it in a moderate oven for an hour. *See Pastry.*

SUSSEX WARE. The mellow charm of the hand-made roofing tiles and flower-pots of unglazed red earthenware for which Sussex is famed is due to centuries of traditional skill working with good material. There can be no doubt that, since at least as far back as the coming of the Huguenot refugees, domestic utensils also were produced in the neighbourhood of the coast ports. These were wrought with mixtures of the fine, fight, local clays, and 18th-century examples may be found here and there, although they are not easy to identify, because they are generally undated and unmarked.

A posset cup in Sussex pottery, a distinctive red ware, with date stamped in white.

A ware of a semi-faience type, which has a red body covered with tiny stamped ornaments embedded in a white slip and lead-glazed, was made at Chailey and Rye in various small potteries for about half a century after 1793, and comprised pipkins, pitchers, flasks, stands and other useful forms. More than 100 years ago a factory was established at Crowborough for the production of glazed and unglazed brown crockery, including the Sussex pig used for rural wedding toasts.

After the mid-Victorian art revival attention was turned, both here and in Rye, to more ambitious forms, such as jugs and vases, candlesticks, and other decorative objects. Upon these foliage was moulded in simple, natural designs and covered with a brilliant brown or green glaze, not unlike that of some Devon ware, and sometimes rivalling old

Rockingham in effect. Cream-coloured clays were used for basketwork and other styles of greater delicacy, and out of this industry has arisen a distinctive type of art pottery known as rustic ware. *See Pottery.*

SWAG. In furniture a swag is a garland or festoon suspended between two points. It was used by the Adam brothers and their successors on carved, inlaid, and painted pieces of furniture, and is seen a great deal in all kinds of decorations of the latter part of the 18th century. Many chair backs by Hepplewhite and Sheraton have swags, and swags are also a frequent ornament on painted tables of that time. *See Adam Style; Queen Anne Style.*

SWAGE. When finishing iron while it is hot blacksmiths use a tool known as a swage. There are several forms, but essentially they all consist of a form of hammer head or some other face which has a ground groove across it. Swages are generally used in pairs. One, known as the bottom tool, has a shank which fits into a hole made for that purpose in the anvil. The upper tool is held with an iron rod handle, which is grasped by the smith in the right hand while the work to be swaged or rounded is held in the left hand.

The metal is brought up to its proper heat, and roughly rounded by hammering in the ordinary way, somewhat as described in the article on forging (q.v.). After this treatment it is reheated, if necessary, and rested in the groove in the bottom tool. The top tool is then placed into position on the upper side of the work, and an assistant strikes the top tool a heavy blow with a sledge or other hammer, according to the size of the work. At the same time the smith partially revolves the metal between each hammer blow, thus ultimately rounding off the metal and working it up to a smooth surface. If carefully done, tolerably good rods can be obtained.

Instead of using the bottom tool, a large rectangular block is often utilized which has grooves across its edges. It is known as a swage block.

SWALLOW-WORT. The celandine (*Chelidonium majus*) has been given this name because its flowers open about the time when the swallow arrives, and the drying-up of the plant takes place when the bird is departing for warmer climes. It is useful for shady garden corners.

It has an old reputation as a cure for warts, and as a remedy for scorbutic eruptions.

SWANSDOWN. Because of its extreme softness the down or under plumage of the swan is the most popular material for powder puffs, but it is also used for trimming purposes on dressing gowns and jackets and on babies' bonnets. It can be bought in white and pale colours and is obtainable in pieces of a suitable size for puffs or as a trimming by the yard in narrow strips.

Swansdown should be washed in warm soapy water. The lather is best produced with soap jelly; for, like many other delicate materials, swansdown suffers if rubbed with soap. Squeeze it gently in the water until it is clean, and dry it before the fire, shaking it all the time to restore its original fluffiness.

SWANSEA WARE. All kinds of pottery and soft paste porcelain fabrics were produced at Swansea for more than a century down to 1870. During the 18th century the styles included salt-glaze, cream ware, black basaltes, gold and ruby lustre, and printed ware, which was done both in dark and in light blue, and also in both black and brown.

A so-called opaque porcelain or china decorated with fine bird and flower paintings is highly prized by collectors. This opaque china is not true porcelain but a fine white earthenware fabric. An example is illustrated of a bough-pot with a beautifully painted floral pattern. A bough-pot was a

vase originally intended to hold flowering boughs, and the term is also spelt bow-pot and used for a pot on which a floral design was painted.

For a few years a translucent porcelain was made. The decorations resemble those of contemporary Staffordshire fabrics, but the body contained no felspar, and was consequently very soft. Later on the paste used was harder, at first with a greenish tinge, and afterwards a dead-white glaze.

Some of the pieces decorated at Swansea by Nantgarw painters were marked Nantgarw. At a second factory, established at the same time, cow milk-jugs and milkmaid figures were turned out and exported in large quantities to France. Etruscan ware, so marked, was made of a local red clay, with classical figures in enamel colours. Another factory turned out useful services in pure white.

It was at Swansea that the Cambrian ware was produced. The usual mark, stamped or stencilled, comprised one or two tridents, with the place-name, and sometimes the potter's name, such as Dillwyn & Co., or Bevington & Co. Pottery is still made in the neighbourhood of Swansea. *See* Cambrian Ware.

Swansea Ware. Bough-pot of "opaque porcelain," a species of white earthenware, with a painted design of birds and foliage.

Sweat. *See* Perspiration.

SWEATER. This heavy type of jersey is made in various sizes both for men and boys, the chest measurement being the usual standard. Sweaters are made as a rule of white wool, but sometimes colour is introduced at the neck and as a border. Sweaters in variegated colours are occasionally seen and they are made with club or regimental colours at neck, wrists and waist. These are worn by members of cricket and football clubs. As regards pattern, some are made with a collar and some without. The collar may be of the roll or turn-down variety.

The knitted garment known as the pullover is a kind of sweater. This is worn by men and boys and is sold in a variety of colours. Most of them have two pockets, some have a decoration around the neck and elsewhere, while others are quite plain. They are also made in check patterns in two colour mixtures, in three colour stripes, and in other patterns. Stockings to match may be knitted, or are sold with many of these garments.

How to Knit. To knit a useful, standard type sweater with a V-shaped neck the requisites are 18 oz. of Beehive fleecy wool, two No. 7 and four No. 10 bone knitting needles, pointed at both ends. The garment should be worked at a tension to produce about 5 stitches and 7½ rows to the inch measured over the plain portion. For the back, cast 96 stitches on the No. 7 needles. 1st row: Knit 4, * purl 2, knit 2. Repeat from * to the end of the row, always slipping the first stitch throughout. Repeat this row 20 times. 22nd row: Knit plain. 23rd row: Knit 2, purl to the last 2 stitches and knit 2. Repeat these last 2 rows until the work measures 30 in. from the beginning. Cast off 26 stitches at each end, and leave the 44 stitches at the centre on a No. 10 needle.

The front should be worked exactly like the back until it measures 22 in., finishing with a purl row. Then begin to shape the neck as follows: 1st row: Knit 45 and then turn. Leave the remaining stitches for the second half of the neck. Continue in the pattern, decreasing once at the neck end of the needle in every third row until only 36 stitches remain; then cast off. Taking the needle where the stitches are left, slip the first 6 stitches, at the centre of the front, on to a No. 10 needle, and, on the remaining stitches, knit the second half of the neck to correspond with the first.

To make the sleeves, cast on 76 stitches, 1st row: Knit 4, * purl 2, and knit 2. Repeat from * to the end of the row. Repeat this row 30 times. 32nd row: Knit plain. 33rd row: Knit 2, purl for the last 2 stitches and knit 2. Repeat these last two rows throughout the sleeve and increase at the beginning and end of the 7th, then every following 6th row until there are 7 increasings at each side of the work. Then knit without shaping until the underarm seam measures 18 in. without the cuff and cast off loosely. To make up the sweater, press each of the pieces carefully. Sew up the shoulder and side seams, leaving 9 in. for the armholes. Sew up the seams of the sleeves and then fix these latter in the armholes, placing seam to seam.

To make the collar, with the No. 10 needles knit the 44 stitches that were left at the back of the neck. Follow on with a second needle, and knit up 29 stitches at the side of the neck and 3 stitches off the extra needle. With a third needle knit the next 3 stitches and knit up 29 stitches at the other side of the neck. Knit 16 rounds in rib of knit 2 and purl 2, increasing 4 stitches in the first round at the centre of each of the second and third needles. Cast off loosely. The collar can be made to look very effective by introducing stripes of a second colour. *See Knitting; Wool.*

Sweating: Of Metals. *See Soldering.*

SWEATING POWDER. In commencing colds and other feverish disorders 5 or 10 gr. of Dover's powder may cause more or less profuse perspiration, and thus diminish the fever. This may sometimes bring the malady to an end. The best time to take such a powder for a cold is at bedtime, and great care should be exercised next day to avoid exposure. Other drugs, such as phenacetin, antipyrin, and antifebrin, also act as sweating powders and reduce temperature, but they are not safe remedies for this purpose, on account of their depressing action on the heart. *See Fever.*

Swede. 1. Soil preparation: bottom spit broken and manured (a). 2. Raised drills (a) for sowing. 3. First thinning. 4. Second thinning. 5. Final thinning. 6. Swedes prepared for storing by wrenching off tops (a) and cutting off tap-roots (b). 7. Properly prepared clamp: a, sand; b, soil; c, straw; 8. Swedes planted close together to provide green tops during winter. 9. Swedes covered with fine ashes (a), through which green tops sprout. (By special arrangement with Amateur Gardening)

SWEDE. The Swedish turnip has been generally accepted as a farm crop, but its value as a winter vegetable is now recognized, and seedsmen offer selected strains suitable for growing in the vegetable plot. Its culture is the same as for turnips, but owing to stronger growth rows should be 18 in. apart, keeping the soil well hoed and free from weeds during summer.

How to Cook. As a vegetable the swede is usually boiled in the same way as ordinary turnips, after being peeled and cut into quarters or smaller pieces. These are put into a saucepan of hot salted water and allowed to boil until tender, which may take anything from 30-60 min. Serve in a: tureen, covered with melted butter sauce.

To serve swedes mashed, boil them in the same way, then rub them through a sieve. Empty the saucepan of water, and put into it a piece of butter the size of a walnut. When this is melted stir in a little flour, then, before it browns, add the mashed swede, well seasoned with salt and pepper. Stir this a minute or two, and it is then ready to serve. *See Sauce; Turnip.*

Swede. Fine roots of this variety of turnip, a useful winter vegetable.

SWEEP. When chimneys require sweeping the sweep should be notified some days beforehand, especially in the spring, when he is in much demand. It is usually found most convenient to select an early hour, and to make the necessary preparations overnight. The sweep often charges a flat rate for all chimneys except a kitchen one, which costs more. These rates are charged on the understanding that he keeps the soot; if the employer wishes to keep it

for the garden, the sweep's charge will be increased accordingly.

The room in which the chimney is to be swept must be covered down. All ornaments should be removed from the mantelpiece, etc., and the shelves covered with newspaper or dustsheets. The furniture also must be covered with dust sheets. *See Chimney; Spring Cleaning.*

SWEETBREAD. These delicate portions of meat consist of the heart sweetbread and the throat sweetbread, and are usually sold in pairs. Both calf's and lamb's sweetbreads can be used and occasionally those of the pig.

It is necessary that they should be very fresh, and before cooking they must be soaked for three or four hours, taking care to change the water occasionally. After soaking, which not only cleanses them from blood, but whitens and renders them more delicate, they must be parboiled for 5 min., then immersed in cold water. This process is known as blanching. Pieces of sinew and gristle are then removed.

They must now be wiped and pressed between two plates, as pressing them will improve the shape and give greater facilities for neat dishing.

To roast sweetbreads, take a pair of calf's sweetbreads and prepare them according to the foregoing directions, then brush them over with beaten egg and roll them in seasoned breadcrumbs. Have ready melted in a saucepan 1 oz. butter, and sprinkle this over the coating of crumbs, then roll the sweetbreads in breadcrumbs a second time. Put them into a baking tin in which 2 oz. butter have been melted, and place them to roast in a moderate oven. They will take 30 min. to cook, and must

be basted frequently with the butter in the pan. Dish them up garnished with fried parsley, and serve with them a good white or béchamel sauce.

Another entrée may be made by the following recipe: Prepare a pair of calf's sweetbreads and cut them in rather thick slices. Put these in a stewpan and just cover them with white stock. Add seasoning of salt and cayenne and sprinkle in a little powdered mace. Add 2 oz. butter and a wineglass of sherry, also 1 teaspoonful lemon juice. Stew very gently till the slices are cooked, then beat up the yolks of 4 eggs with another glass of sherry or ½ gill cream. Add these to the contents of the saucepan and stir over the fire till the whole thickens without letting it boil. Serve very hot garnished with a border of cooked green peas, and just before sending to table squeeze over the strained juice of an orange.

Sweetbread Fricassée. A very good fricassée can be made with either calf's or lamb's sweetbread. If calf's breads are used, procure 1 pair; if lamb's breads, buy from ¾ lb. to 1 lb. Prepare the breads by soaking, parboiling, and pressing, then cut them into neat slices. Have ready 1 pint white stock, add 1 onion, 1 carrot, and a bouquet garni. The onion and carrot must have been prepared and cut up small. Stew the sweetbread in this for 20 min.

Meanwhile melt 2 oz. butter, add 1½ oz. flour, and cook together without browning for 4 min. Remove the slices of sweetbreads from the stock in which they were cooked, then strain it, and add it by degrees to the white roux in the pan. Make it into a smooth sauce, then whiten it with a liaison of 1 gill cream, or milk and cream mixed, and the yolks of 3 eggs beaten together. The sauce must not be allowed to come to the boil after the eggs are added. Mix in the slices of sweetbread, season to taste, add a pinch of powdered mace and 1 teaspoonful lemon juice, and serve garnished with croûtons of fine bread and small rolls of fried bacon.

If no stock is available, cook the pieces of sweetbread in water, and in another pan put 1 pint milk with a prepared and sliced onion and carrot, a bouquet garni, and seasoning. Stew these gently while the sweetbreads are cooking, and then strain the milk and use it for making the sauce in place of stock.

Sweetbread Fritters. Lamb's sweetbreads make excellent fritters. First prepare them as already directed, then cook them in a little stock or milk, well flavoured with vegetable and seasoned. Then cut them in slices about ¾ in. thick, dip each piece in a very light batter, and fry them a golden brown in deep fat. Drain well, and garnish with fried parsley.

Sweetbread Omelette. To prepare this, make a plain omelette according to the directions given under the heading omelette, and before folding it over put some sweetbread, broken into small pieces and reheated in a little béchamel sauce, in the centre. Serve at once in a hot dish. *See Sauce.*

Sweet Briar. Beautiful delicate pink single blossoms of the fragrant Penzance briar.

SWEET BRIAR. Flowering in June, rose pink in colour, with brilliant red berries in winter, the sweet briar or eglantine is noted for the spicy fragrance of its leaves. The perfume emanates from the glandular hairs on the underside of the serrate leaflets and is particularly fragrant after rain. Botanically the plant is *Rosa rubiginosa*. The sweet briar grows wild in the chalk hills and heaths of S. England as

well as in Scotland and Ireland. It forms a delightful hedge for an inner garden. The beautiful large-flowered Penzance briars were raised by cross-breeding between the sweet briar and other roses. *See Rose.*

SWEET CHESTNUT. This is an alternative description for the Spanish chestnut. The chestnut wood used for furniture and other articles is obtained from this tree, not from the horse chestnut, and the same tree produces the nuts which are the chestnuts used for food. *See Chestnut; Spanish Chestnut.*

SWEET CICELY. This plant is a species of myrrh native to England, known botanically as *Myrrhis odorata*. It is a fragrant perennial herb, with graceful feathery foliage and large umbels of creamy flowers. Ordinary soil in any position suits it, and if planted during spring or autumn it will thrive in the shrubbery or wild garden.

SWEET GUM. The hardy, summer-leafing tree that is known as sweet gum or liquidambar has handsome, lobed, maple-like leaves that assume a brilliant colour in autumn. The kind best suited to gardens in this country is *Liquidambar styraciflua*. It thrives in ordinary soil and is increased by seeds or layers. The sweet gum tree attains a height of 50 ft.

SWEET HERB. Parsley, bay leaves, marjoram, thyme, sage, savory, mint, and basil are the sweet herbs most frequently used in cookery. When, as in recipes for stews, etc., the use of a bunch of sweet herbs is recommended, only the first four, tied together with the parsley on the outside, are usually chosen. Sweet herbs can be used fresh from the garden, dried and stored at home, or purchased in packets and bottles. *See Mint; Sage; Thyme.*

SWEET MARJORAM. This is the culinary herb botanically known as *Origanum majorana*. The common marjoram, *Origanum vulgare*, is correspondingly fragrant, and is greatly favoured as a bee flower.

Sweet marjoram thrives in rich soil where the position is sunny. Shoots for drying may be gathered just when they are coming into flower. *Origanum dictamnus*, which bears pink hop-like flowers, and is known as pink hops, is a very pretty pot plant for the greenhouse. *See Marjoram.*

SWEET PEA. This is the loveliest of all hardy annual flowers and a great favourite for cutting. It is grown in immense quantities for market, and is an ideal flower for amateur gardeners. If well grown it will yield four-bloom stems throughout many weeks. In recent years numerous beautiful varieties with frilled flowers of delightful colouring have been raised.

Seeds are sown in pots or boxes in a frame during October, or in a slightly heated greenhouse in January.

During the cold weather the seedlings need only to be kept safe from frost; in mild weather the frame or greenhouse must be ventilated freely. On light soil sweet peas may be sown out of doors at the end of September. When the seedlings are 4 or 5 in. high the tops should be pinched off; this causes fresh basal shoots to develop which will produce finer flowers than the original stem would have done.

After having been well hardened the plants are set out late in March or early April in soil that was dug deeply and manured in winter. To ensure longstemmed blooms and four on each stem the plants must be set at 8 or 9 in. apart and restricted to one stem (unusually vigorous sorts to two stems), all side shoots being rubbed off. Each plant is tied to a tall bamboo cane.

Sweet Pea. A four-bloom stem of a modern frilled variety.

Sweet Peas. 1. Sowing in matchbox: end removed at a. 2. Inner box with seedling ready for planting out. 3. Large box with removable divisions (a, a) for sowing. 4. Strips of turf (grass downward) for use in same, showing seedlings lifted and ready for planting. 5. Seed grown in eggshell: drainage hole at a. 6. Sowing seed in large pot. 7. How to place supports. 8. Ideal compost for sweet-pea seedlings.

How to grow Sweet Peas. 1. Trench opened and bottom soil broken up. 2. Trench left open for manure or accumulation of vegetable refuse (a). 3. Second spit (b) restored after treatment with superphosphate. 4. Top spit (c) replaced with seedling planted out. 5. Result of soil preparation: c, primary roots feeding on top soil; b, secondary roots fed by superphosphated second spit; a, roots gaining stimulation at flowering time from nourishment and moisture. 6. Ordinary cultivation; roots striking poor soil when feeding and moisture are essential.

For ordinary garden decoration seeds are sown out of doors in late February or March at 2 to 3 in. apart, and the seedlings should be thinned out to 4 to 6 in. from each other. The seedlings must be supported by twiggy sticks as soon as they are well through the soil, and subsequently by ordinary pea sticks. It is usually necessary to protect them from birds by means of netting for a few weeks after they show through the soil.

Some of the most beautiful modern varieties are the following: Model, white; What Joy, cream; Valentine, blush; Pinkie, pink; Mrs. A. Searles, cerise; Youth, white with pink edge; Magnet, cream-pink; Blue Bird, purplish-blue; Warrior, maroon; Huntsman, scarlet; Mammoth, orange scarlet; Sextet Queen, white; Gleneagles, lavender; Wembley, lavender; Royal Purple, purple; Charity, crimson; and Ruffled Rose, rose.

SWEET POTATO. A tuberous-rooted plant, the sweet potato requires greenhouse cultivation. Seeds are sown in February in a compost of loam and decayed manure. It is a native of S. America, where it is called batata.

How to Cook. Roasting is the best method of cooking these potatoes. Lay the potatoes on a shelf in a hot oven, turning them occasionally until soft when pressed gently. Scrape off the outer skin, slice and toss in butter, or mash with butter, season and serve hot. They can be boiled as ordinary potatoes.

Sweet Potato Fritters. Peel, boil and mash 1 lb. potatoes, add to them 2 oz. warmed butter, 2 tablespoonfuls flour, 3 eggs, and a little salt. Mix stiffly and form into round, flat cakes. Coat with egg and breadcrumbs and fry in deep, hot fat. Drain well and sprinkle with castor sugar and powdered cinnamon. Serve hot as a sweet.

SWEET ROCKET. The old-fashioned hardy perennial plant *Hesperis* is also known as rocket, dame's rocket, double rocket, and dame's violet. *See* Rocket.

SWEETS AND SWEET MAKING

Recipes for Some of the Most Popular and Wholesome Kinds

In connexion with this general article on candied sweets are those on the two important confectionery sections of Chocolate Making and Toffee. There are as well supplementary articles in our work, e.g. Almond Rock; Fondant; Fudge; Marsh Mallow; Nougat, etc.

See also Browning; Crystallized Fruit; Essence; Icing; Sugar; Syrup; Vanilla.

The word sweets, or candies, is used to describe a great variety of small confections in which boiled sugar is the main ingredient. The materials include flavouring agents such as almond, peppermint, lemon, and coconut, while use is also made of fruit juices and nuts. Colouring matter, which in the case of the cheaper sweets may be injurious, is employed. One large group of confections falls into the class known as chocolates (dealt with under the heading Chocolate Making); others may be classed in a number of ways, such as toffees, fudges, nougats, fondants, fruit jellies, etc.

Sweets should not be given just before meals, or they may spoil the appetite for plainer, but very necessary, forms of food. It is not a good plan to give children sweets just before going to sleep, for the reason that the sugar clings to the mouth throughout the night and encourages the growth of bacteria which may damage the teeth.

It is necessary to add that there is one type of child from which sweets should be withheld, or at most given very sparingly, and that is the fat, flabby child showing a tendency to eczema. Again, if a child exhibits a capricious appetite or suffers from indigestion, a doctor's advice should be obtained as to the propriety of allowing sweets. The sweets given to any child should be of the purest quality.

Sweets. Fig. 1. Coconut Ice, made with a fondant mixture and desiccated coconut. Fig. 2. Coconut kisses, in which the mixture is rolled into balls.

Outfit for Sweet Making. Very little initial outlay is involved in making sweets at home. All that is required to start with is 2 or 3 pans sufficiently deep to boil the requisite amount of sugar, a stirrer or spatula (these may be had in various sizes in wood and metal, and are flat-shaped without a spoon-bowl), a few shallow dishes or tins into which to pour the finished confection, a sugar-boiling thermometer graduated to 400 deg., a small marble slab, and a pulling hook for rock making.

In the trade, copper pans are mostly used, owing to their high conductivity of heat, but quite good results can be got with aluminium pans. Do not use enamelled ware, as the high temperature at which sweets are boiled may crack the enamel. Tin-lined copper pans should not be used as the tin may be melted during the process. A tin or aluminium scraper for cleaning the slab, an extra spatula or two, and a large pair of scissors will complete a good working outfit. For making moulded fondants it is a good plan to invest in a rubber fondant mat. Small rings can also be obtained for peppermint creams, and a dropper made of tin. The latter is shaped like a funnel with a band of copper round the nozzle end, and a stick to fit it, which is lifted for a fondant mixture to drop out in the quantity required to form each sweet. The stick is replaced and the dropper quickly moved to fill the next mould or ring.

Sugar Boiling. Only the best-grade sugar, granulated or loaf, should be used. If inferior sugar is employed, there will be much scum during boiling, and a tendency for the batch to grain, i.e., to come back to its original state of crystallization. Any scum must be removed. Good sugar should show next to no scum, and should boil clear and sparkling. In boiling sugar strict cleanliness is essential. The pan should be well scoured, and all utensils carefully washed. Place sugar in the pan at the rate of 4 lb. to every pint of water. This will be found thick enough in consistency for most sweets, but a rather larger proportion of sugar is allowed for fondant mixtures by some sweet makers who use 4 lb. sugar to $\frac{3}{4}$ pint of water.

Wash down the sides of the pan with a small brush to remove all adhering sugar, and set the pan and its contents over a very low fire so that the sugar will melt slowly and completely. Now bring it quickly to boiling-point, remove it from the fire, carefully stir in cream of tartar or glucose, as in the recipes, wash down the sides as before, and place the pan once more with the lid on over a quick fire or gas-ring. The lid should be kept on for about 10 min., so that the steam may thoroughly wash down any adhering crystals. Remove the lid, insert the thermometer gently. Too much importance cannot be attached to the necessity of removing any scum during the boiling process, but there must be no movement of the pan after boiling point has been reached. The more rapid the boiling after the sugar has dissolved the better will be the quality of the sweets.

Before inserting the thermometer, it should be warmed in hot water and not put directly into the boiling syrup; then leave the thermometer undisturbed in the syrup until the temperature reaches 240 deg., if the sugar is required for fondants or similar sweets. A slightly higher degree is necessary for tablets. At 310 deg. if a little sugar is withdrawn and dipped into cold water it turns quite hard, and cracks between the teeth with a snap without sticking. This is the highest degree advisable to attempt. It is known as the crack, the degree for all hard sweets and rocks.

When the sugar has reached the desired degree, take the pan carefully off the fire. The thermometer should be removed and gently placed in a jug of hot water. The syrup is left to become perfectly still and the air bubbles must cease before proceeding with the sweet making.

Flavouring and Colouring. Next after sugar in importance come flavour and colour. These must be carefully chosen, for, other things being equal, they determine the quality and attractiveness of the sweets. Both colour and flavour should be very delicate for creams and bonbons. It gives them an unprofessional appearance to be over-coloured, and too much flavour is out of character. Essences and essential oils are the chief flavouring ingredients. The former are not satisfactory unless highly concentrated, so that those specially prepared for sweet making must be used.

Essential oils are most suitable for high-boiled candies, but there are many inferior makes on the market, and only the more expensive brands should be used. Cheap essential oils are very impure, require a larger quantity than the better grades to flavour the sugar, and leave a harsh, unpleasant taste in the mouth. Special colours in all shades are prepared and, like the flavours, can be purchased from any bakers' sundriesmen, or in a good grocery department.

Sweets with a Fondant Basis. In a large class of sweets the basis is fondant. Take 2 lb. best granulated sugar, put it in a clean aluminium saucepan and add $\frac{1}{2}$ pint cold water. Proceed as directed for sugar boiling, adding 1 dessertspoonful warm liquid glucose to the boiling syrup, stirring it well, and replace over the fire. Do not allow the flames to come up the side of the pan, but keep the heat well below. When the syrup has reached the temperature 240 deg. remove the pan from the fire, take out the thermometer and allow the syrup to settle, and then gently pour it in a thin sheet on to the marble slab, previously wetted with cold water. Sprinkle the fondant with a little cold water and allow it to cool slightly. In hot weather this takes several minutes; in cold the mass will require creaming almost at once.

Scrape it into the middle with the scraper and then take a wooden spatula and work the sugar backwards and forwards. Hold the scraper in the left hand and the spatula in the right so that as the spatula works the scraper collects the spreading mixture. The syrup will gradually turn into a thick cream and then suddenly to a solid white mass. Experience is needed to get the exactly correct temperature at which to start creaming the syrup. If worked too hot it will cream easily, but the resultant fondant will be coarse. If too cold, or with excess of glucose added to the syrup, it will be difficult to cream.

When required for immediate use, the fondant should be further kneaded on the slab with the hands until quite free from lumps and a smooth, creamy mass. Fondant made in this way will keep for weeks if placed in an airtight jar and stood in a cool larder. The fondant should be left on the slab for 15 min. covered with a clean cloth before being put into the jar. It is really better when allowed to mellow for a day or two before being moulded or used as a basis for other sweets.

Where fondant has been stored it sometimes requires to be thinned down with boiled sugar syrup, and it is well to have some in stock if sweets are to be made often. To 2 lb. granulated sugar in a saucepan, add 1 pint cold water, $\frac{1}{2}$ teaspoonful cream of tartar and 1 dessertspoonful glucose. Boil as directed before but remove from the fire when the syrup reaches 220 deg. Pour it into an airtight jar and store for use.

Coconut Ice. For this sweet (Fig. 1), take 1 lb. fondant mixture and put it into a saucepan. Stand this in a larger pan of hot water and stir the fondant with a wooden spatula. A few drops of the thinning syrup may be added, but care must be taken not to get the fondant too thin. Continue stirring until it is the consistency of thick cream, divide it into two equal portions, and colour one pink by adding a few drops of cochineal and kneading well in. Work into both portions on the slab enough desiccated coconut to make them fairly stiff. Avoid excess of coconut. Press out each piece to $\frac{1}{2}$ in. thickness, and place pink over white. Place a weight on top and allow the cream to sit till firm, then cut it up into bars. For variety, lemon colour and flavour might be used instead of the pink. To make coconut kisses (Fig. 2) the mixture is rolled into little balls and left to cool.

Peppermint Creams. Care must be taken in melting the fondant for peppermint and other creams with this basis. It should be made just so hot that the finger cannot be kept in it for more than a second or two. If underheated, the sweets will not set properly; overheated, they will turn quite hard. When adding thinning syrup be guided by the condition of the fondant. In hot weather it will be more creamy and easier to stir while being reheated; in winter a few extra drops of syrup will be required. Add flavouring (colouring also when necessary) when the fondant is warmed through and the syrup has been thoroughly stirred into the mass with a wooden spatula. For peppermint creams add a few drops essential oil of peppermint to $\frac{3}{4}$ lb. warm fondant mixture. This will be sufficient to fill 24 peppermint cream rings. Quickly pour the fondant into a warmed dropper, and fill the rings one-third full. When cold turn each ring upside down and gently tap it and the cream will drop out.

Bonbons and Creams. The basis of a number of fancy bonbons is almond cream, which can be made thus: To 1 lb. warmed fondant flavoured with vanilla add 4 oz. ground almonds, working the latter in thoroughly. Variations are produced from this basis by adding chopped fruits, figs, dates, glacé cherries, or nuts, Barcelona, pistachio, etc.

Left. Sweets. Fig. 3. Walnut creams, consisting of balls of almond cream surmounted by half walnuts. Right. Fig. 4. Bonbons, for which various centres are dipped in fondant and the tops decorated with coloured sugar, etc.

Neapolitan creams are made by taking four equal portions of almond cream and colouring one pink with cochineal, another with saffron, another with pale green or coffee colour, and leaving the fourth white. On to a piece of waxed paper on a board press out a piece of the pink fondant to a square $\frac{1}{4}$ in. thick, and then proceed to place a square of the same size and thickness of each of the other coloured fondants on the top. Gently press them together. Take a sharp knife and cut the mass into strips. Use a sawing movement while cutting. The strips should be further cut into cubes. Almond cream may be used to stuff French plums or dates. The stone is removed, a roll of the cream neatly inserted, and the fruit pressed together. The almond cream may also be shaped into balls and half a shelled walnut placed on top, as illustrated in Fig. 3. Bonbons (Fig. 4) are made by dipping almond cream centres in fondant, using a dipping fork. The tops may be decorated with

lines, swirls, etc., or with split pistachios, angelica, or coloured sugar. The article on Chocolate may be consulted for further ideas on suitable centres for bonbons.

Moulded Fondants. To make prettily shaped fondants a rubber fondant mat is a good investment. The mats are obtainable in several sizes. They must be used quite dry. The slightest damp or remains of former fondants will prevent the new batch of sweets from turning out properly. When the fondant has been reheated, thoroughly stirred, flavoured and coloured, as already described, pour it gently but quickly into the warmed dropper and fill each impression or mould just level in the fondant mat. When cold the sweets come out easily if the mat is very slightly bent upwards. Should a sweet stick, remove it with a tiny spatula, but do not use that impression in the mat again if refilling the mat for the rest of the batch. The mat should be quite clean and dry to refill several times without washing if the fondant is of the right consistency and each sweet has come out of its impression cleanly. After use the mat should be washed in warm water with a small brush, rinsed in several clean waters and dried on a rack over a low fire before putting away. By means of the ends of two teaspoons fondants can be shaped. Take small portions of the hot fondant and drop them on the slab, quickly pressing the portions into shapes.

Tablets. Tablets may be made as follows: Boil 2 lb. sugar with $\frac{1}{2}$ pint water to 245° , stirring in a pinch of cream of tartar just when it reaches the boiling point. Allow it to settle for a minute or two after removal from the fire, add flavour and colour, and, with a metal spatula, vigorously rub small portions of the syrup against the sides of the pan, and stir these in till the whole becomes cloudy. This is called graining. Add desiccated coconut, almonds, walnuts, etc., as desired, then quickly pour into frames, previously lined with waxed paper. An unlimited variety of tablets may be produced in this way (Fig. 5). Colours and flavours should harmonize.

For ginger tablet add finely chopped ginger, flavour with gingerine, and colour a light brown with kitchen browning (burnt sugar). For raspberry tablet flavour with raspberry essence and colour with carmine. For chocolate tablet flavour with vanilla, colour with melted chocolate or with chocolate powder well stirred in. Chocolate macaroons are easily made. Cut up plain white coconut tablet into bars, dip these into melted chocolate, well thinned down with coco-butter, and roll the bar in fine desiccated coconut.

Fig. 5. Tablets, made from a boiled sugar syrup, variously flavoured and coloured, and desiccated nuts.

Mexican Kisses. The candy known as Mexican kisses is made from 3 breakfastcupfuls best Demerara sugar, 1 cupful milk, 1 lb. chopped walnuts, a piece of butter about the size of a hen's egg, and 1 teaspoonful vanilla essence. Boil the milk and sugar together, then add the butter, and continue boiling until the mixture hardens slightly when tested in cold water. Beat the whole well for 3 min., add the walnuts and vanilla, and beat the mixture again before turning it into a buttered tin. Mark it into squares before it cools.

Sweetmeat Jellies. The sweets that are known as jellies can be made at home and without the aid of special confectioner's tools if a plain cube shape is not objected to. Two recipes are given, one for making them with gelatine and one in which agar agar or Japanese gelatine is used. This can be

purchased at any of the large stores or at a chemist's. To make the jellies with plain gelatine take $\frac{3}{4}$ lb. any stoneless jam, 1 gill water, 1 lb. loaf sugar, and $3\frac{1}{4}$ oz. best leaf gelatine. Boil the jam with the sugar and water for a few minutes, then strain through a hair sieve. Return the mixture to the saucepan and add the gelatine, which should have been previously dissolved in 2 tablespoonfuls warm water. Boil up and skim, and if desired add colouring or extra flavouring. Pour the mixture into bright, shallow tins lined with waxed paper and leave them all night. In the morning reverse the tins to release the jelly, and remove the paper by wetting it. Cut the jellies into small pieces. They look more attractive if rolled in granulated sugar.

To make jellies with the variety of gelatine known as agar agar soak $\frac{3}{4}$ oz. overnight, using 2 pints cold water. In the morning dissolve it over the fire by gentle heat and keep it warm while the syrup is being made. Put the sugar into a strong unlined pan with 1 pint cold water, let it melt, and then boil it till, on a little being dropped into cold water, it will break in a brittle manner, but it must not be coloured. Remove the pan from the fire and pour the gelatine into the sugar. Mix it well.

The jelly can now be flavoured and coloured as desired, or it can be divided and the flavour and the colouring can be varied. Proceed as in the former recipe to mould. A large pinch of cream of tartar should be added to the sugar when at boiling-point.

Pulled Sugar. Sugar boiled beyond 250 deg. and allowed to cool turns into a hard crystalline mass. The addition of some acid substance, as cream of tartar, or of some non-crystallizable substance, like glucose, causes it to be very pliable while hot, and quite transparent when cold. The pliability of hot sugar is a very important point in the making of rocks, and the transparency is essential to appetizing boiled sweets.

In pulling sugar for rock making, a large metal hook, about 6 in. across, is used. It is fixed on a wall, level with the chin. The marble slab must be well greased with butter. The hook and a metal scraper or knife used to work the sugar should also be thoroughly greased. With the scraper gently fold over the edges of the mass, raise it a little at a time, and continue folding over towards the centre until the sugar mass is sausage-shaped and just cool enough to be held in the fingers. Before doing this, grease the hands or the sugar will stick. Keep the sugar as much as possible on the fingers and not on the palms of the hands. Fling it on the hook so that the sugar mass is suspended in the middle and drawn by its two ends towards the operator.

When pulled out several feet, the ends are placed together and held by the right hand, while the left is moved till only a foot or two below the hook and laid over the sugar. The left hand is then drawn downward so that the sugar forms an S, and almost simultaneously both are thrown towards the hook, so that the sugar is doubled over on itself. This is repeated over and over again until the requisite amount of pulling has been accomplished. The sugar will probably take about 15 min. to pull. During this process air is enfolded in the hot sugar, which increases in volume and very perceptibly changes in colour, colourless sugar becoming snow-white, red changing to pink, and black-brown to cinnamon.

Rock Making. The beginner must remember that in all rock making quick handling of the sugar is essential. If it cools too much and is difficult to work, heat it over a gas-ring. To make Edinburgh rock, take 2 lb. granulated sugar, $\frac{3}{4}$ pint water, and a good pinch of cream of tartar. Boil to 260 deg. and pour sugar on to the oiled slab. As it sets round the sides, turn these right over into the centre with the greased scraper or a palette knife, so that it will all cool evenly. Add colour and flavour, fold the sugar over on itself once or twice, and pull it on the hook as already explained. When removed from the hook place it on a board well dusted with icing sugar, roll it into sausage shape, then pull it out to the thickness required and cut the strip into suitable lengths, and let them lie for a day or two to granulate.

Peppermint Rock. Plain peppermint rock may be made with $3\frac{1}{2}$ lb. white sugar, $\frac{3}{4}$ lb. glucose, 1 pint water, a few drops of oil of peppermint. Boil to 310 deg., the crack degree. Pour sugar on the oiled slab and turn in the edges as it cools. Sprinkle over it 2 or 3 drops of peppermint. When fairly firm, but still very hot, pull the sugar over the hook till it has a white satin-like appearance. Knead it up a little on the slab, make it into a thick sausage, then set it on end and pull it out into rope-like strands. Keep rolling these till they firm up, or cut them with a pair of scissors into short lengths.

For striped peppermint rock (Fig 6), boil up the sugar as before. Have a little red colour powder made up with water into a thick paste, and well stir a little of this into a corner of the hot sugar on the slab. While turning in the edges take care that the coloured portion is kept apart. The other portion, which should be the bulk of the sugar, is pulled as before, and rolled into sausage shape. The coloured sugar is well kneaded, then drawn out into long ropes, which are laid along the white in twos or threes, at wide intervals apart. The sugar is then made into a cone, and the narrow end drawn out as before into a thin rope. The result is a peppermint rock with very thin stripes of red, the artistic effect depending almost entirely on the good taste of the maker.

Cough rock is made from the same recipe as that for peppermint rock, but with oil of aniseed as the flavouring. Here about one-quarter of the whole is pulled on the hook, the rest being coloured black and strongly flavoured with aniseed. This latter is rolled into sausage shape, while the white is flattened out and made to enclose the black completely. A cone is formed as before, and drawn out, giving a rock with black centre and thin white case.

Some candy makers do not use a hook, but simply take the two ends of the sugar (when cool enough to handle on the greased slab), pull the strip evenly, then putting the end in the right hand into the left, fold the roll over and pull. Continue in this way until the sugar is firm enough to cut up.

Sweets. Fig. 6. Striped peppermint rock, a favourite and wholesome sweetmeat for children.

Boiled Sweets. The various rocks, while still pliable, may be cut with scissors into lengths of about $\frac{1}{2}$ in., and rolled between the palms of the hands to form balls, striped or plain. These balls are known as boiled sweets.

Acid balls are made by boiling 3 lb. white sugar, with $\frac{1}{2}$ lb. glucose and 1 pint water, to 310 deg. Pour the sugar on oiled slab, turn in the edges as it cools, and add a good pinch of tartaric acid and a few drops of oil of lemon. Knead it well. Draw it out as for rock, cut it with scissors, and roll it into balls. Ingredients for making cinnamon balls are the same as for peppermint rock, but the flavouring is cinnamon. Pull the sugar on the hook till it is of the proper colour. Draw it out, cut it with scissors, and roll it into balls. To make cushions, cut the strip across and give it a half-right turn, which brings the point of a cushion up. Clip it off and then give the strip a quick half-turn left and cut off. Each time the half turn is reversed so that the strip is not twisted. Any pulled sugar sweets may be thus formed into cushions and wrapped in waxed papers to make them look quite professional.

Crystallizing Sweets. Even high-boiled sweets rapidly deteriorate when kept in contact with the atmosphere. It is customary to crystallize many of the finer varieties, so that they may be immune from atmospheric influence. Sweets treated in this way are greatly improved in appearance.

The sweets to be crystallized are set on little wire stands, similar to those used in baking, but on a smaller scale, and these are placed in shallow tins. A deep tin is often used, and the trays, with their rows of sweets, are set one upon another inside it. These trays should have legs about $\frac{3}{4}$ in. long. The sweets on top are covered with another flat wire tray, to keep them from floating in the syrup. The trays thus arranged, the crystallizing syrup, made from the recipe given below, is gently poured in, and the whole allowed to remain untouched for 8 hours, by which time a coating of crystals will have formed. If the coating is not heavy enough, a little longer immersion will be effective.

When removed from the syrup, the sweets are set out on wire trays in a warm, dry room to dry thoroughly. Sweets crystallized in this way will keep for many weeks, even when exposed to the air. The spent syrup can be boiled up again for tablets or rocks.

The recipe for crystallizing syrup is as follows: Boil 4 lb. sugar with $1\frac{1}{2}$ pints water, using no cream of tartar or glucose, to 218 deg. Cut out of soft brown paper a piece to fit exactly the top surface of the syrup, leaving a small hole in the centre of it. The syrup should be set aside to cool, and disturbed as little as possible.

SWEET SCABIOUS. This hardy and useful garden plant is also known as the pincushion flower, the species including perennial and annual kinds. The former includes the very beautiful Caucasian scabious. *See Pincushion Flower; Scabious.*

SWEET SPIRIT OF NITRE. Spirit of nitrous ether, popularly called sweet spirit of nitre, is commonly prescribed in slight feverish attacks, colds, etc., on account of its diaphoretic action on the skin. It thus tends slightly to reduce the temperature. The drug also has a marked diuretic effect on the kidneys, and is therefore often an ingredient in mixtures prescribed in kidney, heart, and lung troubles, where it is desired to increase the flow of urine.

SWEET SULTAN. This is a beautiful hardy annual (*Centaurea moschata*) with fragrant flowers in white, rose, purple, yellow. The modern named varieties have large handsome blooms, and the plants are from 18 to 24 in. high. Seeds may be sown out of doors in spring or in September. Sweet Sultans need well dug friable soil and a sunny situation.

Sweet Sultan, a hardy annual with fragrant flowers in white, rose, purple or yellow.

Sweet William. Four varieties of this richly coloured flower, familiar in cottage gardens.

SWEET WILLIAM. This is a charming old-fashioned garden flower (*Dianthus barbatus*) of which splendid new varieties have been raised. Two of the most striking are Scarlet Beauty and Pink Beauty. The auricula-eyed varieties of mixed colouring are also attractive. These plants are grown as biennials, seeds being sown in boxes of soil in May; the seedlings are planted on a reserve border for the summer, and in October are set out where they are to bloom the following year. They should be destroyed after

flowering, and a fresh stock of plants raised from seeds. Sweet Williams can also be grown from cuttings in summer.

SWELLING. In inflammation swelling is accompanied by redness, heat, and pain. A dropsical swelling of the skin has the peculiarity that firm pressure with the point of the finger leaves a depression or pit which takes some time to fill up. Tumours form fairly well-defined swellings as a rule, at any rate at the beginning. A swelling in the groin or elsewhere on the abdominal wall may be due to a rupture or hernia.

The nature of a swelling should be determined before treatment is undertaken, as poultices or rubbing, which have their uses in appropriate cases, in others may do damage. *See Abscess; Sprain.*

SWIFT MOTH. Being a nocturnal moth that flies after dusk, the swift moth is seldom seen, except by the entomologist, generally during the month of June. Its grubs, however, are more familiar, and may be recognized by their brown heads and bristly creamy-white bodies, about 1½ in. long. These are sometimes found devouring roots of potatoes, beans, asparagus, dahlias, peonies, and other crops. A good remedy is effected by the digging in of naphthalene and lime during the autumn or winter months.

Swift Moth. Natural size.

SWINE FEVER. This disease is often very destructive to pigs. It is also very contagious and is therefore one of the diseases that are notifiable. This means that in case of an outbreak the officials of the Ministry of Agriculture must be informed at once. They will then tell the owner what he must do to combat the disease.

SWINGS FOR NURSERY AND PLAYGROUND

How to Construct an Outdoor Type

This is one of the entries in this work that deal with the recreations of children. See also Nursery.

The builder of a swing will find other valuable information in the articles that describe the various tools and woodworking processes.

Swings that are in the form of a chair to which ropes are attached are sold for indoor use. These can be fastened to the top of a door, so that the child can swing through the opening. This arrangement is suitable only for a small child. The hooks by which it is suspended from the door lintel should be securely fixed. Another lighter type which can be bought has netted sides, the chair being enclosed except at the front, making it safe and comfortable even for an infant. Fig. 1 illustrates a type of swing such as may be erected in a garden or courtyard. Fig. 2 shows a front elevation of the framework, a side view being given in Fig. 3. The parts are marked with a distinguishing letter, those marked with the same letter being similar in size and shape.

Any kind of sound timber which is neither liable to split nor warp may be used. Well-seasoned pine, larch, ash, or elm planks are all suitable, and can be obtained planed and trimmed to size. The quantities and sizes of timber required are given in the following list, each piece being named and lettered for reference.

	Long	ft.	in.	Wide	in.	Thick	in.
2 uprights	A	11	0	6		2	
1 cross-beam	B	5	0	6		2	
1 spar	C	5	6	4		1	
4 stays	D	4	4	4		2	
2 tie-beams	E	6	6	4		2	
1 ground plank	F	5	6	6		2	
1 seatboard	G	1	11	12		1	

The following iron fittings are required.

		Long	in.	Diameter	in.
2 nutted eye-bolts of galvanized iron	H	6		1	
4 round-headed nutted bolts	K	7		$\frac{1}{2}$	
6 round-headed nutted bolts	L	7		$\frac{1}{2}$	
4 screw bolts	M	6		$\frac{1}{2}$	
8 round-headed nutted bolts	R	$2\frac{1}{4}$		$\frac{1}{4}$	

Four lengths of flat bar iron 8 in. long $1\frac{1}{4}$ in. wide, and $\frac{3}{8}$ in. thick are required for the seat-irons P. Two lengths of flat strip iron $10\frac{7}{8}$ in. long, $1\frac{1}{4}$ wide and $\frac{3}{16}$ in. thick are needed for the plates Q. The two chains S are each 6 ft. 6 in. long; the links are of $\frac{1}{4}$ in. galvanized iron and about 1 in. by $\frac{1}{2}$ in. inside size. Four shackles T are each of $\frac{5}{16}$ in. galvanized iron, inside size $1\frac{3}{4}$ in. by $\frac{3}{4}$ in. Fourteen washers with $\frac{1}{2}$ in. diameter holes are also required.

Uprights A A are prepared first, two $\frac{1}{2}$ in. diameter holes being bored through the breadth of the upper end of each upright from the centres given in Fig. 4. A $\frac{1}{2}$ in. diameter hole is bored through the thickness of the lower end of each upright, from the point shown in Fig. 3. A mortise 6 in. by 2 in. by 2 in. is cut in each upper end, Fig. 4 showing how they are marked out. The upper ends of both uprights are cut to the shape detailed in Fig. 5. Checks for the upper ends of the stays D D are cut in the thickness of each upright, Fig. 6. Eye-bolts H H are fitted to the crossbeam B by boring a $\frac{1}{2}$ in. diameter hole through the breadth of the beam from each of the centre points in Fig. 7. A recess of the size of the nut on each eye-bolt is cut in the upper side of the cross-beam at each $\frac{1}{2}$ in. hole. An eye-bolt nut is placed in each recess as shown and wedged tight, then the eye-bolts are fitted securely. Two $\frac{1}{2}$ in. diameter holes are bored through the cross-beam at its right and left sides, as in Fig. 7. The spar C is nailed to the upper side of the cross-beam, as in Fig. 2. The spar is shown in Fig. 9.

Stays DDDD are cut as in Fig. 8, a $\frac{1}{2}$ in. diameter hole being bored through the thickness of each stay. The tie-beams E E have three $\frac{1}{2}$ in. diameter holes bored through them as in Fig. 9. The corners and edges of the seat-board G are rounded as shown in Fig. 10, the positions of the seat-irons being marked out. The bars for the seat-irons PPPP are bent to shape, as in Fig. 12. The centres for three $\frac{1}{4}$ in. bolt holes are marked with a centre punch on each bar, at the point given in diagram A, then the lines from which the bars are bent to shape are marked off from the measurements in B. These lines should be slightly incised with a cold chisel, so that they may show clearly when the irons are heated.

After the bends have been marked, the corners of the bars are cut off with the chisel and the ends filed to the semicircular shape in C. The bars must be heated before they can be bent to shape. Some trouble can be saved if the irons are taken to the local blacksmith to be bent. If the worker prefers to do the work himself he can proceed as set out in the article on Forging.

Swing. Fig. 1. Swing that may be erected out of doors. Fig. 2. Front elevation of framework. Fig. 3. Side elevation. Parts marked with the same distinguishing letter are of similar size and shape. Fig. 4. Front and side views of top of upright, showing position of slots and holes. Fig. 5. Details of shape of upright top.

Three $\frac{1}{4}$ in. diameter holes are drilled through each seat-iron from the points previously marked with a centre punch. The irons are then placed in position on the seat and tested. The plates Q Q, which are fixed beneath the seat-board, are prepared as shown in Fig. 13. Four $\frac{1}{4}$ in. diameter holes are drilled through each plate from the points given in the diagram, then both ends of each plate are rounded in the same manner as those of the seat irons. Both pairs of seat-irons are now placed exactly in their positions, as in Fig. 14. The positions for the holes for the bolts R are marked on the seat, then the irons are removed, and a $\frac{1}{2}$ in. diameter hole bored through the seat from each point. After the irons are replaced, the small bolts R are fitted into the holes in the lower angles of the irons and partly into those in the seat, then the 2 plates Q Q are placed in position on the underside of the seat, and the holes brought in line with the bolts. The bolts are driven in until their ends project through the holes in the plates, a nut being fitted to each projecting bolt and tightly screwed up with a spanner.

The woodwork of the swing is assembled by first fitting and bolting the tie-beams and stays to the uprights, then bolting the crossbeam in position, and finally attaching the ground plank F (Fig. 11) to the lower ends of the uprights. Lay the two uprights A A on the ground and place a tie-beam E across each of their lower ends. Bring the hole in the centre of each tie-beam in line with the hole at the lower end of each upright. Next insert a 5 in. bolt L (Figs. 2 and 3) into the hole in each tie-beam, and pass it through that in each upright. A washer is placed on the projecting end of each bolt, and a nut fitted and tightened up.

Swing. Fig. 6. Base of upright, showing checks cut to receive the stays. Fig. 7. Measurements and details of cross-beam and eye-bolt fixings. Fig. 8. Dimensions of stays, and details of chain and fastenings. Fig. 9. Position of holes in tie-beams; also top spar, C. Fig. 10. Plan and side view of seat-board

The stays DDDD are fitted to the tie-beams and uprights in the following order. A stay is bolted to the right end of each tie-beam, then the upper end of each stay is placed in the check in the right side of each upright. The upper end of each left stay is fitted into the check in the left side of each upright, and the lower ends of the stays are bolted to the left ends of the tie-beams. The 5 in. bolts

should be fitted with washers, and the nuts screwed firmly home. The upper ends of the stays are secured in the checks by means of the 6 in. screw bolts M. Each screw bolt is fitted as follows: The centre of the thickness of each stay is found and marked, at a point 2 in. from the upright. A $\frac{3}{8}$ in. diameter hole is then bored from each centre point at right angles through the stay, and into the upright to a depth of 4 in. The holes are slightly enlarged with a $\frac{1}{2}$ in. rose-bit for a depth of about $1\frac{1}{2}$ in. Each screw bolt is fitted with a washer and inserted into the hole, and screed in with a spanner until each stay is firmly bolted in position.

The cross-beam B is placed in the mortises in the uprights, and the 2 holes at its right side brought in line with those in the right upright. A 7 in. bolt K is driven through each alinement of holes, then a washer is placed on the projecting end of each bolt, and a nut fitted and tightened up. The left end of the cross-beam is bolted to the left upright in the same manner. The ground plank F (Fig. 11) is attached to the tie-beams and lower ends of the uprights by large nails. Care must be taken to see that the uprights are the correct distance apart before the ground plank is fitted.

The cross-beam and those parts of the uprights and stays which will be above ground when the framework is erected are given several coats of varnish paint. The seat may be given a varnish finish or painted. Creosote oil or hot tar is applied to the lower portions of the uprights and stays and to the tie-beams and ground plank.

After the framing and seat have become thoroughly dry, the chains S S are attached to the eye-bolts in the cross-beam. The pins are unscrewed and partly withdrawn from 2 of the shackles T, then the shackles are placed on the eye-bolts. The upper end link of the right chain is placed on the pin in the right shackle, and the pin screwed home. The left chain is fitted to the left shackle in the same

manner. Details of the chain, eye-bolts and shackles are given in Fig. 8. These should be of the dimensions specified.

Swing. Fig. 11. Ground plank. Fig. 12. Diagrams showing how the bars for the seat-irons are bent to shape.

Fig. 13. Plates for securing seat-irons. Fig. 14. Method of securing seat-board. Fig. 15. Shape and dimensions of excavation into which the framework is to be lowered.

The ground where the swing is to be situated is dug out to a depth of 2 ft. 6 in., Fig. 15 showing the measurements and shape of the excavation. After the earth has been removed, the bottoms of the trenches should be well rammed. The framework is then lowered into the excavation and uprighted. If the uprights are not perpendicular, the ground beneath the tie-beams and ground plank must be removed until they become so.

The framework has to be tested with a plumb line and the spirit level, and any errors of position rectified. When all is correct, a layer of earth about 1 ft. deep is shovelled into each trench and rammed down. Large stones or old bricks should be arranged round both uprights and firmly driven into the soil. The chains are attached to the seat-irons P P by placing a shackle in the end link of each chain, then the shackle on the right chain is placed on the right pair of seat-irons, and the pin fitted through the shackle and holes in the irons and firmly screwed up. The shackle on the left chain is then fitted to the left pair of seat-irons and the pin tightened up, and the swing is complete.

The seat will be about 14 in. from the ground, that height being convenient for general use, but it may be raised if necessary by moving the shackles to higher links on the chains. One-inch diameter ropes can be substituted for the chains, but they cannot be compared with the latter for strength or durability.

SWING-BACK: In a Camera. When photographing buildings, street scenes, and other subjects where it is not possible or convenient to get sufficiently far away to include the top of the subject, a rising front gives a useful means of adjustment.

Swing-back. Fig. 1. Field camera in which both back and front can be swung in order to tilt camera without distorting vertical lines in the photograph. (Courtesy of Ensign, Ltd.)

The amateur in such circumstances is tempted to tilt his camera in order to get the whole of a building on to the focussing screen; but this causes distortion, unless means can be adopted to keep the negative itself vertical. If the camera is tilted upward, buildings will appear to be falling backward in the photograph, and to be falling forward if the camera is tilted downward.

The rising front is the simplest adjustment and is one fitted to most hand cameras. At the top of the U-shaped lens front a milled screw will be found on many patterns of cameras. When this is rotated the whole of the lens mount rises or falls. As it rises it will be found that the amount of foreground is reduced on the focussing screen.

This adjustment should not be used more than is absolutely necessary; for, unless the lens has very good covering power, i.e. will cover evenly a plate a good deal larger than that used in the camera, there is a risk of uneven lighting, since the optical axis of the lens is moved from the centre of the plate.

The swing front or swing back adjustments, either or both of which are fitted in good field and other cameras designed for architectural and landscape work, permit the camera to be tilted while keeping the plate vertical.

Fig. 1 illustrates an ordinary field camera whose adjustments permit back or front to be swung with a wide range of variation, while the baseboard can be tilted and the front raised a considerable amount. In the smaller varieties of folding pocket or hand cameras the swing front alone is usually fitted.

Swing-back. Fig. 2. In photographing a tall building the whole cannot be included with the camera in a horizontal position.

In Fig. 2 the camera is so placed that it is impossible to include the whole building on the focussing screen as indicated by the diverging lines. If the camera be tilted so as to include the top of the building, the plate holder, C D, will be tilted as well, so that the vertical lines of the building will converge together in the photograph, giving it the appearance of falling backward.

Fig. 4. Same result as that shown in Fig. 3 achieved by use of swing-front

The remedy is shown in Fig. 3. The camera is tilted, but by the use of the swing-back the plate holder is still vertical. The whole of the building is included, but the axis of the lens, A B, is no longer at right angles to the plate, as shown by the lines C D. This means that the top of the building is slightly nearer the plate, while the bottom is farther away.

The lens therefore must

be stopped down until all parts of the image are seen sharply in focus on the screen. It is impossible to use either swing-back or swing-front without using a focussing screen.

The same results can be obtained more conveniently by the use of the swing-front, as shown in Fig. 4. Here the front of the camera is tilted, while the back and the plate holder remain vertical. As before, it is essential to stop down the lens until sharp focus is obtained. With all these adjustments it is essential that the lens should have a covering power considerably exceeding the minimum required to cover the plate with the lens in the ordinary central and vertical position. A reference to the diagrams will show the necessity for this.

Swing-back. Fig. 5. Showing distortion of vertical lines due to tilting the camera without use of swing-back. Fig. 6. By use of swing-back or swing-front, the camera is tilted but distortion is avoided.

The practical advantages of the swing-back are demonstrated in the photographs Figs. 5 and 6, which show the Bush Building in Kingsway, London, photographed with and without this adjustment. It was impossible to include the whole of the building on the plate without tilting the camera. In Fig. 5 this was done without the swing-back, and bad distortion resulted. Bringing a swing-back

into play, as in Fig. 6, the distortion was avoided, but longer exposure was needed owing to necessary stopping down. *See Camera; Stop.*

SWISS CREAM. This sweet is made by heating up 2 breakfastcupfuls of fresh milk with the thinly peeled rind of a lemon, placing the pan at the side of the fire so that the process may be slow enough to let the milk absorb the flavour of the peel. Add $\frac{3}{4}$ oz. isinglass, 1 gill cream; boil up the whole, strain, and leave to cool at the side of the fire. Stir in the well-beaten yolks of 3 eggs and sugar to taste, put the pan back on the fire and continue stirring until its contents thicken. Then let

the mixture cool again, and add to it a few blanched and split almonds and some small pieces of preserved ginger before turning it into a mould to set.

Swiss Roll. *See* Chocolate Roll; Jam Roll.

SWISS TART. These small sugar-covered tarts can easily be made from 6 oz. flour, $\frac{1}{4}$ lb. margarine, 2 oz. castor sugar, water to mix, and a little jam. Sieve the flour into a basin, rub in the margarine, and then add the sugar, mixing them well. Add about a tablespoonful of water, mix it in, and then divide the mixture into six equal portions, forming each into a ball.

Grease 6 small cake tins, put a ball into each, and in the centre of each ball press the little finger, making a hole almost to the bottom. Drop a little jam into the hole, and decorate the top with a knife, making sharp cuts from the centre round the tart.

Bake the tarts in a moderately hot oven for 20 min., or until they are of a light brown colour, then leave to cool on a sieve, and, before serving, sprinkle the top with icing sugar.

SWITCH: For Electric Light. The purpose of a switch is to interrupt an electric circuit, or to close it at will. Switches are made in a great variety of patterns.

In the tumbler switch the centrally placed lever, when depressed, forces the contact blades into contact with the copper brushes connected by set screws to the conductors. Turn switches have a knob or button which is partially rotated to effect contact. Two-way switches are made for various purposes, including the control of a lamp from one or more points.

A lamp-holder and switch combined, for a lamp near a writing-table or bed, is available with a key or handle to operate the switch, or a press knob device.. Similar switches in a pear-shaped knob are used to control a lamp fixed over a bed. Another variety is combined with a ceiling rose, and is actuated by a chain or cord. This is a better arrangement, since the live wires stop at the ceiling rose and do not hang down over the bedstead.

The larger switches used to connect and disconnect the whole house supply are generally of the knife-switch type, consisting of a lever handle and one or more solid copper contact blades. Such switches are made single pole or double pole. The former disconnects one element of a circuit only, as, for example, the + or flow wire. A double-pole switch disconnects both the + and — wires simultaneously. For heavy duty and greater protection, many switches are mounted in a cast-iron casing with an exterior handle. *See* Earth; Electricity.

SWORD GRASS. This is the name of hardy annual and perennial grasses. The ribbon grass or gardeners' garters (*Phalaris arundinacea variegata*), 2 ft. high, with green and white leaves, is perennial, thrives in ordinary soil and is increased by division in autumn. *Canariensis*, a hardy annual raised from seeds sown out of doors in spring, bears round flower heads and supplies canary seed for cage birds.

SYCAMORE. This is a valuable timber tree (*Acer pseudo-platanus*) much used for planting in parks and streets. It attains a height of 50 ft. or more and has large lobed leaves. The timber is used in the manufacture of mangles. The variety named Prinz Handjery has yellowish leaves, and those of *purpureum* are purplish. Propagation is by seeds sown out of doors in autumn.

Uses of the Wood. The timber obtained from the sycamore is close, compact, and easily worked, and it takes a smooth glossy surface from a finely set plane. If it is properly seasoned and sawn on the quarter it will not shrink or twist to any extent. It is nearly white in colour with a yellowish

tinge. Owing to the method of conversion the surface shows a pretty figuring, particularly when the wood is cut nearly parallel to the medullary rays.

The wood is much in demand for general turnery. It is used for rollers of mangles and washing machines, dairy utensils, and bread boards; it is also employed for violin backs. Owing to its close grain it is adapted for making wooden bowls, and for the same reason it is suitable for wood-carving and particularly for chip-carving. It takes stain well, and can be used as a substitute for ebony. It can be obtained in boards over 12 in. wide, and is also procurable as plywood.

SYLLABUB. A very old-fashioned country dish, syllabubs formerly were made with new milk drawn straight from the cow on to the spiced and sweetened wine in the syllabub bowl. To-day they may prove a highly successful addition to the refreshments at an evening party if made according to one of the following modern recipes.

For a "Farmhouse" syllabub dissolve in a bowl 3 oz. castor sugar by stirring it with 1½ gills sweet home-made wine and 1½ gills sherry. Add the grated rind of a lemon and ½ of a grated nutmeg. Put into a large earthenware teapot 1 pint new milk warmed to the degree of freshly drawn milk, and hold the pot high above the contents of the bowl and pour with a circular movement on to the wine. Strew over the top a little grated nutmeg. Let the whole stand for some hours, then cover the top with clotted cream.

A Staffordshire recipe is to put 1 pint cider with a wineglass of brandy into a bowl, add about 6 oz. pounded lump sugar and ½ teaspoonful grated nutmeg, then stir until the sugar is quite dissolved. Warm 1 quart new milk, and put it into a jug with a sharp spout, or, better still, an earthenware teapot. Pour it round and round on to the cider; grate more nutmeg on the top, and let it stand for some hours. Serve with whipped cream.

A lemon syllabub has an excellent flavour. Grate the rinds of 2 lemons and stir them into 1½ pints sherry or Madeira; also dissolve in the wine 1 lb. lump sugar. Strain the juice of 6 lemons and 1 full-flavoured orange, and add these to 1 pint pure thick cream. Now put both wine and cream into a deep but not very large basin, and beat with a whisk for ½ an hour. Let all stand for 2 or 3 days, and the night before it is required for table arrange it in sundae glasses or custard cups.

A very economical syllabub may be made by dissolving 2 oz. lump sugar in ¾ pint homemade raisin wine, then add the grated half of a nutmeg, and pour on to the wine 1 quart of warm new milk from an earthenware teapot.

To make good syllabubs it is most important to use pure fresh cream or milk and the finest white sugar. Lump sugar is the best. When beating, work evenly and in one direction. It is a mistake to start in a hurry; begin and continue with slow, steady strokes.

SYNOVITIS. Inflammation of the synovial membrane of the joints, or synovitis, may follow sprains or other injuries.

The acute condition is usually accompanied by pronounced swelling, heat, and pain. It is treated by rest and cold applications. Later the joint is massaged, and a woven elastic bandage is put on to maintain pressure and assist in the absorption of the fluid in the joint. In chronic cases iodine or some other counter-irritant is used to reduce the swelling, and a bandage is worn during the day. *See* Bandage; Joint.

SYPHILIS. Syphilis is due to the entrance of a minute organism beneath the skin or mucous membrane through an injury to the surface, which may be exceedingly small. In the great majority of instances the infection is conveyed by sexual intercourse.

The disease begins with a sore, which develops most frequently upon some part of the organs of generation, usually about 4 weeks after infection. During the next 6 weeks to 6 months there may be fever for a few days, headaches, and rheumatic pains in the joints. Rashes of various sorts appear on the skin, and the throat and inside of the mouth become ulcerated. In the later stages tumours known as gummata may appear in any organ or tissue of the body, extensive ulceration of the tissues may take place, the bones may be eroded, the arteries thickened, and aneurism may develop.

Locomotor ataxia and other forms of paralysis may occur, and mental changes such as general paralysis of the insane. In women miscarriage and abortion are common. A particularly sad form is seen in infants when one or other parent has the disease.

Great efforts are now being made to eradicate syphilis and other forms of venereal disease from the community. In the United Kingdom methods for prevention and treatment are advocated by the Society for the Prevention of Venereal Diseases, 4, Fitzroy Street, London, W.1.

Parents can assist by giving their children sound, healthy teaching in matters pertaining to sex, and by impressing upon young adults the danger of promiscuous intercourse. The provision of early and efficacious treatment is also of great importance, and centres have been established in all large towns where those who have acquired the disease can obtain treatment with the assurance that strict privacy will be maintained.

In its primary stage syphilis can be eradicated by treatment with arsenical compounds combined with mercury or bismuth. Treatment should last for at least two years.

SYPHON: For Mineral Waters. Soda and other mineral waters may be obtained in syphons which consist of a glass container with a metal top. A glass tube fixed at one end in the top passes down inside the container, extending almost to the bottom; it must not touch the bottom, otherwise the action of the syphon will be obstructed. The top is fitted with a spout or tap and a small spring lever in the form of a handle which operates a valve. When the lever is pressed down the valve opens and the mineral water in the syphon is forced up through the tube by the pressure of the gas which it contains, and discharged through the spout. The quantity is regulated at will instantaneously by depressing or releasing the handle.

Freshness of Contents. The advantage of the syphon over the ordinary bottle therefore, is that small quantities can be drawn at any time without detracting from the freshness of what remains in the container. Syphons are filled through the spout by a mechanical process which cannot be carried out at home. They can be obtained from any chemist or dealer in mineral waters.

In warm weather syphons should not be kept in a living-room, but should occupy the coolest position in the larder or cellar. For table use they may be cooled by the aid of ice, but should not be placed in direct contact with it. Some refrigerators are so constructed that a syphon may be placed on a shelf right above the ice, or it may be cooled in an ice cave. If the house does not contain these means of cooling food it is best to put the syphon into a wooden vessel and pack the outside of the wood with ice, placing a tray on the top with ice on it. It is not safe to immerse a syphon in ice as it might burst.

Syphon stand in pierced silver.

Syphon Stand. This is an ornamental container for the ordinary mineral water syphon. The pattern illustrated is made throughout in silver, and comprises a tube-

like body ornamented with a band of piercing in a simple design, and provided with handles. *See* Piercing.

SYPHON: For Transferring Liquids. A syphon which can be made at home consists of a glass or metal tube bent to a U shape, with the limbs of differing length.

It provides a simple means of transferring liquid from one vessel to another. The difference in the lengths of the tube is essential to the action of the syphon, the shorter length being placed in the liquid that is to be drawn off.

If suction is applied to the long leg of the tube the liquid is raised in the syphon and flows out until the level drops below the end of the short leg, or, if the long leg dips into a vessel, until the level of liquid in both vessels is the same. As sucking by the mouth may be inconvenient when the syphon is not fitted with a suction pipe, the same effect can be obtained by inverting it and filling it with the liquid. Then, stopping both ends with the fingers, or corks, the short tube is placed into the liquid and the ends unstopped, when the liquid will flow steadily until it falls to the level of the lower end.

Syringa. This is the botanical name of the lilac, but it is often wrongly used to describe the mock orange or philadelphus.

SYRINGE: For the Garden. A syringe is invaluable in garden and greenhouse, but it must be of a good type, provided with spare nozzles and roses capable of impelling water in volume or fine spray. It should be kept properly packed to prevent leakage; for packing, use tow and grease if available, otherwise substitute darning wool. As a general rule plants with hairy leaves or ripening fruit should not be syringed. *See* Insecticide; Spraying.

SYRINGE: In Medicine. Various kinds of syringe are used in the treatment of different disorders. Direction for syringing the ear are given in the article on Deafness (q.v.). Syringing the nose is often dangerous and should be left to a doctor. *See* Douche; Ear.

SYRUP: In Cookery. Syrup is a solution of sugar in water heated until, when poured from a spoon, it drops like oil, or by the sugar thermometer to 220° F. It is used for sweetening various foods, as a means of preserving them, and also as an article of diet in itself. When properly prepared it can be stored in bottles, and will keep in perfect condition for a considerable period.

The syrup may be merely a simple thick liquid, it may be flavoured, or it may be medicated; but the process is the same. Only the purest refined sugar and distilled or filtered water should be employed; if there is any doubt as to its purity it should be clarified.

To clarify, have ready a perfectly clean, thick steel or aluminium pan. Dissolve the sugar in the water, placing both together in the pan, and allowing $\frac{1}{2}$ pint water to every lb. sugar. The water must be accurately measured. Whip up the white of half an egg with 2 or 3 tablespoonfuls of water until light, then pour it into the syrup and place the pan over slow heat. Beat until a good froth forms, then skim the surface carefully and brush the sides of the pan clear with a clean pastry brush, dipped in hot water.

As soon as the liquid begins to simmer, remove the pan from the fire and let it stand until it has slightly cooled, when it should be skimmed again and strained through a jelly bag or blotting paper. Syrup must be boiled very gently; also, while it is boiling, check it once or twice by adding a tablespoonful of cold water. For some dishes a very thick syrup is required, but the syrup out of a bottle can always be thickened to the necessary degree by reboiling it when taken out of store. Use loaf sugar in preference to granulated sugar, as it will be found to be cleaner. To test the syrup, if no

sugar thermometer is at hand, pour it slowly from a spoon or drop a little on a plate, and if it lifts with a thread it is boiled enough.

If syrup is bottled when almost boiling, and at once tied down with portions of bladder or some covering equally impervious, it will keep better and appear brighter. If fermentation should take place, put the bottle into a pan of boiling water ; this will usually clear it.

Fruit Syrups. Any flavour added to syrups must be perfectly clear; if at all cloudy it should be clarified. When making a syrup with a fruit juice, either fresh or taken from a tin of fruit, no clarification is necessary. The juice should be strained through a hair sieve, the sugar added, also a little lemon juice, and then the whole should be simmered in a bright saucepan to the required consistency.

Sweet jellies are brighter and clearer if syrup is used in place of raw sugar, but the proper proportions of liquid must be adhered to. Many excellent summer drinks may be made with syrup and flavouring if aerated water is added. For stewed fruit, flans, and pastry fillings, syrup is both useful and necessary as a sweetener, and the housewife will find it a great help always to keep a few bottles of different fruit syrups in the store cupboard.

Another kind of syrup much used in cookery is golden syrup, which can be substituted for treacle in any of the recipes given under that heading. It can also be used instead of jam in the making of roly-poly puddings, tarts, etc. Golden syrup used for tart-making is usually thickened with breadcrumbs. This syrup is also much used instead of sugar for sweetening porridge and similar foods.

Syrup Cake. To make a good syrup cake, sieve together 1 lb. flour and $\frac{1}{4}$ teaspoonful bicarbonate of soda, rub into them 7 oz. margarine, and add 6 oz. sugar, and $\frac{1}{4}$ lb. ground almonds, mixing all well. Beat up 2 eggs in another basin, add to them 1 teacupful golden syrup, and whisk the mixture well before stirring it into the dry ingredients. If necessary, the syrup may be warmed slightly. Add also about 1 gill milk, then beat the whole for a few minutes before turning it into a greased cake tin lined with greased paper. Bake it in a moderately hot oven for about $1\frac{1}{2}$ hours.

Medical Uses. Certain drugs are dissolved in syrup for the sake of making the medicine palatable to the patient. Various tonic mixtures are prescribed in this form, including syrup of the phosphate of iron; Easton's syrup, or syrup of the phosphate of iron with quinine and strychnine, and compound syrup of phosphate of iron, or chemical food. *See* Compote; Flan; Treacle.

TABLE. One of the oldest pieces of furniture and one of the most common. From the original table that was but a square or oblong piece of wood, standing upon trestles, was evolved, the one supported by a leg at each corner, and from the latter a great variety of styles has developed.

In England, at a later date, were made the massive oak tables, with legs supported by a stout frame. To the Jacobean age belongs the draw table, which, with improvements, has come into favour again as a dining table in the 20th century. The dressing table and also the work table developed on their own lines, and special tables, suited for special purposes, were produced, as the wine table, now a valued antique, and the card table, with its movable top. Folding tables are of considerable age and from these were developed, in Cromwellian days, the gate-leg tables still so popular and, later, Pembroke tables.

Many beautiful examples of walnut tables were made in the reign of Queen Anne, with cabriole legs often having shell ornaments carved on the knees.

Later Chippendale made many tables, including varieties for dining, occasional and specific uses.

Fig. 1 shows an artist's table with square legs and a typical Chippendale design in the strapwork carving. Hepplewhite and Sheraton also made and designed a variety of tables, and readers are referred to the entries on the styles of these great English designers. During the period of the Regency style (q.v.) sofa tables were developed from those of Sheraton on the lines of the example illustrated in Fig. 2, which shows the yoked feet and brass inlay so characteristic of the early 19th century pieces.

Left. Table. Fig. 1. Chippendale artist's table in mahogany with strapwork carving; late 18th century.

(By permission of the Director, Victoria & Albert

Museum, South Kensington). Fig. 2. Sofa table of rosewood inlaid with satinwood and brass, of English make, early 19th century. (By permission of the Director, Victoria & Albert Museum, South Kensington)

Articles on how to make the principal types of table will be found under the headings Afternoon Tea Table; Bed Table; Card Table; Dining Table; Dressing Table; Folding Table; Gate-Leg Table; Kitchen Table; Trestle Table; and Writing Table. These contain working drawings and full instructions showing how the home worker with a little skill in carpentry can construct tables of a useful or ornamental nature. Reference may be made to some of the primary woodworking contributions, such as Cabinet Making; Dovetail; Joint; and to the articles on Leg and Moulding. See Antique Furniture; Billiard Table; Cane; Davenport Table; Furniture; Jacobean Style; Lacquer Work; Occasional Table; Ormolu; Pier Table.

TABLEAUX VIVANTS. This form of entertainment may be given in a somewhat ambitious or in an extremely simple manner; but there are certain general rules which should be observed in either case.

The tableaux should be in charge of three persons: a producer, to select, cast, and rehearse the pictures; a stage manager, to attend to the lighting, any scenery or furniture, and the curtain or screens; someone to superintend and assist with the dresses, to inspect the performers before they go on the stage, and to help generally with difficulties in both makeup and costume.

The succession of pictures must be carefully worked out. People who are appearing in more than one picture must be given time to get ready for the next character while pictures in which they do not appear are being shown. Copies of this programme should be pinned up in any dressing-rooms, behind the scene, and in the stage manager's corner at the left side of the stage. He should have a bell as a signal for the commencement and close of each tableau.

The pictures remain before the audience for two or three minutes. It is difficult to preserve absolute stillness in some poses, and it is better to display the tableaux for a shorter time than to spoil the illusion by movement. Where there are a number of people in the picture the most brilliant and striking dresses are placed in the foreground and those in neutral tones at the back. Good colour schemes are a great help towards success. In selecting subjects, those with strongly marked dramatic contrasts will be the most successful.

Use of a Stage. More elaborate presentation requires a stage about 12 ft. square, with a proscenium screen painted to represent a picture frame, across which a close black gauze, 8 ft. wide by 7 ft. high, is stretched and nailed behind the frame. Behind this gauze, which is stationary, curtains which can be drawn or closed are fixed on a rod, and there is a complete frame of electric light, hidden by the proscenium screen, round the tableaux. The black gauze has a softening effect and keeps the whole picture remote from the audience; otherwise, it is not seen when the lights behind it are full on.

At the beginning of each tableau the stage manager rings a bell and the lights in that part of the room where the audience sits are switched off. The stage curtain would have been down while the tableau was arranged with the lights up behind; when the setting is complete he switches off the stage lights and the curtains are raised in the darkness. Then these lights are switched on and the picture is disclosed behind the gauze screen.

The frame of light is not required for all tableaux. A well-known painting may be copied in which there is a glow of firelight, or a sunlight effect from an open door in a darkened interior. In that case the lighting would be supplied from the side with the help of a lime box and coloured slides. Any special lighting effects would have to be tried beforehand. The whole background may be black; it may be of black velvet, or any light absorbent material; the stage cloth should also be black. Sometimes the sides of the stage are draped with dark curtains, and different back cloths are used for different pictures.

A simpler method, with or without stage, in a large room is to manage with curtains only, or with screens plainly covered in a dark colour. Some of the picture illusion is lost without the framed gauze, but the tableaux, if well arranged, can be quite effective. The lighting in this case is from the top and sides, or from the sides only. When screens are used, two people in fancy costume, as pages or theatre attendants, draw back the front screens at a signal from the stage manager.

Garden Tableaux. Tableaux vivants may be given in a garden. A raised terrace with wall or shrubbery background, or at the top of a shallow flight of steps, below which there is a space which can be utilized for the audience, is a good place to choose for the entertainment. Screens can again be utilized for the change of picture. Sometimes children are rehearsed to form up in a semicircle in front of each picture after it has been shown, holding big branches of foliage to mask the stage, parting when the next picture is ready; or grown-ups with stencilled banners, which they unroll to form a complete screen. These last methods are particularly good when the curtain makers act as a chorus for nursery rhyme tableaux or for illustrations of old songs.

In selecting a series of tableaux the question of costumes must be carefully thought out. Simple dresses can be made at home and special or historical costumes can be hired, but this last expense may be considerable if many elaborate dresses and wigs are needed in the pictures.

A fairy story such as *Little Snow-White and the Seven Dwarfs* or *The Sleeping Beauty*, illustrated by a dozen tableaux, with someone to tell the story as it is shown, is a good item on a programme. Tableaux introducing famous characters from Shakespeare, Dickens, Jane Austen, and other writers, topical cartoons, well known advertisements, and dramatic ballet groups, in poses which can be held, are all effective.

A man and woman dressed in fancy costume may be stationed in front on each side of the tableau stage to introduce the pictures, or for the children's entertainment a fairy godmother may tell the story and appear to control the picture with her wand. *See* Make-up; Amateur Theatricals.

TABLE CENTRE. This style of mat especially designed for the centre of the table, and formerly either placed on the dining table when not laid for meals, or as a decoration over the white cloth, is now usual only as the centre piece of a luncheon or dessert set of table mats. On festive occasions, such as a Christmas party, a special centre is sometimes devised to enhance the decorations. For instance, a gold or silver tinsel square or circle might be outlined with artificial holly leaves and berries, or a square of ivory gauze stencilled with red flowers and silver leaves might form a table centre, to be surrounded with fancy sweet dishes and crackers.

TABLE CLOTH. For the dinner table it pays to buy good damask, not only because of its appearance, but also because it wears well and launders better than the cheaper kinds. For family use such a table cloth should be on the large side. There is no objection to its hanging down nearly to the floor at sides and ends, and if an extra leaf has to be put in the table the cloth will still be large enough. Some people favour table cloths with drawn-thread borders or a hemstitched or lace edge. It may be said that a fine damask needs no further ornament than an embroidered initial or monogram, but a less valuable one is sometimes improved by a little ornamentation, not too elaborate, and lace crochet introduced into a linen dinner table cloth gives it a handsome appearance.

Table cloths for use at other than meal times are not often seen, owing to the liking for polished or painted surfaces and the hygienic dislike for anything that accumulates dust. *See* Appliqué Work; Breakfast; Drawn Thread Work; Embroidery; Linen.

TABLE LAYING AND DECORATING

Attractive Settings for both Everyday and Formal Meals

Other useful information on this subject will be found in the articles on Breakfast; Dinner; Luncheon; Supper. *See* also Christmas; Cocktails; Dining-Room; Flowers; Glass Ware; Hors d'Oeuvres; Napkin; Silver Ware; Spoon.

The art of good table-laying is one which enhances the reputation of the housewife and hostess. Food can only be enjoyed when nicely served and with pleasing surroundings. More attention than ever is paid to the importance of colour, freshness and ordered arrangement of the table appointments, since it has been recognized that these things in themselves create a sense of personal harmony which is helpful to good appetite and digestion. On the decorative side it is easy to give either a charming, amusing or festive air to the table with inexpensive accessories and flowers to suit the season and occasion.

A few preparations have first to be made in the kitchen or pantry. The knives are wiped, the silver polished and special attention paid to the condiment containers, as an attractive table is impossible unless salt cellars are evenly filled, pepper pots are showing no trace of pepper dust, and mustard pots are supplied with freshly-made mustard. Any glasses on the table should be quickly polished with a clean cloth, and water jugs, etc., require the same attention before being filled. For the breakfast table it is most important that the butter and jam or marmalade dishes should look inviting.

The housewife decides whether she prefers a table cloth, table mats, or a sort of combination of the two by means of a linen runner and mats to correspond. The last arrangement is a favourite one for breakfast or luncheon and looks particularly well in coloured linens to harmonize with the table ware. All-over striped linen cloths are a good choice for the family breakfast table with napkins to match. There is great beauty about a plain damask cloth for the dinner table, but lace-edged mats will look more festive if the china ware and other appointments are simple. When a cloth is used the table should be protected by underlying baize, serge or felt; protective mats must be provided under linen or lace table mats. These protections can be dispensed with when a cold supper or luncheon is served.

Table Laying. Fig. 1. Table laid for a formal dinner party, with a white damask cloth to set off the beauty of the patterned china, the glass and the flowers.

An example of a wise choice of plain damask cloth is shown in Fig. 1. Here the table is laid for a small formal dinner party. Unity is achieved by the plain background to the ornamental glass, silver candlesticks, sweetmeat and salted almond dishes, the patterned dinner service and the central flower arrangement of roses and gypsophila. Lace mats would make so much detail fussy and the appearance of the table less dignified. The possessor of Sheffield plate candlesticks, and a cake basket in which a glass bowl could be placed to hold the flowers, could use these appointments with equal success in such a setting.

A complete change of surroundings and ware makes Fig. 2 an equally striking and successful example. On a table with polished wooden top and metal legs, the soup bowls are of the square shape that some English makers are favouring, and the mats are of glass. The centre-piece is of glass and steel and the two ibises on either side of it are of silvered glass, while a tiny cactus is placed in a silvered pot at each corner. The menu cards are on heavy glass stands, the table silver and gold-rimmed drinking glasses are slightly less severe in design than the rest of the appointments, but the whole effect is bright, amusing and sparkling.

In a Queen Anne or Georgian style of room with a fine mahogany table surface, nothing could be in better taste than the setting illustrated in Fig. 3. Cut crystal glasses and flower bowl are the features; the condiment holders are of pierced silver with glass liners, and the mats of beautiful linen Madeira work. The simple luncheon table shown in Fig. 4 is quite as charming with its oblong linen place mats, covered soup bowls, pot of hyacinths and silver wire bread basket.

Laying for Dinner. Where the carving and serving are done at table, a carving cloth should be spread at the end. This may be an embroidered affair or a plain dinner napkin of good size. The sideboard is covered with a cloth, and also the dinner wagon or butler's tray.

In setting the table for dinner the place for each person can be marked out by a napkin. The necessary supply of cutlery, silver, etc., is placed on a small tray, which is carried round the room, so as to arrange each place correctly. Each person should have a large knife on the right hand, a

large fork on the left hand for use with the meat course, with space left between to take the plate. A dessertspoon and fork may be placed horizontally in front, the spoon on the outside with the handle towards the right and the fork on the inside with the handle towards the left. Alternately, and more usually when entertaining, the dessertspoon and fork are placed with the other cutlery on either side of the plate. If a fruit salad or ice is to be served in individual glasses, a small spoon is often put beside the glass on the plate when handed to each person, and no dessertspoon and fork are laid.

If fish is to be served, the fish knife and fork are placed outside the large knife and fork. For soup a tablespoon, or special soup-spoon, is placed on the extreme right of the knives; a cheese knife is placed inside the other knives, or on the cheese plate, as shown in Fig. 1. When grape fruit is served a grapefruit spoon or a teaspoon is provided and a small fork or knife and fork for a savoury.

Each person is given a tumbler for water and one or more wine glasses if wine is offered. Each person may be given a small slice of bread or a roll placed on the left hand, or the bread may be cut and placed on a salver or basket. Sometimes toast is served in one or two small racks.

Carvers and knife rests are placed at one end of the table in front of the person who does the carving and outside his own complement of knives and forks.

Spoons and forks for serving the sweets, etc., are usually laid at the opposite end of the table.

Fish slice and fork are placed outside the meat carvers and the soup ladle next to these. A sufficient number of salt cellars, etc., should be provided and placed at the corners of the table, as illustrated in Figs. 1, 4, or in the case of a small round or square table may flank the centre-piece.

Cheese, butter, biscuits may be placed in readiness on the sideboard and also fruit dishes, etc., if dessert is to be offered, and in this case there should also be put ready a dessert plate for each person, with a finger-bowl containing about one-third of its depth of clear water, a fruit knife, and a fork and spoon. A sugar bowl filled with castor sugar should be in readiness whenever fruit such as oranges, strawberries, etc., are being offered. Before dessert is laid on the table the used glasses, cheese plates, etc., are removed and the crumbs are taken off the cloth with a crumb scoop, kept in readiness on the sideboard. Coffee making equipment may also be placed there, as indicated in Fig. 1.

Table Laying. Fig. 2. A polished table surface is further enhanced by glass mats, steel and glass centrepiece surrounded by cacti in small pots and a pair of silvered glass ibises.

Table Decoration. The choice of effective table decorations is almost limitless, and can therefore always be regulated by individual taste and means.

For those who possess flower

gardens, the problem of expense is practically non-existent except during a few winter months.

Any scheme for decorating a dining table should be influenced by the colouring of the room in general, and of the dinner service, lamp or candle shades in particular. When only two or three people are dining at a long table, and one end is not occupied, an important-looking decoration is a pleasant change when placed at this end instead of in the middle; otherwise a long or oval table is

best with an extended treatment, a round or square table with a more compact one not too high to obscure the view across the table.

Fig. 3. A simple old-world atmosphere is suggested by water lilies in a faintly tinted glass bowl, gleaming silver and cut glass reflected in the polished table; graceful period chairs complete the harmonious effect.

For luncheon or breakfast table pale yellows and blues are charming, but they are apt to lose their effect by artificial light. Violets, purples, and deep blues, also, are not good night colours. When shaded candles are used to light the table, flowers of somewhat more decided tones in harmony with the shades should be chosen for the decoration. Very large blooms are difficult to arrange, except when the size of the table allows of a somewhat massive decoration. Even then they are better when some lighter flower or feathery foliage is mingled with them in order to avoid a heavy or crowded appearance.

Coloured glass is often a deciding factor in a successful scheme. Cherry or ruby red glass on a white lace-trimmed cloth is enhanced by flowers of the same shade; (while amber or pale green glass is beautiful with mauve. In early spring, on a mahogany table, with mats instead of a cloth, so that the polished wood is seen, a bowl of yellow tulips flecked with orange and arranged with red-brown berberis is a simple and harmonious decoration.

Fig. 4. Luncheon table, with small individual cloths, covered soup basins and heavy cut-glass tumblers.

Shirley poppies, daisies, and grasses are attractive for a luncheon table, and yellow roses in a sapphire blue bowl, lightly arranged with plenty of leaves, are a good choice with a dinner service which is patterned with green. For a hot night, coolness is suggested by pink roses in small cut crystal vases set round a block of ice in a large bowl, the table lit by pink-shaded candles in

silver or glass candlesticks.

In winter, when flowers are expensive, a dish of fruit in contrasting colours is a good centre-piece for small vases of flowers or trails of autumn foliage. On a polished table, a pair of brightly coloured china birds or Chelsea figures are sometimes used at either end of a dish of fruit. Glass birds or animals set on a piece of mirror glass form a bright decoration round a vase of glass flowers or a little green glass tree. Old silver-gilt embossed spoons and small glass or silver dishes for sweets and salted almonds can also help towards the decorative scheme.

A miniature Japanese garden set in round or oblong pottery, with lacquered candlesticks and corresponding shades, is a change from flowers or fruit. A good Christ-mastide decoration has for centre-piece a black Wedgwood bowl containing flowering bulbs of scarlet tulips and white Roman hyacinths, surrounded by holly leaves and berries, and groups of scarlet and silver crackers.

TABLE MAT. Protective table mats for meal service on polished tables are made of rubber, rush, raffia, linoleum, asbestos, cork, composition, glass and wood. Ornamental mats to be used over these are of embroidered linen, either white or coloured, wholly of lace or crochet, or linen trimmed with lace or crochet. In some cases the protective mat is also decorative, as for example when made of raffia dyed in bright colours, of cork stencilled with a pattern, of painted glass, or of wood treated with bronzes and brush lacquer colours.

With transparent lace the colour of the protective mat underneath is important. Gilded composition or cork is used with good effect, otherwise the under-mats are best when unobtrusively matching the colour of the table. For ordinary use rubber mats afford excellent protection; also they have the advantage of being thin, and the linen mats over them do not slip when plates are removed. A set of protective table mats usually includes 6 round mats and 2 or 3 oval ones for dishes. All oval shapes can be bought if the linen place mats are oval. With larger square or oblong embroidered and lace mats many people dispense with protective mats and have service plates laid on the mats on which soup cups, etc., are placed. Small tray-cloth designs can be traced on linen to make these, embroidered, and the mat either scalloped, hemstitched or lace-edged.

For decorated cork mats see the article on Stencilling, and for gauze dessert mats that on Pen Painting. In the article on Raffia directions are given for making simple woven mats, while the design for the tea-trolley mat in the same page could be used equally well for a table set. *See Luncheon; Tray Cloth.*

TABLESPOON. This name is given to the largest size of spoon used at the table; they are employed for soup-spoons and for serving food. Tablespoons may be of silver or electro-plate. In giving medicine a tablespoonful is $\frac{1}{2}$ a fluid ounce. *See Silver; Spoon.*

TABLE TENNIS: THE RULES OF THE GAME

A Popular Indoor Pastime for Winter Evenings

A number of articles in this work describe various indoor and outdoor games that are suitable for the home. Such include Billiards; Lawn Tennis

Table tennis is a development of ping-pong, which became popular in Great Britain about 1900. An association was formed, but after 1905 the popularity of the game waned and this ceased to exist, although there were ping-pong leagues in various parts of the country, including Plymouth and Exeter. Each of these leagues, however, had its own rules. In 1921 the Ping Pong Association was revived and under its auspices national championship matches were held. In 1924 the term ping-pong, as it was a trade name, was abandoned and table tennis was substituted. The Ping Pong Association was dissolved and its place taken by the Table Tennis Association.

Table and Implements. Tables specially made for the game of table tennis can be purchased. A useful type is a fight table, coloured green, that can be laid on the top of an ordinary table.

The table should be rectangular, 9 ft. by 5 ft. in size, of solid hardwood, or of such material as will yield a uniform bounce over its entire surface of at least 8 in. when a ball of standard size is dropped from a height of 12 in. The net must be 6 $\frac{3}{4}$ in. high, and should be dark green in colour,

with a white band along the top. It must fit close to the table and to its supports, and must be exactly in the middle of the table's length.

The average weight of the celluloid balls that are used in this game is 13 to the oz.; they must not be heavier than $12\frac{1}{2}$ to the oz. nor lighter than $13\frac{1}{2}$. They should measure between $4\frac{1}{2}$ in. and $4\frac{3}{4}$ in. in circumference.

Almost any kind of light racquet may be used, the surface being of any material. To-day the best players use rubber racquets, with which they can get an astounding amount of speed on the ball.

Scoring. The method of scoring is by games, 21 points making a game. Each player in turn serves until five points have been scored by the two players together. If the score reaches 20 all, it continues to 25, 30 or more points, on the principle of lawn tennis that one side must be two points ahead of the other before game is called.

Rules for Serving. The game is usually played by two persons, but it can be played by four, two against two. In the former case each player defends one half of the table, these halves being known as courts. The one who serves is known as the server, and the other as the striker-out. The choice of courts and of service is decided by tossing, but the following conditions must be observed. If the winner of the toss decides to serve or to receive, his opponent shall be allowed the choice of court. The winner may, if he wishes to do so, leave the choice of service or court to his opponent.

When serving, the server must be behind the end of the table; and the ball, when struck, must be behind the end and also inside the limits of the width of the table. The server must so strike the ball that it will bounce once in his own court and then pass over the net into his opponent's court. The server is not restricted to any particular method or methods of holding his racquet, and the ball may be either above or below the level of the table when the server strikes it.

It is a fault and the server loses the point under the following conditions: when the ball does not strike the server's court prior to passing over the net; when the ball bounces more than once in the server's court; when the ball in play touches anything before striking the server's court; when the ball does not, after one bounce, cross the net and drop into the opposite court; when the ball, after bouncing once only in the server's court, touches any object apart from the net and its supports before alighting in the opposite court.

It is a let when the ball, being in service, touches the net or its supports after the first bounce, and then drops into the court beyond, and when a service or a fault is made before the opponent is ready to play. A let does not count to either side, and the stroke must be played again.

A return is good if the ball in play, after having bounced once only on a court, is returned on to the opposing court, after having been struck once only by the player's racquet, or by the hand holding the racquet. If the ball touches either the net or its supports, it is still a good return if it then drops on to the opponent's court. Volleying is not permitted by the rules of table tennis. If a player strikes or is struck by a ball when it is in play inside the limits of the court and before it has bounced in his court he loses the point. He loses the point also if the ball bounces on his court and then touches any object apart from his racquet or the hand holding it.

The ball is dead or no longer in play and the point counts against the player who made the stroke in the following circumstances: when the returned ball strikes any object, apart from the net or its supports, prior to dropping on to the opposing court; when the ball, having been played, touches the player's court before going over the net (this does not apply to the service); when the ball, after passing over the net, goes beyond the limits of the table without dropping on it.

If either player touches any part of the net or its supports with the racquet or any part of his body while the ball is in play, the ball becomes dead, and he loses the point; when a ball drops on the proper court and screws back over the net, the player whose turn it is to strike may reach over the

net and play the ball, so long as he otherwise makes a good return. If he fails to play the ball, his opponent scores the point notwithstanding the fact that the ball has returned over the net. A player loses a point if he touches the table with his free hand while the ball is in play.

The phrase table surface is to be interpreted as including the top edges and corners of the table top, and a ball in play which strikes these latter is therefore good and still in play; though if it strikes evidently the side of the table top below the edge, it becomes dead and counts against the last striker.

Finger spin may be imparted to the ball in service by projecting it by hand into the air and then striking it; it may not be imparted by holding the ball and rubbing the racquet surface against it before it leaves the hand.

The Game for Four Players. These rules are also applicable to the game in which four persons play, but for this there are certain other regulations. The table must be divided down the centre at right angles to the net by a line or tape, $\frac{3}{4}$ in. wide, so that the table is divided into four courts. Each of the four players defends one court.

The pair who have the right to serve the first five services in any game shall decide which partner shall do so, and the opposing pair shall then decide similarly which shall first be striker-out.

The first five services shall be delivered by the selected partner of the pair who have the right to do so, and shall be received by the selected partner of the opposing pair. The second five services shall be delivered by the striker-out of the first five services and received by the partner of the server of the first five services. The third five services shall be delivered by the partner of the server of the first five services and received by the partner of the striker-out of the first five services. The fourth five services shall be delivered by the partner of the striker-out of the first five services and received by the server of the first five services. The fifth five services shall be delivered as the first five services, and so on, in sequence, until the end of the game or the score is 20 all. Then the sequence of serving and striking-out shall be uninterrupted, but each player shall serve only one service in turn until the end of the game.

TABOURET. A tabouret is a seat or stool with neither arms nor back, the top being stuffed and upholstered. Tabourets are chiefly stools of the period of William and Mary and Queen Anne, 1688-1714.

TACKING. The stitch known as tacking is a temporary one, being used to hold a hem, seam, or other part of a garment in position while the permanent stitches are put in. Coloured cotton should be used for tacking white materials and white cotton for dark materials, so that the stitches can be easily distinguished.

Begin the tacking by knotting the cotton at one end and pushing the needle straight through the material. Work from right to left, and make the tacking stitches about $\frac{1}{2}$ in. long and to lie a little above the line where the permanent stitches are to be made. After pushing the needle through to the wrong side, bring it out again $\frac{1}{4}$ in. further on in a line horizontal to that where it was put in, and continue to the end of the work in this way.

Tacking should be finished with a backstitch. When removing tacking stitches, care should be taken to see that the material is not torn or puckered. *See Basting.*

TACSONIA. These climbing plants are suitable for the hothouse or moderately heated greenhouse. It is of vigorous growth and is suitable for training on a trellis beneath the roof glass. They belong to the passion flower family and bloom chiefly in summer and autumn. The plants may be set in large tubs or flower-pots or in a well-drained border; a compost of loam, leaf-mould and sand is

suitable. A minimum winter temperature of 55 degrees is necessary. The finest sorts are insignis, reddish-violet; manicata, scarlet, and Van Volxemii, scarlet.

TAFFETA. The most popular variety of this cloth is silk taffeta, which is crisp, with a peculiar dull lustre. Silk taffetas, because of the methods used in making them, are, however, inclined to split in wear, and for this reason they cannot be regarded as hard-wearing. Wool taffeta makes an excellent shirting, and is a superior fine flannel made in tasteful patterns. Cotton taffetas are especially good as shirtings, and are generally dependable in colour and wear.

TAGETES. This is the botanical name of the French and African marigolds, two valuable summer and autumn flowering plants. They are grown as half hardy annuals and raised from seeds sown in a heated glasshouse in February. The seedlings are transplanted into boxes of soil to give them room for development and are hardened off and planted out of doors early in June. The African marigolds grow 2 ft. or so high and bear large, round, lemon or orange-coloured flowers which make a striking display in the herbaceous border. There are both tall and dwarf French marigolds, the latter being very useful as edging plants; the double and single flowers are various shades of yellow, or yellow marked with reddish brown. Legion of Honour, yellow and brown, is a favourite dwarf variety.

TAIL PIECE: On Chairs. This term is used for the continuation of the seat backward seen in Windsor chairs. It forms a necessary attachment to the diagonal spars in a stick-backed type of chair. It is usually quite short and of the thickness of the seat. The diagonal spars fixed to it are useful for stiffening the piece. *See Chair.*

TALCUM. There are a number of uses for talcum or talc, which is a soft, greasy mineral, varying in colour from silvery white to yellow and green; it is a magnesium silicate. The name is also applied to mica, and it is used as chimneys for gas burners and for windows in some kinds of heating stoves. Another use for talc in the home is in the crushed or powdered form as toilet powder. Powdered talc is employed as a lubricant, and, mixed with varnish, makes a shiny coating for wallpapers.

When crushed, talc has the property of reflecting light, and when spread over a comparatively large area it imparts a certain lustre to the material. This effect is made use of in the preparation of a number of fabrics with a shiny surface, the result being obtained in some cases by the use of a special talc preparation. Talc is also employed under the name of French or Spanish chalk.

Medical Uses. Talc has also certain medical uses. On account of its smoothness, prepared talc is often used as a dusting powder for babies; boracic acid powder is generally added and a trace of perfume. Venetian talc, which comes from Tirol, is especially soft and smooth. Lassar's paste, a protective and soothing application for irritable and inflamed skin disorders, may be made with talc as follows: Zinc oxide powder and powdered Venetian talc, of each 2 drams; vaseline or soft paraffin, ½ oz.; salicylic acid powder, 10 gr. Mix into a paste and spread on soft linen or surgeon's lint.

TALLBOY. A tallboy is made up of a double set of drawers, one upon the other. This piece of furniture was first made in England in the latter half of the 17th century. The early ones are of walnut, beautifully grained wood being selected to veneer the pieces. A fine example is illustrated, which shows the characteristic Queen Anne features of burr walnut veneer, brass handles and discreet use of marquetry, the bottom drawer alone being ornamented in this manner.

The tallboy belongs to the walnut period of furniture at its best, but at a later date was made in mahogany. The typical piece has 3 or 4 long drawers in the lower part, and 3 in the upper. In the upper there are also usually 2 smaller drawers. The piece rests on 4 short club legs, and beneath the drawers is an arched shaping. The upper part is usually narrower than the lower, from which it is separated by a simple moulding. The decoration is not elaborate, taking only the form of deep moulding at the top and chamfering or reeding on the front angles. *See Chest of Drawers; Queen Anne Style.*

Tallboy. Queen Anne tallboy in beautifully grained walnut with inlays

in the bottom drawer representing rays of the sun. Height 6 ft. 2 in..(Courtesy of Gill & Reigate, Ltd.)

TALLOW. Tallow is an animal fat largely consisting of stearin, palmitin and olein. The highest grades are used commercially for the making of candles and the lower grades in the manufacture of soap and dressing leather. Tallow can be used to some extent as a lubricant in cases where rope or cord runs over a pulley. Fishing and other lines are rendered more or less waterproof when rubbed with tallow.

Tow impregnated with tallow can be employed for the making of joints in the stuffing box or gland of pumps, etc. *See Tow.*

TAMARIND: The Fruit. The fruit of the *Tamarindus indica* is imported from the E. and W. Indies in the form of a reddish brown pulp mixed with sugar. It has an agreeable taste, contains a large quantity of citric and tartaric acids, is a refreshing drink for fever patients, and is slightly purgative. For children tamarind spread on bread and butter is a good laxative medicine. A refreshing beverage for the sick may be made by boiling 1 oz. in a pint of water. Tamarind whey is made by boiling 1 oz. in 1½ pints of milk, or stirring it into boiling milk. The dose of tamarind is 2 to 8 drams. It is usually used with other purgatives; for example, in confection of senna.

Tamarisk. The feathery heads of small rose-pink flowers of the Tamarix pentandra.

TAMARISK. This is a hardy flowering shrub with slender, graceful, leafy stems and rose-pink flowers in early or late summer. It reaches a height of from 4 to 8 ft. or more. The tamarisks are particularly suitable for planting in seaside gardens, where they are often used as hedges. The common tamarisk is *Tamarix gallica*. It bears pale rose-pink flowers in May. *Tetrandra*, which flowers at the same time, is more beautiful; both should be pruned after flowering if necessary. *Pentandra* (*Hispida aestivalis*) is a charming shrub

with rose-coloured inflorescences in late summer; the shoots should be pruned in spring. Tamarisks thrive in ordinary soil and are increased by cuttings inserted in sandy soil out of doors in autumn.

TAMBOUR. This is a method of constructing a lid or shutter to a writing-table or bureau. It was used among others by Hepplewhite and Sheraton. The sliding lid of a rolltop desk is an elaboration of it. Sheraton made bookcases in this style. The lower part is enclosed in a sliding shutter composed of beads made to slip in grooves.

TAMMY CLOTH. Sauces and soups that depend for success upon their smoothness are usually passed through a tammy cloth made of fine woollen muslin. The cloth is spread over a basin or other receptacle, its edges gathered in the hands to form a well in the centre and the mixture poured in. The two ends of the cloth are then twisted in opposite directions until all the mixture has been forced through. If the latter is especially thick and cannot be tammied in this way, it may be rubbed through the cloth with the aid of wooden spoons.

Immediately after use the tammy cloths should be washed in warm water to which a little soda has been added, rinsed well, wrung out, and dried in the open air. *See Jelly.*

TANGERINE: The Fruit. The small Tangerine orange is used as a dessert fruit, and also for various forms of sweets. It makes an excellent marmalade, and the juice is used to flavour fondants, icing, sweets, and a delicate filling for cakes.

The filling for cakes may be made from the following recipe: Boil 3 eggs hard, then pound the yolks fine with 3 oz. butter, 4 oz. icing sugar, the grated rinds of 2 tangerine oranges, and sufficient of the strained juice to form a soft cream. Spread this filling between two sponge sandwiches and dust the top with icing sugar. This cream spread between shortbread biscuits is delicious.

Meringues may be flavoured with tangerines. Grate the rind of one or two tangerines and add them to the sugar which is used to sweeten the whipped cream for the filling.

Tangerine Chips. These make an excellent garnish for cakes, biscuits or fondant sweets. To prepare them, remove the peel from several Tangerine oranges and shred it in long, narrow pieces, then place these in a basin, cover them with water and lay them aside till the next day. In the morning strain and weigh them, and take an equal weight in castor sugar.

Put the chips into an unlined, bright metal saucepan and strew the sugar over them as they warm, shaking and tossing them about over a moderate heat until they appear perfectly dry. Store in a dry place and keep the chips covered up tight. The pulp of the oranges should not be thrown away; it may be used for other sweets.

Tangerine Drop Cake. Tangerine peel may be used to flavour light drop cakes. Rub $\frac{1}{2}$ lb. lump sugar, lump by lump, on the outside of 3 Tangerine oranges until the sugar has absorbed the zest, then pound the sugar in a mortar until it is a fine powder. Separate the yolks and whites of 4 eggs, beating both by themselves and then together, then by degrees beat these into the flavoured sugar until spongy.

Mix in very lightly $5\frac{1}{2}$ oz. fine sifted flour, to which has been added a pinch of salt. Drop this mixture with a teaspoon on to a tin lined with greaseproof paper. Bake in a fairly quick oven, decorate each cake with a Tangerine chip attached with a little marmalade jelly, then cool on a wire, and store in a covered tin. *See Fondant; Marmalade.*

TANGO. The tango differs from other modern dances in that the dancers walk the steps instead of gliding them, the knees consequently being more relaxed, although they should not be bent; also the

man holds his partner a little farther to one side (on his right hip), his left forearm being bent in more. Both dance with the right side of body slightly in advance of the left, consequently the right foot is turned in a little and the left turned out to the same degree.

There are two rhythms to be followed in this dance, the slow (S.), in which each step occupies one beat of the music, and the quick, quick, slow (Q.Q.S.), in which the quick steps take half a beat each and the slow step one beat. The basic steps are as follows: (1) The Walk; (2) Progressive side step (Fig. 2); (3) Reverse turn (Fig. 1); (4) Side promenade (Fig. 3); (5) Back corté (Fig. 4).

The Walk (S.) The walk forward consists of natural length, ordinary walking steps, the weight of the body being kept over the front foot. The back foot is left behind until the last possible moment before stepping forward with it. The step is counted "slow" and takes one beat of music. The body being held with the right side a little in advance of left, contrary body movement (C.B.M.) is consequently used when stepping forward with the L.F. For the walk backward swing leg well back from the hip, going on to ball of foot and keeping weight on front foot. As step continues weight is carried between the feet and the toes of front foot should leave the floor so that all pressure is on front heel. Weight is then transferred on to ball of back foot. The back heel should not be lowered until the front foot passes it. The front foot should remain in front until the last possible moment before stepping back with it. The right side of the body being held in advance of left, the contrary body movement position occurs when stepping back with the R.F.

Tango. Fig. 1. Showing the six steps of the reverse turn. See text for full description

Progressive Side Step (Q.Q.S.). Following a walk forward with the R.F., the man steps forward and across slightly to R. with L.F., takes a small step to the side with R.F. and steps forward and across slightly to R. with L.F. The girl, having taken a walk back with the L.F., steps back and across slightly to L. with R.F., takes a small step to side with L.F. and steps back and across slightly to L. with R.F. In this step the contrary movement position occurs on the first and third steps for both man and girl (Fig. 2).

Reverse Turn (Q.Q.S., Q.Q.S.). The man steps forward with L.F., turning on it to L., takes small step to side with R.F., still turning, and crosses L.F. over in front of R.F.; steps back with R.F., turning on it to L., takes small step to side with L.F., and closes R.F. up to L.F. The girl steps back with R.F., turning on it to L., nearly closes L.F. up to R.F., still turning, and closes R.F. up to L.F.; steps forward with L.F., turning on it to L., takes small step to side with R.F., and closes L.F. up to R.F. On the first three steps half a turn is made. On the last three, a quarter turn (as shown in the diagram) or no turn at all (Fig. 1).

Side Promenade (S.Q.Q.S.). The man steps to side and very slightly back with L.F. crosses R.F. well over in front of L.F., takes a small step to side with L.F., and closes R.F. up to L.F. The girl steps to side with R.F., crosses L.F. well over in front of R.F., takes small step to side with R.F., and closes L.F. up to R.F. Contrary body movement is used on the second step (Fig. 3).

Back Corté (S.Q.Q.S.). The man steps back with L.F., back with R.F., turning very slightly to L., takes small step to side with L.F., and closes R.F. up to L.F. The girl steps forward with R.F., forward with L.F., turning very slightly to L., takes small step to side with R.F., and closes L.F. up to R.F. Contrary body movement is used on the second step (Fig. 4).

In the accompanying diagrams the R.F. is shaded, the left shown in outline only. The dotted outline indicates the ultimate position of foot. It will be easier to follow diagrams if the dancer faces the direction in which the toes are pointing and turns the diagram at the same time. *See Dancing; Foxtrot; Quickstep; Waltz.*

Tango: three of the basic steps. Fig. 2. Progressive side step; it usually follows a walk forward with right foot. Fig. 3. Side promenade, in which the dancers cross one foot over the other. Fig. 4. Back corté. Throughout the dance the right foot is turned slightly in, and the left foot slightly out.

Tank. *See* Cistern; Gallon.

TANKARD. The modern tankard is a plain drinking vessel usually large enough to hold a pint of liquor and made of silver, pewter, glass or earthenware. They are either open or with lids. Genuine antiques and tankards reproduced from old styles are nearly always lidded. The tankard is shaped somewhat after the style of the flagon (q.v.), but the latter is an earlier type of drinking vessel, and whereas tankards vary from about 6 to 9 in. in height, 7 in. being usual, flagons were as much as 15½ in., and more cumbersome pieces.

Tankard in silver dating from 1830, when these pieces were richly ornamented. (Courtesy of Chapple & Mantell)

Tankards are sometimes found in old Sheffield plate, but more frequently in silver and, copied in the plainer styles, in pewter. The lid and hinge are the chief points of interest: in the older examples a thumbpiece on the hinge strap is placed so that the lid may be easily raised. Both handle and thumbpiece were often artistically decorated. The latter was cut in two main shapes, a horizontal corkscrew, and bifurcated. Fine tankards occasionally have a lion thumbpiece and in later examples this is sometimes fluted.

Dating from the end of the 16th century to the reign of Charles I, tankards were straightsided, but often richly chased and ornamented with repoussé designs. Very plain styles with flat lids followed in Puritan times. Restoration tankards were massive with cylindrical bodies, flat lids and engraved with coats of arms and crests. Queen Anne tankards were for the most part fairly plain but elegantly shaped and often embellished by gadroon ornament to edge the lid and base, or by reeding round the body of the tankard. A knob appears on the lids occasionally. This disappeared on the domed lids of Georgian tankards, many of these pieces being bellied and the thumbpiece, or purchase, well in evidence. The tankard illustrated dates from the reign of William IV and shows the reappearance and elaboration of the knob into a floral ornament, the bellied body, spreading foot and lavish raised decoration of the period. It will be noted that the thumbpiece is absent from the hinge strap, the knob by this time having been substituted for it.

What are known as peg tankards have small pegs fixed inside in a line with the handle; the object being to regulate the quantity of liquor to be drunk on ceremonial occasions in honouring each toast. *See Pewter; Silver.*

TANNIC ACID. Oak galls are the source of tannin or tannic acid, which is a brownish powder with a strongly astringent taste. Common preparations are: glycerin of tannin, suppositories of tannic acid and lozenges of tannic acid.

Tannic acid is an efficient astringent, lessening the discharge of fluid from any ulcer or mucous surface to which it is applied. It is also a powerful haemostatic, as it clots the blood flowing from a vessel. The powder may be used as a snuff to check bleeding from the nose.

Internally tannic acid is used in the form of an infusion to check diarrhoea. It may be used in a douche to check leucorrhoea. The glycerin of tannin, 1 part to 8 parts of water, is an efficient astringent gargle in sore throat.

TANSY. This is a small family of hardy herbaceous perennial plants. The average height is about 2 ft., and the yellow, daisy-like flowers are borne in summer. Seed should be sown in spring in ordinary soil. The value of the ordinary tansy, *Tanacetum vulgare*, is in its leaves, which are used for flavouring puddings, and also for decorating dishes. Costmary, *T. balsamita*, is grown for the salad value of its leaves. Tansy tea is also an old-fashioned country remedy. All kinds may be increased by division of the roots in autumn. *See Herb Garden.*

Tansy. Leaves of Tanacetum vulgare, a valuable addition to the herb garden.

TANTALUS. A tantalus is a small upright wooden stand used as a receptacle for spirit bottles, in which the latter are locked up but visible. The bottles are of cut glass and generally number two or three.

Tap: For Screw Threads. *See Stocks and Dies.*

TAPS: THE HOUSEHOLD TYPES

Hints for the Handyman on Fitting and Repairs

This article describes the leading forms of domestic water tap. The articles on Frost and Water Supply should be consulted for further information. See too Bath; Hose Pipe; Hot Water Supply; Sink; also Pipe; Plumbing; Soldering.

The water taps in general use in the home are of two classes, known as plug and screw-down taps. The plug tap consists of a body and a plug, the body having a passage-way through it which is crossed at right angles by a second passage-way tapered in shape. This is occupied by a similarly shaped piece of metal known as the plug. The plug has a hole through it lineable with the first or throughway hole. When the plug is turned in its socket so that the hole in the plug is opposite that in the body, the liquid passes through. When the hole in the plug is at right angles, the through-way is closed and no liquid can pass, if the plug is a perfect fit in the socket. This kind of tap is used for water at low pressure. A similar type is used on gas pipes.

Tap. Fig. 1. Sectional view, showing principal parts of the screw-down type of stop cock.

The screw-down tap consists of a handle and screwed rod which turns in the upper part of the body and has at the lower end an enlarged portion known as the jumper. This can be raised or lowered under the action of the handle, the function of the jumper being to close or open an aperture between an upper and lower water-way formed in the body of the tap. The construction is clearly indicated in Fig. 1, which illustrates a stop cock. Fig. 2 shows a bib cock with the jumper nut and washers removed. A pillar valve for baths and lavatory basins is illustrated in Fig. 3.

Tap. Fig. 2. Component parts of a screw-down bib cock. See text

Screw-down taps are generally used on all water fittings in connexion with public supplies, as they are durable and reliable in use and tend to minimize wastage of water. It may be noted that some considerable pressure of water is needed to operate the screw-down tap, so that it is useless fitting this type to a rainwater tank, for example. A plug tap should be employed for such purposes.

In Figs. 2 and 3 the component parts are indicated as follows : A, handle and barrel. B, jumper. C, jumper nut. D, washer. E,

joint washer. F, body. G, cap. H, fixing nut. J, union piece and nut.

The tap usually fitted to water pipes for domestic purposes (Fig. 2) is known as a screw-down bib cock. The components are clearly shown, as they have been taken apart in their proper order. The body is seen at the bottom, right; above it is the washer which makes the joint between the body and the barrel watertight. Next above the washer is the jumper washer (top, right), and jumper with retaining nut (bottom, left). The jumper seats on to a valve face within the body, and is practically

the only part that is likely to give trouble. It is replaced when needed with a new washer, which can be obtained in various sizes from ironmongers.

A washer of a special material is needed for pipes on the hot-water system. As soon as the pipe commences to drip, and water is not easily turned off, a new washer should be fitted. Sometimes the jumper nut gets corroded and will not unscrew; in such a case it is best to fix a new jumper and washer complete.

The barrel at the top consists of a stuffing box to keep the joint between the screwed part of the handle and the barrel watertight. The lower part of the barrel is threaded to screw into the top of the body. Usually this part is screwed left-handed, that is, the barrel is unscrewed by turning it backward, or against the clock. It is sometimes fitted with a setscrew to prevent it unscrewing. This should be looked for at the start, removed if present, and the barrel can then be unscrewed with a large spanner applied to the hexagonal part at the bottom of the barrel.

The same principle is adopted with stop cocks and other taps, including the pillar types of bath and lavatory basin valves, an example of which is illustrated in Fig. 3. The internal structure and arrangements are similar to the foregoing, but the outlet from the body is set at an angle to enable the tap to stand in a vertical position. This has the advantage that the pipes can be more readily erected and are less obtrusive, as they can be hidden to a large extent behind the basin or bath.

Tap. Fig. 3. Parts comprising a pillar valve, as used for baths and lavatory basins. See text.

As will be evident from an inspection of Fig. 1, there is a right and a wrong way to fit a stop cock, the correct way being with the lower of the waterways towards the direction of flow of the water. This is because the water as it passes the jumper and washer is then able to lift it off its seat, and thus there is a minimum of friction in passing. If the tap be arranged the other way round, the water will tend to force the jumper down and thus partially choke the waterway, and there will be much more pressure needed to force the water through the stop cock. On some makes of tap the jumper is positively attached to the spindle by a floating joint, and this joint automatically lifts the washer and jumper from the valve seat.

TAP BOLT. Alternatively known as a stud bolt or cap screw, the tap bolt, which has a square or hexagonal head, is employed in metal work when an ordinary bolt and nut cannot be used. Examples are found on many forms of domestic work, as, for example, when a small part has to be securely attached to a base plate or other part. The screw passes through a clearance hole in the part to be attached, and bites in a thread cut into the main part of the apparatus. *See Bolt; Nut.*

Tap Bolt for use in metal work

TAPE. It is not always best to buy cotton tape in mixed packets. A small assortment in varying widths is useful, but the stock bundles usually include a proportion of the less needed sizes, and these take up room in the workbox.

Linen tape is naturally stronger and more durable than cotton tape, and, although usually unbleached, it whitens in the course of washing. Tape makes an excellent substitute for twine, especially in packing stationery and books. Stationers sell special tape for such use, as well as red cotton tape for tying documents and narrow green silk tape for batches of typewritten sheets.

Special tape is also made for heading and gathering curtains, which pulls out flat for washing. These headings ensure good pleating and are supplied in all colours and in various widths.

TAPE GRASS. The half-hardy, ornamental grass with small white flowers, which is known as tape grass, is suitable for indoor pools, aquaria, or water basins. It should be potted up in a small receptacle filled with rich loam, and placed at the bottom of the water garden in springtime. It requires a mean temperature of about 60°. Tape grass is also known as eel grass. There is only one important variety of it.

TAPE MEASURE. A good tape measure is an indispensable adjunct to the workbasket. It is, as the name implies, made on a strip of material which looks like tape, usually about 1 in. wide, and is finished off at one end either with a metal tab or a loop. The length is usually 60 in. and is divided into inches on one side and centimetres on the other. The whole can be rolled up neatly and put away in the work-basket without taking up valuable space. Similar measures are made in narrower widths in a box or reel which contains a spring. This draws the measure back automatically when the end is released and involves no winding.

TAPER. Wax tapers bought by the dozen are useful in the house for lighting up purposes, especially with incandescent gas. They are obtainable in colours and in white. The heavier make of white tapers can be inserted in a brass holder which can be adjusted to the length of the taper, and prevent it curling up at the end when a few inches have been burned.

Such a holder is convenient when hung near the gas cooker for lighting one burner from another with the taper contained and for preventing the fall of drops of wax.

Taper Holder. Wax-jack type of holder in Sheffield plate, about 1800.

Taper Holder. This antique was designed for holding a tiny candle or a coiled wax taper when the introduction of sealing wax made some device for melting it a necessity on the writing table. Good specimens in silver and Sheffield plate are greatly valued to-day by collectors. The holder took three main forms, a stick, a box, and a jack. The stick resembles a small candlestick and is also to be found in brass. These pieces followed the standard candlestick patterns. Some have a chimney glass as a protection for the flame against draughts.

The box is a small, rounded canister, about 3 in. across. It has a loose lid, through the centre of which is a tube which holds; the taper. An extinguisher is often attached to it, as it is to the candlestick. The jack is a less familiar piece. Sometimes it, too, was supplied with an extinguisher. The example illustrated has, a cage of flat wire work and a side handle, by which it was held. The ring is fixed to the taper bar round which the long wax taper was coiled, except the small portion in use which comes, through the hole in the top. *See Candlestick; Sheffield Plate.*

TAPESTRY. The word tapestry is used to cover a range of decorative patterned fabrics, the design rather than the texture determining the classification. Thus a type of machine-woven furnishing materials, carpets, wallpapers and needlework, are all spoken of as tapestry. The real thing is confined within the limits of its handwoven texture, of which the design forms an integral part. It may be woven on an upright or a horizontal loom, but the resulting fabric is the same. Tapestry was woven in Egypt many centuries B.C., while beautiful fragments exist of ancient Greek work. Although made in France from the 14th century, important manufactories were first established in England in the 17th.

A textile is not tapestry in the strictest meaning of the word, even when handwoven on a loom in which a double warp (vertical thread) is used and the shuttle carrying the weft (horizontal threads) is thrown between the warps to their full width, the interlocking of the textile being accomplished by use of the treadle, which brings first one set of warp threads to the top, and then the other.

Real tapestry is bobbin woven. One set of warp threads only are used, and the bobbin passes the weft by hand in and out of each warp thread alternately. Only the weft threads are seen on the surface, presenting the design with the ribbed or rep appearance, exactly the same on both sides, which distinguishes the genuine fabric. In the article on looms a simple tapestry pattern is shown being woven on a string warp, and the principle of the weaving is demonstrated by the illustration.

Tapestry. Example of modern pictorial tapestry based on a Renaissance design used as a mural decoration in a hall.

Of all textiles, tapestry is the most durable, as this complete interlocking of warp and weft produces a web which is almost indestructible in ordinary usage; but it will be readily understood that even modern real tapestry must be a costly production when it is considered the time, patience, and artistic skill required to produce a yard, copying the forms by use of the number of colours and shades which go to the making of a fine design. Old pieces fetch prices beyond the purse of the ordinary buyer, except by some lucky chance. Anyone possessing genuine tapestry which has been cut or torn should have it repaired at a tapestry studio; otherwise it may be irretrievably spoiled.

The three great epochs and corresponding «centres of tapestry making were, in the 14th and 15th centuries,

Arras (the name of the town becoming a synonym for tapestry hangings); in the 16th, Brussels; in the 17th, Paris, when the Gobelins workshops were assisted by Louis XIV to become the finest centre of the art. At this period the ateliers at Aubusson and Beauvais were also flourishing, and at Mortlake in England fine work was being carried out.

Designs are classed under two broad headings, verdure and personages. The former may be of massed foliage only, or also introducing flowers and fruit; the style known as mille fleurs, in which flowers and leaves are scattered in profusion over the ribbed ground; the landscape designs, for

which the workshops at Beauvais were particularly famed. Mille fleurs and landscape designs often introduce figures and animals, but the main interests of flowers and foliage class them as verdure. Personages designs, as the name implies, are figure pieces, battle and hunting scenes, cartoons and copies of pictures in which people are the chief interest. Heraldic or armorial tapestries were usually surrounded by borders of verdure. In old tapestries made for mural decoration borders were an important part. Panels are completely bordered by a narrower design or on three sides with inscriptions at the bottom, while lengths, originally part of hangings which covered whole wall surfaces, usually display a border top and bottom.

Besides this broad classification based on type of design, which embraces all periods, tapestries are also classed as Gothic, Renaissance and Later French, and these terms are often used by modern decorators in speaking of various patterns. The Gothic designs of the Middle Ages, which are considered the finest, are flat in drawing and almost without perspective. Fewer gradations of colour were used, and in consequence the patterns have stood the test of time, while subtler shading has become blurred in more recent work.

Some of the loveliest Gothic designs, copied to-day for mural panels or to upholster valuable chair-frames, are the mille fleurs. In the Renaissance designs attempts were made to copy the lifelike style of the painting of this period. The Later French period tapestry, often spoken of as Louis and sometimes as Aubusson, where a great deal of it was made, chiefly shows the charming designs inspired by the paintings of Boucher and Watteau; dainty and delicate in colour and treatment, these are largely reproduced to-day for covering white and gold or gilt frame chairs and settees.

Simulated Tapestry. In the machine-made jacquard tapestries effects are well reproduced at a moderate cost. This fabric is made in panels to copy tapestry pictures with verdure borders, varying in size from big wall-pieces to cushion covers. It is also made by the piece, repeating the all-over verdure design, and sold by the yard. It has splendid wearing qualities, and its texture looks better next to a polished wooden surface than a dull one. The charming effect in a hall of such tapestry in a pictorial form is shown in the illustration. Block printing by hand of a good tapestry design on a horizontally ribbed material, simulating the real tapestry texture, is another form of imitation for mural purposes. The colouring and designs used are good, and at a little distance the effect is rich and pleasing. Above a dado carried out in oak block printed rep looks its best. Pictorial and other tapestry effects are carried out in needlework, using the stitches described in the subsequent article. Painted tapestry in imitation of the Gobelin tapestries has a foundation of corded or rep canvas over which the designs are painted. Its resemblance to the genuine tapestry is due to the particular kind of canvas of which it is made, for the real Gobelin tapestry has also a corded ground, though the designs are woven, as already described, instead of painted. The painting is done by experts, and the finished article is therefore somewhat expensive.

Tapestry carpets are imitations of Brussels. In tapestry wallpapers the verdure designs are copied in pleasant colourings. Sometimes figures are introduced, or landscape panels. *See* Living-Room; Louis Style; Loom.

TAPESTRY NEEDLEWORK: STITCHES & DESIGNS

Embroidery for Chair Seats, and Other Canvas Coverings

This article explains the practical application of this decorative needlecraft in the home. See also Bag; Cross Stitch; Embroidery; Laid Work; Queen Anne Style; Rug; Stool; Victorian Style; Wool; Woolwork.

Included under the heading of tapestry needlework are all the canvas embroideries in which the stitchery covers the whole groundwork of the fabric and in which the work is done on counted threads. This type of embroidery was done in England in early Tudor days and continued in use for wall and bed hangings until the end of the 17th century, and on, when it became the fashion for chair, settee and stool seat coverings. In Victorian days it was much used also for firescreens, draught screen panels, footstools and tapestry pictures. On stools and chair coverings, opaque white and crystal beads were frequently introduced as high lights on the patterns. In some examples of older work silk thread is used for the same purpose and some needle tapestry is embroidered entirely in silks.

Materials Required. One of the most fascinating things about the work for furnishing purposes is that designs can be obtained or evolved which suit any type of room and furniture, but in which the same simple stitch or group of stitches are employed, however intricate the appearance of the work when completed. Another immense advantage is durability. It is therefore wise to use the best wools for embroidery, and canvas for foundation. Materials, including designs with colour charts, canvas already traced for working, or with the patterns outlined and colours suggested by painting them on the fabric, wool and silk embroidery threads, canvases in a variety of meshes, needlework frames and needles are stocked by all good art needlework shops and departments in stores. Work can also be reshaped if pulled, or mounted when finished if required.

Tapestry wools vary in thickness according to the nature of the work, canvas and design. For a large piece of work such as a chair seat, which will be required to withstand constant wear, a heavier type of thread is required than for a bag design embroidered on finer canvas. Among other excellent makes of wool are Pearsall's tapestry and crewel wools. White Heather embroidery wools, Penelope crewel and tapestry wools, and others.

Wools are all made in a wide range of colours and are obtainable in small skeins.

Silk threads should not be used for upholstery covering as they do not withstand wear. In several old pieces where silk threads have been introduced into portions of the original work the wool worked portions are unimpaired, but the silk ones have perished. Silks are however useful for brightening smaller designs for pole fire screens, cushions, cosies, blotters and purses. Artificial silks, owing to their brilliancy, are often liked for this purpose. For very fine work stranded cotton and Filoselle silk threads are recommended as the strands can be split and any thickness used that the worker requires. Mercerized embroidery cottons are sometimes employed, and wear well, but nothing can beat the beauty of wools for this form of embroidery. Tapestry wools are best used for heavier work, light crewel wools for fine petit-point embroidery on such articles as bags.

Tapestry is worked on either a single thread canvas, or double thread Penelope canvas and a variety of meshes are obtainable according to whether the design requires a fabric having many holes to the inch or comparatively few. For instance, there might be 120 stitches across a design, and if the work was required to measure 12 inches across when finished, the canvas should have 10 holes to the inch. Double strung canvas is best for covering furniture. The canvas is obtainable in single and double widths when bought by the yard. Special blunt pointed tapestry needles should be used for the work.

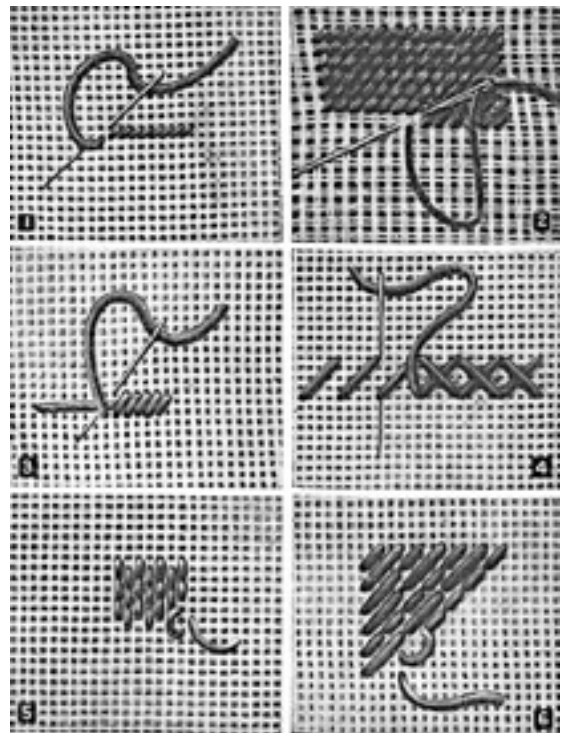

For large pieces of embroidery it is wise to use an embroidery frame, but this is not necessary for a smaller piece. A frame simplifies the task as there is a tendency for the work to pull crookedly. Should this happen the remedy is to damp the work thoroughly on the wrong side, place it face downward on a piece of clean cotton cloth on a board and tack it flat to the board, testing with a ruler to see that the work is stretched to the exact shape required when finished, and leave it to dry.

Colours and Designs. For all fine needle tapestry it is essential that colours should be subtly graded. The richness of pattern is obtained by the use of 4 or 5 shades of one colour in proximity and by the contrasted plain colour of the solid background. Expert workers get wools specially dyed according to their colour charts. When copying some of the older designs it should be remembered that colours were originally brighter and probably cruder. This is especially the case with greens. The lovely blue-greens of the old Jacobean work are to a great extent the result of accident. The blue dyes employed endured, while the yellow were fugitive. The most delicate pinks and yellows in many Queen Anne period pieces have in some places faded to indeterminate whitish shades.

Artistic workers use undyed tapestry wool for these, the natural tint of the wool giving exactly the right tone when used as the lightest member of a group of greens, reds and pinks, blues or yellows. Another hint which can be applied when embroidering a cover for a period chair or stool is to change the pale shades slightly in the repeats of the pattern to give the partially faded effect of mellowing age. The result is to make the new cover belong to the frame instead of proclaiming its modernity at a glance. If in spite of careful choice of "old" colours to suit period pieces the result is still too crude, the tapestry may be dipped in tea and then tacked to a board or frame to dry and preserve the required shape.

While art needlework shops supply designs elaborately prepared there are many pieces of beautiful work which can be done directly on the canvas by counting stitches and following clear charts of designs and colours. The pattern motifs are always worked first and the plain backgrounds put in afterwards.

Tapestry Needlework: stitches most used. Fig. 1. Petit point on single thread canvas. Fig. 2. Tent stitch on double thread canvas. Fig. 3. Gros point over a laid thread. Fig. 4. Cross-stitch as worked in tapestry. Fig. 5. Straight filling stitch. Fig. 6. Mosaic stitch.

Period designs are obtainable in Florentine, Cluny, Gothic, Gobelin, English 17th century, Queen Anne, Chippendale, Adam, Victorian, and also in Louis styles. The last are often used for embroidering beautiful bags, and a typical one is illustrated in Fig. 11, with its landscape motif surrounded by a scrolled frame and floral pattern. A great help to anyone who wishes to work a cover for an antique stool or chair is to visit the Victoria and Albert Museum and study the needlework covers of furniture in the collections there. For the most part earlier designs show a tendency to all-over patterns, which have again appeared in tapestry work for quite modern pieces, particularly Florentine patterns consisting of Vandykes or wavy lines in which the rich effect is gained by use of varied colours. Many of the later designs were composed of central floral or pictorial motifs, either surrounded by fancy borders or a plain continuation of the background stitchery.

The Stitches. The stitches most used in needle tapestry are petit point, gros point, cross-stitch, straight Gobelin stitch and mosaic stitch. Whole pieces can be worked in either of the first two stitches. Petit point is often known as tent stitch, finest effects being gained by it on a small-meshed, singlethread canvas. This stitch is worked diagonally over one thread of the canvas and is

actually worked from left to right upward diagonally, but the row always progresses from right to left, as shown in Fig. 1. For alternate rows the work is turned upside down. Fig. 2 shows the same stitch on double thread canvas.

Gros point is worked in the same way, but over two threads or two sets of double threads on a double-thread canvas. This stitch is greatly used for chair seats and for groundings. A padded effect is gained by laying a thread, as shown in Fig. 3, between the threads of a horizontal line of the canvas, and working the stitch over it. Do not pull the wool tightly when working over a coarse canvas as it is a sign of bad stitchery when the canvas threads show through. Some workers use double wool for heavier types of designs on coarse meshes. Do not thread the needle with more than about 20 in. of working thread.

Cross-stitch for tapestry is usually worked over 2 vertical and 2 horizontal single or double threads of the canvas. To ensure an even appearance stitches must be crossed the same way. In a pattern each stitch should be finished singly, but when working a grounding it is permissible to work the first half of the stitch along a row and return crossing. In Fig. 4 the stitch is enlarged to illustrate detail.

Straight Gobelin stitch is worked in horizontal rows for groundings. The thread is carried vertically over 2 threads of single-thread canvas (or 2 double threads of doublethread canvas), leaving each time one thread of material between the stitches. As clearly shown in Fig. 10, the effect is vertical and not diagonal. This stitch is used to imitate the ribbed grounding of Gobelin woven tapestries. A straight filling stitch shown in Fig. 5 and a wide oblique Gobelin stitch are sometimes used.

Tapestry Needlework. Fig. 7. Queen Anne style chair with a drop-in seat covered by a piece of tapestry needlework in a design of the period. (Courtesy of Bartholomew & Fletcher)

The latter covers 2 vertical and 3 horizontal single or double threads of the canvas, and advances one thread of the canvas at a time. Mosaic stitch makes another useful grounding, as shown in Fig. 6. It is worked along the 1st row with a long slanting stitch and a short one alternately. The 2nd row completes this by adding the second short stitch. The 3rd row is like the 1st, and the 4th row like the 2nd. The final row is all of short stitches. A stitch used in Florentine patterns is worked in slanting lines, the thread being carried alternately over 2 and 4 crossings of the canvas, the stitches in the 2nd row being short where those in the first were long, and so on to cover the canvas.

There are many other stitches which the experienced worker uses occasionally. Sometimes stitches seem to evolve of themselves to suit the particular pattern, but the, beginner is advised to use the simple ones until proficiency is gained in keeping the work flat and the stitchery even.

To secure the first stitch when a laid thread is not used, a knot is made at the end of the wool, the needle passed through the canvas from the right-hand side about $\frac{1}{2}$ in. from the starting point. As the work proceeds from left to right after a few stitches the end of wool is caught in at the back. Afterwards fresh lengths of wool are darned in at the back of the stitches. When using a number of shades of the same coloured wool, knot the cut skeins loosely on to a wooden curtain ring, keeping all the greens together, all the pinks, etc.

Furniture Coverings. The Queen Anne style elbow chair in Fig. 7 shows the beautiful effect of a needle tapestry covered seat. The design is an all-over floral one of the period, worked in petit point

in wool on a doublethread canvas. A cover for a chair or stool with a drop-in seat is easier to make up than one for an over-stuffed frame. When the work is finished, the loose seat is taken out, the tapestry stretched over it, and brought smoothly down to the underside. Tacks with large heads are obtainable, which are placed at frequent intervals to secure the work to the under framework of the drop-in seat. This is then neatened with a piece of hessian, the edges of which are turned in under itself. It is important, when measuring the canvas to be embroidered, to allow a good margin forturning.

Fig. 8. All-over pattern of a single conventional floral motif repeated at regular intervals, a suitable design for the chair shown above.

A conventional floral pattern is shown in Fig. 8 which could be used with any style of furniture, but would look best for a chair of the style illustrated. It is carried out in gros point on a double-thread Penelope canvas with 12 threads to the inch, using tapestry wools. Sufficient canvas should be bought to allow a 4-in. margin all round. This pattern has only one motif, so that the beginner becomes quickly used to working it, and in each alternate row of motifs the colours are the same. Thus the 1st row of these conventional flowers could be done in two shades of pink, with a yellow centre, outlined with maroon, and pale green used for the stem. The 2nd row of flowers have dark green stems and are outlined with the same shade, filled in with deep rose and crimson brown and yellow centres. It will be noticed that part of the centres of a row of flowers are worked at the top of the illustration, repeating the colours of the 2nd row underneath.

The centre of the canvas is first marked and an upright line drawn through it. The rest of the fabric is then spaced out into squares, the size of each recurring motif.

The grounding is put in last, also in petit point, and could be in stone colour, of a dull fawn or black according to the colour scheme of the room.

Fig. 9. Circular piece of tapestry worked for a stool covering.

A charming central floral design is shown in Fig. 9. This is worked on single-thread canvas in petit point for the pattern, and in straight Gobelin stitch for the grounding, and could be used for a round stool or, by filling out the canvas with the grounding stitch, could be used for an oblong or square stool.

Fig. 10. Portion of same design showing detail of petit point stitches used for pattern and straight Gobelin stitch for grounding.

The delicacy of the pattern is greatly enhanced by the different stitchery employed. Fig. 10 illustrates a portion of the design enlarged to show the detail. (The roses,

carnations and leaves are worked first in natural colours on a stone-coloured or grey blue background. Begin with the central flower. About 30 small skeins of wool are required for a footstool.

Bags and Pochettes. For bags worked with beautiful designs in petit point the finest canvas is used, and in some cases silk Filoselle is employed for the design and in others fine wools. Occasionally silks are employed for portions of the design only. Pochettes are often worked on rather coarser meshed double-thread canvas and with tapestry wools, as they are more handled and used for ordinary occasions, while the bags in finest embroidery are reserved for the evening.

Tapestry Needlework. Fig. 11. Bag in which a Louis style design is worked in petit point with silks on fine canvas.

A bag in petit point with a simple floral wreath or posy would require f yd. of 23-in. wide single-thread canvas, a bag frame about 6 in. across, and silk for lining. The shape of the front of the bag is marked out on the canvas, making it the width of the frame across the top, 8 in. deep and curving out the sides with rounded corners at the bottom. The design on the front might require about 20 skeins of coloured silks, while the back of the bag and the grounding would require about 12 skeins of the same shade. A bag of the same shape as the one just described is illustrated in Fig. 11, but a beautiful design of this type requires to be traced for

working. Such designs on canvas ready for working can be bought in a number of patterns.

In gros point or petit point conventional patterns of stripes, triangles, encroaching squares and circles are all easily worked, and patterns can be copied from modern woven fabrics for pochettes and larger bag coverings. Shaded Vandykes worked in wide Gobelin stitch or in a straight stitch taken vertically over 3 holes are most effective for bags with wooden frames. It may, however, be remembered that no stitchery is so durable as petit point or cross-stitch on a medium meshed canvas. The longer the stitch the greater the possibility of threads being caught and pulled out of shape in handling and wear. The making up of bags and pochettes is described in the article Bag. They can also be made up in needlework shops. Some workers merely damp their finished embroidery on the wrong side and tack it on to a covered board to stretch it back to the required shape when finished; others find that it is best to press the tapestry with a moderately hot iron, placing the work face downward on a thickly padded ironing board.

Tapeworm. *See* Worms.

TAPIOCA. In cooking, tapioca, which is obtained from the roots of the cassava plant, is used to make puddings, soups, and jellies, and also forms a good thickening agent. It is nourishing and easy of digestion, and therefore may be included in invalid diet. Tapioca requires long cooking, and should not be placed over too fierce a heat. The grains vary in size. The fine kind may be cooked in the same way as semolina.

A cold sweet that requires little preparation is orange tapioca. To make it, put $\frac{1}{4}$ lb. small-grained tapioca into a pan with a little more than a pint of water and the grated rinds of two large or three small oranges. Simmer the whole until it clears, then draw the pan to the side of the fire and add $2\frac{1}{2}$ oz. sugar and the strained juice of four oranges. More sugar may be used if the fruit is sour.

Let the mixture cool before turning it into a deep glass dish, and serve with cream or custard.

Tapioca Cream. A good sweet with tapioca and desiccated coconut as its main ingredients can be made in the following way: Wash 3 oz. tapioca, then let it soak for 12 hours or more in a pie-dish containing 1 pint water. Any water that has not been absorbed when the soaking is over should be poured off. Mix in 3 oz. sugar and 2 tablespoonfuls desiccated coconut, add 1 quart milk, and bake the whole in a warm oven, first bringing it to the boil and then cooking it slowly for 1-1½ hours. This can be done by lowering the temperature of the oven once the mixture has reached boiling point.

Serve it cold, with 1 gill slightly whipped cream on top, and 1 tablespoonful desiccated coconut sprinkled over the cream. Apricot sauce (q.v.) may be served separately.

Tapioca Pudding. To prepare this, wash 3 tablespoonfuls tapioca, let it soak for an hour in pints milk, and then turn it into an enamelled saucepan, adding a lump of butter about the size of a hen's egg, tablespoonfuls sugar, and the thinly peeled rind of a lemon. Boil these up slowly, and then simmer until the tapioca grows clear. Take out the lemon rind and let the mixture cool at the side of the fire before stirring in the yolks of 2 eggs, and then the stiffly beaten whites. Pour all into a greased dish, and bake it in a moderately hot oven until it sets, and the top is lightly browned. A tapioca and apple pudding can be made in the same way as sago and apple pudding. *See Diet; Food; Semolina.*

TAPPET. In internal combustion engines of the side valve type the tappet, which is a part of the valve gear, is fitted between the end of the valve stem and the face of the cams of the camshaft. A similar device is used on some overhead valves operated by push rods, though a pivoted lever is often used which carries a roller at its free end, the roller bearing against the operating cam. Diagrams illustrating both systems are given in the article on Valve.

Owing to the fact that the face angle of the cam as it makes contact imparts a thrust sideways during the initial stage of raising the tappet, the guide is eventually worn oval. To overcome this fault, anti-friction devices, as shown at C, are frequently employed that provide a rolling instead of a sliding contact.

The feature of the adjustable tappet, which is most commonly used, is that the amount of clearance between the end of the valve stem and the head of the tappet may be definitely set and fixed. This makes it possible, irrespective of wear of the parts, to maintain the valve gear, in respect of tappet noise, in good order. Although tappet noise is primarily due to faulty setting of this amount of clearance, other contributory causes are worn cams, worn tappet rollers, and slackness of the tappet in its guide.

The gap of a few thousandths of an inch can be tested by a feeler gauge of the correct size. The maker's instructions should be followed on this point, but as a guide it may be noted that the clearance for most water-cooled engines is about .004 in. for inlet valves and .005 in. for exhaust valves. In the case of overhead valves the clearance is generally a little more. Tappet clearance should be adjusted when the engine is hot.

Tappet : representative types. A, D, motor cycle patterns. B, side valve type ; C, tappet with roller ; E, pattern used for overhead valve operated by push rod

Valve gear would be almost silent but for the fact that the varying length of the valve stem, caused by engine temperature, makes it impossible to provide permanent contact of the tappet with the face of the cam and the stem of the valve. Tappet noise can be reduced to a negligible quantity, however, if careful attention is given to the adjustment at a time when the engine is thoroughly warmed up. *See Cam; Motor Car; Valve.*

TAR: Its Domestic Uses. Tar is obtained by the destructive distillation of coal, wood, and bituminous materials such as shale. The black semi-solid mass left as a residue after further distillation of the tar itself is commonly known as pitch. Tar can be had in a semi-liquid state or as a solid material. Liquid tar is applied cold, but may require slight heating in cold weather. Solid tar or pitch is broken up into small pieces and can be put in an old iron bucket, supported on bricks, and a fire kindled underneath to melt it, as in Fig. 1.

Tar. Fig. 1. Showing use of tarpot and fire and method of tarring the butt of a post before fixing it in the ground.

This must be done in the open and well away from anything that is likely to catch fire. On no account should a vessel containing tar be heated over a gas ring or a fire indoors.

The tar should be heated just sufficiently to render it fluid enough for use. If it catches fire tar burns fiercely and emits volumes of pungent smoke; it can be extinguished, though not without difficulty, by smothering with damp sand.

The use of tar in the household is due chiefly to its waterproofing qualities, which render it particularly suitable as a protective covering for wood and metal. This property is taken advantage of in the coating of wooden roofs and other wooden structures which are exposed to the weather; but care should be taken to apply such a coating only where there is no particular risk of fire. Iron fences are often coated with tar to protect the metal from rust, and a fence treated in this way looks well and also lasts for many years if additional coats are applied from time to time. On account of its waterproofing qualities tar is also employed for dampcoursing.

Fig. 2. Tarring a roof with a stiff-bristled brush fixed to a long handle.

Liquid tar is applied with a specially, made stiff-bristled brush; this is shaped somewhat like a short-haired sash tool, but the bristles are spread out at the ends. One pattern is made with a short single handle; the other variety has a long handle, and the brush head is set at an

angle to it. The stock brush is made with 1, 2, or 3 rings or sets of bristles, which are mounted on a cross-piece of wood and attached to the handle in much the same way as a garden rake.

Roofs and walls of outbuildings are often covered with tarred felt or similar material which has to be tarred frequently to keep it in good condition. This can best be done with a good grade of liquid tar or one of the preparations having tar as a base. It is applied with the long-handled tar brush as

shown in Fig. 2, and the worker should stand so that the brush can be manipulated at one side of the body, as this tends to keep the person reasonably clean. Tarring operations should be carried out in warm weather and only old clothes should be worn.

Tar is applicable in the form of a paste to such purposes as the floor covering beneath a boarded floor. In such a case the tar is mixed with the aggregate, which may be very small pieces of clean broken brick or ash well worked into a stiff mass and laid in a similar way to a cement or concrete floor. This takes some weeks to set, and then the floor boards can be laid directly on it. If the undersides are tarred and a film of tar be brushed over the floor surface the result will be as nearly as possible damp-proof.

Tar can be employed effectively in the top treatment of a path. A simple method is to prepare the surface of the path, which is assumed to be of ashes or gravel. The top is then brushed clean and the tar applied hot, and well brushed into the surface. This is followed by a sprinkling of sand or fine grit, and as the tar sets the surface is well rolled. A damp sack should be rolled up and rested on the framework of the roller, and secured to prevent it becoming displaced. The sack is placed so that it rests on the top surface of the roller, and acts as a brush to keep it clean. It should be damped from time to time. Tar with stone dust can be used as a substitute for asphalt in laying a path. The method is described in the article on Path.

Medicinal Uses. Wood tar and prepared coal tar are both used in medicine. Wood tar is a blackish, aromatic-smelling semi-solid substance containing oil of turpentine, creosote, phenols, resins, and other constituents. Juniper tar oil or cade oil and birch tar are used in chronic skin diseases, usually incorporated in ointments. Tar ointment is used in the treatment of chronic eczema and psoriasis.

The diluted ointment is also often used with success as a means of checking the very intractable itching of pruritus. Wood tar is prescribed as a stimulating expectorant in chronic bronchitis or winter cough.

Coal tar is the source of a large number of drugs, such as antipyrin, etc., and numerous disinfectants are manufactured from it.

TARNISHING. The best way to prevent tarnishing is to have the objects lacquered when such a course is possible, as this, when well done, is invisible if a clear or crystal lacquer be employed.

To remove tarnish stains from silverware wash the objects in hot water with a trace of ammonia in it, following this with a good washing with clear hot water and finishing with a rouge polish. Tarnished brass and copper ware can usually be cleaned with a very weak solution of sulphuric acid in water. Add the acid drop by drop to the water. Only a trace of the acid must be used, as it is very violent in action and would speedily corrode the metal. The articles should be thoroughly washed afterwards in hot soda water to neutralise the acid bath, and then polished, and, if desired, lacquered.

Another method of treating tarnished silverware is to rub it well with a solution of powdered magnesia and follow with a polishing with the dry powdered magnesia, finishing in the usual way. Steel and iron are best cleaned with a mild abrasive. For slightly affected pieces this may be a light sprinkling of fine emery on an old stocking moistened with a few drops of lubricating oil. When the tarnishing is severe the best plan is to use the finest old emery paper and finish off with a good metal polish. *See* Lacquer; Polishing.

TARRAGON. This is a hardy perennial herb belonging to the *Artemisia*, or wormwood, family. About 2 ft. in height, it is raised from young roots planted about 1 ft. apart in spring. The shoots will be ready to cut down in autumn and store away for future use. Roots may also be started in the

heated greenhouse in October for winter use. Propagation is by division of old roots, which should be done annually.

Tarragon is used in cookery for flavouring soups, and vinegar, and forms an ingredient of many sauces. The whole leaves serve as a garnish for cold dishes. *See Vinegar.*

TARSO. This is a method of cutting a design on wood which gives it almost the appearance of inlay. It is a modern form of the old intarsia and affords a simple method for the amateur to decorate such surfaces as screen panels and trays. For the latter, when glazed it would be almost indistinguishable from marquetry. Many pokerwork

designs can be adapted to this work by those who have no outfit for the former craft. More or less conventional designs can be carried out effectively, and the outfit is of the simplest, consisting of a tarso or cutting knife, a supply of stains in various colours, and some polish.

Tarso Work. Fig. 2. Panel showing a boldly outlined design of an eagle and trees.

The satisfactory appearance of the finished tarso depends largely upon clear, even outline, and therefore it is best to work on a flat panel. A box should not be taken for a first attempt unless books are built up alongside level with the top to provide a support for the hand. It is better to begin on something small and fairly simple in design, such as the tray in Fig. 1, which shows a branch and leaves in tarso work with a full moon, which is filled in with liquid white enamel. Another good design is illustrated in Fig. 2, which would be equally suitable for an empty grate screen panel or for a blotter. The colours used would be dark brown, green, black and white. The incision should be about 1/32 in. The design must be followed very carefully, and the various lines cut correctly. Cut anything that lies

underneath first, and the rest of the design later. When all the lines are incised, the panel should be sandpapered, working with the grain, never against it. Finish off this stage by giving a final rub with the back of the sandpaper.

The next step is to colour the design by painting in water stains with a brush. The stains must be used almost pure, and made to look even and solid. It is an excellent plan to add 1 drop of ammonia to the stain before using it to prevent the colour from spreading. No shading must be attempted, the aim being to make the design look as though it is inlaid and not painted on. The background is left uncoloured. The colours are left to dry; if not sufficiently dense, any part that needs strengthening should be coloured again. After rubbing lightly with a very old piece of sandpaper, the work is ready for polishing.

A very high polish is required (see Polishing). First the whole surface of the wood is covered by applying a coat of wood filler with a brush, and this is left to dry thoroughly. If the surface is not sufficiently covered, a second coat may be applied and left to dry. Then put some fine glaze polish into a pad, and body in until a good covering is obtained. Oil polish should not be used for this work. It is well to avoid working too long on the surface; the moment it becomes tacky it should be put on one side and work started on another piece. As soon as a good body of polish is obtained, take a clean pad, put 1 drop of glaze on it, and rub the surface hard, working up and down as quickly as possible until the whole surface is absolutely bright and free from any disfiguring appearance of streakiness. *See* Poker Work; Tray.

TARTAR: On the Teeth. The deposit of tartar which tends to form about the roots of the teeth consists of phosphate of lime and other mineral substances, mixed with some organic matter. This tends to favour the activities of microbes and provoke decay of the teeth. Tartar is more likely to accumulate when food is soft than when a fair amount of it requires energetic mastication. *See* Teeth.

TARTARE SAUCE. This sauce is made by adding $\frac{3}{4}$ dessertspoonful each of chopped parsley, capers, gherkin, tarragon, and chervil to $1\frac{1}{2}$ large breakfastcupfuls mayonnaise. Keep it in a cool place until required.

TARTARIC ACID. The crystals of tartaric acid irritate the skin and mucous membranes. Obtained from grapes, tartaric acid closely resembles citric acid, and is used similarly chiefly as a refrigerant or cooling medicine in fevers. The dose is 5 to 20 gr.

It is used in making effervescing preparations; 20 gr. of the acid dissolved in $\frac{1}{2}$ oz. of water will saturate, in an effervescing mixture, 24 gr. sodium bicarbonate dissolved in 1 oz. water. It may be used instead of citric acid for lemonade (q.v.).

TASSEL. This form of trimming is frequently used for pelmets, lampshades, cushions, to weight corners of work bags, panels, and other ornamental furnishing and dress purposes. There are many kinds, made of silk thread of any colour, of fine braid or ribbon, of gold or silver thread, of wool, beads, or leather. They are employed as a finish to girdles for dressing gowns and sometimes to edge scarves. Another use for a silk tassel is for a necklet. The necklet itself is frequently a silken cord, upon which is suspended a large, decorated bead or amulet, from the base of which hangs the tassel, of the same colour as the cord.

To make a woollen tassel, such as might be used to finish the ends of a girdle for a dressing gown, take a small piece of card, as wide as the required length of the tassel, and bind the wool round it several times, the number of threads in the tassel depending entirely upon individual taste. These strands of wool are tied tightly together at one edge of the card and are cut at the other, all that remains to be done being to hold the ends in one hand and twist a strand of wool several times round just below the point where it was tied. *See* Curtain; Cushion; Fringe; Pompon.

TATTING: In Needlework. An old-fashioned kind of fancywork, tatting can be worked in crochet cotton or in purse silk, a tatting shuttle and a crochet hook or bone pin being also required. The shuttles are made of bone, tortoiseshell, ivory, and of ebony inlaid with mother-of-pearl, and have a block in the centre, pierced with a hole, through which the cotton is passed.

To fill the shuttle, thread the end of the cotton through the hole, tie it, and then pass it through the ends of the shuttle round and round the block until it is level with the ends of the shuttle. The cotton

should then be cut off, about 1 yard of it being left to hang loose. Workers should note that the crochet needle or bone pin is needed when joining the loops.

In learning the stitch, the chief thing to remember is that the thread over the hand is to be kept loose, while the thread from the shuttle is drawn tightly. The work resembles the buttonhole-stitch used in making a loop for buttons, the thread from the shuttle corresponding with the loops of the button loop, and the thread over the hand corresponding with the buttonhole stitch worked upon them. Take the end of the thread in the left hand, between the thumb and the finger, and pass it over the fingers of the left hand; then bring it back to the thumb and finger again so that there is a ring of thread round the fingers.

With the shuttle in the right hand, throw the thread from the shuttle round the back of the left hand and pass the shuttle under the thread round the fingers; then draw it back over that thread and pull it out tightly, letting the loop over the fingers become slack. This forms a loop on the shuttle string, tightened by expanding the fingers.

The first half of the stitch is now completed, but in making the second half do not throw the shuttle thread round the left hand, as previously, but simply pass the shuttle over the loop round the fingers and draw it back under it, thus reversing the process of the first half. Make quite certain after each stitch that the shuttle thread will draw, for if it will not an error has been made, and the stitch must be unpicked. When twelve stitches have been made, draw up the shuttle thread until the stitches form a ring, the first and last stitch meeting. Leave about $\frac{1}{4}$ in. of thread between this and the next ring, which should be worked in the same way.

These rings are joined together by the picot stitch, which is made by leaving a short length of cotton between the stitches, which, when the ring is joined up, forms a little loop. In a large piece of work the rings are sometimes sewn together, but ordinarily these loops provide the best means of joining them. Begin by making 4 stitches, and leave a small length of cotton between these and the next stitch. Some practice is necessary in judging the right length, for all loops must be of the same size. Then work 4 stitches and another picot, 4 more stitches and a picot, finishing with 4 stitches and then drawing them up into a ring. There is now a ring with 3 picots, and the following ring must be joined to the right-hand picot.

Begin the next ring in the same way, and when 4 stitches are made insert the crochet needle in the picot of the last ring, and draw the cotton which is round the fingers partly through the picot; pass the shuttle through this loop, and then pull the finger thread tight. Proceed with the same number of stitches and picots as in the last ring.

TAXIDERMY FOR THE AMATEUR

A Simple Example Described Step by Step

Herewith are detailed instructions by means of which the nature lover can preserve and mount in natural positions not only birds and small animals, but also reptiles and fish. See Arsenical Soap.

The work of the taxidermist, which consists in preserving the dead bodies of animals, in their natural forms, is well within the scope of any careful amateur. The following tools and materials are required: A pocket-knife, a pair of small scissors, round-nose pliers, flat cutting pliers, 3-cornered file, iron wire of various sizes, plain and coloured glass eyes, thread and fine string, tow and cotton wool, clay, pins, preservative soap and powder, camphor. Glass eyes and preserving soaps and powders can be purchased at a taxidermist's or naturalist's shop.

The preservatives used are generally highly poisonous.

Skinning a Squirrel. Supposing that the animal to be preserved is a squirrel, the first step is to place it as nearly as possible in the attitude in which it is intended to remain when stuffed. Fig. 1. Carefully study the formation and contours of the body, and note down on paper any little details likely to be of use in obtaining a natural appearance. The squirrel is now placed on a board large enough to spread the limbs. The lower portion of the limbs should be tied to the board, holes being bored through the board at convenient places. The specimen is then placed in a good light and at a suitable height, and the skin opened with the large blade of the knife. The cut should be commenced about the middle of the breast and continued down into the lower part of the body, the separated skin being opened out and secured by bent pins attached by pieces of string to a nail.

Taxidermy. Fig. 1. A squirrel that has been stuffed in a natural attitude according to the instructions given in this article.

Proceed to skin the body by first working out the hind legs, cutting the leg bones, under the skin, at the large joints. Use the cutting pliers to sever the joints. Carefully strip the skin off the lower part of the body, at back and front until the tail is reached, the flesh and small bones of which are pulled out from the skin. The operator is now able to proceed with the removal of the skin from the back and breast until the forelegs are reached, the bones of which are cut away like those of the hind legs.

The neck and head are skinned down to the inner edges of the mouth and nose, and great care must be taken to avoid cutting the outer portions of the ears, eyelids, nose, mouth, and lips. After severing the skinned body from the head, remove all the flesh, the brain, and the eyes from the skull, which will now be attached to the skin by the inner edges of the mouth and must be handled carefully. Clean away all the flesh from the bones of the legs, and the skin is then ready for treatment.

Turn the skin completely inside out and scrape off any adhering flesh or other matter, and then apply a good coating of preservative soap, working it well in with a small brush. The skin is now turned fur side out again and hung up for 48 hours to dry and let the soap act. At intervals during the drying period the skin should be gently stretched and worked to keep it soft and supple, and at the end of the 48 hours it should be turned inside out and scraped clean with a blunt knife. Then a liberal application of the preserving powder should be thoroughly rubbed in.

Modelling the Head. The interior of the skull, as at Fig. 2, should be filled with tow, saturated in a solution of camphor dissolved in a little pure turpentine. The first step in stuffing is to bring the head to shape, and this is done by placing clay and tow on those parts of the skull from which the flesh was removed and modelling them to the required form. The skull is then replaced in the skin of the head, the glass eyes having been set in the eye-holes. The clay should be used as dry as possible and allowed to harden before placing the skull finally in the skin. Parts that are too low can be raised by pressing in a small quantity of cotton wool under the skin of the head and directing it to the required place by means of a piece of blunted brass wire.

A strong iron wire, about 10 in. long, is pointed at one end and bent to the shape of the backbone. It is then tightly bound round with tow to the shape of a long, narrow body, and placed in the interior of the skin, the pointed end being inserted well into the skull. A pointed wire, about 8 in. long, is

thrust through the sole of each hind foot, and forced well into the tow body and the ends bent over. After the wires have been inserted, the ends should project for nearly 2 in. from the soles of the feet. The leg wires and bones should be clothed with tow and clay and modelled to shape after the wires are in position. The forelegs are wired by forcing a 6 in. pointed wire through the underside of the claws of each paw, the ends being thrust into the body and clenched over. Bend the forelegs to the desired position and bring to shape with tow and clay as already described. A thin iron wire, pointed at both ends, and about 12 in. long, is passed through the cartilage of the tail, inserting the wire at the root and carefully pushing it up to the tip. Secure the lower end of the wire by pushing it into the body and bending over.

The body and legs are now bent into their permanent positions, and modelled to shape by the addition of more tow or cotton wool until the natural contours are obtained. Powdered camphor should be mixed with the stuffing material. The opening in the skin is lastly neatly sewn up with fine thread, and a piece of wood about 5 in. by 4 in. by $\frac{1}{2}$ in. obtained for a stand.

Taxidermy. Fig. 2. Sectional diagram showing arrangement of wires and stuffing.

Mounting the Specimen. The stand (Fig. 3) will look better if its sides are irregular, and they can easily be made so by indenting and rounding them with a sharp knife. Bore two small holes for the wires of the feet through the surface of the stand, turn over, and cut a narrow groove, radiating like an arm of the letter Y, from each hole, as at Fig. 4. Apply a coating of hot glue to the top surface and sides of the stand, and dust on fine sand until all the glued portions are thinly covered, when it should be set aside to dry.

The leg wires are passed through the holes in the surface of the stand, and allowed to project for about 1 in. after which they are bent over at right angles into the grooves and clenched into the wood, as shown in Fig. 2. A piece of thin brown paper is cut

to the shape of the bottom of the stand and glued thereto to give a neat finish. The tail is bent to a natural curve and a nut placed between the claws of the forefeet, holding it in position by the projecting ends of the wires.

The fur is finally cleaned by gently rubbing it with wadding soaked in benzol, afterwards dusting on fine plaster of Paris, which, when dry, is beaten out with a bunch of feathers. The cleaning is best done out of doors, as the benzol is highly inflammable. Use a fine tooth comb and brush to bring the hairs of the fur into their positions and folds and arrange the tufts on the ears and the whiskers with a fine wire. The specimen is now complete, and should invariably be kept in a dry place.

Fig. 3. Diagram of irregularly shaped stand, showing position of holes for wire attached to the legs. Fig. 4. Underside of stand showing grooves cut from each hole for wire.

Fish and Reptiles. The instructions given above are equally applicable to birds, fishes, and the larger reptiles. With patience and perseverance and the aid of a good text book on taxidermy, large specimens also may be attempted.

A considerable amount of artistic skill and particularly neat workmanship is required in mounting birds, especially when it is desired to show them with open wings. It is worth while spending time and care on the wiring of the legs.

The wire for this part of the work should be of a

stouter gauge than that used for the body; it should be long enough to lock into the body and be sharpened to an acute point at the end. There is only one position in the scaly part of the leg down which the wire will pass freely without damaging the skin, and that is on the inside of the member on the actual sole of the foot, immediately at the base of the hind toe. The actual position of the legs should be decided on and the bird mounted on a suitable base, such, for instance, as a piece of thoroughly dried peat or a piece of virgin cork.

The general shape of the bird is now adjusted, and if the wings are closed the work is simple, two short pointed wires being required for each wing. For open wings a long wire should be passed, right down through the interior of the wing, into the body and then locked in position. For small birds the single wire will generally be sufficient, but with large specimens the principal wire must be stout, and a second wire passed between the wing feathers close to the base. When the final shaping has been effected, the plumage should be worked into position, for it is very little use to attempt it before. The most suitable tools for this work are a pair of fine tweezers and a needle mounted in a convenient wooden handle. All the feathers should be carefully looked over, and in places where shot holes have disarranged them it is often advisable to pull them out, stroke them flat, and replace them with a touch of paste at their bases.

TAXODIUM. This is the botanical name of a beautiful conifer, the deciduous or leaflosing cypress, *Taxodium distichum*. It is a graceful tree with light green leaves which become attractively tinted before they fall in autumn. It will attain large dimensions in the course of time and thrives best in moist soil; it is a good waterside tree.

Gazza, with lid, in wrought iron, inlaid with silver in a floral design. Modern Belgian work.

TAZZA. The silver drinking vessel called by this name consists of a silver bowl, in shape not unlike that of a champagne glass, supported 1 by a short stem and a small foot. Originally made to hold drink, they were afterwards used for fruit and cakes. The word is used sometimes for glass and china dishes of this shape, and also

for those made in other metals. Examples in antique silver are rare and fetch high prices. *See* Silver.

TEA: The Meal. As a general rule, in households where dinner is served in the evening, afternoon tea is a very slight meal. In households where the children's dinner is taken at mid-day, tea is usually quite substantial, combining both tea and supper. Bread and butter, jam and simple cakes or buns comprise the usual nursery menu, with either weak tea or milk, and sometimes with fruit in season.

For high tea, which is a rather more solid meal in place of supper for the family, the table is laid much as it is for breakfast, with knives and forks, as well as the accessories of tea proper, and very often ham or meat of another kind is offered. Eggs, boiled or cooked in other ways, grilled tomatoes, bacon and kidneys, sardines on toast, special salads, or sometimes a large meat pie or a fish dish, are served, while cakes and jam follow. *See* Afternoon Tea Table; Breakfast; Bridge Party; Picnic; Sandwich; Service Wagon; Tray.

TEA: ITS QUALITIES AND BLENDS.

With Hints on the Best Methods of Infusion

Other entries that bear on the matter include Blending; Breakfast; China Tea; Diet; Pekoe; Souchong. *See* also Kettle; Teapot; Urn, etc.

Tea owes the properties which have made it so popular a beverage to a volatile oil and to theine, an alkaloid which has a gently stimulating effect on the nervous system. It also contains a proportion of tannin, or tannic acid, which is liable to cause indigestion when tea is not properly made or is allowed to stand too long so that it becomes overdrawn. The proportion of tannic acid varies in different kinds of tea; it is usually from 10 to 12 per cent. The proportion of the volatile oil is about $\frac{1}{2}$ per cent., and of theine 2 to 4 per cent. A cup of fairly strong tea contains 1 gr. of theine and 2 gr. of tannic acid.

Of the tea imported into Great Britain nearly 90 per cent is produced within the Empire, chiefly in India and Ceylon. The balance is grown mostly in China. China tea contains less tannin than the Indian product. On the other hand, there is a larger proportion of theine in Ceylon tea than is usually found in the Chinese varieties.

There are two classes of tea, namely, green and black, with many varieties of each. The difference lies chiefly in the mode of preparation, green tea being rolled and dried, while black tea is also allowed to ferment. The best green tea comes from China.

Of black China tea the chief kinds are Pekoe, Souchong, and Congou, which are practically three qualities of the leaf. Pekoe consists of the bud and the first leaf; it is the first-fruit of the plant, and is named after the young shoots, the word Pekoe signifying white down. Souchong is obtained from the next leaves after Pekoe, and Congou is the third selection. Among the varieties there are flowery and orange Pekoes, and others which are largely employed in blending.

Practically all kinds of tea are a blend of several different sorts, the reason being that it is very rare indeed to find the requisites of flavour, strength, and colour combined in any single kind. Some varieties are highly fragrant, being scented with flower petals, notably jasmine. Bohea, a name once applied indiscriminately to all teas, and sometimes used to-day for a poorer late-grown leaf, is a variety grown in Fu-kien prov., China, which is also noted for red leaf Congou.

Buying and Storing. Tea is sold in packets weighing from $\frac{1}{4}$ lb. upward. It should be kept in a dry place and protected from the air. This is particularly necessary where tea is kept in a store or pantry in the neighbourhood of other commodities, especially fruit or spices, as they may communicate

some of their flavour to the tea, the dried leaves of which are very susceptible to the surrounding atmosphere. For this reason tea should be kept in a box or metal canister with a close-fitting lid, or else in a tea caddy.

As a rule a chest of tea contains 84 lb. and a half chest 50 lb. Indian and Ceylon chests contain about 100 lb. These cases are furnished with a protective lining of sheet lead.

In buying tea the housewife has a wide range to choose from. Generally speaking, the Indian varieties are stronger than the Chinese, but black teas of all kinds are obtainable, and the purchaser must be guided by her own particular taste. Black blended teas are the most numerous. Most firms sell a household blend of medium strength and good flavour for ordinary domestic use. A fuller and richer flavour is provided by mixtures of Ceylon and Assam.

The addition of a small quantity of China tea in some blends makes for a more pungent-tasting beverage, and occasionally a flavouring of Oolong is added. Unblended Indian teas, of fine and expensive quality have a delicate and slightly pungent taste. Darjeeling is fragrant and full-flavoured.

How to Make. In making tea many people think it is best for the flavour of the beverage to use an earthenware teapot. The water used should be quite fresh, that is to say, it must not have been boiled previously and reheated, nor have been standing some time. The kettle should be emptied and filled fresh from the tap every time that tea is to be made. Soft water is always best for the purpose; where the supply to the house is a hard water, a very little carbonate of soda may be put into the teapot along with the tea, care being taken not to put in more than a pinch, otherwise the tea may have an unpleasant flavour.

It is essential that the water should be actually boiling. A second point to note is that the teapot should be heated. A little water from the kettle is poured into the teapot, and the latter can then be allowed to stand until the kettle boils, when the teapot can be emptied and the tea dropped into it.

An old rule as to the quantity of tea required is to allow one teaspoonful for each person and one for the pot. One good teaspoonful, however, should be enough to make two cups of tea easily; with some teas a teaspoonful will make three cups. Much depends on the quality of the tea.

After the tea has been put in, the pot should be filled up as soon as the kettle boils, pouring the water slowly over the tea leaves. The most usual method is to fill the teapot half full, but some people fill it three-quarters full.

The filled teapot should then be allowed to stand for 3 or 4 min. so that the tea is properly infused. This is much more satisfactory than to stir the contents of the pot with a spoon, as is often done to save time. China teas require to be thoroughly infused, and some may be allowed to stand for 8 or 10 min. without any risk of deterioration. Some tea drinkers allow the tea to stand for 2 or 3 min. and then pour it into a second teapot which has previously been heated. In this way the infused liquid is obtained without the leaves, and there is no risk of tannic acid spoiling the tea if it should be left standing.

Another method of making tea is by putting it into a teaspoon infuser. Many persons, especially those who suffer from indigestion, prefer to have their tea made in this way, because it produces an absolutely fresh cup with no possible excess of tannin.

Tea cannot be said to have a food value, except when it is taken in conjunction with milk and sugar. Tastes differ considerably in this respect. Some persons enjoy their cup of tea with milk alone, some only take sugar, and there are others who take neither, while some choose lemon in preference. Even when reinforced with milk and sugar, tea is inferior in nutritive value to cocoa, and also to coffee made half with milk, but neither coffee nor cocoa possesses the refreshing properties of tea.

From the medical standpoint theine, the active principle of tea, clears the brain, stimulates mental action, and removes feelings of fatigue and drowsiness. The best times to take tea are at breakfast and in the afternoon; for most people twice a day ought to be sufficient. It is well not to give tea to young children, or at least not more than a tablespoonful in a cup of milk.

People who are in the habit of drinking too much tea, or taking it too strong, may suffer sooner or later from indigestion, palpitation, loss of appetite, sleeplessness, depression, constipation, or nervousness. The remedy is to stop drinking tea till the symptoms disappear.

TEA BASKET. A basket made to carry materials for a picnic tea is very similar to a lunch basket, being of wicker, provided with a lid, and straps for security and as a means of carrying it. Cases are more used than baskets. The fittings for either consist of cups and saucers, plates and tea knives for two, four, or six people, a larger knife, and several cake plates, a bottle for milk, and tins for holding sandwiches and cakes. They also include either a vacuum flask or a spirit kettle and stove, teapot and tea caddy. *See Picnic.*

TEA CADDY. The earliest caddies were of Chinese porcelain shaped like a ginger jar. These were made in great variety by the English potters, a common type being one of blue and white chinaware. They are often in pairs, one for green and one for black tea.

Soon they were made in silver, brass, pewter, and tortoiseshell, and in the 18th century fine silver pieces were produced. Some of these are chased with pastoral figures, flowers and scrolls. They had slip-in, pull off, or hinged lids. Some are shaped like a vase, while others are oval, silver bead edging being found on some of the latter type. Sheffield plate caddies were sometimes hexagon in shape, but the more usual type to be picked up to-day are oblong or oval with beaded or gadroon borders. The hall marks should be on the side or bottom.

Tea Caddy of harewood and satinwood, with marquetry of satin and other woods. (By permission of the Director, Victoria and Albert Museum, S. Kensington)

The wooden tea caddy was evolved from the metal one. It became usual to encase two of them in a wooden box, and in the 18th century wooden caddies were largely made. These usually contained three receptacles and were shaped somewhat like a small chest. At either end was a lidded well, one for green and the other for black tea, and in the centre was a receptacle for sugar. The finer woods were used, chiefly mahogany, rosewood, and satin-wood. Some were mounted on brass, and many were beautifully inlaid. Knobs of ivory, ebony, and silver are found on them. Specimens of the older caddies enclosed in a box are sometimes met with. An example is a set of three silver ones fitted in a rosewood case. Shagreen was occasionally used for the case.

Tea caddies were made by Chippendale and Hepplewhite. Mahogany was the wood chiefly used by both. Chippendale made some of his caddies rather in the shape of caskets with richly carved lids and feet, the claw and ball being much used by him. The outlines of Hepplewhite's caddies were straighter than those of Chippendale. Instead of feet he often fitted a plinth to them, and while mahogany was frequently used, delicate veneers were much favoured.

An example of late 18th-century workmanship is an oval box of painted wood, on which is represented flowers, crests, and allegorical scenes, vividly coloured. Some of this type are painted with festoons in the Adam style or medallions revealing Grecian figures. Caddies were also made of papier mâché, usually painted black, and decorated in the Chinese manner or with mother-of-pearl, etc.

In addition to the above, which may be regarded as the chief styles, another type of caddy was introduced early in the 19th century, the decoration of which consisted of rolled paper filigree work. This consisted of a box, usually hexagonal in shape, which had faces slightly recessed. In the recesses were fitted many coils of paper cut in narrow strips, each placed on edge and arranged so as to form an elaborate pattern consisting of scrolls, leaves, festoons, and geometrical figures. The inner edges were glued to the wood, the coils were twisted so that rough handling could hardly move them out of shape, and the surface was protected with glass. Sometimes the parchment paper scrolls were left ivory colour, sometimes gilded. The effect was that of fine carved ivory, or, when the strips were gilded, of metal filigree, while some of the tinted work was like Indian lacquered wood carving.

For use with caddies a special kind of spoon was designed in Sheffield plate, silver and other metals.

TEA CAKE. Tea cakes can easily be made from 1 lb. flour, $\frac{1}{2}$ oz. solid yeast, 2 oz. margarine, a flat teaspoonful of castor sugar, an egg, a pinch of salt, and milk and water to mix. Sieve the flour and salt into a basin, rub the fat into them until the mixture resembles fine breadcrumbs, and make a well in centre. Put the yeast into a small, warmed basin, add the sugar, and mix them together until they form a liquid. Then pour in $\frac{1}{2}$ pint warmed milk and water, mixed in equal quantities, strain the whole into the flour, etc., and mix all to a stiff paste. Turn the dough on to a floured board, knead it until it is smooth and pliable, and then divide it into two or three portions, shaping each into a round. Put these on to a greased baking sheet, cover them with a cloth and leave them in a warm place for about 50 min., or until they have risen to twice their size.

Bake the cakes in a hot oven for 20 min., and just before they are ready to be taken out brush them over with a mixture of milk and sugar. Leave them for a few minutes so that the glaze may dry. The latter can be made from $\frac{1}{2}$ gill milk and 1 dessertspoonful castor sugar. For currant tea cakes add 1 oz. picked and cleaned currants to the above.

Tea Cake. Small cakes which may be served cold or cut open and toasted before buttering.

Smaller tea cakes made with baking powder instead of yeast can be prepared from $\frac{1}{2}$ lb. flour, 1 oz. margarine, 1 teaspoonful baking powder, half an egg, and about a gill of milk. Sieve the flour with the baking powder into a basin and rub the margarine into them. Beat up the egg and add it to the flour, etc., pouring in also sufficient milk to mix the whole to a soft but not sticky consistency. Roll out the mixture on a floured board until it is about $\frac{1}{2}$ in. thick, then cut it into small rounds, brush these over with milk, and bake them on a greased baking sheet for 10-15 min.

Tea cakes may be buttered and served cold, but more often they are sliced in half, toasted and buttered, put together again, and then cut in the same way as an ordinary cake. *See Crumpet; Girdle Cake; Scone.*

TEA CLOTH. The phrase tea cloth has two distinct meanings. In one it refers to the cloth laid on the afternoon tea table, and in the other to the cloth, similar to a glass cloth, which is used for drying the tea things after they have been washed up. Ideas for embroidering and decorating afternoon tea cloths are given in the articles on Drawn Thread Work, Embroidery and Pattern Printing.

TEA COSIES CONVENTIONAL AND QUAIN

Directions for Making These Table Accessories in Various Fabrics

The reader is referred to the article on Raffia Work for, instructions in covering a tea cosy in that material. See also Appliqué Work; Embroidery; Felt; Laid Work; Leather Work; Patch-work; Painting on Textile Fabrics; Quilt; Ribbon Work; Tapestry Needlework; Woolwork.

A tea cosy in common with every other well thought out accessory should be chosen with due regard to its surroundings both in style and colour. As a rule a conventional shape is best for the dainty cosy on an afternoon tea table spread with an embroidered or lace and linen cloth, and also for a cosy to accompany a dining-room breakfast service of handsome and formal design. Conventional shapes are used in smaller sizes for the cosies which form part of a set for the breakfast tray, with egg cosy, and tray cloth to match. Quaint shapes are seen in the cottage designs worked in various materials and in developments of the same idea, such as "The Old Curiosity Shop," Noah's Ark and house boat notions. These are particularly suitable in company with cottage breakfast ware for nursery or dining room, or for garden tea tables. There are also hen, duck and a few other animal shapes designed to cover the nursery tea pot.

Making the Padded Lining. Although padded interlinings can be bought inexpensively in several sizes at art needlework shops, some people prefer to make their own. It is really simpler and wiser to have an independent lining for most cosies of conventional shape, and to slip the cover over it when the latter is completed. In the case of suède or a silk or satin cover which has been hand-painted; stencilled, or very delicately embroidered, it is sometimes desirable to have the lining renewed, or cleaned separately. In the case of a washable linen cover of pale colour, this will require laundering separately. When the cover is of white linen decorated with drawn-thread work or lace motifs and insertions, the lining which will show through should be of a colour to suit the table ware so that the effect of the needlework is enhanced. A separate lining can be attached to the cover by a few stitches to keep it in place.

Cosies vary in size from those designed for individual teapots to the large covers for family breakfast teapots. A very small cosy cut in conventional semicircular fashion measures about 9 in. across the bottom and is 7 in. high at the centre of the curve. A medium size is 14½ in. by 8 in., while a larger one has a height of 10 in. and a width of 16 in. Whatever the size required to fit the outer cover, allow 1 in. all round for turnings when cutting the lining fabric. The wadding for interlining must be cut exactly to the size of the cosy when finished and no turnings allowed. Sateen is a useful material for linings, but for better cosies, silk and crêpe-de-Chine are used for the inside of the lining next the teapot, while a cotton material serves for the outer lining next the cover, unless this happens to be decorated with openwork.

Cut four semicircles of the lining fabric and two of wadding (some workers use this in double thickness), sew the two semicircles for the outside of the lining pad together face to face, stitching firmly all round except at the bottom. Turn them inside out and then stitch the two inner lining pieces together in the same way, but do not turn. The two pieces of wadding are now sewn together

round the top and sides with long tacking stitches. If the edges of the wadding are overcast they will not fray out. Slip the wadding inside the outer lining, catch them together with a few tacking stitches to hold the wadding in place, and then push, smooth and stitch the inner lining into position. The bottom edges should now be neatly sewn together all round to complete the lining pad. An inner lining of silk or sateen to match the cosy cover is made and adjusted to a wadded interlining when the latter is bought covered in white cotton material.

Afternoon Tea Cosies. Whether a cosy cover is a separate affair or at one with the padded lining, any embroidery or painting is done before the fabric is made up. Linen cosies are particularly dainty when of pale colours worked in stranded cottons either with garlands of flowers forming a border, or with a single motif placed on either side. Cross-stitch is another favourite method of trimming and beautiful covers are made in drawn-thread work, broderie Anglaise and Richelieu work (q.v.). The most successful results are obtained by having a tray cloth or table cloth to match this style of cosy. Suitable transfers and designs are obtainable in great variety.

Cloth cosies are trimmed with laid work in gold or silver thread with ribbon work, or with conventional appliqué designs.

Needle tapestry in wool or silk may be employed to cover a whole canvas foundation, or for a motif to be applied to a cloth, silk or satin tea cosy. Decorative patchwork makes attractive cosies in silk, velvet or suède. For these fabrics a good finishing touch is a cord sewn along the bottom and outside edges. This should be done with silk of the same colour as the cord and after the cover has been joined. Take up a tiny piece of the fabric and a few threads of the cord and pull them together ; then run the needle under the covering material for the longer stitches and take small stitches in the cord. The ends of this must be neatly finished off. To form a handle a loop of the cord should be twisted and left in the middle of the top. Tinsel cords are often used when silver or gold thread is introduced into the embroidery. Thonging is sometimes employed as a finish when suède is the material of the cover. (*See Leather Work.*)

Nothing could be more appropriate for a cosy than fancy quilting. The example of this work illustrated in Fig. 1 was carried out in rose-coloured crêpe-de-Chine, quilted by hand with back-stitching in silk thread to match. Italian quilting can be equally well used to decorate a cosy for the drawing-room tea table.

Tea Cosy. Fig. 1. Cosy of rose pink crêpe-de-Chine suitable to accompany a dainty tea service. The design is quilted by hand.

As quilting is done on fabric with an interlining, the inside lining of the cosy made of the same material as that quilted is usually attached to the outer cover, an extra layer of wadding being inserted between the two. Such cosies are prettiest in delicate colours and require to be dry-cleaned. The semicircular edges of the one illustrated are finished with a self-piping and strap handle. Sometimes the piping is twisted into a looped bow to form the handle at the top. It is very interesting to work out quilting patterns for oneself with the aid of an original drawing or suitable embroidery transfer for the centres of the front and back of the cosy, drawing the border for this, diagonal lines and outer border for quilting, directly in pencil on to the fabric after taking a few measurements for correct spacing.

Cottage Shapes. Felt, raffia cloth, linen, crash, blanket cloth and embroidery canvas are all used as foundation materials for the building of cottage cosies. It is not difficult to evolve one's own patterns out of brown paper, cutting the roof portion separately, a back and a front piece of the same size, and two side pieces. The chimney which forms the handle is a straight piece doubled over and sewn on to the middle of the roof.

Fig. 2. Cottage cosy made of felt. The lattice windows, rose trees and flower border are worked in bright coloured wools and easy stitches.

The cosy illustrated in Fig. 2 is made of felt. The thatched roof is of brown, the chimney of brick red, the walls of fawn and the door of dark green felt. The height including the roof should be about 10½ in. when flat. A piece of brown felt measuring about 9 in. deep by 11 in. wide would be sufficient to form the roof, back and front when doubled, and the front and back walls of the cosy would be each 7 in. deep (to allow for joining to the roof), and 10 in. wide. The roof projects slightly at either side. The sides are

about 4½ in. wide and 10 in. high, being cut up to a point between the back and front of the roof. The door is a scrap of green (or other coloured) felt buttonholed to the wall piece. The design of windows and flower bed, etc., can easily be drawn on the felt with a coloured crayon.

Bright coloured wools are used for the embroidery. The windows are done in chain stitch, the woodwork to match the door and the lattice in dark grey. The rose tree is in stem stitch, brown for the stalk, single stitches in green for the leaves and a French knot for the centres of the pink roses. The groups of smaller flowers are worked with single upright stitches, small ones crossing these in green to form the leaves and stems and the flower heads put in with lazy-daisy stitch, buttonhole rings and French knots for the buds. Any other stitches can be introduced which the worker fancies, and the flower embroidery can be continued at the sides in one group and a few brown stitches to represent the earth of the bed. The back can correspond with the front, but leaving out the door and the rose tree. The cottage walls when embroidered are tacked together and made up by firmly buttonholing the edges with wool to match the felt. Begin at the bottom so that all the edges are even at the base. Lay the roof in place over the four sides of the cottage, and stitch it down with long running stitches. It is a good plan to buttonhole the points of the side walls and catch the roof through to the buttonhole stitches. Buttonhole the little piece of brick red felt for the chimney in the same colour, and attach it in the position shown.

Cottage cosies are obtainable, shaped in canvas, and ready to be embroidered in tapestry needlework. Transfers can also be bought suitable for linen or raffia cloth covers. Details vary for roofs, windows and garden effects, but in the main the shapes are much the same.

Nursery Tea Cosies. Linen cosies with applied or cross-stitch designs of animals or figures from nursery rhymes are more commonplace than the plush duck tea cosy which is illustrated in Fig. 3, with the duckling as a miniature egg cosy. For the tea cosy ½ yd. of 36-in. wide woolly plush is allowed, the same amount of sateen for lining, a sheet of wadding for interlining, two black shoe buttons for eyes, and a small piece of orange cloth or felt for the beak.

The cosy is cut in duplicate, each side in one piece, shaping it with a smaller portion for the head, slightly waisting the shape below this and then widening out to form the semicircular lower portion. The wings are cut out in 4 pieces roughly diamond shaped and the beak is simply 4 semicircular pieces, 2 for the upper part and 2 for the lower. The lining is cut in duplicate semicircular pieces.

Tea Cosy. Fig. 3. Plush duck cosy for the nursery teapot. Scraps of the plush left over can be made into ducklings to keep eggs warm.

Join the two halves of the plush covering with the right sides facing and stuff the head part well with cotton wool. Pad and line the cosy.

Join up the two pieces of the wing, leaving an opening at the base so that the work can be turned right side out. Sew up the opening and attach in position on cosy. Make the other wing in the same way. Join up the two pieces for the upper beak, turn, join up the other two pieces, and sew in position.

Sew in the buttons for the eyes.

TEAK: The Wood. This is a heavy hardwood, dark brown in colour, sometimes with a greenish shade. Like oak and some other woods, it darkens with exposure and age. It is oily, does not suffer by contact with iron, and is durable under water. Its grain is straight and rather coarse, with a dull surface. When freshly cut it has a peculiar smell, something like leather. Though not very difficult to work, it contains a phosphate of lime which soon dulls the edges of cutting tools. When well seasoned it does not crack. Teak is largely used for furniture in India, its native place, but only to a small extent in Great Britain, its dull appearance and its weight being against it. It is used occasionally for floors, stair treads, window and door sills, and similar purposes. *See Garden; Furniture; Wood.*

TEAL. Roasting is the usual method of cooking this water-fowl, the bird being trussed like an ordinary duck, basted well while cooking so that the flesh may not be too dry, and garnished with watercress and cut lemon. Any of the sauces served with wild duck and orange salad may accompany teal. About half an hour is required for roasting. *See Duck; Salad.*

TEA PLANT. So far as Great Britain is concerned, the tea plant may be described as a greenhouse, evergreen flowering shrub of purely decorative value, with dark, shiny, oblong, green leaves, and white flowers during autumn and winter. It should be potted up early in spring in a mixture of equal parts of peat and loam and freely watered. As it requires a mean temperature of only 55°, the tea plant may be safely placed out of doors in a shady position during the summer. It is propagated by seeds sown in springtime, or by cuttings, or layers in autumn. Plenty of water and liberal syringing is desirable during the summer months.

TEAPOT. Teapots may be divided into two classes, those made of china or earthenware and those made of metal. The former are often made to match a tea service, and are found in almost all wares from the cheapest to the most expensive. They are also made and sold as single articles. The simple teapot of brown earthenware is considered by many persons to possess unrivalled powers of drawing the best from the tea. There is not a great deal of variety in the shape. Some are round and others oval, and all makes in the first class are fitted with a loose lid.

The best metal teapots are of silver, but they are also made of Sheffield plate, electroplate, aluminium, and enamel ware. Often they are made with sugar basin and cream jug to match. In the better specimens insulating disks are placed in the handles to prevent them from becoming too hot. Alternatively the handle is made of ebony, ivory, or wood. With the exception of enamelled ware, in which teapots are modelled on the same lines as earthenware ones, metal teapots have hinged lids. Silver teapots are marked on the side or on the bottom and the lid; if it is contemporary it should be marked with the same initials as the body and with the lion passant. In buying a teapot of any kind particular attention should be paid to the spout. In some cases the set of this prevents proper pouring of the tea.

Teapot. Two Georgian silver teapots, one of them standing upon ball legs, and both with ebony handles. (Courtesy of Chapple & Mantell)

Silver Teapots. The silver teapot dates from the end of the 17th century, earlier ones having been of oriental porcelain. The earliest are chiefly of the Queen Anne pattern, and a few of them have a hinged lid over the spout. This style was continued into the 18th century. There is a good deal of variety in the early teapots, as their patterns changed considerably during the 18th century. In its early years octagonal and hexagonal pieces were the most usual, but soon the cylindrical shape became the fashion. Later the teapot became somewhat pear shaped, but with the protuberance in the upper, not in the lower part. Elaborate decorations were soon introduced, some being in the graceful style associated with the brothers Adam. Among these decorations are festoons and medallions, as well as repoussé work. Two typical examples of late Georgian teapots are illustrated. That on the left dates from 1787 and has a fine thread edge and an engraved shield. Teapots of this shape often were made with stands to match on four feet. The teapot shown on the right dates from 1827, and has the four ball feet which makers began to put on at the beginning of the 19th century to obviate the need of the separate stand.

About the end of the 18th century some beautiful teapots were made in Sheffield plate. Existing examples, which have been largely reproduced, are very refined, both in shape and in decoration. In these subtle curves, plain surfaces and handles of flowing scrolls are skilfully combined, while the adornment takes the form of pierced ribbonwork and delicate rosettes.

Electric Teapot. A feature of the nickel-plated electric teapot illustrated is the “tea ball.” This perforated cage is filled with tea and suspended by a chain in the water after it has boiled. It can be raised when required, and the chain has a weighted knob which holds the tea ball out of the water so that the tea cannot be stewed. Connector, flexible cord and lamp-holder adaptor are supplied with the teapot.

Electric Teapot. The tea leaves are placed in a tea ball or infuser and then let down into the boiling water. When the tea is made the infuser is lifted out of the water by means of a chain.

Teapot Stand. A teapot stand is often necessary on polished wood tables and trays. For a silver teapot a small salver is sometimes used. Many different types of teapot stands are sold. In shape they are usually circular or square, and they are made of glazed earthenware, various kinds of metal and stone. The metal ones, because of their heat-conducting properties, are usually raised on wooden feet. *See* Salver; Urn.

TEAPOY. This word has two meanings. In one it is a small table supported upon a tripod or upon four legs, and used chiefly for holding a tea service or an urn. In the other it is a receptacle for holding tea. These teapoyes were the early form of tea caddy and were made of china or earthenware.

TEA PUNCH. This good summer beverage is made in the following way: Make a gallon of fairly weak tea, cover it and let it stand for 5 min. before straining and sweetening it to taste. When it is cold, half fill a punch bowl with cracked ice and add the tea and the strained juice of four lemons. Small pieces of pineapple, a few stoned cherries, some sliced banana, a handful of mint, and, if required, a little more sugar, should be added just before serving. *See* Punch.

TEA ROSE. This is a group of garden roses, descended originally from the China rose, *Rosa indica*. They are distinguished by slender and somewhat spreading growth and are rather less hardy than the hybrid teas and hybrid perpetuals. They bloom in summer and in autumn and flourish best on a sunny, sheltered border. *See* Rose.

TEASEL. The dead flower-heads of the teasel or fuller's teasel, owing to the stiff, spiked bracts that cover them, are employed in textile manufacture to raise the nap on cloth. The ordinary household use of this plant is purely decorative, the close oval heads of mauve flowers, each rising from a circle of long spines, on straight, stiff stems, making it an excellent cut plant for a tall vase. Teasels last well in water, retaining their beauty even after the flowers are withered. They are raised from seeds sown out of doors in May, and the plants will bloom the following year.

Owing to use of teasel heads for teasing cloth, the name teasel wool is given to a kind of wool, the surface of which is raised with a wire brush after it has been knitted or crocheted.

TEA SERVICE. People who possess old china tea services rarely care to use them every day. Exquisite reproductions are obtainable from the modern Worcester, Minton, Wedgwood and other potteries, for those who like their tea tables to present an old world appearance and possess the great advantage that each piece is replaceable in the event of breakage. Many are moderately priced. A service for 6 people, for instance, is sold in modern Wedgwood ware for less than 30s., and there are other makes of Staffordshire china reproducing the old designs to choose from at equally reasonable prices.

Slightly more expensive are the modern designs and delightful shapes of the china services from the Shelley and Newport potteries. In semi-porcelain there is a great choice of old and new patterns. In plain colours such artistic services as those in Moorcroft powder blue ware have much to recommend them. Combination breakfast and tea sets are useful, as in this way space is saved and larger cups are at hand to match the tea cups for those who prefer them. In many patterns teapots, hot water jugs, toast racks, cake plates, muffin dishes, butter and jam dishes can be obtained to match. Particularly beautiful is the ware with a honey-glaze ground.

A silver tea service is composed of teapot, cream jug and sugar basin. Sometimes a tray and spirit kettle or hot water jug are included. *See* China: Silver.

TEASPOON. Teaspoons may be of silver or electroplate. They are often sold in sets of 6 or 12, or form part of a set of table silver. In larger sizes they are used with breakfast cups for tea or coffee. For afternoon tea and after dinner coffee ornamental designs in smaller sizes are specially made. The ordinary teaspoon is used as a measure for liquid flavourings in cookery. It is equivalent in this sense to $\frac{1}{8}$ of a fluid ounce. *See* Silver; Spoon.

TEA TABLE. Usually of light build and of small size, a tea table is generally about 27 or 28 in. high. It is obtainable in a large number of shapes with single and folding tops, and is made in both wood and wicker. On account of its uneven top the latter kind is only suitable for use with a tray.

Tea Wagon. *See* Service Wagon.

TECOMA. This is the name of a class of evergreen and leaf-losing climbing plants. Some may be planted against a sunny wall out of doors, while others must be grown under glass. The two kinds suitable for a wall are grandiflora and radicans, both with reddish, tube-shaped flowers. Both are vigorous climbers and will reach a height of 15 ft. or more. They should be pruned in spring by shortening the side shoots.

Of those grown in a heated glasshouse capensis, orange-red, jasminoides, white, and valdiviana, orange yellow, are the best. Pron. Te-cô'ma.

Tecophilaea cyanocrocus, the Chilean crocus, a beautiful spring bulb with blue flowers. It needs a warm, sheltered situation.

TECOPHILAEA. These are blue-flowered bulbs which may be grown in a border at the foot of a sunny wall or in pots in the greenhouse. They are not hardy enough for the open garden. They like sandy, loamy soil and should be planted in autumn 3 in. deep. Cyanocroeus, blue, and Leitchlinii, deeper blue, are two beautiful kinds; both flower in spring. The popular name is Chilean crocus.

TEE JOINT. This phrase is applied to the position of a joint rather than to the form of its construction, and is used when a centre or intermediate upright runs into a top rail. For example, the tee joint may be halved, as in Fig. 1, or it can be dovetailed, as in Fig. 2. The bridle joint in Fig. 3 is often used as a tee joint, and so is the ordinary mortise and tenon. The name is not applied to similar positions of upright and rail where the former is stub tenoned. *See* Joint.

Tee Joint. Three methods of attaching a centre upright to a top rail. Fig. 1. Halved tee joint. Fig. 2. Dovetailed. Fig. 3. Bridle joint.

TEE SLIDE. Used in securing dining-table slides, the tee slide is useful because no cross-rails are required under the table when this form is fitted. The table slides are first worked to the correct shape by special planes and the tee slides are shaped to fit and are let in, glued and screwed to the adjoining slide. The amateur will find some difficulty in planing the groove, but with hardwood the table slide can be built up with 3 pieces of wood, as in Figs. 1 and 2. A suitable groove is cut in the thicker piece, and then the two thinner pieces are glued and screwed on. Accurate workmanship is needed to ensure easy running, but if this is attended to the method is preferable to any other. To

prevent sticking, the inside of the groove should be coated with blacklead. *See Dining Table.*

TEETH. A tooth exhibits a crown, a neck and one or more roots or fangs. The roots are composed of dentine, or ivory, and this exists also beneath the crown, surrounding a hollow in the centre of the tooth, described as the pulp cavity, which is continued down into the roots. In this cavity is the pulp, consisting of blood vessels, nerves and loose

connective tissue. The crown is formed of an intensely hard substance known as enamel; it forms a cap of varying thickness for the tooth and may have two or more eminences, or cusps, on its biting surface.

Teething. The process of cutting teeth is called teething or dentition. There are two dentitions. The first of the milk teeth to appear are usually the lower central incisors, and this generally happens in the 6th month. In a short time the upper central and all the lateral incisors emerge, and then follow in order the first molars in the 12th month, the canines in the 18th month, and the second molars in the 24th month. Variations of these times occur even in healthy children, and in rickets dentition may be much delayed.

The second dentition begins about the 6th year, with the appearance of the first permanent molars, and each year after this the other permanent teeth are cut—the central incisors, the lateral incisors, the first premolar, the second premolar, the canines and the second molar. The third molar tooth may appear about the 17th year or not until the 25th, and is also called the wisdom tooth; sometimes it does not erupt at all.

The first teething is sometimes a trying event for the infant and the gums may be swollen, hot and tender, and the child is feverish and restless. The digestion may be upset, and there may be constipation or diarrhoea. Sometimes there is earache, indicated by restless movements of the head and crying. It is not uncommon also for a child to suffer from bronchitis while teething. Another possibility is that the child may have convulsions (q.v.).

A child that is being suckled should not be taken off the breast while it is having difficulty in teething. Cool, boiled water may be given freely to cool the mouth and relieve thirst. If there is constipation fluid magnesia in the mornings is a useful remedy, and the best remedy for diarrhoea, at any rate at the beginning, is a teaspoonful of castor oil. Earache may be treated by applying cold

cloths to the ear. As the child salivates very freely, it may soak the garments over the front of the chest, and care should be taken to prevent this.

The use of a baby's comforter creates a danger of infection, because the comforter may be dropped on the floor and be put back in the baby's mouth without being sufficiently cleansed, but there is this further count against it, that it may cause malformation of the jaws.

It is desirable that an infant should begin gnawing at crusts or rusks when it is about six months old, as this practice helps to develop the jaws, and insufficient development may be due to the child not having been given firm food to gnaw; but this is quite a different thing from a baby keeping a comforter stuck in the side of its mouth more or less constantly.

There is rarely any trouble with the second dentition. Sometimes the teeth are overcrowded and are placed irregularly. When there is no hope of their settling into a correct position one or more should be extracted. Unless teeth are efficiently cleansed there is a tendency to the deposition of tartar about the neck of the tooth, and this may separate the gum from the tooth, giving access to bacteria and possibly leading to pyorrhoea. Moreover, carbo-hydrate foods, such as sticky fragments of bread, may lodge in the crevices between the teeth, and ferment, giving rise to acid substances which attack and dissolve the tooth-substance. That is the beginning of caries.

The natural method by which teeth are cleaned is by chewing crisp foods and such as require a good deal of mastication. The teeth should also be brushed, however, twice a day at least. The motion of the brush should be up and down and it is necessary to hold it vertically when brushing the backs of the teeth. Parts which cannot be reached by the brush can be cleansed by drawing a strand of dental floss between the teeth.

A smooth dentifrice should be selected, as erosion of the teeth has followed the use of a gritty dentifrice. The tooth is worn away at the gum margin and decay is encouraged. A common cause of erosion is the little metal clip often used by dentists to keep a small denture in position. This should be avoided whenever possible, and so far as the upper jaw is concerned the use of a sufficiently large plate may make clips unnecessary.

As soon as decay begins the parts should be cleaned out and stopped, and it is only prudent to have the teeth examined periodically by a dentist so that the first beginning of caries may be discovered and dealt with.

The importance of keeping the teeth sound cannot be over-estimated. Apart from the digestive troubles that proceed from deficient or defective teeth an enormous amount of illness is caused by the absorption of poisons from defective teeth.

Pain in a tooth, or toothache, is dealt with under that heading. Excessive bleeding after the extraction of a tooth may be arrested by folding a part of a handkerchief into a pad and biting on it, or by plugging the socket with cotton wool.

Artificial Teeth. Artificial teeth must be kept scrupulously clean. They should be taken out at night and brushed with tooth powder, and then be left in water containing some antiseptic. For a vulcanite plate this might be hydrogen peroxide, but for a metal plate it may be necessary to use a weak solution of chlorinated soda from time to time in order to keep the metal bright. A removable denture is much to be preferred to bridge-work, as juices may lodge beneath the bridge and decompose. *See* Caries; Dentifrice; Pyorrhoea; Tartar; Toothache.

TELEGRAM. Telegrams are divided by the Post Office into two classes: those sent within the United Kingdom and those sent to places abroad.

Inland Telegrams. The charge for an ordinary inland telegram is 6d. for the first 9 words and a penny for each additional word. Telegrams to Eire are treated as inland telegrams but are charged at the rate of 1s. 6d. for 12 words, and a penny for each additional word. All inland telegrams and night telegraph letters handed in on Sunday, Good Friday and Christmas Day are charged 6d. extra. In Scotland the extra charge applies to Sundays only. For an extra charge of 6d. an inland telegram is specially expedited both in transmission and delivery. The word “priority,” which is not charged for, should be written before the address of the telegram. The inland priority service is available only for full-rate telegrams within the United Kingdom—it is not available for telegrams to Eire. The address of a telegram should be sufficiently full to enable it to be delivered without difficulty; and in telegrams for towns the name of the street and the number of the house (with suitable indication in the case of flats) should be given. The address of telegrams for towns in which postal district, initials and/or delivery office numbers are in use should include such indications. In telegrams the main principles of counting words are:

Addresses: The essential designation of the place or office of destination counts as one word. As a rule all the necessary words in an address which follow the name of the thoroughfare count as one word.

Message: Place names count as one word. Any other English expression usually written as one word (with or without hyphens) in ordinary correspondence counts as one word.

Latin words or words in any modern European language, including Esperanto, written in English characters, are counted in the same way as English words; but words not forming part of such languages are counted at the rate of 5 letters to a word. Combinations of letters not forming recognisable words, including groups of initials, for example LMS, GPO, HMS, are counted at the rate of 5 letters to a word, provided the letters are to be signalled in group form. With the exception of words which are ordinarily written as one, or coupled by hyphens, such as father-in-law, twenty-six, no combination of words is counted as one word. Any compound name which is ordinarily joined together by a hyphen or hyphens is counted as one word when so written, for example Bouverie-Tracey and Cave-Brown-Cave. Established abbreviations such as can't and won't are counted as single words. Figures are counted at the rate of 5 figures to a word. Fractions are counted according to the number of figures employed, the bar of division being counted as a figure.

Delivery of Telegrams. Telegrams are delivered by messenger free of charge within the town postal area or within 3 miles of the telegraph delivery office nearest the address, whichever is the greater. Beyond the limits of free delivery there is a portorage charge of 6d. per mile or part of a mile, the distance being calculated from the limit of free delivery. In Eire the limit of free delivery is one mile, but the charges for portorage for a telegram to Eire handed in at an office in the United Kingdom are not prepayable. A reply can be prepaid to any inland telegram. If the form is not used its value will be refunded to the sender.

Greetings Telegrams. For an additional charge of 3d. any inland telegram will be delivered on an ornamental form enclosed in a golden envelope. This service is particularly suitable for messages of greeting, congratulation or good wishes. The word “greeting,” which is not charged for, should be written before the address on the telegram. This service is not available to Eire.

Night Telegraph Letters. Night telegraph letters may be sent to addresses in Great Britain or Northern Ireland and to the following towns in Eire: Dublin, Cork and Cobh (or Queenstown). The

message must bear a full postal address. They will be accepted at any time by telephone or at any telegraph office which is open.

Batch Telegrams. Batches of 100 or more identical messages may be handed in for delivery at any address in Great Britain and Northern Ireland on the weekday after the day of acceptance. The charge for each message is 4d. for 16 words of text and 1d. for each additional four words; no charge is made for the addresses.

Business Reply Telegrams. The Business Reply Telegram service enables approved persons or firms who register with the Post Office for the purpose to obtain a telegraphic reply from a client without putting him to the expense of paying the charges. Specially printed telegram forms are supplied for distribution, on each of which must first be inserted by the participating firm (either in printing or by means of a rubber stamp) an identification code, the name and address to which the telegram is to be delivered, the maximum amount up to which liability is accepted and the latest date of validity. The special forms are supplied at the rate of £1 1s. 0d. for ten thousand or, in smaller quantities, at 2s. 6d. per thousand. Accounts are rendered monthly.

Redirection. Fully addressed telegrams may be redirected to a second address either by the Post Office or by an agent of the addressee. The charge for redirection is 6d. per telegram if the original and new addresses are in the same place, free delivery area, or London postal district, and in all other cases at the ordinary inland rate. Instructions for the redirection of telegrams are recorded free of charge for 3 months; and for any period beyond this, up to one year, a charge of £1 1s. is made.

Foreign Telegrams. Telegrams can be sent to places abroad, the charges varying with the distance and other considerations. A full list of these will be found in the post office guide. Special forms are provided for these telegrams. They are accepted without restriction to most places abroad, but a few countries maintain restrictions on them. Particulars of these restrictions can be obtained from any post office. There are special reduced rates for telegrams between any two places within the British Empire.

The maximum number of letters allowed to pass in foreign telegrams at the charge for a single word is 15. Any excess is charged at the rate of 15 letters to a word. A reply of any length can be prepaid. *See Postage.*

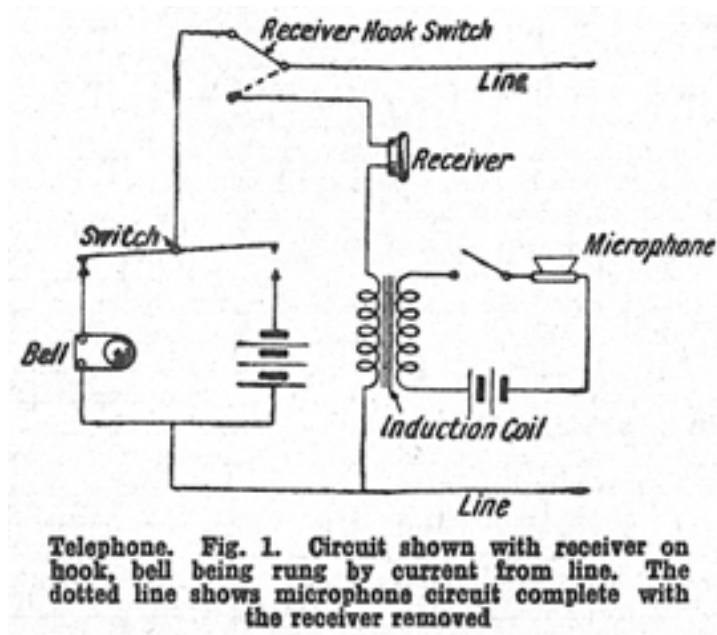

TELEPHONES: PUBLIC AND PRIVATE

Regulations for Subscribers and Methods of Installation

This article is divided into two parts. The earlier is for the benefit of those who have, or wish to have, a post office telephone in their homes. The second part describes how a man of mechanical turn of mind can fit into his house a telephone service connecting one room with another. See
Battery; Bell; Microphone.

The Post Office controls the telephone system of the whole of Great Britain and Northern Ireland (except the local system in the Channel Islands and the City of Hull). Anyone, therefore, desiring a telephone (other than in one of the excepted localities) may apply to the local Postmaster or to the Telephone Manager whose address is given in the local telephone directory. The work of installation will be carried out by Post Office engineers after the necessary agreement has been signed. The subscriber must not interfere in any way with the telephone mechanism; if anything

goes wrong he must tell the authorities, who will put it right. Every telephone line is connected with an exchange and is given a number.

Telephone. Fig. 2. Telephones often spoil the effect of an otherwise perfectly decorated room. Such a cupboard as this

has been found a most satisfactory solution to the difficulty. House and Post Office telephones can be housed in a recessed cupboard, with shutter on the roll-top desk principle to enclose them when not in use. (Margaret Currant Studio.)

Charges. The charges for telephone service payable by a subscriber consist of an initial connexion charge, a continuing quarterly (or monthly) rental and a fee for each call. The connexion charge for an exchange line varies from 5s. to 15s. according to the amount of work involved. The rental varies according to the class of service — residential or business — and to the district where the line is required— London or Birmingham, Glasgow, Liverpool and Manchester or the rest of the country. The charge for each call varies according to the distance to which the call is made.

Rental. Details of the scales of rental charges are given in the Post Office Guide and in the Telephone Directory, or they may be obtained on application at any Post Office. The usual minimum term for an agreement is one year. Telephone rentals are payable in advance on the 1st day of each quarter or month, as the case may be. Where the telephone is installed at a radial distance of more than 3 miles from the relative exchange an extra mileage charge at the rate of 5s. a furlong a quarter is payable in addition to the ordinary rental.

Calls. The scale of charges for local calls is:

Up to 5 miles	1d.
Between 5 and 7½ miles	2d.
„ 7½ and 12 „	3d.
„ 12½ and 15½ „	4d.

the distances being measured between exchange and exchange, and with certain extensions of the above limits in London, Birmingham, Glasgow, Liverpool and Manchester. In the case, moreover,

of subscribers in any area renting a line at the residence rate and without a coin box, 50 1d. calls a quarter Microphone (16 a month) or 1d., 2d., 3d. and 4d. calls to an equivalent value may be made without any charge beyond the rental.

Trunk Calls. Calls to exchanges at a greater distance than 15 miles from the originating exchange (with certain extensions of this distance in the case of London and the four large provincial cities where the area for local calls is larger than a radius of 15 miles) are known as trunk calls. The charge for these varies with the distance involved and the time of day at which the call is made. The charges are lowest during the evening and night. Full particulars will be found in the Post Office Guide and the Telephone Directory. Calls may also be made to most countries outside the United Kingdom and to a number of ocean liners on the high seas.

Extension Lines. It frequently happens that a telephone renter desires one or more of his lines extended from the main station to other parts of his residence, office outbuildings or works or, even it may be, to his premises in another part of the district. In a commercial undertaking such extensions are a necessity, and in a residence a bedside telephone is a distinct convenience, as is frequently a line to the garage or chauffeur's quarters. Such extension lines are classified as internal or external according to the circumstances, and the rentals charged vary accordingly. They are, however, relatively low, and full particulars will be found in the preface to each Telephone Directory. The rentals payable for exchange lines and extensions generally cover the provision and maintenance of any switchboard or Private Branch Exchange which may be required to connect calls between the different telephones.

Call Offices. Numerous public call offices are provided in street kiosks and in many post offices, railway stations and shops. The minimum charge for a local call from a call office is 2d. while trunks calls, etc., are available at the appropriate rate, plus a call office fee of 2d. The charges are either collected by an attendant or, more usually, paid direct by the caller into a metal box fitted below the telephone instrument; these coin boxes are designed to take pennies, sixpences and shillings, and coins of any of these denominations can be used to make up the charge for a trunk call.

Speaking Clock. Oral announcements of the time of day are given from the speaking clock at intervals of 10 seconds. Dial TIM, or ask the local operator for "the time."

Miscellaneous Facilities. There are a number of miscellaneous facilities available to users of the telephone service. The telephone can be used to despatch a telegram, to summon an express messenger, to ascertain the weather forecast or even to secure an "alarm" call in the morning. Full particulars of these or other facilities are shown in the Post Office Guide and Telephone Directory, and any further information concerning the telephone service will be readily supplied on application to the Post Office authorities.

Private Telephone Wires. The above remarks apply to the service of telephones operated by the post office, which department has control of all wires leading to the various exchanges. There is, however, nothing to prevent a private individual from installing a telephone of his own and using it for communication between one part of his premises or estate and another; for instance, between one room and another, between house and garage or stable, or between house and the cottage of a gardener or chauffeur.

A person who possesses, or contemplates possessing, such a telephone line must carefully note one or two matters. He must remember that he cannot use his own line to communicate with any house or premises that only possess a telephone attached to the public system. He must, too, take great care that his own line is not linked in any way with any wire that is part of the public service. With these limitations, however, a private line may serve within its own sphere a very useful purpose.

Simple Domestic Telephone. The circuit for a telephone is shown diagrammatically in Fig. 1, the different parts being indicated. When a receiver is lifted off its hook the latter automatically makes a contact and places the apparatus in circuit. Normally, with the receiver at rest on its hook, the telephone line is connected to the bell. The simplest type of telephone system for domestic use is shown in Fig. 3. The apparatus consists in the main of two parts. At the top is a push, similar to a bell push, with a hook fitted to its underside and a plug projecting from the top. Wires from this plug are taken to the lower instrument, which is the actual telephone. At the upper end is the receiver, beneath which is a handle incorporating a switch, while at the bottom is the microphone. The whole instrument is conveniently shaped so that it fits the ear and mouth.

The connexion of this instrument with another of identical design is shown in the diagram. This scheme enables the line to be worked in one direction only. That is, station A will only be able to ring station B. Station B can reply, but cannot originate a call. Such an arrangement is useful in the home when A is situated in the dining room and B in the kitchen. Ringing is accomplished by pressing the push at station A, but the line will not be clear for speech until the handle switches on both stations are pressed. The latter action is more or less automatically done in the handling of the instrument.

No induction coil is incorporated in this apparatus, as it is only suitable for working over short distances. The number of cells required will depend on the distance and the size of the conductors, but normally two only will be necessary. Such an installation may be fitted entirely with homely tools and by unskilled hands, as it is no more complicated than an ordinary electric bell. The use of twin wire over the longer distances will greatly facilitate the process of installation.

Fig. 4 shows how the same instruments employing a slightly different type of wall push and an extra bell may be made to work in both directions. It will be seen that the main line now consists of three separate conductors, and that there are two bells. Such an installation is still within the scope of the amateur or handyman of the house. In this instance it would be better to use single conductors, either laid side by side along the walls of the house, or else encased in wood or conduit. The battery can consist of two dry cells of large size, and these should last for nine to twelve months, after which they should be scrapped and replaced. Both the above systems may be fitted to existing bell installations with very little addition. All that has to be done is the substitution of one of the telephone appliances for the ordinary bell push.

Telephone Receiver for Wireless. The function of the telephone receivers in wireless reception is to convert the rectified impulses in the detector circuit into audible sound waves.

The headphone magnet windings may be wound to have either a low resistance or high resistance. High resistance headphones are very sensitive, and are thus particularly suitable for use with crystal receivers.

In the case of a valve receiving set, it is better to employ low resistance headphones (which are more robust) in conjunction with a telephone transformer to isolate the magnet windings from the steady current flowing in the anode circuit of the valve. This is highly important in a mains operated wireless receiver. *See Microphone.*

TELEPHONE COVERS AND SCREENS

Several Attractive Kinds to Make and Decorate

Attractive and practical methods for concealing the telephone instrument are suggested in this article. For further information the reader is referred to the contributions on Fretwork; Gesso Work; Italian Renaissance Work; Lacquer Work; Leather; Pencil Painting; Tarso. See also Lampshade; Writing Table.

In some of the newer houses small wall cupboards are fitted into halls and living-rooms for the special purpose of accommodating the telephone, or a compartment is prepared for its introduction into a bookcase or writing-desk fitment. The flap of the cupboard pulls down, and, by means of a metal arm, forms a convenient little table for the telephone, directory, and a pad with pencil duly attached for taking notes.

Where no such arrangement has been thought out a convenient cover for the whole telephone can be made by adapting a small white wood hanging cupboard. This should be of sufficient height and depth to admit of the instrument standing on a shelf, with space beneath for the directory and pad.

The back is cut out to admit the instrument and a small horizontal slot at one side next the wall for the cord. The cupboard should be brought into the colour scheme of the hall with enamel or stain, and the door presents an excellent panel surface for a piece of well-chosen painted, fretwork or tarso decoration.

There are many rooms in which a wall cupboard is not suitable, but in which an undisguised telephone has too businesslike an air. A dome-shaped oak stand can be obtained which is like a small cabinet, or a cover can be purchased or made at home after the style illustrated in Fig. 1. The head and arms and also the wire frame for the billowing-skirt which conceals the telephone can be bought for about 5s. Any silk, velvet, brocade, etc., can be used for the dress, and this can be fashioned in an Elizabethan, early Stuart, Queen Anne, Georgian or early Victorian style, when skirts were worn over farthingales, hoops or crinolines.

If a new piece of material is to be bought $\frac{7}{8}$ yd. of 50-in. width is sufficient to make a dress with gimp or tinsel lace for trimming and ribbon for a sash. A shot artificial silk is inexpensive and quite charming in mauve and blue, or rose and gold. A frame measures usually 10 to 12 in. across at the base and is from 15 to 17 in. high. The wires must be covered in the same way as a lampshade frame and either coloured silk or cambric strips cut on the cross 1 in. wide is best for the purpose.

A variety of heads are obtainable with hair done in different styles and made of silk, of real hair like an ordinary dolls, or with curls of the same composition or china as the face and arms. In some ways the last is the most serviceable choice, as there is nothing to get out of order and the doll has a Dresden china appearance. The head portion is provided with wires which when twisted firmly round the upper wire of the frame attach the two together. This is done before the wires are bound so that there is nothing untidy about the inside of the cover.

Telephone Cover. Fig. 1. Period figure cover. A doll's body to the waist is used for the upper portion and the silk skirt billows out over a wire frame.

The skirt is cut from the width of the material in a straight piece measuring 18-20 in. in depth. The length depends on the height of the frame, and the skirt should be an inch longer than this, after allowing for turnings. Having hemmed and joined it at the back, it is slipped on to the frame and neatly gathered to fit the waist. The bodice on the figure illustrated is simply two doubled strips measured and cut the length required to fit from the waist in front to the waist at the back when crossed back and front. To them are sewn little straight pieces to make the sleeves gathered to fit the arms above the elbow. Cut out and adjust the strips in paper first to see the exact length needed, and

also what width to cut the sleeves.

The frill requires a straight strip about 3 in. wide and out from the width of the material and half as much again.

It may be edged with lace, as may the sleeves, or a tinsel gimp may be used for both. Instead of one wider frill several narrower ones may trim the skirt. A ribbon sash with a bow and long ends completes the dress. A rather more trimmed style has an under petticoat of a lighter shade covered with gathered rows of narrow lace over which the skirt is draped at the sides. The bodice has then a crossed lace fichu and lace frills to the sleeves. A woman clever at dressing dolls can design a charming period dress in colours to suit her room.

Wooden Screens. Small wooden screens are particularly attractive whether painted in plain colours with a severely geometrical border, or handsomely decorated in gesso, Italian Renaissance work, lacquer work, or Tarso.

A screen of the type of that illustrated in Fig. 2 is expensive to buy, but if made at home can be produced for a trifling cost. The materials required are sufficient thin plywood (q.v.) to make the 3 folds, (the middle one being 16 in. high at the top of the curve, and measuring 7 in. across, while the sides each measure $5\frac{1}{2}$ in.), 4 small screen hinges, sandpaper, enamel, or brush lacquer colour for the ground, and oil colours, liquid oil colours or bronzes for the design. A coat of varnish should be given on completion.

Plywood can be obtained in various thicknesses, but a thin one is best, as it is easier to cut. A small fretsaw will be required for this purpose. Draw the outline of the panels on the plywood and cut out carefully. The edges must then be sandpapered thoroughly enamel or paint the background colours,

trace or draw the design and border and paint them. Stencilling medium may be used to thin oil colours, and any type of design can be chosen that is suitable to the size of the panels and style of the room.

Fig. 2. Plywood telephone screen with painted design and border in bright colours. This screen can be easily made at home for a trifling cost.

A pretty telephone pad is made as a companion accessory to the screen by curving out the top of a piece of plywood large enough to extend well beyond the paper pad when this is affixed with glue. The margin of the wood is curved, coloured and decorated to match the screen. A charming pad is shown in Fig. 3. To make one of this type a paper pad is purchased and glued on to a gilded wooden base. The cover is made of imitation vellum on which a design is painted in coloured mandarin inks. The vellum is cut the same size as the paper pad, except that sufficient turning is allowed at the top to cover the thickness of the pad and to be glued down firmly between this and the base. The screen illustrated in Fig. 3 is an expensive one to buy, as it turns on a round base to bring the telephone into position for use. The style of decoration could, however, be copied on a plywood screen without a base, the three sides being of equal width and hinged.

Fig. 3. Wooden screen on a revolving base. The panels are decorated with painted flowers and gilded edges. The telephone pad has a cover of imitation vellum painted in coloured inks, and is glued on to a gilded wooden base.

Another type of plywood screen requires more skill with the fretsaw, and is only useful when the telephone is on a table in a corner, but has a very charming effect when well done. It is a flat representation of a bouquet, basket, or bowl of flowers, painted in natural colours and measuring 16 in. by 12 in. at the tallest and widest points. When drawing out the design on the plywood, care is taken to place large, simple leaf-forms on the outer edge, so that these may be easily cut with the fretsaw. The screen is supported at the base by means of a block of wood glued at the back. The block is large enough for the telephone to stand on,

and sufficiently solid to counterweight the screen when the instrument is removed for use. Sometimes the idea of a lady in full skirts is adapted to plywood and paint, and the figure is then cut out and supported in the manner just described.

Care must be taken when drawing the design to see that the telephone will be fully covered by the skirt before the figure tapers above the waist-line. The block and the back of such screens should be painted the same shade. In the case of the bouquet designs green or brown is the best choice, as they

do not clash with the brilliant colours employed for the flowers. Metallic paint in silver or gold adds a gay note to the figure design.

Although not so durable, excellent little screens and telephone pads can be obtained in parchment-covered cardboard of a heavy make. These are quite inexpensive and can be decorated charmingly with pencil painting, or in any of the ways suggested for decorating parchment in the article on Lampshades. When varnished, the parchment keeps clean for a long time. Parchment paper screens are also supplied in sheet form, traced ready for colouring.

TELEPHOTOGRAPHY FOR AMATEURS

Practical Details of an Important Branch of Photography

Though at one time thought to be the exclusive province of experts carrying specially cumbersome cameras, telephotography is now within the reach of all, and its attractions are clearly set forth in this article. See Exposure; Focus; Lens; Photography.

Telephotography may be roughly described as combining some of the advantages of a telescope with those of a camera. It provides a means whereby with an ordinary hand camera with normal camera extension, photographs may be taken on a much larger scale than with the ordinary medium focus lens.

Thus, with an ordinary camera photographs of distant views, high mountains, or architectural subjects are not only reproduced on a very small scale, but are liable to be wrong in perspective. With a good, telephoto lens distant objects can be photographed directly on a large scale, and subsequently further enlarged. Excellent photographs have, for instance, been taken with telephoto lenses of mountain peaks 90 miles away.

Telephotography. Fig. 1. Dallon telephoto lens, suitable for use without any other lens. Fig. 2 (above). Adjustable type Adon lens, for use on cameras with focussing screens. (Courtesy of J. H. Dallmeyer, Ltd.)

With the type of lens usually fitted to a camera the size of the image given on the focussing screen depends on the focal length of the lens.

Thus, comparing a small pocket camera whose lens is $3\frac{1}{2}$ in. focal length with a large camera the lens of which has a focal length of 7 in., the image seen on the focussing screen or negative will be twice as large with the 7 in. lens as it is with the $3\frac{1}{2}$ in. In order, therefore, to get an image four times the size, a 14 in. lens would be required, and so on in proportion. Now, since with the normal lens the focal length is approximately the distance between the back of the lens and the focussing screen, the greater the magnification required the longer the focal length and the bulkier and more unwieldy the camera.

These difficulties are overcome by the use of a telephoto lens, which consists in principle of two combinations of lenses: (1) the normal positive lens, or combination acting as a positive lens, such as is used in every camera; (2) a negative lens, or lens combination, such as is used in the eye lens of opera glasses. The first combination, the positive lens, may be the ordinary lens of the camera, in which case a negative lens is added. In the majority of cases the negative and positive lenses are combined in a telephoto system, which is used by itself as a complete lens.

An example of the latter is the Dallon (Fig. 1), a series of anastigmatic telephoto lenses of 4 to 40 in. focal length working at apertures of $f/5.6$ and $f/7.7$ (for reflex and miniature cameras) and $f/6.5$ for folding hand cameras. The latter are suitable for use on small $3\frac{1}{2}$ in. by $2\frac{1}{2}$ in. cameras. Another form is the Adon adjustable type (Fig. 2), which is designed for use by itself on all sizes of cameras possessing focussing screens. It includes a micrometer movement for focussing and an iris diaphragm. At the same extension as an ordinary lens it gives a picture three times the size, and it will cover completely any size of plate from $3\frac{1}{2}$ by $2\frac{1}{2}$ in. up to 15 by 12 in., provided the camera is capable of sufficient extension. Thus, for a $\frac{1}{4}$ plate an extension of 6 in. is necessary, which is the normal of a single extension $\frac{1}{4}$ plate camera. Its weight complete is only 7 oz. Of course, it must be remembered that the greater the extension available on the camera the greater the magnification obtained.

Other good types of telephoto lenses are the Zeiss Magnar and the Dallmeyer Grandac, both working at $f/10$; and the Ross Teleros, which is of large aperture working at $f/5.5$ and $f/6.3$. Another Zeiss lens is the Tele-Tessar, working at $f/6.3$. The Dallmeyer New Large Adon series work at $f/4.5$, permitting telephoto snapshots and requiring extensions of $4\frac{1}{2}$ in. for a $3\frac{1}{2}$ in. x $2\frac{1}{2}$ in. camera, and $6\frac{1}{4}$ in., for a $\frac{1}{4}$ plate, the magnification being 2. All the lenses described, with the exception of the Adon (Fig. 2) and the Grandac, are of the fixed focus type, focussing being done by racking the camera front in the ordinary way. Focussing lens mounts, can however, be supplied in most cases for fixed focus cameras such as the Leica, Exakta, etc.

With telephoto lenses of the fixed focus type which are used in place of, not in addition to, the ordinary camera lens, there is no complication of any kind. They are used in precisely the same way as the ordinary lens, and exposures are made according to their aperture or f /number. When adjustable type telephoto lenses are used, or a negative lens is used with the moving positive, or when they are of the variable focus type, certain calculations or references to tables require to be made. With Adon and certain other lenses special calculators, in the nature of ready reckoners, are supplied. The data required are (1) the effective aperture of the combination; (2) its focal length; and (3) degree of magnification.

The magnification, or size of the image, increases proportionately with the camera extension. The degree of magnification is found by dividing the distance between the back of the telephoto attachment and the focussing screen by the focal length of the telephoto or negative lens and adding 1. Thus, to take as an example, a telephoto lens working at 10 in. extension, when combined with a positive lens, the focus of the telephoto negative being $2\frac{1}{2}$ in. $10 \div 2\frac{1}{2} + 1 = 5$, i.e. the magnification on the negative is 5 times linear, and 25 times in area.

If it is desired to find the distance at which the camera should be placed in order to fill the plate or film with an image of an object of given size, the following formula is used:

D = distance of lens from object. F = focal length of telephoto lens. O = size of object. PF = size of plate or film.

Then: $O \div PF \times F + F = D$, distance of lens from object.

The effective aperture of the whole combination is then obtained by multiplying the aperture, or f/number , of the positive lens by the degree of magnification. Thus, if the positive lens regularly used on the camera works at $f/6.8$, the effective aperture when combined with the telephoto lens will be $f/6.8 \times 5 = f/34$. It is therefore seen that exposures must be greatly increased, and further that the greater the magnification and camera extension used the more the aperture is reduced and the exposure increased. Not only does the exposure increase with increasing extension, but magnification is also limited by the capacity of small cameras for extension.

To find the total focal length of the whole combination, multiply the focal length of the positive lens by the degree of magnification; thus, if the focal length of the camera lens be 5 in. and the magnification 5 times, the total focal length is 25 in.

For all normal purposes the magnification of 2 to 4 times will be found sufficient; very effective work is possible with a magnification factor of 2, which actually means increasing the area of the image 4 times, since the magnification factor is a linear one. With some telephoto lenses magnification factors are marked upon the mount.

A little practice will soon enable the amateur to calculate the exposures required. The basic rule for exposure when using a combination of the telephoto negative lens and the ordinary positive camera lens is to multiply the exposure required by the positive by the square of the magnification factor. Thus, if the lens without the telephoto attachment requires under certain conditions an exposure of $\frac{1}{2}$ sec., and the magnification is three times, the exposure required when the telephoto lens is added will be $\frac{1}{2} \times 3^2 = \frac{1}{2} \times 9 = 4\frac{1}{2}$ sec. This, of course, applies only to telephoto lenses of the fixed focus type.

When variable focus telephoto lenses are used in combination, it is necessary to find the aperture or f/number of the whole combination according to the rule already stated. This f/number can then be used with any exposure meter in the ordinary way. If the telephoto lens itself is stopped down the length of exposure must be multiplied by the number of the stop used.

It is necessary to calculate exposures with telephoto lenses rather more closely than with ordinary lenses, and it will be found in practice that exposure times given by the calculations referred to are maximum figures, which should not be exceeded, particularly with distant objects, owing largely to atmospheric haze. It may be found, in fact, that an exposure of half the calculated time will give good results with a distant object. For objects at moderate distances the calculated exposures are correct. When photographing distant objects, results will always be improved by the use of colour screens as used with panchromatic plates. They cut out the atmospheric haze, but must be of good quality, as any defects in them are magnified by the telephoto lens.

Telephoto lenses can only be used with cameras that possess both focussing screens and means of extension. Further, the camera and its tripod should be as rigid as possible, since any vibration will destroy the definition when high magnification is used.

It is not necessary, however, to carry the very heavy apparatus once thought to be essential. If reasonable care is taken, and ample time allowed after focussing, etc., for camera and stand to become perfectly steady, fairly light apparatus may be used. With the higher magnifications an additional strut fitted from the front of the camera baseboard to one of the legs of the tripod will help considerably to ensure steadiness.

Focussing must, of course, be done very carefully and very finely ground glass used as the screen. A magnifying focussing eyepiece used on the focussing screen will be found of great assistance. Such a glass may be purchased from any photographic dealer. All telephoto lenses should be fitted with long hoods, such as that seen in the photograph, Fig. 2; these hoods cut off stray light and greatly improve the brilliancy and contrast of negatives.

Telephotography. Figs. 3-5. Showing magnification obtained with telephoto lens. Fig. 4 represents a magnification twice the size of Fig. 3, and Fig. 5 four times the size, both the latter being taken with the same Dallon lens at different extensions.

Telephotography. Fig. 6. Nature photograph taken with an ordinary lens. Fig. 7. Showing how the Dallon telephoto lens obtains a large scale photograph of the central feature from the same standpoint as Fig. 6.

Figs. 8 and 9. Statue of Louis XII at the château of Blois; a good example of the value of a telephoto lens for photographing from a distance an awkwardly placed subject. (Photo Chas. West)

The series of illustrations Figs. 3 to 9 demonstrate some of the varied uses of telephoto lenses. Figs. 8 and 9 show examples of subjects which could not otherwise be satisfactorily photographed at all.

For nature photographs (Figs. 6 and 7) the telephoto lens offers the immense advantage of being able to secure pictures on a good scale at a considerable distance away. Similarly, groups and street scenes are much more easily obtained. Not

only, however, are the photographs obtained on a good scale, but the actual perspective rendering is greatly improved.

TELESCOPE. There are two main types of telescope, refracting and reflecting. The former is suitable for either terrestrial or astronomical observations, and the latter usually for astronomical observations only.

In the refracting telescope the light from the object observed passes direct through the object glass, and the image formed is observed through a magnifying eyepiece. In the commonest form of reflecting telescope, known as the Newtonian reflector, the light from the object observed is collected by a mirror at the base of the tube, and reflected into a small mirror. The image formed on the small mirror is observed and magnified through an eyepiece.

The function of the object glass, or the mirror, as the case may be, is to gather sufficient light to make a perceptible image in the focal plane. The function of the eyepiece is to enable the eye to see the image when as near it as possible, so that the angle it will subtend at the eye may be large.

TELEVISION IN THE HOME

The Basic Principles and Methods

This contribution is complementary to the interconnected series of wireless articles in our work. It explains the fundamental methods of transmitting an image from studio to receiver.

See Broadcast Receiving Sets; also Wireless Reception.

A daily television service, the first of its kind in the world, is radiated by the British Broadcasting Corporation from the Alexandra Palace in the north of London. Nominally the programmes are designed to serve London only, but successful reception has been obtained at ranges exceeding fifty miles in most directions from the transmitting station.

Ultra-short wavelengths are used—6·6 metres for vision and 7·2 metres for sound.

Two mobile units are possessed by the B.B.C., and these are able to roam round London and the Home Counties up to approximately twenty miles from Alexandra Palace.

This valuable mobility has largely been made possible by the compactness and adaptability of the Emitron television camera, which is probably the most significant single development connected with the new art.

It is in very truth an “electric eye” and works silently and without any moving parts whatever. It will, of course, be appreciated that the pictures are not transmitted as a whole. They are, in fact, traversed in fine lines. The simplest way to understand the principle of “picture analysis” is to look closely at a newspaper reproduction of a photograph. It will be seen that it comprises thousands of dots and that the picture is built up by means of variations in the quantity of ink represented by individual dots.

Similarly, the Emitron camera embodies a screen which consists of thousands of tiny photo-sensitive nodules, and each of these nodules carries a charge of electricity proportional with the light thrown upon it by the lens of the camera. Thus, instead of an ink picture as with the newspaper illustrations, we have an “electricity picture”. The Emitron camera also has an “electron gun” which shoots at this electricity picture an “electron stream” composed of millions of particles of electricity. This stream sweeps across the electricity picture 405 times in a fraction of a second, shifting its line of focus a minute degree with each successive sweep, so that the whole area is explored. As it passes each of the nodules, so it carries away with it the electrical charges on them in the form of an electric current which varies in strength as with the amount of light falling upon the individual nodules.

Therefore, the picture has been transformed into a fluctuating current which is as relatively simple to transmit as that which represents speech or music in ordinary broadcasting.

The Receiver. In the most widely used type of television receiver the end of what is known as a cathode-ray tube forms a screen.

This screen is covered with a substance which becomes luminous when a stream of electrons from a similar “electron gun” to that used in the camera falls upon it.

If the line-traversing effect of this gun is made exactly to synchronise with the sweep of the Emitron’s gun, and its intensity varied to correspond with the light changes recorded, then, line by line, the picture is built up. But this is done at the rate of twenty-five complete pictures a second: so fast that the eye does not see the process of building up, but only the flickerless “moving picture.” The process of picture analysis at the transmitter and the re-creation of the picture on the chemical screen of a cathode-ray tube is styled “scanning.” It is accomplished by what are known as “Time Bases.”

If a cathode-ray tube is examined closely it will be seen that in its extreme, narrow end is the filament or cathode. As in the case of a valve (q.v.) this gives off electrons when it is heated. In front of the cathode is an anode in the form of a disk with a hole pierced through it, a second anode cylinder-shaped, and then a third anode similar to the first, i.e. a disk with a hole in its centre.

The disk anodes are made highly positive and so attract the electrons strongly. A thin stream of the electrons shoots through the holes. The cylinder is made negative and repels the electrons, thus tending still further to squeeze them into a very narrow beam. The positions of the disk anodes affect the focussing of the stream as do lenses in a camera, their object in this respect being to ensure that the fluorescent screen on the end of the tube is struck with an intense beam and made brightly to glow. The stream is also made to pass between horizontal and vertical deflecting plates. These apply the scanning. Increasing voltages are transmitted to them by the “time base” circuits.

Electrical pressures as high as 4,000 volts and over are employed in the operation of cathode-ray tubes, but very little current passes. The total power consumption for the whole of the set may not exceed two or three units per week even if it is switched on for all the programmes. Nor is the high voltage a dangerous one as the current is limited.

Television Sets. The size of the picture varies on different sets from 4 in. by 3 $\frac{5}{8}$ in. on one of the cheapest ones, to 24 in. by 20 in. on an expensive model. 10 in. by 8 in. is an average size which permits very comfortable viewing in the home. True black-and-white pictures sufficiently bright to be seen in ordinary room illumination are obtainable, though greenish reproduction and less brightness are found in the less expensive models.

Owing to the fact that there is only the one programme on a fixed wavelength, television sets require little or no further adjustments once they have been initially installed. An efficient instrument will also maintain perfect synchronisation. Special aerials are available for the effective reception of the programmes with a minimum of interference within the service area of the transmitter. This is usually regarded as 25 miles, but the range is frequently exceeded. The quality of the speech and music is generally greatly superior to that on the medium or long waves owing to the wide side-bands on ultra-short waves.

In conclusion, television in the home is now entirely practical even for those possessing no technical knowledge whatever, and the results are so consistently good and the illusion of obtaining intimate contact with the televised scenes so real, that it is probable that in the near future television will displace blind broadcasting even more than at present.

TEMPERATURE: Of the Body. The average temperature of human beings in health is 98·4° F. Usually it rises a little during the day and falls gradually during the night, so that the body is hottest in the evening and coolest in the early morning.

After a meal or after exertion the temperature is raised a little. In women it goes up more readily than in men. In children a considerable rise, amounting to slight fever, may occur from such trifling causes as a fit of crying or an attack of indigestion. Uniformity of temperature is maintained by a balance between the production and the loss of heat by the body.

The temperature may be taken by placing the thermometer in the armpit, the mouth, or the rectum. To take it in the armpit wipe the skin with a soft towel. Place the bulb of the instrument in the hollow. Fold the arm closely across the chest and cover the patient. To get a correct reading the thermometer should be left in place for a period of ten to fifteen minutes.

A quicker and generally more accurate reading is obtained with the mouth. Carefully wash the thermometer with soap and water. Place the bulb under the tongue. Leave it there for 3 min. The patient should keep his mouth shut and breathe through the nose. The clinical thermometer should always be washed after and before use. *See* Fever; Thermometer.

TEMPERATURE. In Gardens. All greenhouse temperatures and those that are necessary for the well-being of plants, which are given in this Encyclopedia, are those of the Fahrenheit thermometer, with its freezing-point of 32° and a boiling-point of 212°.

Plants are liable to severe injury from sudden changes of temperature. If ventilators are closed down too precipitately the alteration from an open, free, air to a close, stagnant atmosphere is likely to cause trouble.

TEMPERING AND ANNEALING. The process of heating and cooling steel to give it hardness is known as tempering. It is the opposite of annealing, by which a metal is softened. Different methods of tempering are employed according to the size and nature of the steel, but the principle is the same.

The steel is first hardened by being heated to a dull red glow and plunged into cold water or oil, the rapid cooling thus obtained making the metal dead hard. In this state it is generally too brittle and hard for practical purposes, and it is polished up bright and heated again, but this time by a more gradual process. When it has been brought to the required heat it is once more immersed in water or oil, which fixes the temper.

The degree of hardness or temper is indicated by the colour of the metal. If a bar of brightly polished cast steel is slowly heated from one end, a series of colour changes will travel along the bar in a definite and regular order. The first colour appearing is a light straw or yellow. Quenching the hardened metal at this state gives the hardest of cutting edges. The light straw is followed by a dark straw colour, giving a rather softer temper. Dark straw gives place to brown, a usual temper for plane irons and wood-cutting tools. Light blue is the next colour, and this is the stage at which most knives are tempered. When it changes to a dark shade a fairly soft temper is obtained for articles such as wood saws and many forms of springs.

Annealing. Metals are annealed to make them softer and more easily workable. Steel and iron are annealed to remove the internal strains that are incident to manufacture. The piece of metal can be brought to a bright red heat in the stove, or in a forge or furnace if available. It is then left in the hot ashes all night, to allow it to cool slowly. Brass is annealed by slow and continued heating, taking care not to burn or melt the metal. Copper is annealed by bringing the metal to a dull red heat and then plunging it into cold water. In the case of pipes and similar objects the worker should beware of the escaping steam. *See* Case Hardening; Hardening.

TENANT. A tenant is one who holds land or other real property of another. The terms of a tenancy depend entirely upon contract. In the absence of agreement to the contrary, when a tenant enters upon the land and pays rent for a year, or any aliquot part of a year, he is a yearly tenant, whose tenancy can only be determined by six months' notice to quit, expiring at the end of a current year of the tenancy. He is also a yearly tenant if his agreement is at a yearly rent, though that rent may be payable monthly, weekly, or in any other fashion. But if a tenant agrees to take a house at so much a month or week, he is a monthly or weekly tenant, entitled only to a month's or week's notice. In the absence of agreement to the contrary, the tenant is liable to pay all rates and taxes except property tax. As to property tax, the tenant is liable to pay it to the tax collector, but may deduct it from the first rent he subsequently pays to the landlord. *See* Distraint; Landlord; Rent.

TENCH. This fresh-water fish needs careful cleaning. It is usually boiled or fried, and is in season all the year round.

Before boiling tench clean it, remove the gills, and then soak it for about an hour in cold salted water. Rinse it in fresh running water, put it in a pan of boiling salted water, covering it completely, and let it cook slowly until it is tender—about $\frac{1}{4}$ hour. Garnish it with parsley and cut lemon, and serve some melted butter sauce separately.

To fry tench cover it with flour, put it into a pan of smoking hot fat, and brown it well on both sides. Then drain it and serve it garnished with fried parsley, and accompanied by some piquant sauce. *See* Sauce.

TENDON. Sinews or tendons are the strong, tough, fibrous cords by which muscles are united to the bones or other parts on which they act. Rupture of tendons is a not uncommon accident. In dancing, for instance, the Achilles tendon, which connects the muscles of the calf with the heel, is sometimes ruptured. The patient feels as if he had been struck a severe blow above the heel, and he loses power to use the foot, or may fall to the ground.

TENNIS CAKE. This iced fruit cake can be made in the following way: Beat together 5 oz. sugar and $\frac{1}{2}$ lb. butter or margarine until they are like cream; then add 3 eggs, one by one, beating all the time. When they are well mixed, stir in 1 lb. flour, $\frac{3}{4}$ lb. sultanas, 2 oz. peel, a little milk, and a few drops of essence of lemon.

Turn the mixture into a greased tin and bake it in a moderate oven until it is lightly browned; then let it cool on a sieve. When cold, cover the top with almond paste or marzipan, and over this put some fondant or royal icing. Decorate the border of the cake according to taste, write across it the word Tennis, using pink icing, and complete it with a design of two tennis racquets. *See* Almond Paste; Cake; Fondant Icing; Marzipan.

TENNIS COURTS: GRASS AND HARD SURFACES

How to Lay Them and Provide the Necessary Accessories

This article describes the laying-out both of a grass and a hard court, afterwards giving directions for marking out a court. Related entries include those on Garden Lawn; Spirit Level.

For the game itself the article Lawn Tennis should be consulted. *See* also Table Tennis.

Provided there is sufficient space, any household can, at comparatively small cost, provide itself with a grass tennis court. The chief, expense, apart from the preparation of the ground, is caused by

the necessity in most cases of providing wire or other fencing around the ground. The laying of a hard court is a more expensive matter, but it can be done by the amateur.

Laying a Grass Court. If the ground is fairly level the only preparation needed is to cut the grass closely and to water and roll it to as level a surface as possible. Any bad places can be filled in with a few turves cut from unimportant ground, cutting away the turf, making the soil beneath flat and level, and then fitting the new turf and beating it into place.

The preparation of the ground or turf should be carried out in the autumn or very early spring, so that it will have time to settle down before play begins. Slight bumps can be levelled by lifting the turf and scraping out the surplus soil, and immediately relaying the turves in the same place. All disturbed turf ought to be well watered daily for a few days, beaten flat, and rolled with a heavy roller at two-day intervals until the grass looks healthy. Mowing and rolling are then carried out, and in a short time the ground will be in condition for play.

When it is desired to construct a tennis court on a piece of rough meadowland, the nature of the soil, the general position of the site, and the geological conditions should all be taken into account, as well as the amount of money that can be spent in order to lay out the court. On a light or readily and naturally drained site the principal work is levelling, which is generally a matter of removing the earth from the high parts and depositing it at the lower. It is necessary to consolidate the made-up ground, and preferable to let it stand for a few weeks to settle down, and then to finish by very careful levelling. The surface can be made up with turves, or by sowing grass seeds, according to choice. A good result can be obtained by both methods.

When the ground is heavy or likely to become waterlogged in wet weather, it will be advisable to remove the earth to a depth of 12 in. or so and to make up the bottom with rubble or well-broken soil, adding agricultural drains as necessary. The rubble is raked and roughly levelled and then covered with a good layer of medium soil. This is raked and rolled and covered with a good top soil with an admixture of manure. The whole is levelled and watered, rolled, and allowed to settle. The surface is made good as required, and it can then be covered with turves or sown with grass seed.

Hard Courts. There are several types of hard court, some laid with cement or concrete, others with asphalt or a tar composition or with burnt ballast. A system extensively used is that developed by the En-Tout-Cas Co., Ltd., of Syston, Leicester.

Courts laid with this patent method permit of play all the year round; they exhibit the characteristics of the best grass courts, and the bound of the ball is absolutely true. They are made with a special material laid on a bed of ashes, and being semi-porous, they can be played on within a very short time after rain. The patent material is only laid by the company's workmen, but the whole of the preparatory work of making up the ground, levelling, and preparing the ash bed can be carried out privately if desired.

The preliminary stages are dealt with on similar lines to the grass courts. The levelled surface is covered with a layer of ashes to a depth of about 4½ in., but local conditions may call for special treatment. These ashes are levelled and rolled. The foundations are covered with the patent material, well graded, screeded, and rolled until a flat and true surface is obtained. The sockets, for the posts, previously embedded in concrete, are set at such a height that the top of the socket is about level with the surface. The ash foundation is not laid in a haphazard manner, but is properly graded. Generally speaking, when laid on a reasonably well-drained subsoil, no additional drainage will be necessary.

The ashes are laid according to the type used, and graded with the largest at the bottom and the smallest at the top. The nature and amount of fine ashes in the bulk determines the manner of laying and keying the top ashes. A considerable quantity of ashes is needed, amounting to something like

60 tons for a court measuring 120 ft. long and 60 ft. wide, calculating on the assumption that the depth of the court will be about $4\frac{1}{2}$ in.

The surfacing material is a special type of clay burnt in kiln to such a hardness that it will not weather back after it has been laid and subjected to ground moisture. At the same time, it is not so much burnt as to reach the vitrifying stage, otherwise no binding power will be present. The colour is a shade of red that enables the path of the ball to be seen readily, even in glaring sunlight.

After the court has been made the lines are marked out and permanently defined by the use of metal or painted linen strips, the former composed of compressed lead tape. This is fixed to the court with long galvanized nails, and the tape beaten in level with the surface. The only subsequent attention is a coat of white paint about once a year.

Marking the Court. To mark out a tennis court a start should be made with one intended for the double game, as its markings can easily include those necessary for singles. First determine the position of the net and fix in the line chosen two pegs 27 ft. apart, as in the diagram. Then take two measures and fasten their respective ends to the pegs A and B.

Tennis Court. How to mark out a court; one half only is shown, A B being the place for the net.

On the first measure, which will go diagonally across the court from A to C, take a length of 47 ft. 5 in. On the second, which will go from B to C, take one of 39 ft. Pull both measures taut so that at these distances they meet at C, and this gives one corner of the court. At a point marked F, 21 ft. from B, put in a peg to mark the end of the service line. The other corner, D, and the

other end of the service line, G, can be found by repeating the process.

The same measurements on the other side of the net will complete the boundaries of the court. By prolonging the base lines $4\frac{1}{2}$ ft. on each side, and joining the four new points that are thus obtained, the side lines of a double court are made, and to complete the marking all that remains is to mark the central line by joining the middle points of the side lines.

For double court alone the interior side lines need not be prolonged to meet the base lines. In all cases the net posts must stand at a distance of 3 ft. from the side lines. Therefore, if a single game is played on a double court, the net, unless the posts are shifted and a single court net is used, should be stayed up to the right height by means of single posts placed at a distance 3 ft. from the single court side lines.

Tennis Net. For the purpose of playing lawn tennis a net across the centre of the court is necessary. This is usually fastened to posts, one at either end.

These tennis nets are sold in various qualities. For ordinary use a fine hemp net with lines top and bottom is suitable, but a stronger one can be obtained with a linen band.

More expensive ones have a band of woven web and a steel or copper headline with a hempen end and pins. The nets are fastened to posts of wood or metal, the latter being specially suited to hard courts.

Tennis Net. Fig. 1. Square post fitted with patent cone ratchet. Fig. 2. Detail of portable foot. Fig. 3. Post and weights for asphalt and hard courts. Fig. 4. Hard court post with rotary locking device. (Courtesy of F. H. Ayres, Ltd.)

Good wooden posts are of ash, fitted with brass ratchets for winding purposes.

The posts are fitted into iron sockets which enable them to rest on the ground and these are fastened by pins driven into the soil. Metal posts are of iron or steel. As these cannot be pinned down on hard courts, they are set into an iron receptacle sunk into the ground.

Steel posts are also made in the same way as iron ones and with portable iron feet, and ground screws are made for use on grass courts.

The illustrations show the modern methods of fastening the tennis net, both on grass courts and on hard ones. Fig. 1 shows a winding apparatus consisting of a cone drum, which has taken the place of the hollow drum formerly used. In the older types of ratchet the liability of the copper cord to kink and break necessitated the adoption of a rope end for use at the winding post. In the ratchet of

the one illustrated a small hook on the drum receives a loop made in the copper cord itself and the winding is accomplished without the slightest danger of kinking or breaking, this being due to the shape of the drum, which allows the coils of the copper cord to be laid up evenly. The post illustrated, Fig. 1, is 3½ in. square, and its metal points are of nickel and brass.

Fig. 2 shows the socket for the post of a tennis net. This, suitable for use on grass courts, is usually fastened to the ground by feather pins, as shown, but it can be made secure by ground screws. Fig. 3 shows a socket made to stand on a hard court, especially one where no holes in the ground or flooring are allowed. It is kept in position by the weights, of which there are four to each post.

Another method of fixing the net on a hard court is shown in Fig. 4, but for this a hole must be made in the ground. This done, it gives a thoroughly secure hold. The top of the base is level with the surface of the ground and so offers no projections that will impede the rolling of the court.

With ordinary care a good tennis net will last a long time. The winding arrangement may get out of gear, but usually this is not serious. To take off the strain the net should be lowered after play is finished, never left taut.

TENNIS ELBOW. Strain of the muscles of the forearm below the elbow, often referred to as tennis elbow, is usually treated by strapping the forearm for a short distance with adhesive plaster. It is a painful condition, but does not interfere with the stronger movements of the arm, for example, lifting weights, but movements that call for finer adjustment of the muscles are rendered difficult. It has been suggested that the condition may be induced by the handle of the racquet being too bulky for the grip of the player.

The position of the forearm in the back stroke is likely to expose the parts about the upper joint between the two bones of the forearm to injury, and inflammation may occur in the joint itself. Some doctors advise vigorous massage, while others recommend rest. *See Elbow; Strain.*

Tenon. Fig. 1. Marking out tenon before cutting. Fig. 2. Cutting the tenon with a tenon saw. Fig. 3. Finishing the tenon with a chisel. Fig. 4. How a wooden strip is applied to protect the teeth of a tenon saw.

TENON: In Woodwork. A mortise and tenon joint is employed in all classes of woodwork. The tenon is that part of it which fits into the slot or cavity cut in another piece of material. The tenon can be shaped almost entirely with a hand saw, preferably the type known as the tenon saw. In making a tenon the wood is first prepared to its finished size and marked out, as in Fig. 1, with a marking gauge and set square. The breadth of the tenon should be about $\frac{1}{8}$ the breadth of the wood. Resting the material on the bench against the bench hook, a cut is made with the saw across the grain of the wood at the shoulder or termination of the tenon. This cut must be very carefully made. If it is even a fraction out of truth or out of square, or not quite perpendicular to the face, a bad joint will result, especially if, as is often the case, it should be impracticable to trim up the shoulder with a paring chisel. A similar cut is made on the opposite side.

After this, the work is preferably set upright in the vice, and two cuts are made with the saw at right angles to the first, and in the direction of the grain, as in Fig. 2.

Here again it is imperative that the cuts be made very accurately to the lines marked on the work. The aim should be to saw away the exact amount of wood so that the tenon can be fitted into the mortise with the minimum of trimming and finishing.

To ensure a close fit it is desirable to chisel across the grain of the wood, as in Fig. 3, removing the saw cuts, and generally smoothing the surface. It is usual practice to drive a tenon home with a mallet, but common sense must be employed when doing this, as if the tenon is too tight and driven home too violently, the wood in the vicinity of the mortise will split. The aim should be to make all four sides of the tenon fit snugly against the four walls of the mortise. The example illustrated is the simplest form of tenon. There are many developments of it, according to the nature of the joints which are to be made. The principal forms are described in the article Mortise.

Tenon Saw. For household use the most serviceable size of tenon saw is from 10 to 18 in. long, with about 10 teeth to the inch. The saw blade is reinforced by a backing piece of steel or brass.

The teeth are bent over to the right and left alternately, an arrangement known as the set, which enables the blade to move freely in the slot cut by the teeth. If the set is insufficient, the blade will jam in the slot and probably buckle or distort. It is important to allow for the breadth of the saw kerf, for which reason the wood should be sawn on the waste side of the line and not actually on the line itself.

In use the tenon saw is grasped in the right hand with the right forefinger extended on one side of the handle, and the right thumb on the opposite side. The bulk of the handle is gripped with the second, third, and fourth fingers of the right hand, the first finger and thumb guiding the path of the saw. The blade must be kept perfectly upright with sufficient outward pressure to make the teeth bite into the fibres of the wood. The forward stroke does the cutting; the return stroke brings the saw back without allowing the teeth to rasp the surface of the wood.

A wooden strip should be made to protect the teeth. It is equal in length to the blade of the saw, as shown in Fig. 4, and measures about $\frac{3}{4}$ in. broad and about $\frac{3}{8}$ in. thick. A saw cut is made along one edge for a depth of about $\frac{1}{4}$ in. and when the saw is not in use the strip is laid over the teeth of the saw and secured in place with a piece of tape. Before putting the saw away, the blade should be wiped over with a greasy rag. *See Joint; Mortise; Pergola; Saw.*

TENTS FOR HOLIDAY MAKERS

Their Construction and Erection by the Handy Amateur

An article on this subject will be very useful to holiday makers and others who live for a time out of doors, or who for one reason or other may wish to sleep in the open.

See also Bathing Tent; Holiday; Motoring; Sleep.

The main points of utility in tents are the ease with which they can be erected and dismantled, the comparatively light weight of their component parts, and the facility with which they may be packed and transported from one place to another.

Tent trailers, for towing behind a motor car, are dealt with in the article on Motoring.

Tent. Fig. 1. Simple form of bivouac shelter made with sticks and canvas.

A simple form of bivouac shelter is shown in Fig. 1. It is constructed by first marking out the intended floor space, and then thrusting a long stick into the ground at each corner. These sticks are lashed together at their upper ends, in pairs, then the ends of the ridge pole, which supports the canvas, are placed in the forks as shown. After the canvas sheet has been placed in position its lower sides are secured to the ground by means of wooden pegs or heavy stones. The open triangular ends may be covered with separate sheets, or canvas flaps, as indicated by the dotted lines in the diagram, could be made and sewn in position.

Although it is simply designed all the features which a good canvas shelter should possess are embodied in the example illustrated in Fig. 2.

It will house six adults comfortably, with plenty of room for furniture and stores. The canvas is supported by galvanized wrought iron tubes. The covering fabric is light Willesden canvas, which may be obtained in short or long lengths, the widths stocked ranging from 2 ft. to 8 ft. Sailcloth may be used, but it is not readily procured in greater widths than 2 ft. The following is a list of the materials required for this tent.

	Long,	ft.	in.	Diameter.	in.
2 G.W.I. tubes (H)		10	5		1
2 G.I. T-pieces (J)		0	3		1
1 G.W.I. tube (L)		12	2½		1
8 G.W.I. tubes (P)		6	0		½
8 G.W.I. tubes (Q)		0	6		½
12 G.W.I. tubes (S)		1	3		¾
Galvanized iron wire		4	0		¼
Soft iron wire		0	9		⅛
42 brass eyelets and washers					⅜
8 ditto					½
1 iron pipe		3	0		1
1 iron rod		2	0		½

1 length of hardwood, 8 ft. long by 1 in. broad and ⅜ in. thick.

100 ft. of light Willesden canvas, 5 ft. wide.

2 or 3 skeins of white sewing twine.
 2 or 3 medium sized sacking needles.
 1 sewing palm.
 54 yards of $\frac{3}{8}$ in. hemp rope.

When purchasing the two tubes H, it is advisable, if the necessary appliances are not available at home, to get a thread cut on one end of each tube and the T-pieces fitted. The tube L should also have both ends threaded to screw into the T-pieces. The bores of each T-piece should be screwed. The arrangement of the tubes is shown in Fig. 3, their sizes and preparation being detailed in Fig. 4. If the two gable tubes (H) have not been bought ready threaded, a thread must be cut on one end of each of them, for about $1\frac{1}{2}$ in., and a T-piece, J, fitted as in A, Fig. 4.

Fig. 4. Details of framework. Fig. 5. Toggle for stretching ropes. Fig. 6. Arrangement of canvas. Fig. 7. Simple stitch for sewing canvas. Fig. 8. Three sheets of canvas for roof. Fig. 9. Shapes of margins on the roof sheets and gable sheets.

The Metal Framework. A hole of $\frac{1}{4}$ in. diameter is drilled through the diameter of each T-piece, from a point marked off $\frac{3}{4}$ in. from one end of the T portion. Two 10 in. lengths are cut from the $\frac{1}{4}$ in. wire, then each is bent to the size and shape of the shackle K, detailed in diagram B. The upper angles of the shackles are inserted into the holes in the T's and bent over, as shown in diagram C.

Sectional diagram D shows how the angles may be quickly bent by hammering a short length of iron pipe down the bore of each T. The rims of the upper ends of the tubes P should be neatly rounded with a file, then a hole of $\frac{1}{8}$ in. diameter is drilled through the diameter of each tube, from a point marked off 1 in. from the upper end. Each hole should be slightly countersunk with a $\frac{1}{4}$ in. drill. A tube Q is fitted into the upper end of each tube P and driven down for 3 in.; a hole of $\frac{1}{8}$ in. diameter is drilled through the diameter of each of these tubes Q, from the holes drilled through the tubes P.

Eight 1 in. lengths are cut from the $\frac{1}{8}$ in. diameter soft iron wire, then a length is fitted into each alinement of holes, as shown in sectional diagram E. The ends of the wires are riveted over into the counter-sinking of the holes in the tubes P, by rapid and not too heavy taps from a ball peine hammer. This securing of the small tubes by rivets is necessary, as otherwise they are apt to work loose and be lost or be accidentally driven down entirely into the bores of the tubes into which they are fitted. To mark the depth to which the tubes H and P are thrust into the ground, a black line should be painted round each tube at a point 18 in. from the lower end.

The tubes S are prepared by first drilling a hole of $\frac{1}{4}$ in. diameter through the diameter of each tube, from a point marked off $1\frac{1}{2}$ in. from the upper end; then twelve 2 in. lengths are cut from the $\frac{1}{4}$ in. diameter wire and a length fitted into each hole, as shown in the diagram. These wires are prevented from working loose by slightly expanding their centre diameter, as follows: A $\frac{1}{2}$ in. diameter iron rod, about 2 ft. long is inserted into the lower end of the tube and pushed up until it reaches the wire; a centre punch is held on the centre diameter of the wire, and given several sharp blows with a hammer. During the hammering, the lower end of the rod should rest on a block of wood placed on the ground.

Sixteen toggles, T, Fig. 5, each 6 in. long, are cut from the length of hardwood, then two holes of $\frac{3}{8}$ in. diameter are bored through the thickness of each piece, from points marked off $1\frac{1}{4}$ in. from each end. After the holes are made, both ends of each toggle should be neatly rounded as shown in the diagram.

The Canvas. The arrangement of the canvas of the tent is shown in Fig. 6, the roof sheet, A, being raised to allow the gable sheet, B, and the side sheet, D, to be clearly seen. As an ordinary thimble is useless for the purpose of forcing the needle through thick folds of canvas, the form of thimble used by sail-makers and saddlers, and known as a palm, must be procured. It can be purchased at a saddler's shop. The palm consists of an indented metal disk fastened to a leather circle, the latter being buckled round the right hand by an attached strap. The leather circle, with the disk outward, rests on the palm of the hand.

In sewing, the point of the needle is inserted into the canvas by the fingers of the right hand, the eye of the needle being received into any one of the indentations in the disk. By pressing up the disk, the needle is easily forced, up to its eye, into the thickest folds of canvas, after which it is pulled through by the right hand and the twine drawn taut so as to form a firm stitch.

A simple stitch, which will serve for all the sewing required, is shown in Fig. 7. In this diagram the stitches are shown loose, for clearness of illustration, but in practice each stitch must be drawn taut, as it is made, or the seams will not be held firmly together and the sewing will appear unsightly. A firm knot should be made on the long end of the twine before commencing to sew, and better progress will be made if a length of about 1 yd. is used at a time and renewed as required, instead of

one very long length, which will take extra time to draw through the seam after each stitch, and is apt to become tangled during the work, thus involving much delay.

The roof sheet A is composed of 3 separate lengths of canvas, each 14 ft. 2 in. long. The centre sheet is 4 ft. 8½ in. wide, the right and left sheets being both 4 ft. 9¼ in. in width. A 1½ in. margin is marked on the right and left sides of the centre sheet, then a 3 in. margin is marked off on both ends. A 3 in. margin is marked on the right side and on both ends of the right sheet, and a 1½ in. margin is marked on the left side.

A 3 in. margin is marked on the left side and on both ends of the left sheet, then a 1½ in. margin is marked on the right side. A space of 4 in. from the 3 in. margin line is now marked off at both ends of each sheet. A space of 3¾ in. is next marked off from the 3 in. margin on the right side of the right sheet, then a similar space is marked off from the 3 in. margin on the left side of the left sheet. The 3 sheets are shown in Fig. 8, their margins being marked M.

The next step is to cut the ends of the margins to the shapes shown in the diagrams. The measurements from which the cuts A, B, and C are marked out are detailed at A, B, and C, Fig. 9.

After all the cuts have been made, the 3 in. margins are folded double, turned inward, and then sewn to the canvas as shown in Fig. 10. The 3 sheets are joined together by first overlapping the 1½ in. margins on the centre sheet with the 1½ in. margins on the right and left sheets, and then sewing each pair of overlapped margins together, as shown in Fig. 11. When the roof sheet is complete, its dimensions should be 13 ft. 8 in. by 13 ft.

The gable canvases B and C, Fig. 12, are each composed of two sheets of the same size and shape, one being detailed in Fig. 13. To avoid waste, the 4 sheets may be cut from a length of canvas 29 ft. 6 in. long by 5 ft. wide, the sheets being marked out as shown in Fig. 14. After the 4 sheets have been cut to size, a 3 in. margin is marked off on the upper side, lower side, and diagonal side of each sheet.

A 1½ in. margin is next marked on the right and left sides of each sheet, then the ends of the rectangular margins are cut as detailed in Fig. 9, the corners of the diagonal margins being slit and cut as shown in the diagram. The 3 in. upper and lower margins are now folded double, turned inward, and then sewn to the sheets in the same manner as the 3 in. margins on the roof sheet. In shaping the left corners of the 3 in. upper and lower margins on the right half of each gable sheet, the cuts must be reversed, as shown in diagram C, Fig. 9. It is important to place the sheets on a flat surface for accurate marking off, and care should be taken to mark out and shape these cuts correctly. They must be folded and sewn as neatly as possible, so as to lie flat when both sheets are united. The sheets are next joined in pairs, by overlapping the 1½ in. margin on the long side of each right sheet with the 1½ in. margin on the long side of each left sheet, and then sewing both overlapped margins together, as shown at A, Fig. 15. After the upper and lower margins have been folded and sewn, the height of each gable sheet should be 8 ft. 8 in., and the breadth, between the 1½ in. margins on the right and left sides, 9 ft. 4½ in.

The side sheet D, Fig. 16, is made from a length of canvas 12 ft. 10½ in. long by 5 ft. wide; a 3 in. margin is marked off on all 4 sides, then the ends of the margins are cut as shown. The lower margin is folded double, turned inward, and sewn. The margin on the right side is overlapped with the 1½ in. margin on the left side of the right gable sheet, then both margins are sewn together, as at B, Fig. 15.

The margin on the left side is next overlapped with the 1½ in. margin on the left side of the left gable sheet, then both margins are sewn together. After the side sheet has been attached to the gable sheets, its length should be 12 ft. 4½ in. by 4 ft. 6 in. wide, the latter size being measured from the lower edge of the sheet to the inner line of the upper margin.

The two side sheets, E and F, are the same size and shape, and are both detailed in Fig. 17. Each sheet is cut from a length of canvas 5 ft. 6 in. long by 5 ft. wide. A 3 in. margin is marked on the 4 sides of each sheet, then the ends of the margins are cut as shown. The left margin and the lower margin of the right sheet, E, are folded double, turned inward, and sewn, then the right margin is overlapped with the 1½ in. margin on the right side of the right gable sheet, both margins being sewn together as shown in detail at C, Fig. 15.

The right margin and the lower margin of the left sheet, F, are next folded and sewn in the same way, then the left margin is overlapped with the 1½ in. margin on the right side of the left gable sheet, both of these margins being securely sewn together, as described. When attached to the gable sheets, the length of each side sheet should be 5 ft. by 4 ft. 6 in. wide, the latter size being measured from the lower edge to the inner line of the upper margin on each of the sheets.

The door-flap G, Fig. 18, is formed from a sheet of canvas 5 ft. long by 3 ft. 6 in. wide. A 3 in. margin is marked off on all 4 sides, then the ends of the margins are cut as shown. The right, left, and lower margins are folded double, turned inward, and sewn to the sheet. After the 3 margins have been sewn, the dimensions of the flap should be 4 ft. 6 in. long by 3 ft. wide; the length being measured from the lower edge of the sheet to the inner line of the upper margin of it.

Ten holes, each about ⅛ in. in diameter and 6 in. apart, are now made, in a row, in the centre of the right and left margins on the door-flap. A ⅜ in. eyelet is inserted into each hole, from the outer side of the flap, and a washer fitted. The stems of the eyelets are expanded with cone punches and finally riveted over on to the washers by light taps from a ball peine hammer.

Each stem must be expanded gradually, first with a ½ in. cone punch, which should be lightly hammered to avoid crushing the stem, then a larger cone punch is used and the stem expanded to its full extent, after which it is riveted over on to the washer. It is often advisable to use three or even four sizes of cone punches in order to expand the metal without fracture. The margin and eyelets to be riveted should rest on a block of wood during the process. An eyelet and washer, and a sectional diagram illustrating how they are fitted, are shown at A and B respectively, in Fig. 19. A special punch set can be procured for this purpose.

After the practice acquired in fitting 2 or 3 eyelets, rapid progress will be made with the remainder. Eleven ⅜ in. eyelets are riveted in the right side sheet, E, as follows: A space of 3 in. in from the left side is first marked off, then a parallel line is drawn through the point, across the width of the sheet. The points at which the eyelets are to be inserted are marked off on the parallel line, from the measurements given in Fig. 17, then holes are cut and the eyelets fitted and secured in place as previously described. Eleven ⅜ in. eyelets are fitted in the left side sheet, F, a parallel line 3 in. from the right side being drawn and the positions of the holes marked on it, their spacing being the same as those in sheet E.

The next step is to place the right side of the door-flap so that it overlaps the left side of the right side sheet for 3¾ in., then the upper margin of the flap and the upper margin of the sheet are sewn together where they overlap. The left side of the flap is placed on the right side of the left side sheet and overlapped for 3¾ in., then the upper margin of the flap is sewn to the upper margin of the sheet, as before. After the door flap has been sewn in position, the width of the door opening should be 2 ft. 4½ in., which space, added to the 5 ft. length of each of the side sheets E and F, makes the total length of the front of the tent 12 ft. 4½ in.

The diagonal margins on the right gable sheet, B, are folded double, turned inward, and then sewn to the under side of the right side of the roof sheet, as shown in diagram D, Fig. 15, the inner line of each margin being sewn to the line previously marked off 3¾ in. from the right side of the roof sheet. The upper margin of the side sheet, D, is folded double, turned inward, and sewn to the under side of the roof sheet, as shown in diagram E, Fig. 15, the inner line of the margin being sewn to the line marked off 4 in. from the upper side of the roof sheet.

The upper margins of the side sheets E and F, and the door flap G, are folded double, turned inward, and sewn to the underside of the roof sheet, the inner lines of the margins being sewn to the line marked off 4 in. from the lower side of the roof sheet. A $\frac{1}{2}$ in. eyelet is now riveted in the upper and lower sides of the roof sheet at each of the points shown in Fig. 20. The diagonal margins on the left gable sheet C are folded double, turned inward, and sewn to the underside of the roof sheet, in the same manner as the margins of the right gable sheet.

The sewing having been completed, the erection of the tent may now be proceeded with. The ground plan of the tent is first marked out on the site, and a hole 18 in. deep is made at each of the points detailed in Fig. 21. The holes are formed by driving the 3 ft. long by 1 in. diameter iron pipe into the ground by means of a heavy hammer or maul. (The arrangement of the framework members is shown in Fig. 3.) The ridge tube L is now screwed into the T's on the gable tubes H, then the canvas is folded and stretched flat on the ground, as shown in Fig. 22.

The 3 tubes are next placed inside the canvas, then the lower end of each gable tube is laid at the hole prepared for it in the ground. Two 14 ft. lengths of $\frac{3}{8}$ in. hemp rope are attached to the shackle in each T, then the gable tubes are raised, simultaneously, by two men and erected in the holes. After the gable tubes have been brought perpendicular, the roof sheet is adjusted centrally on the ridge tube, then the side sheets are raised and the tube P fixed in position in the holes prepared for them. The eyelets in the roof sheet are placed on the small projecting tubes in the upper ends of the tubes P, then the side sheets are lowered.

Tent. Fig. 10. Method of sewing margins to canvas. Fig. 11. Each pair of overlapped margins sewn together. Fig. 12. Shape of gable sheets. Fig. 13. Detail of one gable sheet. Fig. 14. Economical method of marking out gable sheets. Fig. 15. Various methods of connecting overlapped margins. See text for lettering.

Position of eyelet holes in sides of roof sheet. Fig. 21. Method of marking out ground plan. Fig. 22. Folding canvas and stretching it flat before erecting. Fig. 23. Method of attaching toggle to rope. Fig. 24. How to lace door flap.

Process of Erecting the Tent

The 12 tubes, S, are now driven into the ground at the points shown in Fig. 3. Each tube should be about 4 ft. 6 in. from the tent, and driven in a sloping direction into the ground. Twelve 8 ft. lengths are cut from the $\frac{3}{8}$ in. hemp rope, to form the guys, V, then a toggle is fitted to each length, as shown in Fig. 23. A firm knot is made on one end of each rope, then a small loop is formed on the other. These loops are placed on the small tubes where they project through the eyelets in the roof sheet. The toggles are adjusted, and the large loops of the ropes placed over the ground tubes, S. A toggle is fitted to each of the ropes previously attached to the shackles in the T's on the gable tubes. The ends of the ropes are knotted, and the toggles adjusted to form the ropes into loops, which are placed on their respective ground tubes, as shown in Fig. 2.

The next step is to tighten up all the guy ropes until the canvas is stretched taut. Two 5 ft. lengths are cut from the $\frac{3}{8}$ in. rope, then one end of a length is inserted into the upper eyelet in the side sheet E, and secured with a knot. One end of the other length is secured in the upper eyelet in the side sheet F. These ropes serve to lace up the door flap when required, both ropes being rove through the eyelets as shown in Fig. 24. After finishing the lacing, the lower end of each rope is secured by a knot made inside the tent, which is now complete.

To dismantle the tent is an easy matter. The guy ropes are first loosened and removed from the ground tubes. The side sheets are then raised and the tubes indicated at P in Fig. 3 are pulled up. Two men next withdraw the gable tubes and lower them to the ground, where they are removed from the canvas and the ridge tube unscrewed.

When choosing a site on which to erect the tent, a place where the ground is level, dry, and sheltered should be selected, and if there are any obstructions, such as stones, roots, etc., they should be removed before marking out the ground plan. After erecting the tent, a shallow runnel must be dug in the ground, at the gables and sides, and connected to drain away rainwater.

During wet weather the guy ropes should be kept slack, as rain causes both them and the canvas to shrink. This precaution should not be neglected, as the shrinkage of the tight guy ropes may strain the roof sheet so greatly that it may cause it to split or tear apart at the seams.

Legal Points. In some districts there are by-laws relating to holiday makers and others who live in camps or caravans. Licences may be obtained from local authorities for the use of land for camping. Persons who do not hold a licence may not allow land to be used for camping for more than a fixed number of days yearly. *See Trespass.*

TEREBENE. Obtained by distilling a mixture of oil of turpentine and sulphuric acid, terebene is a colourless fluid with an aromatic odour. It is a powerful antiseptic, disinfectant, and deodoriser. Terebene has been used with much success in the treatment of chronic bronchitis. It may be given internally, as an ingredient of cough mixture, or as an inhalation. It is also a good intestinal disinfectant.

TERRACE: In Gardens. A paved, bricked or tiled terrace at the back of the house is a practical and ornamental feature. Where there is no loggia veranda or summer house such a terrace provides the basis for a garden room, easily made with the help of an awning carried down at the sides to form a screen against cold winds. Garden furniture which can be easily moved adds to the attractiveness of the scheme.

Where there are somewhat larger grounds a paved or brick terrace makes a delightful transition between house and garden and affords scope for some formal gardening items, such as plants in tubs or vases, an ornamental seat and a lavender hedge. A charming paved and stepped terrace of this type is here illustrated with low brick walls, topiary trees and encroaching clumps of flowers.

The banks and slopes in a garden of suitable extent may be arranged to form terraces of grass, with beds of cultivated plants and bulbs. The incline should not exceed 45°, otherwise the making of beds, stepping, and trimming of grass will be a difficult matter, whilst water will quickly run away, to the detriment of plant roots.

Soil preparation, levelling, and turfing should be completed and left to settle down before planting begins. The surface should be a good even depth of sound loam, otherwise there is the risk of hot weather cracking shallow soil, and grass perishing in consequence. Turves should be cut in thick squares, kept flat, and laid from the bottom to the top of the terrace, keeping in place with pegs if

necessary. After making them firm with a turf-beater, fill up the spaces with dry powdered clay, and brush the whole with a very stiff brush or besom.

Shrubs, roses, geraniums, fuchsias, bulbs, and similar plants are all effective on a formal terrace slope; or an alpine bank may be constructed. In shady, gardens a sloping terrace of hardy native ferns and plants in tubs is attractive. *See* Awning; Brick; Crazy Paving; Italian Garden; Lawn; Rock Garden; Steps.

Terrace. Paved and stepped terrace with its gay flower beds and topiary trees, which forms a charming transition between house and lawn. (Humphrey & Vera Joel)

TERRA COTTA. This term, which means baked earth, is applied to a class of pottery made of selected coloured clays, which produce buff, yellow, and red tints. The red is due to the presence of iron. The surface may be left unglazed, or covered with transparent and coloured glazes. The unglazed ware is porous, and includes butter coolers, bottles used for keeping water cool by evaporation as well as pots for the purpose of admitting air to the roots of plants.

Terra Cotta. Fig. 1. Persian jar in glazed terra cotta, with fantastic paintings in black. It probably dates from some time in the 2nd millennium B.C.

Right. Terra Cotta. Fig. 2. Statue group designed for a fountain jet by Antonio Rossellino, 1427-1479.

Because of its cleanliness and brightness it is in demand in the form of bricks and tiles for the paving of garden paths, verandahs, halls, and kitchens. Terra cotta jars, ornaments and vases of good design are used effectively in the formal garden. The Doulton works are responsible for good development in modern glazed terra cotta tiles.

An idea of the beauty and antiquity of this clay fabric and its durable quality is gained by a survey of existing specimens in a museum. The example of ancient terra cotta illustrated in Fig. 1 probably dates from some period during the 2nd millennium B.C. The primitive design of the painted and glazed decoration has no connexion with Persian art of subsequent eras, but is quite unimpaired. Excavations of beautiful terra cotta figurines at Tanagra have thrown light on ancient Greek costumes.

Later, beautiful statue groups were executed in Italy by noted sculptors, and an example dating from 15th century is here illustrated. During the Renaissance the vitrified terra cotta enamelled in colours was introduced.

The older English potters employed terra cotta freely for roof-ridges and finials, as well as for chimney-stacks, of which there are some fine Tudor examples. From the Low Countries came later that form of terra cotta with a tin-enamelled glaze which, under the name of Delft ware, gave the first impetus to modern decorated earthenware in Great Britain. Since then British potters have been so fully occupied in perfecting white-bodied ware of all descriptions that they have done little with portable terra cotta beyond making reproductions of Tanagra figurines and other ancient statuettes. With the exception of Della Robbia reproductions, large modern pieces of glazed and coloured terra cotta are for the most part unpleasing and crude in design and colouring. *See* Delft; Faience; Majolica; Tiles.

TERRIER. Amongst the divisions into which dogs are grouped by the Kennel Club, the most numerous is the terrier family. Generally speaking, all these have characteristics in common, such as loyalty to their owners, an irrepressible vivacity, alertness, and fearlessness. Their keep costs little, and they take up no room indoors, being equally at home within the house or outside. In the country they are ready for every sport.

As regards the various companionable qualities, there is little to choose between them, but for protection or as a trusty guard either an Airedale or bull terrier is to be recommended on account of its size, preferably the former. The bull terrier is somewhat headstrong unless carefully trained, and he is scarcely so amenable to discipline as the other. The Kerry blue (q.v.), though lighter, is perhaps too ready for fighting to be a desirable companion for ordinary people. The red Irish terrier is also a reliable protector.

Fox terriers still stand foremost in popular esteem though the Sealyham has made great headway: he is a dog for the country. The Welsh terrier, somewhat homely in looks is an excellent companion, besides being cheap. Any of the Scottish varieties can be recommended. The Cairn suits those who want a very small dog that is not a toy. Dandies are lovable little creatures with hearts of lions. *See* Aberdeen; Cairn; Dog; Fox Terrier; Irish; Kennel; Sealyham; Yorkshire, etc.

TERRINE. The original form of tureen is terrine. A French dish is so called from terrine, which means an earthenware pan. This dish was composed of quails, chickens, pigeons and mutton, the meat being cut into portions and the whole baked in earthenware in the oven. Terrine is the name usually applied to the small earthen pot employed for potting foie gras and other savoury potted meats. *See* Tureen.

TERRY. Turkey towelling is the kind of terry cloth that is most commonly used in the home. Bath robes or dressing gowns can be made at home from this material, which can be bought in plain bright colours and also with coloured patterns. In making bath mats for floors a thick quality should be used, otherwise the mat will not easily remain flat. Terry cloth is also useful for bathroom curtains and for nursery cushion covers.

TESTER: Of a Bedstead. The tester originally described the flat covering of material that was stretched on a frame above one of the bedsteads used in olden times. Soon it was used for the wooden canopy that was fitted on to many bedsteads, and for this reason these are known as tester beds. Tester beds were popular in England during Tudor times. In many the tester is beautifully carved as are the bulbous turned posts that support it. In most of these bedsteads there are four posts, but in a few the head end is filled in with panelling as far as the underside of the tester: consequently two only are required, these being at the foot end. Sometimes a hiding place was made in the tester. *See* Bedstead; Tudor Style.

Tetanus. See Lockjaw.

TETANY. In the condition known as tetany spasmodic contractions of the muscles, mostly of the hands and feet, occur from time to time. In children it is associated with rickets, and in adults with disturbance of the digestion. It is treated by giving large doses of calcium chloride and by attention to the general health.

TETRATHECA. This is the name given to a greenhouse evergreen flowering shrub with red or pink flowers during the summer months. It thrives in the usual potting mixture in well drained pots in a sunny position in the greenhouse. Propagation is by cuttings. The necessary temperature averages 50°, and plenty of water is necessary at all times.

Tetradlea. Small pink blossoms of this evergreen indoor shrub, which makes an attractive pot plant.

TEUCRIUM. The small family of plants known as teucrium consists chiefly of hardy perennials with fragrant sage-like leaves. They are suitable chiefly for the rock or wall garden and are increased by division. *T. Chamaedrys* has shining leaves and purplish flowers in summer; *T. Marum* is the cat thyme.

THALIA. This plant may be described as an aquatic perennial, of which only one kind, *T. dealbata*, is grown. It is a handsome purple-flowered plant for the margins of brooks and ponds where the position is warm and sheltered. It is hardy if roots are placed deep enough to avoid frost.

THALICTRUM. This is the name of a group of attractive hardy flowering plants with deeply cut, almost fern-like leaves, and popularly called meadow rue. They flourish in ordinary well-drained soil and are increased by division in spring. Those most suitable for the flower border are *aquilegifolium*, 3 ft., purple; *flavum*, 3 ft. yellow, and *diptero-carpum*, 4-5 ft., rosy lavender. *Minus*, which grows only 12 in. high, has yellow flowers; its variety, *adiantifolium*, is commonly called the maidenhair plant, because of the small, fern-like leaves.

THATCHING: THE PROCESS EXPLAINED

Modern Applications of an Old and Attractive Method of Roofing

The reader of this article may with advantage consult the entries that deal with the various types of building, e g. Bungalow; Cottage; House; Summer House.

For other forms of Roofing, see Roof; Slate; Tiles.

Thatch has much to recommend it as a roof covering. It is warm in winter and cool in summer, and when the thatch has settled down the risk from fire is not serious in country districts. It is not expensive as a roofing, but requires certain skill and ability to perform the thatching of a roof in a satisfactory manner. Thatch is suitable for roofing all manner of garden erections, and it is probably in this direction that the amateur may use it.

Figs. 1 to 3 show the manner in which the present-day house is thatched. The thatcher's tools consist chiefly of the bill hook and a somewhat similar but flatter knife, known as an eaves knife,

about 18 in. long. This or a pair of stout sheep shears are used for trimming the eaves. One or two hand rakes with iron teeth are needed, as well as ladders long enough to reach to the ridge of the roof of the building.

Other necessary articles are a supply of pegs, binding cord made of three-strand hempen cord, sometimes known as marling, a wooden mallet, and some stout cord with a running noose to carry the thatching materials from the ground to the roof.

Thatching. Picturesque example of a modern thatched roof on a little country inn.

Preparing the Straw.

Thatching customs vary in most counties. In Norfolk the spear grass found in the fens is largely employed and is the strongest and best thatching material. In Somerset and

Dorset straw is extensively used, and so on with other districts. To begin with the material is made into bundles known as boltings or covings when the material is straw, as threeeves when prepared from heather, and as fathoms when of reeds. These are delivered to the site, when the roof has been prepared for them, and are unloaded and stacked.

Thatching. Fig. 1. Roof prepared by nailing wooden runners to the joists. Fig. 2. Thatching begun by sewing the straw with twine to the runners. Fig. 3. Laying a plaited ridge roll, one way of finishing off the apex of the roof. (Courtesy of Boulton & Paul. Ltd.)

The preparation of the straw is important. Straw of a dry, loose character cannot be packed as tightly and securely as damp straw; for this reason the straw should be well doused with water and turned over with a fork until it becomes thoroughly moistened. The heap must then be slightly compressed by beating with the fork or by treading. The straw should next be drawn from the bottom of the heap where the pressure is greatest.

The usual method is to grasp as much straw as can be gripped by both hands held close together. The straw is then drawn out by a quick movement of the arms towards the right, followed by a swing over to the left, finally laying the bunch of straw at the worker's feet with the thicker end to his right hand. This work of yealming, as it is called, is usually undertaken by the thatcher's assistant.

Fig. 4. Thatched roof nearing completion. Note the ornamental finish of the ridge stack, and how the thatch overhangs the gable ends of the roof. (Courtesy of Boulton & Paul, Ltd.)

When a sufficient quantity of this partially straight straw has been collected the worker goes through it, using his fingers to regulate it and to remove any loose portions, at the same time drawing the bundle to his feet until the layer amounts to as much as he can hold in the grip of both hands. Great care should be exercised to exclude all short ends and pieces of straw, so that, when properly prepared, the yealm will be perfectly straight.

The yealm of straw must then be gathered in the hands and a small quantity pulled out at one end, turned down and wound round the top of the yealm, forming what is known as a staple. The projection thus formed at the head of this staple prevents it from being withdrawn after it has once been inserted in the turves as described below. A yealm thus formed should never be broken, but kept firm and secure until it is placed in position. As the yealms are completed, they are placed crosswise on a short rope or cord, the thick and the thin ends alternating. When sufficient in number and weight for a man to carry, the rope, which should have a running noose, is drawn round the yealms, which are in this way pulled on to the roof.

Two Methods of Thatching. There are two ways of using straw. One is to lay a covering of fibrous turf over the roof and to push the straw through the turves, while the other is to sew the straw directly to the roof. To prepare the roof for thatching by the first method, the rafters must be fixed on to the roof in the usual manner, wooden battens being nailed on at about 6 in. apart. These battens should be about 3 in. broad. The turves are placed upon the roof, working from the bottom and proceeding in an upward direction as with slates. When cutting the turves a thick curved cutting-iron must be used, so as to obtain turves thick in the centre but gradually tapering off towards the sides. Then, when laid on the roof, the overlapping edges will make the turf covering level and the roof will be of one thickness throughout.

For laying the staples of straw a thatching iron will be necessary. This implement is slightly forked at the apex in order to catch the twisted head of the staple. In this manner the latter is pushed through the turf, and is prevented from coming out again by the head of wound straw. The work of laying the staples must be commenced at the eaves, and should proceed upward until the ridge is reached; at this point a layer of turves is placed over the straw in order to form a bolster, or well-defined ridge, and the thatching is then complete. An alternative method of finishing off the ridge is to fix in place a tightly plaited straw roll, as shown in Fig. 3.

When preparing the roof for the second method of thatching, namely, sewing the straw directly to the roof, the rafters are laid, the wooden battens nailed on, and the straw prepared in the same way. The straw is then sewn directly to the battens, commencing at the bottom and working upward to

the ridge. Sewing twine is used for this purpose, and the work will be found quite a simple operation after a little practice has been obtained. In order to finish off the ridge turves may be requisitioned, as in the former method. As an alternative, two pieces of wood may be utilized, the boards being cut to the same length as the roof and fixed so as to overlap the thatch for some distance on each side. This method of thatching is, perhaps, more extensively practised than the one above described, as it is often impossible to obtain firm, fibrous turf. Thatch should overhang the walls to a considerable extent, to allow the drippings to fall clear. Dormer windows, valleys, and hips are all covered in the general run of the work. Separate gutters are unnecessary, and the cost of a broken roof is thus less than when covered with tiles, which have to be carefully fitted.

Heather and Reeds. In certain districts heather is used extensively in the thatching of dwelling houses, and particularly rustic summer houses and similar buildings. This material is not always procurable in abundant quantities, but in the north and central counties of Scotland it forms the staple medium for thatching purposes. When carefully cut, heather will require but little preparation beyond straightening out. The roof is prepared as in the case of straw thatching by the second method, and the heather sewn fairly tightly and closely together. This makes an excellent and very durable roof.

Reeds, where they are procurable, are also a valuable material for thatching purposes. They are used in a similar manner to straw, being either sewn direct to the roof or inserted through turves. Broom is used in other districts in a similar manner to heather.

On the roof of a dwelling-house, ten bundles, or 5 cwt., of straw will be required to each square of thatch. A square is 100 sq. ft. When thatching is carried out in a thoroughly expert and experienced manner, the roof should remain quite watertight for about 30 years, if composed of the finest quality wheat straw, or for 40 years if reeds are employed. If the work is done indifferently it may not last for more than 10 years. Much of this information is taken from Leaflet No. 119, issued by the Ministry of Agriculture.

THEATRE: HOW TO MAKE A MODEL

Main Principles and Practical Hints for Toy Theatre Construction

This article contains, in outline, the necessary information and materials for simple, inexpensive toy theatre construction, to which the model-maker must apply his own skill and originality.

A model theatre can be of value to both the model-maker and to those interested in amateur theatricals (q.v.). It shows, on a small scale, how the stage can be set for a full-sized production, and may therefore be found useful by amateur dramatic societies. The only technical skill needed is proficiency in drawing and water-colouring.

Materials. The essentials are: cardboard of suitably varied thicknesses; stout cartridge paper for the thinner components, such as borders and rows; some good glue and paste; a few watercolours and brushes to paint the scenery and proscenium; a knife, a straightedge and a few gouges or chisels. Cardboard is supremely important: if badly selected, it often leads to a strained temper and the loss of many hours of work. For general purposes, cardboard of 1/32 in. thickness, surfaced on both sides, is advisable. It is easily obtained at stationers' stores, but it is as well to have a small supply of various surfaced boards: e.g., a rough wall calls for a rough cardboard, as in a Dungeon Scene, and a wing of foliage demands thinner board or cartridge paper, which is easier for intricate cutting. Knives are preferable to scissors.

Fig. 1. The back of the stage. Keep this diagram by you for reference when assembling. Below, Fig. 2. a Garden Scene backcloth. (From, V. Hembrow's "The Model Theatre.")

Fig. 3 (left). How to make various connecting components of the stage framework.

Stages of Work. (1) Draw out the scenery, stage components, connecting supports, rails, etc., or detach the ready-made diagrams from the booklet mentioned on next page.

(2) Paste all the pieces on to appropriate cards, and put the whole pile under pressure until thoroughly dry.

(3) Finish all colouring before cutting.

(4) When colour is quite dry, cut out pieces.

(5) Build up on the stage plan (i.e. the bird's eye view of Fig. 1), which consists of the stage frame with proscenium (Fig. 3).

(6) Fit first scene (backcloth, Fig. 2, and the additional wings) into the framework, and afterwards try out other scenes you have prepared.

(7) Arrange lighting.

General Hints. Ordinary home-made flour-and-water paste (q.v.) is cheapest and most consistent. Gummed paper as sold in rolls (that $\frac{3}{4}$ in. in width is a handy size) is very useful, especially for

joining cardboard at corners, and is quite cheap. After pasting, press out the pieces with a clean cloth, or better still a photographic squeegee. Care should be taken to press out all air bubbles. Then put the whole pile under pressure, with plain or tissue paper between each piece to prevent oozing pieces from sticking together. A pile of heavy books or some similar weight will make an excellent press, and it is as well to leave the pieces under press for twelve hours.

All colouring can be done with tints from an ordinary water-colour box, but if a very large model is made, poster colours are preferable. Imagination must be used, but remember that lighting makes a great difference to colours. For the proscenium (Fig. 3) raw umber is suggested for the flat wash and draped curtains. This gives the effect of old gold. Tassels and fringes might be a dull red. The whole effect would be that of a neutral picture-frame for various scenes.

When treating a garden scene (a backcloth for which is seen at Fig. 2), an experiment in colour might be tried and a simple evening effect obtained by using orange for the sky, stronger at the top and gradually getting lighter towards the bottom. Some bright reds and blues would look well in the decorative vases, while for the steps and the little temple a pearly grey, viridian green and rose madder would be very effective. Any wings used for this scene should be slightly darker in colour, as they represent a much nearer distance and so co-operate with the lighting to give the desirable effect of depth. For the wings use a deeper tint of the pearly grey, and the doors and window frames might be picked out with some slight contrast, such as apple green or bright red.

Several stage floors should be made and used appropriately when cut out to fit between the supports. A flat stone-coloured floor for the interior and the dungeon, a yellow ochre tinted paper for the street, a light green for the wood scene, and perhaps a slightly different green to resemble turf for the garden. A yellow ochre strip of path might be a useful addition to the last. All these suggestions might be modified and added to, and there lies the possibility of much instructive amusement.

Fig. 4. The Proscenium. Having cut it out, grooves for the act drop to slide in should be cut out and stuck down the back of the arch parallel to, and on the inner side of, the dotted lines. Then bend at dotted lines and gum tabs to stage floor.

Cutting should be done on a level surface of three-ply wood or stout cardboard. Study Fig. 1 constantly during cutting and assembling, and have the connecting strips (prepared as required according to Fig. 4) all ready before assembling. With a knife

score down the dotted lines and all places of bending, then bend along a straight-edge. Stick together the tabs and hinge-pieces which should have been left attached to the cut-out scenery and components; glue should be used for securing hinges. Let the completed frame-work dry before setting a scene.

Lighting. In a scale model all that one can hope to achieve is a rough general lighting effect. Many rooms have electric light that can be utilized by a length of flex and a light that can be hung just over the back of the model. Movable lights are also often ingeniously used. One good method is to use shutters—strips of cardboard—that can be rested on the flyrails across the top of the miniature stage and the resultant shadows give most interesting effects from the diminution of light on parts

of the scenery. Another excellent idea is to use screens of coloured translucent paper or gelatine to alter the effect of light in various colours. A strip of white cardboard or tin placed at the base of the proscenium will form a reflector and give much the effect of footlights. Again, lighting from the back of the stage through the cut openings could be tried, and small reflectors can be easily made. Square glass mirrors are very handy for this.

There is no cast, but ingenuity can easily endow the numerous tiny figures and animals, generally sold in toyshops and elsewhere, with suitable characters. Small reproductions of figures and animals can be pasted on card, and a hinged base fixed so that they will stand. Historical costumed figures on cards given with cigarettes make admirable little mummers. Although the figures can only be motionless as far as their limbs are concerned, yet they can be moved from place to place by fixing them to strips and working them from the flies or sides. A better method still is to fix stiff wires to them and work as with marionettes from above. If you have a curtain fixed up behind and around the little theatre the effect to the audience is amazingly good.

Framework of the Stage. For structural details, see the back of the stage (Fig. 1). Notice the accessories needed. Grooves for the act-drop or curtain must be drawn, bent and gummed to the back of the proscenium. Rails and uprights must be cut as required—at least two uprights, two flyrails and one backrail—and gummed to the floor, to the proscenium and to each other, as shown. The flyrails support the backcloths and borders. The act does not vary, and its design should give the eye something to rest and interest it between the acts, without containing elements which might be striking at first, but would irritate with repetition. Leave margins at top and sides when cutting out the drop for sliding into grooves. Gum a tab behind the top for raising and lowering. The backcloth should have a margin along the top, ending in two tabs to rest on the flyrails (see the booklet recommended below, and also Fig. 4 for the method of fixing).

The above suggestions are based on the fuller instructions, complete with cut-out diagrams to scale, in Mr. Victor Hembrow's "The Model Theatre," issued at 1s. by The Studio, Ltd., 44, Leicester Square, London.

For further details and ideas, the model theatres exhibited at the Victoria and Albert Museum, London, are well worth a visit, for they are the original models on which scenes for many famous West End plays were afterwards based. Of particular interest is the model setting made as a memento of the production of "The Beggar's Opera" at the Lyric Theatre, Hammersmith. It shows a simple method of scene-changing very suited to the model described above. The "backcloth" consists of three arches, which remain constant throughout the performance. Behind the arches are light screens or panels which can be changed in a few seconds, giving an entirely new appearance to the whole setting. By using this simple trick, the model maker will be able to effect an astonishing variety of scene-changes with the minimum of trouble.

THERAPEUTICS. This aspect of medical art is practised almost unintentionally in home nursing, either pending the doctor's arrival, or with diseases where his attention is unnecessary. The chief propositions of therapeutics are that any treatment should assist "*vis medicatrix naturae*," the healing power of nature, and should be directed to the patient and not to his disease; and that skill in treatment is more important than method.

THERM: In Gas. The therm is a unit of measurement introduced by the Gas Regulation Act of 1920. A therm is equal to 100,000 British thermal units or B.Th.U., and is the basic unit upon which charges for the supply of gas are made to the consumer by the public gas undertakings. *See Gas.*

Thermionic Valve. *See Valve; Wireless.*

THERMOMETER. This instrument is used for measuring heat. One is usually part of a weather glass, this being used to measure the heat of the atmosphere. The heat of the body is measured by a clinical thermometer.

Thermometer for the greenhouse. (Courtesy of Negretti & Zambra)

Heat on the thermometer is measured by degrees. There are two scales in ordinary use, Fahrenheit and centigrade; there is also a third method, namely Reaumur, which is not much used in Great Britain. On the Fahrenheit scale freezing point is 32° and boiling point is 212° . On the centigrade, which is the one most used in scientific circles, freezing point is 0° and boiling point is 100° . On the Réaumur scale, freezing point is 0° and boiling point is 80° .

It is quite easy to convert reading on one scale into the corresponding one for another. For instance, 55° C. is equal to 131° F. This is done by the following formula:

$$55 \times 180 \div 100 + 32 = 99 + 32 = 131$$

The formula for the reverse process, i.e. converting Fahrenheit into centigrade, is:

$$(131 - 32) \times 100 \div 180 = 99 \times 100 \div 180 = 55$$

Clinical Thermometer. A selfregistering instrument known as a clinical thermometer is used in medicine for measuring the temperature of the body. The tube in which the mercury rises is very much constricted just above the mercury bulb, so that when the mercury rises to a certain height in taking a temperature it remains at that height until shaken down. This is what is implied in the term self-registering.

In Great Britain clinical thermometers are graduated according to the Fahrenheit scale, but on the Continent the centigrade scale is adopted. On the former scale the thermometer registers between 95° and 110° , and each degree is subdivided into 5 parts, indicated by shorter lines than those denoting degrees. In reading off a temperature the subdivisions are read as decimal fractions; thus one subdivision is $\cdot 2$, two $\cdot 4$, and so on. The normal temperature of the body, $98\cdot 4^{\circ}$, is shown by an arrow running across the scale.

*Clinical Thermometer, and diagram showing how to read it correctly.
(S. Maw & Sons. Ltd.)*

Before proceeding to take a temperature the mercury should be brought down 1° or 2° below normal, and this is accomplished by grasping the stem firmly with the thumb and index finger and making several forcible flicking movements with the thermometer. There is also a device, here illustrated, for

lowering the mercury in the tube by making the case B, containing the instrument, revolve rapidly on the swivelled crosspiece A.

Thermometer. Device for re-setting a clinical thermometer.

The method of taking the temperature is described under the heading Temperature (q.v.). If there is occasion to use the instrument several times during the day it will be convenient to keep it in some antiseptic lotion in a glass, a piece of cotton wool being placed at the bottom of the glass to minimize the risk of breakage. See Preserving.

THERMOPSIS. These are hardy herbaceous perennials with pea-like flowers in early summer. Montana, 2 ft., yellow, and barbata, 12 in., purplish, are the best kinds. They thrive in ordinary well tilled soil and dislike being disturbed. The best method of propagation for these plants is by seeds.

THERMOS FLASK. This is the patent name of a vacuum flask for retaining liquids in a hot or cold state. The glass vessel can be replaced at a moderate cost if it gets broken, but with ordinary care this should seldom be necessary. The flask should be left uncorked when not in use, as otherwise the stopper may become musty. See Vacuum Flask.

THERMO-SYPHON: Cooling. In the great majority of cases the internal combustion engines used on motor cars are water cooled. The thermo-syphon method makes use of the natural law that a given volume of hot water weighs less than an equal volume of cold water. The water, as it becomes heated in the cylinder jackets, expands and rises, giving place to cooler water entering from below, after passing through the radiator. By suitably arranging the position of the radiator in relation to the engine, the purely automatic circulation of the water through the medium of the radiator keeps the engine at a definite temperature within limits.

Apart from radiator position, there are three points to be considered, namely the capacity of the radiator, the amount of cooling surface, and the diameter of the flow and return pipes. These should be as large as possible, not less than 1½ in. in diameter, so as to restrict the passage of the water as little as possible. A fan is usually fitted to force air through the interstices of the radiator, so that the cooling action is to this extent independent of road speed or wind.

Thermo-syphon. Diagram illustrating principle of thermo-syphon cooling of the internal combustion engine. A and B denote maximum and minimum of cooling surface.

The temperature for a water-cooled engine should be about 200° F. The water should remain somewhere about this figure during the whole time the engine is running. To obtain this result the difference of height between the bottom of the cylinder jacket and the bottom of the radiator is determined by experiment, so that the water, after passing through the radiator, will still be at a fairly high temperature when it again enters the cylinder jackets.

The higher the bottom of the cylinder jacket in relation to the bottom of the radiator, the slower will be the thermo-syphon action. If the bottom of the radiator is level with that of the cylinder jacket, the fullest advantage is taken of the system, and therefore the water, as it enters the jackets, will be at a very low temperature. The most effective arrangement is shown at A in the illustration.

If the relative positions are as shown at B, the amount of cooling surface is considerably reduced, and the water will still be at a fairly high temperature on entering the cylinder jackets.

When the front of the vehicle is lifted, as in climbing a steep hill, a varying extra amount of cooling surface is automatically provided, because for the time being the difference of level is increased. This is all to the good, because it comes at a time when in all probability the engine of the vehicle will be working at full output on the low gear. With the radiator placed behind the engine the reverse is the case, which probably accounts for the fact that for this system pump circulation is invariably employed.

Temperature Control. By the incorporation of a thermostat in the thermo-syphon system the temperature of the cooling water can be automatically regulated. The thermostat, which is pre-set to the desired degree, opens or shuts a valve which governs the flow of circulating water. An increase in flow brings about an increased cooling effect, and vice versa. Thus the temperature remains approximately uniform, irrespective of vehicle speed or weather conditions. See Motor Car ; Pump : Radiator.

THICKENING: In Cookery. A mixture of which flour is the principal ingredient is used to thicken soups and gravies, to convert stock into sauces and for binding cutlets and rissoles. It is used also to thicken milk for invalids, 1 oz. flour being used to every pint of milk. The flour is first mixed smoothly with a little cold milk and the whole then boiled for ten minutes.

The most important thickening is roux, both brown and white, which consists of equal proportions of the finest white flour and butter cooked together until the two are amalgamated.

Roux is fried or baked if brown roux is desired. It is simply stirred over the fire until the flour is incorporated with the fat for white roux. Occasionally a thickening of butter and flour which has not been previously cooked is added to the liquid. It should then be worked together on a plate with a knife.

A more simple method is to mix the flour into a thin paste with cold liquid and stir it into the gravy or sauce to be thickened. This method, however, has a tendency to impoverish the sauce, while the addition of butter softens and enriches it. Colouring must be added if a brown sauce is required.

Certain grains, such as crushed tapioca, rice, semolina or sago, can be used as thickening. The grain should be sprinkled into the liquid while boiling and takes from 10 to 15 min. to cook. Pearl barley is used to thicken broths, but must be blanched first, and given a much longer period to cook. Arrowroot and cornflour are frequently employed in thickening, first mixed with a little cold liquid, and they must be stirred in gradually.

Eggs may be used to thicken white sauces, soups and milk, also for custards and light puddings. The eggs must always be thoroughly beaten before being mixed with the liquid, and must never be allowed to reach boiling point, or they will curdle. Eggs worked with sugar make a thick basis for many kinds of cake, and when mixed with oil or butter form the groundwork of salad dressing.

Lentils and peas when cooked and made into a purée thicken vegetable soups. Haricot beans may also be used for this purpose. Oatmeal is occasionally employed as a thickening for soups, but it cannot be strained away, neither does it become absorbed. *See* Browning; Flour; Gravy; Sauce; Soup.

THIGH. The thigh bone or femur in man belongs to the class known as long bones, that is to say, it consists of a shaft and two expanded extremities. The head is received in a cup-shaped cavity on the haunch bone, known as the acetabulum, so that a ball and socket joint is formed. The average length of the bone in an adult male is about 18 in. the lower end of the femur articulates at the knee with the tibia. These are possible dangers of fracture of the thigh: It may affect the upper extremity, especially the neck, the shaft or the lower extremity. Fractures of the neck are common in old people, and owing to the brittleness of the bone through age the violence producing the break may be inconsiderable, perhaps simply from the foot slipping off the kerb. Fractures about the lower end may involve the knee joint and lead to much subsequent stiffness and lessening of movement. The patient will be found lying where he has fallen, and should not be moved till temporary splints have been applied to the part. *See* Fracture.

THIMBLE. Thimbles are made in gold, silver, plated brass, bone, celluloid, etc., and are either plain or decorated around the edge, the top and sides being covered with small indentations to prevent the needle from glancing off it. A thimble should be used that fits the finger well, as one too small will become painful by the pressure, while one too large will be continually dropping off.

THINNING: In the Garden. When applied to trees and shrubs thinning out means the removal of old and superfluous branches. The term is also applied in gardening to the removal of unwanted seedlings so that those remaining shall have proper room for development. Fruits too must be thinned to allow those left to reach full size. In thinning grapes care should be taken first to cut out all small berries and then those in the centre of the bunch. It should be noted that unless grapes are correctly thinned they will not develop. *See* Swede.

Thinning Fruit. Shaded portions show how to ensure fine specimens. (By special arrangement with Amateur Gardening)

THISTLE. The most ornamental thistle for the garden is the cotton thistle or onopordon, tall handsome plants, 6 ft. or more high with pale purplish flower heads. The chief kind is *Onopordon acanthium*, commonly called the Scotch thistle. These thistles are most suitable for the wild garden; they flourish in ordinary soil and are raised from seeds sown out of doors in spring.

THORN APPLE. This group of annuals and greenhouse shrubs belongs to the potato family. The botanical name is *Datura* (q.v.)

The common thorn apple (*Datura stramonium*) bearing large prickly fruits sometimes appears as a weed in gardens.

THORNBACK. Being a species of skate, the thornback is a salt-water fish found round the British coasts. It can be cooked in the same way as skate. *See* Bay; Skate.

THREE-COAT WORK. When plastering brick and stone walls two or three coats may be applied—the rendering or pricking-up coat, the floating coat and the setting coat. The first coat is made about $\frac{1}{2}$ in. thick and must take up any unevenness of the wall surface. It consists of “coarse stuff,” sometimes hair mortar, and must be roughened before it is dry in order to provide a key for the second coat. This is “fine stuff,” similar to the material of the first coat, but with less hair. It is applied from $\frac{1}{8}$ in. to $\frac{1}{4}$ in. thick with a float and must be absolutely plumb. When the floating coat is dry a very thin final coat of the fine stuff made into the consistency of thick cream is smoothed over the surface and left to set hard.

If two coats are considered sufficient (“two-coat work”) the first two coats employed in three-coat work, that is, the rendering and floating coats, are mixed to make one coat. *See* Plaster.

THREAD. It is an economy not only to buy the best quality of thread but to secure the right kind for the purpose in hand.

Domestic sewing cotton consists of six separate strands twisted together to the requisite tightness. No. 24 is a strong coarse thread for buttons, 40 or 50 for hand seaming. For sewing machines thread of 60 or 80 is suitable.

Linen thread is stronger but more uneven than cotton and especially useful for boot-buttons, carpet-sewing, rug-backing, and similar uses. Silk sewing thread is used throughout by the best tailors; for buttonholes which have to take much wear silk buttonhole twist is indispensable. Mercerized cotton can be used for buttonholing but does not give the same satisfaction.

Threads are specially made for crochet, embroidery, knitting, and other forms of fancy work, and experience has taught the manufacturers which numbers are best for particular purposes, and their advice is always valuable, as threads are prepared with a view to the needles or hooks with which they are to be employed, and with an eye to appearance. Artificial silk threads are largely used for embroidery as well as for knitting, and they may give trouble unless suitable needles are used. *See* Crochet; Embroidery; Knitting; Sewing Machine.

Threadworm. *See* Worms.

Three-ply Wood. *See* Plywood.

THREE-SPEED GEAR: For Cycles. Variable speed gearing is used on pedal cycles. The mode of operation is through the medium of ratchet teeth and pawls (Sturmey-Archer. Cyclo, etc.).

Fig. 1 shows in part section a three-speed coaster hub for pedal cycles. Although termed a three-speed gear, actually only two geared speeds are employed, namely, a low speed and a geared-up speed. The middle speed is called normal, meaning direct drive, i.e. the chain ring drives direct to the hub shell by means of ratchet teeth and pawls. Fig. 1 is a detailed drawing in part section of the complete hub. The outer shell that carries the wheel and tire is driven on all three speeds by ratchet teeth and pawls, so that it is possible to coast or free-wheel with any of the speeds.

Fig. 2 is a diagrammatic lay-out of the gears. A is the stationary pinion, B is the floating cage that carries the four planet wheels, and C is the outer internally toothed ring with which the planets are always in engagement; the pinion A is also in constant mesh with the planets. To obtain the low gear the outer ring C becomes the driven member, driving the cage B through the medium of the four planet wheels that are attached to the cage by their bearing pins. These planet wheels are also in

engagement with the stationary pinion A, so that as they are rotating the planets will travel in the same direction as the outer ring, but will move more slowly. The final drive is from the cage B to the hub shell D.

Three-speed Gear. Fig. 1. Part-sectional drawing of a type of three-speed coaster hub for pedal bicycles. LA, thrust nut sleeve; R, index stud; V, V, cones; X, Y, sleeve nuts; Z, end cover. Other references explained in text. Fig. 2. Diagrammatic lay-out of the gears, showing position for low gear; outer ring C being the driven member. Fig. 3. Position of gears in high gear; cage B becoming the driven member. Fig. 4. Longitudinal section showing low gear engaged. Fig. 5. Normal or direct drive engaged. Fig. 6. High gear engaged. Fig. 7. Diagram showing arrangement of control units. A, pulley; B, control lever; D, E, screw sleeve and nut; R, index stud; S, chain.

The high or geared-up gear is obtained by a reversal of the foregoing, Fig. 3. The cage B is the driven member, which by rotating causes the four planet wheels, through the medium of the stationary pinion A, to revolve, and these by so doing rotate the outer ring C, but at a greater speed than that of the cage B. In this case the final drive is from the outer ring C to the hub shell D, it being understood that the power applied to the driven member in both cases is through the chain ring shown at M, Fig. 1.

Fig. 4 shows the operation of the low gear. The direction of the drive is transmitted from M to N, then via the ratchet teeth T. They engage with the pawls Q, which are a part of the outer ring C.

Then the drive is through the medium of the planets E, that are also in engagement with the stationary pinion A rotating the cage B, of which the ratchet teeth K are a part, and these teeth engage the cage pawls H, that are a part of the hub shell D, thereby completing the drive. This being the low gear, C, M, and N will be rotating at a greater speed than the hub shell D. Fig. 5 is normal, or direct drive.

Through the medium of the chain S and the thrust collar L the cage B with the outer ring C is moved to the right a sufficient distance to disengage the ratchet teeth K from the pawls H. By so doing the pawls F are brought into engagement with the internal ratchet teeth G, that are a part of the hub shell D. The drive is then from M, N through the ratchet and pawl T and Q, thence via the pawl and ratchet F and G to the hub shell D. The drive is now solid, the gear wheels running idle owing to the stationary pinion A.

Fig. 6 is the high or geared-up speed. Through the medium of S and the thrust collar L the cage B with the outer ring C is drawn farther still to the right. By so doing the ratchet and pawls T and Q, Fig. 5, are disengaged, and the ratchets P and W take up the drive. The cage B, of which the ratchet teeth P are a part, is the driven member, through the medium of the planets E, which in turn drive the outer ring C. The pawl and ratchet F and G take up the drive to the hub shell D. Diagrams 4, 5 and 6 should be read in conjunction with Fig. 1. The arrangement of the controls is shown in Fig. 7 below.

Dérailleur Gears. Another type of variable speed gear is the “Dérailleur gear,” in which a free wheel with two or more sprockets is employed, the chain being moved from one sprocket to another by a lever-and-cable control on the top tube of the bicycle frame. A tension cog takes up any slackness of the chain between the smallest and largest sprocket. When the control lever is moved, a rotary movement is given to the actuating sprocket so that the sprocket moves laterally into line with the cog selected. There are many variations of this system, giving two, three or four speeds according to the number of sprockets. By combining this type with a hub gear or with a dual chain wheel, 6, 8 or 12 speeds can be devised, and almost any set of gear ratios may be obtained. Regular lubrication is essential.

Three-speed Gear. Fig. 8. Dérailleur gear, in which a free-wheel with two or more sprockets are used, chain being actuated by a lever-and-cable control. (Courtesy of Cyclo Gear Service.)

See Fig. 1 for reference letter E

THREE-WHEELED CAR. The “ three-wheel ” car is a step between the motor cycle with sidecar combination and the four-wheeled car. An advantage is that in the eyes of the law it is a motor cycle and trailer, and therefore comes under regulations of licensing different from those which apply to a car. The tax on a three-wheeler is £4 per annum, whereas a four-wheeler of the same horse-power would be taxed £7 or £9. Moreover the design is simple, and since the back axle with its complicated worm, or bevel and crown wheel, and differential is eliminated, the cost of construction is distinctly low. The weight of the completed vehicle is somewhat less than that of a similar four-wheeled type.

Three-wheeled Car. Morgan three-wheeler, family model. (Courtesy of The Motor Cycle).

This lightness of weight gives the vehicle a relatively high performance, equalled only by high-powered cars at much greater cost; and it becomes a very fast and relatively powerful car at the price

of a motor cycle and sidecar. This is by no means the limit of the appeal of the three-wheeler, for there are on the market several excellent “family models” which give the same accommodation as a small four-seater car with much lower first cost, running and maintenance costs. Most three-wheelers are driven by a two-cylinder engine of the motor cycle type which drives the back wheel by means of chains; in one design the power is applied direct to the front wheels, thus obviating the use of long chains.

In the Morgan car the power unit is a two-cylinder engine either of the air-cooled or water-cooled type which transmits power to the back wheel by means of a short shaft and chains. There is no gear-box in the accepted sense of the term. From the shaft the drive may be taken at will through either of two chains, which provide different speed ratios. The type of body on this chassis varies from two-seater tourers and four-seater “all-weather models” to two-seater “super sports” models capable of over a hundred miles an hour.

B.S.A. sports model of three-wheeled car. (Courtesy of The Motor Cycle).

The B.S.A. three-wheeler is driven by a two-cylinder air-cooled engine, but, unlike the Morgan, the drive is on the front wheels and not on the single rear wheel. This form of construction is moderately cheap, since all the mechanical elements are concentrated at one end of the vehicle.

Various other types of three-wheel vehicles have been introduced from time to time, but have not caught the public fancy, and are no

longer made, except the Seal, which is in effect a sidecar combination built as one machine instead of two. It is fitted with a two-seater body on car lines.

Theoretically the three-wheeler is not so stable as a four-wheeled car, the relative stability of the two types of vehicle approximating to that of a three-legged stool and the conventional chair, respectively. In practice, however, the disadvantage of a threefold support is not so apparent, and in the hands of an efficient driver the three-wheeler may be reckoned as safe as the four-wheeled car, though it requires greater skill in driving. Motor cyclists probably make the best drivers, since many motor-cycling conditions obtain.

Manufacturers as a rule do not equip a three-wheeler with a reverse gear, and the steering gear is not of the somewhat complicated type used on a car, with the result that steering is perhaps a little more fatiguing. Advantages of the three-wheeler include lower weight, greater power in proportion to weight, greater economy in petrol, simplicity of construction, and lower taxation.

A three-wheeler ranks as a motor cycle, therefore the age limit for holding a licence to drive it is sixteen years, instead of seventeen, as in the case of a car.

THRIFT. This is the name of a low-growing evergreen tufted plant (armeria) suitable for the flower border or rock garden. The commonest is *Armeria vulgaris* (or *maritima*), a favourite edging plant which bears light rose-coloured flowers in summer; *lauchiana* is a variety with blooms of deeper colouring. Sea pink is another name for this plant which grows wild among the rocks by the seaside in the West of England. Two good taller thrifts suitable for the bolder are *latifolia* and *plantaginea*, 12 in., with rose-coloured blooms; of the improved varieties raised in gardens one of the best is Bees' Ruby. *Armeria caespitosa* is a charming low-growing plant with rose-coloured flowers which will thrive in gritty soil in the rock garden.

Thrift. Rosy flower heads of the popular sea pink.

THRIPS. The small noxious insect pest known as thrips infests the flowers, leaves and shoots of plants, especially those under glass. The leaves become spotted and discoloured. Thrips cause trouble by sucking the juices of the leaves. The best remedy is to spray affected plants with a solution of tobacco water or soft soap. Other effective remedies are quassia extract and paraffin emulsion, and there are various proprietary insecticides. *See* Insecticide; Peas; Spraying; Syringe.

THROAT. The space behind the mouth, including the fauces, pharynx and larynx, is called the throat, though the name may also be applied to the front part of the neck. A sore throat, which usually means some degree of inflammatory disturbance, may have many causes. It occurs most frequently, perhaps, in connexion with a common cold, but it may happen also at the beginning or in the course of other infectious diseases. It may also be due to tobacco or some other irritant.

In young children the throat may be sore and there may be little to indicate the fact. For this reason the early stages of diphtheria may be overlooked. It should always be the rule, therefore, to examine the throat of a young child when it is ailing. To do this the child should be held where a good light will shine into the mouth, and the tongue should be depressed with the flat handle of a teaspoon.

A number of methods are available for the application of remedies to a sore throat. Gargling has the disadvantage that the movements made in carrying it out themselves tend further to irritate very sensitive parts. Patients who are old enough to do so may get more good from simply allowing the gargle to lie in contact with the back of the throat for a minute or two. In acute conditions spraying is better, or the parts may be steamed.

Benefit may be derived from the application of hot or cold compresses to the front of the neck. These are of several thicknesses of flannel or lint, covered with gutta-percha tissue or oiled silk, and a bandage. Chronic sore throat may follow the acute or may result from over use of the voice, dyspepsia and other causes. *See* Adenoids; Cough; Croup; Crowing; Diphtheria; Eustachian Tube; Gargle; Inhalation; Laryngitis; Larynx; Quinsy; Tonsillitis.

THROATING. This name is often given to a groove cut on the underside of a projecting portion of a building to check the passage of rainwater. When rain falls upon the top surface of the sill it spreads out and flows over the edges; by capillary attraction it flows underneath the sill, and in the absence of a throating groove it continues until it meets the surface of the wall, where it runs partly down the surface. If a groove is cut near the front edge of the under side of the sill, the water gathers there, and by its weight drips from the edge of the groove, thereby keeping the remainder of the sill and the wall dry.

Throatings are not always set in a horizontal position. Examples are found in many windows in a vertical position, both on the moving part and on the framework or fixed part. The purpose in both cases is to act as anti-capillary grooves, which, by collecting the rainwater, provide a channel for it to run down and drain away.

THROATWORT. This handsome greenhouse plant, 2 ft. or so high, bears bunches of light blue flowers in summer: its botanical name is *Trachelium caeruleum*. It is easily grown in a compost of loam, leaf-mould and sand and is increased by cuttings in late summer or by seeds sown in June. During winter a temperature of 50 degrees is high enough. It is sometimes planted in flower beds for the summer months.

Throatwort. Handsome shaggy blue flowers of Trachelium caeruleum.

THROMBOSIS. The formation of a clot of blood in the heart or in a blood vessel, usually a vein, is called thrombosis. If thrombosis succeeds in obstructing the flow in a blood vessel, little may happen if the blood is able to move on through other blood vessels, but when it occurs in one of the principal veins of a limb it causes dropsical swelling of the limb, with stiffness and tenderness. The symptoms and consequences of thrombosis depend upon its site. *See* Embolism; Varicose Vein.

THROTTLE: In Car and Cycle. With all makes of carburetter the device known as a throttle is used to control the amount of gas entering the cylinder on the induction stroke. There are two types

in common use, namely, the butterfly and the piston, the former being the more popular for motor car work and the latter for motor cycles.

The butterfly type is mounted on a small shaft positioned across the centre of the mixing chamber and over the jet. The closed position is capable of fine adjustment for control of the amount of mixture past the pilot jet, used for keeping the engine running very slowly while the vehicle is stationary. The piston type operates by rotary or sliding movement. The amount of throttle opening is graduated, apart from piston movement, by a V-shaped slot cut in the side of the piston, and with the multi-jet carburettors the slot is so shaped that as the throttle opening increases the jets are uncovered in turn.

A proper use of the throttle consists of something more than opening and closing it, according to the engine power required. It is imperative that the speed of the air sucked past the jet should increase as the throttle is opened if a uniform mixture is to be retained. In other words, unless the speed of the engine rises with the throttle opening, the suction on the jet will fall, with the result that the mixture will be relatively weak. Therefore, although the throttle is wide open, the engine will not be giving its full capacity of power.

When the vehicle is climbing a hill and the revolutions of the engine fall off to an appreciable extent, to open the throttle wide will only result in making matters worse. The correct procedure is to change to a lower gear, speed up the engine, and, if the nature of the gradient is suitable, change up again as quickly as possible, at the same time gradually opening the throttle as the speed of the engine increases.

Wear of the bearings of the butterfly throttle, and wear between the piston and cylinder of the piston type, is of considerable importance. Especially is this the case when the engine is running on the pilot jet, because, owing to the throttle being practically closed, air will be drawn in at any possible point, thereby seriously upsetting the mixture. The only cure is to renew the worn parts in the case of the piston throttle, and rebush the bearings of the butterfly pattern.

The speed and power of the internal combustion engine are directly allied to throttle control. Therefore, careful periodical attention should be given to all working parts, from the control lever or pedal down to the throttle arm. Particular attention should be paid to the spring that retains the throttle in the closed position, because, should this come adrift or break, the throttle may assume the full open position, with disastrous results, unless the driver immediately realizes what has happened and switches off the ignition. *See Carburetter; Internal Combustion Engine; Motor Car; Motor Cycle.*

THRUSH: The Bird. A constant inhabitant of the garden where there is a hedge or bushes suitable as a nesting site, the song thrush is not loved by the fruit-grower, although he has a better reputation than the blackbird. In this connexion, it must always be remembered that the thrush feeds mainly upon worms and snails. The persistent manner in which the latter are hunted and destroyed can be demonstrated by placing a large stone in a convenient spot, and noting how the bird uses it for breaking open its prey; the ring of shell debris around it will testify to the thrush's usefulness.

THRUSH: The Disease. In a parasitic inflammation of the mouth, or thrush, whitish patches appear on the tongue, inside of the cheeks, and also on other adjacent parts. The ailment, which usually occurs in infants, is caused by a fungus. The disease is contagious; that is, it may be carried from one child to another through the medium of bottle-teats or spoons.

Mild cases can be cured in 6 to 9 days, the diseased patches coming away and leaving a healthy surface. If the child is sickly and treatment is neglected, the attack may last for months.

Care should be exercised to keep the mouths of children clean, and this is all the more important when they are sickly. The mouth should be cleansed after every meal, so that no remains of food may be left to form acids. In sickness the mouth should be washed 2 or 3 times a day with a weak alkaline lotion, such as lime water, or water in which a little bicarbonate of soda is dissolved, a teaspoonful to $\frac{1}{2}$ pint of water. If the child is hand-fed, the bottle, tubes, teats, and the utensils used for heating the milk should be kept scrupulously clean. The milk must be pure and fresh. Starchy food should be given with the greatest caution before the age of 10 months. If there are any signs of indigestion or acidity of the stomach, add about $\frac{1}{4}$ lime-water to the child's milk.

As soon as the spots appear they are to be treated with any of the following applications: Solution of boric acid, 10 gr. to 1 oz. water; or solution of salicylic acid, 2 gr. to 1 oz. water; or sodium bi-borate, 12 gr. to 1 oz. water; or permanganate of potassium, 1 gr. to 2 oz. water. Any, of these lotions may be applied with a camel-hair brush, or with a piece of boiled lint wrapped round the end of the finger, or they may be sprayed on the patches of thrush.

THRUSH: In Horses. Horses of every kind are liable to thrush of the feet, which is denoted by a discharge of matter, and is generally due to insanitary conditions in the stable. It is most commonly the horse's hind feet that suffer. Many farm horses get the disease through no drainage being provided. The cobble-stone paved stable is a fruitful cause, unless this has been set in the concrete and is well drained.

The trouble affects the cleft of the foot pad, or frog, as it is called. A frequent cause is through allowing soiled straw, etc., to lodge in the feet, and there remain until it drops out, proper use not being made of the foot picker. The feet should be picked up and cleaned out every time the horse leaves the stable, also whilst it is in the stable. When a horse returns from work it is customary to wash the feet, but care must be taken not to wet the clefts of the frogs and the hollows of the heels.

It is of primary importance to attend to such hygienic matters as a clean dry stable floor, drainage, plenty of straw bedding, and regularity in picking out the feet. Dress the cleft of the frog daily with calomel and pack it into this by inserting a pledget of tow. This will usually cure it in a few days; but if not, try a lotion consisting of 5 gr. of corrosive sublimate dissolved in 1 oz. of methylated spirit. This dressing, which should be used daily, is applied by pouring it into the cleft, soaking a piece of tow in the solution and packing it into the cleft.

THUMB. The human thumb has a very free range of movement. It may be flexed or bent in on itself, extended or straightened out, adducted or drawn across the palm, adducted or carried out from the hand, and opposed or brought across to touch the other fingers. It is characteristic of paralysis of the median nerve that while the thumb may be adducted it cannot be opposed to the other fingers. The part played by the thumb both in performing fine hand movements and in gripping is a very large one, and these functions are seriously impaired in median nerve paralysis.

The ball of the thumb is technically called the thenar eminence. Both this and the hypothenar eminence, the corresponding muscular mass on the inside of the palm, manifest wasting in ulnar nerve paralysis. The thumb is not infrequently dislocated, and great difficulty may be experienced in reducing the dislocation. *See* Bandage; Hand.

THUMB LATCH. This term is used to describe a type of latch which is operated on one side of the door by the thumb. As a general rule it is similar in appearance to that known as a Norfolk latch. *See* Latch; Norfolk Latch.

THUMBPIECE. Known also as the purchase, this is often found on jugs or tankards and other drinking vessels that possess a lid, being placed on or near the handle so that the drinker can raise

the lid by placing and keeping his thumb thereon. The two main shapes for the purchase were corkscrew and bifurcated. On a tankard of the 17th century the thumbpiece is sometimes a very decorative feature. On one it represents a pierced heart, embossed and chased with flowers, foliage and figures. *See Silver; Tankard.*

THUNBERGIA. This is a pretty climbing plant for a heated greenhouse. The favourite kind is *alata*, of which there are several varieties with blooms of various colours. These plants are very pretty when grown in wire baskets suspended from the greenhouse roof. They bloom in summer and are raised from seeds sown under glass in spring; a compost of loam, leaf-mould, sand, and a little decayed manure suits them.

THUNIA. This is a family of hothouse orchids, about 1 ft. in height, and with white, yellow, or purple flowers in the summer time. They need plenty of heat and sunshine during the growing season, which is from March till October. At this period plenty of water is necessary. During the winter months, 60° is sufficient. Propagation is effected by division of the pseudo-bulbs when the plants are repotted in early spring. *See Orchid.*

THUYA. This is the botanical name of a group of evergreen conifers; the common name is *Arbor vitae*. They are closely related to the cypress or *cupressus* and some of them are used to form tall hedges in gardens. One of the most striking kinds is the so-called red cedar (*Thuya plicata* or *Lobbii*) which grows into a large tree. *Thuya dolabrata* from Japan, and *orientalis* from China, are familiar garden trees. There are several ornamental varieties of the Chinese *Arbor vitae* (*orientalis*), e.g. *aurea*, and *glauca* with golden and grey-blue leaves respectively, and of the American *Arbor vitae* (*occidentalis*). These conifers, which should be planted in September-October or in April-May, thrive best in deep loamy soil which does not dry out in summer.

THYME. These fragrant-leaved plants are valued both in the kitchen and the flower-garden; they like light or well-drained soil and a sunny place. The wild thyme is *Thymus serpyllum*, 2 in. high, with purplish flowers: this together with its varieties *coccineus*, which has rose-red blooms, the lemon thyme (*citriodorus*), and the grey, woolly-leaved thyme (*lanuginosus*) are delightful little plants for the rock garden and paved paths. The dried shoots of the lemon thyme are used for scent sachets and for perfuming soaps. The common thyme of the kitchen garden is *Thymus vulgaris*.

Thyme. A flourishing plant of the fragrant common thyme, much used as a flavouring in cookery.

Uses in Cookery. Thyme is used in cookery for flavouring dishes. For this purpose it may be raised either from seed, division of old plants, or from cuttings. Seed should be sown out of doors in light soil, in early spring, or cuttings may be made a little later on in the season. The shoots should be collected, tied up in bunches, and suspended in a well-ventilated room or shed to dry. *See Bouquet Garni; Herb Garden.*

THYROID GLAND. The functions of the thyroid gland, which is situated in the front of the neck just below the Adam's apple, are very important. It has a powerful influence on the nutrition of the

tissues of the human body, and on the mental and bodily development. The gland is larger in women than in men, and sometimes reaches an enormous size in goitre. The secretion of the gland contains a certain amount of iodine in organic combination.

In some children the thyroid is very small when they are born, or it may waste in the early years of life. These children suffer from cretinism. Sometimes in adults the gland wastes until it almost disappears, and in such cases the disease myxoedema is produced. Both diseases result from absence or diminution of the fluid secreted by the thyroid. Enlargement of the gland is a common disease.

Thyroid extract, or the powdered dried gland prepared from the thyroid gland of newly killed healthy sheep, is used frequently in the treatment of disease. It may be employed in cretinism, myxoedema, certain types of goitre, for mental deficiency in young children, and in obesity. *See* Cretinism; Exophthalmic Goitre; Goitre.

THYRSACANTHUS. These beautiful hothouse flowering shrubs grow from 2 ft. to 3 ft. in height. They thrive in the usual potting mixture of loam, leaf-mould and sand, in an average temperature of 60-65 degrees. Propagation is by cuttings of young shoots taken in springtime and inserted in pots of sandy soil. The favourite kind is rutilans, which bears crimson flowers in winter and spring.

TIARELLA. The hardy, perennial herbaceous plant *Tiarella cordifolia* is about 9 in. in height, with white flowers in April. It flourishes in ordinary soil in a sunny or partially shady position in the rock garden or open border. The flowers are borne in masses, suggesting the creamy-white edges of waves; hence the name foam flower. Propagation is by division of the roots in spring.

Tiarella cordifolia, a creamy flowering herbaceous plant for a rockery or border.

TIBOUCHINA. Sometimes called the Brazilian spider flower, this is an evergreen flowering shrub suitable for a heated greenhouse. *Macrantha*, which is the most suitable for amateur cultivation, forms a large bush and bears purple flowers in winter. It should be grown in well-drained pots or tubs filled with peat, sandy loam, plus a little charcoal and sand, all well mixed together. It may be trained to trellis, pillars, or walls.

TIC. A muscular twitching of muscles, usually the muscles of expression, is known as tic. It occurs most commonly in young girls. It is treated by re-education in the control of the muscles affected. Mimic tic is a more serious condition which generally occurs after middle life. It is incurable.

TIC DOULOUREUX. This extremely severe form of neuralgia sometimes occurs in the branches of the fifth cranial nerve, also known as the trigeminal nerve. This nerve has three main branches, one supplying sensation to the eyeball and to neighbouring parts, another supplying the region of the upper jaw, and the third the region of the lower jaw. The pain occurs in paroxysms, at first at long intervals perhaps, but later on almost continuously.

Large doses of quinine are sometimes useful, also such drugs as antipyrin and aspirin. But as they have to be used in large doses, all such medication should be at the hands of a doctor. The application of warmth, of electricity, of cold, or of anodyne liniments or ointments may afford

adequate relief in the mildest cases. Cure, however, can only be secured in one way, and that is by operation. *See Neuralgia. Pron. Tik-doo-lo-roo.*

TICK: On Dogs. This very noxious little insect is sometimes found on dogs, as it is on other animals. In appearance it bears a resemblance, as far as the body is concerned, to the spider, and varies in size from that of a pin's head to that of a small pea. In colour the smaller ones are light grey, but they become dark when too gorged with blood.

The tick fastens on the skin, and holds on with such tenacity that the attempt to remove it will often lead to the insect breaking into two parts, when a nasty sore will usually be left on the affected animal. The insect is found occasionally in the cleanest kennels and on the best kept animals, as a dog may have come into contact with one that is infested with it. As soon as ever the tick makes its appearance, steps should be taken to get rid of it. The dog should be treated with one of the preparations that are sold for this purpose, and the treatment should also include the kennel, as the pest often finds a lodging in the wood. *See Dog.*

TICKING. This very strong linen or cotton material has its chief use in the covering of mattresses, because it is so closely woven that the feathers cannot penetrate it. It is usually twilled, and white in colour, with pink, red, or blue stripes. It is also sometimes employed for awnings and tents. *See Mattress.*

TIE BEAM. In building work, the tie beam is the very important member of a king post roof truss or a queen post roof truss, which ties the truss together at the feet of the principal rafters and prevents the truss from spreading.

The tie beam is fixed to the feet of the principal rafters with the aid of long iron bolts and straps, and it is supported in the centre by a gib and cotter. *See King Post; Queen Post Rafter; Roof; Truss.*

TIE DYEING. This is a form of fancy home dyeing by which very beautiful multicoloured effects can be achieved for lampshade silks, scarves, and short curtains. There is no outfit required beyond thread, wax, and a few brushes and dyes.

Jap silk is one of the simplest materials to use, but crêpe-de-Chine and georgette of good quality also yield good results. A little piece of silk is picked up in the middle of the square, circle or strips and tied with thread which has been dipped in wax. The silk is pulled up again and tied 1½ in. lower down, repeating this at intervals all over the piece of silk, and tying once only. The material is dipped into lukewarm water, then into a dye-bath. When the string is removed the strangest patterns will be found on the silk. Match-ends dipped in wax and placed on the material to form stars, squares, etc., give many variations.

Small portions of the material may be accordion-pleated, tied up, and dipped in wax. This will preserve them, and when the rest of the material is dyed they will remain the original colour of the material. Where several colours are used the material can be tied at intervals, increasing in size while working outward. Wet the silk, then dip each section into a different colour.

When all the tying is finished the material is spread on a piece of damp newspaper, and a large brush charged with colour is used to tap the top of each little tied-up piece. The brush should be charged quickly and the wet material splashed all over, using first one colour and then another. Light shades should be employed first, as dark ones are very penetrating. A small brush dipped in either black or brown is useful for making thin lines, which give a cobwebby effect. The material should be kept as flat as possible on the paper, and untied as soon as all is coloured. When almost dry it should be ironed out.

Good quality dyes naturally give the best and most permanent results, those sold for Batik being excellent. Fixing acid, acetic acid, or vinegar must be added before dyeing is commenced. *See Dyeing.*

TIGER FLOWER. This is a brilliantly coloured bulb flower which needs rather special treatment. They should be planted 3 in. deep in March in a well-drained border of sandy loam in a sheltered sunny place: it is wise to set the bulbs on sand. In autumn they should be lifted and stored in sand for the winter. If grown in pots the bulbs are potted in autumn or winter, placed in a frostproof frame until top growth appears, and then brought in the greenhouse. Great care must be taken not to give much water until the bulbs are well rooted. The peacock tiger iris (*Tigridia pavonia*) is the favourite kind; there are varieties in gorgeous shades of colour. *Conchiflora*, yellow and scarlet, is another handsome sort.

Tiger Flower. Brilliantly coloured flower of the Peacock type, suitable for a sunny border.

TIGER LILY. *Lilium tigrinum* is one of the best lilies for amateur gardeners. It reaches a height of 4 ft., and bears orange-red flowers in August and September. The bulbs should be planted 5 in. deep in autumn or spring in well dug soil with which leaf-mould and sand have been mixed freely; they may be left undisturbed for years. The finest varieties are *Fortunei giganteum*, and *splendens*, with flower stems 5-6 ft. high and orange-scarlet flowers. *See Lily.*

TIGER MOTH. This describes the garden moth, whose caterpillars are known as woolly bears. The caterpillars feed on flowering plants and vegetables. The parent moths may be identified by their red and black bodies, brown and cream forewings, and hind ones of purple, red, and orange. Destruction of the moths and hand-picking of the caterpillars are the only effectual remedies.

TIGER WARE. This ware was used for a certain type of jug made chiefly in the 16th century, and now much sought by collectors. The ware is a dark, mottled pottery, very hard with a fine glaze, and the jugs are often silver mounted. The style has been much imitated by modern makers. One example, dating from 1559, is mounted with neckband, cover, and foot of silver gilt; the neckband is engraved with foliage and strapwork, and the cover embossed with fluting. The thumbpiece is fruit-shaped.

TILES AND THE PROCESS OF TILING

Protective and Decorative Uses Described and Illustrated

This contribution is concerned with a number of structural and other matters, both in house and garden, on which there are entries in this work. Such include Bathroom; Bungalow; Cottage; Garage; House; Kitchen; Path; Roof; Sink. *See also Concrete; Floor; Mosaic; Pantile; Rubber, etc.*

A tile is a comparatively small and thin piece of baked clay, made in substantially the same way as bricks. Such tiles are extensively used for roof coverings, wall surfaces, floors, and other purposes. Glazed earthenware tiles are used where an impervious and cleanly wall covering of a more or less ornamental character is needed, and for fireplaces.

The largest class of tiles consists of those employed for roof covering. Hand-made roofing tiles are noted for their good colour and surface. As a rule they weather better than the machine-made variety. Machine-made tiles are generally harder and more homogeneous, more uniform in colour and texture, and more regular in shape. They are made by processes similar to those used in making bricks, but the material is more carefully graded.

Much of the charm of the small English home is due to the use of the dark red sand-faced tiles. This is especially the case with old tiles, to which time has imparted warm tints often relieved by traces of moss and lichen. Apart, however, from their picturesque appearance, tiles form an extremely durable roofing material; many houses with tiles over 100 years old are as weatherproof as when they were first roofed.

Fig. 1

Fig. 2

Tile. Fig. 1. Pantiles as laid on battens; below, section of a pantile showing nib which catches on batten. Fig. 2. Interlocking flat tiles; below, section of three tiles.

The colour of British tiles ranges from warm reds, browns, and strawberry colours to tints of blue, green, and grey. Among the earliest tiles are those known as pantiles, a flat S shape, averaging about 14 in. in length, 9 in. in width, and $\frac{1}{4}$ in. thick. One edge of the common pantile is turned down rather more sharply than the other, and this edge overlaps the flatter edge of the neighbouring tile (Fig. 1). The projecting nib which rests against the roof batten is shown in the section beneath.

A development of the pantile has been evolved by different makers. Some of these tiles are of considerable size, and are flat for the major portion of their area. One edge is sharply upturned, and the other is more or less semicircular in shape. A roofing tile of the interlocking type is illustrated in Fig. 2.

As will be seen by the section shown, it is moulded so that the overlapping part fits into a grooved portion on the tile beneath it.

By far the greater number of tiles for roofing are of the so-called flat type (plain tiles) illustrated in Figs. 6 to 12. Of these there are many kinds, varying in colour, density, weight and durability. Choice is largely a question of price and effect. The cheapest are a bright red in colour, and machine made. The average size of the plain tile is 10 in. long, $6\frac{1}{2}$ in. broad, and about $\frac{1}{2}$ in. thick. On the average, about 650 tiles, weighing $1\frac{1}{2}$ tons, are needed to cover a square, that is, 100 sq. ft. of roof area.

Plain tiles are made in three widths, known as half-tile, tile, and tile-and-a-half tile. The two latter are used as end tiles in alternate courses, so as to break the joints, that is to say, so that there should

not be a continuous series of vertical joints in the roof covering. In some cases, half-tiles cannot be fixed satisfactorily, and it is customary to use a tile-and-a-half tile, which has the same effect in breaking the run of the joints. The plain tile is rectangular, and there are fancy or shaped varieties for decorative purposes, such as a few courses of bandings or fancy patterns introduced as a variety in a large roof area. Similar tiles employed for covering walls are known as hanging tiles.

The ordinary plain tile is not perfectly flat, but is curved in the direction of its length and across the breadth. Consequently, the upper surface is slightly dome-shaped, which ensures the water draining off the surface. For fixing purposes, tiles are made with small projecting nibs on the top end edge; and two small holes through the tile near the top edge for nailing if required. To support the tiles, horizontal battens are nailed at regular intervals to the roof rafters. In preparing an estimate for tiles for roofing purposes, it is necessary to ascertain the area in terms of squares of 100 ft. superficial. The first thing required is to ascertain the approximate number of tiles that will cover a square. Allowance must be made for breakage in transit and also in breaking or cutting the tiles, if there are any hips or valleys on the roof, and also for cutting around the stacks and other projections. A reasonable allowance for these various purposes is 5 per cent.

A sufficient quantity of half-tiles or tile-and-a-half tiles must be provided, the number depending upon the courses on the roof and the verges or ends, reckoning one tile-and-a-half tile or one half-tile per alternate course. To determine the number of courses of tiles, it is necessary to know the distance from the ridge to the eaves and also the lap or gauge of the tiles. The lap varies from $2\frac{1}{2}$ in. to 4 in., and an average of 3 in. gauge can be taken as reasonable, so that there will be four tiles per foot of length of the distance from ridge to eaves.

Tile. Fig. 3. Common ridge. Fig. 4. Serrated ridge. Fig. 5. Decorated ridge tile.

Fig. 6. Swept valley laid with ordinary tiles.

In addition, there are special tiles made for the top or ridge of the roof, varying from the plain ridge tile, which is semicircular in section, as in Fig. 3, to those of ornate pattern, such as Figs. 4-5. Ridge tiles measure about 12 in. in length, and are laid so that they butt up against each other. The proper number needed for the job is easily ascertained by measuring the length of the ridge. If the roof is

hipped, the junction between the tiles may be covered with small ridge tiling, or it may be completed with special hip tiles. In either case the quantity required is easily ascertained, as one is reckoned for each course of roofing tiles. If two roof surfaces meet and form an internal junction, this is known as a valley. It is finished by a method known as sweeping, in which ordinary tiles are laid continuously, in the manner shown at Fig. 6, or the valley may be constructed with valley tiles, one being allowed for each course. Alternatively, lead or other guttering may be provided for the purpose. Having ascertained the quantity of tiles needed, this should be turned into round figures and estimates obtained for them to be delivered on the site. In comparing prices, it is as well to have samples of the tiles, so as to judge their quality, texture, and colour. When the choice has been made and the tiles are received, they should be unloaded and stacked on a level piece of ground conveniently near to the scene of operations.

The first step in the actual laying of the tiles is to have the roof prepared for their reception. They can be laid directly on to the battens, or the roof may be covered with rough boarding with tarred felt over it, and battens upon which to set the tiles. The battens must be perfectly horizontal and laid at the proper distance or gauge from each other. The meaning of the expressions lap and gauge, as applied to plain roofing tiles, is made clear by the diagram, Fig. 7. From this it will be seen that the gauge is the distance between the top edges of two battens and the lap is the amount by which one tile overlaps the tile on a course next but one below it.

Fig. 7. How tiles are laid, illustrating the meaning of the terms lap and gauge.

For complete protection, it is necessary that at any given point there should be three tiles. The roof remains weathertight not because the surface is sloping, but because the tiles overlap each other. Owing to the triple lap, any water that penetrates the outer layer of tiles will be deflected by the lower layers.

Ordinary tiling is commenced at the eaves, and preferably at the right-hand end or verge. A scaffolding is required, and it should be placed so that the worker stands

about 2 ft. 6 in. from the eaves line. The first step is to lay the eaves course, made of special tiles, which are about three-quarters of the length of the ordinary tiles. These are inclined at a different angle to the rest of the roof, rather flatter than the remaining courses so as to tilt up the lowest course, this tending to make the roof drier. A few are laid as a start.

Tile. Fig. 8. Setting the tile-and-a-half tile for the start of the second course.

The next step is to commence laying the first course whose lower edges coincide with those of the eaves course (Fig. 8). These are rested with their nibs on the upper edge of the batten, and the first few tiles may be further secured by means of galvanized iron nails, about 1½ in. long. Some mortar must be in readiness, and should be spread over the tops of the eaves tiles before fixing the first course, so that the latter is bedded in mortar.

After the first few tiles of the first course have been laid, a tile-and-a-half tile is set on the second course, commencing from the verge as before, and bedded in mortar. The tile is gently tapped down so that it rests firmly on the tile beneath it, by lightly tapping upon it with the end of the trowel handle, as in Fig. 8. Several more ordinary tiles are then laid on the second course, but these will not need to be bedded in mortar. The third course is commenced, the first tile being bedded in mortar and the edges brought up level with those beneath it. The next course is then continued, and the work goes forward, gradually working along and up the roof until the ridge is reached.

To save labour and the time of constantly clambering on and off the roof, an assistant can stack the tiles by resting them between the battens with others at right angles to them, as shown in Fig. 9. Thus the tiler is supplied constantly with tiles, conveniently placed.

It is desirable in exposed positions to nail about every fourth course by driving 1½ in. galvanized iron nails through the holes in the tiles. It is not necessary to nail every tile except in very exposed districts. If half-tiles are used instead of a tile-and-a-half tile, they are set in place in exactly the same way. Should there not be enough of these, ordinary plain tiles can be cut in half by scoring a

line along the centre and cutting them with a sharp blow from the edge of the trowel, cutting downward rather than across the tile.

Tile. Fig. 9. Showing how to stack tiles on rafters ready for use. Fig. 10. Verge with tiles in place and cement fillet around chimney stack. Fig. 11. Tiles cut to form simple valley gutter. Fig. 12. Showing how lowest courses of tiles on a tile-hung wall should be tilted.

The appearance of the verge or end of the roof when it is completed is shown in Fig. 10, which also indicates a simple method of finishing the tiles around a chimney stack with strong cement mortar applied round the sides of the stack and on

top of the tiles. This is not necessary when flashings are fitted, as these come on the tops of the tiles and keep out the wet.

The ridge tiles are set on the apex of the roof and are merely bedded in strong cement mortar. Hip and valley tiles are worked where requisite at the junctures between roofs which meet at an angle. In another method a valley gutter is often formed with lead set upon valley boards, and the tile courses terminated with the tiles cut diagonally. A detail of this class of work is illustrated in Fig. 11. To support the tiles where they overlap the gutter a continuous batten or ridging is necessary to raise them above the surface of the gutter. Usually, however, the valleys should be worked with the proper valley tiles which course and bond with the plain tiling, or the tiles may be swept and laced, as illustrated in Fig. 6. A valley board about 9 in. wide is laid up the valley, and the tile courses are continued from the two intersecting slopes of the roof, so that each tile on the main part of the roof overlaps a tile on the subsidiary part. Alternatively, the courses from each slope may be taken over and under in alternate courses. The last tile of every course, of which only the corner will show, is preferably a tile-and-a-half tile. Tiles can only be laid in this way when one roof is subsidiary to the other, otherwise the ridge line will be broken.

At the verges, the finishing may be by close tiling, that is, the tiles project only from 2 in. to 3 in. beyond the gable wall, and are given a slight inward tilt to throw water away from the edge. Alternatively, a projecting verge and a barge board can be adopted, the ends of the tile courses being pointed with strong cement mortar.

Tile Hung Walls. Vertical tile hanging is a method of covering the surfaces of walls in exposed positions, and it forms an excellent protection. The method is shown in Fig. 12. The groundwork is often composed of horizontal battens of wood nailed to the brickwork. The objection to such a plan is that the timber is liable to rot and decay, but it is often the only practical plan. The tiles are hung on nibs and each is separately nailed. The hollows and grooves are overlapped, the gauge being about $4\frac{1}{2}$ in.

Doubling courses of tiles are used under the roof eaves, and also on the lower courses, and above any openings. The tiles are given a considerable local upward tilt, as in Fig. 12 to throw the drops of water clear of the windowsill or opening beneath it. Fig. 13 depicts a small cottage tile-hung with dark red, sandfaced tiles of ornamental pattern.

Ordinary plain tile roofs should have a pitch of about 45° to $47\frac{1}{2}^\circ$, and be rather steeper in exposed positions. Apart from the tiles already mentioned, there are others specially shaped and adapted for particular purposes. Glass tiles are built into a roof to help to light the interior, and there are various fancy shaped and special purpose tiles.

Fig. 13. Attractive effect of a cottage tile-hung with dark red sandfaced tiles of an ornamental pattern.

The repair of tiled roofs usually consists of raising the tiles in the vicinity of those which are damaged, pushing them upward and lifting them over the battens, replacing them in a similar manner with new tiles. In all such roof repairs, the use of a proper roof board or some adequate method of protecting the tiles from breakage is of paramount importance, otherwise more damage is likely to be caused. One plan is to rest a light ladder upon two large sacks filled with straw. These are beaten down comparatively flat before they are rested on the roof, and act as a soft pad between ladder and the

tiles. The amateur should attempt only the simplest replacements (e.g. to a low roof, such as that of an outbuilding). The builder uses a special “duck” ladder, which is securely fastened at top and bottom. Apart from the likelihood of the amateur damaging the sound part of the roof, there is considerable personal risk in work carried out on a high roof.

Decorative Tiles. With the advance of hygienic wisdom in the home glazed tiling for kitchen, scullery and larder is becoming more general. Though other suitable mural coverings are somewhat less expensive tiles are worth the extra cost where durability, cleanliness and labour-saving are the first considerations; also they do not depreciate in wear. The advantages of tiles in the bathroom are obvious and the scheme is sometimes completed by a tiled floor. Where paint is used for the walls, inset tiles form an excellent splash back for the bath and lavatory basin.

British glazed tiles are unexcelled in quality, colour and designs. Fine decorative mural tiles are made of glass as well as of clay. The glass has a matt surface, is semi-opaque and can be obtained either stained in plain colours or painted with pictorial designs. Use is made of these for inset borders and wall panels.

The depth of the glaze of earthenware tiles varies with the style of the design. In some cases this is in relief, in others it is painted, while a third class of tile depends for beauty only on its fine monochrome glaze. In choosing tiles for a hearth and fireplace, should a pictorial pattern be required, only good designs should be considered, as cheap ones are unpleasant to live with and plain tiles of harmonious colouring are preferable.

These tiles are generally small and square, varying from 3 to 6 in. in size. They are laid in a similar manner to flooring tiles on a concrete bed with plaster or mortar. Generally when a tiled fireplace is purchased a hearth is laid to match, and tiled curbs are obtainable.

Simple Tiled Work. If it is only desired to half-tile a wall, the joint between tiles and plaster wall face is made with a simple wooden moulding. A tiled sink back is invaluable in the kitchen of a small flat. Tiles of a suitable character can be obtained from the better-class ironmongers and may be set in place against the wall with a good backing of plaster, especially when the tiles will fit under a window ledge. A proper key must be provided to the brickwork of the wall, as described in the articles on Cement and Rendering. To avoid the difficulty of cutting the tiles to the slope of the draining board, the latter can be removed, cut back a little, and refixed. The joint between the sink top and the tiles is preferably made with strong Portland cement mortar. The tiling of large areas is hardly a job for the home worker, and the services of an experienced workman should be obtained for this.

Tile Paper. This term is used to describe wallpaper the surface of which is printed to represent tiling. *See* Wallpaper.

TILLANDSIA. These are hothouse evergreen plants with large, strap-shaped, green or coloured leaves and coloured bracts. They flourish in pots in a well-drained compost of loam, with which sand and broken brick are mixed, and are propagated by detaching and potting the suckers or offshoots in spring. *Lindenii* and *splendens* are two of the best sorts.

TIMBALE: In Cookery. Rich and savoury mixtures of meat or fish, such as scallops of chicken, small birds, game, lobster or oysters may be served in the ornamental case known as a timbale. The case may be composed of macaroni, spaghetti, or even of aspic, but the shape is invariably round and it is usually cooked in a special mould.

For a macaroni case the large variety should be used. This must be boiled with stock and then cut into $\frac{1}{2}$ in. lengths. A plain, buttered, round mould with a rounded top should be used, and the pieces of macaroni so arranged that they line the whole inside of the mould standing on end. Over these a layer of forcemeat is placed, and the surface of this is smoothed with a knife dipped in hot water. The forcemeat is necessary to prevent the portions of macaroni from slipping. The mould is then filled up with a savoury mixture and steamed.

Any mixture of cold meat, game or poultry is suitable for filling the timbale. The proportions are as follows: $\frac{3}{4}$ lb. cold cooked meat, chopped small, 2 oz. white breadcrumbs, 1 oz. butter or dripping, 2 eggs, 1 dessertspoonful chopped onion, half teacupful stock, 2 teaspoonfuls chopped parsley, $\frac{1}{2}$ pint brown sauce, salt and pepper.

Melt the butter in a saucepan, add the onion, and fry lightly, then remove it and mix with the meat, crumbs, and parsley. Beat the eggs, add the stock, stir into the rest of the ingredients, season well, and be sure that all the ingredients are mixed smoothly and evenly. Put the mixture, a little at a time, carefully into the lined mould, and press in gently but firmly. Twist a piece of greased paper over the top, and steam the timbale for half an hour.

Take off the paper, and turn out the timbale carefully on to a hot dish, and strain the hot brown sauce around it.

Beef Timbales. Timbales made from spaghetti and cooked beef can be prepared thus. Break 2 oz. spaghetti into small pieces, wash it, and then cook it in a pan of boiling water until it is tender. Grease some small, plain moulds, and line the sides and bottoms with some of the strained spaghetti, pressing it well to make it adhere. Then fry a peeled and chopped onion and a chopped mushroom in 2 oz. dripping. Mince 6 oz. cooked beef previously freed from skin and bone, and add to it 3 tablespoonfuls breadcrumbs, 1 teaspoonful chopped parsley, the cooked onion and mushroom. Mix well, add salt and pepper to taste, about $\frac{1}{2}$ gill brown gravy, and a beaten egg. Put the mixture into the prepared moulds, cover it with the remainder of the spaghetti and tie a greased paper over each. Steam the timbales for about 30 min. and, when they are almost cooked, fry 4 tablespoonfuls freshly cooked or bottled runner beans in 2 oz. butter. Turn out the timbales carefully on to a hot dish, pour a gill of hot brown gravy round them, and use the beans as a garnish.

Fish Timbales. These are usually made with an aspic case. Turbot, halibut, or any firm white fish may be used. Salmon also is good in a timbale. To make, pound some of the cold cooked fish with enough stiffened white sauce to moisten it, adding seasoning to taste; then line the inside of a large timbale mould with some melted aspic jelly. When it has set, mask it with the pounded fish and fill up the centre with some flaked fish, also moistened with white sauce to which has been added some cream and a little piquant flavouring. Put a layer of the pounded fish on top, and leave the whole to set. When quite firm, turn it out of the mould on to a dish and garnish it with chopped jelly and salad.

TIMBER. The trunk and larger limbs of trees are usually known as timber after they have been felled and stripped of the outer covering of bark. Timber trees are those which can be used for general building or woodworking purposes, and they are classified into two groups, conifers and broad-leaf trees. Examples of the former class are northern pine, producing yellow deal; *Pinus strobus*, producing yellow pine; *Larix europaea* or larch; and *Pinus rigida* or pitch pine. Of the latter class, oak, ash, lime, and sycamore are examples. There is also a sub-division into hard and soft woods.

Timber trees which have reached maturity are felled during the autumn and winter, when the sap is more or less dormant. The timber has then to be seasoned, during which process it shrinks and dries; it is then converted to suitable sizes, and further seasoned prior to use. The newly felled tree is called a log; when trimmed it is known as a balk. When sawn, the various sizes are known as deal, plank, board, batten, scantling, and quartering. *See* Beech; Deal; Grain; Mahogany; Oak; Wood, etc.

TIMING: For Engine Speed. The power which is developed by any type of internal combustion engine will depend entirely upon the correct timing of the valves and the ignition, assuming that the compression, carburation, and sparking plugs are in order.

To deal first with the valves, there are four phases in the cycle of their operation, namely, induction, compression, explosion or power stroke, and exhaust. Not less than two valves per cylinder are required, one controlling the inlet of the fresh gases, the other the exit of the burnt gases; these are known respectively as inlet and exhaust valves. They are timed through the medium of the camshaft to open and close at the correct moment of piston position.

The greater the speed of the engine the earlier must the inlet valve open, and remain at its full open position until the piston has just started on the up stroke. The object of this is to give the gases the maximum of time in which to enter the cylinder.

Owing to the continuity of direction or flow of the gases, the fact that the crankshaft has just passed the bottom dead centre and is about to start the piston on the up stroke is not felt by the gases until well after the inlet valve has closed, thus allowing the compression stroke to take place.

Timing. Fig. 1. Showing diagrammatically some examples of chain driven timing gears.

Meantime the exhaust valve is closed, and it remains closed until the piston has descended to within approximately $\frac{1}{8}$ in. from the bottom of the power stroke, at which point it opens, and does not again close until just before the top of the stroke is reached. This period is termed the exhaust stroke. Immediately the exhaust valve closes, the inlet valve opens. Sometimes the timing of the valves overlaps, i.e. the inlet valve opens just before the exhaust valve closes. Especially is this the case with the high-speed engine such as is used in

sports models and racing cars.

In all cases the timing diagram issued by the makers of the engine should be strictly adhered to. Timing gears being positively driven and contained within the crankcase are lubricated by ducts connected with the oil system and protected from any chance of derangement other than a fracture of the parts involved.

Before dismantling a timing gear the setting should always be noted carefully. In most cases marks will be found at the root of a tooth of one wheel that denote its position in relation to corresponding marks on the wheel with which it is in engagement. These marks should be brought together and a reference made of piston position, i.e. make absolutely certain whether the timing is marked for the

commencement of the inlet stroke or the exhaust stroke, as makers are not all in agreement on this point.

Accuracy in re-assembling is essential if untoward consequences due to back-firing are to be avoided. If the amateur is not confident of his ability to re-time correctly he will be well advised to employ expert help.

With multi-cylinder engines the periphery of the flywheel is sometimes marked to show the top and bottom dead centre of the crankshaft, with adjacent marks reading inlet and exhaust, to show the point at which the respective valves open.

Timing Gear. All timing gears for four-stroke engines have a two to one reduction, i.e. the crankshaft makes two complete revolutions to one revolution of the camshaft the former drives. The two types of timing gear in common use are the spur cog-wheel drive and the silent chain drive. The silent chain drive may be carried out in three ways as shown in Fig. 1. The simplest arrangement is that depicted at C, one chain embracing the three sprocket wheels; by varying the position of the magneto sprocket, which is fitted on a separate bracket, the whole of the gear is adjusted.

The arrangement shown at A employs two chains. The magneto chain can be adjusted by the means described for C, but it is only possible to keep the camshaft chain at a uniform tension by fitting a spring-fed jockey sprocket wheel, as shown. In most cases where two separate chains are employed, the arrangement is as shown at B, with the chain adjustment the same as at A.

The gear-wheel design of timing gear as commonly employed for multi-cylinder car engines is shown at A (Fig. 2). With a view to silence in operation, skew or helical gears are frequently used, and very often the large wheel which drives the camshaft is formed of vulcanized fibre, supported

Timing. Fig. 2. Diagrammatic examples of cog-wheel timing gears. A, for multi-cylinder car engines; B and C, types for motor cycles

on both sides by a disk of phosphor bronze. The timing gear for the overhead valve is often identical in principle with long tappet rods, but fitted to connect from the cams to the overhead rocker arms. An alternative arrangement is the positioning of the camshaft as a part of the detachable head, i.e. the detachable head, valves, rocker arms, and camshaft form a complete unit.

With this arrangement the drive to the camshaft is either by silent chain or some form of toothed wheel drive, transmitted to the camshaft by means of a vertical shaft that in turn is driven off the crankshaft. Since the timing gear is disturbed each time the cylinder head is removed in the process of

decarbonizing the engine, careful note should be made of the timing marks on the wheels.

Sometimes the camshaft is connected to the drive of the vertical shaft by means of a disk coupling that is provided with a location stud, thus ensuring the correct timing of the valves when reassembling the unit. With this design the removal of the detachable head in no way interferes with the timing gear.

Timing the Spark. Of equal importance is the timing of the ignition, whether it be by magneto or by the coil and distributor method. The two systems in common use are known as the fixed and the variable. With the former the spark should be set to occur just before the piston reaches the top of its stroke. By this arrangement the crankshaft has crossed the top dead centre before the full force of the explosion is felt. No definite rule can be laid down for this setting, because the actual amount of lead given will vary with different types of engine. On an average the platinum points of the contact-breaker should be set to part just when the piston is still within approximately $\frac{1}{8}$ in. from the top of the compression stroke. With variable ignition the platinum points should separate at the top of the stroke, with the control lever for the ignition at the full-retard position. By so doing, on advancing the control lever the spark occurs earlier.

The time taken by the gases to reach a state of complete combustion is always the same. Therefore, at high engine speeds the spark must occur proportionately earlier, so as to assure complete combustion by the time the piston is starting to travel downward on the power stroke. As engine speed decreases the spark must be retarded, otherwise a pronounced knock will be manifest.

Although with coil and distributor ignition the same end is attained, the method of control is entirely different. The usual procedure is to rotate the distributor about the wipe contact, thus causing the wipe to make contact with the segments of the distributor either early or late in relation to the positions of the piston. *See Magneto; Tappet; Valve.*

TIN: The Metal. A white, soft, and malleable metal, tin is not used to any extent by itself. Owing to its softness and ductility it is easily worked, and articles made from it can be finished with a brilliant polish, but the surface is easily scratched and bruised. It is considerably used as an alloy, and it readily combines with copper, antimony, bismuth, zinc, and lead. Tinman's solder is composed generally of equal parts of tin and lead.

When hardened with a small amount of copper, tin forms the best pewter, and although it is often combined with lead for the same purpose, the result is not satisfactory. Bronze is formed with a larger proportion of copper than that used in pewter. Tin is employed for coating iron and copper vessels used for cooking purposes, in the latter case to prevent the poison from the copper getting into the food.

The most considerable use to which tin is put is in forming a protective covering for thin sheet iron which is commonly known as tin, but correctly described as tinplate. It is also used on iron wire and small articles made of iron. So long as the protective coating remains intact the iron is prevented from rusting. *See Tinplate.*

TIN LIFTER. A kitchen utensil used to take hot tins and dishes from the oven, a tin lifter somewhat resembles a pair of pliers in appearance, and has the same gripping action. If kept in a convenient place near the stove, it does away with the necessity of an oven cloth, and protects the hands from minor burns.

TINNED FOOD. Tinned or canned foods, if they are properly handled and stored, will keep longer and better than any other class of preserved food; in fact, certain goods, such as salmon and sardines, improve with keeping. Some classes of foods, however, should only be kept about a year; these are fruits canned with the stones, such as cherries and plums, and all classes of fruits and vegetables which contain acid in fairly large proportion, such as apples, pineapples, tomatoes and asparagus.

Tinned shellfish is liable to discoloration by reason of the large proportion of natural phosphate contained in it. To overcome this difficulty, such fish as lobsters, crabs, crayfish, prawns, etc., are

now wrapped in heavy vegetable parchment paper, and as a result can be kept much longer than formerly.

Glass containers are also used for preserving foods, and much thought and care has been exercised in producing caps which will form a reliable airtight seal. The practical advantages attached to cans are that they are easier to handle in the factory, are less fragile, weigh less and are more economical as regards transport costs.

Improved Containers. One of the greatest improvements in the canning industry of recent years is the introduction of a tin commonly called the sanitary tin. In this the use of solder is entirely eliminated, thus doing away with the danger from the acid of fruits acting upon it. The side seams are locked and lapped, while the ends are stamped out of tin plate and edged with rubber solution. The bottom is attached by means of a double seam, and the same process is gone through after the can is filled. Further improvement in canning has been attained through lacquering the inside of the tin to keep the contents a natural colour, for such products as fruit, crab, lobster, etc.

Examining Food. The public are protected by the examination of all imported canned goods at the port of entry. The inspectors, acting under the local authority, examine each consignment. As it is impossible to open every case and examine each can, they take a percentage of the consignment, which is usually about 10 per cent, and carefully inspect these. If it is found that only a small percentage of cans are “blown,” or otherwise unfit for food, the cargo is passed. Should the percentage of doubtful tins prove large the whole consignment is thoroughly examined. Further examination of tins is periodically undertaken at the shops.

In case some escape the vigilance of the food inspectors the following may prove helpful. “Blown cans” and “swells” are tins in which certain organisms have not been killed; they develop in the food and form a gas, which causes the ends of the tin to swell out, or become convex. Such tins, when tapped with the fingers or something hard, give off a “drummy” sound instead of the clear resonant note of a perfect can. These should not be used, as in all probability the food is unfit for human consumption. In all doubtful cases, if the tin has only just been bought, either return it to the retailer, or submit it to the local food inspector, or medical officer of health, for his opinion. *See* National Mark; Sardine, etc.

TIN OPENER. A strong and really adequate tin opener should be included in every kitchen outfit. The commonest type has a sharp blade for cutting, with a projecting spike beneath. The latter is used to knock a hole in the side of the tin. The blade is then inserted, and the cutting done all round the edge of the tin. The tin opener must be kept clean and free from rust.

Sardine tins are usually supplied with a key opener, which, when turned, rolls back the top of the tin. These are often unpractical and resort has to be made to the ordinary opener. In opening tins, care should be taken to see that the cutter does not slip, for cuts caused by the jagged edge of a tin often result in blood poisoning.

TINPLATE: How it is Worked. Tinplate is a sheet of iron or steel coated with tin on either side. It is commonly made in two qualities or varieties, known as charcoal and coke brands. These names originated when tinplate was made from charcoal iron for the better quality plate and coke iron for the inferior grades. The distinguishing names are retained, but now represent the depth and finish of the tin coating.

Coke plates are largely used for can construction. For commercial tinplate a common proportion of pure tin to the sq. ft. of plate is .023 or .024 lb. Tinplates are made in sizes measuring 10 in. by 14

in., and also in multiples of these sizes for larger work. The sizes most commonly used measure 20 in. by 18 in. and 20 in. by 14 in.

The thickness of tinplate varies to standard commercial sizes, measured in Stubbs' wire gauge. The thinner gauge plates are known by the table of weights and gauges herewith:

Designation	Gauge	Weight per sq. ft.
56 lb.	38	0.257
75 "	34	0.345
100 "	30	0.459
130 "	26	0.803

Tinplate is often called block tin or simply tin, but these appellations are erroneous. Tinplate in which a certain amount of lead is added is known as terneplate, and consists of soft sheet steel

plates coated with a tin-lead alloy, of which a common alloy is made with $\frac{1}{3}$ pure tin to $\frac{2}{3}$ lead. This form of tinplate has considerable rust-resisting properties, and is used in roofing work. For this reason it is also known as roofing plate. Terneplate is manufactured in the same sizes as tinplate.

Tinplate lends itself to the construction of many articles to be found in the household.

A sharp pair of tinman's snips should be used for cutting the plate, and the amateur may find it an advantage to wear an old pair of gloves, as it is very easy to cut the hands on the rough and sharp edges of the material. In cutting tinplate, care should be taken to keep the tin free from scratches or buckles.

Tinplate working. Fig. 1. Bending to a cylindrical shape. Fig. 2. Closing a seamed joint, which is made by turning up the edges on opposite sides. Fig. 3. Turning over a straight lip. Fig. 4. Forming a neat edge to a sheet of tin by working it round a wire.

How to Bend Tinplate. In order to bend it, the tinplate is smoothed round a cylindrical former where a uniform curved surface is required. Care must be taken to avoid too sharp a bend in one particular place. The whole length of the sheet should be held, and the bending process not localised to one edge of the sheet. In bending the sheet into a curved surface the most difficult part will be

found to be the ends of the material. The commencing end should first be bent to the required radius, then the main body of the sheet.

The operation of bending a sheet of tinplate to a cylindrical shape is shown in Fig. 1. Where an article of conical shape is required, a correspondingly tapered former should be used the tinplate being first marked out to the correct shape. The risk of wasting the material by incorrect cutting may be obviated by marking and cutting a sheet of stiff brown paper to the size required. If this is found to be correct, the paper may be pasted on the tinplate, or the tinplate marked off from the paper. Before cutting, allowance must be made for the seam or method of joining. Where a soldered joint is to be made only a slight overlap will be required; it is known as a simple lap seam.

Further strength is imparted to the joint by means of the grooved seam. This is illustrated in construction in Fig. 2, where the edges are turned up on opposite sides of the tinplate to form a hook when the ends are brought together. After the ends of the cylinder have been folded together the seam is hammered flat by inserting a bar to the inside of the tube, on to which the seam rests during the hammering process. In allowing for the seam in marking out, three times the width of the single turned-over edge should be allowed. If the joint is to be watertight the seam must also be soldered. An easy method of turning over an edge or lip is illustrated in Fig. 3 where a straight strip of metal is held against the bend while the lip is hammered flat to the top of the strip.

Where it is required to fit a bottom to a cylindrical object in tinplate several methods of fitting are utilized. Probably the most simple for the amateur is to cut a disk of tinplate: fitting exactly inside the bottom of the cylinder or container. When in position, the work is turned upside down and the bottom soldered in place. Further to secure the bottom a ring of brass or similar wire is fitted to the inside of it and soldered in position.

Where the edge of a tinplate article is left exposed, it can be bent round a wire to form a smooth and neat edging, as in Fig. 4. This can only be accomplished successfully when the sheet is in a flat state, and it should be done in an early stage. As in the case of a lapped seam, extra metal must be allowed for the wiring of an edge.

Tinplate articles can be purchased so cheaply that it is not worth while to make such things as a kettle, or coffee-pot, which are seamed by machinery and shaped in a press. However, little toys can often be made up from odd pieces of plate or even from material got from a large tinplate box. Tinplate is useful for repairing utensils, as for example in mending a leaking kettle, watering-can, etc. When an acid flux is used all traces should be washed away or the surface will be corroded. A domestic utensil should be boiled out, or washed out with boiling water and well rinsed before using. *See Soldering.*

TIPSY CAKE. This wine-flavoured cake can be made with a tower shaped sponge cake which should be at least 24 hours old. Cut the cake into thick horizontal slices and spread these with apricot jam. Return them to the original shape of the cake and place it in a glass dish. Half a bottle of sherry is usually poured over it, but the quantity varies according to the size of the cake. Baste it at intervals with the wine which runs from it, and when quite soft stick all over the surface splinters of sweet almonds which have been blanched and dried, without colouring, in the oven. Pour over all a cold, thick rich custard and decorate the base of the cake with little heaps of stiffly-whipped cream, glacé cherries and angelica. *See Blanching; Trifle.*

TIRES: THEIR USE, CARE AND REPAIR

How Motorists May Avoid Expense and Danger

Too often the car owner is content to see that his tires are not visibly slack. If he will follow the hints and suggestions given here he will find that a minimum amount of regular attention will secure him from any serious tire trouble. See also Bicycle; Motor Car; Perambulator; Puncture.

The wheels of all vehicles have special outer wearing surfaces or tires, whether they are the flanged steel tires of railway vehicles, the steel tires of horse-drawn vehicles, solid rubber tires, or the pneumatic tires used on bicycles, motor cycles, and motor vehicles. Only the pneumatic tire need here be considered in detail.

The high comfortable driving speeds of modern motor vehicles would hardly be possible without pneumatic tires, which cushion the innumerable minor inequalities of the roads and co-operate with the ordinary suspension springs and with the upholstery springs to reduce the effect on the passengers of the more serious road defects.

The original cycle tire invented by Dunlop consisted of an endless inflated rubber tube fitted in the wheel rim. From this has evolved the modern pneumatic tire consisting essentially of an elastic rubber tube containing compressed air, and a protective outer cover or casing of flexible rubber rendered practically unstretchable by cotton reinforcement embedded in the rubber.

In a pneumatic tire compressed air is utilized to support the weight of the vehicle, to absorb shocks, and to transmit the driving and braking efforts between the wheel and the road. It will fail to achieve these objects unless inflated to the proper pressure. When so inflated the air forces the cover outwards with a uniform pressure of so many pounds per square inch, and the part in contact with the road is flattened until the total pressure exerted by the air from the inside of this flattened area equals the load carried by the tire. The higher the pressure the smaller is this flattened area.

All tires are either of the beaded edge type or the wired (straight sided) type. Practically all modern cars, motor cycles, cycles, or aeroplanes are fitted with tires of the second type. Very large numbers of beaded tires are still in use, but this type of tire is rapidly becoming obsolete.

The beaded tire is fitted on a special rim having inturned edges or clinches, as shown in Fig. 1. Each edge of the tire is made with a hook or bead which engages under the clinch and has a core of hard rubber. The bead can only be placed in position by stretching it over the clinch, but is nevertheless too elastic to remain on the rim except with the aid of the internal pressure, which forces it into the clinches of the rim and thus holds it firmly in position. If the pressure is seriously reduced the beaded tire, unlike the wired tire, is liable to be forced off the rim by lateral pressures when the vehicle is swerving or cornering.

The straight-sided tire, on the other hand, has no beads. The edges are reinforced by several strands of steel wire which render them practically inextensible, and the rim is also of entirely different design. Three forms of rim suitable for straight sided tires are in use, namely: The flat base, split transversely (Fig. 2); the flat base with one fixed and one detachable flange (Fig. 3); the well base

(Fig. 4). The first type has rarely been used on British cars, since the rim is necessarily detachable from the wheel, but it has found much wider application in America.

In the second type of rim the detachable flange is sprung into a groove on one side. The flange can be detached by using a lever, and the tire may then be removed sideways without much difficulty. This form of rim is largely used with heavy commercial tires of the type frequently described as giant pneumatics.

The well type rim is widely used on cycles and motor vehicles. It possesses the advantage of simplicity and lightness coupled with ease of removal and replacement.

The internal air pressure in the tube puts the cover into considerable tension. To render the rubber cover practically inextensible without seriously impairing its flexibility a cotton reinforcement is used. At one time the reinforcement consisted of a number of layers of coarse woven fabric, with the strands running one way, known as the warp, crossing over and under the strands running the other way, and known as the weft. When subjected to tension the strands are continually bent first one way and then the other. As a tire flexes when in use the strands work over one another and the friction and distortion creates a great deal of heat. This method of construction, although widely used until a few years ago, is now practically obsolete. The reinforcement used in all rubber tires to-day consists of four, six or more layers of cord made from fine Egyptian cotton. Each cord is completely embedded in rubber independently of the others, so that friction between them is eliminated and the tire if properly inflated runs much cooler, while much longer mileages are obtained.

A cross section through a modern wired tire is shown in Fig. 5, and the detailed construction of one of the side walls is shown in Fig. 6. The individual cords of each layer are separated from one another by rubber and the superimposed layers are also not in actual contact. Each layer is bent round the wire edge with a fair amount of over-lap, and is led diagonally round the cover, and similarly

Fig. 5. Cross section through a modern wired tire and rim. Fig. 6. Detailed construction of one of the side walls

bent round the wire in the other edge. The next superimposed layer is led diagonally in the opposite direction round the tire. In order to ensure long wear and a reasonable degree of freedom from puncture the tread of the tire consists of a considerable thickness of rubber, while the outermost layer of cord is further protected by the breaker strip A, which consists of a strip of coarse canvas running right round. The tire is finally vulcanized or cured by raising it to a certain temperature so as to render it tough, completely elastic and reasonably hard.

Considerable attention is given by tire manufacturers to the design or pattern formed on the tread. Each manufacturer endeavours, for commercial reasons, to produce a distinctive design, but the tread must also possess good wearing qualities and at the same time show little tendency to skid or slip. For this reason all treads are now manufactured with a number of deep, sharp-edged

depressions which enable it to bite into the firm surface of the road through a layer of mud. When the tire has worn down so that the pattern is no longer visible, risk of skidding is increased, quite apart from the greater probability of puncture. No cover should be worn so far that the breaker strip appears. The police in some districts even prosecute the owners of cars with smooth tires, on the ground of danger to the public through the increased liability to skid and slip when the brakes are applied.

Although in the past motor cars have often been under-tired, most of the standard pneumatic tires supplied to-day are adequate in size to provide reasonable shock absorption and to give long wear. For this reason it is unnecessary, in order to obtain increased comfort, to use lower inflation pressures than those recommended by the manufacturers. All tire manufacturers are substantially in agreement as to the pressures at which the different sizes should be run, and all tires are liable to the same kind of failure if they are not run at the proper pressure. The pressure in any given size depends within limits upon the load carried. The table below shows the pressures recommended by the Dunlop Company for the various permissible loads on various sizes. The diameter as a whole is not mentioned; only the width need be considered. In many cars the load on the front tires is less than that on the rear tires, but the Dunlop Company recommend that, except in the case of high pressure tires, the front tires should be pumped as hard as the back in order to provide easy steering and to reduce wear of the tread.

The appearance of a tire is no guide to the inflation pressure. Long before a tire looks flat, irreparable damage may have been done. The only satisfactory method is by the use of a pressure gauge applied to the valve independently of the pump. The gauge should be used at least once weekly and any shortage should be made up. If this is done regularly very little pumping is required.

Results of Under Inflation.

Reference will now be made to a few of the more probable results of under inflation. Every tire when working is flattened slightly at the part in contact with the ground and one result of this flattening is a slight bending of the side walls. If the inflation pressure is insufficient this bending becomes excessive and is greater than the natural flexibility of the walls can deal with, so that the cord frays and ultimately breaks. The effects may not be immediately apparent. By the time that the outer coating of rubber or the tire paint shows signs of a split running round or partly round the side wall, the cord reinforcement may be ruined beyond repair.

A further result of under inflation is excessive wear due to the tread not being sufficiently supported and therefore being flabby, so that it distorts and scrapes over the road much more than usual. This wear is additional to the normal wear due to the transmission of steering stresses and the driving and braking efforts.

The front wheels on nearly all cars are splayed outwards slightly, so that there is a tendency to wear rather more on the outside than on the inside. When the tires are insufficiently inflated, the outer part wears down rapidly. In the ordinary way any differences are small and can be equalized by turning the tire round about every two thousand miles.

Another form of trouble known as a concussion burst is due to a tire striking a sharp projection, such as a brick, at speed. Such a blow may be so violent and so localized that it will fracture one or two of the cord reinforcements, and this trouble may spread until the cover bulges or bursts. The effects may not become apparent until several weeks after the actual blow causing the trouble. The probability of damage is reduced to a minimum by running the tires at the proper pressures.

The front wheels of a car may be parallel to one another but should preferably be given a small amount of "toe-in," the front edges of the rims being between ⅛ in. and 5/16 in. closer together than the rear edges. Any departure from these conditions of alinement will result in excessive wear.

Apart from troubles due to under inflation or non-alinement, the amount of wear of tires depends very greatly upon the manner in which a vehicle is driven. The forces exerted between the tire and the road when a car is accelerated or braked suddenly are very great and are all transmitted through the tires. It will thus be evident that the service obtainable from tires is largely within the control of the driver.

Care of Tires. However tough the rubber of the tread be, it is liable to be cut by sharp flints, nails, glass, etc. A small superficial cut is of no importance, but a cut sufficiently deep to reach the cord reinforcement may ruin a tire in a short time owing to moisture reaching the cotton and causing it to rot. The trouble may thus spread outwards from the original opening and ultimately result in a burst

which is too large to repair. A lookout should therefore be kept for deeper cuts, and they should be cleaned out and filled up with some special rubber composition.

Rubber is rendered soft and spongy by exposure to oil or paraffin. Any oil on the tires due, for example, to a leaky back axle or pools on the garage floor should be cleaned off with a rag and a little petrol. Petrol itself is a solvent of rubber, but evaporates so quickly that it cannot in the ordinary way cause any damage.

Whenever a puncture occurs, the first consideration should be the cause of the trouble, and the cover should therefore be examined carefully for evidence of a sharp flint, the point of a nail, etc. Punctures or cuts in tubes may be repaired by vulcanizing or patching. The former method need only be applied when the cut is large, and is best left to firms having suitable vulcanizing apparatus. The possession of vulcanizing equipment by a private owner is seldom worth while. Most punctures can, however, be repaired quite readily by patching, and the following remarks will apply to most of the puncture repair outfits available to-day.

The tube must first be thoroughly cleaned and rendered free of oil, grease, or moisture. This may be effected by a little petrol applied with a rag or by rubbing with the special perforated metal scraper supplied with the outfit. Solution from a tube is then applied over a sufficiently wide area and in some cases the surplus is scraped off at once with a knife; in other cases the patch must not be applied until the solution has become tacky, or almost dry.

While the solution is drying the patch can be cut out from the sheet, the edge being bevelled by a pair of scissors. An attempt may then be made to tear it in halves across the middle. The linen protecting the prepared side will thereby be torn in halves, but the rubber will yield and will not be affected. Half of the linen may then be peeled off and care must be taken that the fingers do not touch the surface which is thus exposed. This exposed surface should then be applied to the tube, as shown in Fig. 7. The other half of the linen should then be pulled off and the remainder of the patch stuck down. Finally the patch should be rolled hard or worked down with considerable force to ensure good contact with the tube. Neglect of this final operation may make it necessary to remove the patch—a somewhat difficult operation—and apply a fresh one.

Many small punctures cannot readily be found by inspection and it is then necessary to remove the tube completely, inflate it with air as far as this can safely be done, and immerse it in water. A small bowl of water, in the absence of a large receptacle, is sufficient for this purpose. Each section when immersed should be watched carefully for bubbles of air, which in the case of a small hole may only rise at intervals. The position of the puncture when found should be marked with pencil, but the whole of the tube should be tested for any further punctures. A slight leakage from a tire may be due to a defective valve. This may readily be ascertained by turning the wheel until the valve is on the top and then testing its tightness by means of a small cup filled with water. Should there be any leakage the inside of the valve must be replaced.

Tire. Fig. 7. Showing a patch on a tube partly stuck down

Removing and Replacing Tires.

Reference has already been made to the ease with which a straight-sided tire can be removed from or replaced on a well type rim. The method of doing this is illustrated in Fig. 8 The edge should not in any circumstances be forced over the rim, as no useful purpose is served and it may be damaged. Before removing the tire all parts of the valve should be removed and both edges of the cover

should be pushed right into the well at the part diametrically opposite the valve. The edges of the cover near the valve may then be gently levered over the rim. When replacing the cover one edge should be pushed over the flange of the rim right down into the well and the edge of the other side of the cover can then be pushed easily over the flange. The tube should be slightly inflated but not stretched tight and is then placed in the cover with the valve projecting through the hole in the rim. In many cases the valve projects towards one side and the tube must therefore be placed correctly in position. The second edge of the cover may then be placed in position by pushing it down into the well of the rim at a point diametrically opposite the valve, and it may be gradually worked over the flange. The last few inches may be forced on, if necessary, by small levers.

The removal and replacement of beaded edge tires presents somewhat greater difficulty, since the beads have to be sprung over the clinches of the rim. To remove a tire the straight end of the lever is forced in as shown in Fig. 9 and the lever is bent round, using the clinch of the rim as a fulcrum, as shown in Fig. 10. Two or three levers will have to be employed, working right round the rim in this manner.

In general it is sufficient merely to remove one edge of the tire, leaving the other on the rim. The tube should be partly inflated and then inserted into the cover and as far as possible over the rim, the valve being inserted through the hole in the rim. Starting near the valve the edge of the cover may be inserted in the clinch and worked into position gradually all the way round, using the hooked ends of the tire levers as shown in Fig. 11, but care must be taken that the lever does not nip the tube, as shown in Fig. 12. Two or three levers should be used, but it will generally be necessary to expend some effort to force the last section of bead over the clinch. The levers should always be held firmly, otherwise the elasticity of the tire may cause them to jump up violently into the face of the operator or a bystander.

Fig. 8. Removing and replacing straight sided tires fitted to well type rims. When cover at A is pushed down into the well, the edge at B will come over the rim easily. Force must not be used

Figs. 9 and 10. Removing a beaded edge tire. Fig. 11. Replacing a cover. Fig. 12. The tube must not be nipped, as shown here, when replacing cover

TISSUE: The Dress Fabric. All woven fabrics are tissues in one sense, and certain of them are officially described as woollen tissues or worsted tissues in British trade returns. The French call light cloths tissues as distinct from heavy cloths or draps. The word is often used in English in order to denote tinsel cloths.

TOADFLAX. There are some charming annual and perennial plants among the toadflaxes, all suitable for the rock garden and flower border. The most vigorous kind is the Dalmatian toadflax (*Linaria dalmatica*), it grows 3 feet

high bears yellow flowers in summer, and thrives in ordinary soil. *Linaria alpina* is a pretty little plant for the rock garden, bearing orange and purple flowers. The Kenilworth ivy (*Linaria*

cymbalaria) is a trailing wild plant useful for planting in walls; it has Lilac-coloured flowers. It is best to raise these plants from seeds sown in boxes in a frame in spring. The annual toadflaxes are easily raised from seeds sown out of doors in spring where the plants will bloom in summer: the chief species are *bipartita* and *maroccana*.

TOAD IN THE HOLE. The dish known as toad in the hole can be made from 2 lb. mutton or beef, $\frac{1}{2}$ lb. flour, 3 eggs, $1\frac{1}{2}$ pints milk. Sieve the flour and salt into a basin, stir in the eggs and a little of the milk, and beat all to a smooth batter. Gradually work in the rest of the milk and let the whole stand for at least half an hour.

Free the meat from fat, skin, and bone, cut it into neat slices, fry these in hot dripping, and then put them into a greased pie-dish. Sprinkle them with salt and pepper, pour the batter over, and bake the whole in a moderate oven for $1\frac{1}{2}$ hours. Serve it very hot, with a folded napkin pinned round the dish. If preferred, this can be made with sausage or cold meat, when it will require only about an hour's baking. *See Batter; Sausage.*

Toadflax. Purple double-lipped flowers of *Linaria bipartita*, a hardy annual

TOAD LILY. The chief species of toad lily is *Tricyrtis hirta*, a hardy, or nearly hardy, herbaceous perennial, with white, hairy stems, alternate lance-shaped leaves, and white, violet-spotted flowers in autumn; height about $2\frac{1}{2}$ ft. It should have a sheltered, sunny position in a friable loamy soil. Propagation is by division in spring. These plants may be grown in pots in the greenhouse.

TOADSTOOL. The popular name of toadstool is usually applied to an uneatable fungus as distinguished from eatable agarics, of which the common mushroom is an example. More than 1,000 species of agarics are known, some being poisonous.

It is often difficult to distinguish between edible and non-edible kinds. Suspicion should be aroused if any fungus has a thin cap as compared with its gills, and if the latter are of even length; if its collar is webbed or its juice milky; and if it quickly decays into a dark fluid. Caution should be used, also, if the stalk grows from one side of the cap.

The common edible mushroom grows naturally on hilly slopes or in open meadows, and in its early stage is like a small white globe. This form is followed by development of a flattish top with rough, brownish white skin and pink gills, the latter being just clear of the stem. When fully mature the gills change from pink to brown, and finally to a colour that is nearly black, the skin easily peeling off, quite unlike that of toadstools. It is best never to gather what are apparently mushrooms growing in woods, under trees, or other shaded places, unless with intimate knowledge of mycology. Even in open places indiscriminate picking is risky. *See Fungus; Mushroom.*

TOAST. Bread should be toasted evenly and only on the surface, and it must feel quite crisp to the touch. It is served either buttered or as dry toast.

Toast is used extensively for many culinary purposes. It forms a foundation for dishing various savouries, vegetables and small birds. Toast cut in shapes is used as a garnish.

Dry toast should be made with bread which is at least 24 hours old. Cut as many thin, even slices as will be required and toast each piece under the gas grill, or an electric toaster, or on the fork before a clear fire.

When the slice has been toasted each side lay it on a board, press it flat, and at once remove the crust, then stand it upright where it can be kept warm while the remaining pieces are being toasted. Toast should always be made as required; if kept waiting it will be hard and leathery. If the crust is not cut off immediately, the steam cannot escape and the toast becomes sodden.

For buttered toast, the bread should be cut rather thicker. After being toasted and the crust removed, the slice should be laid on a hot plate and the butter placed on it in small pieces, and as the butter melts it should be spread over lightly without scraping the toast underneath. Lay the second round, after toasting it, on the first, and butter it as in the first instance. Cut the slices of buttered toast into neat pieces and pile them on a very hot dish, covering them over.

For cinnamon toast mix equal parts powdered cinnamon and castor sugar, sprinkle thickly on the toast after buttering and place under hot grill or before a clear fire until the sugar melts and the cinnamon is incorporated with the butter.

French toast is a good way of using up slices of bread and butter which have been left over from tea. It should be made with rather thin bread and butter. Two slices are laid one over the other, with the butter side inwards. They are lightly pressed together, and should be toasted in the ordinary way. No extra butter is needed, as the butter already on the bread penetrates the soft part and also imparts a rich, crisp taste to the toast. It should be eaten very hot straight from the fire. Set a plate on the hearth to catch any falling grease.

Toast Water. This is a refreshing and wholesome drink. To make it, a very thin slice of bread should be toasted until it is thoroughly brown and dry all over, but it must not be burnt or blackened in any way. Put the slice of toast into an earthenware jug and pour over it 1½ pints of boiling water, then cover over the jug and set it aside till cold. The success of toast water greatly depends on whether the water is actually boiling when poured on to the toast and whether it is freshly made.

Toasting Fork. When toasting bread or cakes in front of an open coal or gas fire the use of a special fork is advisable. The simplest form consists of three or four short wire prongs and a long handle of wood or metal. More ornamental designs are also employed and reproductions of old designs in brass can be purchased for a few shillings.

Toast Rack. Toast racks are made of china, earthenware, silver, Sheffield plate, and electro-plate. There is not a great variety of styles in these pieces, but metal designs copied from 18th century models are usually more elegant than later ones. Specimens of the 18th century toast racks are fairly often seen. Some of them are boat-shaped, with beaded borders. Small china and semi-porcelain toast racks are made to match most modern tea and dinner services.

TOBACCO. In purchasing his tobacco the pipe smoker has to consider the qualities which he desires in his particular brand, and also the strength which suits him. The latter consideration is the more important of the two, and the proof of it lies in the fact that practically every good pipe tobacco can be obtained in the three standard strengths, mild, medium, and full flavoured.

Pipe tobaccos are sold either loose or in packets of 1 oz. and 2 oz. Larger quantities are retailed in tins containing ¼ lb., ½ lb., or 1 lb. While the majority of smokers usually buy their tobacco in small quantities, it is often convenient and slightly more economical to lay in a week's supply or more at a time.

Tastes differ proverbially as to the choice of a brand. It does not necessarily always follow that the more expensive sorts are the best for everyone. A good mixture at 10d. or 1s. per oz. may be quite as satisfactory as one costing 1s. 3d. per oz., although it lacks certain choice ingredients only to be found in the latter. It is all a matter of individual taste.

The first object is to get a cool-smoking tobacco. However fragrant and agreeable to the palate a mixture may be, the pleasure of smoking it is entirely spoilt if it is too hot on the tongue and perhaps has a tendency to heat up the bowl of the pipe. It is the lighter mixtures that are apt to offend in this way unless the blending is skilfully arranged; those which are liberally sprinkled with dark shreds burn more slowly and with a steady glow. For those who can smoke the strongest tobaccos no difficulty is likely to arise, and when the pipe is once properly lit a long, cool, and fragrant smoke should result.

The choice of a mixture is assisted by some knowledge of its composition. The principal ingredient is nearly always the Virginia leaf in one or other of its numerous forms. Of all kinds of tobacco this is easily the most popular. Virginia is graded in so many different qualities that only an expert can distinguish them all, but the smoker has usually no difficulty in picking one out for himself to be sampled at home. Several may be tried before the right mixture is obtained.

Between the two extremes of light and dark is the widely popular medium, which is neither too hot nor too strong, and generally has all the fragrant qualities, with only a moderate amount of the dark leaf. Even this, however, is too strong for some smokers, who should therefore select a light quality, as, for instance, one in which a quantity of oriental leaf has been blended with the Virginia. In most of these the leaf is cut very fine, just as it is in such strong, full-flavoured tobaccos as shag and returns. In other mixtures a broad-cut leaf is used, and in some a double-broad cut, so that even in the matter of cut the smoker has a variety to select from.

The range of tobaccos is further extended by the cut plugs, which are extensively in use. This is a very handy form of tobacco for pipe smokers. The plug is cut up into thin slices, which are packed in 1 oz or 2 oz. packets or in 4 oz. tins. From 2 to 3 slices are sufficient to fill the bowl of a pipe of average size. They should be rolled in the hand before being loaded into the pipe bowl. Some smokers prefer to buy their tobacco in plug form and cut it up for themselves. Cake tobacco is another form which is widely used. Like the plug tobaccos, it is sold in various strengths, the milder qualities being light in colour and the strong tobacco almost black.

It is in the loose mixtures that the retailer turns to account his knowledge of all the various kinds of tobacco leaf, the subtle variations in strength and flavour which different soils produce in the plant, and his skill in blending, for which long experience is required. One obvious advantage in buying the loose tobacco is that the smoker can see what sort of mixture he is getting, although, as a matter of fact, the average smoker knows comparatively little of the technical side of the subject, and is generally guided by considerations of price. It is therefore advisable in purchasing tobacco, as with most other things, to deal with a firm of repute.

Blending Tobaccos. Tobaccos of several strengths are used, varying in colour from a pale golden yellow to dark brown and black. These are laid out on a specially made table to be dried and matured, and are then blended in the proportions required in accordance with particular recipes. The bulk of the tobacco is American, the produce of Virginia, Kentucky and the Carolinas, but fine Turkish is also employed. Some of the more expensive blends receive a sprinkling of latakia, the aromatic leaf of Syria, which imparts a distinctive flavour that is highly esteemed by some smokers. Recipes for blending have a commercial value, and the details of many of those in the possession of manufacturing firms are carefully guarded secrets. Some retailers follow certain old-established recipes which they obtained from their predecessors in business, and these form an asset of distinct

value where a particular mixture has been popular perhaps for many years with a large circle of customers. Dealers who have expert knowledge make blends of their own, and sell them not only loose, but also in packets, where they have proved particularly successful, often with their own registered trade marks. Small dealers who are not themselves expert in this class of work may produce blends from recipes supplied by the large manufacturers.

Tobacco Pouch. Most pipe smokers carry their tobacco in a pouch or case made in various sizes and of some soft material such as india-rubber or oilskin, or a variety of leather, such as buckskin, with an inner lining of india-rubber. Tobacco is also kept in leather cases without india-rubber. A widely popular style of pouch is made entirely of rubber, one naif folding over the other in which the tobacco is contained. It is best to choose one in which the material is moderately thick, as the rubber is apt to wear and to cut at the creases.

Pouches of buck-skin or other material with a lining or pocket of rubber are more substantial in appearance, and with ordinary care will last for years.

Reindeer, antelope, chamois, doe, calf, and other skins are employed, and a silver shield or embroidered monogram is a customary form of ornament.

The leather wallet is another favourite variety, made from pigskin, crocodile, sealskin, and other leathers, strongly sewn together. Oilskin pouches are rectangular in shape and can be obtained in both large and small sizes. *See Pipe; Smoking.*

TOBACCO PLANT. The favourite tobacco plant for gardens in Great Britain is the half hardy annual *Nicotiana affinis*, which bears white flowers which are delightfully scented in the evening. It is raised by sowing seeds in a heated glasshouse in February and planting the seedlings out of doors in May or early June. There are several coloured varieties of red, crimson or pink flowers, but they are less fragrant than the white ones. All make good pot plants for the conservatory. *Nicotiana sylvestris* is a handsome plant, 5 ft. high, with large leaves and white flowers in summer. It is raised from seed sown under glass in spring. Commercial tobacco is obtained from *Nicotiana tabacum*, a plant which is of some decorative value because of its fine leaves.

For experiments in tobacco growing the annual *N. tabacum* may be sown in gentle heat in early spring and planted out in a sunny border in June. The plants should be freely watered, and will be ready for gathering for drying at the end of September.

Tobacco Plant. Fragrant white star-like flowers of favourite half-hardy annual.

TOBOGGAN FOR WINTER SPORTS

How to Build a Clipper for Two Adults

The amateur who wishes to make a toboggan should consult also the various articles in our work that deal with the tools and materials used by the woodworker, such as Amateur Carpentry; Bit; Bolt; Joint; Mortise; Spokeshave; while a glance through this article will suggest other references.

Toboggan. Fig. 1. Clipper toboggan to carry two adults. Its construction is described in this article.

As the sport of tobogganing consists mainly in coasting very rapidly downhill, the design of a toboggan, which is a form of sledge, must be strong enough to withstand rough usage. In its simplest form the toboggan consists of boarding fixed across a couple of wooden runners, but more elaborate forms are in use to accommodate parties instead of a single person.

A clipper toboggan large enough to carry two adults is shown in Fig. 1, its component parts being detailed in Fig. 2. Only well-seasoned pine, ash, or elm of the best quality should be used, cut to size and ready planed. The timber and other materials required are shown in the table.

	Long ft. in.	Broad in.	Thick in.
4 boards for the seat (A) ..	1 2	6	1
2 wooden rods for the hand grips (B)	2 0	1	1
2 planks for the runners (C) ..	3 0	4	1
3 pieces of wood for the cross-bars (D)	1 0	2	1½
3 lengths of ½-round strip iron for the brace irons (E) ..	1 3	¾	¾
2 ditto for the runner irons (F) ..	3 10	1	¾
17 wood screws ½ in. diameter	2		
4 " " " " " "	1½		
21 " " " " " "	1		
60 oval wire nails	2		
6 bolts of ½ in. diameter with slotted countersunk heads and square nuts	1½		
2½ yards of ¾ in. hemp rope for the draw-rope (G)			

Having made sure that each piece of timber is cut exactly to size and properly squared, the rods for the hand grips B are prepared. The centre of one of the long sides of each rod is found and a parallel line drawn through the point from end to end of the rod; then four 3/16 in. diameter holes are bored through each rod from points marked off on the centre line. The first point is 1½ in. from the right end; the second, 7 in. from the 1½ in. point; the third, 7 in. from the 7 in. point; the fourth 7 in. from the last 7 in. point. All the points must be placed exactly on the centre lines, then the

holes are carefully bored through and afterwards countersunk with a rose-bit.

Both edges of the side of the rod from which the holes were countersunk are now planed to a slight bevel, as shown in Fig. 3, then both ends of each rod are rounded as detailed in the same diagram.

The two runners C are the same size and shape, the marking out of the planks from which they are made being as follows: A space of 8 in. is marked off from the right ends, then a line at right angles is drawn through each point across the breadth of each plank. A space of 4 in., measured from the upper left corner, is marked off on the upper side of each plank, and a diagonal line is drawn from each point to the lower left corner. The curve at the right end of each plank is next marked out in the

Fig. 10

Toboggan. Fig. 2. Component parts of clipper toboggan. Fig. 3. Preparing hand grips. Fig. 4. Setting out curves on runners and, right, method of drawing curves. Fig 5. Marking out runner

planks. Fig. 6. Cross-bar ready for chamfering. Fig. 7. Marking out brace irons. Fig. 8. Brace iron bent at ends. Fig. 9. Marking out runner irons. Fig. 10. Runner irons bent to shape. Fig. 11. Seat boards fitted to position. Fig. 12. Section showing position of brace bolts.

The next step is to draw the curves with a compass set to a radius of 9-13/16 in., using the points marked on the lines as centres, as detailed in Fig. 4. If a large compass is not available, the curves may be drawn by arranging a pencil, tack, and loop of string as shown. A space of $\frac{7}{8}$ in., measured from the upper side, is marked off on the surface of each plank, then a parallel line is drawn through each point from end to end of the plank, as detailed in Fig. 5.

Four 3/16 in. diameter holes are bored through the thickness of each plank from points marked off on the parallel lines.

The first point is 3 in. from the right end of each plank; the second, 6 in. from the 3 in. point; the third, 11 in. from the 6 in. point; the fourth, 11 in. from the 11 in. point, Fig. 5. The planks are now cut to shape, the waste wood being removed from the right ends by sawing along each curved line with a keyhole saw, then the curves are neatly finished with a spokeshave. The left end of each plank is cut to the angle shown in Fig. 5, by sawing along the diagonal line.

The three pieces of wood for the crossbars D are prepared by planing two of the long edges of one of the broad surfaces of each piece. The portion to be removed from each edge is marked off as follows: From the right and left long edges mark off a space of $\frac{5}{8}$ in. on the surface and right and left sides, then draw a parallel line through each point from end to end of each piece of wood (Fig. 6). The three brace irons E are each made from a 15 in. length of $\frac{3}{4}$ in. broad, $\frac{1}{2}$ round strip iron. Five 3/16 in. diameter holes are drilled through the centre of the thickness of each length from the points detailed in Fig. 7, the points being placed on centre lines. The centre of the breadth of each ground side is found, and a parallel line drawn through the point from end to end of each length, then the points for the holes are marked off. The first point is $\frac{5}{8}$ in. from the right end of each length; the second, $1\frac{3}{4}$ in. from the $\frac{5}{8}$ in. point; the third, $5\frac{1}{4}$ in. from the $1\frac{3}{4}$ in. point; the fourth, $5\frac{1}{4}$ in. from the $5\frac{1}{4}$ in.; the fifth, $1\frac{3}{4}$ in. from the last $5\frac{1}{4}$ in. point.

The points are marked with a centre punch and the holes bored with a 3/16 in. twist drill fitted in either a brace or a hand-drilling machine. Each hole should be countersunk from the $\frac{1}{2}$ -round side of the strip iron, using a $\frac{1}{2}$ in. drill. A little oil or soapy water should be applied to the drill during the boring and the countersinking of the holes.

The next step is to mark off and bend both ends of each length of strip iron to a right angles as in Fig. 8. From the right and left ends of each length mark off a space of 1-11/16 in., then incise both points with a cold chisel so that they may be visible when the ends are made red-hot. The ends are then heated to a bright red and hammered over from the marks to sharp right angles. After bending each end plunge the strip into water. The runner irons F, Figs. 9 and 10, are made from a 3 ft. 10 in. length of 1 in. broad $\frac{1}{2}$ round strip iron. Eight 3/16 in. diameter holes are drilled through the centre of the thickness of each length from the points detailed in Fig. 9. A centre line is first drawn, then the points are spaced in the following order: The first point on each length is $\frac{1}{2}$ in. from the right end; the second, $1\frac{1}{2}$ in. from the $\frac{1}{2}$ in. point; the third, $9\frac{1}{4}$ in. from the $1\frac{1}{2}$ in. point; the fourth, 6 in. from the $9\frac{1}{4}$ in. point; the fifth, $13\frac{1}{8}$ in. from the 6 in. point; the sixth, 6 in. from the $13\frac{1}{8}$ in. point; the seventh, $5\frac{1}{8}$ in. from the 6 in. point; the eighth, 4 in. from the $5\frac{1}{8}$ in. point. The holes are drilled and countersunk in the same way as those bored in the brace irons.

The ends of each length are next marked and bent to the angles detailed in Fig. 10. A space of 3 in., measured from the right end, and a space of $5\frac{5}{8}$ in. measured from the left end, are marked off on the ground side and slightly incised with a cold chisel. The left ends of the lengths are heated to a bright red for about 6 in. and bent from the incised marks to the angle of the left end of the runners,

as shown in Fig. 10. The right ends are similarly treated, after which each length is reheated and bent to the shape of the curved ends of the runners.

Useful hints for manipulating ironwork will be found in the article on Forge. If the home worker has not the facilities for this part of the work the blacksmith from whom the strip iron is bought would doubtless do the bending and drilling for a reasonable charge.

To assemble the parts the runners are placed on a level surface and set in position 12 in. apart, exactly parallel to each other and in line, and hot glue is applied to their upper sides. The seat boards are fitted in position on the runners, as detailed in Fig. 11, both ends of each board being secured by three 2 in. oval wire nails. Hot glue should be applied to the long sides of the boards before fitting them in place. The hand grips B are glued and nailed to the sides of the seat, then a 2 in. screw is inserted into each of the countersunk holes in the hand grip and driven firmly into the seat boards.

The crossbars D are glued and fastened by 3 nails each to the underside of the seat, the position of each bar being detailed in Fig. 2. A 2 in. screw is driven into both ends of each bar from the holes previously bored through the runners, countersinking the holes before inserting the screws. In order to secure the bars further, a 3/16 in. diameter hole is bored through the seat at each of the points detailed in Fig. 11, then each hole is countersunk and a 2 in. screw driven into the centre of the crossbar below. It may be noted that the screws will be easier to drive if a small gimlet hole is made for each and a little vaseline applied to the threads.

Fitting Brace and Runner Irons.

The brace irons E are fitted to the crossbars as shown in Fig 2, each iron being secured with three 1 in. screws. A 3/16 in. diameter hole is bored with a gimlet through each runner from each of the holes in the angles of the brace irons, then a recess of the exact size of the nuts on the 1¼ in. bolts is cut at each hole on the outside of the runners and a nut placed in it. The bolts are inserted into the holes in the angles of the brace irons and driven in with a screwdriver until they are firmly screwed into the nuts, as shown in the sectional diagram in Fig. 12. If the ends of the bolts project, they should be filed down nearly flush and then riveted.

The runner irons F are now fitted in position on the runners and attached with screws. A 1½ in. screw is driven into each end hole, and a 1 in. screw into each of the other holes. The drawrope G is attached by first enlarging with a 3/8 in. drill, the 1/8 in. diameter hole previously bored at the curved end of each runner, then an end of the 2½ yd. length of rope is inserted into each hole from the inner side of the runner and secured.

The woodwork should be well smoothed with sandpaper, and all the corners and edges carefully rounded with a rasp. A nail punch should be used to drive each nail in the seat, hand grips, etc., a little below the surface of the wood, to remove a possible cause of torn clothes or injuries while sledging. When the runner irons have been polished smooth and bright with coarse emery cloth, the toboggan is complete and may be given several coats of good varnish paint as a finish.

TOBY JUG. The original Toby jug used for holding beer was in the form of a stout figure of a man wearing a cocked hat and knee-breeches, and generally embodying a variety of glazed colourings. A typical example shows a squat little figure attired in a purple coat, green waistcoat, yellow breeches, and white stockings, in Staffordshire pottery. Potters frequently rang the changes on these colours by varying the colour of the coat or breeches in products of the same mould. There are many variations in the design of the figures, which have recognized values among collectors according to their artistic merit, and rarity.

Favourite designs include the typical English squire, John Bull, the sailor, the snuff-taker, Simple Simon, the postboy astride of a barrel, the watchman with his lanthorn. Others represent historical

characters like those which bear the name of Nelson, Napoleon, Lord Howe, and many other celebrities in the later varieties of the Toby jug. Green and buff glaze is common, but at least one variety is blue and white with a flat beaver hat.

Modern Toby jugs of brown Doulton and other ware are decorated with small facsimiles of the old English figures and other designs in white enamel. These may be bought singly or in sets of three in different sizes. Toby ware is also used for tobacco jars and for small cruets.

Toby Jug modelled by Walton early 19th century. (British Museum)

TODDY. Toddy is a mixture of whisky, sugar, and hot water. To make it, put into a tumbler a lump of sugar, a piece of thin lemon peel, and a silver teaspoon. Fill the tumbler one-quarter full of boiling water. Cover it over until the sugar is dissolved, and then add a wineglassful of whisky.

According to the old practice toddy or grog should be made in the large, wide-mouthed glasses generally known as rummers. The whisky is always added last, and according to one of the old recipes it should be laid in spoonfuls on the top of the boiling water. This process is supposed to get rid of fusel oil.

In serving toddy it was customary to use ordinary wineglasses as well as the rummers. These were intended for the ladies of the party, and were filled from the rummer with the long, curved silver spoons or ladles known as toddy spoons.

Many choice examples of cut-glass toddy tumblers and spoons are to be found in private houses, and are still brought into use on occasions when it was formerly the custom to brew a bowl of punch. *See* Rummer.

TODEA. This is a genus of filmy ferns which, with the exception of *Todea africana*, should be grown in a closed case kept moist and shaded. One of the most beautiful is *Todea superba*. *See* Fern.

Toe. *See* Foot.

TOFFEE AND TOFFEE SWEETMEATS

Recipes for Butterscotch, Caramels, Humbugs, and Other Varieties.

This contribution deals with confections that require a basis containing as its main ingredients sugar and butter, or cream. Other sweet-making information is given under the headings Chocolate Making; Nougat; Sweets; Turkish Delight. *See* also Glucose; Sugar; Treacle; and the entries on other ingredients

The hard sweetmeat known as toffee is made chiefly from butter and sugar. Unlike other hard sweets, such as rocks, for which white sugar is used, a large proportion of brown sugar or treacle is used in most toffee-making to prevent granulation during boiling and stirring, and a fatty constituent is required. Glucose or cream of tartar is also included in many of the recipes. Various flavourings or nuts are added to make the different kinds. Recipes for the toffees are here given before proceeding to the toffee sweetmeats.

A good plain toffee, often known as hardbake, can be made by melting 3 oz. butter in a small bright pan, stirring in 1 lb. brown sugar and continuing to stir until the mixture becomes hard and brittle when a small portion is tested in cold water. If stirring is discontinued the toffee will burn. When ready pour it into an oiled tin and leave to set. Before it is quite hard mark it into squares.

Toffee. Fig. 1. Butterscotch, made with white sugar.

Butterscotch. This is a delicious variety of toffee distinguished by being made with white sugar instead of brown. Place 1 lb. loaf or granulated sugar into a saucepan containing 1 gill fresh milk. Heat slowly and stir occasionally till the sugar has

melted. Add a pinch of cream of tartar, and 3 oz. fresh butter, the latter a small piece at a time. Boil the mixture until it is a light coffee colour, drop a little of it into very cold water, and leave it a few seconds.

Take out the little lump, and, if it is quite brittle, add a few drops of essence of lemon and lemon-juice, and pour the mixture at once on to oiled tins or plates to the depth of a $\frac{1}{4}$ in. When it is nearly cold, cut it into oblong-shaped pieces, as shown in Fig. 1. If to be stored in a tin first wrap each piece in wax paper, and then in tin foil. Keep the toffee in a cool, dry place.

Everton Toffee. The ingredients for Everton toffee are 2 lb. white sugar, $\frac{1}{4}$ lb. dark sugar (Barbados), $\frac{1}{4}$ lb. glucose, $\frac{1}{4}$ lb. fresh butter, $\frac{1}{2}$ pint milk, a pinch of salt, and a few drops oil of lemon. Melt the sugar, glucose and milk in a large pan, then place it over a slow fire, add the butter and boil to 270° . Stir in salt and oil of lemon very gently, and pour the toffee into greased tins. Brush these over with pure vaseline first. This is tasteless and harmless, and, unlike butter and vegetable oils, free from rancidity.

Ginger Toffee. To make ginger toffee, mix in a saucepan 3 lb. brown cane sugar and 2 level teaspoonfuls ground ginger, and add about $\frac{1}{2}$ pint white vinegar and a lump of butter slightly larger than a hen's egg. Let these stand by the side of the fire until the sugar has melted, then boil them up and continue boiling until the toffee snaps when a little of it is dropped into cold water. Pour the toffee into oiled tins, and let it harden.

Honey Toffee. Melt 1 lb. loaf sugar in $\frac{1}{4}$ pint water over the fire. When it is on the point of boiling add 1 dessertspoonful glucose, $\frac{1}{4}$ lb. each honey and butter, and 2 or 3 tablespoonfuls cream. Boil the whole to 285° F., stirring all the time; then pour it on to a buttered marble slab, and when cold break it up, wrap the lumps in waxed papers twisted slightly at either end, and store in a tin.

Nut Toffees. Walnut toffee is composed of 1 lb. white sugar, 1 lb. brown sugar, $\frac{1}{2}$ lb. glucose, 2 oz. butter, a full $\frac{1}{2}$ pint water, $\frac{1}{2}$ lb walnuts, slightly roasted, a few drops oil of lemon. Boil to 270° as already explained. Remove the pan from the fire and add the walnuts, either whole or chopped. Stir gently. Place on the fire again for a few minutes, add the lemon, and pour. Mark toffee deeply with oiled knife, and when set cut into bars.

Almond and brazil nut or peanut toffee may be made in the same way, using blanched, skinned and neatly cut almonds or the other nuts in place of walnuts. Coconut toffee is made a little differently. Put 1 oz. butter in a saucepan, add to it when it is melted 1 small tablespoonful golden syrup and the

same of milk. When these are mixed, add lb. fine white sugar and 2 tablespoonfuls desiccated coconut. Stir frequently and boil the mixture fast, until it candies and grains well on the sides of the pan. Stir in half a teaspoonful of vanilla and pour it out into an oiled tin. Leave it until cold and cut it up.

Toffee. Fig. 2. Walnut toffee cut into bars.

Peppermint Toffee. Put into a saucepan a tin of sweetened condensed milk, 1½ lb. brown sugar, ¼ lb. butter, and two tablespoonfuls golden syrup, and stir them at the side of the fire until they melt. Then place the pan directly over the fire and boil its contents rapidly, stirring all the time. When they are a dark chocolate colour, take the mixture from the fire and drop a little of it into a basin of cold water. If it hardens, the toffee is cooked, and some peppermint essence may then be stirred in. Pour all on to a greased tin and let it cool a little before marking it into squares, then set it aside to become quite cold.

Russian Toffee. This is made with the following ingredients: 1 lb. brown sugar, 1 lb. white sugar, ½ lb. glucose, ½ pint milk, ½ pint cream, ½ lb. fresh butter, a few drops of vanilla essence. Place the sugar, glucose, and milk in a large-sized pan and boil carefully to 260°. Add the cream, and bring up to 260° once more. Add melted butter and boil to 270°. Remove from the fire, gently stir in the essence, pour into oiled tins, mark off when partly set. When cold, cut into squares as seen in Fig. 3. If desired to store, wrap the block in waxed paper and cut off the marked squares as required.

Fig. 3. Russian toffee, a very rich variety.

Treacle Toffee. The main ingredients of treacle toffee are 2 lb. each of black treacle and brown cane sugar. Put these into a pan with a lump of butter about twice the size of a hen's egg, and let them melt slowly at the side of the fire. Then boil up the toffee, stirring it all the time, and continue stirring until it becomes brittle when

a spoonful is dropped into cold water. Add a little vanilla flavouring, and pour the whole into an oiled tin.

Caramels. A softer type of toffee is the basis of the sweets known as caramels. Coffee, chocolate and vanilla are popular flavours.

Vanilla caramels may be either of the hard or soft varieties. For the hard caramels take 2½ lb. white sugar, 6 oz. glucose, 1 pint cream, 4 lb. tin condensed milk (unsweetened), ½ pint milk, vanilla essence. Place the sugar, glucose, and milk in a large pan, melt, and boil to 250°. Carefully add cream and boil continuously to 280°. Stir all the time. At 280° gently stir in the vanilla, and pour into an oiled tin (olive oil) to the depth of about ½ in. Mark deeply with an oiled knife into 1 in. squares before the mixture is set. When cold cut it right through and twist up the squares in waxed papers. Chocolate caramels are similarly made by stirring in about ¼ lb. plain melted chocolate.

For soft vanilla caramels take 2 lb. white sugar, ¾ lb. Barbados sugar, ¾ lb. glucose, 1 quart cream, 2 oz. coco-butter, 1 pint water, vanilla essence. Melt as before and add cream gradually at 250°. Slowly boil to 255°, stirring continuously. Just before removing the pan from the fire, stir in the essence. Pour on the oiled tin, mark off, and wrap up when cold.

To make coffee caramels, melt 1 lb. loaf sugar and 6 oz. glucose in a pan containing a small teacupful of water, placing the pan at the side of the stove or over a very low fire so that the process may be slow. When the whole is reduced to liquid, boil it to 245° F., then add 3 oz. butter and enough coffee essence to give the desired flavour. Continue boiling without stirring the mixture, and when it has reached 245°-250°, pour it into a well-oiled tin, cutting it into squares when almost cold, with an oiled knife or a caramel cutter.

Fudge. This type of toffee sweetmeat is of American origin. Vanilla chocolate fudge requires the following ingredients: ½ lb. granulated sugar, 4 tablespoonfuls cocoa powder, 2 tablespoonfuls butter, 1 dessertspoonful golden syrup, small tin unsweetened condensed milk, about ½ teaspoonful vanilla essence.

Blend the cocoa with the condensed milk to a smooth paste and add gradually to the melted butter in a small bright saucepan. Add the sugar and syrup and stir while the mixture boils up. Allow it to boil until a little dropped into cold water hardens to the desired consistency. Add the vanilla essence to the mass, beat it up well and then put it into a nougat frame lined with waxed paper to set.

Another recipe requires 1 teacupful brown sugar, 1 dessertspoonful golden syrup, 1 teacupful finely grated chocolate, 1 teacupful milk (half milk and half cream is used for a richer fudge), 1 dessertspoonful glycerin, ½ teaspoonful vanilla essence, and 1 oz. butter.

Place the sugar, butter, milk and syrup in a saucepan and bring to boiling point. Add the glycerin and boil rapidly for 10 minutes, and stir in the chocolate. Continue boiling and test in cold water. Turn into an oiled tin and mark into squares when almost set.

Humbugs. These old-fashioned sweetmeats are also called bull's eyes, and are made from pulled toffee cut into the shape known as a cushion. To make, dissolve ¾ lb. best brown sugar and ¾ lb. loaf sugar with not quite ½ pint water in a strong pan; the pan must not be tinned inside. When the sugar is melted add 2 tablespoonfuls glucose and boil to the soft ball, then by degrees put in 1½ oz. butter cut in thin slices.

Boil again till the toffee will snap. This can be tested by dropping a little of the syrup into cold water and breaking it between the thumbs; it should harden at once and break with a crack. Pour the toffee mixture, with the exception of about two tablespoonfuls, on to an oiled marble slab. Then drop in essence of peppermint to taste. It is impossible to give exact quantities of essence required, as the strength varies in all essences.

Turn in the edges of the toffee as soon as it can be handled and pull it until it is a light cream colour. It may be pulled with the hands or thrown repeatedly over a candy hook, as explained in the directions for making rock in the article on Sweets. The toffee will take about 10 min. to pull. The remaining toffee should be kept liquid in the pan over hot water.

When the pulled toffee is ready turn the clear liquid on to an oiled dish. Take up small pieces and stretch them in thin strips; lay them along the pulled sweet, which should be in even lengths; straighten the length out and cut into cushions with a strong pair of scissors. The humbugs should be cream with pale brown transparent stripes.

TOFFEE PUDDING. To make this, take 10 oz. self-raising flour, 3 oz. butter, 2 oz. granulated sugar, and 1½ oz. each of shredded suet and lard. Make a short crust with the flour, suet, and lard, and a little water, and roll it out to ½ in. thick. Next cream the sugar and butter together and spread the mixture on the pastry, which should then be rolled up and both ends securely fastened. Put it into a pie-dish and bake it in a quick oven for 35 min. As the butter and sugar ooze out of the pastry use them to baste the roll, on which they will form a toffee-like surface.

TOILET. Cleanliness and neatness are the chief factors of success in the everyday toilet which achieves a well-groomed appearance. Well-brushed and cared-for clothes, clean linen and footwear, immaculate hands and hair, are most important. The morning toilet for those who go to business away from home should be particularly efficient.

After a few exercises, and thorough brushing of the hair, a warm bath concluded by a cold shower, or sponge down, and followed by a brisk rubbing with a loofah or bath brush and drying with a rough towel, has an invigorating effect on most people. A good rubbing with the towel across the back of the neck and behind the ears stimulates the circulation.

When housework has to be done at home, most women complete the toilet afterwards. A cap should be worn to protect the hair from dust while sweeping, and the hands should be protected by rubber or wash-leather gloves when possible.

Articles for the toilet such as hair brushes, tooth brushes, sponges, soaps, powders, creams and lotions, should be of the best quality. It is a mistake to economize on these things. In particular powders and soaps for the baby's toilet should be absolutely pure. Should a wrong soap have been used—that is, one in which there is free alkali, and irritation of the skin has been caused, gently rub in a little pure olive oil. The powder must contain no white lead and the puff must be kept scrupulously clean. *See Baby; Beauty Culture; Hair; Shaving; Soap; etc.*

Toilet Cover. *See Duchesse Cover.*

TOILET MIRROR. Of the toilet mirror as a distinct article of furniture there are many varieties. Some are fitted into a frame and swing between a pair of supporting columns with a cross-piece between, or perhaps with a base in which is a drawer. Others have a flap that lets down in front and rests upon supports that pull out. The frame may be of mahogany, walnut, or the, cheaper woods. Some are inlaid with a line of satinwood, while others are hand painted or lacquered in black, green, red, or yellow, with raised designs gilded and lined with black in the Chinese style. Triple mirrors are also made both framed and frameless.

Toilet mirrors can be placed on any table or chest of drawers, provided it is a suitable height. For a mahogany piece a plain Chippendale design is perhaps more suitable. Mirrors with only a frame, or only a frame with a box or shelf at the base, are frequently very useful for hanging on the walls of bedrooms, bathrooms and dressing-rooms. Sometimes these are hung above a dressing-table. Others are fixed to a door or the inside of a wardrobe door.

Toilet Mirror in Queen Anne style, made of walnut and decorated with gesso work. (Courtesy of M. Harris & Sons)

Many of the mirrors made to-day are reproductions of 18th-century pieces, and a typical example is here illustrated of Queen Anne style in walnut with gilt gesso decoration. Most of these mirrors swing from uprights that rise from bases having three trinket drawers, this being a pattern that has been much copied. Their frames have a decorative shaping at the upper part, and occasionally a cresting such as is seen on the wall mirrors of the period. Some of these are inlaid with veneers, and occasionally two or even three sets of drawers, one above the other, are seen in the lower part.

A magnificent example of Queen Anne work is in the Victoria and Albert Museum. It is of pinewood and is decorated with gold lacquer in the Chinese style on a green ground. Below the

glass, which is in a rectangular frame, are small drawers and pigeon holes very like those seen in a bureau, the resemblance being carried further by the presence of a lid that when open serves also as a desk.

Later, in mid-Georgian days many oval toilet mirrors were made. The example here illustrated with the cut-glass toilet set is typical of the mahogany style in vogue with its curved support and lower part inlaid with satinwood lines, bow fronted, and having three drawers. *See Bathroom; Dressing Table; Mirror; Queen Anne Style; Silvering.*

TOILET SERVICE. Sets of toilet ware for the washstand are sold under the name of toilet services. They are sold in single or double sets. The single set of five pieces is composed of basin and ewer, chamber, soap dish, and tooth-brush vase. The double service is composed of 12 pieces, which includes a toilet pail and sponge bowl. The last two articles can be bought separately and added to the single service. Sets in stock patterns are to be had in many good designs, any article of which can be replaced in event of breakage. Spode designs look particularly well with mahogany, and are reproduced with squat-shaped or tall ewers.

Services in plain bright colours must be chosen with due regard to the colour scheme of the room. Sometimes the tiles in the fireplace are matched, or a predominating shade in carpet or curtains. For small and corner washstands the miniature services in a Spode design or in willow pattern are pretty. For a country cottage leadless glaze toilet services are liked, also sets of rough brown pottery with yellow glaze inside. Glass services are beautiful and costly, whether of cut crystal or decorated with gold.

TOILET SET. A toilet set usually refers to the collection of articles that stand on the dressing-table, and the toilet service to those that stand on the washstand, although the two are sometimes confused. The usual constituents of a toilet set are a brush tray, two scent bottles, a powder jar or bowl, ring stand, and one or two small vessels for holding cold cream, etc. A beautiful set in modern English cut crystal is here illustrated in which a pair of candlesticks is also included.

Toilet Set. Modern English cut-glass toilet accessories look their best on a polished mahogany dressing table, as illustrated in this photograph. (Courtesy of Webb & Corbett)

Sometimes the whole equipment of a dressing table, including hair brushes, etc., is bought to match. In silver, for instance, the articles can be chosen in a plain or in an engine-turned pattern with silver tops to jars and scent bottles. Dark or blond tortoiseshell, either quite plain, with gold or silver monogram, or with inlaid pattern in gold or silver, is used for beautiful inclusive services, and so is enamel either in delicate or rich colourings.

Ebony and ivory brushes may be used with glass accessories, but trays, powder bowls and boxes can be had to match, and also shoe lifts and buttonhooks. Lacquered services give a distinctive note to a dressing-table, and a number of pieces can be obtained to form complete sets. *See Dressing Table.*

TOILET VINEGAR. Glacial acetic acid or acetic ether when it is added to a toilet water forms a toilet vinegar which has refreshing properties when inhaled. A small sponge soaked with this aromatic vinegar was placed in an ornamental box called the vinaigrette, and was in general use as a smelling bottle in the 17th and 18th centuries. The vinegar is now sold in various perfumes, such as Cologne, lavender, millefleurs, and violet.

TOKAY. This sweet and world-famous wine with an aromatic flavour is made from several kinds of grape in Tokay, Hungary. The distinguishing characteristic of Tokay which gives it a value as a medicinal agent is the quantity of phosphoric acid it contains; no other wine except Malaga has anything approaching the same proportion. *See Wine.*

TOKEN: How to Collect. To form the nucleus of a localised collection of tokens is not by any means difficult or even expensive. To begin with, the collector must learn how to recognize a genuine currency token when he sees one. Every metallic currency token is a coin, but a coin of a distinctive character. It is a redeemable coin issued by cognizable authority to circulate at a higher value than that of the metal it contains. The silver and bronze coins now minted in Great Britain are regal or national tokens.

Tokens of Three Periods. For the purpose of the amateur collector, it will be sufficient to restrict these hints to such as concern the issues of localised non-regal currency tokens taking place in Great Britain during the three periods 1648-72, 1787-99 and 1811-15. Most of these issues were in copper but the third period included numerous examples in silver and some, such as those of Reading and Sheffield in gold.

Tokens of the first period are generally thin pieces of copper, or other base metal, about the size of a sixpence, and forgeries are seldom met with. About 20,000 varieties of these quaint little tokens are believed to have been struck, but only about half that number are extant. These are catalogued, in counties, in a work by the late William Boyne, which may be consulted at any large public library.

The second and third periods exhibit better workmanship on more substantial disks of metal, and contain many private tokens, that is to say, imitation tokens issued by collectors for exchange with other collectors. These private tokens are not currency tokens, and good authorities, such as Charles Pye, have noted and distinguished all the private tokens of the second period.

Other more or less spurious pieces of the two later periods are: The several series of public buildings (notably at Coventry, Birmingham, and London, and in the scattered series with a globe on the reverse) made by coin dealers for sale to collectors; political and satirical pieces, such as Spence's, and medalets—all easily distinguishable by their designs and legends: mules, so called from each being struck from two dies never originally intended to be combined for one coin, non-local tokens manufactured in mass by die-sinkers to sell to traders, who profitably circulated the

Token. Obverse and reverse of tradesmen's copper coins issued in Great Britain. 1. London (Jewin Street) halfpenny, 1667. 2. Swansea halfpenny, 1796. 3. Cheltenham penny, 1812

stuff without liability for redemption; any apparent token not showing clearly the name of the issuer and the place of origin or redemption.

The most confusing of the spurious pieces are the mules of the second period. Experience, however, and a reference to Charles Pye's volume of plates, will soon train the collector's eye to reject spurious pieces. Mules of the third period are comparatively scarce. *See Coin Collecting.*

TOMATOES: GROWING AND COOKING

With Recipes for Some Tasty and Economical Dishes

This contribution deals first with the growing of this useful plant, the section including some information about the diseases to which it is subject. Information about various ways of cooking the fruit follows. See Disbudding; Greenhouse; Kitchen Garden; Omelette; Salad; Snow Fly.

This half-hardy plant, of which the fruits are used as vegetables, has increased enormously in popularity in recent years and immense quantities are sent to market. It can be grown to produce fruit throughout spring and summer under glass and out of doors in summer.

For summer fruiting it is raised from seeds sown in a heated greenhouse in February; the seedlings are potted singly in small pots in a compost of loam and leaf-mould, and subsequently in 5-in. pots in loamy soil. The plants should be grown in a temperature of about 50 degrees, the greenhouse being ventilated freely in mild weather; close, moist conditions will lead to failure.

Early in June tomato plants may be planted out of doors: a border at the foot of a sunny wall or fence is the most suitable. The soil should be dug deeply but not manured and must be trodden firmly; tomatoes do not thrive in loose soil. The plants are set about 2 ft. apart and are supported by strong stakes. All side shoots must be rubbed off to restrict each plant to a single stem. When the first fruits are set, superphosphate of lime, at the rate of 2 oz. per square yard of ground, should be applied and forked beneath the surface. The tops of the plants should be cut off when three or four bunches of fruit have set.

Tomato. Fine fruit of the variety Sunrise.

If the summer happens to be dry and warm tomatoes will do well in the open garden, but in a dull, wet season they are likely to prove disappointing.

For cultivation under glass the plants in 5-in. pots should be re-potted into those 9 or 10 in. wide, or planted in a border of loamy soil not more than 12 in. deep and made firm by treading. The stems must be supported by stakes. The secret of success is to keep the plants as cool as possible and the soil moderately moist. Free ventilation is necessary. When the fruits are well developed superphosphate of lime and liquid manure may be given alternately once a fortnight. Great care in watering is necessary, especially if the tomatoes are planted in a border; if the soil becomes sodden the plants are not likely to do well. To produce a crop of tomatoes in spring under glass, seeds should be sown in September.

There are innumerable varieties of tomato: almost every seedsman has his special sorts. Some of the best for cultivation out of doors are Essex Wonder, Bide's Recruit, Best of All, Ailsa Craig, Sunrise and A1. For cultivation under glass, Princess of Wales, Abundance, Scarlet Beauty, and Earliest of All are suitable. The yellow tomatoes, e.g. Golden Perfection and Golden Queen, are more suitable for the greenhouse than for out of doors.

Tomato Diseases. The chief diseases which affect tomatoes are black spot, sleeping disease, and yellow spot or stripe. Black spot attacks the eye of the fruit and causes it to crumple up and decay. Sleeping disease attacks the leaves of the plants. It causes them to lose their freshness of colour and droop, with the result that the whole plant ultimately perishes. There is no effective remedy, and affected plants should be destroyed. The house in which the pest is found may be disinfected by a spray of a solution of sulphate of iron.

Stripe is mainly a disease of plants grown under glass, but it has been seen on those grown in the open in a position facing south and sheltered by a high wall. The symptoms are dark, vertical stripes on the stems, brown sunken patches on the fruit, and brown shrivelled areas on the leaves. The disease frequently occurs in the seed bed, producing rapid destruction of the plants and necessitating fresh sowings.

The varieties of tomatoes differ very much in their susceptibility to disease. Generally speaking, those varieties that show rapid, soft growth in the early stages are most susceptible to stripe. Manure has considerable influence upon this susceptibility. As with other diseases, excessive quantities of nitrogen and a lack of potash tend to lower the resistance power of the plant to the invasion of the parasite. The effect of too much nitrogen can be largely counteracted by an increase in the amount of potash. Sterilization of the soil by heat should be practised when an attack has occurred. Dry, airy conditions should be maintained under glass. Soil infected by eelworm ought to be removed from the glasshouse and replaced by fresh soil.

How to Cook. Tomatoes that have been picked before they are ripe may be used to make chutney, but if it is desired to ripen them they should be placed in rows on a shelf in a warm room or where the sun can reach them. A little space should be left between each, otherwise they will become soft. Tomatoes too soft for serving whole, but only bruised and not over-ripe, may be used for stews and soups, but those that are to be served raw should be firm and unbroken. Tomatoes give a good flavour to stewed beef and mutton. To peel tomatoes without damaging the pulp, dip them into boiling water for a few seconds, and the peel will then come away easily. They should not be left in the water too long, otherwise they will become partially cooked.

Boiled tomatoes can be served either as a substitute for, or in addition to, a green vegetable. To prepare them, wipe them with a clean cloth, pull off the stalks, and drop them into a saucepan of slightly salted boiling water. Boil them slowly for 5 min. or a little longer, then drain them; place a few small pieces of butter on them, season with pepper and salt, and serve in a hot vegetable dish.

Breakfast Dishes. Grilled tomatoes are excellent with bacon or sausages. Cut each tomato in half, season with pepper and salt, and place it under the grill. Fried tomatoes served on slices of fried bread are also a good breakfast dish. Fry the bread in some beef dripping, then cut the tomatoes into halves and fry them in smoking hot fat until they are tender. Serve three or four halves on each piece of bread, according to its size.

Tomatoes stuffed with fish can be made thus: Choose 1 lb. firm, even-sized tomatoes; with a sharp knife cut a round piece from stalk end of each, and scoop out some of the soft interior, reserving the pulp. Take the skin and bones from $\frac{1}{4}$ lb. cooked dried haddock, break up the flakes, and mix them with a large tablespoonful of boiled rice, a tablespoonful of chopped pickled gherkins, a chopped

hard-boiled egg, 1 oz. melted margarine, the tomato pulp and seasoning to taste. If the mixture is too dry, a little milk may be added. Fill the cavity in each tomato with this stuffing, heaping it slightly on top. Sprinkle over some browned breadcrumbs, then bake the tomatoes in a moderately hot oven until they are tender, but not broken. Have ready a croûton of fried bread for each tomato, placing the latter on top and serving very hot.

Devilled tomatoes, served on squares of grilled ham, are prepared thus: Cut 3 or 4 tomatoes into thick slices and spread each slice with a mixture made by seasoning a lump of butter about the size of a hen's egg with mustard, pepper, salt, and cayenne. Bake the slices on a tin in a moderately hot oven and serve them as has been already stated.

Tomato culture. 1. Seed sowing : *a*, turf ; *b*, compost ; *c*, fine, sandy soil. 2. Seedlings transplanted to large pot with topping of sand (*a*). 3. Good fruiting type. 4. Poor seedling of little use. 5 and 6. Successive pottings of seedlings. 7. Fruiting plant finally potted : *a*, turf ; *b*, crocks ; *c*, chopped turf ; *d*, compost ; *e*, space for top dressing

By special arrangement with Amateur Gardening

Tomato Savouries. Tomatoes stuffed with a mixture of breadcrumbs, herbs and grated cheese make excellent savouries. To prepare them, cut a small, round piece from the tops of five tomatoes and scoop out a little of the insides. Mix 5 dessertspoonfuls fine breadcrumbs with 1 teaspoonful chopped parsley, a pinch of mixed herbs, 1½ teaspoonfuls grated cheese, a chopped truffle, and a peeled, chopped and fried onion. Melt 1 oz. butter, add it to the mixture with the yolk of an egg, and then use the whole to stuff the tomatoes, piling it up well on top. Bake the tomatoes on a greased baking sheet in a moderately hot oven until they are tender, but do not let them break, and when they are cooked take them from the oven, sprinkle a little grated cheese over the top of each, and brown beneath a gas grill.

A tomato and rice savoury can be made by wiping two tomatoes, cutting them into slices, and putting them in a baking-tin in the oven with a little dripping. Cook them until they are tender, and in the meantime wash and boil a teacupful of rice until it is soft. Melt 2 oz. butter in a saucepan, fry a peeled and chopped onion in it, then stir in the drained rice and 3 oz. cooked and chopped ham. Add seasoning to taste, stir all together, and then mix in two gills of tomato sauce. Make the mixture thoroughly hot, put it into a pie-dish, and place the slices of cooked tomato on top. Serve sprinkled with chopped parsley.

Tomato culture (continued). 1. Top dressing : *a*, original soil ; *b*, *c*, and *d*, successive top dressings ; *e*, zinc collar to accommodate same. 2. Positions for seedlings to encourage sturdy growth. 3. Box planting ; *a*, leaves ; *b*, firm soil ; *c*, prepared soil and compost. 4. Growth to pinch out. 5. Leaf reduction to avoid shading of fruit. 6. Defoliation of plant in detail. 7. Outdoor planting : *a*, soil ; *b*, manure ; *c*, mulch. 8. Roots damaged by eelworm

A savoury supper or luncheon dish is provided by tomatoes au gratin. To prepare it, mix $\frac{1}{4}$ lb. breadcrumbs with the same quantity of grated cheese, and shake a layer of them into the bottom of a greased fireproof dish. Cover them with some thick slices of tomato and a little chopped onion, add a sprinkling of pepper and salt, and continue these layers until the dish is full. About 2 lb. tomatoes will be required. The last layer, which should be a fairly thick one, must be of cheese and crumbs. Put 3 or 4 small lumps of butter on top, and bake the whole in a hot oven until the top is browned. The dish should be sent to table immediately it is ready.

Tomato Chutney. To make this chutney, put 6 lb. sound tomatoes into a large enamel pan, break them with a wooden spoon, and then add $1\frac{1}{2}$ lb. apples cut into quarters but not peeled or cored, 3

small onions peeled and minced, 1 oz. crushed mustard seeds, $\frac{3}{4}$ oz. ground ginger, 4 oz. salt, a small teaspoonful of cayenne, and $1\frac{3}{4}$ pints malt vinegar.

Bring all these to the boil, then simmer them until they begin to soften. Add 1 lb. moist sugar, stir until it dissolves, and then continue simmering until the tomatoes and apples are a soft pulp. Rub them through a hair sieve, stir them well, and bottle the chutney in two days' time.

Tomato Jam. This vegetable jam can be made by wiping and stalking 6 lb. tomatoes, cutting them into slices, and putting them in a preserving pan with $1\frac{1}{2}$ pints water. Cook them slowly until they are tender, then rub them, together with the water in which they were cooked, through a sieve. Put the purée back into the pan with 5 lb. sugar and the strained juice of six lemons.

Bring the whole to the boil, remove the scum, add the grated rind of the lemons, and continue boiling for about 45 min. or until the mixture forms a jelly. Stir the jam occasionally to prevent it from burning, and skim it whenever necessary. When it is sufficiently cool turn it into pots, tie it down when quite cold and store in a dry, cool place.

Tomato Ketchup. For this relish 4 lb. tomatoes, $\frac{1}{4}$ lb. onions, $\frac{1}{2}$ oz. each whole ginger, cloves, and allspice, a gill of vinegar, and a little salt are needed. Cut the tomatoes in halves, place them on a dish with the cut sides upward, and sprinkle them with salt. Leave them thus for 24 hours, then put them into a pan and simmer them until the skins become loose. Strain them through a coarse sieve, and to the liquid add the minced onion, the ginger cut into small pieces, and the pounded cloves and allspice. Turn all into an enamel pan, and boil them until they are reduced by one-third. Add more salt, if necessary, and when the ketchup is cold strain it into bottles. Store it in a dry, cool place.

Tomato Omelette. A savoury omelette, with tomato and onion as flavouring ingredients can be made thus: Melt $\frac{3}{4}$ oz. butter in a small frying-pan, and fry in it a skinned tomato cut into slices and 1 teaspoonful chopped onion. In the meantime separate the yolks from the whites of 2 eggs, beat up the former, adding salt and pepper to taste and a teaspoonful of grated cheese. Whisk the whites with a pinch of salt to a stiff froth, and fold them lightly into the yolks.

Melt $\frac{3}{4}$ oz. butter in an omelette pan, and when it is hot pour in the egg mixture, stirring it round to prevent it from sticking to the bottom of the pan. When it begins to set, place the hot tomato and onions in the centre, and finish the omelette in the usual way.

Tomato Sauce. Tomato sauce for serving in place of gravy may be prepared with fresh or tinned tomatoes. Weigh out $\frac{1}{2}$ lb. tomatoes, wiping them and cutting them into slices if they are fresh; then put them into a saucepan with an onion and a carrot, peeled and sliced, $\frac{1}{2}$ oz. margarine, $1\frac{1}{2}$ gills stock or water, $\frac{1}{4}$ teaspoonful celery seeds tied in muslin, a teaspoonful sugar, and pepper and salt to taste. If tinned tomatoes are used, only 1 gill stock will be required.

Cook the whole slowly until the vegetables are tender, then take out the, celery seeds and rub the sauce through a hair sieve. Put it back into the saucepan, thicken it with a teaspoonful of cornflour mixed to a smooth paste with a tablespoonful of cold water, and then let it boil slowly for 5 min., stirring all the time.

Tomato Soup. To make tomato soup, put into a frying pan 2 oz. ham or bacon, cut into dice, and 1 oz. butter. Fry in this for 5 min. a carrot, a turnip, 3 sticks of celery or a little celery seed, and a bouquet garni; then add 2 lb. ripe tomatoes, or for preference 2 lb. tinned ones. Let all simmer for 20 min.; afterwards remove the bouquet and pass as much as possible of these ingredients through a hair sieve. Have ready at boiling point a pint of good, well-seasoned stock, which should be

thickened with $\frac{1}{2}$ oz. cornflour made into a thin paste with some stock. Add the purée to the stock, and, if required, a squeeze of lemon juice and some more seasoning. Boil up and simmer for 10 min., stirring well. Fresh tomatoes may need rather more stock than the amount mentioned.

TON. This measure of weight consists of 2,240 lb. or 20 cwt. It is used for weighing coal and other heavy materials. *See Avoirdupois Weight.*

TONGS: For Household Use. Tongs are appliances for gripping and moving any object with safety or comfort, and without soiling the hands. In their general form for household use, in moving coal from the scuttle to the fire, they consist of a pair of levers pivoted at one end, or with an open spring loop, their length depending upon the purpose for which they are required. The longer varieties have a handle fitted at the end at which they are pivoted. These are now seldom used, but are still seen in ornamental brass and steel as a decorative finish to period fenders or curbs of the same metal. Tongs are a component part of a set of fire irons.

TONGS: For Metal Work. Special tongs are used to hold iron pipes in gas and hot water fitting. The gas tongs illustrated in Fig. 1 is a convenient tool for gripping gas piping without damaging the pipe. It is made of forged steel and hardened at the gripping end. One end is curved to encircle the pipe, while the other end is short and has a sharp square inner edge which bites into the softer metal of the pipe, thereby holding it securely. Tongs of this type are made only for one size of pipe.

A further application of tongs is found in the blacksmith's trade. These invariably take the general form of those illustrated in Fig. 2, the salient feature being that their handles are long compared with their gripping ends, in order that great leverage, and therefore gripping powers, may be applied. The larger of the two pairs illustrated is made primarily for gripping flat pieces of metal and enabling the latter to be held securely on the surface of the anvil while forging is in progress. The smaller pair finds its greatest use in gripping chisels for the purpose of cutting metal by that tool. In this particular case the chisel would be held in position by an assistant while the blacksmith applied the hammer. *See Casting; Forge; Pipe; Plumbing; Spanner; Wrench.*

Tongs : for metal work. Fig. 1. Pair of gas tongs. Fig. 2. Blacksmith's tongs, which are very useful in brazing and other amateur work

TONGUE: Its Diseases. The tongue is composed of a number of different muscles the fibres of which run in various directions. Over the surface are scattered numerous small, reddish, pointed projections, which have to do with the sense of taste. The chief duties of the tongue, in addition to acting as the organ of taste, are to assist mastication, swallowing, and the pronunciation of words.

Amongst diseases of the tongue is cancer, which is about six times as common in men as in women, generally occurring about the age of 40. Predisposing causes include decayed or broken teeth, badly fitting dental plates, excessive smoking, and anything that sets up inflammation or irritation.

Acute inflammation or acute glossitis is most often caused by wasp stings, or stings and bites of other insects; also by burns and scalds, and by wounds which become septic. Treatment would be directed by a doctor.

The commonest cause of chronic inflammation are syphilis, tobacco smoking, drinking alcohol not sufficiently diluted, decayed teeth, and previous attacks of acute inflammation.

Ulcers of the tongue may arise from injury or dyspepsia. The former variety is generally due to decayed teeth or badly fitting artificial teeth. The ulcers due to dyspepsia are generally on the tip and upper surface.

Wounds are most commonly caused by jagged teeth, but may be caused by the person biting his own tongue, or by instruments or weapons. If bleeding is very free, try to grasp the wound firmly between the fingers while awaiting the doctor. Otherwise give ice to be held in the mouth.

Tongue as an Aid to Diagnosis. The state of the tongue varies in different diseases, as the following particulars will show: In chronic dyspepsia the tongue is often swollen, flabby, and coated with fur, which may be white yellowish brown, and sometimes black. In acute gastritis the fur is white, but does not extend to the tip and edges of the tongue, which are bright red. In prolonged constipation the tongue is coated with a thick white or brownish fur. In fevers the tongue is usually dry, but when furred the colour is yellowish or brownish. In typhoid fever the middle is covered with thick brown fur, the colour becoming yellowish towards the edges. In scarlet fever the tongue is swollen and covered with white fur, with scattered bright red spots, the inflamed papillae. This is known as the strawberry tongue. In thrush, common in very feeble children, the tongue is covered with raised white spots and small patches. In debilitated states the tongue is often found to be large, pale, and flabby.

TONGUE: In Cookery. The tongues of sheep, oxen, and pigs are cooked and served in various ways, while that of the reindeer, which is considered a great delicacy, also can be prepared in many ways. Directions for cooking ox tongue will be found under that heading, and any of the recipes given there may be applied to reindeer tongue. The latter, however, needs longer soaking and very slow cooking. Pigs' tongues are prepared in the same way as sheep's tongues. Cold tongue, either alone or with salad or cold cooked ham, makes a particularly good luncheon dish, and, like most other cold meats, can be made into sandwiches. It may also be potted.

There are various ways of serving cooked tongue when a hot dish is needed. If minced, combined with breadcrumbs, and heated up, for instance, it makes excellent savouries. Pass the tongue through a mincing machine; then pound it with about one-third its quantity of breadcrumbs and enough sauce to bind it. Season it with cayenne and a little lemon juice and rub the whole through a sieve before heating it over a slow fire. When it is thoroughly hot, pile it high in some newly-fried cases of bread and garnish each savoury with a little parsley.

Another method of heating up cold tongue is to cut it into neat slices, season them to taste, sprinkle them with lemon juice, and let them stand for a while before dipping them in egg, coating them with breadcrumbs and then frying them to a golden brown colour in smoking hot fat. Serve them at once, garnished with parsley and thin slices of lemon. *See* Calf's Head; Ox Tongue; Potted Meat: Sheep's Tongue.

TONGUED JOINT. This is a joint in which a small projection along the length of one part, known as the tongue, fits into a slot or groove in the other part and so completes the joint. A common

application is found in tongued and grooved floor-boards. This material is finished on one side and generally measures in width 4 in. to 5 in. The average thickness is nominally 1 in., but actually it measures slightly over $\frac{7}{8}$ in. Thicker boards are available, but are seldom used except in high-grade work or where very considerable strength is needed, ordinary 1 in. tongued and grooved flooring being quite satisfactory for most domestic work. The amateur will find that this class of timber with its tongued joint is extremely useful for a great many purposes.

Tongued Joint, Fig. 1. Plane used in preparing tongue. Fig. 2. Use of grooving plane.

In the construction of tongued joints, a tonguing and grooving plane is usually employed, such as that illustrated in Fig. 1, which has variously shaped irons and adjustable fences, and makes grooves $\frac{1}{4}$ in. in width. On one side is an adjustable fence composed of a strip of hardwood which locates the position of the groove in respect to the working face of the material.

The method of using this plane, as Illustrated in Fig. 2, consists of securing the work in a vertical position on the bench between blocks of wood or by holding it in the bench vice. The plane is rested on the upper surface of the work with the fence resting against the face, and worked backward and forward in the usual way. The tongue can be made with the same plane, and finished by the regular tonguing and grooving plane or matching plane, specially prepared for the purpose. The plough plane is also used for this class of work.

Tongued joints are found in many kinds of woodwork, particularly in cabinet work and the better quality joinery. Examples are also seen in metal-work. In both cases they are akin to the feathered joint, except that, instead of using a separate strip and sinking it into a groove in each piece of material, the joint is formed from the solid. For woodwork, the tongued joint forms one of the best methods for jointing the edges of long pieces of material, and when well cramped up and supported by cross battens it makes a particularly rigid structure. *See Joint; Plane.*

TONIC. Drugs or mixtures of drugs which increase the efficiency of the body as a whole, or of any of its systems, are called tonics. Thus there are nerve, blood, heart, and general tonics. The following are examples of a tonic designed to brace up the nervous system:

Tincture of nux vomica	1 dram
Spirit of chloroform	1 „
Water, enough to make	6 oz.

Dose for a grown person: 1 tablespoonful 3 times a day after meals.

Solution of strychnine hydrochloride $\frac{1}{2}$ dram

Iron and quinine citrate 1 „

Spirit of chloroform 2 drams

Tincture of calumba 6 „

Water, enough to make 6 oz.

Make into a mixture. Dose $\frac{1}{2}$ to 1 tablespoonful in a little water 3 times a day after meals.

The following are examples of tonics directed towards improving the quality of the blood:

Sulphate of iron 15 gr.

Sulphate of quinine 8 „

Dilute sulphuric acid 40 minims

Simple syrup 1 oz.

Water, enough to make 8 „

Make into a mixture. Dose for a grown person: 2 tablespoonfuls 3 times a day after meals.

Sulphate of iron 16 gr.

Magnesium sulphate 1 oz.

Dilute sulphuric acid 1 dram

Glycerin 6 drams

Water, enough to make 8 oz.

Make into a mixture. Dose for a grown person: 2 tablespoonfuls 3 times a day. This prescription is appropriate when there is any tendency to constipation.

The following is an example of a bitter tonic often very valuable where the patient's appetite is capricious and he is run down:

Tincture of nux vomica 2 drams

Iron and quinine citrate 2 „

Dilute phosphoric acid 4 „

Tincture of orange 2 „

Chloroform water, enough to make 4 oz.

Make into a mixture. Dose 1 to 2 teaspoonfuls $\frac{1}{2}$ an hour before each meal.

The following is an example of so-called simple digestive tonic mixtures:

Tincture of cascarrilla 1 oz.

Dilute hydrochloric acid 3 drams

Syrup of orange 1 oz.

Water, enough to make 8 oz.

Make into a mixture: Dose for a grown person: 2 to 4 teaspoonfuls 3 times a day.

One of the best all-round tonics for general debility is Easton's syrup, dose, $\frac{1}{2}$ to 1 dram 3 times a day after meals. No tonic should be taken for longer than a month or 6 weeks at a stretch, as otherwise it may upset the digestion, also losing its original efficacy.

TONING: In Photography. Toning is a method of changing the colour of a photographic print after development and after or before fixing. Whether on P.O.P. or bromide paper, all prints which include a silver salt in the light sensitive film can be toned. Prints made on P.O.P. by daylight invariably need toning, as otherwise the colour is not pleasing. Prints made on gaslight or bromide papers are only toned when it is desired, from black and white to warmer colours or tints.

Many varieties of P.O.P. have toning chemicals included in the film on the surface of the paper, so that when placed in the fixing bath toning is carried on automatically at the same time. These are known as self-toning papers (q.v.). With the non-toning printing-out papers the toning process may be combined with the fixing, or the two operations may be carried out separately. The latter is the better course, as when a combined bath is used there is a risk that the print may be removed from the bath before fixing is complete because the desired colour has been obtained. Thus prints, not being sufficiently fixed, will not be permanent.

Toning of P.O.P. This is practically always carried out with a salt of gold, although warm black tones can be obtained by using platinum compounds. Both agents are extremely expensive, but are only required in minute quantities. The gold is used in the form of gold chloride, sold in tubes containing 15 gr.

The following are standard formulae for gold toning the common gelatino-chloride papers:

A
GOLD STOCK SOLUTION

Gold chloride	15 gr.
Water to	15 oz.

B
SULPHOCYANIDE STOCK SOLUTION

Ammonium sulphocyanide	100 gr.
Water to	10 oz.

For use, mix in the following order:

Stock solution B	2 oz.
Water	16 „
Stock solution A	2 „

A bath recommended by the Ilford Company for warm tones is the following:

STOCK SULPHITE SOLUTION

Sodium sulphite	15 gr.
Water to	10 oz.

The toning bath is made up as follows:

Stock solution A	2 oz.
Stock sulphite solution	2 „
Stock solution B	2 „
Water to	20 „

Mix in the order given. The sulphocyanide toning bath should not be used more than once. If a large number of prints are being toned at the same time, it will be found necessary to strengthen the bath

when toning becomes slow. This may be done by adding small quantities of the following solution, which must be made up as required:

Water	5 oz.
Stock solution B	1 „
Stock solution A	5 „

All gold solutions work best after they have been allowed to stand for at least 24 hours. This toning bath will give red to purple tones. Before toning P.O.P. in this or other baths, prints must be well washed in water until the washing water shows no trace of milkiness. At least six changes of water are required if running water is not used. This washing removes the soluble silver salts from the paper, which would otherwise act on the gelatine and produce discoloration.

In hot weather it is important to harden the prints before toning. They should be immersed for 10 min. in the following bath and washed thoroughly for 10 min. after hardening. The employment of this alum and salt bath will secure regularity of tone.

Common salt	1 oz.
Alum	1½ „
Water to	20 „

Toning P.O.P. may be carried out in weak daylight well away from a window. A large porcelain dish should be used and kept for this purpose only. Prints are immersed in the solution one by one, care being taken that air bubbles do not cling to their surfaces. The prints must be kept in constant motion and must not be allowed to stick together. If these precautions are not observed, unequal toning or stains may result.

While in the bath the prints must be carefully watched, and a little experience is necessary to determine when they should be removed. The colour gradually changes to brown, then to purple, ending with a slaty blue. The shorter the time of toning the warmer or redder the finished print, the longer, the colder or bluer will be the final colour. A cold solution is liable to give muddy tones, whilst a bath which is too warm will give pinkish prints. The temperature should be about 65° F. A bath containing too much gold hastens toning, but gives muddy tones; while a slow bath, due to deficiency of gold or excess of sulphocyanide, gives pinkish tones.

When toning is judged to be complete, prints should be washed at once in running water to prevent continuance of toning. The quickest method of stopping toning is to immerse the prints in a weak solution of sodium sulphite, 5 gr. per oz. of water.

Poor negatives will never give good prints on gelatino-chloride P.O.P. Defects in the finished prints are due to the following causes: Handling the prints before toning with moist or greasy fingers will cause red patches. Allowing prints to stick together in the toning or fixing bath, or insufficient washing after the hardening bath, or other stages, causes unevenness of tone. Small quantities of hypo introduced into the toning bath will cause brown discoloration or complete absence of toning. It is, therefore, advisable to complete toning and washing before beginning fixing or otherwise handling hypo solutions.

Combined Toning and Fixing.

If sufficient care is taken to ensure complete fixing, combined toning and fixing will give good and pleasing colours. The prints must be made distinctly darker than when separate toning is carried out, and placed face downward without previous washing, as distinct from the careful washing of separately toned prints, in the combined bath. They must be left in the bath at least 7 min. to ensure fixing: they should not be in more than 10 or 12 min. Following is a good formula:

Water	20 oz.
Hypo	3 „
Lead acetate	20 gr.
Gold chloride	1 „

Dissolve in hot water in the order given and prepare at least 24 hours before use, shaking well. After standing, decant the clear liquid, allowing $\frac{1}{2}$ oz. for each $\frac{1}{4}$ plate print. Throw away after use. Keep the prints, moving.

Sulphide Toning. Gaslight and bromide prints may be toned in a variety of colours. The most popular process is the sulphide method, because of its simplicity, good colours, and permanent results. After fixing and washing, bromide prints should be dried before toning by the sulphide process.

The print is first bleached in the following bath, which can be made up as a stock solution and used until its bleaching powers fail:

Potassium ferricyanide	1 oz.
Potassium bromide	1 „
Water to	20 „

The solution should be stored in a yellow or brown bottle away from the light. The print bleaches to a faint yellow in a few minutes in this bath, is then rinsed well, not washed too long, and put into a sodium sulphide toning bath, which restores the image in fine brown and sepia tones. Make up a stock solution of 2 oz. of pure sodium sulphide (white, not green crystals), in 5 oz. of water. For use, take $\frac{1}{2}$ oz. of this solution and add 10 oz. of water. The print is toned rapidly, and no variation in colour is obtained by leaving it in after the image is completely redeveloped. Wash thoroughly for about 15 min. in running water. After use, the sulphide solution must be thrown away.

Variations in colour with this process can be obtained by first bathing the print in the sulphide solution, then washing, bleaching in the ferricyanide solution, and finally redeveloping in sulphide solution. To get deep sepia and warm black tones the process is carried out as first described, with the exception that bleaching is stopped before it is complete. The more of the original black image left the deeper will be the final colour.

All the processes described above for bromide papers are applicable to the toning of lantern slides. *See Developing; Fixing; Negative; Photography; Printing.*

TONSIL. The tonsils are two small glandular bodies situated on each side of the back part of the mouth, at its juncture with the throat. Their main function appears to be that of trapping toxic material as it passes backward from the mouth. *See Adenoids.*

TONSILLITIS. Inflammation of the tonsils is of several types and occurs in an acute and a chronic form. The former occurs most commonly in young people during spring or autumn. People of a rheumatic tendency are more liable to the disease than others. The most common causes blamed for exciting an attack are exposure to cold and damp or to overheated and impure air.

The earliest symptom of acute catarrhal tonsillitis is pain when swallowing. If the tonsils are examined they will be seen to be red and swollen, dry at first and then covered with a layer of mucus mixed with pus. An attack seldom lasts more than a few days. It is often associated with pharyngitis, and may be followed by inflammation of the middle ear.

The symptoms of acute follicular tonsillitis are more severe. The patient should be kept away from other members of the family, as tonsillitis is more or less contagious, and it is not always easy at first to distinguish between an attack of this disease and diphtheria. He should not be allowed to talk or to swallow anything but liquids or semi-solids.

To prevent relapses the mouth and teeth should be cleansed morning and night, some antiseptic mouth wash being used. A good protective measure is to bathe the neck in cold water.

Chronic tonsillitis, popularly known as enlarged tonsils, is usually the result of repeated attacks of the acute form. It is met with mainly in children from 5 to 15 years of age, and is more common in boys than in girls.

Usually the affected child breathes through the mouth, keeping it always open, in consequence of which he has a stupid expression. At night his breathing is noisy and irregular, and he is often the victim of nightmare and night terrors. Cough may be troublesome at night. The patient is especially liable to attacks of nasal catarrh. He continually hawks up mucus from the throat. At times swallowing is painful, and both the sense of taste and the sense of smell are often defective. The hearing also is frequently impaired, and this may develop into complete deafness.

In very slight enlargement, measures to build up the health may be effective in subduing the symptoms and preventing the development of the enlargement. But the correct treatment of diseased tonsils is to have them removed. *See* Adenoids; Quinsy.

TOOLS FOR THE HOME WORKER

A Selection to Suit All Ordinary Requirements

This contribution gives some detailed advice on the selection and care of tools for simple wood and metal work. Further information about individual tools will be found under such specific headings as Chisel; Plane; Saw. *See also* Amateur Carpentry; Bench, etc.

Prepared collections of woodworking tools often contain some which are seldom used by the beginner, and it is better for the amateur to start with the few indispensable tools and add to them gradually as he acquires dexterity and experience in his hobby. The outfit desirable for simple carpentry will also be adequate for most of the odd jobs which fall to the handyman, if supplemented by a few metal working tools. A start could be made with the following, and if desired only those marked with an asterisk (*) need be procured at the outset.

*Hammer, Exeter pattern, ½ lb.

* „ ball peine, 1 lb.

•Panel saw, 24 in.

*Tenon saw, 15 in.

*Screw driver, London pattern, 9 in.

Ratchet screwdriver, 3 in. blade

*2 Gimlets

*2 Bradawls

*Carpenter's brace

*Set of centre bits; *3 twist bits; turnscrew bit, countersink for wood, rose bit countersink, flat countersink bit for iron, auger bits, ¼ in., ⅜ in., ½ in.

*Steel rule, 2-fold 24 in.

*Carpenter's square, 8 in.

Spirit level, 10 in.

*Marking gauge
 Compass saws (handle and 3 blades)
 Keyhole saw
 Coping saw and spare blades
 Chisels, firmer, $\frac{1}{4}$ in.; $\frac{3}{8}$ in.; $\frac{3}{4}$ in.; 1 in.
 *Mallet, joiners,
 *Metal vice 4 in. jaws; Carpenter's bench vice
 Spokeshave, metal
 Jack plane, 2 in. iron
 *Smoothing plane
 *Nail punch
 Putty knife
 Glass cutter (wheel)
 *Glue pot
 *Oil stone in case
 *Pincers, Lancashire, 8 in.
 Wing compasses, 8 in.
 Hand axe, American pattern
 Combination pliers, 8 in.
 Centre punch
 Hand drill and set of twist drills $\frac{1}{16}$ in. to $\frac{1}{4}$ in. rising by $\frac{1}{32}$ in.) in metal holder
 Broaches, $\frac{1}{8}$ in., $\frac{1}{4}$ in., and $\frac{3}{8}$ in.
 Broach holder, adjustable
 Files: *Saw file, 6 in.; hand file, *8 in. bastard; 8 in. second cut; * half round, 8 in. second cut
 Cold chisels, flat chipping, *8 in. by $\frac{1}{2}$ in.; 16 in. by $\frac{3}{4}$ in.
 Mason's hammer, 2 lb,
 Soldering bit, adjustable, 12 oz.
 Tinman's snips, straight, 8 in.
 Hacksaw and assorted blades
 *Adjustable spanner wrench, 10 in.
 Adjustable pipe wrench
 Set of fixed spanners

Tools should be kept in a simple rack or in shelves adapted to each type or group of tools. Orderliness preserves the tools and saves time.

In the article on Amateur Carpentry will be found helpful information about the lay-out of a workshop and the arrangement of a bench. Should the home worker decide to make his own bench he will find the necessary plans and details in the article Bench. As a makeshift a stout false top can be used on the kitchen table if the latter is of substantial construction. The top should be of 1 in. T. & G. flooring or similar stuff, and can be cramped to the table top when in use by a pair of 6 in. G cramps. A piece of board can be interposed between the screw of the cramp and the underside of table to prevent marking the latter, and a recess might be formed in the upper side of the false top to take the jaw of the cramp.

With the kit of tools enumerated above the handyman will be equipped to tackle all sorts of repairing jobs about the home, and to do simple constructional work. Since timber can readily be obtained in a prepared state, the amateur will not be called upon to do much planing. If he further arranges for his boards to be ripped to width at the timber yard (in cases where a stock width board

will not work in) there need be little sawing but that involved in cross cutting to the desired dimensions.

Moulded sections in a wide and useful variety can be obtained, and turned sets of legs suitable for tables, cabinets, or stools. The stiles and rails for a panelled door, e.g. for a cupboard, can be made from ready grooved material, the groove being of a size to take stock plywood. The legs for a cabinet can be purchased with grooves formed in them, saving much labour to the novice. These refinements permit of quicker and easier construction, and avoid the purchase or use of tools like the moulding planes, plough, fillister, etc. Joints can be simplified by the use of dowels to a considerable extent.

The woodworker as his skill increases may desire to undertake cabinet making and perhaps inlaying, marquetry and similar ornamental work. The tools for these are detailed in the specific articles on the subjects mentioned. Woodcarving also demands tools of a special nature.

Apart from these special requirements the worker can well supplement his tool kit with the following:

Rip saw, 28 in., 4 points to inch

Hand saw, 26 in., 7 points to inch

Bow saw

Trying Plane, 24 in.

Rebate plane

Side fillister

Plough

Mortise chisels, 3/16 in., 5/16 in.

Mortise gauge

Firmer gouges, 1/4 in., 1/2 in., 3/4 in.

Saw set and assorted saw files

Sash cramps (2)

Plumb rule

Plumb bob and line

Bevel square

Half round rasp, 8 in.

Mitre box

In place of the separate rebate, fillister and plough planes mentioned above, the worker could buy a combination tool with an assortment of cutters.

Tools for Outdoor Work

For outdoor work the following will be handy: farmer's saw, for cross cutting rough wood; Kent axe, draw knife; beetle or maul, for driving posts, splitting timber, etc.; one or two augers and handle; brick trowel, 10 in.; pointing trowel, 5 in.; sledge hammer, 3 lb. If a permanent workshop is available it will pay to invest in a leg vice, which stands on the floor and is screwed to the bench. A small anvil will be invaluable for riveting operations, and can be had to rest on bench, or with a spike to knock into a wooden block. The latter is useful in dealing with a job which cannot be taken to the bench. The amateur who wants to do a little forging should refer to the article on that subject, where the necessary implements are detailed. A grindstone or some type of bench grinding machine will be needed to keep the cutting tools in proper order.

The tools used in wood turning are dealt with in the article on that subject, while the amateur metal worker will find appropriate tools listed under such headings as Lathe; Metal Turning and Metal Work. The cutting of screw threads by hand and machine demands special tools, about which the

relevant information is given in the articles Screw Cutting; Stocks and Dies. If any considerable amount of metal work is done it is well to include in the tool kit a small steel set square, spirit level, scribing block, surface plate and sliding caliper gauge. A steel rule about 12 in. long is convenient for this work.

Care of Tools. Ordinary wooden trying, jack, and smoothing planes are made of beech. In making a choice, the direction of the grain should be carefully noted; it should run straight along the side, and the annual rings should be of large radius curving towards the sole, with the medullary rays vertical. The irons should be double and with parallel sides, with the back iron well arched, and should fit snugly in the mouth. The mouth of a new plane should be stopped with putty and the opening filled with linseed oil and left until fine globules of oil appear on the ends, the surface being wiped over from time to time. Iron planes of the above type should have double irons, those fitted with single irons being of little use for serious work.

Much trouble can be avoided by the amateur in planing if the right sort of plane is used for the work in hand. The smoothing plane, for instance, should on no account be used except for taking the finishing shavings off a previously planed surface. This plane is short and light, the mouth is small, and the irons should be set close together; it is not intended to true a surface in the sense of making it level, but to render the trued surface perfectly smooth.

For most general purposes a correctly adjusted jack plane, either wood or metal, is capable of doing all the work the amateur is likely to tackle, but, even considered as a general-purpose plane, there is a correct way of holding it, and several ways of adjusting it to suit particular uses. The shavings from a correctly set and properly sharpened jack plane should be parallel and have an even curl, and the sound of the cut is easily recognizable by the experienced woodworker. The necessity of a sharp cutting edge is very important in the case of the smaller planes, such as the rebate, plough, beading, moulding, and similar tools, and it is not a simple matter to sharpen the small curves while retaining the correct shape.

Choice and Care of Saws

Saws of all kinds should be of the best quality obtainable. The skew-back hand or rip saw with the blade extending well into the handle is generally preferred, as it is more under control and is not liable to work loose in the handle. The brass or iron back on a tenon saw should be heavy and made of stout material, and it should be noted that its own weight ought to be sufficient to carry it through the wood. A good handsaw can be tested by the sound when struck sharply with the finger nail, and it should be possible to bend the blade to a semicircle without affecting its straightness.

When not in use, tools should be kept in a drawer, cupboard, or chest, and arranged with a special place for each. When they are on the bench, care should be taken that the cutting edges do not come into contact with other tools or with the bench. The planes should be rested on a thin lath placed across the bench. The wedges should be carefully driven in with a mallet, but the same tool should not be used to adjust the iron. The mallet is the best tool to use when loosening the irons. The sole of the plane should be frequently wiped over with linseed oil, and to protect the surface unplanned wood should be brushed over before planing to remove grit, etc. The cutting irons of rebate, beading, moulding, and similar narrow planes are liable to damage if allowed to lie on the bench, and these tools should be put away directly after use.

Saws should be hung up when not in use, unless there is a special place for them; they should be frequently wiped over with vaseline, tallow, or a good lubricating oil. If they are not kept in a chest or cupboard properly supported, it is a good plan to cover the cutting edges with a strip of wood in which a groove has been sawn. Chisels should be placed down on the bench after use with the bevel side downward, as there is less risk in this way of the edge getting damaged; but the better plan is to

have a rack on the bench, conveniently placed at the back so that tools being used on a piece of construction can be placed out of the way of damage. The handles of chisels used for mortising soon become bruised on the ends, and unless the small chips are trimmed off they will act as wedges and split the whole handle. It is useful to keep a coarse-cut file handy for trimming the end of the wood.

On no account should wood-boring bits of any kind be allowed to lie on the bench after use; they should be placed in a rack or drawer. The try square is another tool requiring careful usage, as it soon gets out of truth if allowed to fall on the floor or get knocked about. Quite as much care is needed with metal-working tools, although they are as a rule heavier and less liable to damage. Tool racks should be provided for the metal-working bench, not only to prevent damage to tools, but in order to be able to find them when required. Metal clips are obtainable for attaching to the wall, but wooden racks or other suitable means of support are easily made. The amateur craftsman should make a point of providing a place for each tool and see that it is in its place when not in use.

Tools such as a hand-drill need a special place in the tool box or cupboard, and should not be buried among all sorts of heavy implements. Smaller tools, well smeared with grease, can be kept in a long narrow tin biscuit box. Drills, reamers, broaches, taps, etc., are best kept separate in flat cigarette tins, each sort in a special box. Only one layer should be accommodated in the tin, or the cutting edges will suffer damage by contact with tools above. The tools if greased will be free from rust, and the arrangement mentioned will enable any one to be found quite readily.

TOOL CHEST : HOW TO CONSTRUCT

With Working Drawings for a Simple Type

Our article on the receptacle for the tools used by the amateur carpenter or mechanic is complementary to the preceding one dealing with the selection and care of tools themselves.

It is followed by a contribution describing how to make a tool cupboard. Reference should

also be made to the entries on the various tools and processes.

Tool Chest. Fig. 1. Chest with six shelves fitted above a series of compartments

A chest large enough to take a complete equipment is shown in Fig. 1. There are six shallow shelves, and the bottom is divided into compartments. Half the front is hinged for greater convenience in getting at the shelves, and certain of the tools are attached to the inside of the lid. The wood should be sound yellow pine; if ordinary yellow deal is used it should be free from knots. The main dimensions of the chest are shown in the sectional plan and elevations in Figs. 2, 3, and 4. The carcass is of 1 in. wood (finished size), and the wood should be at least 1½ in. thick before planing. It saves much labour and time to have the wood machine-planed.

The carcass of the chest, as in Fig. 5, is made to inside measurements of 34 in. by 18 in. by 18 in., but as it is impossible to obtain pine or deal of this width it will be necessary to glue up 2 boards. Allowing for waste ends, 16 ft. by 11 in. by 1 in. and the same length of 9 in. by 1 in. boards will be required, with the top and falling front flap.

First prepare the boards for glueing by planing up one side and edge, cutting the front and back pieces to 36½ in. and the end pieces to 20½ in. long. Each joint should be tested before glueing, as it is important that the join should be perfect. The pairs of glued boards should be placed between cramps and left until the glue has set. If the wood is already machine-planed to the correct thickness, the edges only need be planed, but care must be taken to have square edges to ensure the pieces having a true surface when glued.

The best method of joining up the sides of the carcass is by dovetailing, as in Fig. 5, but an easier and alternative method is to use the lock corner joint. In both cases the lengths should be left as glued up. The width of the back piece should be reduced to 19 in., the sides to the same width, and the front to 10½ in. wide. First mark off 17 in. each side of a centre pencil mark on the wood on both the back A and front B pieces (Figs. 3-5), and then mark another line 1 in. further along. The end pieces C are marked 9 in. each side of a centre fine and then marked 1 in. further along.

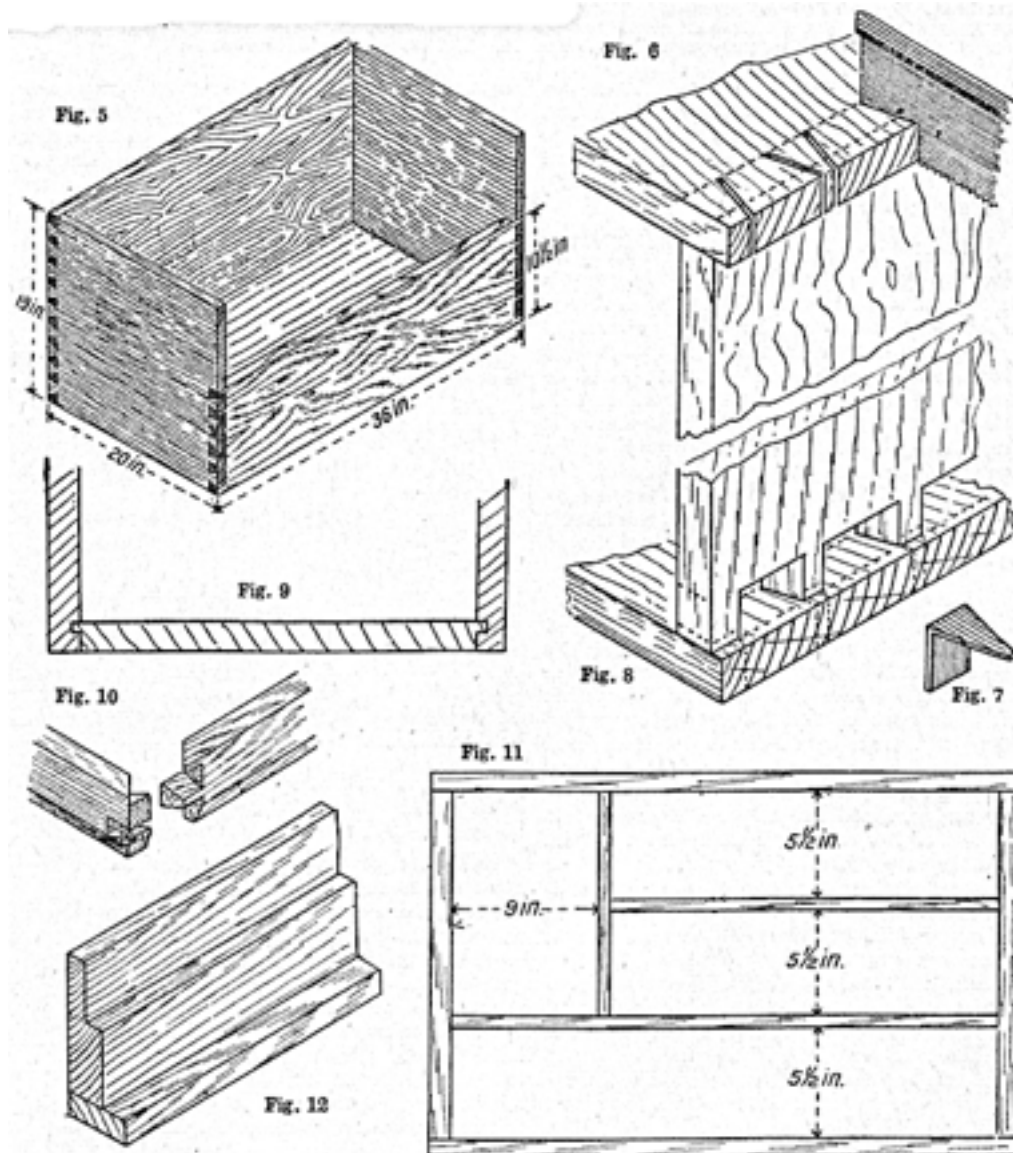

There are two methods of making the dovetail joint. That in ordinary use by the cabinet maker consists of marking out the sockets and sawing them complete. The saw cuts are placed on the ends of the front and back pieces in turn, the tenon saw placed through the cut and marked on the ends of the wood as in Fig. 6. This is a good method in the hands of a skilled worker, but the amateur who is not practised in making the joint is advised to proceed with the cutting of the pins first.

In the former method the pins are cut out by sawing on the waste side of the saw cuts and the waste cut out of both pieces with a chisel. In cutting the pins on the ends of the back board, first set off

two $\frac{1}{2}$ pins top and bottom and then space out the remainder; 8 is suggested as a reasonable number. The amount of the slope need not be more than $\frac{1}{8}$ in. in the 1 in. width, and it may be less in hardwood.

The easiest way of marking out a number of pins is to cut out a dovetail marker from a piece of tinned sheet or brass as in Fig. 7. This is placed on one set of marks, and a pencil fine drawn each side. When the marks have been made, the saw should be placed in each case on the waste side of the line and carried down to the correct depth. The waste is cut out with a chisel from the narrow side first, and the remaining portion cut from the other side, taking care not to allow the chisel to go below the line.

The pins are placed upright on the side of the end pieces so that the widest portion of the pins is on the inside of the two fines, as in Fig. 8. A sharp pencil is drawn along the sides of the pins, and then the waste side of the pencil fines is sawn down with the tenon saw. In cutting out the waste with a chisel, commence about $\frac{1}{8}$ in. from the back with a chisel measuring about half the size of the widest part of the opening, and cut a hole as in mortising, taking it half-way through. Turn the wood over and repeat, the remainder of the wood being cut out afterwards with little risk of breaking the sides of the sockets. The bottoms of the sockets as well as the pins may be slightly undercut in the middle, but great care must be taken not to go below the lines on the outside of the wood.

Other Methods of Joining.

The alternative lock corner joint is marked out by setting off equal spaces of 1 in. or more on the ends of all pieces, and before sawing it is important to mark very distinctly those portions to be cut out and to saw on the waste side of the line. Instead of joining the corners in either of the above methods, the side pieces can be accurately cut to. 18 in. wide for a height of $10\frac{1}{2}$ in. and 19 in. for the remainder; the front and back are in this case glued and screwed to the ends. Although this

method will be strong, it is not so satisfactory and does not look so well, but it certainly saves time.

The sides and ends are now ready to fit together, but before this is done the method of securing the bottom D must be considered. The easiest way is to fit the wood exactly as in Fig. 4, after the work is glued up, and then either screw or nail it in. The nails or screws will be covered by the plinth moulding. The most satisfactory method is to tongue the edges of the bottom board and plough a corresponding groove in the sides and ends, as in Fig. 9, so that the wood can be glued only. If this method is followed, the work of rebating the edges of the bottom and grooving the sides and ends of the carcass must be done before the work is glued up. The bottom board is accurately finished to $34\frac{1}{2}$ in. by $18\frac{1}{2}$ in. and gauged $\frac{1}{4}$ in. from the top and from the edges, and the waste is removed with a rebate plane or fillister. A gauge line of $\frac{3}{4}$ in., followed by another of 1 in., is made from the bottom edges of the back, front, and ends of the case, and the groove made with a plough plane.

The joints of the carcass can now be fitted together, but in driving the sockets home, a piece of waste wood should be placed on the ends to avoid damaging the material. The wood for the falling flap is now prepared, and accurately fitted in position as at E, and strengthened at the ends with two $8\frac{1}{2}$ in. by 4 in. by $\frac{3}{4}$ in. pieces glued and screwed on, the flap being 34 in. by $8\frac{1}{2}$ in. by 1 in. It is joined to the front B by two 2 in. by $\frac{3}{4}$ in. brass butt hinges, let in flush with the surface.

The bottom plinth or moulding should be prepared from $\frac{3}{4}$ in. wood and planed to $3\frac{3}{4}$ in. wide. The front and back pieces G are $37\frac{1}{2}$ in. finished, and those at the ends, H, $21\frac{1}{2}$ in. They are chamfered on the top edge to a line the sockets home, a piece drawn $\frac{1}{4}$ in. from the inner edge and another of waste wood should be $\frac{3}{4}$ in. from the top. The corners can be mitred, placed on the ends to butt the better method is to dovetail them to avoid damaging the form a frame, the top corners only being cut material. The wood for to a mitre, as in Fig. 10. In the latter case it is enough to glue them, but if simply mitred the wood must be bradded. Before the plinth can be fitted to the carcass the projecting ends of the dovetails on the latter should be carefully sawn off a little away from the surface and then neatly planed down with a smoothing plane, but this must be left until a later stage. The plane should be used towards the centre of the sides and ends, as this will avoid breaking of the corners. The lid J is planed down on the edges to the exact size of the top, 36 in. by 20 in., and a moulding $2\frac{1}{4}$ in. by $\frac{3}{4}$ in. prepared for the front.

Tool Chest. Fig. 2. Sectional plan of tool chest shown in the opposite page. Figs. 3 and 4. Side and end elevations shown in section. Fig. 5. Sides of carcass joined by dovetailing. Fig. 6. One method of marking a dovetail joint. Fig. 7. Dovetail marker. Fig. 8. Alternative way of marking dovetail joint. Fig. 9. Joint for securing bottom of chest. Fig. 10. Top corners of moulding cut to a mitre. Fig. 11. Bottom arranged with partitions. Fig. 12. Support for shelves. An explanation of all lettering will be found in the text and ends as at K and L. This is dealt with in the same way as the bottom plinth, with the front corners dovetailed, but in addition to the moulding it will be necessary to screw on two battens M of 2 in. by $1\frac{1}{4}$ in. wood, chamfered on one side and cut to 18 in. long. These are screwed on 1 in. away from the moulding and slightly tapered in front to allow the lid to fit down easily. The lid is hinged with $2\frac{1}{2}$ in. by 1 in. brass butts let in flush, and should fit snugly on the top.

The next stage is to fit the partitions in the bottom. These can be made with $\frac{1}{2}$ in. wood, but $\frac{3}{4}$ in. is better. It will be seen in Fig. 11 that 4 compartments are arranged at the bottom; those at the back are divided into 3 parts, and the front one is a single one covered with a hinged lid. The actual dimensions do not matter very much. If the space is divided out equally it will be sufficient. It is suggested that the division pieces N and O should be about 5 in. wide; the partition pieces can be $5\frac{1}{2}$ in. apart, and all let in $\frac{1}{4}$ in. deep grooves. This with $\frac{3}{4}$ in. wood will leave a $5\frac{1}{2}$ in. space to be covered with the hinged lid P, measuring 30 in. by $6\frac{1}{4}$ in.

Tool Chest. Fig. 13. Plywood cover on top shelves of tool chest described in the previous pages. Fig. 14. Sloping partitions. Fig. 15. Compartments for nails and screws. Fig. 16. Partition cross-halved. Fig. 17. Fitments for saw-tips and handles in lid. Fig. 18. Grooves for handled tools.

Details of Trays and Fitments

For the lid to clear the upper fitments, a 2 in. by $\frac{3}{4}$ in. piece Q is fitted at both ends, and a ledge or fillet R is screwed to the front for it to rest on; this should be $\frac{1}{2}$ in. square in section. Loose lids may be fitted over the open partitions, as shown by dotted lines, if desired, but they need not be more than $\frac{1}{4}$ in. plywood with $\frac{1}{2}$ in. fillets on back and ends. The shelf trays are arranged on supports T screwed to the ends of the case, and made from a 1 in. board, as in Fig. 12. The length is $17\frac{1}{4}$ in., and it is built up with one $4\frac{1}{2}$ in. wide piece rebated 2 in. down the side and $\frac{1}{2}$ in. deep with a $1\frac{3}{4}$ in. by $\frac{3}{4}$ in. piece screwed on underneath. Instead of rebating a 1 in. board, one 2 in. by $\frac{1}{2}$ in. and one $2\frac{1}{2}$ in. by 1 in. piece can be fitted each side, the $1\frac{3}{4}$ in. by $\frac{3}{4}$ in. strip being screwed to the latter piece. The top of this fitment is 3 in. down from the top of the case.

The two top trays are made with $1\frac{1}{2}$ in. by $\frac{1}{2}$ in. wood, with long sides 34 in. long and ends 8 and $7\frac{1}{4}$ in. respectively (Fig. 4). The corners can be nailed, but the shelves will be stronger and more workmanlike if dovetailed, and in this case the ends should be 1 in. longer than stated. The bottoms are nailed or screwed on, using $\frac{1}{4}$ in. plywood. The trays below are made in the same way; they are the same width exactly, but the lengths are 33 in. and the total depth with the plywood bottom 2 in. The lowest shelves are $2\frac{1}{2}$ in. deep and 32 in. in length.

The top trays should be provided with a plywood cover with $\frac{1}{2}$ in. by $\frac{1}{4}$ in. fillets on the inside edges for it to rest on, and holes drilled for lifting up, as in Fig. 13. The trays can be partitioned off with strips of plywood to suit particular tools. One can be reserved for bits of all kinds, and have sloping partitions as in Fig. 14; another can be fitted to take the oilstone, bradawls, gimlets, rule, pincers etc.,. The two top front shelves should be reserved for nails and screws, and partitioned off

as suggested in Fig. 15. The partition pieces should be cross-halved where they join, as in Fig. 16, and are neater if they are housed into the sides, this being done before the tray is made up.

Ball feet or ball castors can be attached to the bottom, and handles fitted to the sides. A strong box lock fitted to the flap will keep the shelves secure, even if the chest should be overturned. The outside of the chest should be painted with 3 coats of good oil paint, removing the handles beforehand. The saws can be fitted to the inside of lid, as in Fig. 1; the method is to cut out shapes to fit the handles, screw them on, and fit a wooden turn-button. The tips of the saws should be fitted in slotted pieces glued and screwed on; these pieces are shown in Fig. 17. All the small tools, such as chisels, gouges, and other handled tools should be placed in grooves in the bottom of the trays, as in Fig. 18, leaving the bottom partitions for the larger and heavier tools. A special part of the chest should be reserved for metal-working tools.

A tin of petroleum jelly should be kept in the chest so that all steel tools can be wiped over periodically. A place should be made for a tin of lubricating oil and a small oil can. If a paraffin blow lamp is used a special compartment will be needed for it, and a place to take a can of methylated spirits for priming the lamp. Soldering flux, kept in an earthenware bottle, will require accommodation also. If a petrol lamp is used it should be kept in a safe place out of doors, with the petrol supply; paraffin blow-lamps are preferable.

TOOL CUPBOARD. It is often found convenient to arrange a small number of tools in a cupboard such as that illustrated in Fig. 1. The outside dimensions are 36 in. wide and high and 10 in. deep; the doors fit inside the framing and are stiffened with battens.

The internal arrangements allow of a 26 in. cross-cut saw on one door, attached to the shaped block at A; alongside is placed a tenon saw at B. The two racks on the other door, C and D, will take such tools as gauge, square, pincers, screwdriver, hammer, gimlets, bradawls, etc., suitable slots being cut to hold them securely. Inside the cupboard a jack plane will fit in the space at E, with the smoothing plane underneath at F; a bow saw can be hung at the back on hooks at G, and on the other side can be hung a brace at H. Inside the cupboard a jack plane will fit in the space at E, with the smoothing plane underneath at F; a bow saw can be hung at the back on hooks at G, and on the other side can be hung a brace at H.

Fig. 1

Tool Cupboard. Fig. 1. Small cupboard, shown open, for the handyman's tools.

Fig. 2. Elevation of cupboard when closed. Fig. 3. Side elevation. For lettering see text.

A mallet, oilstone, and rebate plane will rest on the top shelf at J; chisels and gouges can be placed in slots cut in a length of wood as at K, at the back of the lower shelf at L. In front of the piece K, a flat length M will hold the bits, and leave room in front for other tools. There are two pigeonholes at N and O for glass paper, etc., leaving the top drawer P for small tools, and the lower ones, Q and R, for nails and screws. The advantage of this arrangement is that each tool has its own particular place and is easily picked out. The whole collection can thus be placed in a convenient position.

The construction of the cupboard is quite simple. The outside boards are 1 in. thick finished, and should be obtained machine-planed to this size; two finished lengths of 36 in. and two of 34 in. should be prepared to a width of 10 in. The back is $\frac{3}{16}$ in. or $\frac{1}{4}$ in. plywood, and, although it can be nailed or screwed on the back edges, a much neater job is made if it is rebated, as shown in Fig. 3, which also shows the two sets of drawers.

The method of making the carcass is shown in Fig. 4. The sides T are nailed or screwed to the top and bottom pieces U, but the various partition pieces should be housed into the outer frame first, as in Fig. 5. To do this work accurately, the wood must be marked out as far as possible with the parts placed together. The two sides T should be placed side by side, a line being marked 1 in. down from each end to indicate the position of the top and bottom pieces U. A line is marked off 2 in. up from the bottom line, and this should be followed by another $\frac{1}{2}$ in. above, in order to give the position of the groove for the lower shelf V. The next shelf is 5 in. above, and two lines are marked off, one 5 in., and the other 4 in. above it. These shelves, L and V, measuring $34\frac{1}{2}$ in. by $8\frac{1}{4}$ in. by $\frac{1}{2}$ in., are placed together so that the groove for upright W and its continuing piece underneath can be marked out, as well as a corresponding piece to the under piece on the other side between V and L. These pieces are 3 in. from the outside pieces, so that the grooves should be $\frac{3}{4}$ in. from the ends. The

piece W is $26\frac{1}{2}$ in. by $8\frac{1}{4}$ in. by $\frac{1}{2}$ in., and the 2 pieces Z under the shelf L are $5\frac{1}{2}$ in. by $8\frac{1}{4}$ in. by $\frac{1}{2}$ in. The piece at X is 8 in. above the shelf L, and is cut to $3\frac{1}{2}$ in. by $8\frac{1}{4}$ in. by $\frac{1}{2}$ in., the shelf J is 31 in. by $8\frac{1}{4}$ in. by $\frac{1}{2}$ in., and is the same height. The division piece at Y is fitted half-way between the sides, and cut to $2\frac{1}{2}$ in. by $8\frac{1}{4}$ in. by $\frac{1}{2}$ in. It will be seen from Fig. 5 that the long shelves which fit in the sides T are let in the full width, but the other parts are notched at the ends and fitted in stopped grooves, $\frac{1}{4}$ in. deep and $\frac{1}{2}$ in. wide. When all the parts shown in Fig. 4 have been prepared, and a 1 in. deep slot cut at the back of the shelf L, the carcass can be glued, nailed, or screwed together. In doing this, care should be taken to see that the corners are quite square.

The back is next cut to fit in the rebate. If, however, this method is not used, the width of the partition pieces should be $8\frac{1}{2}$ in. instead of $8\frac{1}{4}$ in. Small brads or screws will be sufficient to retain the back in position and make a solid case. A 27 in. by 5 in. by $\frac{1}{4}$ in. piece should be fitted in the space between L and V and be flush with the back of the narrowed portion of the shelf L, to provide a boxed portion for the chisel blades. The drawer to fit in this space is shown in Fig. 6; it is made with a front 27 in. by 5 in. by $\frac{3}{4}$ in., two sides $6\frac{3}{4}$ in. by $4\frac{3}{4}$ in. by $\frac{1}{2}$ in., and a back 26 in. by $4\frac{3}{4}$ in. by $\frac{1}{2}$ in. The front piece should be rebated $\frac{1}{2}$ in. each way at the ends, and $\frac{1}{2}$ in. by $\frac{1}{4}$ in. underneath to take the bottom, measuring 27 in. by $6\frac{3}{4}$ in. by $\frac{1}{4}$ in. Glue, nail, or screw the parts together, and smooth with glass paper to allow it to move freely in the space. Suitable handles are fitted on the front as shown.

The two bottom drawers, Fig. 7, have fronts $16\frac{3}{4}$ in. by 2 in. by $\frac{3}{4}$ in., sides 8 in. by $1\frac{3}{4}$ in. by $\frac{1}{2}$ in., and end $15\frac{3}{4}$ in. by $1\frac{3}{4}$ in. by $\frac{1}{2}$ in., and a bottom $16\frac{3}{4}$ in. by 8 in. by $\frac{1}{4}$ in., the fronts being rebated as for the drawer above. If flush handles are fitted the drawers can be full length from front to back, but if the handles project suitable allowance must be made in the lengths of the sides and the bottom. The inside of the drawers can be divided off to provide compartments for nails and screws, plywood being quite suitable for this purpose.

The doors are each 34 in. long and $\frac{3}{4}$ in. thick; one is $17\frac{3}{8}$ in. wide and the other 17 in. wide. A rebate $\frac{3}{8}$ in. each way is cut on the meeting edges of each door, as in the section at Fig. 8, and then a batten of 2 in. by $\frac{3}{4}$ in. wood is placed along the bottom of each door and glued and screwed on.

The fitments to hold the saws and other tools should be attached before the doors are hung; the hinges can be fitted at this stage but not screwed up. The saws are fitted with a shaped block to fill in the handle space, a turn-button made to the length, and then the pieces can be screwed on at the top. The tip of the saw should be arranged to fit just in the top of the bottom batten, but it will be necessary to make a slotted piece to take the end of the tenon saw. The slotted piece in Fig. 9

indicates the method of making the supports for the tools on the other door; each tool should be separately fitted, and the correct sized hole cut.

Tool Cupboard. A well-stocked tool cupboard for the home worker in wood and metal. (Courtesy of R. Melhuish, Ltd.)

The various hooks are now placed in the back to hold the bow saw and brace. A long strip of $1\frac{3}{4}$ in. sq. wood is fitted to the back of the top shelf L, and slots as at Fig. 9 cut in to take the chisels and gouges. These should be placed side by side as closely as possible; $\frac{1}{4}$ in. in between the handles will be ample space. The slots are marked off on the strip and cut out. When fitted in position, the blades will fit in the space between the top drawer and the back of the cupboard. A 1 in. by $\frac{3}{4}$ in. or 1 in. strip will be large enough to hold the bits, shanks downwards. The best method of making the holes for them is to drill a slightly smaller hole, and then cut square with a narrow chisel, as in Fig. 10.

Cupboard bolts are fitted, together with a lock, and then the outside can be either painted or sized, stained, and varnished. As the cupboard will be fairly heavy when completely filled with tools, special precautions should be taken to secure it to the wall. One method is to screw on strong brass mirror plates on the top and on the sides near the bottom, and screw to a wooden wall or to fibre

plugs in a brick or plaster wall. As an alternative, two mirror plates can be fitted at the top and the bottom supported with iron brackets.

Tooth. *See* Teeth.

TOOTHACHE. There are two different diseased states of a tooth which may give rise to toothache. One results from inflammation in the soft centre or pulp of the tooth.

The pain in this form of toothache is sharp or shooting. It varies in intensity at different times; usually it is increased on lying down. But the tooth itself is not painful on being tapped. The taking of a meal tends to increase the pain, more especially if food is pressed into the cavity or hot liquids reach the exposed nerve.

In the treatment of this form of toothache it is most important to find the cavity in the tooth and, if possible, to clear away any food which may be causing pressure on the nerve. The next step is to fill the cavity with a small, loosely rolled pledget or wad of cotton wool dipped in oil of cloves or strong carbolic acid. The excess of these drugs should be gently pressed out of the cotton before insertion. The gum in the neighbourhood of the painful tooth may also be painted with tincture of iodine. After drying the gum with cotton, this should be applied with a small brush, and the mouth held open for 2 or 3 min., so as to ensure that the iodine may not be washed quickly away. A dentist should be consulted at the earliest opportunity.

The other diseased condition of the tooth which may give rise to toothache requires different treatment. In this variety the pain is dull, continuous, and boring. The tooth is painful on pressure or tapping. The tooth frequently appears elongated or raised in its socket, and when the teeth are closed it is often acutely painful. The inflammation in this case is really outside the tooth, round its root. From the inflamed stage it may pass on to suppuration, and the pain is then likely to be more or less continuous for two or three days, until the pent-up matter is able to force a passage through the bone, when a gumboil appears over the root of the offending tooth. The gumboil is itself painful to pressure, but the boring pain usually passes away almost suddenly with the appearance of the swelling.

Some relief may be got by painting the gum in the manner already described with a mixture of equal parts of tincture of iodine and tincture of aconite. Water, about as hot as it can be borne in the mouth, may also be tried. A saline purge is often useful in the early stages of the disease, and 5 to 10 gr. of aspirin will frequently give relief in this form of toothache. All these remedies are, however, quite unsatisfactory except for temporary relief, as the cause of the trouble remains. For this reason it is most important that the sufferer should have the offending root or tooth properly treated or extracted by a dentist. *See* Caries; Teeth.

TOOTH BRUSH. Handles that are fashioned from bone are much the best for tooth brushes, as they do not easily chip or warp, and cut lengths of white French or unbleached yellow bristle are principally used for good tooth and palate brushes. The latter are made with larger handles and more rows of knots for cleaning dental plates, etc.

Substitutes are very little used in toothbrush making, although in very common varieties a fine fibre horse-hair or poor bristle may be found. All quality brushes are made either by trepanning or are wire-drawn, the former being recognizable by the plugged holes in the end of the brush, and the latter by the lined back. The tops of the bristle are cut straight, concave, or serrated, the last style being preferred by many for thorough brushing.

It is essential that a tooth brush should be kept clean and dried after use. Washing the brush occasionally in warm water should not be neglected, as this will remove any accumulation round the roots of the knots. A holder or rack should be found for tooth brushes where they can hang, or

they should be stood up to drain and dry. On no account should they be left lying about, as they are liable to pick up undesirable matter. The importance of the operation a tooth brush is intended to perform warrants a more careful selection than is generally made. As in the case of all other brushes, cheapness is not only poor economy in the long run, but in use a poor tooth brush is decidedly unpleasant. Bristles break off or come out in the mouth, and most of those remaining are entangled and cramped, with a few in a likely position to puncture the gums when the brush is again used after being dried. A brush in this condition should always be discarded and a new one obtained. *See* Dentifrice; Mouthwash; Teeth.

TOOTHPICK. Toothpicks may be either of quill or of wood, being short pieces sharpened at one end. The latter are easily made with a penknife. The use of a toothpick, however, is not, in the opinion of the best authorities, advisable, as it is liable to injure the enamel. If there exists a cavity in the tooth in which food lodges, it is well to consult a dentist. *See* Teeth.

Tooth Powder. *See* Dentifrice; Teeth.

TOPAZ. A semi-precious stone, the topaz is surpassed in hardness by very few other gems. It is found in several parts of Great Britain. Its value depends upon its depth of colouring, the sherry-coloured stones being considered the best. The white topaz is not unlike the diamond in appearance, but diamonds can always be distinguished by their excessive hardness, apart from their lustre. Pink topazes enjoy a certain measure of popularity, but their colour is artificial, being produced by heating the sherry-coloured stones. There are also blue, green, orange, and pale and golden-yellow topazes.

TOP DRESSING: Of Plants. Rich soil or manure that is spread over the soil to assist the development of trees or plants is called a top dressing. It may be put on for the purpose of keeping the soil moist in hot, dry weather, or to increase the size of fruits or flowers. When such plants as chrysanthemums, lilies, or tomatoes are grown in pots it is usual to leave space at the top for a top dressing of rich soil when flower buds or fruits are developing. Sand is an excellent autumn top dressing for a lawn on heavy land; sifted leaf-mould and decayed manure benefit a lawn on sandy soil.

TOPIARY. The art of clipping and training trees into various artificial and formal shapes is known as topiary. The yew is the principal subject, but other trees and shrubs are frequently treated in this way, including box and holly. Many firms make a speciality of growing trees in tubs suitable for topiary work. Topiary trees should be clipped in May and again in August. *See* Box; Hedge; Yew.

Topiary. Clipped yew and holly trees which are attractive in a formal garden.

TOPSIDE: Of Beef. The top or outer portion of the round of beef is known as the topside, the inner half being the silverside. It is a most economical joint for a family, especially where a large number are to be

catered for; but, although well flavoured and full of gravy when served hot, it is apt to eat dry when cold. It makes excellent pie meat, being full of gravy and free from bone or gristle. It is also good for stews, or à la mode beef, which requires lean meat.

Topside is often salted and boiled, but silverside is preferable for this purpose. The topside, however, is excellent if spiced for Christmas beef. A good-sized piece will take from a fortnight to 3 weeks to pickle. It eats better if it is larded with strips of fat bacon inserted in it at intervals. Portions of topside of beef may also be potted; the meat should be freshly cooked, flavoured with vegetables and spice. It is better to stew it in the oven, adding as little water as possible. When cooked, the vegetables should be removed and the meat minced, then pounded and potted in the usual way with butter, spice, a little of the gravy it was cooked in being strained and added. *See* Beef; Carving; Stew, etc.

Torch Lily. This is an alternative name for the red hot poker (q.v.).

TORENIA. This is a greenhouse annual flowering plant, with violet-blue or yellow flowers. It should be grown in pots, or baskets suspended from the roof, containing a mixture of loam, leaf-mould, and sand. The seeds should be sown in February in a temperature of 60 degrees. When large enough, the seedlings may be transferred to 5-in. pots, and the side shoots pinched off as they develop, in order to induce the plant to make bushy growth. The best species are *T. Fournieri*, violet-blue, and *T. Bailloni*, yellow.

TORTOISE: In the Garden. A reptile with four feet and encased in a strong shell protection, the tortoise is cold-blooded and lives to a great age. The two kinds usually kept in Great Britain are the land tortoise and the marsh tortoise or terrapin. The former is mainly herbivorous and can be fed on lettuce, cabbage, grass, dandelion and buttercup flowers, also soft fruits. The marsh tortoise is mainly carnivorous.

If the land tortoise is to be kept in the garden it must be restricted in some way, or it will cause damage to vegetation. If possible, it should be assigned to a sunny position near a wall bounded with wooden boards, with a portion of the space covered with felt or Willesden canvas to provide protection from the sun and rain. Tortoises will bury themselves in the ground during the winter. They may be placed in a box containing soil or leaves, and left in a cool room until spring when they awake they can be fed on lettuce or cabbage leaves, although they will eat very little at first.

TORTOISESHELL. Tortoiseshell, which is the horny covering of a species of sea turtle, varies in value, the finest shells being marked with reddish-brown and golden yellow shades. Many consider the blonde shells to be the most beautiful, but for brush-making the darker less transparent kinds are more popular.

Tortoiseshell is used to make all manner of toilet accessories. Manicure sets, powder boxes, hair brushes and combs, and complete dressing-table sets can be bought both in genuine and imitation tortoiseshell. Other articles made from tortoiseshell include spectacle rims, cigarette, card, and match cases, lorgnettes, purses, mirror backs and vanity cases. This shell is also used for inlaying clock cases, cabinets and other articles of furniture with delicate metal or brass tracery after the style of Buhl.

Whether tortoiseshell should be mounted or not is a matter of taste, some maintaining that it needs no adornment. Tortoiseshell may be cleaned with olive oil. *See* Buhl; Fan; Spectacles.

TOUCH: The Game. Perhaps the simplest form of this popular outdoor children's game consists in one player running after the others with the object of touching one of them. When he does this he

must call out touch, and the one touched takes his place and becomes the chaser. A variant is known as touch wood. In this the players can secure a respite from being chased by touching anything of wood. As long as they do this they cannot be touched.

A further variant requires the player who seeks a respite to whistle in addition to touching a piece of wood. As soon as he ceases to whistle he can be touched.

TOURMALINE. The mineral that is known as tourmaline is found in a wide range of colours, but it does not rank among the most expensive gems. Its tints include various shades of red, green, grey, blue, and yellow, the green tourmaline bearing some resemblance to the more valuable aquamarine. Red tourmalines sometimes possess deep tints and are known as rubellites.

The blue tourmaline, which is less valuable than the green, is also called the Brazilian sapphire, while the colourless kinds are known as anchorite. There is also a black variety, sometimes found in Cornwall.

TOURNIQUET. Tourniquet describes an instrument by which a pad can be applied tightly to a blood vessel to stop bleeding or to keep the limb bloodless during an operation.

An emergency tourniquet may be made with a folded handkerchief, a scarf, towel, stocking, or piece of calico.

A stone or other hard object is fixed so that it will compress the artery. The band is tied round the limb, and then tightened sufficiently by running a stick under the bandage and twisting it. A tourniquet is for temporary use only, and it should be removed as soon as possible.

Should it be left in position too long, gangrene of the limb may set in. *See* Bandage; Bleeding.

Tourniquet. Improvised tourniquet applied to right brachial artery. Lower bandage is applied to hold the stick used for twisting.

TOW. Whenever flax is being prepared, a certain proportion of short fibre or tow is combed out of the linen. This tow is manufactured into crash, canvas, cheap towels, and so on. Little woody particles can usually be seen adhering to the cloth in fabrics that are made from tow. Ropes are made from strong, coarse tow.

In surgery, hemp tow is an excellent substance for padding splints, and for applying to sprained parts when elastic pressure is desired. It is also a good material on which to spread a linseed poultice, preserving the heat for a longer time than a piece of linen cloth. Carbolized tow makes a very efficient dressing for wounds. *See* Rope.

Towel. Bath towels ornamented with stitchery in colours. The upper has lines and stripes carried out in shades of blue and the lower has circles in mauve.

TOWEL. Towels are generally classified as roller, bath, hand, and guest towels. Roller towels may be of strong unbleached linen, coarse huckaback or brown Turkish towelling. The first of these materials is most suitable and gives the longest wear. These towels are easily made at home as they are simply formed by a straight strip or towelling 3 yd. long, or the most convenient length for the particular door on to which the roller is fitted. The strip is neatly seamed in order that it may revolve when required.

Bath towels are made of Turkish towelling in different qualities and sizes. The largest are known as bath sheets and are usually stocked in two sizes, 48 in. by 72 in., and 48 in. by 80 in. Other white Turkish towels vary in sizes from about 20 in. by 40 in. to 30 in. by 60 in. These towels are sold hemmed ready for use. Terry towelling which is obtainable in colours and also in patterned designs is used to make coloured bath towels. Coarser bath towels are light brown in colour, but are strong and hard-wearing.

Hand towels vary greatly in quality and price, and are made in 3 usual sizes. 18 in. by 32 in., 20 in. by 36 in., and 22 in. by 40 in. Huckaback towels in fine weaves with damask borders finished by hemstitching are always pleasing. For family use a somewhat stronger weave is recommended and plain hemming may be considered more satisfactory than hemstitching. Huckaback towels may also be purchased with coloured borders, and coloured damask guest towels are obtainable. The usual size for these is 15 in. by 22 in.

Ornamental Towels. Bath, hand and guest towels may be improved by worked monograms or borders in coloured cross-stitch. A pretty design of a type suitable for the latter purpose is shown in page 420. Guest towels can be made of fine white huckaback, measuring 15 in. by 22 in. after being hemstitched. Embroidery is usually placed only at one end, but both ends are hemstitched. Very dainty trimming is supplied by a small design in Renaissance or Khetha work. The embroidery can be worked in colour, or in white on a coloured towel. Crochet lace is also a suitable edging and trimming.

Many women buy plain towels of a good quality and decorate them with a little stitchery. The towels here illustrated are embroidered in coloured stranded cottons. The top one has 3 lines and the row of short vertical stripes worked in chain-stitch in 3 shades of blue. The lower one has 3 lines of stem-stitch and a row of circles worked in plain and raised satin-stitch, using several shades of mauve. Other borders may be carried out with sprigs of flowers in lazy-daisy stitch, buttonhole rings and snail-stitch. Three rows of different feather-stitching is also an effective trimming.

Roller towels and the coarser bath towels may be marked with marking ink, but bath towels of good quality are improved by initials boldly designed or embroidered monograms.

Towel Airers and Rails. A towel horse to match the wood of each washstand is usually provided, when there is general bathroom accommodation for a number of bedrooms. A towel airer is a convenience in the bathroom. It is often made in the form of a plated stand either heated by electricity or by connexion with the hot-water system. Aluminium towel rails are obtainable in lengths varying from 24 in. to 26 in. with wall brackets for fixing. Swing towel airers in the same metal are made with 2 or 3 arms. Burnished aluminium is labour-saving, rustless, untarnishable and inexpensive. *See Linen.*

TOYS AND TOY MAKING

Suggestions that will Interest both Parent and Child

The important part played by toys in child life is recognized in this article, which adds to the information given under the headings of individual toys, such as Aeroplane; Doll; Kite Knitted and Stuffed Toys; Jigsaw Puzzle; Noah's Ark, and various model engineering contributions, such as Boat; Engine; Locomotive; Railways. See also Casting; Child; Christmas; Nursery.

Children find expression in toys from earliest infancy. A rattle or a coral with tinkling bells inspires them with the desire to repeat the pleasant sound. A brilliantly coloured ball excites their admiration. They pass through a stage of surprise at a jack-in-the-box or clockwork animal to curiosity, which, though perhaps indulged in at the expense of the particular toy, is the beginning of knowledge and invention. Imagination is stimulated by the games of make-believe, from a Noah's ark or doll's house to the wonder of things made by hand out of toy looms, from carpentering sets and plasticine to a meccano set.

The playing of games of skill with hard and fast rules develops a child's character by the discipline of competition within limits, but into his play with toys he weaves the fancies which are the outcome of his individuality.

For this reason it is a mistake to interfere too much with his choice among his toys. Having had the winding-up of a new tumbling clown explained to him, he may be delighted with its novelty for a while, but when that has worn off he has no further use for it, and turns to play for hours with a grocer's shop, weighing out commodities from bottles and tins on miniature scales, or doing up tiny parcels and falling in gladly with a suggestion that his horse and cart should be a delivery van. The great thing is that he should learn concentration by being absorbed in whatever he is doing at the time. Boredom lies in going from one toy to another in a desultory fashion.

Toys should be put away when playtime is over, and a child should have a special shelf if a cupboard or locker of his own is not possible.

If it can be avoided, it is a mistake ruthlessly to sweep away his unfinished creation of bricks or the setting of a farmyard drama, but a warning can be given that time is nearly up, and sometimes a little assistance will help towards the satisfactory completion of an edifice or episode. The care and repair of toys should be taught to children from an early age.

Nearly everyone who has had to do with young children has had the experience of seeing an expensive toy fail to please or be cast aside in favour of a cheap one. Value is represented to their minds not by its cost but by the amount of interest and amusement that they can get out of the toy.

The younger the child the more eager he is for a toy which is symbolical rather than realistic. The round block of wood spotted red and blue, with roughly carved neck and head edged with fur, and set on four legs and a green wheeled stand, is more dearly loved than the finest model of a pony with real skin and hair. They outgrow this stage when a Noah's ark becomes silly because the elephant is out of all proportion to the rabbit; or the nursery floor as an ocean for the ship on wheels fails to satisfy the little boy who has seen a friend launch his boat on real water.

Some children delight in miniature things. They like to collect families of tiny dolls, furniture, and animals. A few low shelves where they can set out these things and leave them undisturbed till the next playtime is a happy arrangement, especially if provided with a curtain on rod and rings. Other children like to impersonate the characters in their games. A toy outfit of a bus conductor may give more pleasure than a mechanical model of a motor bus, even though a sofa with a few dolls on it represents the vehicle to be driven.

Outdoor toys are nearly always fascinating. Hoops, skipping-ropes, scooters, battledore and shuttlecock, sailing boats, balls, and dolls' perambulators all have their attractions, but probably none give more joy than the wooden spade, the shrimping net, and the tin pail at the seaside. The garden becomes an absorbing toy. Such gifts as a practical toy gardening set, consisting of a number of tools and a wheel-barrow, and a small piece of the garden, usually have a great appeal.

When choosing a toy as a present, especially for a small child, occasionally people make the mistake of giving something which amuses them, such as a mascot or novelty of the moment, which has no meaning to the little recipient, instead of some simple toy which would really please. Should the present be intended to impress the parents of the child rather than the child himself, it is better to let it take some other form.

Mechanical Toys. Constructional toys in the form of collections of parts afford much entertainment to children of the age to understand them. It is a waste of money to give such sets to a younger child, who will be better pleased with a robust clockwork toy. The constructional set depends for much of its entertainment and educational value upon the appeal it makes to the imagination and ingenuity of the owner, who can combine and re-combine the parts in a variety of ways. The parent can initiate the work, and assist, but the youngster should be left to solve his own problems as far as possible. Steam engines and clockwork or electric motors can be purchased to supply power to the working models thus built up.

Model railways are dealt with in a separate article, but a word or two here about toy train sets may be appropriate. The common tinplate track as supplied with train sets is usually neither strong nor durable, and it is well worth while to purchase a good set of rails from one of the reliable firms which specialize in these goods.

A word of advice may be given here about electric sets. An accumulator is the best means of supplying the current to the conductor rails. It can be placed on a shelf out of harm's way, the leads being taken down to floor level and ending in a plug fastened to the skirting. The leads should be secured to the wall in some way, and also to the shelf, so that the battery cannot be dislodged by a pull on the wires. Another method is to make a simple wooden box to hold the accumulator, the lid being secured by a small lock, and the box being screwed to the floor in a corner of the room. In this case also the leads can be taken to a plug on floor or skirting. Train sets can be obtained for connecting to the electric light mains, but these are not suitable for children without supervision.

There is a third method of running an electric train, in which a small battery carried in the engine or tender supplies the current. The battery has to be replaced by a new one at frequent intervals, of course, but this is a simple method, and no conductor rails are needed on the track. The above remarks apply to the smaller or toy train sets.

Mending Toys. The cheaper clockwork toys do not usually admit of repair, and even in the case of the better made ones the gears and spring wear out or lose resilience, as the case may be, after a period of strenuous service.

In repairing mechanical toys made of metal, a certain amount of skill with the soldering iron will reduce labour considerably. Where toys are finished by a lithographic printing process, it is absolutely necessary to remove the coating of paint entirely, and to get down to the bare metal by scraping, before attempting to apply the solder. Many cheap toys are made with cog wheels fitted to their shafts or axles with lugs or slots, or by flattening the spindle each side of the fly-wheel boss. Such devices usually give trouble, and even a new toy will be considerably improved in strength and its life trebled by soldering such joints together. If the paint has to be scraped off to do the soldering, the part can be touched up afterwards with a little oil colour. Points in body construction

can also be dealt with in a similar manner, the soldering of the lugs being effected from the inside wherever possible.

Toy. Fig. 1. Diagram illustrating methods of repair. A. Detail of lug and slot for wheels of mechanical toys. B. How to solder lugs in body construction. C. Securing a metal wheel to spindle by soldering. D. Insertion of wood screws to mend a fractured wooden joint. E. Another repair for a wooden toy. (F. Brass bush fitted to a wooden wheel)

Glue is the proper adhesive for wooden toys, but in addition it is often advisable to drill a hole and insert a wood screw across the joint of a fractured part. In fitting screws the preliminary drilling for the screw should not be forgotten, as toys are generally made of the cheapest kind of wood.

The toy maker frequently drives a big nail or screw into the end of a wooden rail and makes the nail the axle of a wheel supporting the whole weight of the toy. Such fixings in end grains are never satisfactory. A cure may be effected by crossing the screw with a wooden plug, as illustrated, or by fitting an all-metal axle such as is used in a perambulator. Wooden wheels should be bushed with short pieces of brass tube. The methods of repair mentioned are illustrated in the accompanying diagram (Fig. 1).

Soft Toys. Instructions are given in the article on Dolls for making a rag doll, and other soft toys are dealt with in the article on Knitted Toys. Plush or fur cloth covered toys are easily made by the home worker.

An odd length of white fur cloth can be utilized for the rabbit shown in Fig. 2. The main part of the body and the head are cut in one, but the underpart and the ears are added separately. A quarter of a yard of cloth, 48 in. wide, is needed, together with a little pink flannelette for lining the ears.

Toy. Fig. 2. Fluffy rabbit which is very realistic when made in white fur cloth. Fig. 3. Diagrams for making the fluffy rabbit, showing the shapes for ear; base and body, and (above) how to join up the cover before stuffing.

Fig. 4. Tinker Boy, a strange but appealing animal covered in woollen plush and easily made at home. (Courtesy of "Best Way")

When cutting out, use the cloth folded with the selvedges together, and arrange the patterns, cut to the shape shown in Fig. 3, in the positions there seen. First join the long, straight seam of the base or underpart; then take it, still folded, so that the seam runs along the top, but with the wrong side inside, and slip it between the two layers of the main body. The latter should be so put together that the right sides face.

Stitch the edges of each layer of the base to the edges of each layer of the main part, matching the sets of two notches, and also drawing the curved back part of the base down to the lower edge of the main part. Next stitch the two main parts of the body together above the inserted base portions, commencing at the front just below the head, and working around this and along the top of the body to the back of the inserted base.

Leave a small opening in one part of this seam, however, so that the stuffing may be put in. Turn the shape inside out, stuff it tightly with kapok, and then sew up the opening. Line each ear with the flannelette; then make a pleat in the straight edge and sew it to the head. The addition of two boot buttons for the eyes gives the finishing touch.

Patterns for other toys of this description can be obtained from "Best Way" 291a, Oxford Street, London, W.1. A delightful example, called Tinker Boy, is illustrated in Fig. 4. This curious creature requires 1 yd. woollen plush, 2 glass eyes, bell and ribbon for the neck, a little black darning wool, and kapok for stuffing. The latest "Best Way" book on Home-made Toys should be obtained at a newsagent's, as new patterns are frequently invented and described.

Wooden Toys. Toys can be made by the home craftsman from wood with a few simple tools.

To begin with balancing toys, there is considerable scope for inventiveness with either the fixed or flexible balance. A good example of this kind of toy is shown in Fig. 5, in the form of the balancing

horse. The outline of the horse, or any other animal, is marked out on a piece of thin wood about $\frac{1}{4}$ in. thick and cut out with a fretsaw. Any close-grained hardwood is suitable for the work, but with plywood there is little risk of breakage. The pendulum or balance should be of lead, which is cast in a plaster of Paris mould or in a well-greased tin lid. The wire is placed in the mould before the lead is poured in, and the other end of the wire is pressed into a prepared hole in the body or other suitable position on the animal. The stand is made from short lengths of dowel fitted in a wooden base; the uprights can be square in section provided sufficient space is allowed for the balance wire to move freely. It is not essential that the stand should be made, as the toy will act equally well on the edge of a table or mantelshelf provided the balancing wire is long enough.

Another form of balancing toy is shown at Fig. 6, string being substituted for the wire to hold the weight, and the various parts of the body hinged together. It is advisable to use a close-grained wood or 3-ply, the thickness of each piece being $\frac{3}{16}$ in. The various parts are shown in Fig. 7, and are cut out with a fretsaw; the two pieces for the body should be pasted together temporarily with a piece of paper between and sawn to shape, as this ensures their being alike. All edges and surfaces should be glass-papered.

The small pieces are glued to one of the body pieces in the positions indicated by the dotted lines. Small nails are driven into the ends of the head and tail pieces, which should be further rubbed with glass paper to make them a little thinner than the small pieces attached to one of the body pieces. Holes are bored or drilled through the body and the head and tail for the hinge screws, and slightly enlarged in the two latter pieces to allow free movement. The balance weight can be of the same

shape as that used for the horse, but it should have a groove or a hole through it to enable the string to be fastened. A round ball can be cast in the same way, and looks neater than the flat weight. Each length of string should be about 8 in., but the longer it is the better, as the toy will work for a longer period. It is necessary to support the stand either by a weight at the back or a small G clamp. The toy can be made more realistic by fitting it on a platform and making a small food trough under the head. A development of this kind of toy is made by arranging two parrots on a strip of wood and connecting the strings to a pendulum, or cutting the shape of two men holding a hammer and striking an anvil, which is arranged between them.

Toy. Fig. 8. Pole cart with small cast iron wheels. Fig. 9. Axle block slotted for handle fitment. Fig. 10. Stationary crane. Fig. 11. Component parts of the stationary crane. Fig. 12. Ratchet wheel and catch. Fig. 13. Axle and handle. Fig. 14. Simple travelling crane.

The pole cart in Fig. 8 is composed of two sides nailed to end pieces and to a base. Cast-iron wheels are screwed to axle blocks, and the handle, which is fitted to a projection in front, is so arranged that it will not fall down further than an angle of 30° in front. The two sides are 16 in. by $6\frac{1}{2}$ in. by $\frac{1}{2}$ in., the ends 9 in. by 7 in. by $\frac{1}{2}$ in., and the bottom 20 in. by $10\frac{1}{2}$ in. by $\frac{1}{2}$ in., planed up and finished smooth, preferably from a hardwood such, for example, as birch or elm.

The sides of the cart should be securely nailed or screwed to the ends and the bottom attached in the same way. The axle blocks are 12 in. by $2\frac{1}{2}$ in. by $\frac{3}{4}$ in. and must be of hardwood. One side is quite straight, and the other shaped to 1 in. deep at the ends from a line drawn 3 in. each side of the centre, and the ends cut off with a chisel to an octagonal form.

One of the axle blocks is screwed to the bottom board $1\frac{1}{4}$ in. from the end; the other, as in Fig. 9, is slotted to take the dovetailed end of the projection to carry the handle. Plane up a length of hardwood to 11 in. by $4\frac{1}{2}$ in. by $\frac{3}{4}$ in., reduce the end to $2\frac{1}{4}$ in. wide, and cut a $2\frac{1}{4}$ in. long by $\frac{3}{4}$ in. slot at the small end, undercutting it $\frac{1}{2}$ in.. The dovetail to fit in the slot in the axle block should be sawn out and the piece glued to the block. A thin washer is cut from a piece of tinned sheet, and the axle block is screwed from the centre of the bottom and 5 in. from the end, with an ordinary washer under the screw head and the thin washer between the block and the bottom.

The pole or handle is planed to 22 in. by $1\frac{1}{4}$ in. by $\frac{3}{4}$ in., one end is sawn off to an angle of 30° , and the other rounded and fitted with a $3\frac{1}{2}$ in. length of $\frac{1}{2}$ in. dowel. The handle is fitted to the slotted projection with a stout wire nail or a rivet. The wheels should be 3 in. diameter, and preferably of cast iron. Wheels made of some close-grained wood may be used instead, or metal wheels fitted with rubber tires. The wheels should be attached to the axle by means of stout round-headed screws, washers being provided in the case of wheels fashioned in wood. The latter should also be bushed with a piece of brass tube.

Cranes can be made stationary, as in Fig. 10, or to travel; in the latter case a truck being made as indicated at Fig. 14. The parts of the stationary crane are given in Fig. 11. The base is 9 in. by 4 in. by $\frac{1}{2}$ in., and the uprights to hold the winding gear are 3 in. by 3 in. by $\frac{1}{2}$ in. with one corner sawn off to leave 1 in. The winding roller is cut to 3 in. from a length of 1 in. or $1\frac{1}{4}$ in. round, axles being provided by suitable lengths of hard brass wire fitting through holes bored in the sides of the uprights. The latter pieces are nailed to the base with a 3 in. by 1 in. by $\frac{1}{2}$ in. piece, and a 4 in. length of $\frac{3}{4}$ in. dowel between at the end to strengthen the base, as shown.

The uprights to support the base of the arm or jib are $2\frac{1}{2}$ in. by $1\frac{3}{4}$ in. by $\frac{1}{2}$ in.; they are tenoned at the ends, fitted into slots in the base, and the top corners trimmed off. The slots or mortises in the base are 3 in. from the end and $\frac{3}{4}$ in. apart; the arm is made from two pieces 15 in. by $\frac{1}{2}$ in. and tapered evenly from $1\frac{3}{4}$ in. to $\frac{3}{4}$ in. Two $\frac{1}{2}$ in. thick blocks are prepared for fitting between the lengths.

They must be shaped to allow of a width of $1\frac{1}{2}$ in. at the bottom and sufficient to take a small grooved pulley at the top. The ratchet wheel and catch in Fig. 12 are made from a piece of sheet brass. The method of flattening the ends of the wire for the axle, together with the handle, is shown in Fig. 13. The arm is held in position with suitable lengths of small brass chain, and similar material can be used for the rope, a hook being fitted on the end.

The travelling crane in Fig. 14 is shown in a small size, but if the main proportions are retained it can be built much larger. The number of parts have been reduced as low as possible, and the construction could hardly be more simple.

Dimensions for a push horse are given in the elevations in Figs. 15 and 16, and represent a medium size. The body is cut to 10 in. from a round of 4 in. diameter, and flattened at the bottom; the legs are 10 in. by 1 in. diameter, tapering to $\frac{3}{4}$ in. at each end. The head is shaped from a piece of $5\frac{1}{2}$ in. by $4\frac{3}{4}$ in. by $\frac{1}{2}$ in., and let in to a depth of $\frac{1}{2}$ in. The base is 12 in. by 4 in. by $\frac{1}{2}$ in., with 1 in.

square lengths underneath to screw the wheels to, the latter being $2\frac{1}{4}$ in. diameter and $\frac{3}{4}$ in. thick if of wood, as is usual.

Fig. 15. Push horse shown in side elevation, with dimensions. Fig. 16. End elevation of the push horse.

The handle is formed with two 18 in. by 1 in. by $\frac{3}{8}$ in. lengths, with a 4 in. length of $1\frac{1}{8}$ in. diameter round between, these pieces being joined together with $1\frac{1}{2}$ in. wire nails. The saddle and harness is usually formed with coloured paper, such as the imitation morocco paper used by bookbinders. The mane and tail can be made from a piece of an old skin rug. By fitting a projecting block to the front axle a pole can be fitted, in the same way as for the pole cart, that will enable the horse to be pulled instead of pushed.

TOY DOG. This name is given to various small dogs which are sufficiently diminutive to be carried on the arm of their mistresses. They are obtainable in many breeds, the Pekinese being one of the most popular, while Pomeranians and Yorkshire terriers are also much sought after.

The original toy terrier, which was only obtainable as a toy dog, is not so often seen since breeders took to breeding small dogs of other and more attractive types. The Belgian griffon is another favourite, while the King Charles was perhaps the first of all, and still maintains its popularity to a great extent. With Yorkshires, Pomeranians, pugs, and the like, it must be specially mentioned if a toy size is required, as they are also bred to their normal sizes. *See Dog; Japanese Spaniel; Pekinese; Pug.*

T PLATE. Steel or iron plates in shape resembling the letter T are sometimes employed to strengthen the joints of woodwork. They are arranged in pairs, one on either side of the joint, and bolted right through the timbers, holes being provided in the wood and the plates for this purpose. T plates are also placed on the tie-beam and the vertical posts of a queen-post truss.

TRACHELOSPERMUM. This is an evergreen climbing shrub for greenhouse cultivation, sometimes known as Chinese jasmine or Chinese ivy. The best species is *jasminoides*, which produces fragrant white blossoms from June to August and reaches a height of 12 ft. It should be planted in spring, in pots of fibrous loam, peat, and sand, or in well-drained borders, training its twining growth to trellis or walls. The plant should be pruned slightly after flowering.

TRACING: On Paper. The operation of transferring a drawing or picture by means of prepared paper can be done in two ways. A sheet of tracing paper, which is a specially prepared semi-transparent paper, is placed on the drawing, and the lines underneath are drawn over with a pencil. This method of providing a duplicate of a prepared drawing is used by architects and builders as well as woodworkers and engineers, but tracing cloth is often employed instead of the paper, as it is not so easily torn. Duplicate plans and elevations can be made in this way, colouring being done with coloured inks or water colours.

Another method of transferring drawings is to trace them through a sheet of carbon paper placed underneath the drawing. This method is useful for transferring designs on to metal, wood, and other materials.

In all tracing it is necessary to keep exactly to the original lines; at the same time it gives the skilled draughtsman an opportunity of correcting faulty lines on the original. In using carbon paper, it is advisable to pin the drawing at the top so that the progress of the work can be followed, otherwise it may be found on the completion of the work that important details have been omitted. *See Drawing; Embroidery; Plan.*

TRADESCANTIA. This is the name of a genus of hardy herbaceous and greenhouse plants. The favourite hardy kind is the Virginian spiderwort (*virginiana*), 2 ft. high, which bears purplish-blue flowers in summer and will thrive in ordinary soil in a shady border. It is known as Flower of a Day, because the individual blooms soon fade, but the plants flower throughout many weeks. The greenhouse species are valuable trading plants which will flourish in soil beneath the greenhouse staging, or if grown in pots they form an attractive edging. They may also be planted in hanging baskets. A compost of loam, leaf-mould and sand suits them and they are very easily increased by cuttings.

Tradescantia. Trailing foliage of a greenhouse variety of this plant.

TRAGACANTH. This describes a gummy exudate from a Syrian tree, which has the property of swelling into a gelatinous mass when added to cold water, and has a soothing and demulcent action when applied to irritated mucous surfaces. It is an ingredient of some throat lotions, but its chief use is as a means of holding in suspension insoluble powders, resins, and oils.

TRAINING: Of Plants. During the first few years of growth the training of fruit trees is of paramount importance. The nursery specialist supplies young trees in various shapes, chiefly bushes, pyramids, standards, cordons, espaliers, and fans.

Bush Trees. Bush trees are the best allround kinds for the amateur. They are easily accommodated to limited space if kept properly trained, and are particularly suitable for simple cultivation and the production of such utility crops as apples, pears, plums, gooseberries, and red, white, or black currants.

Yearling maidens of apples, pears, and plums usually consist of one main stem which is shortened during winter to about six buds. The following season these buds will produce leader and side shoots, all of which will require shortening to about one-fourth their length.

During their third season they will develop further, leading and lateral growths, one of which should be permitted to grow at the extremities of each branch, all laterals being reduced to their fourth leaf.

Gooseberries and red and white currants can be raised from simple cuttings, denuding each of all its buds except the three top ones. These will produce three shoots, all being allowed to continue growth until the fall of the year, when they are cut back about half-way. Thus, the following season a larger number of shoots will progress, these in turn being reduced in length during the winter. The next, year they will require summer pruning of all laterals, with another slight trimming during winter. In preparing cuttings of black currant none of the buds must be taken off.

Pyramids. Pyramids are suitable for apples, pears, plums, and cherries, and are trained by cutting back a maiden tree to about 12 in. from its stock as a result of which leader and side shoots will appear. During winter the leader should be reduced by about one-third and laterals by half, staking the former securely to keep it upright. Subsequent training is similar to that for bushes, but particular care must be taken to ensure pyramidal shape.

Training of trees and plants. 1. Method for frames: *a*, cane or wire supports. 2. Espalier for fruit: *a*, wood; *b*, canes; *c*, wire. 3. Greenhouse trainers: *a*, rings, ringed staples and wire. 4. Garden trainer for weeping roses or climbers: *a*, child's hoop; *b*, cross strainers; *c*, wire; *d*, wooden support with tarred base and holed apex. 5. Garden trainer of wood and netting for sweet peas; *a*, tarred bases for insertion in soil

Standard Trees. These have a clear stem of about 6 ft. and a head of branches which develops from the uppermost buds. Every winter for the first few years the season's main shoots should be cut back by about half to ensure a foundation of strong branches. Care must be taken to keep them about 2 ft. apart to prevent overcrowding in subsequent years. Side shoots should be pruned to two or three buds each winter for the first few years, but established trees are pruned chiefly by thinning

out superfluous shoots and branches. Half standards, which are on stems about 4 ft. high, are treated in the same way.

Cordons. Single cordons are trained from a maiden stem and cut back about half-way during winter. The resultant leading shoot is then permitted to grow on, all side growths being carefully reduced to two buds in winter. This procedure is continued until the stem is well furnished with fruiting spurs.

Double cordons are trained by allowing two shoots to grow on after the first pruning back of the maiden stem. Another form of cordon is horizontally trained, its two cordons being trained to strong horizontal wires about a foot or so from the ground, to which point the primary cutting back of stem is carried. Apples, pears, red and white currants, and gooseberries all do excellently in cordon form.

Espaliers. Espalier is a term given to the method of training fruit trees on supports of iron, stout wire, or wood, as useful and decorative margins to walks of kitchen gardens, trees thus trained being known as espalier trees. Such trees are almost beyond the average amateur, and therefore should be obtained ready formed from a fruit specialist. Treatment subsequent to planting is merely training to supports and suitable pruning to maintain and increase fruiting spurs.

Fan-trained trees, also, are best secured from the specialist. This type is suitable for the cultivation of apples, pears, plums, peaches, figs, and cherries on walls. *See Wall.*

The Diagram Above Explained. The diagram shows also methods of training adaptable to roses of a weeping character, and also to greenhouse and outdoor plants. Fig. 1 shows a simple fixture for frame culture of cucumbers, tomatoes and plants of similar habit. It consists of a simple stem support, with a top length of cane or stretched wire from front to back of frame. Fig. 3 gives at a glance an excellent wiring method of training plants in a lean-to greenhouse, the principles of which may easily be extended to the full-span or any other type of house.

Fig. 4 is an umbrella trainer of particular value for the display of standard weeping roses or other drooping plants, its simple components being merely a child's hoop, an upright with cross pieces, and a sufficient quantity of stout wire; its construction is quite easy to follow from the sketch. Fig. 5 is another simple but useful type of trainer, specially suitable for sweet peas, but handy also for climbing nasturtiums and plants of similar habit. It may be constructed of two circular pieces of wood—butter-tub hoops will do quite well, these being attached to four fairly stout uprights as sketched. The bottom ends of the uprights should be tarred or creosoted to prevent decay. Wire, or preferably rot-proof string, is then arranged, tubular fashion, securely to hoops and uprights, thus forming an inexpensive contrivance. This is particularly effective for sweet peas when grown in tubs. The netting employed should have a good open mesh.

TRANSFER. Designs printed on thin, transparent paper and capable of being transferred to other surfaces are known as transfers. They can be bought from most fancy needlework shops and artist's colourmen and are obtainable in flower, fruit, and other designs. They are used for embroidery, bead work, painting on glass and textile fabrics, pattern printing, leather work, gesso and barbola work, batik, and for transferring designs on to lampshades.

To use a transfer on a textile fabric, place the latter on an ironing table with the right side upward, then pin the transfer to it with the waxed side down, and press with a moderately hot iron. If the material is thin, the flat of the iron should not be used, otherwise the wax may spread and cause disfiguring marks. The heel of the iron may, however, be used without harmful results. When painting on transparent materials such as gauze or fine georgette, the design may be tacked underneath the fabric, or the latter may be pinned over the transfer on to a board.

Transfers can be used several times, even though the wax has been ironed off, for the outline still remains. They are also used in the following manner for transferring to paper, parchment and prepared wood surfaces: Cover the portion of the fabric to which the design is to be transferred with a sheet of carbon paper, lay the transfer on top, and pencil over all the lines.

Various women's periodicals specialize in transfers for embroidery and designs which may be adapted for other art crafts.

Transfer for Applying Decoration. Another kind of transfer is specially prepared for applying decoration to various materials in the form of lines, coloured designs, and pictures. Imitations of painted decoration, marquetry work, bandings, stringing, sign writing, graining, floral patterns, and pictures in miniature can be obtained in the form of transfers.

In applying transfers to wood, the surface must be perfectly smooth and clean, and preferably bodied up with french polish, although this is not essential. The exact position of the transfer must be marked lightly, the outlines of the design being indicated on the back of the transfer, so that it is not difficult to place the paper in the correct position. First cut away most of the unnecessary paper surrounding the edges of the transfer, leaving a margin of about $\frac{1}{8}$ in.

The face of the transfer is wiped over with a clean duster, and then with a small, stiff brush it is given a thin coat of gold size.

The paper is then placed on one side, free from dust, for the size to dry. A suitable size can be made by dissolving $\frac{1}{2}$ oz. of best gelatine in 1 pint of water. If the wood has been bodied up, the surface should be rubbed down with powdered pumice-stone placed in a pounce bag and finally wiped over with a clean, dry rag.

The transfer is ready for application when the gold size is tacky. On no account must the surface be wet. It can be tested by placing the end of the finger on it. If the finger sticks without pressure the surface is not dry enough, but if a little pressure is needed to make it stick to the finger it is ready for application. If the transfer is on duplex paper, it should be divided and the thick backing paper thrown away. The surface of the transfer is carefully placed in position and well rubbed into contact with the work. It should be noted that when once the transfer has been placed on the wood it cannot be shifted without spoiling it. It is therefore best to commence with one corner and gradually press it into contact; this method also minimizes the chance of air bubbles appearing under the transfer when finished.

Immediately the transfer has been pressed well down on the surface, rub it further into contact with a slightly damp sponge. The sponge is dipped in warm water to wet it thoroughly, and the paper surface of the transfer is wetted, allowing about 5 min. for the water to soak in. One corner is lifted up and the paper is peeled off, leaving the design on the wood. The coloured surface is lightly washed over with the wet sponge, working from the centre to the outsides, and it is then dried by gentle pressure with a clean cotton rag. If there are air bubbles, they may be removed by pricking with a needle point and pressing the transfer down with a wet finger tip.

On no account should the transfer at this stage be touched with a dry finger, as the paint will stick to it and spoil the work. The superfluous gold size round the edge of the transfer can be removed by dipping a dry sponge in turpentine and wiping over the transfer from the centre to the outside until all traces have disappeared. This operation should not take more than a few seconds or the turpentine will attack the paint and dissolve it. Directly the size has been removed, the surface should be wiped dry with a clean cotton rag. When dry the colour will harden, and can be coated, if desired, with a transparent polish.

The method of applying coloured transfers or linings to polished metal surfaces is somewhat similar, but special care will be needed to fit the paper on curved surfaces, otherwise the finished work will appear slovenly. In transfers of lines making a panel with ends, these portions should be applied first and then joined up with butt and not overlapping joints. To make an effective join, the length of line between the end portions must be accurately measured, and, in the case of the end pieces as well as the lines, as much of the outside paper as possible cut off. *See* Embroidery; Graining; Painting on Textile Fabrics.

Transfer applied to wood in imitation of decorative inlay work.

TRANSFORMER: In Wireless. This is an apparatus for converting an alternating current from one voltage to another and more convenient voltage. The simplest form comprises two windings, a primary and a secondary, and these are coupled to each other so that energy is transferred from the primary to the secondary by electromagnetic induction. An iron core is almost invariably used in order to increase the inductive effect. This core is laminated (built up in layers) so that losses due to eddy currents are minimised. When the primary winding is connected to a source of alternating current supply, a magnetic flux is set up which becomes linked with both windings, the voltage per turn being the same in each winding (neglecting losses). The voltage across the secondary winding is, therefore, directly proportional to the ratio of the number of turns on the secondary to the number of turns on the primary. Thus, if the ratio of secondary to primary turns is three to one the voltage across the secondary terminals will be three times the voltage across the primary terminals.

In this case the transformer would be referred to as a “step-up” transformer. When the voltage is reduced (the secondary winding having fewer turns than the primary) the transformer is of the “step-down” type. In the transformer used in a mains wireless receiver there may be several secondary windings, each producing a different voltage from that of the supply to which the primary is connected. For example, there may be a low voltage for the filaments of the valves “step-down” and a high voltage for the anode circuits.

One of the most frequent sources of trouble in the cheaper mains sets is the “burning out” of the transformer. This may not necessarily be an actual fusing of the wire in the device, though this sometimes happens; the term “burning out” is also applied by wireless engineers to a fracture of the wire due only indirectly to heat such as may follow a crystallization or corrosion of the metal. Although separate secondary windings are frequently used for the production of different voltages from the one transformer, it is also a common practice to take tapplings from the one secondary winding. Also, primary windings of “mains” transformers are often “tapped” so that the wireless receiver can be adjusted easily by that means to different supply voltages. Some transformers are provided with “centre taps”: the input transformer in a “push-pull” circuit has its secondary winding so designed, and it becomes a double secondary with centre point electrically connected to valve filaments.

Transformer Coupling. This is a method of coupling wireless receiving valves in cascade for amplifying at high or low frequency. In a high-frequency transformer the secondary is usually tuned and the primary is untuned, the number of turns on this winding being adjusted to give the required degree of selectivity. The coupling between the two windings is normally fixed, and the degree of selectivity will be minimum when the transformer has a turns ratio of 1:1. Decreasing the number of turns on the primary increases the selectivity but may decrease the energy transfer between the primary and secondary circuits, and therefore the sensitivity. In practice it is necessary to effect a compromise with the object of achieving good sensitivity and selectivity.

Transformer coupling is employed in low-frequency magnifiers, and provides greater magnification per stage than either resistance-capacity or choke coupling. A good low-frequency transformer should possess a high primary inductance and a secondary winding of low self-capacity.

A high primary inductance ensures an adequate amplification of the low notes, but it is essential that the valve connected in the primary circuit should have an appropriate A.C. resistance or impedance. Suitable types of valves are usually recommended by the makers of the transformers, and these should be employed. The high-tension voltage must be adjusted so that the current flowing through the primary winding is within the limits specified for that particular transformer.

TRANSMISSION: In Motor Cars. Transmission is the mechanical means by which the power developed by the engine is transmitted to the road wheels.

The usual lay-out of the transmission in a bur-wheeled vehicle consists of the clutch, the gear box, propeller or cardan shaft, and the five or back axle. Two other lay-outs are clutch and gear box as a part of the engine unit, and the gear box as a part of the back axle unit. Of the three the second is the most common, and the third is seldom met with. The clutch, of whatever type, forms part of the flywheel or is directly connected with it. In the three-unit system (independent gear box) the driven member of the clutch is connected by a short shaft to the primary shaft of the gear box. A universal joint is fitted at each end of the clutch shaft so that in the event of chassis distortion undue strain will not be placed upon the bearings of the gear box and the clutch spigot.

The propeller or cardan shaft, if of the open type, is fitted with a universal joint at each end, one of which is designed for sliding as well as universal movement. This feature is necessary owing to the difference of centres between the axle and the spring anchorage and that of the gear box and the cardan shaft. With the enclosed cardan shaft one universal joint only is provided at the gear-box end, the springs being anchored by shackle plates at both ends. The road wheels of the back axle are driven by either bevel or worm gearing through the medium of the axle shafts and the differential gear.

The clutch and gear box unit construction follows exactly the same lines, except that a clutch shaft fitted with universal joints is dispensed with. A short semi-floating shaft entirely enclosed takes its place, and a longer cardan shaft is necessary, which may be either of the open or the enclosed pattern.

In the third system, gear box and back axle unit construction, the drive is transmitted by a cardan shaft, fitted with universal joints at each end, if of the open type, and one universal joint at the clutch end if of the enclosed pattern. As a rule the clutch is provided with a short shaft that goes to a bearing at about the position usually occupied by the gear box. The cardan shaft is universally jointed to the clutch shaft at this point. The object of this is to relieve the clutch mechanism of the lateral strains imposed as well as to reduce the length of the cardan shaft.

Chain transmission is now found only in the motor cycle and a few three-wheelers. For the motor cycle the transmission is either solely by silent roller chain, or by chain from engine to gear box and thence by another chain to the back wheel.

To revert to the motor car forms of transmission, there are, of course, other principles that have been tried, such as hydraulic, electric, and patent devices that give an infinite number of gear reductions, also the friction drive, formerly used on some fight cars.

Fluid Flywheel. This is a hydraulic transmission device introduced by the Daimler Co. The mechanism, which replaces the ordinary clutch, consists of two cup-shaped members facing each other—the one, filled with oil, attached to the crankshaft, and the other, enclosed by the driving cup, rotating with the first motion shaft of the gear box. Both cups are divided off by radial webs into a number of cells, and the adjacent edges of the two sets of cells (in driving and driven members respectively), are separated by a narrow gap. When the driving cup revolves, the oil receives a circulatory motion and, in passing to the driven member, gives up its energy to the latter, so rotating it. At very slow engine speeds the amount of slip is large, and practically no drive is transmitted, but as the engine is accelerated the slip quickly diminishes until at normal speeds the loss is only about 2 p.c. Thus the device acts automatically.

Loss of road speed and of general efficiency, often attributed to minor engine faults, can frequently be traced to neglect and want of lubrication throughout the transmission. Such parts as the universal joints of the cardan shaft should be frequently looked to, because, apart from rotary movement, they have also to bear a considerable movement that is set up by the varying axle position in relation to the chassis.

It is perhaps seldom realized that when the car is travelling on top gear the clutch shaft and cardan shaft, including all the universal joints, are revolving at engine speed, a fact that easily accounts for the rapid wear that takes place unless proper attention is paid to lubrication.

A worn universal joint should be immediately replaced or rebushed and new pins fitted, otherwise a fracture may easily occur owing to the severe blows imparted by the torque of the engine. In the case of chain drive it is imperative that the sprockets in the system should be dead in fine. All worn parts should be attended to, as it is through neglect of these that transmission noise is caused.

With reasonable care and intelligent driving, transmission wear or risk of breakdown should be negligible in the modern car. The driver, however, of a moderate powered car who is afraid to use his gear box and forces his engine to labour on hills, or after turning a corner is placing severe strain upon the transmission system at every point from the clutch to the back axle. *See Clutch; Differential Gear; Gear; Live Axle; Motor Car; Motor Cycle; Propeller Shaft.*

TRANSOM. The prepared piece of wood which divides the upper glazed portion of a window or door frame is usually known as the transom. In casement and French windows, or doors with a glazed opening above, the transom serves also as the door head. In an ordinary window of this type, the transom would be about 6 in. wide and 2 in. thick on the inside, tapering on the top surface to a thickness of $1\frac{3}{4}$ in. outside the window. This

Transom. Sectional view showing position of transom

is technically termed weathered, and is designed to throw off the water. A groove is generally cut underneath to prevent water running along to the sash, or, to use the technical terms, the underside of the transom is throated.

In many windows, the transom is bevelled off from its highest point. Casement windows or sash windows with a fixed or fan light above are called transom windows. This type of window is often made in metal, but the division between the small upper portion and the lower portion is still called a transom. *See Casement; French Window; Window.*

TRANSPLANTING: Of Plants. Carelessness in transplanting is the cause of many failures in the garden. Plants, whether seedlings or mature specimens, should be lifted from seed box or open ground with a good ball of soil if possible, but always with their fibrous roots intact. Care of these roots is of paramount importance, for it is their hair-like tendrils that collect the nourishment upon which the health of the plants is entirely dependent.

After plants have been lifted they should never be left exposed to the air, but should be transferred to their new quarters or deposited in a shady place. The smaller kinds should be covered with wet moss and soil and large specimens such as roses and fruit-tree enclosed in sacking and drenched with water. They should be replanted at the earliest possible moment, when the sun is down, and watered frequently until they are again established. Syringing during the evening will be of additional benefit, particularly in the case of transplanted evergreens.

Transplanting. 1. Transplanting streptocarpus : *a*, corks ; *b*, rough ; *c*, peat ; *d*, fine soil. 2. Lapageria rooted cutting detached from parent, transplanted to pot and plunged in a frame. 3. Transplanted tree carnation layer : *a*, corks ; *b*, broken turf ; *c*, compost ; *d*, sand. 4. Calceolarias transplanted to box : *a*, leaves ; *b*, soil ; *c*, ventilating block ; *d*, glass. 5. Transplanting a standard, showing circular trench to be filled with water before lifting tree. 6. How to lift a seedling. 7. Same transplanted correctly. 8. Transplanted too deep. 9. Dry weather transplanting. 10. How to transplant on wet soil

TRAP. This word has three main meanings, as far as the household is concerned. It refers to a piece of mechanism widely employed for catching obnoxious insects and animals, such as beetles and mice. It means secondly a contrivance used to hinder the passage of foul air from a waste pipe, and finally a small vehicle which is drawn by either a horse or a pony. *See* Beetle Destruction; Carriage; Dog Cart; Drains; Fly Paper; Mice; Pipe; Rat; Vermin.

TRAPDOOR. The general use of a trap door is to close an aperture through a floor, ceiling or roof. It is a horizontal door and usually consists of stout boards jointed together and strengthened by cross battens. The framework round the trap door must be strong enough to support any load which may be brought upon the floor.

Trap Door. Fig. 1. How the flap hinges are fitted. Fig. 2. Making a small trap door of floor board with deal cross pieces. Fig. 3. Simple lifting device consisting of a small ring.

A commonly adopted plan is to make an aperture between two or more joists or rafters, bridging the space between them with stout timber about 25 per cent thicker and equal in depth to rafters or joists. These timbers are known as trimmers and should be tusk tenoned to the others. Intermediate rafters or joists that have to be cut to form the aperture are mortised and tenoned into the trimmers.

In the Floor. Fillets of wood are in the majority of cases fitted around the inner faces of the trap hole with their upper surfaces at such a depth as is necessitated by the thickness of the trap door. Notches or openings are cut in the fillets where necessary to clear the battens. The upper surface of the floor is cut back so as to reveal about half the thickness of the joists and this is then filled in with a mitred framework.

The trap door should be very solidly constructed and fit the hole accurately, and when in position should be flush with the normal surface of the floor. It requires to be properly hinged with cellar or trap door hinges. These comprise three parts; two are fitted to the framework and the trap door, and the third serves as link connecting the other two, there being two hinge points, one near each end of the link. The trimming has to be cut away so that the flap hinge can be sunk into it with its upper surface level with that of the floor. Fig 1 illustrates this type of hinge and the mode of recessing the timber for its reception.

When the trap door does not exceed about 21 in. square, ordinary butt hinges may be used. These are fitted vertically into the joint between the trap door and the floor boards, as illustrated in Fig. 3. Good stout screws should be used to secure them, the hinges being of the malleable cast variety, or of some other kind that possesses sufficient strength to stand the strain.

To enable the trap door to be lifted, it is desirable to fit a small ring handle, such as that shown in the illustration, and, to prevent the trap door being opened, it is a wise precaution to provide it with a couple of bolts on the underside.

Loft Doors. When fitting a small trap door for access to a loft, or other similar part of a building, its width should not be greater than that between two joists, and then it will suffice to fit two cross members between them and secure them with stout spikes driven through the ceiling joists. The trap door can be composed of floor board with cross-pieces of 3 in. by 1 in. deal, screwed to the upper side as in Fig. 2. This rests on fillets in the aperture.

As commonly fitted, the trap door giving access to the space above the ceiling of an upper storey is made of stout matching, and has no hinges. It rests on a lining fixed to the trap aperture and is simply pushed upward into the loft to open the trap.

Roof Doors. Trap doors when fitted into a roof are usually made to lift off bodily, although examples are found in which the hinged flap is used. However it may be arranged the outer surface must be covered with weatherproof material, such as sheet lead or zinc.

A cross sectional view of an external trap door is shown in Fig. 4, the aperture through the roof being framed up with trimmers. The inner faces of the opening are lined with stout timber projecting several inches above the normal roof surface, and covered by a flashing (q.v.) of lead or

other material to ensure a water-tight joint. The trap door should be several inches larger each way than the trimming, and should fit on a bed, or fillet on the under side, to keep it in position. The outer edge of the door is preferably fitted with a small, downward projecting batten of wood and the whole covered with lead. The lead is turned under the outer batten to provide a drip for rain water. Two stout bolts should be located about the middle of the trap. *See Attic; Cellar; Ladder; Loft.*

TRAVELLER'S JOY. This is the popular name of *Clematis vitalba* (old man's beard), a rampant climbing plant. It bears a profusion of white flowers which are followed by fluffy fruits. This plant is used as a stock on which to graft named, large-flowered varieties of clematis.

TRAVELLING BAG. Several of the receptacles employed for luggage are covered by this term, which is applied to suit cases, Gladstone bags and kit bags amongst others.

Bags made of leather should be rubbed over from time to time with neat's foot or harness oil if a polished surface is not required, but, as the small leather bag is usually finished with a polished surface, the best treatment is with a good white or brown boot polish. To renovate an old leather bag, the grease and dirt must be removed with a strong solution of common soda, in the proportion of 2 oz. of soda to a pint of hot water. Apply the soda water with a soft rag when warm, not hot, and if very dirty rub the material with a brush. If the leather is stained, a weak solution of oxalic acid will generally remove the marks, but it should not be applied until the soda solution has been used. The cleaned surface should be washed with lukewarm water and placed in the sun or a warm spot away from the fire to dry.

The leather should now be treated with a wax polish, applied with a soft rag, rubbed in with a soft brush and then polished with a clean cloth. *See Luggage; Suit Case; Trunk.*

TRAVELLING RUG. A good travelling rug is an expensive article when made of thick pure wool. A favourite type has a plaid design with fringed ends. Others are woven in reversible colours. Large numbers of travelling rugs are manufactured for car use in fur fabrics, real furs made up into the standard oblong or square shapes and lined with cloth leather lined with a woollen check material, and livery cloth, or some waterproof material lined with wool.

TRAYS: SHAPES, STYLES AND MATERIALS

Choosing, Decorating and Making for all Household Needs

Several articles in this work describe the materials or processes used in making and decorating trays, i.e. Inlaying; Lacquer Work; Papier Mâché; Repoussé Work; Tarso. See Salver; Sheffield Plate; Silver; also Ash Tray; Fruit Tray.

No housewife need have an ugly tray even in the kitchen, as the plainest variations in tin, papier mâché, stainless composition and lacquered wood are obtainable in good colours at very moderate prices. Oak trays with handles are always useful as waiting trays when laying or clearing the dining-room table.

Veneered and inlaid mahogany trays of Sheraton style should be provided with a glass top to fit inside the border. Such trays when solidly constructed are apt to be rather heavy.

If it is desired to use one as a tea tray, it can be laid on the table with the cups, and the teapot, etc., carried in on a lighter tray and placed on it. The same method of service is often resorted to with old Sheffield plate and other metal trays.

A pretty tray with handles suitable for after-dinner coffee service is made of mirror glass framed in polished steel. This idea can be adapted by the home worker, the tray being made up with a wooden moulding and bottom to fit a piece of mirror glass of desired size. The moulding should be silvered or gilded with metallic paint and handles should be attached; as shown in Fig. 4.

Small trays for occasional use are made of papier mâché. These may be bought finished in black with gilt stars, or in some light colour. A further suitable decoration when something more uncommon is liked is to cut out large roses from a flower seedsman's catalogue, paste and varnish them on to the centre of such a tray, maintaining the Victorian aspect of the papier mâché foundation. Another idea is to embellish the tray with pictorial patchwork.

There are many ways of ornamenting trays constructed on the simple methods described in this article. Any kind of coloured embroidery could be substituted for the silk needlework under glass in the example illustrated in Fig. 10. A sampler or a group of conventional trees and figures in multi-coloured cross-stitch, a wreath or basket of flowers in tapestry needlework are all effective. A tray cloth in real lace may be mounted on silk to tone with the tea ware. Pen painting and pokerwork, tarso and pencil painting are all art crafts which may be utilized and are quite serviceable when frame and glazed in this manner.

Special deep-sided trays are made for carrying bottles, or decanters with a number of glasses. These trays are provided with movable, raised frames having cut out sections in which the glasses, etc., stand. They are specially useful for carrying drinks into the garden. Other trays are fitted with china or glass dishes for hors d'oeuvres. Early morning tea trays are often made of stainless composition and surrounded by a wicker-work border. A useful wooden breakfast-in-bed tray is illustrated in Fig. 11. This type of table tray is light to carry and more comfortable to eat from than a tray placed at the side of the bed.

Making Trays. There are several forms of construction suitable for trays. The simplest method perhaps is that in which special metal corners are used in conjunction with a simple moulding

having a rounded top edge. Plywood forms the bottom of the tray. Figs. 1 to 4 show progressive stages in making a tray, and are self-explanatory. The moulding, copper corners and suitable copper nails can be had from any good suppliers of materials for woodwork hobbies.

Tray. Figs. 1-4. Showing the construction of a tray from the parts supplied, which are ready for assembling. Fig. 5. Section of a tray consisting of moulding screwed to a base, also a section made with cabinet makers' moulding. Fig. 6. Oak framed tray. Fig. 7. Selection of tray mouldings. Fig. 8. Tray handles of various kinds.

Another simple method of tray construction is to screw mitred lengths of moulding on the top of a wooden base, as in the section at Fig. 5. The base should be of oak-faced plywood about $\frac{1}{4}$ in. thick. The use of a rebated moulding is shown in the lower section, the finished tray being seen in Fig. 6. If the decoration is effected with transfers the surface must be thoroughly cleaned with glass paper and well boiled in with french polish. The position of the transfer decoration can be marked with a chalk line, which should be thin; a length of thread passed over a piece of chalk will provide a suitable line.

The directions for laying the transfer should be carefully followed: on no account should the work be hurried, and when in position the wood should be placed on one side to allow the surface of the transfer to harden. A final coat with a transparent polish or varnish should be applied, and then the moulding can be placed on the edges, the mitres being carefully planed up on a mitre planing board in order to obtain a clean joint.

The usual handle for this type of tray is seen in the section at Fig. 5. A few other patterns are illustrated in Fig. 8. It is screwed directly to the outside of the moulding, or the plates can be let into the wood if desired. It should be sufficient to glue the mitre joints and screw the base to the moulding, but a nail can be driven in at the ends to give further security. A number of tray mouldings are shown in Fig. 7. The uppermost is for screwing direct to the base, the next being a grooved section and the third a rebated one. The bottom moulding is for use with metal corners as shown in Figs. 1 to 4.

A varied assortment of mouldings can generally be obtained at the shops which specialize in woodworking materials. As will be gathered from the illustration here given, there are various methods of fitting the base of the tray.

Tray. Fig. 9. Simple form of decoration with inlays of different coloured woods.

In the tray shown at Fig. 9 the sides should be from $\frac{1}{4}$ in. to $\frac{1}{2}$ in. thick, according to the dimensions of the base, but a tray measuring about 18 in. by 12 in. will not require a greater thickness than $\frac{1}{4}$ in. and a height of $1\frac{1}{2}$ in. on the long sides. The ends should be about 3 in. high, shaped to an even curve, and the handle opening cut to about 4 in. long and $1\frac{1}{4}$ in. deep. The neatest method of joining the corners is by the dovetail joint illustrated in the diagram.

A simple form of inlay decoration is illustrated, consisting of four small squares, each of a different coloured wood, arranged in the form of a square.

Trays. Fig. 10. Pretty afternoon tea-tray made from a piece of embroidery, backed, framed and glazed. Fig. 11. Breakfast-in-bed tray of Wood, with wicker surround and legs. Fig. 12. Well planned table tray for invalid, with adjustable baize-covered wooden centre, and side panniers of wicker for books and work. The tray shown underneath is used in conjunction with the table portion for meals. (Fig. 12 by courtesy of London Association for the Blind.)

These may be joined with a length of stringing, but the effect of the corner decoration is quite pleasing. The small squares should be cut from wood planed to $\frac{1}{8}$ in. thick and from $\frac{1}{2}$ in. to 1 in. side, according to the size of the tray. The holes are marked out in pencil and recessed with a sharp chisel, giving the edges a slight undercut so that the inlays will fit tightly in the recess.

Fig. 10 illustrates a tray made up with oak moulding and a wooden bottom, over which is placed a piece of embroidery, the latter protected by a sheet of glass. In constructing this type of tray the greatest care must be taken to ensure that the glass lies flat and that the groove or rebate in the moulding does not "bind" the edges at any part.

The home worker who can manage a little simple basket work may like to construct the useful bed tray shown in Fig. 11. It has a wooden bottom, which might be lacquered, or stained and varnished. The table portion should be made up first, the top fixed, and the basket-work guard then attached to the latter. A development of this idea is illustrated in Fig. 12, consisting of an invalid's work-table and "breakfast-in-bed" tray. The adjustable sloping work-table is of wood covered in baize. The removable tray shown beneath is used to fetch and carry the meals, and rests on the table, the latter, of course, being adjusted to the horizontal position.

Trays are also used in travelling trunks, drawers, tool chests, etc. In the case of trunks they are usually made with wooden sides to fit inside the trunk and rest on fillets. The bottom is formed with webbing, which is stretched from side to side and end to end, and covered with canvas or other material, and in large trays with one or more wooden strips nailed across from side to side to strengthen the bottom.

Trays for drawers and tool chests are made from thin wood resting on fillets which form runners. They can be divided into compartments, and are useful for storing small articles, or, when used in drawers, to avoid crushing delicate materials. Trays are made of wire for confectionery and letters and of vulcanite for photographic work.

TRAY CLOTH. Small cloths of washable materials made to fit round, square, oval or oblong trays are provided either as protective mats or to enhance the appearance of a tray. They are also needed when a meal is served on a tray. Besides their nominal use they make covers for small dressing-tables and chests, and are often preferred on the afternoon tea-table to a larger cloth, especially when embroidered on linen to match a cosy cover. Sets of tray cloths are also most convenient as place mats for the dinner table.

The housewife can hardly have too many of these charming little cloths, which are so easily made and laundered at home. They may be of brightly coloured linen, embroidered and scalloped with white embroidery cotton, of unbleached linen worked in colours, and with hemstitched edges, of crash with amusing designs in woolwork, or of finest white linen, lace trimmed, or decorated with beautiful Richelieu, Renaissance, or drawn thread work. They may also be made entirely of filet, or crochet lace, of oil baize or raffia cloth.

Tray Cloth. Set of linen tray cloths, which may also be used as table mats, decorated with drawn thread work.

Linen is the most useful material for tray cloths intended for ordinary household purposes. The set illustrated is made in coral pink linen with a border design of drawn thread work. Usual sizes, unless made especially to fit a tray, are an oblong measuring 12 in. by 17 in., or one measuring 15 in. by 20 in. Transfer designs are obtainable in great variety and to fit different shapes and sizes. Scalloped edges are used for oval and round tray cloths. *See Drawn Thread Work; Embroidery; Hemstitch; Pattern Printing; Raffia Work; Scalloping.*

TREACLE. The uncrystallized syrup that drains from raw sugar in the process of refining, and is known as treacle, contains a large proportion of saccharine principle, and is valuable as an article of household diet. It is cheaper than sugar for many purposes.

The uses of this syrup in cookery are manifold. It is used in making all kinds of ginger cakes, gingerbread, and brandy snaps. It is often added to the pickle employed for curing hams and spiced beef. The finer variety of syrup known as golden syrup is usually employed for making roly-poly puddings or treacle tarts, but the pure brown treacle will be found superior to a highly refined syrup for most puddings or for cakes. The very darkest form of syrup, called black treacle, is not suitable for table use.

Treacle Fruit Cake. Golden syrup or treacle is used to mix this fruit cake, which is made according to the following directions: Wash 6 oz. each currants and sultanas, wipe them in a clean cloth, and put them aside to dry. In the meantime, sieve together 1 lb. flour and $\frac{1}{4}$ flat teaspoonful carbonate of soda; rub in $\frac{1}{2}$ lb. margarine until the mixture resembles fine breadcrumbs.

Treacle Fruit Cake. A wholesome cake for nursery tea.

Add the fruit, previously stalked, and 2 oz. candied peel cut into small pieces, mixing all these ingredients well. Break 2 eggs into a small basin, whisk them well; then add $\frac{1}{4}$ lb. syrup or treacle, and continue whisking. Dissolve $\frac{1}{4}$ lb. sugar in 1 gill milk, add these to the eggs, and when they are thoroughly mixed pour them into the dry ingredients and beat the mixture for a few minutes before turning into a large,

round cake-tin previously greased and lined with greased paper.

Bake the cake in a moderately hot oven for about 2 hours, lessening the heat after the first 20 min. If it becomes brown on top before it is thoroughly cooked, cover it with a piece of paper. When ready, lift it out of the oven on to a cake-sieve and leave it to cool.

Treacle Pudding. Mix together 6 oz. flour, a little more than 2 oz. finely chopped suet, $\frac{3}{4}$ teaspoonful ground ginger, a pinch of salt, and 1 saltspoonful bicarbonate of soda. Then add an egg, $1\frac{1}{2}$ oz. treacle, and enough milk to mix the whole to a soft consistency. Turn it into a greased basin, cover it with a piece of greased paper, and steam it for about 2 hours. Serve it with heated golden syrup or golden sauce (q.v.).

Another variety of treacle pudding is made by sifting $\frac{1}{2}$ lb. flour with $\frac{1}{4}$ teaspoonful salt into a basin, adding $\frac{1}{2}$ lb. finely chopped suet, $\frac{1}{2}$ lb. raisins stoned and cut small, or $\frac{1}{4}$ lb. raisins and an equal amount of cleaned and picked currants. Stir together 3 tablespoonfuls treacle with $\frac{1}{2}$ pint cold water, and with this mix the dry ingredients in the basin to a dough. Grease a pudding basin, turn the mixture into it, cover with a cloth, and boil for 4 hours. Serve with sweet or golden sauce.

For Palmeston pudding, another form of treacle pudding, equal quantities of breadcrumbs, suet, and treacle are required. The pudding is boiled in a greased basin covered closely with a cloth for about 3 hours.

Treacle Roly Poly. This is made in the same way as jam roly poly (q.v.), and $\frac{3}{4}$ lb. treacle or golden syrup is required. This should be mixed with 3 oz. breadcrumbs and $1\frac{1}{2}$ teaspoonfuls lemon juice, being first warmed in a pan if the weather is cold. Golden sauce should be served with it separately.

Treacle Tart. Some short crust pastry, $\frac{1}{4}$ lb. golden syrup or treacle, 2 tablespoonfuls fine breadcrumbs, and $\frac{1}{4}$ teaspoonful ground ginger are needed to make a treacle tart. Roll out the pastry

to a round about $\frac{1}{4}$ in. in thickness, use some of it to line a round greased tart-tin, and decorate the edges with a fork. Mix the breadcrumbs with the ground ginger, add to these the treacle, previously warmed, and pour the whole into the lined tin.

Treacle Tart, a cheap and attractive sweet.

Roll out the remainder of the pastry, cut it into strips about $\frac{1}{4}$ in. wide, twist each of these two or three times, and then lay them across the tart so that they form a trellis-like pattern, as shown. Bake the tart in a hot oven for 20 min., and then turn it out of the tin. It may be served hot or cold. See Golden Pudding; Pastry; Suet Crust; Toffee.

TREADLE. Used in foot-driven sewing machines, fretsaws, lathes, and other small machines, for propelling a fly-wheel, the treadle or foot-motor is a hinged plate fixed to a base or to the framework of the machine and attached to the fly-wheel by a connecting-rod known as a pitman. The treadle is balanced on a spindle to give an up-and-down movement to the pitman, and is variously shaped from a single foot rest of the portable treadle here illustrated, the double foot rest fitted to some makes of sewing machine, to the heavy bars, and pierced iron plate of the lathe. The portable treadle driving wheel is useful in the amateur's workshop for driving a polishing head, a small circular saw or drilling machine, but it must be securely-screwed or bolted on the floor.

Treadle. Portable treadle with a single foot rest. (Courtesy of B. Melhuish, Ltd.)

Inconvenience is often caused when using a treadle by the flywheel stopping at dead centre. It is not experienced to any extent with a light machine but generally with a lathe fitted with a heavy fly-wheel. The best method of overcoming the dead centre on the crank and so bringing the treadle into the correct position for starting when the machine is at rest is to clamp a weight on the fly-wheel so that when the machine is at a standstill, the treadle up, and the crank just over the top centre, the weight is at the bottom of the wheel. A sharp downward push on the treadle will send the crank over the bottom centre, and the impetus given will carry the wheel round. See Fretwork; Lathe; Sewing Machine.

TREE: For the Garden. Trees should never be planted close to a house. Not only when fully grown do they hinder the free passage of light and air, as well as inducing dampness, but their presence is a menace to the structure of the building itself.

As a rule, the roots of a tree spread just as far underground as the radius of the branches above. In the course of time, therefore, this spread of roots is quite likely to undermine the foundation of a house, and to render it unsafe. Oaks and yews are the least desirable trees to have near houses.

Some of the most attractive trees for planting in the garden are various Conifers; for example, cypress, deodar cedar, spruce and silver fir: hawthorn, laburnum, catalpa or Indian bean tree,

bronze-leaved plum (*Prunus Pissardi*), ornamental crab (*Pyrus floribunda* and others), ornamental cherry, scarlet oak (*Quercus coccinea*), variegated maple (*Acer negundo variegatum*), and green and variegated hollies. *See* Apple; Fruit; Grafting; Hazel; Laurel; Rose; Sycamore, etc.

TREE CARNATION. This name was used to distinguish the original type of winter and spring-flowering carnations grown under glass, a type which has been to some extent superseded by the perpetual-flowering carnations. They need a minimum temperature of about 50 degrees, and are propagated by cuttings inserted in sand beneath a propagating case in the greenhouse. A few of the finest varieties are Spectrum, red; Laddie, salmon; White Pearl, white; Topsy, crimson; and Enchantress, light pink. *See* Carnation.

Tree Carnation. Blooms of the variety Enchantress, a beautiful greenhouse carnation.

TREE LUPIN. This vigorous hardy shrub grows quickly and soon forms a large spreading bush 4 ft. or more high. It needs plenty of room and is scarcely to be recommended for small gardens. The

flowers of the typical kind (*Lupinus arboreus*) are pale yellow and fragrant: they are produced very freely in May and June. Somerset is an improved yellow variety. The variety Snow Queen has white flowers. These plants thrive best in well-drained soil and dislike being disturbed; they are easily propagated by seeds sown out of doors in spring. Straggling shoots should be cut back in March.

Tree Lupin. A profusely blooming clump of the early summer flowering plant.

TREE OF HEAVEN. This is the popular name of a hardy leaf-losing Chinese tree (*Ailanthus glandulosa*) which will reach a height of 50 ft. or more. It is valued for its long pinnate leaves and red fruits in autumn. This tree, when young, is often hard pruned each spring and restricted to one new stem, for under this treatment the leaves are exceptionally fine, though its height does not then exceed 5 ft. It does well in town gardens and flourishes in ordinary soil. Propagation is by suckers in spring, by layering in summer or by sowing seeds.

TREE PEONY. This shrub (*Paeonia moutan*) bears immense double or single flowers in spring. It is scarcely suitable for general planting, for it starts into growth early and the young shoots are liable to be damaged by late frost. It needs loamy soil and a position in which the morning sun will not reach it. It is a Japanese shrub and the numerous varieties have chiefly Japanese names. *Paeonia lutea* is a handsome tree peony from China and hybrids have been raised between this and the common tree peony.

TREFOIL. The trefoil, which is a favourite form of Gothic ornament, as employed in architecture, is an ornamental foliage of three divisions that is based, like the quatrefoil, on a geometrical construction. The simplest form of it is shown geometrically in Fig. 1 and a pointed form often seen in stonework in Fig. 2. There is another form taken from the clover leaf in Gothic carving. It may be used with good effect in relief carving and is one of the most suitable motifs for the amateur woodcarver. *See* Quatrefoil.

TREILLAGE. Literally this is another name for trellis but it is applied specially to a frame of stout wooden uprights crossed with squared laths of lighter substance and adapted for the support and training of fruit trees.

TRELLIS AND TRELLIS WORK

Structures for Screening and Beautifying the Garden

A number of articles in our Encyclopedia have reference to one or other of the uses of this form of woodwork, for instance Arch; Fence; Garden; Pergola; Porch; Roof Garden; Rose Garden. *See* also Rustic Work; Summer House.

As an ornamental support for flowering plants trellis work is much akin to lattice and rustic work, although the latter term is generally applied to the construction of articles of rough, natural material. As a rule trellis work is carried out with relatively thin prepared timber, in which sawn plasterer's laths play an important part, but the term is often applied to work carried out with wood in its natural state. The work consists essentially of interlacing, either at right angles or diagonally, thin strips of wood, which are fixed to some form of support or rough grounds. In some cases the strips are not actually interlaced, but are placed so that they cross over one another either at right angles or diagonally, and the appearance of interlacing is obtained.

Trellis. Figs. 1 and 2. Two methods of fixing the laths: in one they cross at right angles, in the other diagonally.

A general idea of the method of fixing the laths is given in Figs. 1 and 2, where they cross at right angles and diagonally. The joint where they cross is completed by driving a small nail through it and clenching it. The ends should be fixed to some supporting framework. The common expanding diagonal trellis can be obtained so cheaply that it is only when some more robust and permanent form is desired that the worker will be called upon to make up this type.

Trefoil. Fig. 1. Simplest form of this Gothic architectural ornament. Fig. 2. Pointed form seen in stonework

Trellis. Fig. 3. Type of trellis work composed of prepared timber which will be found exceedingly useful for the purpose of providing a screen. The lettering refers to details of joints given in Figs. 4 to 7

Fig. 3 shows trellis work in prepared timber, which is very suitable when its purpose is to act as a screen rather than purely as a support for plants. The framework has grooves worked on the inner edges in which the trellis is fitted. The latter is carried down to just below half the total height, and the lower portion is filled in with match boarding. The framework, which is made from specially prepared timber, is joined together by stub tenons cut in length to just the depth of the grooves, the joint being strengthened with nails.

The length and height of the whole should be first decided upon, and a decision made as to the number of intermediate uprights that will be required: The various lengths are then cut off, always allowing for the tenons. The latter are marked out, using a square to get them true, and sawn with a tenon saw. The thickness of the tenons may be obtained from the grooves into which they fit, and it is advisable to cut them rather full so that a tight joint is obtained, affording the necessary strength and rigidity. The top rail, which is bevelled on both edges, runs through

the whole length, as in Fig. 3, the middle or intermediate uprights being jointed into it as in Fig 4, and the end uprights as in Fig 5. It should be noted that the end uprights are grooved on one edge only. Fig. 6 shows the details of the jointing of the centre rails, which are also bevelled on both edges, and are further rebated on one of the lower edges to take the matchboarding. The lower rail is also rebated on the upper edge as in Fig. 7, and is jointed to the end upright as there shown; the intermediate uprights are tenoned into it, mortises being cut for this purpose. These latter should be carefully measured off and marked out in accordance with the length of the centre rails so that the uprights are perfectly vertical when they are fitted in position.

The trellis work may be composed of plasterer's laths, or a quantity of narrow, thin stuff may be obtained for the purpose. Whichever is used, it should be obtained in conjunction with the timber for the framework, since the trellis fits into the grooves in the framework. The width of the grooves equals double the thickness of the laths, since one series of the latter is placed flat on the other. It is not always necessary to nail every joint where the laths cross, especially where a very close mesh is required, each alternate joint being usually sufficient. The matchboarding is secured after the main framework has been erected by nailing. After the whole is in position, it may be coated over with one of the various preservative stains.

An oak trellis is shown in Fig. 8, suitable for erection at a boundary or in place of a solid wall. It is supported at intermediate distances by brick pillars. The horizontal members are alternately placed on the outer and inner sides of the uprights, and the lower rail is supported by short uprights built into the top of the brickwork. The whole is toned down to a dark colour, and when covered with climbing plants forms a very effective screen.

The trellis in Fig. 9 is erected against the sides of a house, for the purposes of training creepers. It is built up in set designs with a border and is secured to a groundwork of battens applied to the walls. The porch on the right is of prepared timber, mortised together, roofed in at the top with timber and

covered with one of the patent roofing materials. A fairly heavy moulding is mitred round at the top, the trellis built up in sections and afterwards secured to the whole. When deciding upon trellis to be made up in sections and applied to a wall, careful measurements should be made for the position of windows, doors, drain pipes and the like, and allowance made for them; also for the rough grounds to which they are to be fixed, since this materially enlarges the length required for the trellis. A method of fixing the grounds is shown in Fig. 10, which illustrates the use of a spacing gauge.

Rustic Trellis. The trellis made of laths has many applications as a screen, but natural appearance given by rustic construction is very pleasing, and a rustic trellis is often more in harmony with the garden and its surroundings. A completed trellis is shown in Fig. 11, stages in its construction being illustrated in Figs. 12 and 13.

Having obtained suitable and sufficient material, the first step is to mark out the position in which it is required to place the screen. This can be done in the ordinary way with a line and a few pegs, marking out the positions of the supporting posts. The next stage is to prepare the posts to the requisite height, this depending upon the nature of the surround and the plants to be trained thereon. If such plants as rambler roses are to be trained over the screen, the posts may be anything up to 8 ft. or 9 ft. in height, and the screen illustrated has been constructed on this assumption. It is a good plan to treat the bottom of the posts with either tar or creosote. The posts should be sunk from 18 in. to 2 ft. into the ground. After the posts have been erected in position and well rammed and consolidated, the positions of the horizontal members are decided upon, and these are placed in position and nailed to the posts. The horizontal members should be less in diameter than the posts, and of such length that the joint made between any two comes at one or other of the upright posts. If the poles are of any considerable thickness, the ends can be trimmed off flat and nails driven through both into the posts.

Trellis. Fig. 8. Type of rectangular trellis carried out in oak. Fig. 9. Example of trellis work applied to the walls of a house, the porch being designed in the same medium to harmonize. Fig. 10. Use of spacing gauge, fixing the horizontal strip to vertical. Fig. 11. An example of a completed rustic trellis forming an excellent support for rambler roses, etc. Fig. 12. Fixing principal diagonal members. Fig. 13. Fixing lighter diagonals into trellis screen.

Having fixed these pieces, which in the example illustrated are located one along the top of the posts and the other about 3 ft. above the ground, the principal cross pieces are placed in position and fixed to the posts or horizontal members with stout wire nails. This operation is illustrated in Fig. 12. These cross pieces may either be fixed in their natural round shape or flattened on one side.

The spaces between the main cross members are filled in with lighter material in much the same way fixing these in an X fashion and, if possible interlacing them one over the other until the required degree of closeness is obtained (Fig. 13).

Trellis in needlework. Method of making this stitch, useful for covering large spaces.

TRELLIS: In Needlework. This filling stitch is used to cover large spaces in embroidery on linen and is worked on counted threads of the fabric. It consists of horizontal and perpendicular lines of working threads held down by a cross stitch where the lines meet. In some designs a small running stitch crosses the junction of the lines.

The threads of the ground material should be counted both ways, so that they are set evenly apart. If the small stitches which form the first half of the crosses are worked in one direction in one long

row, and in the reverse direction on the return journey, all the crosses will be worked in the same way and give a more even effect.

The illustration shows the needle in the correct position, working downward and forming the cross stitch at the junction of two lines. *See Cross Stitch; Embroidery; Laid Work.*

TRENCHING. This is the best method of cultivating garden ground; it ensures the finest possible flowers and vegetables. Those who grow for exhibition trench the ground three spits (about 30 inches) deep; for ordinary purposes it is sufficient to trench two spits (about 20 in.) deep. If the land has been in cultivation for some years the upper soil may be brought to the surface and the surface soil buried. When trenching new ground, however, the layers of soil must be kept in the same respective positions.

When trenching cultivated land the first thing to do is to dig out the soil two spits deep and 2 ft. wide; the excavated soil is placed near the other end of the plot. The bottom of the hole is forked over and leafy garden rubbish is mixed in. The next top layer of soil is transferred to the first trench and the next second layer on top of that. Thus the first trench is filled and the second is emptied. Each trench is dealt with in the same way, the last trench being filled with the soil first taken out.

In trenching new land the turf should be stripped off and stacked for a year. The first trench is dug two spits deep and 2 ft. wide and the top layer of soil is also taken off the next strip, both lots being placed at the other end of the plot. The second layer of soil from the second strip of ground is put in the first trench and the top soil from the third strip of ground is placed on top of it.

Thus the first trench is filled and the layers of soil remain in the same respective positions. Farmyard manure or hop manure should be mixed with the second layer of soil when trenching both new and old land. When trenching is finished new land must be limed, using one bushel to three rods. The lime should be turned in with the garden fork. The best time for trenching is in autumn and winter. *See Celery; Digging; Spade.*

TRESPASS. There are three kinds of trespass in law, namely, trespass to land, to goods, and to the person. The last of these is more usually called assault. Trespass to goods consists of any actual taking of or a direct and immediate injury to another's goods or chattels. For instance, it is equally trespass if A rides away with B's horse or hits the animal and causes it to run away. If A throws a stone and hits B's head it is trespass.

Remedies for Trespass. The remedy for trespass to goods is by an action for damages. The damages recoverable are, where the goods are taken away altogether, the value of the goods; and where they are merely injured, then the amount of the damage done to them. An action for trespass to goods will not lie unless the plaintiff had the goods in his possession at the time of the trespass.

It is, however; trespass to land that is usually spoken of as trespass. This is committed where anybody, whether wilfully or otherwise, goes upon the land of another without his permission. The word land includes houses and other buildings. This offence, like trespass to goods, is an interference with possession rather than with ownership, so that the tenant of a house or land can bring the action.

The remedy is an action for damages, and these damages are by no means limited to the actual pecuniary loss sustained by the occupier of the land or house. Thus, very heavy damages have been awarded against a trespasser who walked into another man's ground and paraded up and down in front of his windows, into which he stared in an offensive manner. In the same way, when a moneylender has seized furniture under a bill of sale, and has wrongfully kept a bailiff in possession for several days, he has been made to pay very heavy damages, and this although the bill of sale was only void on a technicality.

Besides actions at law, the householder or landowner has the right to protect himself against a trespasser by turning him out, provided that he only uses as much force as is necessary, and no more. He should first be requested quite civilly to go out.

Trespass is not generally a crime, in spite of the common notice that "trespassers will be prosecuted." It is, however, an offence to trespass on to land belonging to a railway company or on to any land if damage is done to the land, or in pursuit of game. It is also an offence to drive a motor vehicle on to private land or on to a common.

Trespass by Animals. The owner of tame animals is liable to an action of trespass if he allows them to escape on to the land of his neighbour, unless the neighbour was under some duty to maintain a fence and failed to do so, whereby the cattle, etc., were able to stray upon his land. This does not apply to dogs or cats. If cattle are being driven along the highway, their owner is not liable for any damage they may do or for trespass at all if, without any negligence on his part, they stray upon unfenced land.

Anyone who takes upon his own land something which is liable to cause injury if it escapes, must pay damages if the dangerous thing does escape and goes upon the land of a neighbour, and this whether there was negligence or not. The best-known case was where the defendant constructed a reservoir upon his land and it cracked and the water escaped and flooded the workings of an adjoining mine. The owner of the reservoir was held liable, although it was no fault of his that the reservoir gave way. A trespasser must take the land as he finds it and will have no remedy if he injures himself by falling into a pit or quarry.

Man Traps, etc. Even a trespasser is entitled to be protected against man traps, spring guns, or other engines calculated to do bodily harm or to destroy life. Anybody who sets such a device on his land with intent that it shall destroy or inflict bodily harm upon a person coming in contact with it, is guilty of a criminal offence, and is liable to penal servitude for not less than three or more than five years, or imprisonment for not more than two years with or without hard labour. It is equally an offence to leave such an engine in position if it has been set by a previous occupier.

The householder is, however, entitled to protect his dwelling house by setting a man trap, spring gun, or other engine between sunset and sunrise. Nor is there any law to prevent him setting traps for vermin, and a trespasser who walks into a rat trap has no remedy if he is hurt.

TRESTLE. In building operations and redecorating, the trestles mostly used take the form of a self-supporting pair of steps. They are most usually employed in pairs, placed at a convenient distance apart, generally from 6 to 8 ft. span. Scaffold planks or other strong boards are rested upon the treads of the trestles to form a platform.

A strong trestle of another type which is useful for such purposes as the support of a wash tub is illustrated at left.

Trestle. Example of a strong trestle suitable for domestic use.

It is substantially built from stout timbers, the top about 9 in. wide and 2½ in. thick; the legs about 4 in. wide and 2 in. thick; the cross pieces 3 in. wide and 2 in. thick; the whole being securely halved and screwed together. It will be noted that the legs splay in two different directions, spreading outwards like the letter A.

When viewed from the side and from the front they incline outward from the top part, this being done to give greater stability. A pair of light hinged trestles is used to support a table such as that described in the succeeding article. *See Scaffolding; Steps.*

TRESTLE TABLE. There are many uses in the ordinary home for a table supported on a pair of trestles such as that illustrated in Fig. 1. It may serve for the support of a table tennis table, and may also be used as an emergency table at Christmas or other times. To the amateur constructor it affords a temporary support for work, and when papering a room it is most useful as a pasting board.

Trestle Table. Fig. 1. Home-made trestles used to support a table top. Fig. 2. Component parts of the trestle, showing dimensions. Fig. 3. Drilling the side bar and cross piece for the dowels. Fig. 4. Joining the parts together by means of hinges.

A complete set of the components required for the trestles is illustrated in Fig. 2, which also gives the leading dimensions. The legs are of deal or other tough wood measuring 2 in. wide and 1 in. thick. The crossbars are of similar material, but

those on the top should be 2 in. deep and 1½ in. thick. The crossbars can be dowelled and screwed to the legs, which are glued and screwed into notches or housings cut in the top bar.

When the timber has been prepared to the correct length and size, planing it up on all four sides, the positions for the crossbars at the lower part of the leg are marked out. It will be noticed that the legs of the trestles are splayed in order to afford stability. In addition, considerable care must be taken so as to get the notches in the top pieces cut at the proper angle, and the ends of the crossbars also must meet the legs at a similar angle.

One of the side pieces and a crossbar are grasped in the vice in the manner illustrated in Fig. 3, at the proper angle, and both of them are drilled through with a brace and bit as shown. A dowel pin is driven temporarily through this hole and a second drilled about 1 in. from it. All the dowel joints are prepared in the same way and are assembled by inserting the dowels into the side pieces, placing the crossbar against them, and after coating the joint faces with hot glue they may be cramped up until set.

The top pieces are prepared and notches cut in them, so that the legs can be fitted. The legs should fit very closely against the shoulders of the slot in the top bar, to add to the stiffness and general stability of the structure. When fitted, they should be glued and screwed in place. After the glue has set hard, any overhanging or projecting portions should be planed off.

The final operation is to hinge together the two members of each trestle with stout butt hinges. This is best accomplished by placing the two top edges together, laying the hinges flat on the upper surface with half on each crossbar. Holes are then drilled and the screws driven home. Two screws should be placed in each hinge as a start and one of the legs lifted up, as shown in Fig. 4, to see that it folds back properly. Any necessary corrections in the alinement of the hinges should be made, and the remainder of the screws then driven home.

The table top is constructed from a few lengths of tongued and grooved floor board, the outer edges planed up smooth, and the ends and the centre strengthened by cross battens of wood about 1 in. thick and 3 in. or 4 in. broad. To prevent the legs of the trestles from opening too far, a stout cord is threaded through holes drilled through the centre of each of the lower crossbars and prevented from

pulling out by tying a knot in each end of the cord. The length of both the cords should be equal, to ensure the heights of the two trestles being uniform. *See Folding Table; Table.*

TRICHOMANES. This is the name of a group of beautiful filmy ferns which are grown in glass cases in a shady greenhouse in an exceptionally moist atmosphere. They should be set in well-drained pots or earthenware pans, in a compost of sandy peat with pieces of sandstone intermixed. Propagation is by spores, at any time during the year, or by division of the roots in early spring. On no account should be plants be syringed.

TRICHOPILIA. The small evergreen orchid called *Trichopilia* flourishes in the intermediate house. It has flowers of various colours, some of which are slightly fragrant. They grow best in pots or baskets hung from the roof of the greenhouse, in a mixture of peat, sphagnum moss, and charcoal. The necessary average temperature is 50°, rising to 60° during the summer months or growing period. *Trichopilia* is propagated by division of the pseudo-bulbs in early spring, when the plants should be repotted. *See Orchid.*

TRICYCLE. For the use of children tricycles are made in considerable numbers as well as for adults of both sexes who are unable to adapt themselves to the bicycle. The modern type of light tricycle is as easy to propel as a bicycle. A differential axle allows the rear wheels to turn independently at different speeds when going round a bend. The frame is made generally in two sizes, 22 in. and 24 in., and the wheels are usually 26 in. The same methods of cleaning and adjustment used for the bicycle also apply in the case of tricycles. *See Bicycle; Tire.*

TRIFLE. A sweet with a basis of spongecake, trifle can be made from a variety of added ingredients and is usually named according to the predominant flavour. Whipped cream, almonds and other nuts, angelica, crystallized flowers, and glacé fruits are all used in the decoration of trifles.

A good plain trifle can be made by splitting six small sponge cakes, spreading the cut sides with jam, and arranging the lower halves in a glass dish with the cut sides uppermost. Boil up ½ pint milk, soak the cakes in the dish with some of it, put on the top halves, and then pour on the remainder of the milk. Prepare some custard with 1 pint milk, 1 tablespoonful custard powder, and 1 oz. castor sugar, flavour it with a few drops of vanilla and let it cool. Then pour it over the cakes, set the whole aside until it is cold, and decorate it with glacé cherries.

Trifle. Plain variety of this party sweet.

Another variety of trifle is made either from a Swiss roll or two jam sandwich cakes. Cut the cake into blocks each about ½ in. thick, heap these on a glass dish, and pour over them 1 pint custard, basting them until they are well soaked. Whisk ½ pint cream until it thickens, stir into it the stiffly whipped whites of 2 eggs, and add sugar and vanilla flavouring.

Heap the mixture all over the soaked cake, decorate the top with a few ratafias, and blanched and shredded almonds. If liked, the quantity of cream may be lessened and the cake may be soaked with fruit syrup flavoured with ratafia before the custard is poured over. *See Banana Trifle; Fruit Trifle; Ratafia.*

TRILLIUM. This is the botanical name of the wood lily or trinity flower, a charming hardy plant for the rock garden; it bears large, three-petaled flowers in spring. The roots should be planted in autumn in slight shade in soil with which peat and leaf-mould have been mixed. The common wood lily is *Trillium grandiflorum*, 12 in., with beautiful white flowers; sessile, 9 in., has reddish blooms, and those of *nivale*, 10 in., are white.

Trillium. Curious three-petalled flowers of the wood lily (Trillium nivale), a low-growing plant for the rock garden.

TRIMMER: For Cutting. Various kinds of trimmer are made for cutting paper, prints, card, and wood. A useful tool of this kind for photographic prints is made with a curved knife blade attached to the side of a flat base, but as the edge of the blade requires frequent sharpening it is generally more convenient to use a detached knife.

TRINKET. The word trinket is used to describe a small ornament usually of slight value, as for example the cheaper kinds of brooches, bangles, fancy pins, and necklaces. A small box suited for holding such articles and to stand on the dressing table is known as a trinket box, but for these there is no conventional pattern. *See Enamelling.*

TRIPE: How to Cook. Tripe is the inner lining of the stomach of the ox or cow. As a food it is tender and easily digested. There are various kinds, named according to the part of the stomach from which they are taken. Honeycomb, blanket, and book tripe are perhaps the best known.

As sold in the shops, tripe is usually partially cooked, but if totally unprepared it needs careful cleaning in three or four different waters, and should be left to soak in clean, slightly salted water for two or three hours. It needs long preliminary boiling. As many as 16 hours may be required before the tripe is tender. After cleaning, it should be covered with cold water, brought to the boil, then strained, and more cold water added.

This process should be repeated until the tripe has lost its unpleasant smell. It should then be covered again with cold water and cooked until tender. For prepared tripe the process is simpler.

The cold water needs to be strained off only once, and two or three hours' slow cooking is usually sufficient. The tripe may then be prepared.

Tripe and Onions. The most popular method of cooking tripe is to stew it with milk and onions. To do this, boil 2 lb. tripe for two or three hours, adding, after about one hour's cooking, three or four peeled and quartered Spanish onions. When this preliminary cooking is over, cut the tripe into pieces of a convenient size and chop the onions. Melt 2 oz. butter in a saucepan, thicken it with 2 tablespoonfuls flour, and when the two are smoothly mixed strain in 2 large breakfastcupfuls of the stock in which the tripe was cooked. Stir the sauce until it boils, add 1 breakfast cupful milk, seasoning to taste, and the pieces of tripe and onions, and cook all slowly for about 20 min. Serve the whole on a hot dish.

Casserole of Tripe. Tripe can also be cooked in a casserole. Slice six onions and fry them brown in butter or dripping. Then, having cut the prepared tripe into pieces, put it into the casserole, where the onions have been placed, and add to it 1 pint white wine, one or two carrots cut into small

pieces, a teaspoonful each-chutney and salt, a few peppercorns, and a bunch of herbs. Shut down the lid very tightly and, if necessary, close the edges with a thin strip of dough so that no steam can escape from the interior. It should then be cooked in a gentle oven for four or five hours. If made the day before, it can be reheated, the fat being first of all skimmed from the surface. It can be served in the casserole, the herbs having been first removed.

Curried Tripe. To serve tripe as a curry, cut 1½ lb. prepared tripe into small pieces. Melt 1½ oz. butter in a pan, cook 5 tablespoonfuls minced onion in it, and when it is lightly browned add ¾ tablespoonful curry powder and the same quantity of flour. Fry all these ingredients well before pouring in 3 gills white stock and half that quantity of milk. Stir the whole well until it boils, and then add seasoning to taste. Add the tripe to the sauce and cook it slowly until it is heated through. Freshly boiled rice should be served with this dish, either as a garnishing border or handed separately. *See Casserole; Curry.*

TRIPOD: For the Camera. The amateur photographer who attempts anything but snapshots is immediately faced with the question of the kind of tripod to use. There are innumerable varieties on the market, few of which, however, fulfil all the requirements of the ideal tripod.

Such a tripod should be of very light weight and fold up compactly: it should extend to 4½ to 5 ft., and when extended should be rigid and able to support without vibration the weight of a good-class ½ plate camera, using metal slides and glass plates. The old-fashioned folding wooden tripod on

which ½ plate and larger field cameras were supported met none of these requirements except that of rigidity.

Tripod. Fig. 1. Aluminium tripod with automatic closing action. Fig. 2. Folding tripod made from sections of brass tubing. Fig. 3. Featherweight flat tripod. (Courtesy of Westminster Photo. Exchange, Ltd., and Ensign, Ltd.)

The most successful of modern tripods are those made in metal, brass, or aluminium, generally in tubular, telescopic form. A very good example is made in triangular aluminium tubes

(Fig. 1). It is extremely light, rigid when open, while its automatic closing action overcomes the tediousness of closing section yellow flowers in summer: it is raised from seeds sown under glass in March, the seedlings being planted out of doors in May. The common climbing nasturtium is *Tropaeolum majus*. *Tropaeolum polyphyllum* is a hardy perennial of low growth with grey leaves and yellow flowers: it should be planted in a sunny place in the rock garden and given some protection in winter. The scarlet flowered *Lobbianum* is a popular annual for pots in the greenhouse. *See Nasturtium.*

TROUGH. Employed for holding various kinds of food for animals and poultry, troughs are made of wood, iron, stone, and cement. The simplest form is made of two boards nailed together in the form of a V at an angle of 60° or so with two ends of square wood. It can be used in thin wood for chickens, in thicker wood and to a larger size for rabbits and fowls, and in hardwood for pigs.

The usual type of trough for fowls, ducks, geese and turkeys is made from galvanized iron with wire guards and is obtainable in two sizes, 18 in. long and 6 in. wide and 24 in. long and 7 in. wide. The advantage of the guarded trough lies in the fact that the food cannot be trampled on and therefore it effects a saving of food. *See Fig.*

TROUSER PRESS. This is an appliance for pressing the creases in trousers. Some are provided with an extension to which the trousers are attached for the purpose of stretching as well as pressing them, in order to remove any bagginess at the knees.

Trouser presses are obtainable in several sizes, from those suitable for placing in a suit case to those large and heavy enough to take several pairs of trousers. They are generally made in polished hardwood, with plated fittings.

A press can be constructed quite inexpensively. The plated fittings can be purchased for three or four shillings, and also moulded oak boards for the top of the press. The base may be made of ½ in. plywood. A stretcher attachment can be added if desired.

In use the press is opened out, the trousers carefully folded and placed on the bottom board, and the top placed in position. The screws nearest the bottoms of the trousers are screwed down first; the top of the trousers is stretched, being held in position by the fingers while the second set of screws is tightened. If the press has a stretching attachment the top is removed and the top bar of the stretcher is folded back. The trousers are placed in position, the top replaced and tightened at the bottom, and the top bar of the stretcher placed over the cloth and screwed down tightly. The projection is folded back underneath the bottom board and the top screws tightened up.

The method is the same when two or more trousers are placed in the press, but pieces of stout cardboard or thin plywood must be provided to place between each pair. When placing trousers with the permanent turn-up bottom in the press, this portion of the trousers must be left outside, otherwise it is impossible to obtain a long crease.

Trouser Press. Compact press for several pairs of trousers. It is not too heavy to pack in a travelling trunk.

TROUSSEAU. The trousseau or outfit of a bride is usually supplied by her parents, the amount spent upon it varying according to circumstances.

Fashions change so quickly that the old idea of the outfit which lasted for years has been modified considerably. A trousseau merely contains as adequate and charming a collection of dresses, wraps, underwear and dress accessories for the immediate season as can be afforded.

Extra money which the parents can give for the purpose is more useful in the form of a cheque for later spending than in buying up an excess of clothing which cannot be given reasonable wear before it is old-fashioned.

The girl who is clever at needlework can make delightful additions to her trousseau at small cost. Dainty embroidery and handwork add greatly to the charm of lingerie, and are well worth the time and trouble they demand, as these things are expensive to buy when ready-made in beautiful styles and qualities. Underwear should be marked with the bride's Christian name or initials and her new surname. This marking can be done in ink, or the letters may be embroidered. *See* Wedding.

TROUT. Amongst the various species of trout the river fish is most highly esteemed for its delicate flavour. It is in season from March to September. When buying this fish, care should be taken to select one with bright eyes, red gills, and firm flesh, and it should be cooked as soon as possible after purchase. There are various methods of cooking trout, the larger fish being prepared much in the same manner as salmon.

Baking Trout. Baking is a favourite way of preparing trout. Clean 3 small fish, split them open and take out the bones; then lay them with the skin side uppermost on 3 thin rashers of fat bacon placed at the bottom of a fireproof baking dish. Season them to taste. Sprinkle a little chopped parsley and some lemon-juice over them, cover them with a greased paper, and then bake them in a moderately hot oven for about 20 min.

Frying Trout. To fry trout, clean the fish, split it and remove the bone as directed in the previous recipe, then sprinkle it with seasoned flour, brush it over with beaten egg, and coat it with breadcrumbs. Fry it in a pan of smoking hot fat, and when browned on both sides, drain and lift on to a hot dish. Fried parsley is the most suitable garnish, and mayonnaise sauce can be served separately.

Broiling Trout. Trout may also be broiled. To do this, first clean and split open the fish and take out the bone. Season it to taste with salt and cayenne, sprinkle it with lemon-juice, and then brush it all over with melted butter. Broil it before a clear fire for about 8 min. and serve with parsley sauce. To boil trout, the fish, after cleaning, is put into a pan of boiling water to which a little vinegar and salt have been added. About one teaspoonful each of vinegar and salt are needed to every pint of water. Take the scum from the top as it rises. The time required for boiling depends upon the size of the fish, one weighing 2 lb. needing about 15 min. When ready, drain it and serve with shrimp sauce. Cut lemon makes a suitable garnish. *See* Fish; Salmon; Sauce.

TROWEL. Various patterns of trowel are used in building by bricklayers and plasterers, and small trowels of a different shape are useful to the gardener. *See* Brick; Casting; Cement; Plaster; Pointing; Rendering; Tool.

TROY WEIGHT. This weight is employed for weighing gold, silver, diamonds, and precious stones generally. It is as follows: 24 grains = 1 pennyweight (dwt.), 20 pennyweights = 1 ounce (oz.), 12 ounces = 1 pound (lb.). The pound troy is not the same as the pound avoirdupois, as it only contains 5,760 grains against 7,000.

TRUFFLE. The truffle is really an edible fungus which is found just below the surface of the ground in wooded districts and in forests on the Continent, some parts of France being famous for truffles. They are also obtained in limited numbers in England, but these are usually found to lack the particular flavour of the continental varieties.

In colour, truffles are red, white, or black. The black ones are the ripest and the most commonly seen, and are used to flavour sauces and stews and also sometimes served as a dish by themselves. They are very expensive, whether bought by the pound or in bottles, and are in season in October, November, December and January.

Bottled truffles need no preparation before they are cooked, but fresh ones need to be soaked in cold water for an hour or more to remove any particles of earth that still adhere. They should then be washed in several cold waters, brushed well, dried, and peeled and cut into shapes. The peel may be used for flavouring purposes and should on no account be thrown away.

If served alone, truffles should be left whole, each one wrapped in a piece of buttered paper and then baked for about an hour in a hot oven. They are sometimes stewed in champagne, flavoured with vegetables and herbs. When used as a garnish, truffles are first boiled for about 15 min. They may be cut up either before or after boiling, according to taste.

Truffle Sauce. Clean a dozen truffles, cut them into thin rounds, and then stir them in a frying-pan over the fire, with a lump of butter slightly larger than a hen's egg, 2 dessertspoonfuls each finely chopped parsley and shallot, and seasoning to taste. After about 10 min. cooking, drain off some of the fat, add a little more fresh butter, $\frac{1}{2}$ gill gravy, the strained juice of $\frac{1}{2}$ a lemon, and a dust of cayenne. Continue stirring the sauce until it boils and then serve it immediately.

TRUG. A convenient type of basket for gathering vegetables and flower sprays is that known as a trug or Sussex trug. It is a wooden arm basket with rounded bottom, and in length is about three times its width. It is largely employed for garden purposes in most country districts.

TRUMPET FLOWER. This vigorous, climbing plant, 18 ft. or more in height, bears tube-shaped flowers in summer. Only two are suitable for cultivation out of doors, and they must be planted against a sunny wall. *Tecoma grandiflora* and *T. radicans*, both with reddish-orange flowers. In mild districts they form admirable wall plants. They should be planted in autumn or spring in deeply-dug soil with which old turf and decayed manure have been mixed. The side shoots should be pruned in spring. For a heated glasshouse two of the best kinds of trumpet flower are *capensis* and *jasminoides*.

TRUMPET LILY. This name is usually given to the familiar white-flowered *Lilium longiflorum*, often called Easter lily because it is forced into bloom in large numbers for decorative purposes at that season. It is more useful for cultivation in pots under glass than for planting out of doors, where it does not usually flourish for more than one or two seasons. Bulbs should be potted in autumn or winter, singly in 5-in. pots placed in a frost-proof frame or greenhouse, and covered with fibre until they are well rooted. They should then be set in a light position in a heated greenhouse where they will make quick progress. The bulbs must be set low down in the pots to allow of a top-dressing of soil when roots form at the base of the stems. *See Lily.*

Trumpet Lily. Fine heads of this fragrant species grown as a pot plant.

‘T’ RECIPES: A SELECTION SHOWN IN ACTUAL COLOUR

Tomato Egg: Wipe some large, firm tomatoes. Cut off a slice from top of each and scoop out some of the pulp. Season and sprinkle grated cheese over insides, and place in pattv pans. Carefully drop a small egg into each, season again, cover with a mixture of grated cheese and crumbs fried in butter, and cook in oven until eggs are set and tomatoes soft. Serve on croûtes. **Tomato Jelly:** Fry two shallots in a lump of butter about the size of a hen's egg. Add 2 lb. sliced tomatoes and salt and cayenne to taste. Cook slowly until vegetables are tender, then rub all through a sieve and put back in pan with 1 oz. gelatine previously dissolved in $\frac{1}{4}$ pt. water. Bring to boil and pour into mould to set. Just before serving, sprinkle with a little grated cheese. **Twelfth Night Cake:** Made as Christmas Cake. **Tangerine Jelly:** Dissolve a pint packet orange jelly in 1 pt. hot water and put thin coating of it at bottom of shallow dish. Peel 4 tangerines, quarter them and remove pith and pips. When jelly in dish is set, dip some of tangerine quarters into remainder of jelly, arrange all round edge of dish and leave to set. Cover with more jelly and continue layers until dish is full, with jelly for final layer. Mix 1 gill cream with a sprinkling castor sugar and a few drops vanilla flavouring. Whisk until stiff and pile it in centre of jelly. A few pieces of rind may be used as garnish. **Tangerine Baskets:** Cut neat round hole in tops of some tangerine oranges and scoop out inside without damaging cases. Whip some cream, flavour with a few drops of tangerine orange essence, and stir in also a little grated rind and castor sugar to taste. Fill cases with this mixture, heaping up slightly on top. Use angelica to form handles.

TRUNK. This word is used for a box made to carry luggage. A useful type is that known as the cabin trunk. The essential feature of this is a lack of height, which enables it to be stored away in a cabin. A serviceable size is 36 in. by 20 in., with a height of 12 in., but they are sold in larger and in smaller sizes.

One variety of cabin trunk has a frame of three-ply wood covered with brown canvas. It is strengthened by wooden hoops and is fastened by two locks. A tray that can be lifted out is the only internal fitting. A better type has a fibre foundation and the corners are protected by stout pieces of leather.

Wardrobe trunks are bulky, but their fittings and compartments make them easy to pack and unpack. It is not advisable to buy large trunks in cheap qualities.

So much confusion arises when trunks of similar appearance are unmarked, or when the labels are torn off, that it is always wise for the owner to have his or her initials painted on in a conspicuous place. This will help to avoid loss or delay. *See* Holiday; Lock; Lost Property; Packing; Suit Case.

TRUSS. By the term truss is generally meant an apparatus usually composed of a leather-covered spring and a pad used in the treatment of hernia or rupture. Its object is to prevent the hernia from slipping out after it has been reduced.

A truss should be worn continuously while the patient is in the upright position. While in bed it may be discarded, unless the patient suffers from a cough. The whole virtue of a truss lies in its being correctly fitted and adjusted. In young children the complete cure of rupture may sometimes be looked for if a correctly fitting truss is worn constantly for two or three years. In children in their teens, and adults up to well past middle life, a complete cure by operation is nearly always preferable to the wearing of a truss. *See* Piles; Rupture.

TRUSTEE: His Duties. When one person holds property of any kind for the benefit of another or others he is said to be a trustee, and to hold the property upon trust for the beneficiary or beneficiaries, who are also called cestui qui trustent. A trust may be created by will, deed, or other writing, or even by word of mouth; but it must be evidenced by writing if it relates to land or other hereditaments.

If a trustee dies or becomes incapable of acting or desires to be discharged, refuses or is unfit to act, or remains out of the United Kingdom for more than 12 months, then a new trustee may be appointed. If the instrument creating the trust gives to anybody the power of appointing new trustees, that person makes the appointment; but if there is no such person then the surviving or continuing trustees or trustee or the executor or administrator of the last surviving or continuing trustee appoints the new trustees or trustee.

If there are more than two trustees, and one of them dies or retires, it is not necessary to appoint another in his place so long as there are two left; but if there are only two, then one cannot retire without another being appointed to replace him. If a trustee misconducts himself, an action may be brought by any beneficiary or co-trustee to have him removed and another trustee appointed.

A trustee should only invest trust money in trustee securities, unless the trust deed or will gives him power to do otherwise. If he invests money on mortgage, he should have the land or houses valued by a competent surveyor, and not lend more than two-thirds of the valuation. A trustee is liable personally for breaches of trust; but he may apply to the court to be protected should he have acted honestly though mistakenly.

A trustee ought not to carry on a business unless the trust deed or will gives him power to do so. Suppose the testator who created the trust left the whole of the property to trustees in trust for his widow and children, and amongst the assets is a business, it is the trustees' duty to realize the business and invest the proceeds in trustee securities, because it is for a trustee to look to safety

rather than to high interest. In some cases, however, the will or deed gives trustees wide power of investment, and then they are safe so long as they keep within the four corners of the instrument. If a beneficiary tries to persuade a trustee to make an unauthorized investment, the trustee should always take from him a letter requesting such investment to be made, and giving an indemnity against the consequences.

Trustee Investments. The sort of investments allowed by the law are the following: British Government securities; Bank of England stock; Indian Government stock; Metropolitan stock; Metropolitan Water Board stock; British railway debentures or preference stock, if the railway for 10 years has paid 3 per cent dividend on its ordinary stock; guaranteed Indian railway debentures; British water companies incorporated by royal charter or special Act of Parliament, where the company has paid 5 per cent on ordinary stock for the past 10 years; municipal borough or city corporation stock, where the place has a population exceeding 50,000; mortgage of real property up to two-thirds value; any security for the time being authorized by the high court.

Breaches of Trust. When trust property has been improperly disposed of, the beneficiaries are entitled to follow it as long as it can be traced and identified. If a trustee mixes trust money with his own, as by paying it into his own account at his bank, the beneficiaries are entitled to be paid out of that account in priority to anybody else; because it is always assumed that any money which he drew out for his own purposes was his own money and not trust money, and therefore all that is left is trust money.

Where there are co-trustees, each one is liable to see that the funds are properly taken care of and duly administered. Therefore, a co-trustee should never allow the other co-trustee to administer the trust without constant checking. It is his duty, if he allows his co-trustee to receive trust money, to take care that it is properly invested-or otherwise disposed of at once.

If he is informed that the money has been invested on certain securities, he should demand to see those securities; and he ought to take care that all trustees' securities, such as mortgages and stock certificates, are made out in the joint names, and are deposited in the joint names at some bank or other place of equal safety.

If a trustee is found guilty of a breach of trust, and is ordered by the court to make good the money which he has lost, the beneficiaries can compel any one or more of the trustees to make good the loss; but the one who has in fact made it good can sue the other or others for their share. If a breach of trust has been committed at the instigation of a beneficiary, and the trustee is ordered to make it good to the trust estate, the court will also order the beneficiary in question to indemnify the trustee out of his share of the trust funds.

Trusts are very often family affairs, and it is sometimes inconvenient to administer them on strict lines; but a trustee who departs from the straight path, even with the best intentions, may find himself landed with heavy liabilities, as a consequence of his mishandling of trust funds. The following case, although an hypothetical one, may serve as an example.

Suppose, for example, a man left all his estate to trustees upon trust to pay the income to his wife for life, and after her death to divide the capital amongst his children. It may be that the estate is a very small one, and that upon some emergency the widow's income does not suffice for her needs, and she asks that a portion of the capital shall be handed to her or used for the benefit of herself or one of the children. If all the children are of full age, the trustee will be safe if he procures them all to sign a letter requesting him to make the payment which their mother requests; otherwise he is running a risk.

A trustee is not allowed to use money for his own purposes out of the trust money, or to make any profit out of his trusteeship, unless expressly permitted to do so by the trust deed. It sometimes

happens that where money is invested at low interest in government securities a trustee will say. Let me use the money in my business and I will pay $7\frac{1}{2}$ per cent. If he does use the money in his business, and makes a profit out of it of more than $7\frac{1}{2}$ per cent he can be compelled to hand over every penny of that profit. On the other hand, should he lose the money, he is liable to pay the whole of it back with 5 per cent interest.

When a trustee is in doubt as to the proper course to take, especially where the will or deed is of doubtful construction, his best course is to apply to the court. Anybody interested in the trust has a similar right to apply to the court on doubtful points. *See* Executor; Guardian; Ward.

TRY SQUARE. This is a carpenter's tool employed for testing the accuracy of right angles. As can be seen from the accompanying illustration, it consists of a flat parallel-sided steel blade attached to a stock made of a parallelsided piece of hardwood. The working edge of the stock is faced with a strip of brass, the angle between the face of the brass and the inner edge of the steel blade being exactly 90° .

Try Square. Testing a joint for uprightness.

In a well-made square the outer edges should be at right angles, and when the square is placed on a level surface in a vertical position, the blade should be at right angles to the level surface.

T SQUARE. Employed for drawing parallel lines, usually horizontal, a T square comprises a long blade of mahogany or other wood and a stock made of thicker wood. The working edges of the blade and the stock should be at right angles to one another, the blade and the stock being firmly united by dowel pins and screws. Its most extensive application is in the preparation of drawings, when the T square is used in conjunction with a drawing board. It should be slightly longer than the board. Probably the most serviceable pattern is a mahogany T square about 30 in. long. A common type is made in pearwood. The usual practice is to have the left hand edge of the drawing board smooth and true, and to work the T square from this edge. The mode of operation is illustrated in Figs. 1 and 2. *See* Drawing; Set Square.

T Square. Fig. 1. T square in use, being guided by the prepared edge of the drawing board. Fig. 2. How to hold the T square while using at the same time a set square rested against it.

TUB. Tubs are employed for various domestic purposes. In former days they were much used for washing, and the dolly tub, as it is still called, is sometimes seen to-day. Another use is for holding plants that serve to ornament a garden, while a tub may also be let into the ground and used to hold water.

Tub Plants. Many attractive shrubs and plants can be grown in tubs; they look particularly well on terraces, on either side of garden steps, in paved courts, by the side of doorways and are admirable in town and roof gardens. Tubs made of teak are particularly to be recommended because they remain sound indefinitely, but they are expensive. Tubs of oak and other wood are also used; they are usually painted dark green. Holes must be bored in the bottom for drainage and crock (pieces of broken flower-pot) placed over them. It is necessary to use loamy (turfy) soil for the bulk of the compost; a little decayed manure may be mixed in with advantage.

Some of the best flowering plants for tubs are hydrangea, blue African lily (*Agapanthus umbellatus*), plantain lily (*funkia*), fuchsia, lemon-scented verbena, myrtle and rosemary. The myrtle, verbena, hydrangea, fuchsia and agapanthus should be kept in a frost-proof place for the winter. Suitable evergreen shrubs are holly, box, bay laurel, retinospora, rhododendron, skimmia and laurustinus. Roses too may be grown in tubs.

TUBER. In gardening a tuber is the swelling or underground expansion of the stem of a plant, stored with starchy food, which gives nourishment to the young buds or eyes which it bears at intervals, until they are strong enough to obtain nourishment direct from the soil. When a stock of plants is increased by separating the tubers, as in the case of potatoes or dahlias, the resulting crop is always true to type. *See* Artichoke; Begonia; Dahlia; Gloxinia; Nasturtium; Potato, etc.

Tuber. 1. Of flame nasturtium. 2. Ranunculus. 3. Peony. 4. Madeira vine. 5. Richardia. 6. Incarvillea. 7. Potato. 8. Wax fountain flower

TUBERCULOSIS. This disease is characterized by the development of small nodules called tubercles, which are due to the presence and activity of the tubercle bacillus. The commonest means of entrance of the bacillus into the system are by inhalation, the patient breathing in the germ; by inoculation, the germ finding its way through a broken surface in the skin or mucous membrane; and by means of food or drink infected by the germ. Milk and meat are the commonest articles of diet which are likely to be contaminated by the tubercle bacillus.

Persons crowded together in the poorer districts of cities are naturally more liable to contract the disease than those who live in the country and get plenty of fresh air and sunshine. Thin, flat-chested persons account for many victims, but the disease is by no means uncommon in the well developed. Indoor workers, particularly in dusty trades, such as stone cutters, miners, mill hands, and factory hands in general, are all more than normally open to the disease.

Those who live in close association with people suffering from the disease run great risks unless care is taken to use a sputum flask and disinfect the sputum, in which the real danger lies. If this is allowed to be disposed of about a room it dries up, and the dust of the room becomes impregnated with it. Using a book the pages of which have been turned over by a consumptive moistening his finger with saliva, or using his food utensils which have not been properly cleaned, may convey the infection. Infants fed on milk from tuberculous cows are liable to incur infection of the glands of the bowels, whence the disease may spread to other parts. Children convalescing from measles and whooping cough often fall victims to the disease.

Tuberculosis attacks certain parts of the body seemingly by preference, but practically no part is exempt. The most common site is the lungs, the disease in that case being known as consumption. Tuberculosis also attacks the bones and joints, the intestines, lymph glands, kidneys, peritoneum, bladder, and the brain, heart, spleen, and generative organs.

In the treatment of tuberculosis in general, sunshine, fresh air, and a generous diet, including plenty of fat and especially cod liver oil, play a very important and indispensable part. Specific treatment in the shape of injections of tuberculin are of the utmost use in some cases.

The Disease in Poultry. This is one of the most common diseases of fowls and other birds. Affected fowls become anaemic, thin, listless, emaciated and lose weight. The comb and wattles become pale, and in the later stages there is usually persistent diarrhoea. When this sets in, the appetite, which was good in the earlier stages, becomes impaired and feeding is very erratic.

As a consequence of extreme emaciation, which is a noticeable symptom, the bones become very prominent. The joints of the foot, knee, or shoulder are sometimes affected and slowly become enlarged and painful, causing lameness or drooping of the affected wing, according to the position of the lesion. The onset of diarrhoea is followed by exhaustion and death. These facts are taken from Leaflet No. 1, issued by the Ministry of Agriculture.

Healthy birds become infected with tuberculosis by eating food or drinking water which has been contaminated by the droppings of infected birds. Damp, dirt, and absence of sunlight greatly favour the spread of the disease; good ventilation and strict cleanliness in the runs and sheds assist against, though they do not prevent, its spread.

All diseased birds should be killed and buried in lime or burnt; the poultry house should receive several thorough applications of disinfectant, and the tainted run should be heavily dressed with quicklime and dug over. Several months should elapse before birds are put back into old quarters that have been cleansed and disinfected.

Where the disease breaks out, it is best to clear off old stock and make a fresh start with new stock later. Attempts to deal with diseased birds only with a view to saving part of the stock are almost certain to lead to disappointment, and new cases among birds in the flock will come to light from time to time. When the premises have been thoroughly disinfected, the new stock should be

carefully selected from strong, healthy birds, which should not be brought on whilst any part of the original stock remains. If this is impracticable, the old and the new stock should be carefully separated from each other.

The disease, in exceptional cases, may be transmitted from affected birds through the eggs to the chicks, though the latter may not show symptoms until they are fairly well grown. It is advisable, therefore, not to use any eggs for hatching which have been derived from fowls amongst which tuberculosis is known or suspected to exist. *See Consumption; Curvature; Gland; Light; Lupus.*

TUBEROSE. This is a pretty and popular half-hardy tuberous plant, with white, fragrant flowers; the double forms enjoy the greatest favour. Pearl is one of the best varieties. The botanical name of the tuberose is *Polyanthes tuberosa*.

The tuberose is grown from imported bulbs, which are best potted singly in 4 in. or 5 in. pots, in a compost of loam with a third of decayed manure or leaf-mould and a liberal admixture of sand. Leave the upper part of the tuber exposed. Stand the pots in a frame or cool greenhouse, and give very little water for two or three weeks; then put them in a warm house in successional batches and keep the soil moist. This will ensure a long supply of bloom.

The flowers are charming for wreaths, buttonholes and bouquets. It is not worth while to keep the tubers after flowering, and fresh supplies should be procured annually.

TUBING. Flexible metallic tubing is largely employed for connecting gas rings or gas table lamps where portability is desired. The best method of cutting this tubing is to file a slot along one of the spirals until it is thin enough to break off. A three-square file is suitable for the purpose, but a hack saw may be used. The brass and copper tube used for gas is dealt with in the article on Pipe. Other information will be found in the articles on Brass and Copper.

Rubber or canvas tubing is much employed for garden watering or washing down the concrete floors of garages or outbuildings. It is dealt with in the article Hose Pipe. *See Barrel; Gas.*

TUCK: How to Make. A stitched fold taken up double in the material and arranged to lie over single material constitutes a tuck.

They are made on the right side of the fabric, and vary in width. Generally, they are arranged in groups.

The distances allowed between the tucks is very much a matter of taste. Narrow tucks may almost touch each other, or the space apart may be the tuck's width; where the tucks are very wide the distance between may be less than their width.

Unless the tucks are being made in a garment cut from a paper pattern, on which both the tucks and spaces would be marked, it is a good plan to experiment with a piece of paper till a satisfactory effect is gained.

The narrowest tucks are termed pin tucks. As these only necessitate the taking up of a few threads of material in each a group will not seriously effect the length or width of a garment, but for wider tucks extra material must be allowed. For instance, a tuck that is to be $\frac{3}{8}$ in. wide when finished will take up $\frac{3}{4}$ in. of material, and lie over $\frac{3}{8}$ in., i.e. the tuck width.

In making tucks the great point is that they must be straight whatever the width. For a pin tuck it is sufficient, at the position needed, to take up the tiniest fold of the material, crease it, and run in the stitches as near as possible to the fold, repeating the process for succeeding tucks. For a deeper tuck, take up a fold in the material at the position needed, crease firmly, then below the fold at the requisite depth put in a row of stitching right through the double thickness of the material.

To keep the tuck of an even width throughout it is a good plan to use a guide as shown. For this guide cut a narrow strip of cardboard, place the top edge to the folded edge of the tuck, and where the stitching is required make a straight cut into the card, and cut down again in a sloping direction as shown. When working, this piece of cardboard can be slipped along the tuck, and the stitching put in a thread or so below the straight cut, so keeping it even. For each succeeding tuck, the same notch is used for the width, but to maintain an equal distance between the tucks another straight and sloping cut is first made in the card at the position of the folded-down edge of the first tuck. *See French Fold; Running.*

Tuck. Showing the use of a cardboard gauge to ensure evenness of the tucks

TUDOR STYLE IN HOUSE AND FURNISHING

Models which Influence Design and Craftsmanship To-day

This article belongs to the group in our work dealing with British period styles in building, decoration, and furnishing. Other entries containing information on Tudor style are
Chimney; Door; Fireplace; House; Linenfold; Panelling; Settle; Sideboard;
Silver Ware; Stained Glass; Staircase. See also Jacobean Style

Although the Tudor style in architecture is described as transitional between the Gothic and Renaissance, it possessed marked features which resulted in a blend that was essentially English and culminated in the erection of many beautiful buildings including such famous dwellings as Hampton Court, St. James's Palace, and Haddon Hall.

Tudor Style. Fig. 1. Tudor room in the richly decorated manner of the latter half of the 16th century. The oak panelling, inlaid in holly and bog oak, was removed from the room known as the "inlaid room," at Sizergh Castle, Westmorland. (By permission of the Director, Victoria & Albert Museum, S. Kensington)

Nominally including the years between 1485 and 1603 it found its chief national expression during the reigns of Henry VIII and Elizabeth.

Founded on the austerity of the Gothic tradition, colour and comfort were added as the rich influence of the Renaissance spread during the latter reign.

Throughout the 16th century there occurred in England a remarkable development in domestic architecture, made possible by the increased security that followed the abatement of the civil wars. Manor houses were built instead of moated and fortified dwellings and town planning was carried out.

Early Tudor houses, even the important ones, show little orderliness either of elevation or plan, but the lack of symmetry gives them picturesqueness. Gables and central or flanking towers in the larger ones, lean-to roofs in the smaller farmhouse type, very substantial chimney stacks, beautiful stonework around doors and windows, cusped window heads showing trefoil and quatrefoil formations, the Tudor arch, and the half-timbered walls to be found on many, are all features which make them attractive.

One way to distinguish early from late Tudor is by the windows. In the former there is only one row of lights, and these are quite small, though probably large enough for the height of the rooms they served. The reluctance to have large windows in outside walls still lingered, a relic of the tradition that a house should show as few vulnerable points as possible to hostile missiles from outside. Also glazing was not in general use and glass was expensive. As late as 1573 it is recorded that the windows of a country mansion belonging to the duke of Northumberland were carefully stored during his absence in London for fear the precious glass should be broken, and other similar cases are on record.

Later the window space was enlarged, transoms or crossbars were introduced, and windows were brought into conformity with the loftier ceilings and larger apartments generally that were characteristic of the end of the 16th century.

Tudor designers always made a feature of their chimneys. The method was to group two or three fireplaces together, as is done nowadays, but the flues were carried up the great stone or brickwork stack in single shafts, which were often surmounted by handsome caps. In the reign of Henry VIII chimneys were often twisted and counter-twisted; they were wreathed with spiral bands of stone or brick, or the shafts were intricately panelled. This characteristic feature is revived in moderation and adapted to-day by architects for suitable houses. Some examples are shown as illustrations to the article on Chimney.

The arched window disappeared in favour of the square-headed one, and in important houses classic pilasters were used to frame the mullioned windows; a complete entablature at every floor level made the circuit of the building instead of the plain string course, and the gables were frequently linked together by a balustraded parapet, all in obedience to the new feeling for orderly design in the Renaissance manner.

The various wings of the larger Tudor houses were, as a rule, only one room wide, which meant that some of the rooms had to be thoroughfare rooms; a very inconvenient arrangement in modern eyes. Then the typical staircase of the Tudor house was of the corkscrew type; a straight flight in the thickness of a wall was its alternative.

One feature, however, of later Tudor architecture, viz., the bay window, readily adapts itself to modern building, and even the overhanging oriel window can be copied with charming effect where the design admits of something of this kind.

It is probably true that a larger proportion of country and suburban houses built during the latter years of and since the end of the 19th century are based on the Tudor model than on any other period style. They are only beautiful when designs are modified and adapted by highly skilled architects, who avoid superficial imitations which have either lost significance in modern surroundings or are out of keeping with the size of the house, but bring into the scheme the essential features evolved to suit an English background. The builders and craftsmen of the Tudor period used the materials close at hand. Thus in the Cotswold district and in Somerset 16th century houses are mainly of stone, while in Surrey, Sussex, and Kent they are half-timbered, oakframed, the

panels between the timbers being filled in with wattle and daub, both inside and out, and washed with buff or white.

Interior Decoration and Furniture. Excepting the halls of the larger mansions, or manor houses, rooms of the earlier Tudor period were low built, while doors and fireplaces show the flat arched openings of the shape known to-day as the Tudor arch. Linenfold panelling was replaced in the houses of the rich by more decorated styles and as rooms were built higher in the larger houses, ceilings were also intricately and lavishly decorated. Colour was often introduced into their plaster work modelled in floral and heraldic designs.

Tudor Style. Fig 2. Double seated bench or settle in oak. The carved motifs in the panelled back and the frieze of the seat show designs in low relief characteristic of the period. (By permission of the Director. Victoria & Albert Museum)

An example of a beautiful Elizabethan room, reconstructed in the Victoria and Albert Museum, is shown in Fig. 1. The panelling was removed from the room known as the "inlaid room" at Sizergh Castle, Westmorland, and the, frieze and ceiling are reproductions in plaster from the originals still at Sizergh Castle. The ceiling is enriched with pendant ornaments from which spring ribs forming compartments with floral designs, medallions of goats, chained stags and shields of arms. The plaster frieze has a repeating floral pattern with demi-figures. The panelling is of oak inlaid in holly and bog oak. The upper portion has a row of arcades, while the lower portion or dado is divided into panels by mouldings. There are three horizontal bands of geometrical inlay.

In Tudor days colour was lavishly used in strong, bold tones; reds, greens, and white were most general. Besides inlay, gilded and coloured wood and plaster enrichments, tapestry (mostly imported) and painted canvas or tapestry needlework hangings were employed as wall coverings. Stained glass was introduced into the windows by wealthy householders. Chimney pieces were massively decorated above the fireplaces with coloured and gilded ornamentations in stone, plaster, and woodwork. Floors were of wood blocks, of elm planks and of brick or stone.

Carpets began to be imported from the East. They were small in size in comparison to the rooms, as may be seen in Fig. 1, but made up for this in richness of colour. Delicate tones are out of place in any Tudor decorative scheme, and the same may be said of flimsy materials. Velvet, linen (plain or embroidered) heavy satin and damask were the textile fabrics used.

The pieces of furniture, though still scanty, increased in variety in late Tudor times. In Fig. 1, the forerunner of the gate-leg table is seen on the right, and a carved oak side table on the left, while the beautiful chair, the chest and also the tester and headboard of the bed are decorated with inlay and carving.

The oak settle illustrated in Fig. 2, has the panelled back with carved motifs frequently seen on later Tudor pieces of the less costly type. Strapwork and guilloche decoration was also much used on these. Renaissance ornament consisted of classical heads in medallions, dolphin-headed scrolls, vases and floral forms. Fine carving in this style was done on seats, court cupboards, and chests designed for great houses.

Earlier furniture was more austere. It was often carved with linenfold, horizontal, and vertical and the pieces were simple in shape. The oak cabinet illustrated in Fig. 3 has inspired the shape of countless cabinets in different styles of decoration and in different woods which have been constructed through intervening periods, and still find places in modern rooms.

Tudor Style. Fig. 3. Oak cabinet, 4 feet high on a stand with legs united by square stretchers. The carving is simple, but the design of the lower panels shows the popular arcaded formation. (Victoria & Albert Museum)

TULIP. This is the most brilliantly coloured of spring and early summer flowers and unsurpassed for providing an attractive display in beds and borders. The two chief types are the early or April flowering tulips and the May flowering tulips, which consist of Darwin and Cottage varieties.

The tulips which bloom in April are great favourites for planting in spring flower beds, where they provide sheets of glowing colour. The bulbs should be set 3 in. deep and about 7 in. apart in October; as the soil is dug, some thoroughly decayed manure and a sprinkling of bone meal should be added. If the soil is clayey it is a good plan to add sand. Some of the finest varieties are Artus, bright red; Chrysolora, yellow; Cottage Maid, rose and white; Couleur Cardinal, crimson-scarlet; Primrose Queen, pale yellow; Prince of Austria,

orange buff, fragrant; Queen of the Netherlands, pink; White Swan, white; and Yellow Prince, yellow, fragrant.

The double tulips which bloom in April have large and handsome flowers. Couronne d'Or, orange yellow; El Toreador, red and yellow; Imperator rubrorum, red; Murillo, pale rose; and Vuurbaak, scarlet, are some of the best. The April flowering tulips are about 12 in. high when in bloom.

The May tulips are magnificent flowers; the large, handsome blooms are on stems from 20 to 30 in. high. The bulbs should be set early in November, 5 in. deep on heavy soil, 6 in. deep on light soil, and about 10 in. apart. In association with Siberian wallflower and forget-me-not they provide many brilliant colour schemes.

Most of the Darwin tulips have immense cup-shaped blooms, those of the cottage tulips are chiefly long and pointed. A few of the finest Darwin tulips are Antony Roozen, rose; Bartigon, red; Clara Butt, pink; Europe, rose red; Farncombe Sanders, red; La Tulipe Noire, almost black; Pride of Haarlem, carmine; Rev. H. Ewbank, lavender; The Bishop, pale purple, and Zwanenburg, white.

These are beautiful cottage tulips: Amber Crown, amber-rose; Bouton d'Or, yellow; Carrara, white; Dom Pedro, maroon and brown; gesneriana lutea, yellow; gesneriana spathu, lata, deep red; Golden Crown, orange-red and yellow; Inglescombe Pink, rose pink; La Merveille, rose and buff; Moonlight, pale yellow; Mrs. Moon, yellow; Walter T. Ware, golden yellow.

The parrot tulips are striking flowers of brilliant colouring with deeply cut petals. They bloom in May: the stems are weak and must be supported or the flowers will be spoilt. The old English tulips, which are classified as bizarres, bybloemens and roses, according to their colours, are rarely grown nowadays, except by connoisseurs and exhibitors. The flowers of the Rembrandt tulips, which open in May, are blotched and striped with various colours. Three new types of tulip are the lily-flowered with reflexed petals, which are in full bloom in May: Mendel, specially adapted for cultivation in pots under glass, and the Triumph tulips, which are intermediate between the April and the May flowering varieties.

Some of the wild species of tulip are very beautiful and suitable for planting in the rock garden. *Clusiana*, red and white; *Greigii*, scarlet; *Kaufmanniana*, cream; *linifolia*, scarlet, and *persica*, bronze yellow, are particularly attractive.

The Duc Van Thol tulips, which bear small red, pale rose or yellow blooms, are useful for forcing; if potted in August-September and grown under glass they will bloom in winter.

Some of the April flowering tulips also do well in pots.

Tulip. Beautifully shaped pink blooms of the Inglescombe variety, suitable for outdoor planting. Left, vivid flowers of the parrot tulip.

Tulip Culture. 1. Placing bulbs in pots or bowls. 2. Bowl culture : *a*, charcoal ; *b*, fibre ; *c*, moss. 3. Stage at which light should be allowed. 4. Pot culture : *a*, crops ; *b*, rough soil ; *c*, compost ; *d*, moss. 5. After planting : *a*, ashes ; *b*, covering box ; *c*, glass. 6. Correct outdoor planting ; *a*, sand ; *b*, fine soil. 7. TULIP: SOME VARIETIES OF THE SPRING FLOWERING BULB

Instructions for the general culture of tulips, together with information on the different varieties, are given above.

TULIP TREE. This is the common name of a North American leaf-losing tree (*Liriodendron tulipifera*), which is hardy in Great Britain. It belongs to the magnolia family, will reach a height of 60 ft. or more, and thrives best in loamy soil. The green and white flowers open in spring.

TULIPWOOD. This is a richly figured wood used in former days for inlaying and marquetry. It was used to decorate pieces of furniture made in the Adam and Louis styles, and was employed with much effect by the great French cabinet makers. *See* Inlaying; Louis Style; Marquetry; Wood.

TULLE. The thin gauze-like silk material which is known as tulle can be obtained in a large number of shades, and, in spite of its transparency, wears fairly well in a good quality. Its chief use is for scarves and evening dresses, although fine silk net is more suitable for the latter.

TUMBLER. The original tumbler drinking vessel had a pointed base, and could not therefore be put down without tumbling over. Tumblers are made in varied qualities. The best are of fine cut glass. They are usually sold in dozens or half-dozens, sometimes to match the rest of the table glass, and can be had in several sizes.

Antique tumblers may be valuable. They were made toward the end of the 17th century by the great glassworker John Greene. These were either plain or ribbed, horizontally or perpendicularly or adorned with surface moulding, pressed, as it is called. They were of different sizes, and many were originally arranged in nests, each nest containing 6 or 12. For beer they were made in their present shape early in the 18th century, but good specimens are rare.

The best tumblers date from the middle of the 18th century. These taper very slightly and are sometimes engraved with sprays of roses, with hops and barley, or with a vine pattern. Toward the end of the 18th century the tumbler became fairly common. Those seen in antique shops are chiefly of the early part of the 19th century. They include squat and heavy examples made of fine cut glass as well as the taller pattern, tapering considerably and cut nearly all over in a series of indents. *See* Glass Ware; Rummer.

TUMOUR. In medicine the technical name for a growth is tumour, and there are two main groups, the simple and the malignant. A simple tumour, if it does damage, does so only by pressing on neighbouring structures. A malignant tumour, on the other hand, infiltrates and destroys adjoining tissues, and at the same time its cells are carried by the lymph or blood streams to distant parts, where they grow. Thus a cancer in the breast or in the stomach may lead to a secondary growth in the brain. Hollow tumours are given the name of cysts. They contain some kind of fluid. *See* Cancer.

TUNICA. These pretty little hardy plants belong to the pink family. The most attractive is *Tunica saxifraga*, 8 to 10 in. high, with slender stems and small, blush-coloured flowers in summer. It is suitable for the rock garden or for setting in the crevices of paved paths. Seeds may be sown in spring where the plants are to bloom in summer, or the seedlings can be raised under glass and transplanted.

TUNING: In Wireless Reception. This is the act of bringing the tuned circuit, or circuits, of a receiver into resonance with the wave-length of a broadcast transmitter.

Tuning is normally carried out by means of a variable condenser connected across an inductance coil, and the circuit is said to be in resonance or tune when the condenser control is adjusted so as to give maximum volume.

A receiver will normally only give the best results when the wave-length to which its high-frequency circuit or circuits are adjusted is the same as the desired broadcast transmission.

In a super-heterodyne receiver, however, certain of the high-frequency circuits are permanently tuned to one definite wave-length, the energy from any broadcasting station being changed to this one fixed wave-length by a special process in the receiver, after selection by initial variable tuning. *See Selectivity.*

TUNING FORK. A tuning fork consists of a bar of steel bent into an elongated U-shape, with the prongs supported at the bend by a foot. When struck smartly upon a firm but not hard body it gives a musical note.

Owing to the fact that the tuning fork is practically invariable in its pitch, and that its tone is singularly pure, it is commonly used to indicate an exact standard of pitch. For ordinary use they are procurable generally for A or C.

TUNNY FISH. This is a fish of the mackerel tribe, and, like lax, it is preserved in oil. It is served as hors d'oeuvres, being cut into thin slices and having fresh oil poured over it.

A good savoury of tunny fish can be made in the following way: Prepare a thick white sauce, add to it some flaked tunny fish, and cook them over a slow fire until the fish is heated through. Then pour the mixture on to small rounds of hot buttered toast and serve at once. *See Fish; Lax.*

TURBOT: How to Cook. The finest of all flat fish, turbot is at its best from April to September. The flesh is firm and white, cuts and considered the best.

Turbot can be cooked in many ways, but boiling is the most favoured method. To prepare the fish, first clean it, wash it in several waters, and then rub it with a piece of cut lemon to remove any discoloration of the skin. Do not cut off the fins. Turn the fish over so that the black skin is uppermost, and score this down the middle to prevent the white skin on the other side from breaking while the cooking is in progress. Then put it into a pan of boiling salted water or fish stock, laying it so that the white side of the skin is uppermost, and cook it gently until the flesh begins to leave the bones. Keep the water or stock in which the fish is cooked well skimmed. Boiled turbot may be served with melted butter, shrimp, oyster, or hollandaise sauce.

To broil turbot, first season it to taste and lay it in a dish containing a gill of salad oil and half that quantity of lemon-juice. Then broil it in front of a clear fire, basting it frequently with the oil and lemon-juice and turning it several times. It may be served with oyster sauce and garnished with parsley.

Steamed turbot, coated with egg sauce, provides another good dish. To prepare it, clean the fish, place it in a steamer over boiling water, and steam it for 15-20 min. If a steamer is not available, stand the fish on a plate over a saucepan of boiling water and cover it with a saucepan lid or a basin. If cooked in this way it will require a little more time. Pour the egg sauce over it on the dish and proceed to serve it at once.

Made-up Dishes. Remains of cold turbot may also be utilized in the following way: Melt a lump of butter about half the size of an egg in a small pan, stir in 1 dessertspoonful flour and when they are smoothly mixed add 1 teacupful milk, salt, pepper, and cayenne to taste, and ½ teaspoonful anchovy essence. Keep stirring all the time, and when the last of these ingredients has been added, draw the pan to the side of the stove so that its contents may cool a little and stir in the yolk of an egg.

Pour a little of this sauce into a fireproof dish, then cover it with some cold cooked turbot that has been boned and broken up with a fork. Continue with these layers until all the ingredients are used,

then sprinkle some browned breadcrumbs and grated cheese over the top and bake until it is heated through.

Reheated and served in the following way cold turbot makes an excellent luncheon dish.

Peel a small onion, stick a few cloves into it, and put it into a saucepan with $\frac{1}{2}$ pint milk and 1 oz. butter. Let these stand at the side of the fire for an hour or so, so that the milk may become well flavoured, and in the meantime boil an egg for 15 min., then shell it, cut it into halves, and take out the yolk. Cut the white into small pieces, rub the yolk through a fine sieve, and take the skin and bones from 6 oz. cold turbot, breaking the flesh into small flakes.

When the milk has stood for the required time, bring it to the boil, take out the onion and cloves, and sprinkle in half a tumblerful of breadcrumbs, the flaked fish, white of egg, and salt and cayenne to taste. Stir these well over gentle heat until they are well mixed and thoroughly hot, allowing time for the bread to cook; then add 2 tablespoonfuls cream and reheat the whole for a few minutes.

Serve it on a hot dish, garnished with lines of powdered parsley and the sieved yolk of egg.

Cold turbot may also be curried, adding the flaked cold fish to a good curry sauce. Serve very hot with a border of freshly-boiled rice.

The roe of turbot should be blanched and sliced, baked in a buttered dish in a moderately hot oven, and basted frequently with the butter. It will need about 20 min. cooking. *See Curry; Fish; Hollandaise Sauce; Sauce.*

Turbot. Boiled turbot garnished with slices of lemon and some parsley.

TUREEN. A tureen is a large dish or bowl, usually fitted with a lid. Either round or oval in shape, it is used for holding soup or sauce at the table. Tureens are often made to match a dinner service, and range, therefore, from pieces of the costliest china to those of the cheapest earthenware. They are also made in silver and Sheffield plate and some of the 18th-century specimens are of great value. *See Ladle; Sauce Boat; Soup.*

TURF. This is a term used to denote the top spit of

Turf and its uses in garden and greenhouse. 1. Stack for potting soil : a, turves ; b, layers of lime. 2. Marrow mound. 3. Turf as base for pot plants : a, ashes ; b, turf. 4. Dimensions for cutting. 5. As rooting medium for seedlings. 6. Gentle hotbeds : a, ground soil ; b, turves ; c, manure ; d, mounds of soil ; e, centre crop. 7. Turf frame : a, turves ; b, top light

meadow land, or a stretch of lawn. Lawns laid with turf become fit for use sooner than others made by sowing lawn grass seeds, but it is most important to lay turf which is free from weeds and coarse grass or it will cause endless labour. The chief details needing attention in the maintenance of a perfect stretch of turf in the garden are mowing, rolling, the destruction of weeds, and the use of fertilizers. If the top spit of meadow land is pared off in turves, about 4 in. thick, and stacked for a year, it becomes what the gardener calls turfy loam, the chief ingredient of potting composts. If alternate layers of manure and turf are stacked the loam will be still more valuable. *See Lawn.*

TURKEYS : REARING AND COOKING

Hints on the Treatment Needed to Produce Good Table Birds

The early part of this article is mainly for the benefit of country readers. The sections on preparing and cooking the bird will be of value to readers in all districts. The articles Duck; Fowl; Poultry; also Casserole; Forcemeat; Stuffing, deal with related subjects. *See Carving; Christmas.*

The rearing of turkeys is best carried out on a large scale, one reason being that the abundance of natural food required by the birds necessitates extensive feeding grounds. They require, too, a good deal of care. Nevertheless, as smallholders and other persons with a little land may like to keep one or two, some information, from Bulletin 67 issued by the Ministry of Agriculture, is here given.

Although turkeys may be raised on heavy land, as a rule they do better on lighter soils, except in dry weather, when there may be a deficiency of green food. The best results are obtained upon a rich soil which is not absolutely heavy in character. If a choice of position is possible, preference should be given to a dry and sheltered one, facing south and protected from cold winds. Every advantage should be taken of banks, hedges, and belts of trees which will serve as windscreens.

The Best Breeds. The American Bronze is a popular breed of turkey, but the Cambridge Bronze is probably a better one for ordinary keeping purposes. On the average, its males reach from 20 to 24 lb. and its females from 12 to 16 lb. They fatten up readily. For those who want a smaller bird the white turkey is recommended, while a cross between this and the Cambridge produces a hardy bird comparatively easy to rear.

Roosting. Adult turkeys should roost in the open all the year round. Special protection may be necessary to enable them to do this, but it is better than placing the roosts under cover. Where large trees are available, the birds may be allowed to roost on the branches, if they are strong enough. If not, perches should be placed under the trees. They should be removable, and should be of fir poles, broad enough for the birds to grip firmly and raised three feet or so above the ground.

Sheds for the Birds. When turkeys must, for one reason or another, be accommodated under cover, a special form of shed is necessary, because they need an abundance of fresh air. The floor must be dry, and the roof should, if possible, be thatched and lofty. The walls should preferably be made of wattled furze about two feet thick, as this ensures, not only perfect ventilation, but fresh air without draught.

Turkeys usually remain on their perches until let out in the morning, when it is their habit to fly straight out and alight on the ground some distance in front of the roost. Therefore, to prevent the birds from damaging themselves, the greater part of the front of the house should be made to open with folding doors or gates consisting of strong frames hung on hinges and covered with wire netting.

Breeding Considerations. As regards breeding, close breeding should be avoided. Mere size is not very important. An approximation to 25 lb. in the males and 15 lb. in the females are suitable weights for ordinary breeding purposes, other considerations including width of shoulder, contour of breast, and a medium length of leg. Stock birds should preferably be from two to three years old, and eight or ten hens should be mated with one cock bird. Yearling hens are not recommended for breeding, but may be employed as mothers during the first season.

The correct feeding of these stock birds is important. Their diet varies according to weather and other conditions, but a suitable mash can be prepared by using equal parts of ground oats, or barley meal and middlings, to which 5 or 10 per cent of meat meal may be added, with grain at night. Many breeders, however, prefer a whole grain diet for both morning and evening feeding, using wheat, barley and oats, and adding cabbages and swedes where the pasture is poor.

Much depends upon the supply of natural food available. When this is plentiful a supply of grain as stated above is sufficient, but when natural food is scarce some soft food in which meat has been mixed should be given three or four days a week. From January onward breeding turkeys need to be in a hard condition, and they must, therefore, have plenty of exercise. A generous supply of grit and oyster shell is also essential.

Turkey. Handsome specimen of a full-grown turkey cock with wings and tail outspread.

During March the hen birds require watching, or they will choose an out-of-the-way spot in which to nest. It is therefore advisable to make up nests in sheltered and secluded positions in which the birds may lay their eggs. April is the best month for hatching, and it is generally undesirable to continue hatching beyond June. Turkey hens are usually good mothers, but their eggs may also be hatched under barndoor hens. Artificial methods of hatching and raising are not recommended, though incubators are sometimes used. A turkey hen will cover 15 or 16 eggs, and a large barndoor hen 8 or 10. The period of incubation is 28 days. The nests should be upon earth bottoms, and the management of the eggs is similar to that of the ordinary fowl's.

Care of Young Birds. In rearing young birds the principle of the roost house should, as far as possible, be applied to the coops. The doors should be wire-netted and covered, if possible, in severe weather with sacking. The birds should be cooped with their natural or foster mother in a dry, sheltered position with a sunny aspect; a rich, medium soil is the most suitable. The coops must be moved a short distance daily to a fresh patch, and the hens allowed out with the young birds whenever possible. The coops should be placed on short, fresh grass where the soil is quite sweet, and for the first 10 to 14 days they should be fitted with enclosed runs in front. The coop and run should be moved daily to fresh ground.

Young turkeys should receive no food whatever for 36 hours after hatching. After that a suitable diet consists of steamed rice dried with fine sharps and mixed with curds and finely chopped green food. With any soft food an admixture of finely chopped grass food, particularly dandelion leaves, clover and lettuce, is especially beneficial. It is important that the feeding board should be sprinkled with fine, sharp grit and powdered vegetable charcoal if curds are absent from the diet.

The feeding should be begun early and continued until late in the day. Very little food is required at one time, but it is necessary to give it at frequent intervals, commencing with six meals daily, and the soft food alternated by a feed of coarse oatmeal and cracked wheat in equal parts. At about the

third week the diet may be changed to include most of the foodstuffs given to ordinary chickens. Boiled wheat is also a good food during early days. Later, new corn will be found helpful in the birds' diet. Unless plenty of natural food is available, some meal must be included in the ration.

Fattening for the Table. The selection and separation of the birds for stock purposes should be made during the autumn, preference being given to birds of good frame and stout legs, rather than to merely heavy specimens. The birds intended for fattening should be allowed full liberty until November. Until that time, in addition to the run of the field, they should receive a liberal feed of grain twice a day. The birds that respond most satisfactorily to the fattening process are those that have been kept in good condition from the earliest days.

About a month before they are to be killed the birds should be confined at night in a large open-fronted shed situated in a quiet position. They must be liberated daily to prevent their fretting from confinement and to allow them exercise. An abundance of soured skim milk or buttermilk is necessary in order to give colour and mellowness to the flesh, and, in addition, to stimulate, by the acid in the milk, the appetite which might otherwise fail.

A suitable food for these days is Sussex ground oats, wheat meal, or barley meal and sharps, and in many cases cooked potatoes or beetroots are mixed with the meal in the proportion of one part of the roots to two parts of meal. Soured skim milk or buttermilk is used for mixing the meals into a crumbly, moist condition. Once or twice weekly boiled meat offals should be given with the soft food. The meat should be finely chopped, and the liquor used in place of milk for mixing the meals. The Sussex ground oats is made by grinding oats into a fine meal. The special finely ground product is obtained by mixing a small proportion of barley with hard, flinty oats.

During the fattening period some give the birds rice boiled in milk, in order to whiten the flesh. For the evening wheat, oats or barley is usually given in place of the mixture mentioned above, though some prefer to give soft food entirely. Plenty of grit, to which may be added small pieces of vegetable charcoal, should be supplied in a box, or hopper, so that the birds may use as much as they want.

Turkeys should be killed by dislocation of the neck after having been starved for 24 hours. They should be plucked at once. The birds should be plucked quite clean, except for the neck and the feathers on the back, covering the hips, which are usually left on in order to prevent the skin from rubbing.

How to Cook. Turkeys are in perfection at the age of about 6 months. For braising or stewing, which demands long, slow cooking, an older bird may be used, but for roasting turkeys should be young and tender. Young turkeys are known by their smooth black legs, bright eyes, red heads and supple feet. Immediately after they are killed they should be hung up to bleed and kept for 3 or 4 days before being cooked. Turkey may be boiled, roasted, braised, made into soup, or served cold, plainly or as a poultry salad.

To roast a turkey, singe and draw the bird, wash it as quickly as possible in cold water, and stuff it with chestnut stuffing or a good veal forcemeat. Sew it up, truss it as for a roast fowl, wrap it in greased paper, and cook it in a good oven for about 2 hours. This is the time required for an average-sized bird. Keep it well basted and take the paper from the breast a little while before lifting the bird out of the oven. When it is ready, put it on a hot dish, remove the trussing threads and strings, and strain some good brown gravy round it. Fried rolls of bacon make a suitable garnish, and some extra gravy should be served in a sauceboat. Cranberry sauce is often liked with turkey. If preferred, fried sausage may be used instead of bacon, and sausage meat is often employed for stuffing.

Boiled Turkey. Choose a medium-sized bird for boiling and, after plucking it, draw it by cutting off the head, slipping down the skin round the neck, cutting off the neck and removing the crop. Turn the bird round and from the other end take out the inside, being careful not to break the gall bag. Cut off the feet and part of the legs to the first joint, draw the sinews, wipe the inside of the turkey, and truss it into shape.

To do this loosen the skin round the legs, draw the legs under it, press them well in so as to push up the breast, and skewer them into position or sew them with a trussing needle. Fold the loose skin from the neck over the back, and turn the wings and skewer them so that they keep this skin in position. Put some thin slices of lemon over the breast, then cover the latter with a greased paper. The bird has next to be tied in a piece of muslin.

Put the turkey in a large pan of boiling water or stock, add a few mixed herbs tied in muslin, an onion stuck with a few cloves, and a carrot and turnip. Take out the herbs after ½ hour's cooking, or they will discolour the stock. Simmer the turkey gently for about 2½ hours, keeping the stock well skimmed, then add 2 lb. of sausages and continue cooking for another 40 min. Serve the turkey on a large dish, place the sausages round, and pour the sauce over all. Some of the liquor in which the turkey was cooked may be served separately.

Casserole Of Turkey. Braising is a good way of cooking an old turkey. Pluck, singe, draw and cut the bird into neat joints, cover these with thin slices of fat bacon (remove the rind), place some more bacon at the bottom of a large casserole and lay the pieces of turkey on it. Add also the washed heart and liver. Peel and cut into dice 2 carrots, 2 turnips, and an onion, add them to the casserole with the green tops of 2 sticks of celery and 4 cloves, 12 peppercorns, and some parsley stalks, thyme and bayleaf tied together.

Pour in enough cereal or vegetable stock to cover half of the turkey, bring all to the boil, and then simmer gently for 4 or 5 hours. Serve in the casserole with the vegetables, but first skim the gravy, and if necessary add a few drops of browning. Season it to taste, and pour it over the turkey.

Deville Turkey Legs. The legs of a cooked turkey make a dish in themselves if devilled according to the following directions. With a sharp knife score the legs round and lengthways in deep, regular gashes, brush them over first with melted butter and then with a mixture consisting of 1 teaspoonful each French and English mustard, 2 teaspoonfuls chopped chutney, and a sprinkling of salt, pepper, and cayenne. Over this sprinkle a few browned crumbs, then grill the legs on a greased gridiron before a clear fire.

When browned all over, serve them on a hot dish, with a few small lumps of butter placed here and there. Garnish with watercress.

Turkey Blanquette. For this method of using up the remains of a cold turkey, first put the bones into a stewpan, cover them with cold water, and cook them slowly for an hour. Then strain the liquor, and with it make some white sauce, seasoning it to taste. To the sauce add some white pieces of turkey cut into neat squares, simmer all gently for about 20 min., and then draw the saucepan to the side of the fire.

Beat up the yolk of an egg with the juice of a lemon and a little of the hot sauce, and add it to the stew, stirring all the time. Return the pan to the fire, and continue stirring until its contents thicken, but take care that they do not boil or the egg will curdle. Just before serving, stir in a little finely chopped parsley. Triangles of fried bread, placed round the dish on which the stew is served, are a good garnish.

TURKEY CARPET. The style of knotted floor coverings that is universally recognized as Turkey carpets or rugs comprises woollen fabrics with deep red grounds, bearing conventional medallion designs with broad borders, usually carried out in strong blues and yellows. A regular industry, with headquarters at Istanbul and Smyrna, is engaged in meeting the demand for these productions from all parts of the world, and the designs and sizes have been more or less standardized.

The term fancy Turkey is used for similar commercial makes, especially in carpet sizes, in which the colourings and designs are more varied. The grounds of these are available in greens, rose, orange, light blue, ivory, mauves and pinks. There is a large output of Turkey patterns in British and continental makes, especially for stairs and corridors. By being able to tackle warps of considerable length, power-loomers readily turn out these goods in the piece, although such carpets lack the hand-knotting of the native weavers.

There is a large production of carpets and rugs in Turkish lands, especially in Anatolia and Kurdistan. They differ from the more characteristic of the Persian rugs by being invariably made with the so-called Ghiordes or Turkish knot, one effect of which is to turn the nap toward the right or left top corner instead of straight up the rug. They also usually have wool warps and wefts, often dyed to the prevailing colour of the design, with selvaged sides and knotted warp-ends.

Styles and Qualities. Various styles and qualities are distinguished by such names as Yapraks and Spartas. Some of them are very loosely woven; a Karaman, for example, may have not more than 10 knots to the square inch. There is also a modern output of fabrics made in the homes of the native population, in which the traditional features have a better chance of being perpetuated.

The Ghiordes rugs, formerly among the choicest of the Anatolians, and now often the poorest, frequently have a separate web sewn on the upper end, instead of being finished with plain warp threads. Kulah rugs, mostly of the prayer type, and often passed off as Ghiordes, are readily recognized by their many narrow border stripes, which may run to 14 in number. They usually have the field filled in with smallish objects instead of being left plain, and show one instead of two cross-panels outside the prayer niche. They are short-piled and almost lustreless, and generally contain in the border the distinctive Kulah design, which suggests derivation from the dragon associated with Central Asia.

A large class of small fabrics, generically known as Anatolian mats, either display the varied characteristics of this region or reproduce more or less closely the more distinctive geometrical features of the Caucasian types. *See Carpet; Persian Carpet; Rug.*

TURKEY RHUBARB. This drug-providing member of the rhubarb family is *Rheum palmatum*. It is an ornamental-leaved plant flourishing in deep, rich soil in sunny positions near the water-side. Propagation is by division of the roots during the winter months. The drug is used as a stomachic and purgative. *See Rhubarb.*

TURKISH BATH. A Turkish bath is carried out in a number of rooms of different temperature, ranging from about 90° F. in the coolest to 220° or even higher in the hottest room. The greatest precautions should be taken to avoid exposure on the way home from the bath, which may lead to the contraction of a chill or severe cold. As a Turkish bath may be depressing, it is as well to have medical opinion as to one's fitness for taking it.

The hot-air bath is an improvised Turkish bath, and usually takes the form either of a portable cabinet or an arrangement for an invalid for which the only apparatus required is a large spirit or candle lamp with a metal funnel which can carry the hot air into a framework cage.

The interior of a hot-air bath cabinet is lined with asbestos. The heat is supplied by a lamp as above or by electric lamps (the radiant heat bath). The patient sits on a chair in the bath. and care should

be taken that unprotected skin does not come into contact with parts which may be unduly hot. This bath may be used by healthy persons who wish to have the luxury of a Turkish bath at home, and it is desirable to follow it with cold sponging or a cold plunge. It is used with benefit, however, by persons affected with chronic rheumatism and rheumatoid arthritis, and in their case the application of cold must be graded to their capacity to bear it.

The hot-air bath in bed may be used in acute nephritis in place of the warm bath or the vapour bath. See Skin; Vapour Bath.

Turkish Bath. Fig. 1. Folding vapour bath cabinet. Fig. 2. Measurements of sides. Fig. 3. Plan, showing method of attaching frames. Fig. 4. Halved joint and position of rubber draught strip. Fig. 5. Portion of flexible top.

Fig. 1

Fig. 4

Fig. 5

Making a Bath Cabinet. A folding vapour-bath cabinet that can be made easily by the home craftsman is illustrated in Fig. 1, and consists of four sides hinged together and provided with a flexible top. Inside measurements can be varied to suit requirements; in the example given they provide a square floor space of 2 ft. 9 in. and a height of 3 ft. 6 in. The floor should be covered with a piece of stout cork linoleum measuring at least 3 ft. 6 in. square.

The sides, as shown in Fig. 2, are made of either $\frac{3}{16}$ in. or $\frac{1}{4}$ in. plywood secured to a framework of $1\frac{3}{4}$ in. by $\frac{3}{4}$ in. wood. Many of the manufactured baths are made with a framework of wood covered on one or both sides with a closely woven canvas or American cloth, but the plywood covered frame is more satisfactory, as there is little risk of its being damaged, which is the main disadvantage of the cloth-covered frame. The construction of the framework is quite simple; two of the sides are 2 ft. 10 in. wide, the others are 2 ft. 11 in. and 2 ft. 9 in. wide, and all four are 3 ft. 6 in. high.

The method of attaching the frames, as shown in the plan at Fig. 3, allows of the side A being turned back on the side B, the side at C is folded back on B, and the remaining side, D, which acts on the door, folds back on the side C. The wood for the framing should be machine-planed to the required width and thickness; if not, it must be hand-planed from 2 in. by 1 in. deal batten selected in straight lengths and free from knots and blemishes. For the uprights eight lengths of 3 ft. $6\frac{1}{2}$ in. should be sawn off and four lengths of 2 ft. $10\frac{1}{2}$ in., two of 2 ft. $11\frac{1}{2}$ in., and two of 2 ft. $9\frac{1}{2}$ in. should be cut off for the rails.

Place the uprights in pairs and set off $\frac{1}{4}$ in. from one end, then $1\frac{3}{4}$ in., and from this mark set out 3 ft. $2\frac{1}{2}$ in., taking care that all the pairs are accurately measured to the same distances. The four 2 ft. 10 in. lengths are marked out together, the first mark being $\frac{1}{4}$ in., the next $1\frac{3}{4}$ in., and the third 2 ft. $6\frac{1}{2}$ in. The 2 ft. 11 in. pieces are placed together and the first two marks are the same, but the third is 2 ft. $7\frac{1}{2}$ in., while the remaining pair are marked off with the same two distances at the end with a 2 ft. $5\frac{1}{2}$ in. distance for the third mark.

The frames are fixed together with halved joints, as shown in Fig. 4. A marking gauge is set to $\frac{3}{8}$ in., and lines are gauged from the face side of each piece across the ends and down each side to the inner mark. A pencil mark is made at the ends of the uprights on the opposite side to the face, and on the rails on the face side to indicate the waste. The ends are sawn down on the waste side of the gauge lines in each case, and then the waste cut off at the shoulders, care being taken not to saw beyond the lines. The plywood is cut to the required sizes, two are 3 ft. 6 in. by 2 ft. 10 in., one is 3 ft. 6 in. by 2 ft. 11 in., and the other 3 ft. 6 in. by 2 ft. 9 in. To allow for cleaning up the edges, these sizes may be exceeded by $\frac{1}{4}$ in.

The frames should be glued up and a screw driven in each joint, but they must be tested for squareness. The best method of doing this is to take a thin lath, place it diagonally between opposite corners, and mark. If on placing the lath on the opposite diagonal the marks coincide, the frame will be square; if not, the necessary adjustment must be made. The frames are now glued to the plywood and further secured by screws driven in at intervals with the screw holes countersunk. When the glue has set hard, the projecting ends of the framing are sawn off and the edges of the plywood planed down to the outer surface of the frame. The wood is cleaned up with glass paper and coated with size before varnishing.

The positions of the hinges are shown in Fig. 3. At E the hinges are screwed to the end of A and at the back of B; at F they are screwed to the inside of B and C, and the hinges at G are fitted as at E to the outside, in this case to C and D. Ordinary butt hinges or back flaps can be used, but the appearance of the work will be improved if the hinges are let in flush with the surface. In order to

make the joints comparatively vapour-tight, rubber draught strip should be tacked to the uprights as in the sectional detail at Fig. 4.

The same material is tacked along the edge of the door piece D on the outer upright of the side A, so that the door can butt against it. It will also be an advantage to edge the bottom rails with the rubber strip. To keep the door fast when closed, two hooks and eyes should be fastened on the inside.

The top can be made of any closely woven material, but rubber sheeting is the most suitable. It is made in two portions, as in Fig. 5, which, shows the dimensions for marking out, each piece being 3 ft. 3 in. by 1 ft. 10 in., with an opening of 11 in. diameter in the centre of one side. Commence by marking off a line 1 in. away on one side and both ends, and on the same side set off lines 2 in. inside and make cuts 3 in. long as at H. On the other side set off two 1½ in. lines and cut the opening with the centre on the inner line; the diameter can be lessened if required. The material to the first line is turned under and sewn; at the same time the material is folded at right angles at the inner 2 in. line and the corners sewn up with the hem. The edges surrounding the opening can be hemmed, but the neatest method is to bind it with a roll or use some of the draught edging.

To attach the top covering to the frame thread some elastic through the hem and fasten it at each end, the meeting or overlapping edges being provided with a buttonhole and button. The latter method should be used in joining the two halves, and the buttons arranged on the top overlapping piece so that it can be fastened from the inside. Another method of attaching the top cover to the sides is to make holes in the hem and fit small turn-buttons to the frame.

Special lamps burning oil or spirit can be purchased; those for use outside require a hole cut through one of the sides or the back. A small gas stove can be fitted or one of the small oil stoves of the Beatrice type. A bentwood chair with a perforated wood seat forms the most convenient seating accommodation. For steam or vapour, the water or vaporizing solution should be placed in a shallow pan on top of the stove.

When using the bath, the sides are arranged on a mat or square of linoleum and the top fastened to the sides and back. The lamp is lighted and regulated and placed in position. The user enters the cabinet, the door is closed, and the top fastened to the door and buttoned below the head, which is, of course, outside the covering. The outside heater has advantages, as it can be regulated by an attendant, but it is somewhat difficult to regulate an inside heating arrangement. The correct temperature can be found after one or two trials. After use, the sides are wiped with a dry cloth and the cover dried before being packed away.

TURKISH COFFEE. More care is required for the preparation of Turkish coffee than of ordinary coffee. The metal pots in which it is made are sold specially for the purpose, and have long handles and spouts. They are heated on the small stands with which they are sold. The coffee must be very fresh and very finely ground.

Enough Turkish coffee for two people can be prepared by putting 2 or 3 lumps of sugar and ½ pint water into the pot, boding them and then drawing the pot away from the flame while 2 large tablespoonfuls coffee are added. Reboil the whole, take the pot from the flame again for a second or two, and repeat the re-boiling 3 times. Serve the coffee without milk in small cups. *See Coffee.*

TURKISH DELIGHT. This is a favourite Eastern sweetmeat which is imported into Great Britain. The following is a good recipe. Take 2 lb. loaf sugar and make it into a syrup with 2 pt. water. This syrup should be cleared with the whites of 2 eggs. Add 2 tablespoonfuls lemon-juice and turn all into a sugar boiler; meanwhile dissolve in ½ pint water 4 oz. rice starch, and when the syrup in the pan boils stir in the dissolved starch and cook all gently, stirring the whole time until the mixture is firm and has been reduced to ⅓ of its original bulk. Pour half the mixture into another pan, colour it pink, and flavour with rose essence. The remaining half should be sufficiently flavoured with the

lemon, but if not add a little essence. Have ready a few blanched almonds and pistachio nuts cut in pieces. Add some of each to both portions of delight.

Turkish Delight. A favourite soft sweetmeat.

Set the mixture between candy bars on a slab dredged with confectioners' starch or icing sugar and cornflour. A tin similarly prepared may be used instead of the bars.

When set, divide into blocks, roll well in starch and sugar, and store in a wooden box with plenty of starch and sugar. Line the box with wax paper. Another method is as follows: Soak 1 oz. gelatine in $\frac{1}{2}$ gill water in a saucepan and stir over heat till it boils; let it simmer 3 or 4 min. Place in a large saucepan 1 lb. granulated sugar with another $\frac{1}{2}$ gill water, melt slowly, and bring to boiling point, then remove from the fire and cool slightly. Add the dissolved gelatine and boil for 20 min., stirring all the time. Add 1 tablespoonful rum, the juice of an orange and of a lemon, and a strip of thinly cut lemon rind. Stand this for 20 min. in a warm place, then colour half pink and flavour with rose essence. Add a few nuts to each portion, and cut separately. *See Sweets.*

TURK'S CAP LILY. Two lilies are known by this popular name. Of these *Lilium chalcedonicum* bears blossoms of scarlet with petals rolled back, while martagon has tiers of drooping, recurved purplish flowers. A beautiful variety of the latter bears waxy white flowers. *See Border; Lily.*

TURMERIC. The roots of the turmeric plant yield a condiment which is used in the preparation of mustard, curry powder, and pickles, and is also of commercial value for dyeing purposes. It must be grown under glass in Great Britain.

TURN BUCKLE. This name is given to a type of straining device, and also to a fastener for a cupboard door. Dealing first with the former appliance, the turn buckle, or bottle screw, comprises a body in which are screwed one or more portions adapted to receive the ends of wires, cords, or the like. The common type has two screwed ends, and will thus exert a tension upon two cords simultaneously, this usually being accomplished by providing the body with some form of rotation, threading one end with a right-handed thread and the other with a left-handed thread, the eye bolts or screwed portions being similarly threaded. When the body portion is turned with a spanner or a tommy bar the screwed portions are drawn together, so tensioning the guy rope or straining wire to which the turn buckle is attached.

Numerous varieties of this style of turn buckle are available, and should be chosen according to their utility, length of travel, and so forth. When used out of doors, for example, as a means of tightening the stay wires supporting an aerial mast, they should preferably be of galvanized iron or some other non-corrosive material. They should also have a fairly long travel, something in the nature of 6 in. being practical for the average wireless mast.

Cupboard Turn Buckle. The second type of turn buckle, for securing cupboard doors and other hinged structures, comprises a brass base plate in which a square, screwed shank turns, the outer end being provided with a handle and the inner end having a small lever adjustably attached to the spindle. The lever is fixed either with a small setscrew or by a screw thread and lock nut. In use the spindle passes through a clearance hole drilled through the framework of the door, the plate being screwed to the outside. The position of the lever is adjusted on the spindle so that when the door is

closed and the handle turned the lever stands at right angles or parallel with the floor, thus preventing the door from opening. Sometimes the fastener is provided with a more ornate plate and a drop handle, when it is usual to dispose the handle so that when it is in a vertical position the lever is horizontal. This prevents the weight of the lever rotating the handle and so allowing the door to open.

There is another kind of turn buckle which is used chiefly for securing shutters. It is in the form of a pivoted catch which operates by gravity, the weight of the handle being so disposed that it keeps the catch normally in a locked position.

Cupboard turns are liable to wear the edge of the door, especially if carelessly used. To avoid this and to repair worn doors, a neat angle plate should be fitted on the opposite door. It can be made in thin brass and let into the wood; the screws used should be placed in countersunk holes. In fitting all turn buttons care must be taken to clear the edge of the door frame and allow sufficient projection to hold the door. *See Cupboard; Door.*

Turn Buckle. Fig. 1. Turn buckle and hook for use as a straining device. Fig. 2. Type of cupboard turn buckle, showing method of fitting to a cupboard door.

TURN BUTTON. Used for fastening doors and flaps, the turn button is made in wood and metal. The simplest form is shown in Fig. 1, and consists of a small piece of hardwood shaped at both ends and bored with a hole for a screw.

Turn buttons in japanned iron and brass are of the shape shown in Fig. 2; those made in iron are obtainable in sizes from 1½ in. increasing by ¼ in. to 2½ in. The same pattern in brass increases in like proportion from ¾ in. to 2½ in. Half buttons, as in Fig. 3, in japanned iron can be obtained from 1¾ in. to 2 in., and in brass from ¾ in. to 1 in. A neater form of turn button is shown in Fig. 4, the button being riveted to a brass plate, and the corresponding metal plate being attached to the face of the door stile. This is used on thin wood or where extra neatness is desired, and it should be attached by means of flatheaded brass screws. One great advantage of this type is that the button cannot wear away the edge of the door, as often happens with the common pattern. *See Cupboard; Door.*

Fig. 1

TURNING. The mechanical processes which are grouped under the general heading of turning divide into two independent groups, those associated with the turning of wood, which are dealt with in this Encyclopedia under the heading of wood turning, and the whole series which apply substantially to the turning of any kind of metal and most of the manufactured compositions, such as ebonite, celluloid, and the like. These are treated under the title of metal turning (q.v.). The

mechanical requirements of the wood and metal turner respectively are somewhat different. For wood turning a lathe with a large flywheel is needed, and a small mandrel pulley, whereas in metal turning the proportions are reversed. Information on the choice of a lathe for either of the specific uses is given in the article on Lathe. Small wood-turning work—ornamental woodwork especially—can be carried out satisfactorily on a metal-turning lathe; but for larger work—e.g., a chair- or table-leg—the space between headstock and tailstock is not nearly sufficient.

TURNIP. A prolonged supply of this favourite root vegetable can be assured by sowing the seeds out of doors in March and early April for summer produce and in late June and early July for an autumn crop. Ordinary well cultivated soil free from fresh manure is suitable. For spring sowing the drills should be 12 in. apart; the seeds need only a slight covering of soil. To allow them full room

for development the seedlings ought, to be thinned out to 4 or 5 in. apart. Suitable varieties for spring sowing are Early Snowball, Early Milan, and Six Weeks.

The seedlings of autumn turnips should be thinned out to 6 or 8 in. apart; some of the best varieties are doors in August and September the leafy tops will provide a useful winter vegetable.

Turnip Culture. 1. Type to grow. 2. Gross type inclined to woodiness. 3. Outdoor drills for sowing. 4. Good thinning. 5. Outdoor forcing: a, leaves; b, friable sandy loam; c, top soil; d, shelter and drill. 6. Plant protected with top glass. 7. Bad thinning. 8. Good thinning. 9. Turnip attacked by gall weevil. 10. Gall weevil (magnified). 11. Turnip flea beetle (magnified)

The Turnip Flea.

The turnip flea or fly is the most troublesome pest of this vegetable. It attacks the seedlings and riddles the leaves. Frequent dustings of soot are recommended, together with an occasional application of nitrate of soda, 1 oz. per square yard of row, to encourage the seedlings to grow quickly and strongly.

Cooking Turnips. The turnip is served as a vegetable with boiled mutton, and it can be made into various dishes of dressed vegetables. It is also used for flavouring soups. Old turnips should never be served as a vegetable, as no amount of boiling will render them tender, but they can be used for flavouring. The turnip is not easily digested by delicate persons or invalids.

To prepare turnips for boiling, pare them thickly and always under the brown line which is apparent when the peel is cut into. As they are pared divide them into halves or quarters and throw them into cold water. Have ready a good-sized pan of boiling water, as they need plenty of room when being boiled. Young turnips take about $\frac{3}{4}$ hour to cook and those which are rather more matured $1\frac{1}{4}$

hours. When the turnips are cooked, drain them thoroughly and press them in the colander with a vegetable presser in order to extract all moisture, then rub them through a wire sieve or pass them through a mincer. Rinse out the pan in which they were boiled and melt in it $\frac{1}{2}$ oz. butter for each lb. of turnips (weight before cooking) and $\frac{1}{2}$ gill milk, season with salt and pepper, then return the turnips to the pan and heat all together over the fire. If preferred, the butter may be omitted, but margarine should not be substituted, as it is too oily.

Turnip. Fine round roots of the green top white turnip.

To stew turnips, pare and wash them and cut them first into slices and then into dice. Allow for each lb. of turnips 2 oz. butter and melt it in a stewpan. Add the pieces of turnip, put on the lid, and stew very gently from $\frac{3}{4}$ to 1 hour. Stir frequently, and when half cooked add seasoning. This method of cooking turnips is suitable for serving them in the centre of a dish of cutlets or for garnishing. They may also be served with a roast leg of lamb. A little chopped parsley sprinkled over them adds to their appearance. *See Kohl Rabi.*

TURNOVER. The turnover is made with short or flaky pastry, rolled about $\frac{1}{2}$ in. thick. The shape may vary, but the filling, which may be savoury or sweet, is always placed in the centre, one half of the shape being folded over until the extreme edges meet. *See Cornish Pasty; Jam Turnover; Pastry.*

TURN THE TRENCHER. This is always a popular game with small children, and is very pretty to watch. All that is needed is a bread trencher, or a small, round tray. The children sit in a circle, and each chooses some article of a lady's toilet, e.g. brush, comb, hairpin, sponge, etc. The person leading the game then tells a story, describing how some young and beautiful lady is getting ready for a ball. As each article of the toilet is mentioned, the child who represents it has to spring into the centre where the trencher is lying and give it a brisk spin.

Another way of playing the game is for each child to choose a flower. One then picks up the trencher and spins it, at the same time calling out one of the flowers, and the child called has to catch the trencher before it stops spinning, or pay a forfeit. It will be seen that the game lends itself to much variety as far as the names are concerned; they might be animals or birds, or even parts of a motor car. In the latter case it could be modelled on Family Coach. *See Children's Party; Forfeits.*

TURPENTINE. Oil of turpentine is a colourless fluid with a peculiar balsamic odour and pungent, bitter taste. Externally it may be used as turpentine liniment or the acetic liniment of turpentine. Sprinkled on a hot fomentation it makes a turpentine stupe, which is often applied to the abdomen to relieve colic and gaseous distension. It may prove of value in neuralgia, lumbago, and other forms of muscular rheumatism, and in the later treatment of a sprain.

The uses of turpentine in the home are many and varied. Its odour helps to keep away black beetles, ants, flies, and mice, and shelves and cupboards sprinkled with it are rarely troubled by insects. A little turpentine sprinkled in boxes or wardrobe where woollen clothes are stored will also keep out moths.

Paint stains on clothes can be removed with turpentine and household ammonia. Dip the stain first in turpentine and then in ammonia, rubbing it after each immersion. If the stain is not an obstinate one, turpentine alone is often sufficient. Grease marks on coloured fabrics will also yield to vigorous rubbing with turpentine. Place the stained part over a cloth, and rub it with a clean rag dipped in turpentine, until the spot is dry.

Turpentine has antiseptic properties, and its use in the home can therefore also be recommended on medical grounds. *See* Clothes; Grease; Paint; Patent Leather.

TURQUOISE. An opaque sky-blue or greenish-blue stone, the turquoise owes its popularity mainly to its colour. It is sometimes set in rings, but, being very easily scratched, it is better suited to pendants, brooches, and necklaces. While the turquoise cannot be classed with the more precious gems, large stones of good colour fetch a high price. They are subject to changes of colour.

TUSK TENON. The joint used in carpentry under the name of the tusk tenon is so called because the tenon itself is longer than usual and extends beyond the face of the material to which it is jointed. It is held by means of a wedge driven through a hole near the outer end of the tenon.

The disposition of the parts is shown in the accompanying illustration of a trimmer tenoned and wedged to a floor joist. This joint is largely used in building construction for all openings through floors and ceilings, the chief reason being that the wedge holds the tenoned member firm against the rafters or joists, and prevents the latter from springing or starting.

Tusk Tenon. The completed joint.

The length of the tenon which extends beyond the rafter should be at least equal to the thickness of the rafter through which it passes. It is shaped and fitted in the same way as a tenon joint, after which the exact position for the wedge is marked, the tenon withdrawn from the mortise, and a hole drilled through, using a brace and large diameter bit. The hole has to be enlarged with a paring chisel, and the outer face should be slightly tapered.

The inner face, that is, the side nearest to the shoulder, is cut back so that the wedge will bear firmly against the outer face of the rafter and the outer inclined face on the tenon. The wedge must not bear on the inner wall of the hole through the tenon. The wedge should be preferably of hardwood tapered to suit the hole, and should fit exactly. When the trimmers have been fixed in place, the wedges are inserted, the rafters preferably being cramped together while the wedges are driven home. *See* Floor; Tenon.

TUSSILAGO. This is the botanical name of coltsfoot (*Tussilago farfara*), a common British weed which bears yellow daisy-like flowers in early spring. For cultivation in gardens the best species is the winter heliotrope, *Tussilago (petasites) fragrans*, a hardy plant, 12 in. high, which has sweet-scented, pale purple flowers in winter. Propagation is by division in autumn.

TUSSORE. The silk that is known as tussore is obtained from the cocoons of uncultivated silkworms, such as feed upon oak leaves instead of mulberry leaves. This silk is coarser, darker in colour, but often stronger than the more expensive cultivated kind. It is made into cloths of several sorts both in Europe and Asia, and the goods are often sold in their natural cream to brown shade, which withstands any amount of washing and exposure. *See* Shantung; Silk.

TUTSAN. Sometimes known as sweet amber, the tutsan is a shrubby species of *Hypericum*, *H. androsaemum*, suitable for growing on banks or under the shade of trees. It bears yellow flowers similar to other members of the St. John's wort family. The tutsan is evergreen, and only requires trimming during April.

TUTTI-FRUTTI. Sometimes referred to as a mixed fruit ice, the sweet called tutti-frutti is prepared by cutting up some mixed fruit, dredging it with castor sugar, and soaking it with a little liqueur. When it has stood for a short time it is stirred into some half-frozen water ice, and then the freezing is continued. *See* Freezer; Ice.

TWEED: The Material. Hand-spun and woven tweeds are necessarily expensive to produce and command high prices. Harris tweeds made in the Hebrides carry with them a peculiar odour of peat-smoke, and of certain of the ingredients used by the dyer. Donegal tweeds, in which there are usually lumpy, bright-coloured irregularities, are much liked for sports wear.

Scotch tweeds, machine-made in Scotland, are amongst the best wearing, and are procurable in heather mixtures, checks and flecked designs, and in heavy, medium or gossamer weights. Hand-made tweeds do not usually wear as well as the best machine-made. The cheapest mill-made tweeds are often of very poor quality, containing much shoddy and cotton. *See* Harris Tweed; Loom; Weaving.

TWEEZERS. Miniature pincers known as tweezers are sold by chemists and beauty specialists for removing superfluous hair from the face, especially from the eyebrows. It is not claimed for tweezers that they destroy the roots of the hair, but their frequent use has a weakening effect. Tweezers are intended as a remedy only for slight growths of hair. *See* Electrolysis.

TWELFTH NIGHT CAKE. If a children's party is held on the 12th day after Christmas, Jan. 6th, a Twelfth Night cake is sometimes specially made for the occasion. The cake is after the style of a Christmas cake, and ornamented with icing and coloured candies or candied fruits. Sometimes 12 small candles are distributed round the iced top, as is done with birthday cakes, and there may be a large gilt star in the centre.

TWILIGHT SLEEP. When childbirth is conducted under the influence of scopolamine and morphine the drowsiness induced by these drugs may be made sufficient to send the patient to sleep in the intervals of the labour pains. Such a condition is popularly referred to as twilight sleep.

Pain is not abolished by such treatment, and, indeed, it would be dangerous to attempt this. The memory of pain may be abolished, however, so that although the patient, on the occurrence of labour pains, may have given obvious indications of suffering, yet at the conclusion of labour she may know nothing of this.

The method is not required for short labours, as in these a few whiffs of chloroform may sufficiently ease the pangs, but in prolonged labours twilight sleep may be a decided advantage. It should, of course, be supervised by a doctor. *See* Childbirth.

TWILL: The Material. For materials of all kinds the method of weaving known as twill is employed, the threads being so arranged as to throw up diagonal ribs upon the surface of the cloth. Cloths are made to feel thicker by being twilled than if plain-woven. It is apparent that the twill lines commonly seen upon cloths vary in width, some being much coarser than others. Also they

vary in the steepness of the diagonal, and the higher angles are most met in the finer and more closely woven fabrics.

In addition to plain twills, there are the fancy sorts, twilled alternately in opposite direction to form herringbones or chevrons, and these cloths are generally satisfactory, as this method binds the threads firmly together. Twill cloths are not always alike front and back, and some of the most solid twills used for coats and costumes have a plain back.

In twilled sheets made in the best manner, the strongest threads are brought up to the surface and take most of the wear. Cheap sheets are often twilled and made partly from good cotton and partly from cotton waste. They feel thick and soft, but the twilled ribs are lumpy and irregular, whereas in the better qualities the twill lines are sharp and smooth.

Most linings are twills, and so are all serges and many tweeds. Gabardine is a kind of twill, and so is Venetian. Some of the hardest wearing cloths for riding breeches are twilled. The best velveteens are woven with twilled backs to hold the pile more firmly. Twilled mattings do well for kitchen and cottage floors.

TWINE. This is the name given to a strong thread made up of two or three strands, twisted, or twined, tightly together. Usually stronger and of better quality than string, its uses are practically identical. *See* String.

TWO STEP. This was a simple ballroom dance at one time danced as part of the fox trot. The steps were similar to those in the galop, but danced more slowly, being written to six-eight time, although they could be danced to four-four time.

The man's steps were as follows: Glide the left foot to the second position, bring the right up behind the left, glide the left again to the side. Repeat the movement, beginning with the right foot. The girl's step was the same, but she began with the right foot. *See* Dancing; Galop; Roger de Coverley.

TWO STROKE ENGINE. This is a type of internal combustion engine in which the cycle of operations comprises one power stroke at every downward stroke of the piston. It is contrasted with the four stroke engine, in which the power stroke occurs at alternate downward strokes of the piston. *See* Four-Stroke; Internal Combustion Engine; Motor Cycle.

TYDAEA. This is a group of hothouse decorative plants with flowers of various showy colours. They flourish in the usual potting mixture of loam, leaf-mould, and sand, in shady positions.

Propagation is by seeds sown in a mixture of sand and leaf-mould in the springtime, by cuttings of the young shoots at the same period, or by separating the rhizomatous roots. Rhizomes should be planted in 5 in. pots, several in a pot, in spring to flower in summer.

TYING: Of Plants. The staking of trees and plants is of great importance, and, as a rule, due attention is paid to the selection and placing of supports, but the work is often rendered ineffective or even entirely useless by the neglect of proper tying. The material used for tying trees must be strong enough to stand sudden strains; it must also be sufficiently sound to hold securely for a considerable time without rotting.

A knot is required that will hold firm under practically any strain, and can be united easily. The knot that best answers these requirements is the ordinary reef or sailor's knot. Green raffia is an excellent material for tying plants to their supports.

TYPEWRITERS : THEIR USE AND CARE

How to Ensure the Working Efficiency of These Machines

Followed by an entry on typewriting, this article deals with the management and care of the typewriter. Articles on subjects for which the typewriter is useful include Letter; Postage.

Typewriters may fall into one of two classes. The type may be arranged round the circumference of a wheel or a segment, as, for example, in the Hammond, the action of the keys rotating this wheel until the particular letter struck on the keyboard is brought opposite the printing point; or, alternatively, the type is carried at the end of levers or type-bars which strike the paper when the keys are depressed. Typewriters of the second class are much more numerous than those of the first, examples being the Empire, Remington, Oliver, etc.

Typewriter. Remington 16, an up-to-date and popular model. A noiseless machine of similar calibre is also obtainable. Improvements include a light shift key for capitals, avoiding finger fatigue; a paper feed which needs no straightening; automatic ribbon colour change —when indicator shows white, ribbon is cut out for stencil work—type faces protected by small heel to lessen battering. (Courtesy, Remington Typewriter Co., Ltd.)

Various devices are employed for inking the type. This may be accomplished by means of an ink-pad before the depression of the keys causes the levers to move and the type to strike the paper, but more commonly an inked ribbon is inserted between the paper and the type. This ribbon is wound from one spool to a second by the action of the machine, and so it is not worn threadbare at any particular point. A further variation is a ribbon in two colours, typing in red or black being performed by bringing the necessary part of the ribbon opposite the type-face.

A third classification may be found in the arrangement of the keyboard. Occasionally there is one key for each character. Thus the capital ABC and the small a b c would each have a separate key, the capital and the small letters being arranged in two banks.

Often each key strikes a capital letter, a small letter, a figure, or a punctuation mark, the particular impression depending on the use of a subsidiary key brought into use simultaneously with the letter key. These subsidiary or shift keys move the carriage forward, or backward, or into midposition as required for the character to be used. Obviously this type of machine is preferable, since the construction is simpler and therefore less costly. All machines are fitted with the universal keyboard, so that it is an easy matter for anyone who has learnt on one machine to work equally well on one produced by a different firm.

The Essential Operations. Although there are many kinds of typewriters, with numberless differences in detail, the mechanical parts of each bear a close relation to one another. The essential operations may be reduced to two. When the key is struck a letter must be printed, and the paper must be carried a short distance to the left before a second letter is impressed, so that the letters are printed separately, and not one on top of the other. The mechanism of the first of these operations has been described, and for the second it is better to watch a machine actually at work.

It will suffice here to say that the action depends upon the mainspring and the dogs and rack. The mainspring is trying all the time to pull the carriage right across to the left, and would do so but for the dogs and the rack. Each time a letter is struck the mainspring is allowed to pull the carriage along to the width of one letter, after which the next tooth in the rack stops further progress until another letter is struck.

Typewriter. Remington portable model, showing names of principal parts
By courtesy of the Remington Typewriter Co., Ltd.

Other Points to Note. Apart from these two main actions, a typewriter may be fitted with many subsidiary appliances. A bell may give warning of the end of a line, a lock may prevent the machine working after the end of the line is reached, there may be attachments for corrections and tabulation, for facilitating the insertion of fresh paper, and the like. But it must be confessed that many of these innovations, although useful, are introduced by the manufacturers to add points to their advertisements, and the first thing an expert typist often does is to disconnect and remove most of these additional luxuries.

Most typewriters have been modified to perform visible writing, which is, indeed, put forward by the manufacturers as a recommendation of great importance. Possibly a beginner may like to see that the letter printed corresponds to the key struck, or intended to be struck, but a practised typist no more needs to look at the keyboard than a pianist needs to look at the keyboard of his piano. A mistake is usually felt automatically, without any reference to the typing.

Accuracy of alinement is essential. To ensure this has called for great ingenuity on the part of the designers, confronted with the problem of making a system of levers at once strong, rigid, and light, and of supporting them on bearings which are steady and adjustable for wear in conditions where space is much restricted.

A tabulator is a very useful device when complicated tabular work has to be carried out. The carriage can be moved instantaneously from any point in one column to any point in another column, while the columns themselves can be arranged along the width of the paper.

Portable Machines. Portable typewriters are made of the toughest materials and designed to resist rust, survive neglect, and withstand all the bumping incidental to travel. The three principal makes of these portable typewriters are the Remington, which is here illustrated, the Corona, and the Underwood. Each of these, without the case, weighs 6½ lb.; with case the Corona weighs 9 lb. and the Underwood 8¾ lb. One general rule should be followed by the operator—his or her attention should be confined to oiling the machine and keeping it free from dust. The less tinkering there is with a screwdriver or spanner the longer the machine will give efficient service. Permanent loss of alinement and similar troubles are few if a typewriter is properly oiled and dusted.

Cleaning the Machine. Cleaning is a very simple operation. Once a day the machine should be dusted over with a soft rag, the bright parts being rubbed over occasionally with a piece of chamois leather. Any accumulation of dust from erasures or the surface of the paper used in the interior of the machine can be removed by using a long-handled brush sold for this purpose. Oiling is almost as simple an operation. Use only a fine quality of typewriter oil, non-gummy, and oil judiciously. Too much oil is as bad as too little. Ordinary oil clogs the mechanism.

A small camel-hair brush is a convenient method of oiling every joint and moving part of contact where friction can be caused. The mechanism should be thoroughly oiled and cleaned regularly—say, once a week.

The post of the spring drum and the dogs of the escapement should be oiled twice a week, any superfluous oil being afterwards wiped off, and occasionally, about every six months, the type-bar bearings should receive a drop of oil. A darning needle dipped into the oil bottle will collect sufficient oil in the eye for each individual bearing.

Other parts should only be oiled when a squeak is heard, and in these cases the squeaks must be traced to their source, and there treated. The machine should not be given a wholesale oiling to remove a single squeak. Sliding contacts should always be wiped clean before oiling to remove dirt and gum, and after oiling all surplus outside the spot of friction should be wiped off. If this is not done the oil, instead of acting as a lubricant, will attract a large amount of dust and check the smooth working of the mechanism. If infrequent use or neglect has caused any parts to become stuck with gum, either kerosine or benzine may be used for cleaning, afterwards oiling in the usual manner.

The type, which must never be allowed to become filled with dirt from the ribbon, is best cleaned by a type brush and a drop of benzine. The letters should be taken in their regular order, depressing a key with a finger of the right hand, so as to push the type-bar forward, when it is held by the thumb and forefinger of the left hand, and cleaned with the bristles of the brush with a downward and not a circular movement. The type-bar is held in this manner to avoid straining the bearings, and should be released gently. If the round characters have become very much clogged with ink or dirt, the point of a pin may be used with advantage, although the necessity for this should be avoided by frequent cleaning when possible.

Rust on the bright parts is usually caused by settling dust, which holds moisture from the air. If the machine is dusted regularly, rust will not usually make its appearance. A piece of chamois leather should be kept for rubbing the plated parts, and, of course, when not in use the machine should always be protected by its cover.

Just as a piano needs attention every few months, so a typewriter should be given a thorough overhauling by the makers or other responsible firm every few years. As originally sent out from the factory, all machines are accurately alined, and unless the instrument is abused, it should not be necessary to return it for overhauling for at least five years. Mechanical intricacies, such as the readjustment of alinement, should never be attempted by the typist.

Ribbons and Stationery. Good typewriting can hardly be expected unless the ribbons and stationery employed are of the best quality. A good ribbon should neither be thin and short-lived on the one hand, nor thick and muddy on the other. Even when new a good ribbon, assuming correct touch, will give delicate work, and it should last from 300 to 600 hours, say, on an average, 500 hours. If a ribbon supplied by a good firm gives less than 300-400 hours' work, it may be taken for granted that the operator's touch is too heavy, and an attempt should be made to lighten it. Even when a ribbon grows faint, its useful period is by no means over, since there will be still a large amount of ink on the side of the ribbon away from the paper. If the ribbon is turned, its life can, therefore, be prolonged by 30-40 per cent.

Ribbons are in different sizes and of different colours, and it is important to see that the machine is fitted with a ribbon of the right size. A ribbon which is too wide has to be cut down, a dirty and cumbersome process, while on a ribbon which is too narrow one set of type may not strike at all. Both the ordinary noncopying ribbon and the copying ribbon for use with the letter-book can be obtained in all ordinary colours. In addition to these there is the hectograph ribbon for use with the jelly copying process; the lithograph ribbon, for making lithographic transfers for use by the printer in striking off a number of copies; and the indelible ribbon, the results of which cannot be erased from the letter-book once the writing has been passed through.

A cheap typewriting paper easily rubs into holes, and shows patches wherever any erasures have been made. The best of workers make occasional mistakes, and unless good paper has been used the corrections will show. Cheap paper may, of course, be used during practice, but never on actual work.

Envelopes of ordinary shape and make, unless they are of thin paper, usually give a double impression where the paper is double, that part of the envelope upon which the gummed flap is secured. To avoid this, special typewriter envelopes, in which the whole paper surface is even and level, should be employed.

TYPEWRITING. The most obvious necessity for a person wishing to become an expert typist is practice, but no amount of practice will teach the finer shades of the work, nor will practice alone produce the high speed which may be attained by means of the best methods. The touch method increases speed enormously, because the typist does not look at the keys at all, but can keep the eyes on the copy the whole time.

In typing it is important to use all the fingers, much as in playing the piano. The position at the machine should also be much the same as that of a pianist, with the elbows on a line with the wrists. The right thumb should be used for the space bar. The touch should be even and steady, and not too heavy. A heavy touch will strike the keys too sharply and cause them to cut the paper.

It is very largely by the setting out of the work that an expert typist may be known from an inexperienced one. Such matters as margins, spacing, and good paragraphing make all the difference to its appearance.

Margins and Spacing. The width of the margin depends very much upon the kind of work in hand. For literary work, official reports, or legal work the margin should be wide, varying from 1½ to 2

in. Letters usually look well with a good margin, but this will vary with the taste of the person writing.

It may be laid down as a fairly safe rule that it is better to err on the side of wide spacing. Single spacing may do for long business letters, for extensive quotation in the body of another work, and for one or two similar matters; but for ordinary clearness, as required in literary work and the like, double or even treble spacing is the best.

All paragraphs should be marked or indented by taking the line several spaces inward, five being the usual distance. In official work it is well to double the space between the last line of the preceding paragraph and the new one, in other words, to miss a line. This makes for clearness and heightens the effect of the paragraph. In addition, the typist should remember to leave one space after a comma, two after a colon or semi-colon, and three or more after a full point. Long quotations, as already mentioned, may be done with single spacing. They should also be indented to add to the effect.

In numbering pages, the number may be put in the centre of the top, enclosing it either in brackets or by a dash on each side; or it may be put at the bottom of the page.

A two-colour ribbon can add greatly to the finish of the completed work. The title may be underlined in red, or typed in red and underlined with the black or purple of the other half of the ribbon. Numbers look well done in red, and a red capital letter to start the matter is also effective. On the other hand, the two-colour ribbon is by no means essential for ordinary work, though it may be wanted for special work, such as plays.

Duplicating. If many copies of the same manuscript are required, they may be produced either by means of carbon paper or by cutting a stencil and using one of the many duplicators on the market. The former method is simple; the number of copies done at a time depends on the sharpness of the type, the thickness of the paper, and the kind of machine. It should be possible to do at least half a dozen good copies if thin paper is used. A layer of carbon paper is placed between each sheet of typing paper, and the whole is then inserted into the machine so that the face of the carbon is away from the typist. Care should be taken to insert them evenly, in order that the lower sheets should be straight.

For stencil cutting a special waxed sheet has to be procured. The ribbon is then removed and the copy typed with the bare type. This cuts the letters into the wax sheet, which can then be used as a stencil and rolled off on the duplicating machine to any quantity required.

TYPHOID FEVER. Typhoid fever, which is also known under the name of enteric, is an infectious disease that occurs mostly in the last quarter of the year. Infection may be conveyed in drinking water, milk, ice, salad, celery and other uncooked vegetables, also through oysters taken from beds that have become polluted by sewage.

The symptoms develop from two to three weeks after exposure to infection, and during that time there may be no suspicion that anything is wrong. There may be, however, constant headaches and abdominal pains, with a steadily rising temperature until the patient becomes too ill to get about.

About the seventh day the rash appears in the form of rose-coloured spots on the chest or abdomen. In the second week the abdomen may be swollen and the patient lies in a semi-unconscious condition. During the third week the loss of flesh and strength is less marked in a favourable case. Convalescence should begin with the fourth week. One attack usually protects from future attacks.

Many complications may develop in typhoid. Two of the most dangerous are haemorrhage and perforation of the bowel, which are not uncommon and occur oftenest after the second week. A warning sign of bleeding is a sudden increase of weakness or collapse, followed by a drop of several degrees in temperature.

During an epidemic or when typhoid occurs amongst people who are all using the same milk or water supply, it is only common prudence to submit to inoculation with anti-typhoid vaccine.

All drinking water and milk must be boiled, and every precaution taken to protect food from flies, which are notorious carriers of infection. Cups and dishes used by the patient should be kept in the sickroom and never used by other people.

The patient's bed linen, towels, etc., should be soaked for 24 hours in a pail containing a 1 in 20 solution of carbolic acid or other disinfectant and then they should be laundered separately. The excreta of the patient should be emptied into a closed vessel half full of carbolic acid, 1 in 20, and allowed to stand for two hours before being emptied.

The nurse should scrub her hands with soap and a nail brush and soak them in a solution of one part of perchloride of mercury to 2,000 parts of water before going to her meals.

Efficient nursing is all-important, by night as well as by day. Milk should be the main food until well on into convalescence, but the patient may have as much water or fresh weak lemonade as he likes. During convalescence strict attention must be paid to diet.

After convalescence a person may continue to carry typhoid bacilli in his system. Such a carrier of the disease is a danger to the public, especially if he handles milk or other food. It is his obvious duty to refrain from handling the food or food utensils of others. *See* Convalescence; Fever; Infectious Disease.

TYPHUS FEVER. Typhus fever describes an acute, very contagious fever, usually coming on suddenly, causing great prostration and severe nervous symptoms, marked by reddish rash and terminating by rapid fall of the temperature (crisis). Formerly common among poorer people, it is now extremely rare. The infection of typhus fever is carried by lice.

Whenever possible, a person suffering from the disease should be taken to an isolation hospital. General treatment is set down under the headings Fever and Infectious Disease.

UKULELE. This musical instrument is really a small guitar. It has four strings, and is played by plucking them. It was introduced into Britain and the United States after the Great War from the Hawaiian Islands, and was used with dance and jazz music. *See* Guitar.

ULCER. A sore that involves the true skin or sometimes the mucous membrane is described as an ulcer. It is kept open and extends by the death of minute particles of tissue which are liquefied and removed in a discharge. Many different types of ulcer are described, but each consists of an area more or less depressed below the general surface of the skin or mucous membrane, which is known as its floor, and around this a margin, or edge. From the surface of the ulcer there exudes a discharge which may be purulent or watery and profuse or scanty; sometimes it is mixed with blood.

As regards causation, ulcers fall into three main groups, namely, those due to mechanical, chemical or septic irritation, those due to specific micro-organisms, such as the tubercle bacillus and the spirochete of syphilis, and those due to malignant new growths.

A trophic, or perforating, ulcer is one that occurs in locomotor ataxia, diabetes, or some other condition in which there is disease of nerves. An ulcer of this kind is quite painless.

The treatment of an ulcer depends on its cause. In the treatment of ulcers belonging to the first group the main considerations are rest and cleanliness and, where necessary, the removal of any constitutional factor in so far as this is at all possible. Commonly, an ulcer can be cleaned up by applying boracic fomentations. Each time the fomentation is taken off the ulcer should be washed with an antiseptic lotion. An alternative treatment is to apply lint smeared with boracic ointment.

To obtain healing of varicose ulcers it is necessary to support the limb by applying a pure rubber bandage, a woven elastic bandage or a crêpe bandage. The pure rubber bandage is liable to cause irritation by imprisoning the sweat. A useful application for varicose ulcers is found in Unna's paste. When the ulcer has healed it may be desirable to operate for the cure of the varicose veins. *See* Antiseptic; Gastric Ulcer; Varicose Vein.

UMBRELLAS AND THEIR REPAIR

Smartness and Utility Combined in This Protective Device

This article, after some information on umbrellas in general, describes in detail, with the aid of illustrations, the methods of repairing a damaged one. *See* Hall Stand; Walking Stick.

While the choice of an umbrella may depend to some extent on the prevailing fashion, there are two factors, the ribs and the cover, which should always receive careful attention.

The size is determined by the length of the rib, which varies between 24 to 26 in. for men, 27 to 36 in. for golf or carriage umbrellas, the usual length of rib for a woman's, short-sticked or "chubby" umbrella being 18 to 20 in., and for one with a full-length stick 21 to 23 in. The ribs may be fluted or solid, the latter being cheaper, and of course heavier, but not always so strong. Generally it may be said that an umbrella with solid ribs is a cheap class of article. Paragon or fluted ribs are made from a strip of steel bent to a U-section, the curve of the U being arranged to come next the cover in a finished umbrella.

Five types of material are used for covering umbrellas: alpacas or dagmars, levantines, glorias, artificial silks and mixtures, and pure silks. In addition to their bulk, alpacas, and more especially the cheaper varieties, have a coarse texture. A good gloria wears well, but many so-called glorias, which ought to be a mixture of silk and wool, contain a large percentage of cotton. Artificial silks and mixtures have a glossy appearance, but are comparatively harsh in texture. Silk always looks better than anything else, but a mixture of silk with cotton or wool should be chosen for durability, since silk covers have generally a tendency to split.

An umbrella ought not to be kept rolled up when not in use, otherwise splits and rents are sure to result. After being out in the rain it should be allowed to stand or hang, handle downwards, until dry. If the moisture is not allowed to drain away from the ribs in this manner, rust and broken joints will ultimately be the consequence.

To roll an umbrella neatly, shake out the cover, gather the ends of the ribs in the left hand; pull each fold into place, and, grasping near the bottom with the right hand, commence to roll. After fastening the elastic, roll again, and pull each fold taut if any looseness collects. If the elastic is worn, replace it with 6 in. of narrow black hat elastic.

Silver and metal collars and bands are fixed to the stick by means of a mixture of weak glue and plaster of paris. A special cap-filling cement, obtainable from the wholesale manufacturer, is used for fastening on knobs and caps. A little of the cement is melted and poured into the cap, the stick being inserted immediately, as the cement sets very rapidly. Only a little cement should be used, or the stick will not go home.

Umbrella Repairs. The two repairing operations most usually necessary are mending or changing the cover and replacing a broken rib. Neither of these operations should offer any real difficulty.

When repairing a broken rib care should be taken to see that the new rib is of the same type as the others, and that it and its stretcher are exactly the right size, otherwise it will be left projecting or will close before the rest, as the case may be. If it is only the stretcher that is broken, a stretcher

taken from a broken rib can be used to repair it. Take off the outside cap, by punching out the rivets and withdrawing it, as shown in Fig. 3, then unwire the runner and turn the umbrella inside out. Before doing this it is better to unstitch a couple of the corners from the ribs; this will guard against splitting the cover or breaking another rib. To turn the umbrella inside out, stand with it partly open, the stick passing between the left arm and the body, the inside of the cover resting against the left side, but outside the left arm, and pull with the right hand.

Umbrella. Fig. 1. Drilling a fine hole for a new rivet in the handle. Fig. 2. Filing down the rivet head, the handle being protected by a piece of cardboard. Fig. 3. Removing the tapered cap covering the ring that supports the ribs. Fig. 4. Withdrawing the tying wire. Fig. 5. Fixing the tying wire to the notch.

A rivet will be seen in the joint between the stretcher and the rib. The head of this should be filed off, and the rivet punched out, a rivet for the new stretcher being made from a bit of spring wire.

The new stretcher must be exactly the same length as the old one, and it should be fitted so that its hollow side is towards the handle when the umbrella is open. The tamper cap should be replaced and carefully riveted to the stick. The same process of turning the umbrella inside out and measuring carefully must be adopted in the case of a broken rib, but here it will, in addition, be necessary to unpick the stitches on the broken rib and remove it entirely. If it is only the eye of the rib which is broken, it is only necessary to replace the top tip. The new tip is measured along the rib, the broken end cut off at the right spot, and the tip knocked on, taking care not to close the eye. If a small slit occurs in the cover, an effective method of repair is to obtain a small piece of black silk, or other material similar to the covering itself, and, after opening the umbrella, carefully stitch

the patch on the inside of the cover, commencing on one side of the slit first. The slit is drawn together with a few tacking threads, and the patch neatly sewn all round. The tackings are then removed and the stitches caught together, and to the patch, with a few threads. Any damage to the fastenings of the cover at the outer ends of the ribs can be remedied with ordinary black cotton. A few turns are sewn into the cover at the point or apex, the needle is passed through the small hole or eye on the end of the rib, the cover drawn tight, and a few stitches are then passed through the eye on the cover.

When the handle breaks, its mode of repair will be determined by the material of the handle and of the stick. Many umbrellas are made with composition handles and wooden sticks, and the handle sometimes becomes loose. To refix it the end of the stick is smeared with liquid glue, a few strands of cotton twisted round it, and the handle pushed on. The same procedure will serve if the wood or composition cap on the In many forms of construction the ribs lower end of a short umbrella works loose, fit into little slots cut across the grooved. To make a secure job of a handle it may be riveted on after the glue has set hard.

The handle may be grasped in the vice, as in Fig. 1, the other end of the umbrella being supported on a block. A very fine hole, about 1/16 in. diameter, is drilled through the handle and the stick; the two ends of the hole are slightly countersunk, and a small piece of brass wire, which should fit nicely in the hole, is pushed through it. The two ends can then be cut off about 1/16 in. from the handle on each side and riveted; any surplus that may project being filed away, as in Fig. 2. To avoid scratching the handle, a piece of card or tin should be wrapped around it immediately above the rivet, as shown. This prevents the file coming in contact with the handle.

Re-covering. In the re-covering of an umbrella several processes are involved, and the amateur may find it difficult to make an efficient job the first time, but care and a little patience will ensure a tolerably good result, as can be judged from the accompanying illustrations. The first step, as illustrated in Fig. 3, is the removal of the tapered cap covering the outside of the notch ring which supports the ribs. The stitches on half of the tips of the ribs are cut away with a sharp knife, thus releasing the cover in readiness for the next operation, which consists in removing the wire which holds the ribs to the runner, the tubular member which slips up and down the stick, shown in Fig. 4. In many forms of construction the ribs fit into little slots cut across the grooved ring formed on the end of the runner. The ends of the ribs have small holes through them, and if these ribs be inserted through the slots the holes will register with the groove on the runner. A wire is threaded through the holes, and the ribs are drawn into the groove on the runner, thus forming a kind of hinge pin for each of the ribs. The operation pictured in Fig. 4 is that of cutting this wire so as to release the stretcher or stay, this being the strut-like portion on the rib which connects with the runner at one end and about the middle of the length of the rib at the other. The umbrella is opened and turned inside out, using the method earlier described, and the stick and ribs are brought into line. This provides access to the top eyes, that is, the little joints in the notch near the end of the stick.

The cover is then entirely stripped from the ribs, and if the latter are rusted they may be cleaned by rubbing them with emery paper and then reblacked. They should be set aside to dry thoroughly hard, and are then refixed to the top notch. This operation is illustrated in Fig. 5, and is accomplished by first arranging all the ribs so that the stays all point in one direction, and a piece of tying wire, which may be of tinned iron, is bent through the top eyes. The wire is twisted around and the ribs pushed on it until the wire is in more or less a U-shape.

The first few ribs are inserted in the notch, taking care to note that an additional small notch is generally cut at one point, and is intended for the reception of the twisted end of the tying wire. Consequently the first pair of ribs should be inserted into the slots opposite to this notch. The others

are pressed into place, as shown in Fig. 5, and finally the wire is drawn tight and twisted back with a pair of pliers, the surplus being then cut off and the ends of the wire pressed into the little notch.

The ribs have now to be opened to ascertain that all the stays point towards the handle, and to ensure that none of them have been inadvertently fixed the wrong way round. If so, the process is repeated and the fault remedied, after which the runner is replaced. The muffles, that is, the little pieces of black material which are stitched to the ribs to prevent friction of the ribs wearing away the cover, are examined to see that they are in good condition; if not, they should be replaced by new ones. They may be any black material, but are preferably the special waterproof oval muffles which only require sewing in place. The method of fixing is by stitching them around the ribs.

The next step is to fit the cover, the size depending, of course, on the length of the ribs. The cover can be obtained ready made, or, if preferred, can be made up at home. Assuming the cover is bought ready for use, the stick is inserted through the hole in the centre of the cover, this being accomplished while grasping the whole of the ribs in the left hand and supporting the cover with the right. To prevent the cover from splitting, it is stitched with waxed thread around the hole where the stick comes through. The cover should be stitched in two or three places to each of the ribs in turn. It is then worked into place at the corners and seamed parts and drawn to the top of the ribs by passing a thread through the cover and fastening it, passing the needle through the top eye, thus drawing the cover upward and firmly sewing it. The cover is sewn to each rib in the same way taking care to draw it well into place before fastening the top corners.

A small rosette is sewn on the outside of the cover to protect it from the chafe of the taper cap on the outside, which is then fixed in position and secured with a couple of small pins. A rosette should also be stitched round the runner near to the ribs to prevent it chafing the fingers while opening the umbrella. The umbrella can then be tested, and if properly covered should open uniformly and conveniently. A new tassel or loop may be added if desired.

The foregoing is a general method of re-covering an umbrella, and will enable most patterns to be dealt with. Sunshades may be treated in the same way. Some particular makes of umbrella are rather differently arranged, and may call for modification in the treatment.

The short umbrella used by women has a cap to match the handle, in wood, glass or some composition, and the stick fits into a socket formed in the cap. The cap is usually cemented on, and must be carefully loosened and eased off the stick before turning the umbrella inside out to get at the top eye. The end of the umbrella may be held in a jet of hot steam to loosen the cap, or a little of some spirit solvent might be carefully poured into the joint to dissolve the cement. Since some of the compositions used for handles and caps may be of an inflammable nature, it is necessary to use great care in applying heat to them. In refixing these fittings the ends of the stick should be roughened to afford a grip for the cement. Should the stick fit too loosely into the socket, a few threads of cotton may be twisted round the former after coating it with cement.

UMBRELLA FERN. This is a popular name of the greenhouse fern, *gleichenia*. Of slender climbing growth, it is very ornamental when trained to cover a wire trellis or sticks. The plants should be potted in a compost of loam, peat and leaf-mould, with sand added freely, and they should be provided with ample drainage of clean crocks. A temperature of 50 degrees is high enough in winter, and care must be taken not to over-water them at that season. Plants may be propagated by spores, or by selected portions of creeping stems to which roots are attached.

UMBRELLA PLANT. This is the common name of an ornamental greenhouse plant, *Cyperus alternifolius*. It is easily grown in a temperature of 55 to 60 degrees if potted in sandy loam and leaf-mould; the soil must be kept thoroughly moist. Propagation of the umbrella plant is effected by division or by taking off the tops of the stems and inserting them as cuttings.

UNCONSCIOUSNESS. It is very important when a person is found in a state of unconsciousness to ascertain the exact cause of his condition. Mistakes are frequently made, with serious consequences to the patient. These errors occur most commonly when the unconscious person smells of alcohol. This suggests drunkenness; but the cause may be apoplexy, a fractured skull, or some one of a dozen other abnormal conditions.

The following are the principal causes of unconsciousness: Fainting from temporary weakness of the heart; apoplexy, due usually to bleeding into the brain; epilepsy following the fits; concussion of the brain caused by a fall, etc.; compression of the brain, the result of a depressed fracture of the skull and other causes; heat stroke or the effects of cold; meningitis and other forms of brain disease; asphyxia due to gas poisoning or other causes; electric shock; hysteria, in which the loss of consciousness is seldom complete; catalepsy and trance; internal poisons, as in diabetes; external poisons, such as morphia, chloral, etc. In stupor the patient can be aroused for a moment by speaking very loudly or stimulating him in some way.

Sometimes the person appears to be unconscious when he is not so, but only in a weak and dazed condition. A simple test to apply in this case is as follows: Raise the upper eyelid by pushing up the eyebrow with the index finger. Then most gently touch the eye with the tip of the second finger. If the person is unconscious, the eye remains open; if he is not wholly unconscious, he winks more or less and the eye closes.

Treatment will depend chiefly on the cause. In ascertaining this certain observations should be made. Note any evidence of a struggle or indications of an accident. If any bottle is near the patient, this and any vomited matter should be preserved for examination by the doctor who has been summoned. It should be remembered that when the smell of alcohol is found it may only signify that the patient drank some whisky when he found a fit coming on, or that, though he had taken alcohol, even more than was good for him, the unconsciousness may really be due to fracture of the skull sustained in a fall or to some other serious cause. Whenever there is the slightest doubt, the person should be treated on the assumption that he is ill.

Unless the cause is clearly known, it is better to keep the patient perfectly quiet until a doctor comes; otherwise serious injury may be done by adopting wrong treatment. The clothing should be loosened, the patient made as comfortable as possible, and covered with blankets or any warm article available. He should not be raised into a sitting posture. *See* Apoplexy; Artificial Respiration; Asphyxia; Brain; Bright's Disease; Catalepsy; Epilepsy; Fainting; Gas Poisoning; Heat Stroke; Poisoning; Uraemia, etc.

UNDERCUT: Of a Sirloin. The undercut or lower portion of a sirloin is also known as fillet of beef, and, while usually of small size in proportion to the upper part, it is considered by many to be the prime part of the joint. In carving, the undercut is carved vertically or at right angles to the upper part. It should always be eaten hot, and consequently in carving a sirloin it is customary to begin with the undercut, which will often suffice for a small household, leaving the more substantial part of the sirloin to be eaten cold. Sometimes the undercut is removed before the joint is cooked and is served separately as a braised dish or grill. *See* Beef; Carving; Fillet; Noisette; Sirloin; Steak.

UNDERLAY. This word is used for the material that is placed beneath carpets and other floor coverings to make them wear longer and to improve their feel to the feet. Felt of a coarse kind makes the best underlay for pile or hair carpets. Another underlay is felt paper, which can be obtained up to 60 in. wide. Cedar felt is a paper of this kind. It contains disintegrated cedar wood, and holds the aroma of this wood for years. It is, therefore, an excellent antidote to moth. Coarse

canvas makes a good underlay. A waterproof underlay, which gives a soft tread and is suitable for linoleum and other floor coverings, prevents board marks and is inexpensive. *See Carpet.*

UNDERPINNING. The act of supporting a wall, the lower part or foundations of which are defective, and the building up of new solid work for the wall to rest upon is known as underpinning. Underpinning is sometimes necessary owing to the subsidence of the foundations, a common example being the failure of a bay window or other construction.

Essentially, the operation comprises the shoring up of the building to prevent it falling; the provision of local supports to take the weight of the wall above the portion affected; the removal of the old wall and foundations, and the construction of the new work.

Underpinning is resorted to also when it is desired to make some alteration to the lower portion of an existing building which would necessitate the removal of the main structure at the base. If, for example, it was desired to insert a shop front into what was originally a blank wall, or construct a cellar under an existing building, underpinning would have to be carried out. The materials used are principally timber of rather large size and of good quality. For the insertion of a shop front a girder or bressummer is placed across the opening to carry the weight of the building above the window, and the weight of the building has to be supported while the girder is built into position. To do this it is necessary to erect a raking shoring, to prevent the building falling outward, and for this also timbers are needed. Needles are first placed into the wall, these being made from pieces of 4 by 3 in. timber. They are placed in holes cut into the wall to a depth of 4 to 6 in. and project beyond the face of the wall about 9 in.

Over the needle is placed a walling piece, that is, a piece of timber 9 in. by 3 in. of the length required in the particular case. A mortise or hole is cut into this walling piece sufficient to let the needle pass through the piece, which is placed lengthways to the vertical of the wall. A notch is then

taken into the needle level with the face of the walling piece placed over it. This notch receives the raking shore, which is cut so as to fit into it, and extends from the wall to a solid base in the ground. The needle is further strengthened by nailing a cleat above and against it, a cleat being a piece of wood cut out of 4 in. by 3 in. stuff and 9 to 12 in. long.

The piece of timber forming the raking shore may consist of 7 or 8 in. square stuff cut to the length required. The raking shore being firmly fixed lateral support is ensured. The number of raking shores depends upon the size of the opening that is being made, and they are spaced as stated for the needles. The interior of the building has also to be considered, and a vertical strut has to be placed between the floor below and the ceiling above. This strut is formed of 4 by 4 in. stuff, and is securely wedged top and bottom.

Now it is necessary to arrange to take the weight of the wall, that is, to erect the underpinning proper. A sufficient number of holes are cut through the wall to allow other needles to pass through. These needles are of a larger size than those previously mentioned, not less than 9 in. square. They are put right through the wall and are supported in turn by stanchions of the same sized material as the needles, the stanchions resting on sole plates that are placed on the ground. These timbers are then wedged tightly into position; they are strutted and cleated as may be necessary, and generally arranged as shown in Fig. 1 on the previous page.

Underpinning. Fig. 2. Method of arranging support while making alterations to damp course

When sufficient of these for the size of the opening have been erected, the work of making the opening is proceeded with. The girder or bressummer is placed in position and built up, and, when properly set, all of the timbers erected to carry the weight are gradually removed. A similar procedure is followed in forming a cellar, but the work is rather more complicated. The large needles are placed at a height that will just clear the position into which the girder, etc., is to be placed.

A form of underpinning often necessitated by the failure of the damp-proof course consists in removing a couple of courses of brick work from a wall, inserting the damp-proof course, and building the wall up again. Providing the wall is sound and well built and that the bricks are removed carefully, it is generally possible to carry out this work with no particular support except at such places as the brickwork beneath a window opening, or under the support of a particularly heavy part of the building. The work may be locally supported in the manner illustrated in Fig. 2, by placing a short, stout timber through the aperture and resting it upon a couple of built-up timber supports, so as to relieve the wall of some of the weight imposed upon it. *See Brick; Concrete; Damp Course; House.*

UNION CLOTH. Cloth made half of one material and half of another is known as union, and is usually cheaper than the goods which it imitates.

Union wool cloths are partly cotton. The cotton threads are generally concealed by the woollen ones, and are ordinarily the up-and-down and not the cross wise threads.

Union cloths are preferred for certain purposes. Union flannels, for instance, are less inclined to shrink than all wool. Union linings are neater than all-wool and warmer than all-cotton linings. Union blankets are cheaper than wool blankets, and the better qualities of union blanket are superior

to the poorest of the guaranteed all-wool kind. Union linen is half cotton and usually not so strong as pure flax. Union linen is not so good for glass cloths as pure linen.

UNIVERSAL JOINT. For nearly three centuries universal joints have been occasionally used to transmit rotary movement from one shaft to another at an angle to it, but their present wide use is due to the development of the motor car industry. They have been generally employed on motor vehicles for a number of years to give flexibility to the propeller shaft by which power is transmitted from the engine and gear box to the rear or live axle; when so applied they are often termed Cardan joints and the propeller shaft is often termed a Cardan shaft.

The simple ball-and-socket joints used so largely in the steering connexions and the controls of motor cars do not transmit rotation and, although they are not usually termed universal joints, an example will be described later.

The earliest universal joints were known as Hooke's joints, after their designer, and were constructed on the principle illustrated in Fig. 1. Each of the two shafts carries a fork on its end and the forks are connected by an intermedial member, in the form of a cross or star. The arms of the cross pivot in the ends of the fork, and very little consideration will show that the two shafts can easily move out of alinement, but that they will always rotate together. In another form of this joint shown in Fig. 2 the cross is replaced by a ring, but the action is the same.

Universal Joint. Figs. 1 and 2. Examples of common types of universal joint. Fig. 3. Principal component parts of a universal joint as used in the propeller shaft of a motor vehicle. For details

see text. Fig. 4. Hardy disk joint. Fig. 5. Ball centre support for shaft.

Fig. 6. Left, sectional view of a rubber disk type of universal joint with ball centring arrangement. Right, details of the disk

Joints of these designs, although satisfactory for many purposes, require some modification before they can be used on motor vehicles, in view particularly of the exposure of the transmission to mud and dust, the high speed of working, and the power transmitted. They are, therefore, properly enclosed and carefully lubricated, an example being afforded by the widely used Hardy-Spicer joint, the various parts of which are shown in Fig. 3, as applied at the forward end of the propeller shaft and at the rear end of the gear box.

The intermediate member, C, is pivoted both to the driven fork, B, and to the driving member, A. The latter comprises two pivot lugs on one face of an annular disk which is bolted to a disk, D, fixed to the end of the gearbox driven shaft. The driven fork is formed with a long splined boss engaging the forward end of the propeller shaft so as to allow a small amount of sliding movement which results from the up and down movements of the rear axle. The joint is enclosed in a hemispherical cover in two parts, of which one part, E, is bolted to the driving disks and the other part, F, fits on the boss of the driven fork, but is pressed up against the first part by a helical spring. The method of pivoting the intermediate member, C, to the fork and disk is interesting and ingenious. Between each pin on the member C and the open-sided hole in the other part is introduced a hard steel bush, G, which is pushed into position inwards, the four bushes being held in position by spring rings and by the hemispherical cover. The bush is thus held securely in the recess in the fork.

The joint should be refilled with special non-separating grease after about every five thousand miles run.

Owing to the high speed of rotation the lubricant is impelled by centrifugal force towards the outer part of the casing close to the pivots which form the principal working parts. The pressures on the pins are very high and any shortage of lubricant may bring about excessive wear.

Other Types. Another type of universal joint which has been widely used on motorcars employs a reinforced rubber disk or ring to obtain flexibility. Fig. 4 shows diagrammatically a light form with a two-armed spider fixed to the end of each of the shafts to be connected, this pattern being sometimes used for auxiliaries such as the magneto.

Joints for propeller shafts are constructed with three-armed spiders, as shown in Figs. 5 and 6. The opposing arms alternate with one another and are connected by bolts to the rubber disk or annulus, which is made of solid rubber with a number of layers of coarse fabric embedded in it. The fabric renders it practically inextensible, so that a heavy drive can be transmitted, while leaving it quite flexible. In this type of universal joint the rubber disk may distort so that the two shafts will not be maintained strictly in line, in which case one is bound to run out of truth with consequent vibration. To avoid this, the self-centring construction shown in Fig. 6 is adopted. The driving shaft carries a ballshaped extension, K, which fits in a cylindrical socket in the driven shaft, the ball being in line with the rubber ring. The two spiders J, L, may both be fixed permanently to their respective shafts; that is, a splined connexion need not be employed since the rubber ring and the ball joint will allow some end play of the shafts. This type of joint is silent under all conditions and only the ball connexion requires lubrication. Care must, in fact, be taken to avoid oil or grease on the rubber, which would in that case become soft and useless. Petrol, if used at once for cleaning, will prevent trouble.

The axes of the two shafts connected by a universal joint should always be as nearly in alinement as possible, both to resist wear and also, in the metallic type, to avoid irregularity in the running. In this type if one shaft rotates uniformly the other will be slightly accelerated and retarded twice during each revolution, and this periodic variation of speed, together with the accompanying loss of power, increases as the angle between the shafts increases.

The simple ball-and-socket joint forms a most useful connexion since it allows freedom of movement in all directions, but without slackness. An example as applied to the ends of the drag link on a motor car is shown in Fig. 7. This link connects the steering gear to the axle, and it is, therefore, continually flexing. A ball on the arm works between two sockets which are held in position by a strong helical spring. The screwed plug which in this case forms one of the sockets and compresses the spring must always be locked in position by a split pin. The ball and the sockets are usually case-hardened and regular lubrication with grease is necessary. Small joints of similar construction are often used on motor car controls.

Universal Joint. Fig. 7. An example of a ball joint as used on the steering drag link on a motor car

UPHOLSTERY AND UPHOLSTERING

How the Amateur can Save the Cost of Repairs

This contribution describes in detail how various articles of furniture can be upholstered at home. Reference may be suggested to the entries in this work on the articles themselves, e.g. Armchair; Chair; Chesterfield; Pouffe; Sofa; and to those on the materials, e.g. American Cloth; Chintz; Cretonne; Horsehair; Tapestry Needlework; Weaving. See also Colour and the entries on the various rooms, e.g. Drawing Room; Sitting-Room.

This article explains with the aid of the illustrations how to cover a plain seat, a sprung seat, and a fully upholstered divan easy chair, thus covering practically the whole range of the upholsterer's craft, with directions for the subsidiary branch of cutting and making loose covers.

Upholstering consists chiefly in stuffing, covering, and re-covering furniture. The materials and tools required are by no means expensive; those used for the coverings are perhaps the most costly.

The most beautiful and durable covers are hand-made. They may be of hand-woven silk or tapestry, or they may be of tapestry needlework on canvas, which is cut to fit the chair or other piece to be upholstered, good turnings being allowed before the design is embroidered in wools, colouring and patterns being chosen to suit the frame and room. Needlework coverings can be adapted to modern pieces, but are most suitable for re-covering antique chairs or reproductions of antique styles.

Hand-woven fabrics can be produced in a variety of stripes, small patterns and shot effects in wool, silk or flax fibres, separately or in combination, and many variations are possible with a simple setting up of the loom. One piece of furniture can be covered in such fabric, or a whole set of chairs to match, with excellent results if due regard is paid to colour and weaving.

A great deal of work is carried out with machine-made tapestry, which may be woven either from cotton, silk, artificial silk, wool, or a mixture of either. Ordinary upholstering tapestry varies in width from about 48 to 52 in. and is thus economical for cutting. It can be obtained in a variety of patterns and colours, and is thus adaptable to all forms of decoration. Many of the finest designs are in artificial silk mixtures.

Tapestry of good quality is expensive, and it is therefore important to choose a design which will cut to the best advantage. Thus, if the selected pattern has a marked feature, such as a cluster of flowers, which is only repeated every 50 in., obviously this should appear in the centre of the back or seat of the chair. To obtain this result, especially if only one or two pieces of furniture are to be covered, would mean a considerable amount of waste, consequently it is better to choose a simple all-over style of covering. The same difficulty has to be coped with in damask, another excellent upholstery fabric.

A material in extensive use is velvet, in 50 in. width, and obtainable in many colours. Plush is also used but has not the same rich effect. Other materials include mohair fabrics in plain colours and checked designs, rep, chintz, and cretonne, the latter a braided cotton fabric, much cheaper but less durable than tapestry.

Good leather upholstery is suitable for dining-room furniture. Leather, particularly morocco or pliable goat skin, is dyed in many colours and finished with a grained or bright surface. It is obtainable in the form of skins of irregular shape, ranging from about 22 by 26 in. in the smaller ones to about 30 by 35 in. in the larger. As the leather has to be stretched in upholstering, even minute blemishes are speedily revealed. Other leathers include the hides or cow-hides, which are cheaper than morocco and obtainable in fairly large skins.

Leather Substitutes and Ornamentation

Many excellent leather substitutes are on the market with various trade marks and branded names, among which may be mentioned pegamoid and rexine. Most of these are woven fabrics covered with a waterproof material and closely resembling leather. Oil baize, or decorene, of British make, is another fabric of this class which is often used. Among the various forms of ornament for coverings are the gimps or strips of tape-like material for edging, fringes and cords, brass-headed and other tacks, and buttons, which may have a covering similar to that used in the upholstery.

Most of the tools required, illustrated in Fig. 1, will be found in the average home, an exception being the webbing strainer. The upholsterer uses a special form of light hammer, called the cabriole hammer, but the more common one illustrated will serve for most jobs.

Upholstery. Fig. 1. Necessary tools and equipment, including webbing strainer, needles of various shapes, tacks, scissors, hammer and chisel, also chain springs, webbing, canvas, and stuffing materials.

The webbing strainer is a pair of pliers with wide jaws or flanges. One of the jaws has a broad projecting portion which engages the side of the chair, while the webbing is gripped between the jaws; the flanged portion rests against the side of the chair, and the handles are pressed downward, thus getting a leverage on the webbing.

The other tools include a strong pair of scissors and a small chisel, such as a carpenter's old firmer chisel, with a mallet to drive it. A rasp, tape measure, and rule are also needed, and preferably some sort of low table or stand whereon to rest the work. A selection of needles is required, and several are shown fastened into a piece of material in which they are rolled when not in use. The selection should include two or three upholsterer's packing needles, which have two points, ordinary packing needles, and a regulator. The latter is a piece of steel from 6 to 18 in. long, and tapered at one end to a fine point, the other having a flattened portion. The pointed end of the regulator is inserted into the stuffing material while the operation of stitching is in progress.

The flattened end of the regulator is used in buttoned work, and also for tucking away any odd ends of stuffing or fabric. The needles should range from 4 to 12 in. in length. In difficult cases it is desirable to use a semicircular as well as a pattern known as a spring needle. This latter type of needle is straight for some three-quarters of its length, while the remaining portion is curved. Some needles are made with bayonet-pointed ends, so as to cut cleanly through the covering material.

The amateur desirous of taking up upholstery work should start with some simple operation such as re-stuffing and re-covering a chair. Broadly speaking, there are two methods of upholstering. In one, the chair seat or other part of furniture is simply padded with some suitable stuffing and the exterior covered with the desired tapestry or other fabric. By the other method, upholsterer's springs are used to give resiliency to the seat, etc. The springs illustrated in Fig. 1 are spiral or coil springs. They are made in various sizes, and can be obtained from any furnishing ironmonger's.

Webbing is one of the most important of the materials employed. It must be made of very strong braid, and only a really good quality should be purchased. The best qualities are made of flax, and are sold in pieces about 18 yd. in length, the width varying from 1 in. to 2½ in. The webbing has to be thoroughly stretched before it is used. One method is to suspend it by looping it over stout bars hung from the ceiling and hanging heavy weights on the lower ends of the webbing.

Hessian, a kind of canvas woven from jute or hemp, and sometimes known as spring canvas, is used for the coverings of the tops of the springs. Scrym, a light canvas with an open mesh, is employed to keep the padding on top of the springs in its proper place and shape.

Special kinds of twine are required. Fine or stitching twine should be obtained for sewing the edges of the scrym; spring twine, which is thicker, is used to fasten the springs to the webbing. The stoutest material is often known as laid cord, and is used to tie the springs down to the proper size and shape. The webbing is attached to the framework by tacks, which should be of the cut or fine variety, and either brass or black enamelled. Proofed tin tacks are stouter and have larger heads. Those about $\frac{5}{8}$ in. long should be used for fastening the webbing; others, from $\frac{3}{8}$ in. to $\frac{1}{2}$ in., being utilized for tacking the canvas or other materials.

Materials for Stuffing. For the stuffing, nothing beats horsehair, the best being obtained from the tail and mane. In the treatment to which it is subjected it is cleansed and curled into ropes, the curl being the feature which gives horsehair its peculiar springy property. Inferior qualities are short in length and lacking in resiliency. A material known as fibre, which is a species of fine cord, is often used as a substitute for horsehair, but lacks its springiness. Coconut fibre can be employed for common work, or alva, which is a kind of dried seaweed. Wood wool, composed of finely shredded shavings of wood, is extensively used, and possesses considerable springiness, besides being exceptionally clean and sanitary.

A great deal of stuffing is carried out with wool and flock, the latter being a waste product made from rag. Its manufacture is regulated by Act of Parliament, which has the effect of keeping it reasonably clean. Ordinary wadding is useful to the amateur for stuffing, and particularly as a covering immediately beneath the outer covering of tapestry, etc. It imparts a smoothness to the finished work. A supply of the materials mentioned can be obtained from a good-class draper's or furnishing house.

Upholstery. Fig. 2. Chair, with old covering and webbing removed, ready to be re-covered. Fig. 3. The first stage, stretching and tacking down the webbing. Fig. 4. Tacking down folded end of webbing for security. Fig. 5. The seat completely webbed. Fig. 6. Tacking on first layer of canvas. Fig. 7. Showing stuffing in place and second piece of canvas being tacked over it. Fig. 8. Applying the covering.

Re-upholstering a Chair. In re-upholstering an ordinary chair the old coverings and webbing are first removed. This is done by prizing out the tacks holding the gimps, tearing off the covering, removing padding and springs and finally removing the webbing by means of an old chisel and a mallet. If the chisel is pressed against the head of the tack and given a sharp blow, it will drive the tack from the wood. The chair should then be thoroughly cleaned, and, if necessary, any repolishing or staining carried out on the framing, particularly around those points adjacent to the upholstery, or where the upholstery will ultimately go. The result at this stage is illustrated in Fig. 2.

The first process in the actual re-upholstering is to take a piece of webbing, fold over the end so as to double it, and nail it to one side of the chair frame. The webbing is cut to length, which should be rather more than the width of the frame. The overhanging end of the webbing is grasped between the projecting jaws of the webbing strainer and the latter pressed downward with the left hand. The webbing is then secured while it is stretched very tightly by driving a tack or two through it near to the inner edge of the framing, this operation being shown in Fig. 3. It is important to obtain the utmost leverage on the webbing so as to stretch it as tightly as possible. The overhanging part is folded back on to the top of the webbing and nailed as in Fig. 4. It should be noted that when the webbing is arranged in this way the loose end is doubled under the webbing in the first fixing, whereas the second end is finished by being doubled over and tacked down on top of the webbing.

The remainder of the webbings have now to be fixed. A common arrangement is that in Fig. 5, two webs being arranged across the chair seat from side to side and three from front to back. The webs should interlace with one piece alternately over and under the others, as shown, each of these webs being attached in exactly the same way as the first. A piece of the canvas has to be fastened to the framework, and old canvas may be used if it is in good enough condition. It is secured by folding the edges under and tacking it neatly to the framework, as in Fig. 6.

The seat can be padded with any of the materials mentioned. In the example in Fig. 7 ordinary flock is used. This is worked between the hands to make it even and uniform. It should be distributed over the canvas and worked into the desired curvature of the finished seat, using more flock in the centre than at the sides. After the flock has been arranged, the second canvas or scrym is laid over the flock and tacked to the edges of the framework of the chair, as shown in Fig. 7.

Upholstery. Fig. 9. Showing how the gimp is arranged round top of the leg and secured by covered tacks.

The material chosen for the covering must be cut to allow sufficient overhang on all four sides. It is then fixed to the front part of the chair frame, as in Fig. 8, by driving in a few tacks. The cover should be pleated neatly at the corners by folding the material so as to leave only one fold showing at the corner. The covering is drawn tightly and uniformly as the tacks are driven, and should be neatly and carefully fitted around the tacking lines. It is finished, as Fig. 9 shows, by trimming with gimp, secured with covered tacks. The gimp should be carefully worked all round to cover the joint between the covering and the frame of the chair, for which purpose the covering must be cut accurately.

Use of Springs. The method of upholstering a chair with springs differs considerably. In this case the webbing is applied to the bottom of the frame. The chair is first prepared as already described. It is often placed upside down on a stout table or trestle, and the webbing applied to the underside of the frame, as in Fig. 10. Springs have to be sewn on to the top of the webbing. The usual plan is to employ three springs, two on the front part of the chair and one behind them centrally. They are sewn in place by stitching through the webbing in three positions for each spring, drawing the twine tightly each time and continuing from one spring to the other until this part of the work is completed. The method of stitching is explained in Fig. 11, where the fastening of the last- spring is in progress. The needle is thrust through from the top of the webbing with the right hand and pressed through with the left hand and, when necessary, passed backward again from the left to the right, and so on until the fastening is quite completed.

Upholstery. The various stages in upholstering a spring chair: Fig. 10. Nailing webbing to underside of seat. Fig. 11. Sewing springs to webbing. Fig. 12. Springs lashed together with thick string, and fastened to frame of seat. Fig. 13. Springs covered with canvas, which is firmly tacked down to frame. Fig. 14. Sewing the springs to the canvas covering with a spring needle and strong string. Fig. 15. Placing the stuffing over the canvas. Fig. 16. Tacking down a second covering over the stuffing.

The springs have next to be fastened with thick spring or laid cord, usually in the manner illustrated in Fig. 12. The springs are secured in such a way that the strings draw them down and slightly depress them. They should be fastened in the first place to each side of the framing, the strings

being attached to tacks driven into the frame itself. Another string is used to connect between the front two and the rear spring, and the latter is secured by another supporting string to the back of the frame. The object of fastening the springs in this way is to prevent them from grinding or rubbing when the chair is in use and to keep them in place while the upholstering is in progress.

The purpose of compressing the springs at the start is to ensure that they will constantly exert a pressure between the lower webbing and the underside of the covering material, and thereby keep the chair seat in its proper shape. The size of the springs is usually about 6 in. in length and No. 8 gauge. The height of the set from the bottom of the frame to the top of the seat, when it is finished, should be about 5½ in. If the seat is to finish 6 in. from bottom to top, it is usual to allow 1½ in. for the thickness of the filling or stuffing, and therefore it is necessary to compress the springs by about 1½ in.

In placing the springs the finishing end of the coils should all point in the same direction, towards the front of the seat. The springs should always rest on two webs where they overlap each other. It is also necessary to tie the springs in such a way that their upper surfaces conform generally to the curvature of the seat or other part of the chair, and the springs must always be lashed in such a way that they can exert their pressure in the same line as that of their own length, i.e. upwards and not sideways.

Covering the Springs

When the springs are fixed satisfactorily they have to be covered, in the manner shown in Fig. 13, with a piece of strong canvas. This is first fixed to the back rail with a few temporary tacks. The canvas is then held tightly and tacked to the front rail. The sides are tacked alternately: first with a tack near to the back of the chair on one side, then the canvas is pulled tight and fastened with tacks on the opposite side and so on until it is tacked all round. It must not be drawn tightly enough to depress the springs further, but should just lie evenly upon them. The tops of the springs are sewn to the canvas with a spring needle by the method illustrated in Fig. 14. The needle is passed through the canvas and each spring sewn in three places, the string being worked continuously from one spring to the other, and finished ultimately at the starting point.

The method of applying the stuffing is illustrated in Fig. 15. Whatever material is used it must be picked or teased out into a loose mass, packed on and around the canvas, and built up as nearly as possible to the desired shape of the seat. To prevent the stuffing from moving, it should be fastened with a hair tie, which is a twine worked around the outside of the curved part of the canvas and caught to the stuffing by sewing at the corners. The string should be about 3 in. up from the frame, and there should be about 8 or 9 in. of space between each tie. This twine is left quite loose and is tightened up when all the stuffing has been worked in.

After the sides have been packed up tightly with stuffing, the centre is filled in and the whole arranged as smoothly and evenly as possible. The scrym has then to be applied to the whole so as to cover and enclose the stuffing, this operation being shown in a nearly completed stage in Fig. 16. The scrym should be of such a size as to allow for turning up on all sides. The first side to be fastened is the back, the canvas being temporarily secured with three tacks. The stuffing is lightly compressed with one hand and the scrym secured temporarily to the front rail. The scrym is an open mesh, the strands of which can quite easily be seen, and in fastening or tacking it down these strands should be kept as straight as possible. This little detail will prevent the risk of subsequent slackening, or at least minimize it.

The sides of the scrym are tacked to the frame, being turned in so as to reveal the edge. This being accomplished, the scrym has to be tied or sewn to the spring canvas with an 8 in. straight needle. This is used with a fine twine and stitches are made by thrusting the needle through from a point at a distance of a few inches from the point which will form the edge of the chair, the start being made from one back edge. The point of the needle is worked through the stuffing, and emerges through the side of the canvas. To form the edge of the seat, twine is worked in a similar manner from the upper part through the stuffing and out at the side, as in Fig. 17, and drawn tight to form an edge or roll of stuffing. It is important that the line of this work be kept of good shape, as upon that will depend the appearance of the finished chair.

Second Stuffing. When the roll or edge has been sewn in this way the chair is in the state known as first stuffing, and can be covered, if desired, without further stuffing. It is, however, an advantage to apply an additional stuffing, which may be of horsehair, wadding, or other material. It should be sewn in such a way that the stuffing cannot shift or work up into lumps, for which reason ties made with loops of fine twine are provided. The ties are made around the seat about 2 in. from the edge,

and several ties provided in the centre portion of the seat. The hair is closely worked under the ties, and when completed with horsehair the surface should appear to be covered with short, curly pieces. The corners are fitted with buckram or thin cardboard folded and tacked to the corners of the frame to give it a clearly defined shape.

They terminate a little distance below the upper surface of the stiffening, and the edges should be rounded so as not to reveal any marked angles. This second stuffing may be covered with unbleached calico, or some light material, which is temporarily tacked to the chair, the back corners being nailed and fitted in the manner already described.

It only remains to cover the underside of the chair with a lining of canvas, turning under the edges and taking them firmly to the underside of the frame, thus covering the web completely. The manner in which this is done is illustrated in Fig. 18.

The chair is now ready for its covering, which may be of any desired material, and is applied as shown in Fig. 19. The cover is carefully tacked to the sides of the framework of the chair and neatly worked around the corners, being finished with any desired kind of gimp, as in Fig. 20.

Upholstery. Fig. 17. Stitching the edges in order to form an edge or roll of stuffing. Fig. 18. Covering the underside of the chair. Fig. 19. Tacking down the material that is to be used as the final chair covering. Fig. 20. Fixing the gimp in place to cover the join.

Stuff-over Work. A more ambitious undertaking is that of completely upholstering a chair from the frame and doing the work on a system usually described as stuff-over. The rough frame can be obtained ready for use or taken from an old chair

which has been stripped of its stuffing. Instructions and working drawings for making a frame are given in the article on Easy Chair. The appearance of a divan chair frame is seen in Fig. 21. Fig. 22 shows the frame after being webbed and sprung.

The first step is to apply the webbing to the underside of the lower framework of the seat and also to the back part of the framework and the sides. The spaces between the arms are filled in with a piece of scrym or canvas, and the springs are then sewn to the web. A stout cane or similar light, flexible bar is lashed across between the two upper portions of the upright part of the chair frame, attaching it to the springs, as in Fig. 22, and not to the framework of the chair.

The purpose of the cane is to provide a resilient edge for the seat. The method of sewing the springs of both back and seat and connecting them together with laid cord is shown in the illustration. In this type of divan chair with a spring edge the lower cross rail on the upper part of the frame, known as the front rail, is located only a few inches above the floor. The cross rail must be sufficiently wide to support the greater portion of the bottom part of the spring. Before the springs at the front are actually fitted, a piece of webbing or a double piece of canvas should be placed between them and the rail, and the end pieces attached to them to avoid any chance of their working forward. Another point is to support the middle portion or waist of the spring by lashing from back to front and from side to side with cord.

The seat is covered with spring canvas sewn together around the spring edge so as to case or enclose it. A still better plan is to cover the springs only, and arrange a separate covering for the spring edge by working the canvas so that the pull on it when the chair is sat upon does not draw the spring edge inwards. This can be managed by temporarily fixing the canvas on the front by passing it over the spring edge, fastening it to the stuffing rails at the sides of the chair, then removing the temporary tacks from the front part of the canvas and folding it back along the edge of the spring edge. This portion is then fastened to the front rail with stout cord or ties, the canvas folded back again over the spring edge and tacked to the front rail. In this way a furrow is formed between the spring portion and the spring edge, which relieves the latter of the bulk of the pressure from the springs.

The chair is stuffed by the double stuffing method. The first stuffing should be with horse hair for preference, tied in the manner already described. After the seat has been stuffed it is covered with scrym; the back and sides are permanently tacked, the scrym being fastened at the front by means of a circular needle and fine twine. The second stuffing is then proceeded with and covered as before. The back and arms are started after the seat has been stuffed. The arms may be sprung, if desired, with springs about 4 in. long. The spring of the back of the chair should be commenced with the springs, the form being obtained by the use of those of proper length and strength. The swell at the back part should have thicker springs 6 to 8 in. long. In canvassing the back, care must be taken not to strain the fullness of the material, and to obtain neatness by folding where necessary. A few ties are worked through the stuffing at various points to keep the whole firm. The appearance of the work at this stage is seen in Fig. 23.

Upholstery. Fig. 21. Frame of a divan easy chair ready for covering. Fig. 22. Chair with back and seat webbed and sprung.

Fig. 23. Divan easy chair, stuffed and covered with canvas and requiring an outer covering of tapestry or leather or loose cover of cretonne.

Applying the Cover. In the final covering the utmost care will be found necessary in planning the various pieces, and if the material to be used is expensive the amateur will probably find it well to cut a set of patterns in calico or some cheap material and try them in place to see that they fit properly. This having been ascertained, the proper material can be cut. It is not necessary to allow much for overlap, as the edges of the material need only be sufficiently long to enable them to be

tucked out of sight. Any fastenings that have to be made to the framework are accomplished with strips of stout calico or linen, known as stretchers, which are sewn on where needed; they serve as an extension of the covering and provide the necessary support.

When all the pieces have been prepared they should be marked for identification purposes. The whole of the seat, back, and other parts should be covered with a sheet of wadding, carefully smoothed down and trimmed at the joints. The various portions of the covering are applied, first the

seat, which may be tacked temporarily in place, and then the coverings for the arms and back. Slight adjustment of the covering will ensure the design being central and any lines uniform. The seat is tacked in position, and after it the arms and the back.

In the case of a bordered chair the covering is pinned under and sewn with the circular needle, the border being bulged with wadding and a little hair. The covering is pinned under the edge and corded wherever necessary. Any fullness should be disposed of as the work progresses, by pleating and folding. The outside pieces are then fitted. The bottom of a chair of this type is covered with linen or canvas, as shown in Fig. 24, and the chair is finished with gimp and cord. Gimp is used to outline the design and to cover any bad surface that may show. The cording is secured with a small circular needle and carpet thread. The amateur will probably find it helpful, if a corded edge is to be worked on the tapestry, to apply it first in the manner adopted for making loose covers. Some of the finishing cords and circular gimps are merely applied with tacks or sewn in place, according to the nature of the materials.

Loose Seats and Frames. There are many other applications of upholstery which can be carried out in a similar manner. In some cases loose seats are used, and are webbed and upholstered on an independent wood or metal frame. The general procedure is the same as has been described, except that in the case of metal frames the webbing is folded round the rod and secured by sewing. When buttons are sewn through the material to form a depression and so add to its appearance and strength, they are secured with fine twine sewn with a long, fine needle, and they are sewn through the stuffing to the spring canvas. Provision for the button points must be made in the early stages of stuffing. Button work should not be undertaken by the amateur until some experience has been gained in more simple work.

Many forms of box-spring mattress are upholstered in substantially the same way as a large spring seat, the underside of the frame being webbed, the springs sewn to them, and the upholstery carried out by the double-stuffing method, with buttons at appropriate intervals. If any difficulty is met with in the actual covering of the chair it can often be met in the finishing stages.

Loose Covers. Detachable coverings made of printed linen, cretonne, chintz, cotton rep, or gingham are useful either to protect a delicate upholstery fabric or to cover up a shabby one. An enormous variety of patterns in modern and period designs to suit every conceivable colour scheme are available in 31 in width, and many in 50 in. When making loose covers for settees, chesterfields and large armchairs, it is sometimes more advantageous to buy the 50 in. width if it saves extensions on either side in order to get a whole width in the middle to balance the design. Small patterns will join more easily than those with large bunches of flowers or medallions. Plain reps are simplest to plan and cut to advantage, but somewhat dull in most rooms unless there is a good deal of colour and decoration elsewhere in the furnishing scheme.

Paper patterns should be taken of the chairs, etc., which require covers. If this is done the total length of material required can be fairly accurately estimated by planning out the patterns and measuring them. Ordinary large newspapers can be used and the type and folds of the sheets are a guide to accurate placing on the chair when taking the pattern. Accuracy in shape and fit is most important, both to appearance and durability.

The parts to be measured for an armchair or settee of the usual types are: Inner back; Outer back; Seat, front to back and the width from side to side; Inside arms; Band for front of seat to cover stuffed upholstery or frame; Two outside arms; Two small front arm pieces (not always necessary); Frill. Measure off a length twice round the bottom of the chair, if this frill is to be box pleated, $1\frac{3}{4}$ times round if to be gathered. The depth of the frill varies, but it is usually made just to clear the floor.

A narrow piece may have to be included in the parts to join the inner and outer backs so that they fit nicely at the top. If the armchair is straight this extra piece may be avoided by taking the pattern right over and cutting the inner and outer backs in one length. In some chairs with rounded tops, as in Fig. 23, the inner back is taken over the stuffed top, and seamed over the outer edge of the top to the outer back piece.

Take a sheet of paper and pin it to the inner back. Let a fold of the paper run straight down the middle. The pattern need only be cut on one side if the paper is doubled in this way. Cut off by the seams of the upholstery, but an allowance of 6 in. for a tuck in at sides and back of the seat and of 2 in. for turnings must be allowed when cutting out the material. Next take the pattern for the outer back and then for the seat. Pin the paper from the back of the seat with a fold of the doubled paper down the middle. Cut off at sides where it touches the arm and back and at front edge. It should be noted that an allowance for the tuck in of 6 in. for both sides and for back of seat portion must be made when cutting material.

Take a pattern of one arm only, first from inside over the stuffed edge and cut off at seam. Again 6 in. will have to be allowed for the tuck-in at sides in order to join the seat portion, when cutting material; then pin the paper outside the arm and cut off the pattern by the top seam and lower edge of the chair. Pin a piece of paper to the front of the arm and cut out to shape of the upholstered piece. Any fullness will have to be pleated up to fit the curve of the front arm. Next take pattern of the straight band in front of the seat which connects the two arms.

If notches are cut in the pattern pieces at connecting points it is a guide to joining them correctly. A duplicate of the right arm should be cut out in paper to avoid the danger afterwards of cutting out 2 lefts or 2 rights in the material. Mark the patterns of the arms left and right.

When making up, pin the pattern carefully on to the material, remembering to leave 2 in. or at least 1½ in. for turnings and the 6 in. for the tuck-ins where necessary. Make sure that the fabric is quite straight before cutting out. The pieces of material can be pinned on to the chair before sewing to ensure accuracy.

Upholstery. Fig. 24. Showing how the bottom of an easy chair is covered with linen or canvas. (Courtesy of Our Homes and Gardens)

The seams may be bound with bias strips of the material or piped. For the latter method strips of the material cut on the cross and 1 in. wide are required. Allow an extra ¼ yard for each chair, or strips of plain fabric, such as linen or casement cloth, look well to match the ground colour of a patterned cretonne. Lay the material for the covers right side up to cut out. If a fabric with a large design has been chosen see in planning out the pattern pieces on it that the main motifs of the design are well placed to come in the centre of the inner back and seat. Also that the design matches on the arms. With a large flowered pattern it is well to allow an extra yard of material as it may cut to waste.

For bound seams the cover should be pinned up with turnings on the right side, and fitted closely on to the chair. For piped seams the turnings are pinned up on the wrong side and the cover should fit easily as the piping takes up room. All visible seams should be piped. Any fullness at curves should be neatly darted, gathered or pleated into position.

The tuck-in seams and any others that do not require piping or binding should be machined first. An opening is left at one side of the outer back, or at both sides if the chair is large or in the case of a settee, so that the cover can easily be removed and replaced. The edge of the open seam must be

faced on one side and have a wrap over to neaten it on the other. Press studs of strong quality are the most convenient fasteners.

For making the frill join up the pieces and press the seams first. For a box-pleated frill take up a 2-in. wide tuck at every 4 in. Flatten each tuck to make a box pleat (see Pleating), press, and tack into place along the top. Seam to the cover with neatened raw edge on the inside. A gathered frill is simpler to make. Having joined the pieces, divide them into even sections and gather with double cotton. Divide the edge of the cover into the same number of sections, pin together, right sides facing, and stitch.

UP JENKINS. This is a parlour game suitable either for children or for adults, the only apparatus required being a threepenny piece or a sixpence. The players divide into sides, which occupy different sides of a table. One side, usually chosen by toss, has the coin to start with, and all put their hands under the table, passing the coin from one to the other until it reaches the person destined to hide it. They may do this until the captain of the other side says "Up Jenkins," when they must hold their clenched hands well above the table for inspection by their opponents. The person who has the coin must do all in his power to keep it concealed.

Hands may be put on the table in one or two ways, according to the opposing captain's choice. "Smash" means that they must be brought down with open palms as violently as possible; "crawl" means that they must be put down quietly, and the fingers extended slowly when they are on the table. It is then the business of the opponents to remove all hands from the table except the one containing the coin. If this is cleverly concealed between the thumb and forefinger it is very difficult to detect.

If the captain succeeds in his task, the coin then passes to his side and the game proceeds as before. If he does not, but orders off the hand containing the coin, the same side has it again. As the captain's position is one of responsibility, it is best for it to be filled by each member of the side in turn.

URAEMIA. The form of blood poisoning due to the presence in the blood of substances which ought to be excreted in the urine is called uraemia. It may occur quite suddenly, the patient sometimes becoming totally unconscious without previous warning. The condition may arise in any disease of the kidneys and in any other affections in which the urine ceases to be excreted by the kidneys. *See Bright's Disease.*

URIC ACID. Uric acid describes a nitrogenous substance formed in the body, partly from the wear and tear of the muscles and organs and partly from the oxidation of food. Very small quantities, in the form of sodium urate, are passed out of the body in the urine. If the urine is very acid, uric acid is deposited in crystals.

Uric acid is increased in a variety of diseased conditions, including gout, leucocy-thaemia, ague, and pernicious anaemia. But the importance of uric acid as a cause of disease is now considered much less than formerly. It is very slightly soluble in water, but dissolves readily in alkaline solutions. This last quality is of importance in the treatment of gout and gravel.

Some foods give rise to a good deal of the acid, while others are free from the substances out of which it is formed. This fact has led to the diet system which admits the consumption only of what are known as purin-free foods. The foods which contain in the largest quantities the bases from which uric acid is made are red meat (beef, mutton, etc.), livers, kidneys, sweetbreads, meat extracts, yolk of egg, peas, beans, and lentils, tea, coffee, and cocoa. Purin-free foods include white bread, tapioca, potatoes, cauliflower, cabbage, lettuce, rice, macaroni, nuts, among vegetable foods;

apples, grapes, figs, dates, and raisins, among the fruits; milk, cream, butter, cheese, fats, white of egg, sugar, honey.

URINE. The purpose of the urine is to remove from the blood certain waste materials formed in the body. Urine is separated from the blood by the kidneys and passes to the bladder, from which under normal conditions it is discharged in average daily quantities of, roughly, 2½ pints for an adult. This may, however, vary, being increased in cold weather and diminished in hot weather, when sweating is profuse. The quantity is also greatly affected in some diseases, as is the colour.

Various causes produce pain in passing the urine. In simple cases, the eating of more vegetables and fruit may effect a cure; or a few doses of citrate of potash may be given, 20 gr. in a little water. Stoppage may be due either to the kidneys ceasing to form urine or to inability to void it from the bladder. The first is called suppression and the second retention. Urgent medical treatment is required in all cases. *See Kidneys.*

URN. Urns in pottery, marble, and stone are used for garden ornaments. These are of the classical vase shape with or without lids. The urn used for tea, when large quantities are required, is made in silver Sheffield plate, or in copper and various alloys, and old pieces are sought by collectors. Some are fitted with a spirit lamp for heating the tea and keeping it hot. Sometimes the urn is used for boiling water only, and the teapot is filled from it at the table.

The first urns of this kind, which appeared in England about 1740, had lamps placed under them, and the tea was made in them. This did not produce a very satisfactory tea, so an urn was made which had in its centre a vertical tube into which a round bar of hot iron was dropped, the heating being done in this way.

Urn. Silver tea urn, with spirit lamp beneath. (Courtesy of Chapple & Mantell)

URNFLOWER. This greenhouse bulb belongs to the amaryllis family. The chief kind is *Urceolina pendula*, which bears drooping bunches of green and yellow flowers in June. The bulbs should be potted in autumn or in winter in a compost of loam, leaf-mould and sand. Propagation is by offsets which develop on the old bulbs. When the leaves fall watering must be discontinued.

UTRICULARIA. Bladderwort is the common name of this group, which includes aquatic and insectivorous plants provided with small pitchers by means of which insects are caught. The chief species is *montana*, grown in suspended pots and baskets in a hot house in a compost of peat and moss.

UVULA. The small rounded mass of muscle covered with mucous membrane that hangs from the middle of the soft palate is called the uvula. In relaxed sore throat the uvula may elongate till it touches the upper pharynx wall or larynx, when it causes an irritating cough, especially when the patient lies down. This should be remembered when a cough is troublesome at night. Elongation, if it is slight, may be corrected by the doctor painting with glycerin of tannic acid or solution of nitrate of silver. *See Pharyngitis.*

UVULARIA. These are lily-like herbaceous perennials, related to Solomon's Seal. They are suitable for planting out of doors in moist soil of loam and peat in a partly shaded place, or in the bog garden. The chief kind is *Uvularia grandiflora*, which grows 12-18 in. high and bears yellow flowers in early summer. Propagation is carried out in spring by separating the underground stems. *See* Solomon's Seal.

Uvularia. Graceful stems and drooping yellow flowers of the species grandiflora.

VACCINATION. An inoculation with the liquid contents of a cowpox vesicle is used for the purpose of either preventing an attack of smallpox or of mitigating the effects of smallpox which is incubating. It produces a local pock at the site of the injection, but in the large majority of cases no general disease beyond some little feverish disturbance.

Vaccination is usually done on the arm, but in girls the leg may be preferred in order to avoid any disfigurement. In young, restless children it is often extremely difficult to prevent rubbing of the skin and irritation, and this difficulty is met with whether the arm is covered or left bare. Wire protectors increase the risk of injury. A piece of boracic lint held in place with a soft bandage or adhesive plaster is the best appliance. The arm must be kept at rest as far as possible.

The best age for vaccination is before teething begins. If smallpox is prevalent the child may be vaccinated even on the first day of life. If vesicles do not appear, as sometimes happens, then the vaccination is not successful, and should be repeated. Protection is said to last for 10 or 12 years in the majority of cases, but the period varies in different individuals, and may be as short as two years. It is therefore recommended that a child should be re vaccinated between the ages of 7 and 12, and that the operation should be repeated between the ages of 20 and 25.

If an epidemic of smallpox breaks out, however, it is advisable for everyone likely to be exposed to infection to be vaccinated if his previous vaccination dates back further than five years. When infection with smallpox takes place, if the patient is vaccinated within three days the attack may sometimes be entirely prevented, and if within 8 or 10 days the severity of the attack is usually diminished.

The Law of Vaccination. By the law of England every child must be vaccinated before it is six months old, unless the parent has a conscientious objection to vaccination. It can be performed either by a private practitioner or by the public vaccinator, who will visit the house and vaccinate the child free of charge. If the parent or person in charge of the child has an objection to vaccination, he must within four months of the child's birth make a statutory declaration before a commissioner for oaths or a magistrate, and within seven days from that time must send this declaration to the public vaccinator for the district. *See* Smallpox.

VACCINE. The name vaccine was originally applied to the substance obtained from the vesicles of cowpox. The term is now employed for any substance used for protective inoculation, and what is generally used is an emulsion of dead bacteria, of the kind which produces the disease against which protection is required. The use of such vaccines assists the natural action of the body in meeting and combating infection.

The diseases treated by vaccines, either protectively or curatively, include influenza, gonorrhoea, acne, pneumonia, tuberculosis, enteric fever, common colds, anthrax, rheumatism, and many others.

VACUUM CLEANERS

The Hygienic Method of Removing Dirt from the Home

In connexion with this article on an important appliance for household cleaning the reader is referred to the contributions on Labour Saving; Spring Cleaning; and for safety hints to that on Electricity. See also Oiling.

The appliance known as a vacuum cleaner is designed for extracting dirt and dust by suction. The value of any particular machine of the type is therefore chiefly in its suction powers, which must be strong enough to dislodge and extract deep-lying dirt, as well as to gather up surface dust. The powerful current of air should pass through the thickest carpet and draw out every particle of grit and dust without damaging the fabric.

The fact that the dirt thus extracted is at once drawn into the dust-bag of the machine, instead of being disturbed by sweeping with the ordinary broom or brush, when a portion of dust must be allowed to blow about the room to escape even the most careful housewife, makes the vacuum cleaner the most efficient and hygienic cleansing appliance. An additional advantage which is claimed for the best machines is that as the suction created by the vacuum is sufficiently strong to penetrate closely woven materials, a floor can be cleaned at the same time as the carpet, hangings can be rendered dust-free without taking them down, and dirt can be extracted from upholstered furniture or bedding without removing the covers.

There is a great choice of these cleaners available. Improvements have rendered most of them capable of removing embedded as well as surface dirt. Also, by means of various accessories, such as special brushes for polished wood floors and linoleum, and others for ledges, different sized nozzles, including a large one for carpets, a smaller one for upholstery and in some models a bookcase nozzle, a complete house-cleaning system is devised. There are two main shapes, the handle type such as that illustrated in Figs. 1 and 2, in which the dust-bag hangs on the handle, and the enclosed bag type protected by a light metal case.

Vacuum Cleaner. Fig. 1. Non-electric vacuum cleaner which can be used for cleaning carpets, and also with the various attachments for cleaning furniture, walls, beds, and curtains. (Courtesy of The Vacdus Engineering Co., Ltd., Northampton)

A variation of the latter type possesses an upright metal container and a patent hinged nozzle, as is shown in Fig. 3.

Non-Electric Cleaners. Most of the vacuum cleaners are electrically operated. Where electric current is not available a non-electric cleaner can be purchased complete with standard accessory attachments and a three years' guarantee of service. This machine is of the handle type, is built of solid aluminium castings, all parts and accessories being standardised, interchangeable and rust-

proof. In its mechanism there is nothing to slip, with consequent loss of suction, because it is gear-driven on both pedal and floor motion. It is illustrated in Fig. 1.

Another make of suction cleaner for which no electric power is needed is also of the handle type, but without attachments, and can only be used for carpeted floor areas. The bellows type is suitable for small rooms with rugs and for upholstery, and there are inexpensive cleaners of the small pump type which can be used either for floors or upholstery. Nonelectric vacuum cleaners cost nothing to operate, and, in common with electric cleaners, are purchasable on deferred terms. The best makes are fully guaranteed.

Electric Types. Many of the less expensive electric cleaners of British make are excellent value. The handle type illustrated in Fig. 2 is particularly convenient for general cleaning. It may be used at its full length (as seen in the illustration) for carpets and floors, or by simply detaching the long handle the machine can be held in the hand for cleaning upholstered furniture, stairs and for general dusting. The carpet nozzle is fitted with a patent agitator device which picks up cotton and fluff quickly, as well as extracting embedded dirt. In the upholstery cleaning tool the suction is concentrated, and the nozzle reaches every corner. A floor brush is also included with the accessories for polishing plain floors. This is fitted with a buffer band to avoid damage to furniture or skirtings. The dusting brush for ledges and shelves, etc., has long bristles, and the suction behind them gathers in the disturbed dirt. The same company also makes more expensive models in the enclosed dust-bag type of cleaner.

Vacuum Cleaner. Fig. 2. Electric vacuum cleaner with handle. By simply detaching the latter, the machine can be used in the hand for cleaning upholstered furniture, stairs and for dusting. (British Vacuum Cleaner & Engineering Co., Ltd.)

Cleaners vary much in weight, especially those of the metal-enclosed dust-bag type. Made with a flexible hose and without a handle, such cleaners are very useful for rooms with much furniture and houses with many stairs. The light-weight models are particularly convenient for the latter, as some of the handle machines are large for placing on a step. In the case of much furniture time is saved by the use of such a cleaner as the one illustrated in Fig. 3. It is possible by means of the flexible hose to get under and round the pieces without moving them.

Fig. 3. In this model the usual type of dust-bag is replaced by a sanitary steel canister. Another fixture which makes for efficiency is the patent hinged nozzle. (Tellus Super Vacuum Cleaner Ltd.)

In a house with many delicate ornaments, carved surfaces or radiators a vacuum cleaner which possesses a blowing apparatus is advantageous. The air jet is reversed, and instead of being sucked in, the dust is blown out of such inaccessible places as the inside of a piano or behind gratings. A damp cloth should be placed to catch the dust as it is disturbed.

Two developments of interest are quietness in operation and a disinfecting pad impregnated with a pleasantly scented germicide.

With the accessories included in the outfit, the vacuum cleaners provided with this air purification feature not only clean but to some extent disinfect. The dust-laden air drawn from the room is cleaned and purified.

The enclosed bag type of cleaner is provided with a storage case for the safe retention of the complete apparatus with special clips for each accessory. Unless a separate polisher is used, this type of cleaner is not so suitable where there are large polished floor areas as a handle cleaner with polishing attachment.

When using electric vacuum cleaners it is not desirable to obtain current by means of an adaptor inserted into a pendant lamp-holder. Plugs and sockets on the skirting board of room or staircase landing are the correct means of connexion. Note the position of the wall socket for the vacuum cleaner at the foot of the stairs in Fig. 8 of the article on Staircase.

As guarantees are given with all the best makes of vacuum cleaners, no amateur attempt should be made to repair any deficiency or breakage. Various machines depend for efficiency on proper oiling, and the housewife should thoroughly understand this at time of purchase; also the correct method for assembling and detaching the various parts and accessories.

The lubrication of the electric motor is arranged for by the manufacturers, and the grease cups require refilling only at long intervals. This job should be attended to by the makers' agent, or the local electrical engineer shop.

VACUUM FLASK. Vacuum flasks refer to those which are made with the purpose of maintaining the temperature of liquids put into them, either hot or cold. This is done by surrounding the containing vessel with an outside shell, a space being left between, and the air eliminated from this space.

Before a vacuum flask is filled with any beverage it should be rinsed with boiling or cold water, according to the temperature of the drink to be carried. This will keep the latter cooler or hotter than it would be if poured directly into the flask. After use, the flask should be washed out with hot water and left to dry at the side of the stove. If it has held milk, the washing process should be repeated several times to prevent a sour odour from clinging to it. When the flask is not in use the cork should be removed.

Vacuum jars and jugs are purchasable in various shapes and sizes. The jars are made with wide openings to permit easy filling and cleaning, and can be used for keeping soups, stews, or any other food hot, or to maintain ice cream in a proper condition. *See Picnic.*

VALANCE. The box-pleated or gathered frill which surmounts the curtains of a window or other opening is called a valance. It may be fixed to a pelmet board, or to a valance extension supplied with a gliding curtain rail.

Valances round the frame and canopy of a bed are seldom seen except on the 18th century style of bed. The effect of a valance is now obtained, when desirable, with a pleated frill at either side of the bedspread.

VALERIAN: The Plant. Most of the valerians are of little value in the garden, but *Valeriana Phu aurea* is an exception. It grows 2 ft. high, has yellow leaves and white flowers in late summer. It flourishes in ordinary garden soil. The roots of *Valeriana officinalis*, 3 ft. high, bearing rose pink flowers in summer, are of medicinal value.

Uses of the Drug. Valerian root is a drug with a characteristic, highly disagreeable smell and an unpleasant taste. It is chiefly used in medicine in the treatment of hysteria and similar nervous conditions, sometimes with striking effect.

VALLAURIS WARE. Two types of French pottery are associated with the village of Vallauris, near Cannes. One of these consists of kitchen utensils, including a porous terra cotta, often covered with an opaque green glaze, with or without floral decorations.

A more important class of decorated faience comprises the majolica and lustred ware developed especially by the Massier family. Discarding the conventional shapes introduced from China, the Vallauris potter, Clement Massier, based his patterns upon the Greek vases, and decorated them in brilliant colours resembling old oriental lustre and medieval majolica.

The ware, usually a lead-glazed soft-paste, comprises ornaments covered with lustrous fish-scales, peacock feathers, etc., or with silvered lustre enriched with colour glazes.

VALLOTA. This is an alternative name for the half-hardy greenhouse or room window evergreen flowering bulb known as the Scarborough lily. *See* Scarborough Lily.

VALSE. This is the French name for the dance more usually spoken of as a waltz. It is used considerably in music for works which are written in waltz time, such as Chopin's waltzes. *See* Dancing; Waltz.

Valves for Wireless Receivers

The Different Kinds: Their Characteristics and Uses

This contribution deals in a thorough yet concise manner with the types of thermionic valve in use.

After a brief account of the basic principles upon which valves work, information is given about the various types and their function in a modern receiving set. Finally the reader is told how to select valves for given purposes, and how to read the characteristic curves which are issued by manufacturers. *See* Broadcast Receiving Set; Detector; Filament; Grid; Rectifier; Wireless Reception; and other relevant entries.

The thermionic valve (called vacuum tube in America) is the heart of the wireless receiver. It transforms electrical energy developed in a receiving aerial by the ether waves of a broadcasting station into a form suitable for working a loudspeaker, and it has the power to magnify it.

With modern valves there is no theoretical limit to the magnification which can be obtained. A wireless signal can be magnified hundreds of thousands of times; the practical limitation is that beyond a certain point parasitic disturbances are also magnified to such an extent as to interfere.

The first valve, devised by Sir Ambrose Fleming, was, however, only a "detector." In effect, it comprised an electric light bulb with a separate plate of metal, in addition to the filament, from which a wire was led through the glass.

Fleming had made the important discovery that from a heated filament of wire enclosed in a vacuum there was "boiled off" a cloud of minute particles much smaller than atoms to which, later, the name of electrons was given. These electrons are particles of negative electricity. When, as in the Fleming valve, a plate of metal is present near the heated filament, these electrons will flow to it and form a path conductive to an electric current between the filament and this plate.

But current can pass across it only in the one direction, from filament to "plate."

Therefore, if these two electrodes (filament and plate) are connected in a circuit to which is fed an alternating electric current (i.e. a current which flows first in one direction and then the other) the device acts as a valve by allowing the current to flow only the one way. In a modern radio receiver this simple form of valve is used for changing high-frequency alternating current into uni-directional current (diode detection) suitable, after amplification, for working a loudspeaker, and the supply from alternating current mains (A.C.) into direct current (D.C.) and this process is referred to as "rectification." Thus, diode detector valves and rectifier valves are direct developments of the Fleming valve.

Wireless Valve. Fig. 1 (left). A range of Ferranti modern battery valves. The glass bulbs of the Screened Grid and H.F. Pentode valves are "metallized" to provide screening. Fig. 2 (below). Chassis of a modern Mains Superheterodyne set (Cossor 584), fitted with Triode-Hexode, H.F. Pentode (intermediate amplification). Double Diode Triode (detection, amplification and Automatic Volume Control), and L.F. Output Pentode.

It was subsequently discovered that if a third electrode consisting of spiral or mesh of wire were interposed between the plate and the filament, the electron stream flowing between these two electrodes could be varied in intensity by applying varying voltages to the intervening and third electrode.

It was further observed that small voltage variations applied in this manner produced relatively larger voltage variations across the filament and plate of the current flowing from a battery over the filament-plate electron "bridge." The insertion of a "grid" thus enabled the valve to act as an amplifier.

The grid volts-anode current "characteristic curve" of a three-electrode valve is a simple graph which shows at a glance the plate (anode) current flow for a given grid voltage. It reveals that as the grid is made increasingly negative so the anode current falls. A positive grid voltage increases the anode current. A limit is set to this increase by the "saturation point" of the valve. This is equivalent to the maximum emissions of electrons from the filament. The emission can be made greater by raising the anode supply voltage (H.T. battery or mains) but there is a practical maximum for any given valve.

Classes of Valves. Valves are divided into two main groups, battery and mains valves. Battery valves are fitted with filaments which can be heated by a 2-volt accumulator, and the current taken will vary with different types of valves from about 1/10 to 1/3 ampere.

A copious electron emission is ensured, even although the filament reaches only a red heat, by the use of special metallic compounds in the manufacture of the filament.

In a mains valve the filament, or cathode as it is more correctly described, is heated either directly or indirectly by the mains current. Direct heating has, however, almost entirely disappeared, and the principle is now restricted to mains rectifiers, certain output and other valves for special purposes.

The cathode of the indirectly heated valve has no direct series connexion with the mains current. It is heated, by radiation, through an electrically-insulating material such as porcelain, from a "heater" substantially similar to one of the heating elements of an electrical fire, though it is, of course, very much smaller and is enclosed first by the porcelain (or other such material) and then the cathode. In one representative type of indirectly heated mains valve the cathode is a nickel tube coated with a mixture of barium and strontium oxides from which, at a dull red heat, a generous flow of electrons is emitted. There is no hard and fast standardization of heater voltages and currents for indirectly heated valves in wireless receivers. For ordinary sets designed to work on A.C. mains the heater voltage may be 4 or 6·3 volts and the current taken anything between 0·1 and 1 or 2 amperes.

Normally, the heaters of the valves in an A.C. set are wired in parallel and fed by a low-voltage secondary winding on the mains transformer. For working on D.C. mains there used to be special D.C. valves, but universal valves (AC/DC types) have now almost completely replaced them. These are mainly for use in universal sets which, able to operate D.C. or A.C. mains, have rendered the D.C. receiver obsolescent.

AC/DC valves usually have 13- or 26-volt heaters which take a certain constant current. This may be, for example, 0·2 ampere. When used in a universal type of receiver the heaters are joined in series. By means of a resistance the current is then adjusted to the required constant value on either D.C. or A.C. mains.

The 13-volt AC/DC valves are sometimes applied to car radio receivers, the car accumulator (12 volts) supplying the heaters which are, for this special purpose, joined in parallel. The current-adjusting resistance is not necessary in such a circumstance.

Types of Valves

There are scores of different types of valves, and every conceivable requirement encountered in modern radio receiver design can be satisfied by a valve of exactly suitable type. At first sight the characteristics of similar types in cases do not appear to reveal substantial differences, but the performance of any set cannot reach maximum efficiency unless the valves for which it was designed are used.

Diodes. These each contain only an anode and a cathode and are used either for detection or for A.C. mains current rectification. The half-wave type of rectifier is a straightforward diode of suitable design. More frequently there are two anodes in a rectifier valve in order that full-wave rectification can be carried out. That is, both the half-cycles of the A.C. supply are used instead of, as in halfwave rectification, the one half-cycle being suppressed by the "valve" action of a diode.

Triodes. These are 3-electrode valves possessing a grid either in the form of a mesh or spiral of wire interposed between the cathode and anode. Triodes can be employed as detectors (q.v.) and substantial amplification, obtained by means of the reaction or "feeding-back" principle (q.v.). Triodes are also used for magnifying impulses at low frequency subsequent to detection. Triodes are not suitable for amplification at high frequency, as they would permit an undesired reaction effect and cause instability. In order to prevent this feeding-back of energy from the anode circuit to the grid circuit (this occurs much more readily with H.F. currents), a second grid is introduced between the anode and "control" grid. Thus we have the Tetrode or Screened Grid Valve. The "screening" grid is connected to a tapping from the H.T. supply (H.T. battery in the case of a battery set). It is, therefore, given a positive charge which assists the electron stream on its way to the anode. It does

not divert it as the anode is given a still higher positive charge. By being taken direct to the H.T. supply this second grid is, from the point of view of the H.F. circuits, connected to the "earth line" of the set and, therefore, neutralizes the capacity coupling that would otherwise exist between the "control" grid and the anode, and which would cause undesired feeding-back.

Fig. 3 (left). Osram mains-operated Screened Grid. Fig. 4 (right). Marconi X63 Heptode. Both have an Octal type base.

The Pentode. This is a development from the screen-grid valve and has a third grid which, in most cases, is connected internally to the cathode of the valve. The purpose of this "suppressor" grid is to suppress the emission of secondary electrons from the cathode. This tends to occur as a result of the bombardment of the anode by electrons from the cathode.

Variable-mu Tetrodes and Pentodes. The term "mu" (Greek μ) denotes the amplification factor of a valve. Special tetrodes and pentodes are made whose amplifying powers can be varied by applying biasing potentials to their grids. Thus the volume is controlled by adjusting the sensitivity of the receiver. As a further aid to

effective Automatic Volume Control, "short-base" variable-mu tetrodes and pentodes have been introduced for use in H.F. stages. With these a very small change in the grid-biasing voltage makes a big change in amplification.

Double-Diode Triode. The combination of two-diode and one-triode valves in the same bulb with the one common cathode. It is a valve used mostly in superheterodyne types of set. One diode detects, the other is employed in the automatic volume controlling circuit, and the triode is used for L.F. amplification. The Double-Diode Pentode is similar except that instead of a triode for L.F. amplification there is a pentode section.

Class B Valve. A combination of two valves for use in the double output section of a special push-pull type of circuit for economical battery operation.

Triode Pentode, Triode Hexode, Heptode, and Pentagrid are combination valves acting as "oscillators" and "mixers" and, in cases, intermediate frequency amplifiers in superheterodyne receivers (q.v.).

Bases and Holders. Many different types of bases are fitted to valves. The most widely used in this country comprise groups of from 4 to 9 pins for insertion in holders of appropriate design. Normally these pins are so disposed that it is possible to insert the valve only in the correct manner. In the Octal base the pins are equally spaced, but there is a central projection from the base which has a key section to facilitate the insertion of the valve in its correctly oriented position.

Performance of Valves. The amplification factor of a valve gives its theoretical efficiency as an amplifier in that it states the ratio of anode voltage change to grid voltage change. For example, if

the voltage on the grid were changed to the extent of one volt and that produced a change of 10 volts on the anode, then the amplification factor would be 10.

In practice, however, the “goodness” of a valve cannot be measured in those terms. Impedance must be taken into account. This is its internal A.C. resistance between cathode and anode under operating conditions.

The “goodness” of a valve is more definitely expressed in its mutual conductance, or “slope” as it is sometimes called. This is its rate of change in Anode Current to the change in grid voltage which produces it, the applied voltage of the anode current remaining constant. It is usually given in mA/V (milliampères/volts).

The superiority in performance of mains types of valves over equivalent battery valves is indicated by their greater Mutual Conductances. In modern battery valves mutual conductances of 2 and slightly over are achieved, though in mains types 5 and 6 by no means represent unusually high figures.

No valve performs its work unaided; in practice, before its performance can be assessed the practical circuit conditions associated with it must be taken into account. The term Stage Gain is used to denote the amplification of a single valve and its circuit as distinct from the magnification given by the valve itself. The stage gain therefore depends upon the values of the components used with the valve and the efficiency with which they perform their specific functions. It is in stage gain that the only real difference between American and British set design is evident. The American designer usually works to low stage gain. He prefers to have a larger number of valves each giving a comparatively low magnification. The tendency in British design always has been to obtain the utmost efficiency from each valve.

That is why in the U.S. 12- and 15-valve sets are quite common, and sometimes standard American radio receivers will have as many as 20 valves, whereas 4 represents the average number of valves per set in this country. This does not apply to television sets, for which designers are forced to employ a plurality of valves to deal with both vision and sound and the various time-base circuits for building up the pictures.

The factors directly governing the suitability of any valve in a particular stage in a receiver are its impedance and its input limitations.

Clearly it must be able to handle, without “overloading,” the maximum energy passed on to it from the preceding stage.

Its impedance should be such that it suitably adapts itself to that section of the circuit with which its anode is associated. It is generally desirable that valves used for H.F. amplification should possess very high impedances, so that the least possible damping of the H.F. circuits occurs.

An H.F. screened grid or pentode valve may have an impedance of as much as one million ohms. Ordinary triode detector valves normally possess impedances of from ten to twenty thousand ohms. It is especially important that the last or output valve of a set should be “matched” with the loudspeaker if the power output and quality are to be as high as possible. Valve-makers generally give the “optimum loads” in ohms for their output valves. The “optimum load” is the exact impedance that the output circuit should have in order that the maximum undistorted output can be given.

The operating conditions demanded by a valve before it will function correctly are that its grid should be biased and a voltage impressed upon its anode in strict accordance with the valve-maker’s instructions. The biasing of the grid is particularly important in regard to battery valves used as low-frequency amplifiers. It sets the anode current for a given high-tension anode voltage at the most economical and efficient value. Divergencies in either anode voltages or grid-bias voltages can result in an undue consumption of H.T. voltage, reduced amplifying effectiveness and distortion.

Valve Troubles. One of the commonest sources of trouble is the loosening of a valve in its holder or the pins of a valve becoming dirty and making bad contact with the holder socket. Severe crackling disturbances or a complete breakdown of reception can result through these easily rectified faults. A general decline in the performance of a set, or marked distortion, may be due to one or more of the valves losing emission. A valve should be replaced when its anode current for a given anode voltage and grid voltage falls by more than 25%. As listeners are not usually able to test their valves for emission they are advised to hand them to a radio dealer for this purpose if they

suspect them of having aged in this way. Most radio dealers run a free valve-testing service.

Fig. 5. Graph showing the grid volts and anode current curve. (Courtesy of "The Wireless World")

During the first few hundred hours of use the efficiency of some valves may actually tend to increase. This is because a valve works best in a very high vacuum. The degree of vacuum may rise during a valve's first period of life. A falling-off of vacuum is, however, to be expected owing to grid emission as the device ages.

Distortion will occur if any one or more of the valves used in a set is overloaded. Overloading is less likely to occur in a set fitted with Automatic Volume Control so long as none of the valves has lost its emission or is incorrectly biased.

VALVES IN MOTOR VEHICLES

Practical Information About the Different Types

This is one of a group of articles in our work which deals with various parts of the motor car. The reader is therefore referred to such headings as Exhaust; Four-stroke; Internal Combustion Engine; Motor Car. See also Pump.

The flow of a liquid or gas through a port or opening is always controlled by a valve, of which many types are in use. To the motorist the inlet and exhaust valves, which control the working of the engine cylinders, are probably the most important and certainly call for most care and attention. Other valves, though essential, so seldom even require inspection that their presence is apt to be overlooked. Among these may be mentioned tire valves, the carburetter throttle valve and needle valve, the valves in the Autovac or in the fuel pump, and ball and similar one-way or non-return valves used in the engine lubrication system, in tire pumps, in grease nipples, and in the grease gun. Only engine valves and tire valves will here be considered in detail.

When the internal combustion engine was first applied to the propulsion of vehicles, experiments were made with valves of various types, but only the sleeve valve and the ordinary lift valve now survive.

The usual conical lift valves, known also as mushroom or poppet valves, consist of a head with a narrow conical face and a stem working in a guide. The head and the stem merge into one another with a good radius to facilitate the flow of the gases and to avoid the possibility of the stem breaking off under the head.

The several ways in which the valves may be arranged in relation to the engine cylinder are shown diagrammatically in Fig. 1. The side valve engine shown at B is to-day used as widely as the overhead valve type shown at C and D. In the former, the combustion chamber extends from the cylinder over the exhaust and inlet valves which are arranged side by side (one only being shown), and both being operated from separate cams on the same camshaft. The overhead valve engine gives a more compact combustion chamber, the valves being inverted so that they open down wards. Two methods are adopted for valve operation. In one method, shown at C, the exhaust and inlet valves are both opened by rocking levers, mounted side by side on a fixed shaft, each being operated from a separate cam. The

Valve. Fig. 1. Diagram showing various methods in which valves may be arranged. B, popular L-head or side-by-side arrangement. C and D, two types of overhead valve design

camshaft is some way

above the crankshaft, from which it has to be driven at half speed, various methods of driving being adopted, such as a vertical shaft with skew or bevel gearing on the upper and lower ends, or chain gearing with or without toothed gearing. In the push rod construction shown at D only one valve is visible, the other being arranged in line with it.

A detailed section of the popular side valve engine is shown in Fig. 2, the combustion chamber being shown as formed in the detachable head. The stem of the valve works in a bush, *e*, pressed into the main casting. A coiled or helical valve spring *f* abuts at its upper end against a flange on the bush *e*, while its lower end engages a washer *g* of special shape which is secured to the lower end of the valve stem by a cotter. The valve is raised from its seat, when required, by the cam *b*. The cam engages the lower end of the sliding tappet *c*, the upper end of which lifts the valve. In some constructions the lower end of the tappet carries a roller which runs on the camshaft, but more frequently it is provided with a disk shaped end, as shown. The tappet is free to rotate so that wear is distributed all over the face of the disk. A stem *d* may be screwed into and out of the upper end of the tappet in order to vary the clearance between the head of this screw and the lower end of the valve stem.

Fig. 2. Arrangement with sliding tappet in side valve engine

The screw, after it has been adjusted, is secured in position by a locknut. A small but definite clearance must always be left to ensure that the valve can engage its seat properly, except when it is lifted by the cam. The tappet should always be set to give the clearance specified by the makers. In side valve engines this is usually of the order of $\cdot 004$ in., when the engine is cold. Greater clearance will create noise and may, if excessive, cause wear and affect the running of the engine. A smaller clearance will probably, when the engine is hot, result in the valve not seating properly, and in that case there will be some loss of power, while the valve face and the valve seat will certainly be damaged by the leakage past them of the flaming gases.

The recesses in the cylinder casting in which the springs and the upper ends of the tappets work are closed by covers *h* which serve to reduce noise, to keep out dust, and to prevent splashing of oil.

Valves were at one time made with cast iron heads into which steel stems were screwed, for the reason that cast iron withstands the destructive effect of the flaming exhaust gases better than ordinary steel. All valves are, however, now constructed with the body and head in one, from special alloy steel adapted to resist corrosion.

The helical springs work under very severe conditions, since they have to be designed to fit into a very limited space and consequently have a smaller factor of safety than is desirable; that is to say, the load to which they are subjected is too near the breaking load. This may result in their failure by fatigue, due to the many millions of times they are compressed, even though their working load is well below their customary breaking load. Special alloy steels having fatigue-resisting properties are therefore employed for valve springs.

A section through an engine in which overhead valves are operated by push rods is shown in Fig. 3,

Fig. 3. Overhead valve engine with push-rod operation. Fig. 4. Three types of valve lifters that may be set and left unattended. Fig. 5. Double sleeve valve Daimler engine; in which inlet and exhaust ports are opened and closed by sleeves

one valve only being shown. The combustion chamber *a* is in this case formed as a recess in the detachable cylinder head and the inverted valves are raised up on to their seats each by a spring *b*. The train of mechanism between the camshaft and the valve includes a sliding tappet *c*, a push rod *d*, and a rocking lever *e*, pivoted at or about its centre. The push rod is tubular for lightness and it operates the rocking lever *e* through a ball-and-socket joint, which allows freedom of movement. The ball is carried on the end of a screw, by means of which the valve or tappet clearance may be adjusted, the screw being then clamped in position, or held by a lock nut as shown. The valve or tappet clearances necessary in overhead valve engines are generally slightly higher than those that are found in side valve engines. The push rods pass with complete freedom through openings in the detachable head. The rocking levers are in nearly all cases lubricated automatically and the operating gear is protected by a cover, but it is well with many engines occasionally to remove the cover and use the oil can to ensure that some oil reaches all the working parts such as valve stems and

the ends of rocking levers.

Whenever an engine is decarbonized it is desirable that the valves should be ground in until all marks are removed. If this operation is neglected there is considerable risk that the pitting marks will penetrate somewhat deeply and that a considerable amount of metal will have to be removed at a later stage when truing up the valves. In order to detach the valve it is necessary first to compress the valve spring and collar or washer so that the cotter pin or similar securing device may be removed from the stem, after which the valve may be removed. The spring is in nearly all cases too stiff to be compressed by the fingers, and a proper valve lifter or valve spring compressor saves a great deal of time. Many different designs of valve lifter are available for this purpose; examples being shown in Fig. 4. The valve should be down on its seat before the valve lifter is brought into use, and the forked end of the lever should be placed squarely in position under the spring collar to avoid the valve rising with the spring when it is compressed. The collar when lifted clear allows the cotter pin to be readily removed. The valve and lifter may then be taken out together or the spring may be released, but this should always be done gradually.

Sleeve Valve Engines

The sudden and jerky operation of the ordinary lift valve has stimulated attempts to replace it by valves having a more continuous movement, but practically the only successful alternative is the sleeve valve.

A section through a Daimler double-sleeve engine is shown in Fig. 5. In this construction the piston moves up and down within a thin steel sleeve or tube *a*, which is also given a short vertical travel by a rod connected to a small crank on a shaft driven at half-engine speed. Between the inner sleeve *a* and the main cylinder casting is interposed an additional sleeve *c* which is similarly reciprocated by a connecting rod *b*, from the half-time shaft. The up and down movements of the two sleeves are out of phase, but they co-operate to ensure quick opening and closing of the ports connecting the cylinder to the inlet and the exhaust passages.

Sleeve valve engines are very silent in operation and valve grinding, and valve adjustments are quite unnecessary. The rate of oil consumption is, however, somewhat higher than in poppet valve engines, this being indicated, particularly when starting, by blue smoke from the exhaust.

In single sleeve valve engines the sleeve is interposed between the piston and the cylinder casting. It receives an elliptical movement, being operated at half-engine speed from a crank in such a way that it is moved both up and down and is given a small amount of rotation.

Tire Valves. Valves used for tire inflation are always of the non-return type, and since there must be no air leakage, although the pressure may be considerable, a rubber seal or seat is always used. In the ordinary cycle type construction shown in Fig. 6 the stem which projects inwards is covered by a short length of thin rubber tube. When the valve cap is removed air may be forced upwards through the centre of the stem and then sideways through a small hole which opens

Fig. 6. Showing construction of a cycle type valve. Fig. 7. Schrader tire valve; valve unit, shown separately at A, is readily removable

against the inside of the rubber tube. The tube is thereby lifted and air flows into the tire but the tube prevents any return of air through the stem.

On motor car and motor cycle tires the Schrader valve shown in Fig. 7 is generally employed. The valve and its seat are shown separately at A and form a complete unit, which may be screwed into the stem *b* when the cap *c* is removed, by means of a slot *d*, in the head of the cap. The two main parts of the valve unit include: (1) a screw *e*, and a conical rubber plug *f*, which engages a conical seat in the stem; and (2) a metal ring *g*, enclosing a rubber valve *h*, which bears on the metal seat *j*. The parts *g* and *h* are secured to a wire stem running from end to end with some clearance where it passes through the part *e*, *j*, *g*. The valve *h* is forced on to its seat *j*, by the pressure in the tire, but is lifted off during inflation by air forced through the space between the stem *k*, the screw *e*, and plug *f*. These valves are practically impossible to repair, and on the rare occasions when trouble develops new ones should be fitted.

VANILLA: The Plant. The vanilla is a hothouse climbing orchid, which may be grown in pots in the hothouse and trained up the rafters. The flowers are borne in summer, and are followed by seed pods which are from 4 in. to 6 in. in length. Water freely during the hot months, but only occasionally during the cold weather.

The vanilla plant grows best in a mixture of peat and sphagnum moss, and the pots or pans should be well drained with clean crocks. *See Orchid.*

VANILLA: The Flavouring. The dried pods of the vanilla plant, which are used in cookery and confectionery as a flavouring, are about 7 in. long and dark brown in colour, the best qualities being nearly black. A small piece of the dried pod, or bean, as it is often called, if broken off and added to milk or cream imparts a delicate aromatic flavour.

The extract is commonly used for household purposes, but, although more convenient, it does not possess the same qualities for flavouring that belong to the bean itself. The housewife should carefully avoid all cheap extracts of vanilla, as they have not the true vanilla flavour. Vanilla is a favourite flavouring for ices, custards, blancmange, caramels and other sweets, biscuits, and small fancy cakes.

Vanilla Sauce. To $\frac{1}{2}$ pt. white foundation sauce add 2 teaspoonfuls castor sugar. After cooking the sauce, as described in the article under that heading, add vanilla essence to taste, and serve in a hot tureen.

Vanilla Shape. An inexpensive and quickly prepared sweet, this is made in the following way: Heat up 1 pt. milk, dissolve in it $\frac{1}{2}$ oz. sheet gelatine, and then add the beaten yolks of two eggs and sugar and vanilla flavouring to taste. The milk must not be boiling, otherwise the eggs will curdle. Lastly, beat in the stiffly whipped white of egg and the strained juice of a lemon, pour the whole into a fancy mould previously rinsed with cold water, and leave it to set. When firm, turn it out and serve it with thick cold custard or whipped cream.

Vanilla Wafer. Sieve $\frac{1}{2}$ lb. flour and $\frac{1}{2}$ teaspoonful salt into a basin and make a well in the centre. Beat up the yolks of 2 eggs, add to them 1 teaspoonful cold water, and then pour them into the centre of the flour, working in as much of the latter as the eggs will take up. Then add gradually enough water to mix the whole to a stiff dough, turn the latter on to a floured board, and knead it for about 10 min. or until the dough is smooth and soft.

Roll it out very thinly, stamp it into rounds or fancy shapes, and bake these in a hot oven on a slightly floured baking-tin for 5 to 8 min. or until they are yellowish-brown in colour. When they are done, brush them over with the whipped white of egg, dip them in powdered icing sugar, and put them back into the oven for 2 or 3 min., when they will be ready to serve.

VANISHING CREAM. Unlike cold cream and other similar toilet preparations, vanishing cream is non-greasy, and is used by many women as a basis for face powder.

VAPORIZER. The appliance known as a vaporizer is used for converting a combustible liquid into a gaseous state. In its domestic applications the vaporizer is limited chiefly to apparatus for generating light or heat. The usual plan is to force a small quantity of the liquid through a restricted space, as, for example, a fine bore tube, or block of metal with small-sized holes through it, which has been heated to a sufficiently high temperature to convert the liquid into gas.

Another plan is to force the liquid through a spiral tube on to a revolving vane, which, by distributing it over a large area, breaks it up into fine particles, forming a gaseous mixture when air is added. By a third method the liquid is allowed to flow by gravity into a chamber, the lower portion of which is filled with absorbent material, such as asbestos wick or some special form of porous brick. This becomes moistened with the liquid, which on exposure to the air is given off as vapour.

The name vaporizer is also given to an arrangement of various kinds for producing a fine spray of some liquid. *See* Air Gas; Blow Lamp; Cooker Lamp; Oil; Sprayer.

VAPOUR BATH. In chills, oncoming colds, rheumatism, certain diseases of the kidneys, and other conditions for which it is desirable to produce free perspiration, vapour baths may be used for the purpose. Some skin diseases, such as psoriasis, and types of eczema may also be benefited by a course of these baths. As they are, however, very depressing in their effect, no person who has a weak heart should take them without medical advice.

A simple arrangement for taking a hot vapour bath at home is to sit on a wooden chair placed over a large pan containing a few inches of hot water. Blankets should then be draped over the body, chair, and pan in the form of a tent, the body acting as the tent pole. Someone should then lift up one corner of the blanket, and place in the hot water (by the aid of some fire-tongs) a brick which has been heated in the fire. As the steam from the first brick subsides another may be added, until, after about 10 min., a profuse perspiration breaks out. This may be followed by a cold plunge. *See* Turkish Bath.

VAPOURER MOTH. The caterpillars of this moth attack the foliage of a great variety of plants, including most of the fruit trees, and a large variety of other trees. They also devour herbaceous plants in garden and greenhouse, and may be described as general feeders.

Vapourer Moth, the caterpillars of which attack both greenhouse and garden plants

The following method of dealing with this pest is in Leaflet 25, issued by the Ministry of Agriculture. The cocoons with eggs may be destroyed during the winter. The caterpillars which are conspicuous may be dealt with by hand picking if spraying is not desirable, or shaken off their food plant and destroyed from May to September.

Attacked plants may be sprayed with lead arsenate to poison the foliage on which the caterpillars are feeding. The formula is $\frac{1}{2}$ lb. of lead arsenate paste dissolved in 10 to 12 gallons of water. The

females being wingless and moving very little, the species can only spread in the caterpillar stage. *See* Fruit; Insecticide; Pear; Spraying.

VARICOSE VEIN. From a variety of causes veins often become dilated and tortuous, when they are said to be varicose. The most common site is in the legs. Policemen, shop assistants, washerwomen, and others whose work involves standing for most of the day are the principal victims. Tight garters and constipation, where frequent and prolonged may have the same result. Thrombosis, that is, the formation of a blood-clot which results from inflammation of the vein, may sometimes block the vessel and cause dilatation of the veins below. Pregnancy and pelvis tumours are other causes. Once the swelling begins it tends to increase. Ulcers may develop and be very difficult to heal.

Garters should never be worn in any circumstances. Constipation should be prevented. Long standing must be avoided, and in the evening or at intervals during the day it is well to sit or lie on a couch and raise the legs. Exercise is necessary, but should be moderate. Cycling is one of the best forms, and some people find improvement follows dancing if not carried to excess.

So long as the veins do not give trouble or increase much in size nothing more may be necessary. Very often, however, some support is needed. If an elastic stocking is worn it should be of a good quality and a perfect fit. When bandages are used, the patient must learn to apply them properly. Any support, whether stocking or bandage, should be put on before getting out of bed and only removed at night while lying down in bed.

When the veins become painful, when ulceration or eczema is likely to ensue, or when the veins adhere to the skin and the risk of rupture arises, a radical cure should be sought. This may be procured by operation, but most people prefer to have their veins treated with injections of sodium salicylate or some other substance that produces a firm clot and thus closes it. *See* Elastic Stocking; Thrombosis; Ulcer.

VARIEGATION: In Plants. There are many variegated or coloured-leaved varieties of various shrubs, and plants which normally have green leaves. The leaf colouring is usually white and green, yellow and green, or cream and green, though there is a purplish tinge in some. Familiar examples are the variegated aspidistra, euonymus, privet, india-rubber plant and tradescantia. The leaves are liable to lose their colouring if the plants are grown in rich soil. *See* India-rubber Plant.

VARNISH AND VARNISHING

How the Amateur Can Obtain the Best Results

In this contribution, after an account of the kinds of varnish suitable for home use, the process of varnishing is described. Allied information will be found in the entries on the woods, fixtures and pieces of furniture that are varnished, e.g. Door; Floor; Oak; Table. *See* also Brush; Enamel; Paint; Sprayer; Stain.

Varnish is a transparent liquid used to form a protective coating with a glossy finish on woodwork and other material. It is applied with a brush or sometimes a spray, and after the lapse of a period varying in length according to the nature of the ingredients the varnish dries, leaving a hard and glass-like skin on the surface.

Generally speaking, varnishes are composed of oil, alcohol or water into which are dissolved various gums, resins, or colouring substances. Oil varnishes are the best for most house decoration. Spirit varnishes are employed for floors and margins, and are quicker in drying. Both kinds may be obtained ready made, and the best quality should always be used. Cheap varnishes are composed of

poor ingredients, which not only render them difficult of application and cause an uneven and streaky finish, but make the work liable to such blemishes as bloom and a tendency to remain wet.

Varnishes for household use comprise inside and outside. The latter variety is more suited to withstand the effects of the atmosphere, and it may also be used for interior work. Inside varnish should never be used for work out of doors, as it is not only inferior in waterproof qualities, but is apt to peel off when exposed to sunlight. A better class of varnish for outside work where a very good quality of finish is necessary is that known as carriage varnish. These varieties are all made in various shades, white, light or dark oak, pale and dark, the two latter referring to carriage varnish. It is not advisable to apply two consecutive coats of varnishes made by different makers or of a different nature, as in the process of drying one may contract more than the other and so cause the surface to crack and exhibit other blemishes.

To apply varnish successfully requires some experience. This can be obtained by experimenting, and it is advisable for the amateur, before commencing any serious work, to practise on spare pieces of wood. A suitable class of varnish should be selected in accordance with the nature of the work and the position in which it will be exposed.

The Necessary Materials. The materials required are, firstly, two good camel or hog's hair brushes, one of these being wide and flat for wide surfaces, and the other rather smaller for working in corners, etc. The brushes should be kept with the hair in either varnish or linseed oil, and on no account should the varnish be allowed to harden on the bristles. A jar can be used specially for the purpose of storing them, partially filled with oil or varnish. The cork should be a good fit, and have two holes cut through the centre large enough for the brush handles to pass through and tight enough to prevent them dropping right through into the jar. If necessary, a nail may be put loosely through the handle in order to hold the brush. The bristles only should be submerged, and it is a bad practice in all phases of the work to allow the handles to become covered with the varnish. If oil is used to keep the brushes in they should be thoroughly cleansed of the oil before use.

Varnishing a Door. Fig. 1. Working the first coat on the panels with a flat brush. Fig. 2. Using the felting pad between the two coats of varnish. The motion of the hand should be circular.

Two other requirements are glass paper and a felting pad, these being used for rubbing the work down between the coats. The pad consists simply of a piece of felt, and if desired may be mounted on a wooden base; the method of using it is described later. Pumice powder, for use in conjunction with the felting pad, is also needed. Apart from

the bottle or can in which the varnish is stored, an open vessel is required in which to pour the varnish during the actual operation.

For indoor work the chief thing to guard against is a draught. The temperature should be moderate and consistent, and in cases where an open door or window causing a draught is unavoidable a good plan is to use a screen. Another danger to be avoided is dust, which once it clings to wet varnish cannot be removed. In many cases it is necessary to rub the work down with glass paper before

varnishing, and it is essential that the dust caused thereby be allowed to settle and be removed from the work before commencing to varnish.

The Processes Described. When new wood is to be varnished it is first necessary to prepare the surface with size, to prevent the wood from soaking up the varnish and thereby causing it to become blotchy and uneven. If the wood is not stained it should be first glass-papered flat and smooth. Size should then be applied with a brush. If the wood is of a coarse, open nature the size should be rather thicker, and when the whole surface has been coated it should be allowed to dry thoroughly. Care must be taken to prevent the size running into quirks and comers and accumulating, these parts being brushed out with a fairly dry brush.

A small quantity of varnish is poured into the open vessel, just sufficient for the immediate portion of the work to be covered. It is inadvisable to pour out too much, as it is liable to thicken, owing to evaporation.

Varnishing a Door. To get the best results a job like the varnishing of an outer door should be done at a time when there is the least likelihood of dust or disturbance. Probably the early morning would be chosen for the work. After removing any dust and rubbing down any parts which require such treatment, the application of the varnish may be commenced.

The brush is dipped into the varnish to about one-third the length of the bristles and applied straight to the door. A surplus should be avoided so that the brush does not drip. It is worked in the same direction as the grain of the wood with a light pressure, then crosswise once, and finally with single strokes with the grain. It is necessary to work smartly, as the varnish sets fairly quickly. The object in view is to obtain a flat surface free from brush marks. Experience will soon show the worker just how much the varnish may be worked.

As shown in Fig. 1, the panelled portions of the door are varnished first, taking care to work well into the corners and edges. The varnish should be applied in a fair body, but great care must be exercised to avoid running. Having completed the recessed part, the rails and stiles are next attended to. The stiles are first varnished, and the rails last, so that the joints are cleanly finished off. If, on a similar door, mouldings are present, these should be picked in lastly with the smaller brush, being careful to avoid touching the panels or stiles, and working the varnish well out of the corners. The whole should then be left to dry thoroughly.

The same process is adopted when varnishing all kinds of panelled work, working the panels first, then the rails, stiles, and finishing with the mouldings. All the joints in the woodwork should be cleanly finished, so that the brush is always drawn in the same direction as the grain of the wood. The time for drying varies, according to the varnish used and the atmospheric conditions, and this can only be decided by the conditions under which the amateur is working.

Rubbing Down. When thoroughly dry the whole should be rubbed down with the felting pad. This is done by damping the work slightly with a sponge, dipping the felting pad into the pumice powder, and rubbing it on the surface with a circular motion, as in Fig. 2. The quirks and mouldings may be smoothed down with fine glass paper, care being taken not to rub the projections too vigorously, as this may remove the varnish, and when the second coat is applied it will present a patchy appearance owing to the varnish sinking into the bare wood. The whole should be dried with a duster, removing any traces of dust caused by the glass paper.

The second coat is applied in a similar way to the first. If only two coats are desired, this should be finished off as cleanly as possible, the final strokes being always in one direction and the brush only lightly charged. When a third coat is to be applied, this is done in a similar way, rubbing down between each and being sure that the first coat is quite dry before attempting further work. Working

on wet or tacky varnish has the effect of pulling off the previous coat. The process above detailed may be adopted for all outside work.

Re-varnishing woodwork requires a similar process, but it must be remembered that varnish is transparent, and any defects in the under coat will show plainly when the whole is finished, so that if the original varnish is badly damaged it will probably be best entirely to remove it. If, however, it is in fair condition, it should be first thoroughly cleaned with soap and water to remove any dirt and grease. A cotton rag is used for this purpose.

A painted surface may be varnished over, provided that the surface is flat and not glossy. Plenty of turpentine in place of oil should be used in the final coat of paint when intended to be varnished. The process is then similar to that described for new woodwork, except that it is unnecessary to size the work.

For old painted work, the surface should be cleaned with water to which is added soda, and any nail holes or other indentations filled in with putty toned to the required hue with colours ground in oil. The putty is applied with a knife, care being taken not to smear the surrounding surface and to smooth it. If soda is used to clean the work, it should be well rinsed off afterwards with clean water and thoroughly dried. The varnishing may then be carried out.

Treating a Floor. A task which often falls to the home worker is the varnishing of a floor. If the boards are quite bare, it will probably be desired to stain them first. The whole floor, or that part of it to be varnished, should be first well scrubbed, and when dry given a coating of size, and once again left to dry. It is then smoothed down with fine glass paper, and all dust removed, first with a brush and finally with a cotton duster. The area can then be coloured as described in the article on Stain. Assuming an oil stain has been used, a varnish with a similar composition can be employed in much the same manner as described for other work.

The varnish is used freely, and is well worked out, especially at the corners. The best method is to commence at one side and work towards the door when the whole floor is to be coated, as otherwise it may be impossible to leave the room without treading on the wet varnish. If two coats are desired, the first should be allowed to set first, and is then felted down and dusted before the second, in the manner described above.

In cases where a large area has to be dealt with it may be worth while using one of the clear cellulose varnishes, applied by a spray. A portable sprayer with foot pump can be obtained for a quite small outlay, and would soon pay for itself on the many and varied jobs for which it is suitable.

Information on these points will be found in the articles Enamel and Sprayer.

VASE. Though vases may be of china, pottery, marble, jade or other semi-precious stones, of gold, silver, brass, bronze, lead or pewter, of glass or papier-mâché, the classical shapes continue to serve as models even when new forms of decoration are introduced or applied. A glance at our illustrations of beautiful pieces, varying in styles and periods, reveals familiar shapes seen in vases made to-day of ordinary wares, except that Fig. 4 is often copied or adapted in cut glass without the lid.

Richly ornamented, precious metal, or genuine antique vases are either collectors' pieces or have a decorative value only. Apart from the risk of damage or breakage they are not usually even effective as flower vases. For this purpose reproductions in plainer styles of pottery and glass of the classical shapes are most satisfactory. Two other shapes are popular: the straight jar for long stemmed flowers and the globe in glass with a small opening in which it is easy to arrange a few fine blooms.

For table decoration one or two sets of four small vases in iridescent, cut, coloured or engraved glass, in white ware, in green or brown pottery, silver or silver lustre are useful. Whether small or large, flower, vases should be shaped so that proportionately they hold plenty of water.

Glass vases need attention if they are to be kept bright and clean. They are very easily stained by flowers, and soap and water is not always sufficient to remove these stains. They should be cleaned periodically with a little spirit of salt, and if they are fluted, or in any way difficult to reach with a cloth or the hand, a brush or small mop should be used for the purpose. *See China; Copenhagen Ware; Crown Derby; Flowers; Garden Furniture; Glass Ware; Jasper Ware; Pottery; Satsuma Ware; Sealing Wax.*

VASELINE. One of the most useful remedies extensively employed in the home for chapped skin and for various other purposes is vaseline, which is a greasy, whitish-yellow, semi-solid paraffin. It is a useful basis for certain ointments, as it does not become rancid.

VAULTING HORSE. As used in gymnastic exercises, the vaulting horse is made of wood suitably padded and covered with leather and supported on wooden legs which are adjustable as to height. A typical vaulting horse is illustrated in Fig. 1. It has a total length of 6 ft., a width at the top of 16 in., and a height, without extension, of about 3 ft. 3 in. The curved handles, known as pommels, are fitted in the centre, the portion of the horse between the pommels being the saddle. The left-hand pommel is the neck pommel (N.P.), and the left-hand end of the horse is the neck (N.). The right-hand pommel is the croup pommel (C.P.), and the right-hand end of the horse the croup (C.).

The horse is generally used with a spring board, referred to also as the beating board. When the performer is standing so that the shoulders are parallel to the side of the horse, the horse itself is called side horse or horse sideways. Positions in which the line of the shoulders is at right angles to the length of the horse are called cross positions. The side of the horse at which the spring stands is the near side, and the side farthest away from the board the off side.

Vaulting Horse. Fig. 1. Gymnastic appliance which is adjustable to various heights

Fig. 2. Smaller appliance known as a vaulting buck. It is preferable in small gymnasiums

The whole of the upper portion of the horse is covered with hide, and the pommels, which are 17½ in. apart, 4¾ in. above the saddle, 1½ in. diameter, and 4½ in. circumference, are of iron covered with leather, flesh side outside, tightly sewn to the metal. The pommels are removable and are attached by large fly-nuts underneath the saddle. Exercises on the vaulting horse are begun with or without a run, but are always finished in the half-squat position prior to the upright position. The pommels are generally grasped with the hands, back upward, known as the pike grasp, with the palms of the hands slightly beyond the centre of the pommels towards the off side of the horse.

There are less expensive alternatives to the vaulting horse, such as the vaulting buck, in Fig. 2. It consists of a padded top covered with leather or stout canvas and measuring 30 in. by 14 in. by 11 in. high, and supported on four adjustable legs, 1 ft. 9 in., with no extension, and 3 ft. 3 in., with the legs fully extended, the splay at the full height being 3 ft. 6 in. by 3 ft. on the ground. The buck is used for ordinary vaulting exercises, and for small gymnasiums is preferable in many ways to the vaulting horse.

With a Selection of Attractive Recipes

The reader of this article will also be interested in those that describe other joints of meats, e.g. Beef; Mutton; and other items of household food. See also Bacon; Boning; Brawn; Curry; Food; Force meat; Pastry; Soup; Stuffing.

The flesh of the calf is closer in texture than beef or mutton, and on this account it has been said to be less digestible, but when properly handled in the kitchen it is one of the most nutritious and palatable of meats. Veal must be eaten while fresh and requires to be well and judiciously flavoured with a stuffing or lemon, otherwise it is rather tasteless. Bacon or ham should accompany it to make up for the absence of fat.

Veal may be eaten in some forms by invalids. Excellent broth is made from veal and also meat stock for white soups. The superior flavour of calf's head, liver, sweetbread, etc., is well known, while the suet surrounding the kidney is particularly adapted for light boiled puddings or forcemeats.

The calf, when it is killed, should be 8 or 9 weeks old, and never more than 12 weeks. The best roasting pieces are the fillet, loin, and neck, and occasionally the oyster part of the shoulder. For cooking, 20 min. to the lb. is the correct average time.

A fillet of veal from a calf 8 weeks old should weigh just 12 lb., but the butcher will always divide it into two or more portions. It is an economical joint, as there is very little bone and no waste. Before roasting, the centre piece of bone must be removed and the cavity filled with a well flavoured veal stuffing, of which lemon is always a feature. The stuffing must be well secured in the meat either by binding the joint together by tape or skewering it. Loins and necks of veal are not boned before being roasted, but the bones must be jointed carefully. The stuffing should be inserted by separating the skin from the flank from end to end with a sharp knife and forcing it in place, then it should be secured with string.

The outer skin of veal should be protected with a buttered paper or a piece of the caul, and when the joint is almost cooked the protecting paper should be removed, the surface dredged with flour, well basted, and the outside allowed to brown. Veal must be basted frequently while cooking with butter or good dripping provided for the purpose, as the meat possesses little or no fat. Bacon or ham should always accompany roast veal.

Veal Hotch-Potch. Breast of veal makes a good hotch-potch. Use a piece about 5 lb. in weight. Chop the bones so that the breast may be divided into small pieces, and remove all gristle. Put into a frying-pan about 4 oz. butter and bacon fat mixed together. Flour the pieces of veal and fry them in the fat till a light brown, then put them into a casserole and pour on them 2 quarts boiling water. Let all boil up, then add 1 pint green peas, a well-washed cos lettuce cut in strips, 2 blades of mace, 3 cloves and 15 black peppercorns tied up in a piece of muslin, a bouquet garni, and 2 onions cut in rings.

Season with salt and simmer for 3 hours. Before serving remove the bouquet and the bag of spices. In winter-time sprouts or the hearts of small savoy cabbages and celery cut small may be substituted for the green peas and lettuce.

Knuckle of Veal. This may be boiled or stewed, but much depends on the cut of the joint and how much meat accompanies the knuckle. If cut very low down in the leg, always stew it. A joint of 6 lb. will take from 2 to 2½ hours to boil, but much longer in proportion for stewing, even if only 3 to 4 lb. in weight. Veal must always be cooked in plenty of water when boiled; it must be carefully

skimmed and amply flavoured with vegetables. When dished, a sauce should be poured over it into which part of the liquor in which the meat was cooked should be introduced. A small quantity of milk will whiten the sauce and soften it, and it may be finished with parsley, hard-boiled eggs, or, if preferred, it may be left plain.

Veal is a useful meat as the remains of cold joints can be made up into a number of excellent luncheon dishes and entrées. It curries and minces well, makes good rissoles and quenelles, and is excellent in such cold supper dishes as brawn, Cornish pasties, pies, and patties. Recipes for these veal dishes, or recipes which may equally well be adapted to the use of veal, are given under the various headings.

Veal and Ham Croquette. Mince finely $\frac{1}{2}$ lb. cooked veal and ham mixed, allowing about; 6 oz. veal to 2 oz. ham. Add 2 teaspoonfuls grated onion, the same chopped parsley, and a small teaspoonful grated lemon-rind. Mix all these to a creamy consistency with about 1 gill hot, thick white sauce, and season carefully. Turn the mixture on to a plate to cool, shape it into even-sized shapes, such as balls, ovals, pear or cork shapes. Roll these in fine white crumbs, then brush them over with well-beaten egg and give them a second coating of crumbs. Fry the croquettes in plenty of smoking hot fat. Drain, and serve on a fancy dish paper, garnishing with fried parsley.

Veal and Ham Pie. Make some flaky pastry according to the directions given in the general article on Pastry. Roll out to required thickness. Cut $1\frac{1}{2}$ lb. lean veal and $\frac{1}{2}$ lb. lean ham into neat squares, slice 2 or 3 hard-boiled eggs, and use the slices to ornament the sides and bottom of the dish, pressing them in firmly. Put a layer of veal on top, and shake over it a little chopped parsley and some powdered mixed herbs, a little grated lemon-rind and seasoning to taste. Cover these with a layer of ham and continue thus until the dish is full. The last layer should be of ham. Pour in some stock, preferably made from veal bones, half filling the dish with it. Damp the edge of the dish, lay a strip of pastry on it, damp this also, and then cover the pie with the pastry, ornamenting the top with pastry leaves and tassel.

Bake the pie in a hot oven for about two hours. In hot weather a little gelatine should be added to the stock so that it is certain to set in a jelly. To make a raised veal and ham pie see directions for pork pie and the illustration of pie mould.

Veal Force meat. Suet is an important ingredient in stuffing for veal as the fat is essential; 1 oz. shredded suet should be allowed to $1\frac{1}{2}$ oz. breadcrumbs. Chop 4 oz. shredded suet finely, mix with it 6 oz. breadcrumbs, 1 tablespoonful finely chopped parsley, the grated rind of a lemon, 1 teaspoonful mixed herbs, 1 dessertspoonful lemon-juice, 1 pinch nutmeg, pepper and salt to taste, 2 rashers fat bacon minced finely. These ingredients are bound together with a beaten egg and a little milk.

Veal. Underview of a side of veal.

The stuffing when made can either be pressed inside the joint to be stuffed, or, if preferred, formed into balls rolled in flour and baked in the oven.

Veal: some of the joints. Above: forequarter, a joint which cuts up into shoulder, breast and neck; hind quarter, comprising leg and loin; right top, leg and 2 loin shown separately; right, shoulder, a good roasting joint.

Veal Galantine. To make this, take a small breast of veal, 2 lb. pork sausages, $\frac{1}{2}$ lb. cooked ham or bacon, 3 hard-boiled eggs, with a little each of salt, pepper, and nutmeg. Remove all the bones and tendons from the meat and spread it, with the skin downward, on the table. Season the meat carefully with salt, pepper and a little nutmeg. Next remove the skin from the sausages, season the sausage meat, and spread half of it evenly over the veal. Cut the ham and eggs in long strips, and arrange them alternately and evenly down the length of the veal so that when it is rolled up the strips run from end to end.

Season the veal again and then spread on the rest of the sausage mixture. Roll up the veal neatly from side to side and tie it up in a cloth like a roly-poly pudding. Put it in the stock pot and let it simmer gently for 2 or 3 hours. Then untie the cloth, re-roll the meat in it, and place it between two tins or dishes with weights placed at even distances on the top one. Leave it until it is quite cold, then take off the cloth, trim a small piece off each end, and brush it all over with a little melted glaze.

Veal Goulash. This stew is made by slicing a large onion into thin rings, frying it in a stewpan, containing $1\frac{1}{2}$ oz. dripping, and when it is lightly browned adding $1\frac{1}{2}$ lb. lean veal cut into small squares and freed from skin. Put the lid on the pan and cook the meat until it has lost its rawness; then sprinkle in $1\frac{1}{2}$ oz. flour and seasoning to taste, stirring the whole well so that the flour is mixed thoroughly. Pour in about a teacupful of stock and a large glassful of Madeira, and cover the pan again, simmering its contents at the side of the stove, stirring them now and again to prevent burning, and adding more stock if the stew becomes too dry. The time required for cooking is about

2 hours. Half an hour before the stew has finished cooking add four average-sized potatoes cut into small cubes.

Veal Mould. This very serviceable and appetizing dish can be made from 1 lb. uncooked veal, 2 hard-boiled eggs, 4 oz. bacon, a little grated lemon-rind, some mixed herbs, and a little parsley finely chopped. A little seasoning, some salad for garnishing, and a pint of white stock are also necessary.

Grease a mould slightly, cut one egg into slices, and with it decorate the bottom and sides of the mould. Remove any skin or gristle from the veal and cut it and the bacon into small dice; then chop up the other egg. Mix the veal, bacon, egg, herbs, and lemon-rind together, add a little parsley and season it with pepper and salt. Place this in the prepared mould, taking care not to pack it too tightly, and moisten each layer with seasoned stock.

Cover the mould with a greased paper, place the tin on a baking sheet, and cook it in a moderate oven for 1¼ or 1½ hours. Then remove it from the oven and fill up the mould with some warmed and seasoned stock. When it is cold and set, dip the mould in hot water and turn the contents into a dish. Garnish it with a little green salad composed of lettuce, endive, and cress, season it with pepper and salt, and sprinkle a few drops of lemon-juice over it.

Veal Pudding. Make 1 lb. suet crust (q.v.). Cut 2 lb. lean veal and 4 oz. ham into small dice. Grease a pudding-basin, roll out two-thirds of the pastry, and line the basin with it. Put in a layer of veal and ham, sprinkle over them a little chopped parsley, grated lemon-rind, and seasoning to taste, and then cover them with some slices of hard-boiled egg; 2 eggs should be sufficient. Continue until the basin is full, and then pour in a gill of water.

Roll out the remainder of the pastry to fit the top of the basin, wet the edges, and put it on, pressing it well. Tie a pudding-cloth over the basin, and then put the latter into a pan of boiling water. Boil for two hours, adding more boiling water when necessary.

Veal Ragoût. This stew may be cooked and served in a casserole. Cut 2 or 3 thin rashers of fat bacon into small pieces, fry them lightly in an earthenware casserole, and then add an onion cut into thin rings. Cook this without browning it for a few minutes, and then put in 1 lb. veal, previously freed from skin and bone and cut into pieces of a convenient size, a bunch of mixed herbs, a little shredded celery, and seasoning to taste. Add also 1 teacupful stock; then cover the pan and cook its contents at the side of the fire or in a cool oven for about 2 hours or until the meat is tender. When it is cooked take out the herbs.

VEGETABLES AND VEGETARIAN COOKERY

Directions for Preparation and Recipes for Appetizing Dishes

In addition to this article, which deals with vegetables in general and the main principles of Vegetarian Cookery, our work contains entries on the different vegetables, e.g. Cabbage; Celery; Onion; Potato. See also Casserole; Diet; Food; Kitchen Garden; Pastry; Preserving; Pressure Cooker; Salad; Sauce; Saucepan; Soup; Steamer.

In gardening the name of vegetable is given to those plants which have edible roots, stems, shoots, flowers, or leaves. Vegetables are divided into the following chief classes, examples being given of each: Legume—peas and beans; edible rooted—beet, turnip, onion, potato; salads—endive, lettuce, mustard, and cress; vegetables which are really fruits—tomatoes, vegetable marrows, cucumbers

and capsicums. Cabbage, kale, Brussels sprouts and asparagus are valued for their leaves or shoots, chicory and seakale for their blanched growth, rhubarb and celery for their leaf stalks, and cauliflower and broccoli for the edible flower heads. The mushroom is invariably classed as a vegetable, although it is really a fungus. Herbs such as parsley, sage, thyme, and other savoury flavourings are usually classed among the vegetables.

Methods of Cooking. The time for boiling vegetables varies. The Cook's Time-table (given in back cover Part 4) should be consulted. Salted water must always be used, the proportion being 1 oz. salt to each gallon of water. Most vegetables should be plunged into fast-boiling water, old potatoes and onions excepted. Old potatoes require cold water, and should not be cooked too fast. New potatoes should be cooked in hot water.

Jerusalem artichokes, salsify, and roots of a like character may be cooked partly with milk. An acid, such as lemon-juice, should be added.

Blanched vegetables—seakale, celery, etc.— require careful handling, and are usually tied in bundles before being boiled. They are served on toast, being soft and watery. Asparaguses also tied and served on toast.

Onions are better if they are blanched before boiling, that is, if they are boiled up and allowed to cook about 10 min., then the water thrown away, cold water poured on them, and finished in the second water. If treated thus they will be whiter and a finer flavour. Leeks are cooked like onions, but are easier to dish if tied in bundles for cooking. All dried pulse must be soaked for at least 12 hours before being cooked, and must be carefully picked over.

When soaking greens to revive them from packing or handling, add no salt to the water until they have freshened up a little, then change the water and salt it. They should remain about 20 min. without salt. After being thoroughly cleaned they should be plunged in plenty of fast-boiling water and salted according to the directions given.

Green vegetables should be boiled with the lid off the pan to keep their colour. Common soda should never be added to soften hard water. A pinch of bicarbonate of soda may be used with an enamelled pan or earthenware casserole; not with aluminium ware. Many salad herbs may be boiled and served as green vegetables. Lettuce particularly is adapted for this purpose. As soon as the vegetables are cooked they should be drained in a strainer or colander, otherwise they absorb water, lose flavour and become discoloured.

It should be the first aim of the cook to preserve as completely as possible the health-giving salts in vegetables. The usual method of boiling vegetables is too often uneconomical, unwholesome, and destructive of flavour. The more hygienic method is steaming.

All the garden roots are more palatable and wholesome when steamed. There is great loss in boiling carrots, parsnips, and turnips. The nutrients are not abundant in these vegetables, and after boiling only a small residue remains. Artichokes and beetroot may be steamed, and the taste will be improved. The starch and sugar in parsnips and carrots is much wasted by boiling. When large roots are steamed they should be cut into portions. Small carrots, turnips, parsnips, and beetroots can be steamed whole. A little salt should be sprinkled over all vegetables before cooking.

Drying of Vegetables. Vegetables are dried commercially by machinery, but the housewife may dry small quantities in the oven. Drying trays may be purchased ready made, or may be constructed by nailing together in a square four wooden laths, and stretching wire gauze across the framework. Vegetables should not be put on the iron trays of the oven. Drying must be done only in a moderately warm oven. After the oven has been used for cooking, take out the oven shelf, put in the drying tray with its charge of vegetables, and leave it all night, with the oven door ajar. On the

following morning remove the tray, but if the contents are not dry, put it back in the oven in the evening.

The warm, dry air arising from the kitchen fire may be used for drying fruit and vegetables. The drying tray may be placed on the plate rack, or, if the fire is low, the tray may be hung below the rack. In the case of old-fashioned fireplaces, with the chimney opening immediately over the fire, the tray must be placed sufficiently in front to prevent smoke from passing through the tray, for although the fumes of charcoal, coke, or gas will not cause the dry material to taste, coal or wood smoke will do so. In all cases the heat must not be sufficient to scorch the vegetables.

Carrots, parsnips, turnips, swedes, and beet need peeling and scraping in order to remove the outer skin. They should then be cut into slices $\frac{3}{16}$ in. thick, or into shreds by means of a hand grater. Steam them for a few minutes, then place them thinly on the tray and transfer them to the oven. The temperature must not exceed 160° F., otherwise the vegetables will brown. With onions, to avoid the unpleasantness of peeling, immerse them in boiling water for a minute. Then peel and slice them, but do not steam them before drying them as the other vegetables mentioned. Leeks should be treated in the same way, except that they should not be placed in boiling water.

Spinach, parsley, or mint should be blanched by plunging them into boiling water, to which has been added a little bicarbonate of soda, until well scalded. Cool in cold water, drain, and spread on the drying trays. The more quickly these are dried the better the colour is retained, but when drying rapidly they should be hatched closely to prevent scorching. These may be dried without blanching, but the colour is not usually so good. Green peas should be well developed but not old. After shelling, put them into a saucepan with some good sprigs of mint, a little salt and a pinch of bicarbonate of soda, cover with cold water, and bring to the boil, or they may be plunged into boiling water and retained there for a few minutes. Finally, cool them in cold water, drain, spread evenly on trays, and dry until quite firm.

With runner beans select those that are not quite full grown, string and slice, then blanch and cool the same as for peas, but without mint. Spread on the trays to a depth of about $\frac{1}{2}$ in., and when well warmed move them about occasionally to allow the air to circulate freely. When the pieces break upon bending them with the fingers they are quite dry. As regards broad beans, shell well-developed but not old ones. Blanch them in plain boiling water in the same way as peas, and dry them until they become like seed beans.

Celery may be dried in the long leaf or cut up into small pieces. It is improved by blanching, although this process is not really necessary. The green outside leaves are also excellent for flavouring when dried, but these should be blanched like runner beans. Thyme and sage should be dried slowly, at a warm temperature, or simply hung up in bunches in a warm, airy place.

When soaking vegetables for use, a little bicarbonate of soda added to the water will assist them to regain size more quickly.

To store them, the best way is to put the dry vegetables in stout brown paper bags and to hang the bags in the kitchen. If no thoroughly dry room is available, store them in tins or in airtight bottles.

During spring and summer, when fresh vegetables are plentiful, it is a wise plan to bottle some of them for winter use.

Vegetable Presser. Constructed from a good hardwood, the presser is employed to remove the surplus water from vegetables which have been placed for the purpose in a colander. These pressers are obtainable in turned wood with a flat and a slightly domed surface.

Vegetable Rack. Racks for the storing of vegetables are made in wood and in metal. An inexpensive, clean and convenient type of wire rack for the small larder is here illustrated. The air is

able to reach all the contents of the rack and to keep them fresh and crisper than when stored in wooden trays. The racks are obtainable enamelled in colours.

Vegetable Rack. Convenient type of wire rack for the small larder which allows for access of air to the vegetables contained.

Vegetarian Cookery. Vegetarian dishes should not be principally composed of vegetables, as excess of the everyday vegetable will cause flatulence. Nuts, cereals and, where they are included in the diet, eggs and cheese are all useful as main ingredients for these dishes. Peas and beans seem more easily digested if taken in a moist form and if mashed or made into a purée. Hence pea or bean soup is both wholesome and agreeable, but, on the other hand, pease pudding or a dish of plain boiled beans will prove indigestible to some persons.

The sweet course in a vegetarian dinner or luncheon may be much the same as that for a meat meal, only no suet or lard may be used in the preparation of puddings or pastry, neither may lard be used for any kind of cakes or even for greasing tins. Vegetable butter or real butter is the only fat permissible. Oil is the best medium for frying.

Fresh salad herbs should form part of the meal where foods somewhat deficient in mineral salts are the principal dish, pulse foods, for instance. If salad is difficult to obtain, the use of lemons is recommended; oranges also are beneficial, while grapes contain the necessary health salts. Many excellent recipes for salads are given under that heading.

Dried fruits such as dates, prunes, raisins, and figs are nourishing and useful in the preparation of many dishes. Nuts are usually ground, particularly if they are to be added to other ingredients, and a nut mill can be bought for this purpose. Cheese is a strength-giving food, and therefore most valuable where meat is omitted. For persons of sedentary habits it is more digestible if grated or cut in small pieces and mixed with other ingredients.

Specimen Menus. The following are two specimen menus for a vegetarian meal, the first being suitable for winter and the other for summer:

No. 1

Salsify Soup

Lentil Stew

Cauliflower au Gratin. Mashed Potatoes

Orange and Chestnut Cream Dessert

No. 2

Tomato Soup

Haricot Bean Cutlets

Green Peas New Potatoes

Cherry Pie Cream

Dessert

Salsify soup is made like ordinary white soup, except that the necessary liquid or stock consists of $\frac{2}{3}$ water and $\frac{1}{3}$ milk. The lentil stew is made by soaking overnight and preparing 1 pint red lentils, then stirring them for 5 min. in 2 oz. butter which has been melted in a stewpan. Add 1 quart cold

water, and when all boils up put in 2 onions, 3 sticks celery, 2 carrots (all prepared and cut small), 1 teaspoonful grated lemon-rind, and seasoning. Simmer for 1¾ hours, then stir in 1 oz. barley flour mixed to a thin paste, also 1 tablespoonful chopped parsley and the same of red currant jelly. Cook again for 15 to 20 min., when the stew should be thick enough. Serve it with croûtons of fried bread or toast.

Orange and chestnut cream is made with chestnut purée and sections of oranges peeled and pipped and tossed in a strong syrup. The purée and oranges should be piled in alternate layers on a dish and masked with whipped and sweetened cream.

In the summer menu the tomato soup differs little from an ordinary tomato soup, except that bacon is omitted and bran stock is substituted for the meat stock. This is made by pouring 1 quart boiling water over 2 tablespoonfuls bran, letting it stand till cold, and then straining it. A small quantity of cream should be boiled up in the soup just before serving it, and it should be well seasoned.

Haricot bean cutlets are made by cooking 1 pint white haricot beans with 4 shallots till tender, then chopping them fine. A thick sauce must then be made, using 1½ oz. butter, 1½ oz. flour, 1 gill water that beans are boiled in, and 1 gill milk or cream. Season the sauce well, add the beans, 1 tablespoonful prepared and chopped mushrooms, ¼ teaspoonful each mace and lemon-juice, and a little chopped parsley, and mix all together. When cold, shape into cutlets, egg, crumb, and fry in boiling oil. Serve with horseradish sauce.

Many savoury vegetarian dishes may be made by using Italian pastes, macaroni, vermicelli, spaghetti and noodles as a foundation, including also Tagliatelli. For this make a smooth, firm dough with 1 lb. flour, 5 eggs, 1 oz. butter, salt, and warm water as required. Roll out the paste 1/16 in. thick, let it set, and then fold it over and over flouring it to prevent sticking. Cut it into shreds and poach for 6 min. in salted water.

Porridge is useful as a breakfast dish. An uncommon kind to-day is the old-fashioned frumenty, a wheatmeal porridge flavoured with raisins and cooked in a jar in the oven for several hours. Gelatine must not be used in vegetarian cookery. Aga-aga is sometimes substituted, but it is not recommended for general purposes. Recipes for vegetable curries are given in the general article on Curry.

Galantine. Excellent vegetarian entrées are made of nuts, onions, or lentils as the basic ingredient. Nuts of any kind and breadcrumbs, boiled rice or mashed potatoes form the main ingredients of a good galantine. It is made by shelling and blanching 3 oz. nuts, skinning them, and putting them through a mincing machine. To this mince add ½ lb. breadcrumbs, or the same quantity of rice or potatoes, a finely minced onion, and 1 teaspoonful each of chopped parsley and mixed herbs. Season the mixture well, and bind it with 1 gill stiff white or tomato sauce, and the well-beaten yolks of two eggs.

Shape the whole to form a large sausage. Put it into a scalded floured cloth, tie the ends securely, and place it in a saucepan of boiling water. Let it simmer for 1½ hours, put it on a dish, remove the cloth, and press the galantine between two tins with a weight on top. Leave it until it is cold, then trim the ends neatly, and brush it over with glaze.

Lentil Cake. The ingredients for a lentil cake are ½ lb. cooked lentils, ½ lb. cooked potatoes, 1 oz. margarine, ½ teaspoonful powdered herbs, a teaspoonful each of chopped parsley, grated onion, flour, milk, breadcrumbs, and frying with a little salt and pepper.

The lentils, which should not be watery, should be rubbed through a sieve with the potatoes. Then melt the margarine, add the lentils, potatoes, herbs, parsley and onion, after which the whole should be heated, seasoned and mixed well together. Turn the mixture on to a plate to cool, and make it into small flat cakes on a floured board. They should be brushed over with milk, coated with

breadcrumbs and fried in hot fat. When ready, drain them on soft paper and serve them on a hot dish garnished with fried parsley.

The cakes will be improved if a beaten egg is added to the mixture while it is being heated. Another way is to place on each cake either a poached egg or half a hard boiled one with the cut end downwards, the egg being coated with tomato sauce.

Onion Pudding. To make an appetizing onion dish, take six small Spanish onions, 1 breakfastcupful breadcrumbs, an egg, a little milk, and some brown gravy, together with 1 dessertspoonful melted butter, a little grated lemon-rind, a pinch of nutmeg, and a little pepper and salt. Slice the onions and fry them to a golden brown, and then line a small pudding basin with them. Mix the breadcrumbs, the egg, which has been well beaten, the butter, nutmeg, and lemon-rind together; add the pepper and salt, and mix all thoroughly with a little milk. Pour this mixture over the onions and steam it for hours. The gravy should be heated and used for serving with it.

Vegetable Patty. Cooked vegetables, such as carrots, turnips, peas, etc., can be made into patties in the following way: Line some greased patty pans with short pastry, using butter instead of lard, or half butter and half margarine, fill the cases with rice so as to prevent them from rising in the centre, and then bake them in a hot oven until they are lightly browned. Bake also some strips of pastry shaped like handles. In the meantime, cut all the vegetables, except the peas, into small dice, heat them up in a little thick white sauce, and season them to taste.

When the pastry cases are cooked, take out the rice and turn them out of the pans, fill them up with the hot vegetable mixture and fix a handle to each, using a little raw white of egg to fasten these to the sides. Serve the patties at once. They are better eaten hot than cold.

Vegetable Pie. A hot vegetable pie can be made thus: melt 1 oz. margarine in a small pan, add 2 tablespoonfuls chopped onion and fry these to a pale brown colour before pouring in 1 gill brown sauce or gravy. Simmer the whole for about 4 min., then add ¼ lb. cooked macaroni cut into small pieces and 2 oz. grated cheese.

Break a small cooked cauliflower into sprays, and peel and slice 3 tomatoes and 4 large mushrooms. Arrange these in layers in a well-greased pie-dish, cover them with the macaroni and sauce, and then put on a lid of short-crust pastry. Decorate the edges with a knife, ornament the top with pastry leaves, and then bake the pie in a hot oven until it is lightly browned. Serve it in the dish in which it is cooked.

VEGETABLE MARROW. This is the full name for the vegetable more usually known as the marrow. *See Marrow.*

VELLUM: How to Mount. Vellum is the name given to parchment made from the skin of young calves and lambs, which is exceedingly durable, and is used for legal documents, bookbinding, and for illuminated addresses. It is finished with an ivorine appearance and is unequalled as a surface for lampshades and other articles for which imitation vellum or vellum paper is generally used. Vellum can be stained by first soaking it in water and then dipping it in a chemical or vegetable dye, but it is advisable to test the effect of the dye on a scrap of the material before attempting a whole skin, as dyes differ widely in their action.

In the preparation of vellum for writing or illuminating considerable care is required, and although it is often stretched on a board by professional workers, the better plan for the amateur is to mount it on a suitable board. The materials required are a sheet of mounting board of the thickness known as 8 sheet, a basin in which hot water is placed, covered by a saucer, two teaspoonfuls of seccotine and

two of hot water being mixed together in the saucer, a basin of cold water, some sheets of clean white paper and some greaseproof paper or thin vegetable parchment, two pieces of clean linen about the size of a handkerchief, two small sponges, some fine pumice powder, two flat boards, a piece of heavy cardboard, and some weights for the purpose of keeping the mounted vellum under steady pressure.

First of all the vellum is placed right side up on a sheet of clean paper and thoroughly damped with a sponge with cold water; the surplus water is wiped off with one of the linen cloths, and then the vellum is turned over and the same procedure carried out on the other side. Wipe off the surplus moisture as before, and then dip the other sponge in the seccotine mixture and thoroughly cover the back, taking care that the extreme edges are covered with the seccotine.

The vellum is now lifted up and placed in the centre of the mount, with the edges quite square. Beginning at the top, the surface is stroked down with a clean linen cloth to remove the air from underneath and to bring the material into the closest contact with the mount. A sheet of clean white paper is placed on the top of the vellum, the cardboard is laid over it, and the mounted work is put between two boards with the weights on top. The vellum should be kept under pressure for at least twelve hours in order to allow it to dry quite firm and even before decorating it.

The material is now ready, and should be dusted over with some fine pumice powder, but on no account should it be touched with the fingers. The design or lettering to be placed on the vellum is first drawn out on a piece of thin paper as carefully as possible. The back of the paper is rubbed over with blacklead and thoroughly rubbed in with a piece of rag. The drawing is placed in position, and the lines transferred to the vellum with an agate tracer or fine stylo, only the thinnest line being required. Ordinary carbon transfer paper is not suitable for use with vellum, owing to its greasy nature and the liability of making other marks caused by the pressure of the fingers on the paper while working.

For the ink work, a waterproof Indian ink should be used. A ruling pen should be employed for straight lines and other lines that can be drawn with a compass; for freehand lines and lettering a fine drawing-pen is required. Colouring is done with the best quality of water colours mixed with a little gum arabic. Gold can be applied, but it should be shell gold and mixed with gum arabic. For silver effects it is better to use aluminium in the same way as the gold, as it is not liable to tarnish as is the case with silver. Lines can be rubbed out with putty rubber.

Scraps of vellum boiled down make an excellent size for applying gold-leaf, and this is the material generally used. For the purposes of bookbinding there are several kinds of vellum available. Prepared or artist's vellum is prepared in the natural colour of the skin. Roman vellum is similar but darker; it is always attached to the boards with the flesh side downward. Vellum can be cleaned with benzine applied with a sponge, stains being removed in this way without destroying the texture. *See Bookbinding; Lampshade.*

VELOUR: The Material. The French name for velvet is given in Great Britain both to wool and cotton plain cloths made with a short and more or less velvety nap, which is produced by finishing the cloth in a special manner. This nap is soft to the touch, and it enriches the colour, lending a peach-like bloom.

Wool velour cloths sometimes show a fancy design, and are known as jacquard velours where the design is woven. Sometimes the pattern is merely embossed and therefore less permanent.

Cotton velour, which makes rich-looking curtains, showing a double tone of colour, is obtainable in a fine range of colours, warranted not to fade.

VELOUR HAT. Made essentially for winter wear, velour hats are manufactured from hare fur on a foundation of soft felt. The better qualities have a silky, plush-like surface, and Austrian velours,

which are the finest of all, are among the most expensive and durable of hats. The cheaper kinds, and especially the imitation velours, wear badly, and quickly lose their shape.

VELTHEIMIA. This is a South African bulb suitable for cultivation in pots in the greenhouse or in a warm sheltered border out of doors. A suitable compost consists of loamy soil with a little leaf-mould, decayed manure and sand. The chief kind is *Veltheimia viridiflora*, with rich green leaves and pale rose-coloured flowers in summer on a stem 12 in. or more high.

VELVET. Millinery velvet is usually narrow. Collar velvet is a specially dense and fine fabric, built for hard wear. Old-fashioned dress velvet was a warm, hard-wearing silk pile fabric which is not much used nowadays. The chiffon and ring velvets are made with a lighter and more open pile. They hang in graceful folds, and have a soft, rich and glossy surface in which the separate rows of tufts can often be seen.

The most exquisite shades can be dyed on silk velvet, and no fabric shows off a fine colour to greater advantage. The mohair velvets or moquettes are used largely in place of silk velvet for upholstery.

When cutting velvet for millinery and trimmings care should be taken to cut it on the cross, otherwise there may be trouble in getting it to lie flat. Velvet can be freshened in appearance by steaming with a hot iron. The face of the iron should be turned uppermost and the velvet passed over the surface by hand. Cuttings of velvet should always be saved. Worn-out velvet can be used as a polishing cloth for boots, metal and furniture.

Unless velvet is so arranged that the pile lies all in one direction, different shades will appear on the garment, and the result will be patchy. The material should be examined in a strong light before it is cut, and the pieces so placed together afterwards that the shading is uniform. If the pile is running in the right direction the velvet will appear dark when held up to the light.

Catch Stitch. A special stitch used for hemming velvet is termed catch stitch. It is done by turning down the velvet once—not twice as is usually the case in hemming—and sewing from right to left. Commence by taking a stitch on the turned-down portion without bringing the needle through to the right side; then make a tiny stitch immediately below the turning, taking up only a thread of the right side of the material. Continue thus until the hemming is completed. When accurately done no stitches can be seen on the right side of the velvet. This stitch is also used in millinery.

Velvet. Catch stitch, the special stitch used when velvet has to be turned down and hemmed.

VELVETEEN. The best velveteens to buy are those guaranteed to have a fast pile, meaning that the tufts are not loose enough to work out easily and are a fast colour. In the better class fabrics there is a good range of colours.

VENEERING FOR THE AMATEUR CABINET MAKER **A Decorative and Useful Method of Surface Treatment**

In this work are associated articles dealing with Inlaying and Marquetry. The use of veneers in renovating old furniture is explained in the article on Chest of Drawers. See also Cabinet Making; Dressing Table; Sofa; Wardrobe.

Veneering is the process of applying a comparatively thin sheet of wood of fine or rare quality to a groundwork of a plainer variety of wood. It thus enables many beautiful woods to be employed for decorative work which are prone to twist or crack if made use of in the solid. A typical example is the employment of curls and burrs, which would prove completely unsatisfactory unless applied in the form of veneers.

It is also the only satisfactory method of employing such decorative effects as quartering, balanced matching of grain, and other flat treatments in which the work relies for its effect upon the disposition of various woods, the grain of which runs in contrary directions. In shaped work veneering is almost indispensable. To cut the wood in the solid would entail a certain amount of end graining showing, an undesirable feature in itself owing to its exhibiting no beauty of grain and the fact that it does not polish well. Also it would involve weakness of construction.

There are two kinds of veneer, known as knife and saw cut, according to the instrument employed. Knife cut is the thinner of the two, and is cut by one of two methods, either rotary or flat. In the former a log is placed in a structure similar in principle to a lathe and having a long knife edge stretching along its whole length. The knife is adjusted to cut the required thickness and moves forward against the log as it revolves, thus cutting a veneer the same length as the log and of practically unlimited width.

This method has the effect of giving a very enlarged grain, and is impracticable when, for example, a wood is to be cut which relies for its appearance upon the medullary rays, as in figured oak, for which the flat-knife method is adopted. The finer woods are cut in this way, a machine similar to a plane taking off veneers. Saw-cut veneers run from 1/32 in. to 1/16 in. and are cut with a circular saw, all such woods as curls being cut by this method.

Veneering. Fig. 1. Cutting knife-cut veneer with a chisel. Fig. 2. Cutting saw-cut veneer with a veneer saw worked against a straight edge.

Preparing the Ground. A very important consideration in veneering is the ground to which it is to be applied. The wood should be as straight in the grain as possible, clean and dry, and with the least tendency to warp and shrink. For these reasons Honduras mahogany is the most suitable, as it is not only reliable but holds the glue well. Yellow pine also makes a good ground, and, if possible, a board having the medullary rays running through it should be chosen, as boards cut in this way are less likely to twist. All soft woods should be sized before the glue is applied for the veneering process, as otherwise the ground will be apt to soak up more than its share of the glue and leave the veneer liable to peel off.

As the tendency of veneer is to pull the ground, making a hollow surface, it is advisable to apply the veneer on the heart side of the wood so that the natural pull of the wood is opposed to that of the veneer. Another good plan, in order to avoid undue twisting, is to damp the back of the ground. Note that wherever possible, the wood should be veneered on both sides.

All grounds should be roughened with a toothing plane before any veneer is applied. This is done after the ground has first been planed perfectly true and flat. After the use of the toothing plane the ground is ready for the veneer, except in the case of a pine or deal ground, when it is necessary first to size it. The size, which is composed of thin glue, is applied hot with a brush and allowed to harden, when it is rubbed down with coarse glass paper and all dust removed with a brush.

Cutting the Veneer. A piece of veneer is now cut to the size required. If knife-cut veneer is used, this operation may be accomplished with a chisel, as in Fig. 1, using a straight edge to ensure a straight cut. The straight edge should be firmly held down with the left hand as shown and the chisel held in the right with the bevelled side against the straight edge, and drawn across the veneer. The veneer should be placed on a flat board during the cutting to give support for the chisel, and care should be exercised at the completion of the cut to avoid tearing away the edge of the veneer. An extra allowance of about $\frac{1}{2}$ in. should be made on all sides.

Saw-cut veneers may be cut with a chisel, if desired, although a better method is to use a veneer saw, as illustrated in Fig 2. The saw consists of a blade having a slightly rounded edge and fitted with a handle screwed to one side of the blade. It is worked against a straight edge, which, if a wide piece of veneer is being cut, should be hand-screwed or cramped to the bench to avoid its shifting.

For cutting narrow strips of veneer of equal width a cutting gauge may be used. In this case the sheet of veneer is placed to overhang slightly a flat board, and another board or a batten sufficiently long to reach the width of the sheet placed on the top a short distance from the end and firmly held down with the left hand. The purpose of the top batten is to prevent the veneer from buckling, which would render it liable to split. A cutting gauge is then set to the required width and worked along the edge of the sheet in the manner shown in Fig. 3. Only a slight pressure should be maintained, making several light cuts in preference to one deep one. The veneer should not be cut right through from one side, but is reversed after being cut half through and the process then completed from the other.

Applying Veneer. For the actual process of veneering two methods are available, the hammer and the caul. The latter is used for laying saw-cut veneers, and in all cases where built-up patterns of veneers such as quartering and the like are employed. The former method is employed successfully for the majority of knife-cut veneers. Having trued up the ground a flat-iron is heated and glue prepared.

The glue should be as hot as possible, and of such a consistency that when the brush is lifted from the pot the glue runs down in a continuous stream. All the ground is coated with the glue and also the underside of the veneer, care being taken that no grit or foreign matter is allowed to remain in the glue. The veneer is placed on the ground in position, and the surface rubbed lightly over with the hands. A wet swab is rubbed over the whole to moisten it, and a little glue added so that when the iron is applied the glue underneath is not unduly weakened.

The hot iron is passed lightly across the surface to heat about half the glue, as shown in Fig. 4. A veneering hammer is used to remove the surplus glue under the veneer. Fig. 5. The hammer is placed first in the centre of the work and worked outward with a zig-zag movement, thus driving the heated glue outward. A diagram showing the correct movement is given in Fig. 9. It is essential to work outward from the centre, since the object is to bring the veneer into as close proximity with

the ground as possible, and this can only be accomplished by driving out the surplus glue. It will be found necessary to reheat the glue with the iron once or twice during-the process.

When the whole has been worked over with the hammer, the surface is wiped clean with the swab and tested to see that the veneer is everywhere down. This may be done by lightly tapping with the finger nails, when, if the work is correctly done, a solid feel is apparent. Any bubbles will be obvious from a hollow sound, and any such places should be remedied by reheating and working flat with the hammer.

Veneering. Fig. 3. Cutting narrow strips of veneer with a cutting gauge. Fig. 4. Heating the glue under the veneer with a flat-iron. Fig. 5. Use of veneering hammer to squeeze glue out beneath veneer. The movement of the hammer is shown in the diagram below. Fig. 6. Cutting overhanging edges away with a chisel. Fig. 7. One-half of veneer laid and remainder being placed in position, edges overlapping. Fig. 8. Cutting through both thicknesses to make a clean joint.

Particular attention must be paid to the edges, which are apt to work up. The overhanging edges are cut away, as shown in Fig. 6, placing the work veneer side downward on a flat board, pressing tightly downward with the left hand and drawing a keen chisel across the veneer. The cross-grain ends should be cut first, since these are the most apt to split away at the ends, the remaining sides being cut after cleaning off any ragged corners. The work is then left to harden, placing it with the veneer side downward.

Fig. 9. Showing z i g - z a g movement of

veneering hammer illustrated in use in Fig. 5 above. Fig. 10. Details of veneering hammer; it consists of a brass blade fitted into a block of wood with handle attached.

With a very wide board requiring two widths of veneer, one sheet should be laid as described and the second sheet put down in a similar way, allowing it to overlap the first by about, 1 in. Fig. 7 shows the second half being placed in position. A straight edge is placed along the overlapping portion and firmly held in position, while a cut sufficiently deep to pass through both thicknesses is made along its length with a chisel, as in Fig. 8.

The surplus of the upper thickness is removed and the veneer raised, as shown in Fig. 11, so that the surplus of the lower veneer may be taken away. The veneer is then replaced, heated with the iron, and rubbed down with the hammer. Pieces of old newspaper should be glued over the joint to prevent it from opening while drying.

Details of a veneering hammer are given in Fig. 10, which shows it to consist of a brass blade having a rounded edge fitted into a cut made in a block of wood, this being fitted with a rounded handle. One method of holding it has already been illustrated in Fig. 5, using two hands. An alternative method is given in Fig. 12, in which the hammer is grasped with the right hand only. When the work is quite set, if any bubbles or blisters are seen they should be removed by slitting the veneer with a thin chisel or penknife to let the air out, working a little glue under the veneer and then heating and finally pressing out with the hammer.

Veneering. Fig. 11. Raising one piece of veneer and removing waste after cutting with chisel. Fig. 12. Alternative method of holding hammer, with one hand; compare with Fig. 5. Fig. 13. Laying banding, using the back of an ordinary hammer to press out the superfluous glue.

Cross Banded Work. Fig. 13 shows the treatment of veneered work having a cross banding and an inlaid line at the edges. This is easily accomplished by first veneering the centre portion as already described, except that it is unnecessary to allow the veneer to overlap, rather cutting it slightly smaller than the actual size of the ground. This done, it should be allowed to set.

Several strips of cross-grain veneer are then cut with a cutting gauge, as in Fig. 3, to slightly more than the width required for the finished banding. One edge of all these should be planed true

on a shooting board, a batten being placed on the top of the veneer to prevent it from buckling. An iron plane or finely set trying plane is used.

The cutting gauge is set to the width required for the banding, including the line, and a cut made on all four edges of the work deep enough to cut through the veneer, the surplus veneer being removed with a chisel. If any difficulty is experienced in removing it, the glue should be heated with the flat

iron, when the veneer will be found to peel off. The line is then mitred to fit at the corners and glued round, driving in a few veneer pins at the side of the line if any difficulty is found in keeping it in place. It should be left to harden. (Useful hints will be found in the article on Inlaying). The banding is cut to length with mitred corners and glued in position, using the flat peine of an ordinary hammer to press the glue out, as in Fig. 13. If this is done quickly and very hot glue used, it will not be necessary to reheat the glue with the flat iron. Paper should be glued over all the joints in order to prevent them opening.

The edges of a board or other piece of work are veneered by placing the work in a vice for the purpose. This should not be done until the veneer on the top surface is quite set, after which the edges should be planed, using a very keen-edged plane finely set. Strips of veneer are cut and laid by means of the back of a hammer. When set they are trimmed off and the surface scraped and glass-papered.

It is essential to allow all veneered work to set thoroughly before attempting to clean it up, which is done with a steel scraper, and afterwards finished with glass paper (*see Scraper*).

Use of the Caul. To lay saw-cut veneers and built-up patterns by means of a caul requires a different procedure. The veneer is first cut to size and the ground prepared as described for the hammer method, and both then glued, the veneer placed in position, and a sheet of paper placed on top. In the case of a pattern, two veneer pins should be driven in to prevent it from shifting. The caul consists of a board about 1 in. thick and slightly larger than the ground to be veneered, It is slightly rounded in shape on one side. This is thoroughly heated and quickly hand-screwed, round side down, on to the veneer on top of the paper, the latter being used to prevent the caul from sticking.

For a large surface to be caul veneered, cross pieces are used as shown in Fig. 14. The upper pieces are rounded on their under edges to force the glue out, and the lower pieces straight and thicker than the top ones, so that when pressure is applied at the ends the top pieces are bent so that their lower edges become straight. It is essential in all cases of caul veneering to work smartly when once the caul has been heated so that the glue is thoroughly melted. Other information about the process is given in the article on Marquetry.

To veneer patterns such as those given in Figs. 15 and 16, the design is first drawn on paper and the various pieces of veneer cut to shape and glued on to the design. It is then treated as a whole and laid with a caul. For further information reference should be made to the article on Inlaying, where the treatment of simple designs is dealt with in detail.

Veneering. Fig. 14 (right). Showing use of cross piece in caul veneering a large surface. Figs. 15 and 16 . Two examples of built-up veneer patterns.

VENETIAN BLIND. Although it has been largely replaced by the ordinary spring blind, which is easier to keep clean and in order, or by casement curtains, the Venetian blind has advantages. It is the British substitute for the continental shutter, and has the same useful quality of keeping out the sun and at the same time permitting effective ventilation. Moreover, it permits the gradation of the light, which may be fully obscured by having the slats closed or partially by having them slanting. The great drawbacks are the clumsy appearance of these blinds and the extra cleaning which they entail. Few people would select them for a new house, but where already installed they can be used without trouble for long periods providing the adjustments are correct.

The blinds should be dusted with a soft brush at frequent intervals, the laths should be turned down with the laths inclined to the window, and the brush stroked from side to side, working from the top to the bottom on the window side first. The laths are then turned in the opposite direction and the same procedure followed on the inside of the room. In the event of broken cords or tapes it is a waste of time to attempt to repair them. New material should be fitted, and, although this can be done with the blind in position, it is usually more convenient to take it down, and at the same time to look over the other adjustments. The top lath of the blind is either screwed directly to the window framing with two screws or supported on small metal brackets, the latter being the more satisfactory. In old fittings the screws become loose and fail to hold the blind up. The remedy is to use screws of a larger diameter, to plug up the old holes with a glued peg, and to rehang the blind with two small iron angle brackets.

To remove the blind either for thorough cleaning or repair, it should be let down, the tapes unfastened at the bottom, and the cord unknotted and withdrawn. The laths are now slipped out and the top screws removed. With a bracket fastening the blind will remain in place after the screws are removed, but with those fastened direct to the window frame each screw should be undone for a few turns, so as to equalise the strain and allow the top bearer board to be held in position while the screws are entirely withdrawn. The blind is laid on the floor and the tapes gathered up close to the laths, so that the blind can be carried away.

If possible the shop practice of supporting the blind on angle brackets should be adopted. The brackets can be attached to the wall, to an old door, or to a temporary framework erected for the convenience of handling. If this method is not possible the blind should be spread out at full length on a large table or on the floor. The tacks securing the tapes to the bottom lath should be pulled out with a pair of pincers, the tops of the tapes taken off in the same way, and the lengths can be washed if they are in good condition.

To clean the laths, they should be gathered together and placed in a bucket of soapy water, so that the edges can be rubbed over with a scrubbing brush. Each lath should be scrubbed over on both sides, and then rinsed in clean water, and placed on one side to dry. The laths should be rubbed over with a dry cloth, and then with beeswax and turpentine, the final polish being given with a soft clean duster.

In some cases a better appearance can be given to Venetian blinds by painting them cream colour or almond green. All blinds in front of a house should be of the same colour. The old paint must be removed and the surface of the laths smoothed with glass paper and given a coat of weak glue size, before applying the necessary coats of paint. Paint with a very hard glossy surface, suitable for exterior work should be chosen for the purpose, otherwise with exposure to the sun there will be a tendency to blister.

Re-taping the Blinds. The work of re-taping and re-cording can now be proceeded with. The tape, known as ladder tape, is obtained in several qualities; the best has the ladder or connecting pieces woven in with the webbing, as in Fig. 1, and no other kind should be used. It is made in unbleached,

half-bleached, and white, as well as in green, buff, and red. In addition to the lengths required for the laths, two or three short lengths are needed to attach the top lath to the bearer, and these are known as the shading tapes. The total lengths of the new tape and cord after being carefully measured can be secured to the laths with tintacks.

The shading tapes are supported on rollers, which are provided with a long spindle, and fit in slots cut in the top of the bearer. They are not, as a rule, liable to damage, but they should have free movement, and be fixed so as to be parallel with the surface of the bearer. Each length of webbing, which can be taken from the ladder tape by cutting off the cross pieces, should be 10 in., threaded through the roller opening, carried over the roller, and brought out to the same side. The ends are folded under and tacked to the top lath, as in Fig. 2, resting the lath on a block of wood so that the tacks can be driven in tightly. In blinds where there are three shading tapes, the two end ones should be secured first, taking great care that the top lath and the bearer are quite parallel, and that the lath just clears the bearer when turned up.

Venetian Blind. Fig. 1. Webbing or tape with ladder pieces woven in. Fig. 2. Method of securing shading tape to bearer. Fig. 3. Blind complete with new tapes and cords, showing laths in position.

The centre tape is adjusted to support the lath and prevent sagging. The long ladder tapes are secured to the top lath, so that the centre is exactly underneath the pulley wheel opening (Fig. 3), about $\frac{3}{4}$ in. of the material being turned in underneath to hold the nails. The ladders must be the same height each side to ensure that the laths will be horizontal, and it is an advantage to hang the blinds on temporary brackets and to fit a couple of laths in position. The double cord for the shading adjustment is secured to the top lath by nailing it in a narrow groove provided for the purpose. Before the cord is fastened on, a Venetian driving eye should be threaded on.

The laths are slipped in position while the bearer board is suspended on the brackets, and the new cord can be threaded through each lath, taking care that the cord runs between the alternate cross

pieces of the webbing. Sufficient length of cord should be allowed to bring the loop within easy reach when the blind is fully down. This is adjusted by securing one end by means of a knot, which should fit in the enlarged hole in the underside of the bottom lath, and then pulling the other end through the hole until sufficient remains on the outside. The spare cord is cut off, the end knotted and pulled into the hole.

With large blinds and those screwed to the window frame, the cord should be threaded through the pulleys and tied while the bearer lath is secured. When the cord has been threaded and secured at the bottom the blind should be tested, and if correct the ends of the tape should be folded underneath and secured with two or three tacks.

In the event of a lath being broken, a new one can be made from a piece of yellow pine planed to the required width and thickness and cut to length. The holes should first be bored with a small centre bit and enlarged with a fairly flat scribing gouge; the blind-maker would punch the hole out, but this is rather a risky proceeding for the amateur. There is no need to take the blind down to fit a new cord. It is a simple matter to thread the cord through the holes and over the pulleys in a bracket-hung blind; in a screw-hung blind the screws can usually be undone sufficiently to allow of enough space to slip the cords over the pulleys.

Old blinds sometimes cause trouble through the cord slipping off the pulleys, caused by the edges of the pulley being broken or by the opening of the slot being too large. The remedy in the first case is to fit new pulleys; they are generally held in place by a pin, which can be withdrawn with a pair of pliers. A new pulley wheel can be fitted in and the pin replaced. In the second case, the best method is to attach thin strips of wood, to provide a guide for the cord. Another method is to drive a staple as close as possible to the pulley so that the position of the cord is always over the pulley no matter how slack the cord is.

VENETIAN GLASS. This phrase is applied primarily to glass made in or near Venice, but also to pieces made in the same style by workmen in other countries. The Venetians discovered the way of making the type of glass since linked with their name in the 13th century, but their furnaces were on the island of Murano, being regarded as too dangerous to be in the city itself. The industry flourished until the 18th century, partly owing to the jealous care with which its secrets were guarded. It then fell into decay, but was revived in the 19th century.

The characteristics of Venetian glass are its extreme lightness as regards weight and a slight cloudiness of hue. The general features of

the simpler drinking glasses are a very open bowl, a high, often almost conical, foot, with a folded edge and a stem slight in proportion to the bowl. In the design there is a sense of poise and balance. Engraved decoration is rare, but enamelling and gilding adorn the earlier pieces, which sometimes have diamond-scratched designs.

Venetian Glass. Three beautiful specimens of white Venetian glass, that on the right having a stem enclosing orange flowers in coloured glass.

Early pieces, being extremely valuable, are rarely seen in private collections. The glasses of the 15th century, as they were modelled on silver cups of the Gothic style, have a somewhat heavy appearance, but in the 16th century more delicate pieces were made, and some of the finest existing examples date from that time. In that period the glass became thinner and lighter, relying less and less on enamelling for its beauty. The filigree was elaborated and different colours were employed. Pieces were also made in the form of lions, dragons, gondolas, etc. The mascaron (q.v.) or raised ornament of glass was often used on vases and bowls. *See Glass Ware.*

VENISON: How to Cook. Before it is fit for the table venison requires to be hung for two or, if the weather is cold, three weeks.

The principal joints are the haunch, which includes both the loin and the leg, the shoulder, the neck and the breast. Of these the favourite is the haunch, which is roasted and served with rich brown gravy, accompanied by either red currant or rowan jelly. The meat for the greater part of the time it is roasting should be covered with buttered paper placed over a flour and water paste, in order to keep in all the juices and retain the flavour.

To roast haunch of venison, saw off the shank bone, also trim the chine and pare away darkened skin and sinews. It is often necessary to remove entirely the outer skin of venison before roasting it, especially if well hung. Butter a large sheet of kitchen paper and place two more sheets underneath it. Cover the meat with a stiff flour and water paste, roll in the greased paper and place it with sufficient butter or good beef dripping in a baking pan and roast it in the oven from 2½ to 3½ hours. It must cook gently after the first 15 min., and must be well basted several times during the process of cooking. About 12 min. before the haunch is ready, remove the paper and paste, season the meat with salt and pepper, dredge it with flour, baste it and expose it to sharper heat to give it a brown tint. When well frothed up and a rich but not very deep brown, dish it up and serve it very hot, with a superior thick gravy, in a tureen.

The gravy is made as follows: Chop small the knuckle bone and trimmings off the chine and fry these, with any game or chicken bones left over, in 2 oz. butter, adding 4 prepared and chopped shallots, a bouquet garni, and a shredded stick of celery. Fry all until a pale brown, then add seasoning and 1 gill white wine. Simmer these until they are reduced to a glaze, stirring all the time that the liquor is reducing. Then add ½ pint good stock, mix it in well, and cook very gently for 25 min. The essence is now skimmed and strained through a fine hair sieve. Have ready heated in a saucepan 1 pint good brown sauce and mix in with it the game essence, also the strained juice of half a lemon. Boil all up together and pour the gravy into a tureen.

Venison Pasty. For an old-fashioned pasty, bone the shoulder, but as it is sinewy beat it well and steep it in vinegar to which 2 glasses port wine have been added, leaving it in this pickle for 24 hours. It is better to rub the joint well with sugar before putting it into the vinegar. Do this for 2 or 3 days. When required for use, be careful that all traces of sugar are cleared away and that the joint is wiped quite dry from the wine and vinegar. Season it with salt and pepper, then lay the boned shoulder in a large earthenware dish.

Melt ½ lb. butter and pour it over the meat, adding ½ lb. fat from a loin of mutton cut fine. Sprinkle over it a little grated nutmeg, clove or mace, and 12 shallots which have been peeled and chopped. Half fill the dish with good stock, and cover it with a light pastry as for meat pie. Bake the pastry sharply for about 20 min., then slowly for from 3 ½ to 4 hours. The crust must be very rich or it will dry in the long baking.

To make a more modern dish use about 2 lb. of a boned shoulder of venison, beat and soak fit, and prepare as for the pasty, but cut it into neat pieces. Lay these in a pie-dish and season well, also

dredge them with flour. Arrange among the pieces 12 small rolls of bacon and the same number of forcemeat balls, then fill up with good strong stock into which a wineglass of port wine should be introduced. The pie must be covered with a rich rough puff pastry, and will take about 2 hours to bake. It should be ornamented and glazed. After it is cooked the centre ornament should be removed, and in the vent should be poured as much extra gravy as the dish will hold. Venison dishes must always be served very hot. French beans are a good accompaniment.

Jugged Venison. For this savoury dish bone the shoulder and cut the flesh into neat square pieces, but first prepare the meat by beating it and soaking it. Fry the venison with $\frac{3}{4}$ lb. bacon cut in dice until it is a good brown, then drain off all superfluous fat. Dredge over the meat 3 oz. flour and fry again a few minutes in order to cook and colour the flour. Keep all moving, and be careful that the flour does not burn. Now moisten the contents of the pan with $2\frac{1}{2}$ pints good brown stock and $\frac{1}{2}$ pint port wine. Season well, and add a bouquet garni.

Stir frequently till the whole comes to a boil, and then simmer while preparing the following flavouring: Procure 24 small button onions, peel them and fry them in butter for about 5 min., or until well coloured. Put them with the meat and gravy into a stewing jar, add 24 button mushrooms, and cook all gently in the oven or on the top of the stove, drawn back from the fire, for about 2 hours or until the venison is tender.

When ready to serve, remove the bouquet garni, clear the gravy from fat and scum, and dish neatly garnished with croûtes of fried bread. Mushrooms suitable for this dish may be procured preserved in bottles, and if button onions are not obtainable a Spanish onion peeled and cut into neat pieces may be used in place of them.

Casserole of Venison. For a stewed loin of venison, trim the loin and cover the fillet portion underneath with thin slices of bacon. Tie or skewer these in position, then place the joint in a large casserole with a prepared and sliced carrot, 2 onions, also sliced, a bouquet garni, a lump of butter as large as a hen's egg, 4 oz. bacon rashers trimmed and cut into strips, 4 cloves, and seasoning. Put the lid on the casserole and let all cook together.

After it has cooked for an hour add 1 pint stock and continue cooking for at least another hour, still turning and basting occasionally. Dish the meat, removing the string or skewers, and keep it hot. Strain the liquor in which it has been cooked and free it from fat. Add 3 gills brown sauce, a small pot of red currant jelly, a wineglass of port wine, and seasoning to taste. Pour the gravy round the meat and garnish with potato croquettes.

The remains of a cooked joint of venison may be hashed. Place a sliced onion in $\frac{3}{4}$ pt. stock, season, add 1 tablespoonful red currant jelly and boil for a few minutes. Dust neat slices of venison with flour, add to the stock, etc., and remove the onion. Stew a few prunes with lemon-juice to taste. When the venison is heated, place it round the prunes on a hot dish and garnish with sippets of toast.

The fry of venison makes a good breakfast dish. Wash and soak the fry well, then cut into neat pieces and roll each in seasoned flour. Fry them in butter and dish on fried' parsley. *See* Casserole; Fry; Rowan; Sauce.

THE VENTILATION OF THE HOME

Modern Ideas on a Matter of Vital Importance

This subject may be pursued further in this work under such entries as Architecture; Chimney; Heating; House; Window. See also Air-Brick; Bathroom; Geyser.

Inefficient ventilation is often a contributory cause of ill-health. Unless a room is supplied with ventilators, or the windows are kept open, sufficient fresh air cannot enter. An outlet for impure air is as necessary as an inlet for pure air. Therefore, if there is no chimney, an opening must be made in the wall.

The air of a room becomes impure mainly through the breathing out of the occupants and the carbonic acid gas produced by burning gas lights or oil lamps. Besides carbonic acid, the expired air contains organic matter and watery vapour. A man sitting in a room will breathe out $\frac{1}{6}$ of a cubic foot of carbonic acid gas in an hour. To keep it at a wholesome degree of purity, from 2,000 to 3,000 cubic feet of air should be introduced per hour for each 1,000 cubic feet of space. The carbonic acid content of the air is important as an index of the freshness of the air, and therefore of the efficiency of ventilation, or, in other words, of the movement of air within the room. The malaise, or sense of illness, which is a consequence of a stuffy atmosphere has been shown to be due to stagnation of air round the bodies of the occupants.

The general result of such stagnation is a diminution or suppression of perspiration, which function is always going on, although we may be unconscious of it. The regulation of body temperature is thus interfered with. Equally important is the loss of stimulation of the nerves of the skin, caused normally by the circulation of the air about the skin. The effect of this stimulation is to produce an exhilarating sense of well-being.

It has been found that average air in town areas contains about 4 parts per 10,000 of carbonic acid gas; the air of a room ought not to contain more than 6 parts. Closely related with this matter is the size of the room. A bedroom for one person should be of at least 800 and preferably 1,000 cubic feet. In calculating the cubic capacity of a room the length, breadth, and height are multiplied together, but any height above 12 ft. is not to be counted, because above that level little change occurs in the air. The floor space is also important, and for that is suggested TV of the cubic space.

In the climate of Great Britain it is found that the air cannot ordinarily be changed oftener than three times in an hour without the process causing a draught, so that to secure a supply of 3,000 cubic feet of fresh air per hour the room space must be 1,000 cubic feet. A certain degree of draughtiness does not matter so much in a bedroom. A good airing of a bedroom in the daytime is not sufficient, and ventilation during the night also must be provided for. It is usually best to keep a window widely open; there is less draught than when only a small slit is left for the air to enter, as the smaller the opening the greater will be the velocity of the air current. If the bed is not between the window and the fireplace no harm results, as a rule, from the wind blowing through the window on to the sleeper. But if he is liable to neuralgia or toothache he may have to avoid this. With a screen properly placed, full protection can be obtained from draughts.

Using a Sash Board. For ventilating a room a good plan is to raise the lower sash 4 to 6 in. and fill up the open space with a 1 in. thick board placed between the sash beads. The lower sash is shut down on to the board, which can be painted to match the window frame. This arrangement allows air to come in between the lower and upper sashes, and as it is directed upward there is no appreciable draught. This is called natural ventilation. Some artificial system may be necessary for sitting-rooms, and may be applied to sleeping-rooms as well. There are many such systems. In some houses one sees a small grating fixed near the ceiling to draw away the hot air. It may be arranged that the air passes into the chimney, a backward current being prevented by a valve.

A good appliance is the Sheringham valve, in which there is a wedge-shaped projection let into the wall of the room, communicating with the outer air and directing the current of air upward. This ventilator should be placed about 5 or 6 ft. from the floor. Another is the Tobin tube. This consists of a shaft leading up the inside of the wall to a distance of 5 or 6 ft. The lower end communicates with the outer air through an opening in the wall, guarded by a grating. Valves are attached to

regulate the amount of air admitted. A screen may be placed in the shaft to filter the air from dust, or a coil of hot-water piping to warm the incoming air.

Perforated bricks in the wall also serve to ventilate a room. The openings through these are wider on the inside so as to diminish the force with which air enters. Air movement can be brought about by an electric fan, and if this is placed so that it can direct an air stream in a suitable manner, i.e. towards an outlet, the air is not merely agitated, but exchanged.

Ventilation. Fig. 1. Ventilator consisting of a movable piece of perforated glass fixed to a window pane with similar perforations.

The Cooper ventilator (Fig. 1) consists of a piece of glass which is perforated with four or five holes of about $1\frac{1}{2}$ in. diameter. The perforation is covered with a disk of glass having perforations to correspond with those in the other piece of glass. The disk moves on an ivory pivot which passes through glass and the disk; a stop is also arranged so that the disk will not revolve beyond a certain point, that is, either open or closed. To open the ventilator the disk is turned until the holes of the glass disk and the glass

sheet coincide.

With the Boyle type of ventilating radiator fresh air is admitted by adjustable air inlets in the wall, and passes through a radiator heated to a suitable temperature, thus providing heat as well as ventilation. This method has the advantage that two objects are served by one piece of apparatus, and there are no objectionable fittings beyond the radiator.

A very simple outlet can be provided by inserting in the external wall a Boyle's mica flap valve. This consists of a metal box having a grid in the front; the inside has a smooth seating on to which fits a piece of mica suspended from the top of the grid. The expired air lifts the mica flap and passes outward. The action cannot be reversed, because any air which attempts to pass through from the outside pushes the mica flap on to its seating. By the use of this appliance good ventilation can be arranged for bedrooms or upper rooms.

Fig. 2. Boyle air inlet panel.

The Boyle air inlet panel shown in Fig. 2 is adjustable by opening or closing the flap at the front, which when open directs the entering air in an upward path so that the fullest advantages are obtained from its use.

When a fire is burning and the window is open there is a good flow of air, but if there is no fire the outward current may be very slight. It is a good plan, therefore, if a room tends to get stuffy, to burn an oil-lamp in the grate, or to light a gas-jet in the chimney when no fire is going. This is essential in a sick-room. It must be remembered that

gas and oil lamps vitiate the air of a room to a considerable extent, but against this may be set the fact that air currents are caused, which effect an exchange if suitable inlet and outlets exist. Even when a room is large the air will be impure unless there is free and constant circulation and renewal.

Under-floor Ventilation. The ventilation of the space above the ground and beneath the floor of a house is provided for by building airbricks or gratings into the outer walls just below the damp course. The sleeper walls, too, on which the joists are supported, are built up in honeycomb fashion, so as to leave a number of interstices through which air can circulate. Unless the underfloor space is well ventilated the timbers and floorboards are prone to the attack of dry rot (q.v.). It is important—though frequently neglected—to ensure that the ventilating bricks or gratings should not be obstructed on the outside by earth, plants, etc.

VENTILATION: For Plants. In the greenhouse ventilation is of supreme importance, for whilst the glass, will rapidly conserve and bottle up sunshine, it will not readily allow the accumulated heat to escape. Too much fresh air cannot be given from the middle of May to the middle of September. During April and the early days of May more care is necessary, owing to weather vagaries.

Ventilation : for plants. 1. Greenhouse ventilation : *a*, lights ; *b*, pipes ; arrows denote direction of air currents. 2. Frame ventilation : *a*, bricks ; *b*, light block. 3. Cloche ventilation. 4. Pot ventilation : *a*, sticks ; *b*, glass. 5. How to remove top light, *a*, of a frame, the dotted lines showing insecure method of standing after removal. 6. Ventilation of a forcing house : *a*, flues ; *b*, pipes ; *c*, lights ; arrows denote air circulation

In winter, ventilation should be allowed whenever the air is mild, opening up during mid-morning and always closing down between 2 and 3 p.m. When the air is very dry or very cold, ventilation should be reduced to a minimum, and unless heat is available to give it warmth before entrance, top ventilators should be opened in preference to those at the sides. Another point to remember is that ventilators must be opened to leeward and closed when the wind direction

changes. During spells of very severe weather ventilation must be restricted to an hour, or even less. It is a safe rule to open top ventilators first, following, when necessary, with the lower ones, but always opening them on the same side of the house. Sliding lights are now out of date, and in modern houses the runs of ventilators are levered open to any desired aperture at one time, separate levers controlling top and bottom. Another important detail is provision of holes in the brickwork to admit air, where it will be forced to pass around the hot water pipes as shown in the diagram; this arrangement is usually adapted to large houses, but it may very well be arranged in those of smaller type. Ventilation of garden frames is often necessary, and our sketches show simple and effectual methods.

VENUS FLY TRAP. The plant to which this name is given is a greenhouse herbaceous perennial with white flowers. The leaves are edged with sensitive teeth, which are said to close up and interlock when a fly or other insect alights upon them. As soon as the insect is dead the leaf reopens. The plant, popular only as a curiosity and for collections, is grown in equal parts of peat and sphagnum moss. Latin name: *Dionaea muscifera*.

VENUS' LOOKING GLASS. The best known species of this hardy annual flowering plant is *Specularia speculum*, which grows 1 ft. high, with oblong or lance-shaped leaves, and purple flowers in July. It will thrive in any fairly good garden soil in a sunny bed or border.

VENUS'S NAVELWORT. This name describes a small group of low-growing plants suitable for the rock garden. One of them, *Omphalodes linifolia*, is a pretty hardy annual, 10 in. high, with white flowers in late spring or summer from seeds sown out of doors in autumn and spring respectively. It needs rather light soil and partial shade. Of the perennial kinds the best are *cappadocica*, *verna*, and *Luciliae*.

VERANDAH. In its usual form a verandah is a raised covered-in extension from an outside wall of the house. In some styles of architecture it is a special feature of the building. A certain type of Victorian villas, for instance, have long narrow verandahs, situated a few steps above the ground level. The chief drawback to this style is that it darkens the rooms opening on to the verandah, with its curved iron roof, trellis, pillars and railing all obscuring the light; also it is not wide enough to afford the compensation of being a useful open air sitting-room.

Verandah. Constructed of timber and glass, this first floor verandah with its comfortable furnishing forms a pleasant sun parlour. (Humphrey & Vera Joel)

In more recently built houses of corresponding size the comparatively spacious bricked, tiled or paved loggia has largely supplanted the old-fashioned verandah. The latter, however, in a wider form is a convenient extension over a porch or in conjunction with a large balcony on an upper floor.

When constructed of timber and glass after the manner of a conservatory, as shown here in our illustration of a first floor verandah, it forms a

sun parlour. Sections of its glazed front wall are movable and the glass roof does not darken the adjoining living-room. *See* Conservatory: Garden Furniture; Glass; Loggia.

VERATRUM. This is a vigorous hardy herbaceous perennial plant with large leaves and flower spikes which reach to a height of 3 ft. to 4 ft. It is suitable chiefly for the wild garden or large herbaceous border. It flourishes in ordinary well-tilled and manured soil. The chief kinds are album, 3 ft., greenish; nigrum, 3 ft., dark maroon; and viride, 4 ft., greenish: all bloom in summer. The rootstocks have poisonous properties and hell-bore powder, used as an insecticide, is made from the roots of *Veratrum viride* and album.

Verbascum. This is the botanical name for the border plants known as mullein (q.v.).

VERBENA. This is the name of a popular half-hardy plant which is largely grown for use in summer flower beds. There are several named varieties, of which the prettiest is the pink one named Miss Willmott, but a packet of mixed seeds will provide flowers of brilliant and varied colouring. If these are sown in a heated greenhouse in Jan. or early Feb. the plants will bloom in summer. They must be grown in a compost of loam, leaf-mould and sand and gradually hardened off for planting out in June. Cuttings may be taken in August and inserted in pots of sandy soil in a frame.

Verbenas make charming summer flower beds and yield a wealth of bloom if the shoots are pegged down. *Verbena venosa* bears lilac-purple flowers. *Verbena chamaedrifolia*, which is suitable for the rock garden or a sunny border of light soil, has scarlet blooms.

Verbena. Flowers of the pink variety, Miss Willmott.

VERDIGRIS. This is a green or greenish blue substance formed by the action of an acid on copper and on metal alloys containing copper. It is used as a stain and a dye, and for this purpose is produced by subjecting copper to the action of acetic acid.

Articles made of brass are liable to the formation of verdigris, which can be removed by dipping in a strong potash solution. Hydrochloric acid in a weak solution can be used for removing verdigris from articles of rolled gold, and, unless plated articles are badly coated, when the above method can be used it will be sufficient to wash them in strong soda water. Sub-acetate of copper or verdigris can be employed as a green stain by dissolving it in a hot solution of vinegar. It is also employed in making an ebony stain. *See* Brass; Bronze; Bronzing.

VERGE. In gardening operations the straight or curved edge of a lawn is known as the verge. It has to be kept clean and true after the mower has cut the grass as near to the boundary as possible. An edging iron is the best implement to employ, aided by a garden line stretched from end to end of lawn.

There is also a machine called a verge cutter, which trims off all projections of lawn edges. This cutter is supplemented by a knife blade, which requires frequent sharpening. *See* Lawn.

VERMICELLI: Cookery Uses. A delicate Italian paste, vermicelli is so called because of its thread or wormlike appearance. It is used for puddings, sweets and savouries; soups are thickened with it, and it forms an excellent substitute for breadcrumbs in the coating of small cases.

All Italian pastes differ in the time required for cooking them, as if the paste is old or stale it takes longer to soften. Good fresh vermicelli should be done in from 5 to 7 min., and on that account is valuable when time is limited. No Italian paste should be soaked before it is cooked, but just dropped into plenty of salted boiling water, stirred occasionally, and drained off as soon as it is done.

For thickening clear soup, boil the vermicelli as directed above. Have the soup ready flavoured and strained, put the vermicelli into the tureen, and pour the soup, boiling, over it. Use 2 to 3 oz. paste to each quart of stock. For a family soup the vermicelli may be sprinkled into the boiling soup about 10 min. before serving it and stirred till it is soft. This latter method saves the use of extra utensils.

The following is a simple but nourishing dish for children: Put into 1 pint boiling white broth or milk 2 oz. vermicelli, season and flavour to taste, and then boil for 5 min., stirring all the time. This should be served with rusks.

Vermicelli Sweets. Vermicelli pudding is steamed, and will take 1 pint milk, the rind of a lemon, 2 oz. castor sugar, 4 oz. vermicelli, and 3 eggs. Infuse the rind of the lemon in the milk for 40 min., adding a pinch of salt, but be careful not to let the milk waste. Then strain out the lemon and return the milk to the saucepan used for the infusion. Bring it to the boil, and stir in the vermicelli (cooked). Continue stirring over the fire for 4 min., then draw the pan back. Beat the eggs and sugar together, and mix them thoroughly with the milk and vermicelli. Turn into a greased basin and steam $1\frac{1}{4}$ hours.

A trifle may be made in this way: Cook 6 oz. vermicelli in salted water and drain it. Have ready $1\frac{1}{4}$ pints rich custard. Melt $\frac{3}{4}$ oz. gelatine in 2 tablespoonfuls of water, mix this with the custard, and pour both over the vermicelli. Set the mixture in a border mould or in a dish, the centre of which has been filled in with a smaller dish. When firm, turn it out and arrange it in a glass dish. In the middle of the border place a layer of sponge fingers and ratafias soaked with sherry. Cover them with red chopped jelly, and heap it in a mound. Then pipe the whole with flavoured and sweetened whipped cream. Finish by decorating with coloured sugars.

Vermicelli Pie. An excellent pie is made with 4 oz. cooked vermicelli, $\frac{3}{4}$ lb. cold meat minced (chicken or veal for preference), 3 or 4 tomatoes, a little grated nutmeg, seasoning, $\frac{1}{2}$ pint vegetable flavoured stock, 4 oz. grated cheese and breadcrumbs. Arrange all these ingredients in layers in a greased fireproof dish, reserving sufficient breadcrumbs to cover the top, on which place small dabs of butter, and bake about 20 min. in the oven.

VERMIN. In English law this word is defined to include bugs, fleas, lice, itch, mites and their eggs, larvae and pupae. The Housing Act, 1936, states that for houses of a certain rental there is an implied condition that the house is at the commencement of the tenancy in all respects reasonably fit for human habitation, and a similar condition is to be found in the Rent Restriction Acts. Therefore if a tenant moves into a house and directly afterwards finds that the house is infested with vermin, he or she has just cause for complaint against the landlord; damages have been awarded in the courts in such cases.

Many large towns, including London, have acquired powers to deal with vermin, verminous rooms and persons by means of local acts; in addition there are particular sections of the Public Health Act, 1936, dealing specifically with vermin, and action can be taken under this act against the persons who cause the vermin. Again, all local authorities have powers given them under the Public Health

Acts, enabling them to deal with premises which are a nuisance, and injurious or dangerous to health. Several towns have obtained powers by local Acts to deal with the dirty tenant, and where it is proved to the satisfaction of the court that within twelve months of a room having been properly cleansed they have by neglect and filthy habits made the room verminous a fine may be imposed.

London has considered this subject fully at various times, and borough councils have the right to enter premises, inspect and serve notices in writing upon the owner or occupier of a house or room to have it cleansed within a certain time, and if necessary to remove the paper from the walls for the purpose of destroying and removing the vermin. Failure to do so may upon conviction cause a fine of 10s. a day for every day of failure, or the authority may do the work and recover the costs.

The practical working of this is as follows: A complaint is lodged, or it comes to the knowledge of the sanitary authority, that a house or room is verminous. The sanitary inspector visits and possibly finds the tenant has only been there a short time, obviously then the liability is the landlord's and a notice is served upon him to remedy same. However, if it is found that the tenant has occupied the room for some time and the vermin is caused by his or her dirty habits, then the liability is theirs. Much trouble is caused by people buying old furniture and clothes and importing them into their rooms.

A new departure in public health law which applies to London only came into force in 1928. On the report of the medical officer of health that a person and clothing is infested with vermin, and such person will not consent to be removed to a cleansing station, the court, if satisfied with the application of the local authority, may order his removal and detention. The local authority may take such measures as necessary to free him and his clothing from vermin. Females are protected, inasmuch as the examination of such must be carried out by a woman or a doctor. No charge is made for this personal cleansing.

The Children's Act, 1908, gives the school medical officer and nurse power to examine children, and if it is found that such children are infested with vermin or in a foul or filthy condition, the local authority can give the parents or guardians of such child a notice in writing requiring them to cleanse properly the person and clothing of the child within 24 hours of the receipt of the notice. Failure to do so gives the officers power to remove the child and detain him or her till they are satisfied that the child is properly cleansed.

VERMOUTH. The mild cordial known as vermouth is made from white wine flavoured with wormwood and certain vegetable extracts. It is used mainly as an aperitif before luncheon and dinner and as an ingredient in several cocktails. A favourite appetizer is a French and Italian vermouth mixed half and half.

A vermouth cocktail is made with two dashes of Angostura bitters and one portion of Italian vermouth, filled with ice, mixed and strained into a cocktail glass. Another cocktail is made with three dashes each of Maraschino and Angostura bitters. Add one portion of Italian vermouth, fill with ice, mix and strain into a glass, the rim of which has been moistened with lemon peel and then dipped into some powdered sugar. *See Cocktail.*

VERNIER: On Calipers. This is a device applied to a scale to give accurate readings in fractions of the smallest division of the scale. It is used on micrometers, caliper gauges, and scientific instruments that are designed to work very exactly.

A sliding caliper vernier is shown in the accompanying illustration, as engraved on the sliding jaw. The scale on the shaft gives measurements in tenths of inches. The vernier scale has ten divisions, together equal to nine divisions of the scale; each therefore representing $\frac{9}{10}$ of $\frac{1}{10}$ of an inch. In the illustration the zero mark of the vernier has passed the inch mark of the scale, but has not reached the next $\frac{1}{10}$ inch mark. To decide the value of the fraction the vernier is consulted, and its

7 line is found to correspond exactly with a scale mark. The 6 line of the vernier is $1/10$ of $1/10$ inch to the right of the nearest scale mark on its left; the 5 line, $9/10$ of $1/10$ inch; and so on to the zero mark, which is $7/10$ of $1/10$ inch beyond one inch. The reading therefore is 1.07 inch. A finer reading could be made if the vernier scale had 20 divisions equal to 19 of the scale, as the difference would then only be $1/20$ of $1/10$ inch.

Vernier. Diagram of portion of a scale, reduced, showing a measurement of 1.07 in. See text

The vernier incorporated in a micrometer gauge is essentially similar in principle, though the scale is engraved around the thimble of the gauge. See Gauge; Micrometer.

VERNIS MARTIN. A brilliant lacquer or Varnish used in the painted decoration of articles such as fans, fancy tables, and cabinet panels, takes its name from a French family who during the 18th century developed a form of artistic

decoration based on oriental lacquer work. See Lacquer ; Watch.

Veronica. Hardy and half-hardy evergreen flowering shrubs and perennial plants popularly known as speedwell (q.v.).

VERTEBRA. The spinal column is composed of a large number of separate bones superimposed one on the other, the object of such an arrangement being, of course, to secure flexibility. Typically, a vertebra consists of a mass of bone in front, the body, and a bony arch behind. The first cervical or neck vertebra, known as the atlas, the one on which the skull rests, does not possess a body, but consists simply of a ring of bone. The next one has on the upper surface of the body a long tooth-like process which engages in the front part of the ring of the atlas. The object is to permit of rotation of the head.

The bodies of the vertebrae are separated from each other by disks consisting of fibres and gristle. These, known as the intervertebral disks, increase the elasticity of the spine. The arches placed one over the other and the broad ligaments connecting the vertebrae form the spinal canal, which contains the spinal cord. The five sacral vertebrae are fused to each other in adult life, forming a single bone, and the same is true of the four coccygeal or tail vertebrae. See Spine.

Vertigo. See Dizziness.

VETCH. Plants with small pea-shaped flowers, vetches are of little decorative value. *Vicia fulgens*, of slender climbing growth, has red flowers in summer. *Vicia faba* is the broad bean. *Coronilla varia*, 2 ft. high, has vetchlike leaves and rose-pink blooms.

Vetch. Dainty rose-pink flower clusters and vetchlike leaves of *Coronilla varia*.

VIBURNUM. This is a family of beautiful hardy flowering shrubs, with white flowers. Most of the species are deciduous, or summer-leaving, while some are evergreen. See Guelder Rose; Snowball Tree.

VICE: Different Types. The principal requirements in a vice are strength, rigidity, and a tight grip. Vices are made of many patterns, each specially suitable for some particular class of work, but the type in Fig. 1 is the most useful when a single tool has to be depended on for jobs of all kinds.

One jaw is fixed while the other is moved in or out as required, by a screw mechanism concealed in the body of the vice. The screw is turned by a tommy bar which can slide through a hole in the projecting head of the screw, and has knobs on its ends to prevent it from dropping out. In addition there is a spring catch at the side, a touch on which frees the screw mechanism so that the vice can be open or closed rapidly by hand, the screw mechanism being then used for the final closing of the jaws tight on the job.

The jaws of a vice are serrated and hardened in order to provide a good non-slipping grip, and therefore some protection is needed when finished surfaces have to be held. This protection is conveniently afforded by covering the jaws with pieces of tinplate, sheet copper, or lead, bent to angle iron form; hardwood blocks are often convenient, especially when holding objects of awkward shape.

When fixing a vice it is essential that it should be held on to something very rigid, as any movement, however slight, is most objectionable, especially when filing. If the available bench proves to be unsteady, it can generally be improved by screwing wooden battens, say, 2 in. by 1 in., diagonally from the bottom of one leg to the top of the second all round the bench and screwing the legs to the floor with angle brackets.

In choosing a vice the first consideration is the purpose for which it will chiefly be required. If heavy work is to be done, such as forging or smith's work, then one of the regular blacksmith's leg vices is essential, but for the repair of a car or for bending heavy metal the regulation engineer's vice shown in Fig. 1 should be chosen. The width of the jaws should preferably be about 3½ in., and the opening up to about 6 or 7 in. This class of vice must be securely bolted to a strong and rigid bench. For lighter work, a vice of the pattern illustrated in Fig. 2 is suitable. It is made of cast iron from 1½ to 3 in. wide, and is not, as a rule, provided with quick release mechanism. It is screwed to the top of the work bench with stout wood screws.

For occasional use, the portable bench vice in Fig. 3 has many advantages, chief of which is the provision of a self-contained clamp with clamping screw which enables the vice to be attached to the work bench, kitchen table, or other convenient means of support. If the vice is to be used for any length of time, a couple of wood screws can be inserted in addition to prevent it shifting.

Woodworker's Vice. For woodworking, a joiner's or carpenter's vice, as shown in Fig. 4, is usually most serviceable. It is made in several sizes, usually with a quick release mechanism. This comprises a small trigger, located near the screw handle, the action being to press the trigger and pull the vice-jaw in or out to its approximate position, then release the trigger and tighten up the vice in the usual way.

These vices have smooth faces to the jaws, and can often be used with wooden faces which can be screwed in position when they are needed, holes being provided for that purpose. This type of vice is attached to the underside of the work bench with the upper edges of the jaws flush or slightly below the surface of the bench. It is imperative that the vice should be securely fixed, as by the use of coach screws or by bolts with the heads recessed below the surface of the bench and the holes properly plugged with wood.

When circular work is to be dealt with, a pipe vice like that illustrated in Fig. 5 is the best. It consists essentially of a horizontal sole plate or base with an upright portion upon it, through which works the jaw with a V-shaped end. This slides in a passage way formed within the case and closes down to a slot in the lower jaw which is similarly V-shaped. When the handle is turned, the jaws are forced together and the pipe is securely held. As such a vice is subjected to considerable twisting strains it must be bolted to a rigid bench.

In addition there are the various hand vices, ranging from that shown in Fig. 6 down to the jeweller's pin vice designed to hold fine wire while being worked. Some forms of the last named resemble a chuck in shape and action. A useful pattern for the amateur is the hand vice shown in Fig. 6. It is virtually a small vice with a long extension piece on the opposite side to the jaws, these being hinged together. This part of the vice can be held in the hand, the work being grasped between the jaws by tightening up the thumbscrew. A considerable range of work can be dealt with by , such instruments and they will often take the place of a bench vice, in cases where it is not practicable to take the work to the bench.

Vices as a rule do not receive sufficient care and attention. Except in the very heaviest patterns the vice should not be used as an anvil. The screw and the working portions ought to be lubricated from time to time so that they may work freely and easily. In this connexion it is well to clean out the screw and screw thread of the moving part occasionally by washing them out with paraffin, brushing away any chips or grit, and thoroughly oiling. *See Hand Vice; Napkin.*

VICTORIA. The Victoria is an old-fashioned four-wheeled vehicle having a low seat for two persons and a raised seat in front for the driver. *See Carriage.*

VICTORIAN STYLE IN BUILDING & FURNISHING

Its Distinctive Features and its Good Craftsmanship

The contribution on the Adam and Regency Styles may be referred to as immediately influencing the development of early Victorian decoration and furniture. See also Buhl; China; Davenport Table; Dressing Table; Jacobean Style; Jewelry; Papier Mâché; Sheraton Tapestry Needlework; Tudor Style; Woodworking

Much that was cumbersome, badly proportioned, crude in colour and ornament, lacking in appropriate design and in meaning is associated with the decorative art and architecture of the Victorian era. It should, however, be remembered that the period was a long one, and its sixty-four years are generally divided into Early, Mid and Late Victorian phases by certain marked features and developments.

The first of these phases was chiefly characterized by a continuation of the classical revival started at the end of the 18th century and emphasized in the Adam and Regency styles. In the Mid-Victorian phase there was a great medley of the so-called artistic in ornament and design combined with keen commercialism. The rise and prosperity of the middle classes was accounted for by the huge output of the factories which in turn led to the amassing of material possessions as evidence of social standing. After the Great Exhibition in 1851, china and glass ware factories and all the furnishing trades poured forth a stream of goods, and quantities were also imported, in which domestic comfort and the new mechanical processes were supposed to be allied to artistic designs. In the last Victorian phase reproductions of Tudor houses, Jacobean, Queen Anne and Sheraton furniture were in vogue. These were usually distorted with affectations of the day and stereotyped ornaments.

Machine-cut decorations glued on to so-called Chippendale pieces took the place of hand carving. In the early phases colours were bright and designs were naturalistic. In the nineties curiously conventional designs and "art" shades, lacking in purity of colour, were the fashion. The vast accumulation in most homes of unnecessary accessories, draperies and heavily framed pictures reached a feverish pitch. Many things of beauty, old and new, might be included in the furnishing of a room, but owing to lack of tasteful display and the jumble of other shapes and colours their decorative value was lost.

Domestic Architecture. Victorian architecture of the first two phases owes its character to two main influences. The classical style of the preceding period and the Gothic revival which was fervently advocated by Pugin, the prominent architect who designed many churches, was connected with the planning of the new Houses of Parliament, and whose woodwork in the House of Lords is one of the really considerable artistic achievements of the early Victorian years.

Most of the public buildings and many large dwellings of the period are marred by badly proportioned pseudo-classical or Gothic features, while most of the small terrace houses were very ugly in design. In the towns the dominating consideration was a so-called elegance and gentility. Typical Victorian houses are from three to five storeys in height, faced with stucco, and almost invariably adorned with a columned portico surmounted by a balcony, of which a narrower extension is carried to the boundaries. The windows are of the sash variety and the roof of slates. Balcony parapets are generally of wrought iron in a straight or curved pattern, but the square portion over the portico is often composed of stone pillars, curved or bulbous, supporting a flat entablature.

To these houses there is usually attached, at the side of the entrance, an area, with stone steps descending to the basement and servants entrance. Even in comparatively small houses of this type the pretentious portico is adhered to on a reduced scale.

Above the solid front door there is usually an oblong fanlight. This often consists of fully proportioned panes of glass, whereas the fanlights of the Georgian period were works of art when completed by grilles of scrolled ironwork. The hall is narrow, and, once past the foot of the main staircase, continues in a narrower passage to the top of the kitchen stairs.

Distinctively Victorian features of the dining room on the ground floor and the double drawing room divided by doors or by a heavily curtained archway, on the first floor are the substantial marble mantelpieces. The first flight of the stairway, up to the drawing room, is broad, with stone or

wide oak steps. The flights diminish in width with each successive stage, culminating in the steep and narrow wooden staircase to the attics.

In the short transitional period before the Tudor revival in suburban and rural districts, a type of house was built in town and country that was free from the worst faults of Victorian classicism. Round-arched windows are often a feature of these façades, and verandahs were another, steps leading up to these and to the front entrances. There is either a semi-basement or this depressing feature is absent. The portico is also absent, the front door being merely recessed with a semicircular fanlight above it. The door usually has four panels, the two upper ones being sometimes glazed and covered with a wrought iron grille.

The ceilings of most Victorian rooms are lofty, and there is a good deal of ornamental moulding. Structurally, the Victorian house is often far better than its modern counterpart, the woodwork especially being of greatly superior quality.

Victorian Furniture. Much of the early Victorian furniture was superbly made. The more solid pieces were of mahogany and designs were gracefully curved. Cabinet making retained the excellent quality of the preceding period. Carving was little used, but mouldings were introduced and plain panels showed off the grain of the fine wood to advantage. In contrast to the plain mahogany pieces which included wardrobes, sideboards, large bookcases and writing tables, were the drawingroom pieces, chairs with gilded or ebonized frames, fine cabinets writing tables and bookcases, walnut chiffoniers and what-nots, interesting small tables, couches and sofas, all of which pieces continued to be made in Empire and Regency styles with brass mountings and decorated with inlay and marquetry or with buhl work. Many charming small pieces were made in papier mâché, japanned black, delicately painted and inlaid with mother-of-pearl.

Conventions governing the choice of furniture for different rooms were much stronger than they are to-day. Solidity was the keynote for the dining room in the mid and late Victorian phases, and so the dining-table had to be of large and heavy structure in keeping with the sideboard, which often measured 8 or 9 ft. in width, was topped by a heavily framed mirror, and had drawers and capacious cupboards below. Victorian dining-tables of the early period were often circle topped, but later they were fitted with an interleaving arrangement. Even without the extra leaf or two specimens still in use generally occupy a great deal of floor space. These are oblong in form for the most part, having solid bulbous legs attached at the four corners, the last being rounded. Dining-room chairs are leather-covered, the backs being slightly sloped. Everything in this room was of plain and aggressively formal design, but much pattern was introduced into the decorative scheme by the wallpaper, the curtains with festooned pelmets, draped portières, chimney pieces also draped and crowded with ornaments and an array of Sheffield or silver plate on the sideboard, including probably a massive tea-tray and urn.

Pianos were mostly of the cottage type with pleated silk backings to tracery panels in wood, but immense grand pianos were also seen with cases of mahogany, walnut or rose wood. Another musical feature often to be found in the early Victorian drawing room was a handsome gilded harp. Gilding was much to the fore in the decorative scheme as the walls were sometimes literally covered with pictures in heavy gilded frames, all of one pattern irrespective of the size and style of the painting. For common use chairs and sofas were upholstered in horsehair, but finer pieces were covered in damask, striped satin, brocade or tapestry needlework. Two quite charming examples of the last are seen in the chairs in Fig. 1. Shown with these is a neat little davenport writing desk of the period.

In the middle of the 19th century a walnut fashion arrived and some excellent furniture was made in the Italian and Spanish varieties of this wood. The former was particularly favoured for wardrobes and other bedroom pieces, as the grain is close and the surface takes a high polish. After this time

furniture makers became obsessed with the suite, and many hideous sets of furniture for drawing room, dining room and bedroom were designed, and so well made that they still exist almost unimpaired.

Victorian Style. Fig. 1. The two charming examples of Victorian chairs are covered with wool tapestry needlework. The davenport writing desk was a characteristic piece of the period.

Early Victorian bedrooms in well-to-do households were charmingly and suitably furnished. They were characterized by clear bright colour, crisp silks, chintzes and muslins for curtains, bed and dressing-table draperies, and usually excellent carpets with floral patterns or wreaths on dark grounds. Woodwork was painted in colours to which the polished mahogany furniture formed an agreeable contrast.

With the late sixties arrived the large and cumbrous suite, the stuffy upholstery and the heavy curtains. Bedrooms as well as sitting-rooms were crammed with superfluous ornaments. Fig. 2 is a good example of the bedroom chimney piece of the mid-Victorian period, and also of the chaotic effect of too many patterns so characteristic of the day. A charming little papier mâché table is doing duty as an empty grate screen, but it cannot be appreciated with the designs of the pierced fender, ugly tiles, and floral brocade drapery fighting against it, while the domes of wax flowers in turn kill the delightful pieces of Staffordshire pottery.

Fig. 2. A mid-Victorian bedroom chimney piece. The illustration affords an excellent example of the prevalent fashion for a medley of discordant patterns.

While many of the productions of the art crafts were as inartistic as are some of the specimens turned out to-day, and as some have been in most other periods, the Victorian output of these things was so vast that collectors are now finding much that is delightful and amusing among the treasures preserved particularly from the earlier work. Examples are also being widely copied. Apart from the undoubted beauty of the Victorian papier mâché work and exquisite coloured glass, minor crafts were admirably executed. Paper patchwork, which was popular in the previous century, had a continued vogue, as also had needlework and tapestry pictures. The Berlin woolwork of a later phase was crude in colour and design.

Beadwork in coloured glass beads was introduced into upholstery covers and widely used for fire screens and purses. Silhouettes and tinsel work pictures of early Victorian theatrical celebrities are now eagerly sought in curio shops, as also are the pretty or quaint specimens of Victorian jewelry, the tea caddies and intricate workboxes. The gay colours and ingenious patterns appeal to modern tastes, and certain of the pieces and ornaments discreetly chosen look particularly well in the plain settings of to-day.

VICTORIA PLUM. One of the best plums in cultivation is the Victoria, which succeeds well in pyramid, standard, or bush form, and will give good crops on a west wall.

As a preserve fruit the Victoria is unrivalled; even the thinnings of green and immature fruit make excellent tarts. Unfortunately this variety is subject to the silver leaf disease, for which there is no cure. *See Plum: Pruning.*

VICTORIA PUDDING. This usually makes an excellent substitute for the more expensive kinds of Christmas pudding. When intended for that purpose it is a good plan to add $\frac{1}{4}$ lb. raisins and two or three apples minced.

Boil together $\frac{1}{2}$ lb. potatoes and the same quantity of carrots. When they are tender chop them very finely, add to them $\frac{1}{2}$ lb. finely chopped beef suet, $\frac{1}{2}$ lb. flour, $\frac{1}{2}$ lb. cleaned currants, $\frac{1}{2}$ lb. brown sugar, and lastly a little spice or grated nutmeg. Mix all well together and press the mixture into a well-greased mould or basin. Cover it with a cloth, put it in a pan of fast-boiling water, and boil steadily for three hours, or longer. Turn on to a hot dish and serve with any good sweet sauce. *See Sugar.*

VICTORIA SANDWICH. Beat 2 eggs and 4 oz. castor sugar for about 10 min., then stir in $1\frac{1}{2}$ oz. melted butter, afterwards folding in gently $3\frac{1}{2}$ oz. flour, and 1 teaspoonful baking-powder. Turn the mixture into two greased shallow tins, and bake in a hot oven for 10 min. When cold, spread with jam or cream.

VICTORIA WATER LILY. Often called the royal water lily, this is the magnificent aquatic plant scientifically known as *Victoria Regia*. Its cultivation is quite beyond the scope of amateurs, but under suitable conditions splendid specimens have been raised from seed in Great Britain. *See Lily; Water Lily.*

VICUNA CLOTH. Very little of the cloth bearing its name comes from the soft, and expensive hair of the vicuna goat. It is a plain, generally dark cloth finished in a particular manner.

Vienna Bread. This term describes a light milk bread prepared with Vienna flour, and is also known as French bread. *See Bread.*

VIENNA CREAM. Heat $\frac{1}{2}$ pint milk and 1 tablespoonful castor sugar in a small saucepan, and bring them almost to boiling point. Then strain in $\frac{1}{4}$ oz. leaf gelatine previously dissolved in about 3 tablespoonfuls hot water, add vanilla or other flavouring to taste and enough cochineal to give the whole a pretty pink colour. Pour the mixture into a flat dish, allowing the jelly to measure about $\frac{1}{8}$ in. in depth, leave it to set, and then stamp it into neat rings with two plain cutters, one slightly larger than the other.

Have ready $\frac{1}{2}$ pint clear wine or lemon jelly, coat the inside of a mould with it, and when it is set decorate the bottom and sides with the rings of milk jelly, arranging them as tastefully as possible and setting them in place with a few drops of the clear jelly. When these, too, are firmly set, fill the

centre of the mould with a cream filling made as follows: Dissolve $\frac{1}{2}$ oz. leaf gelatine in 3 or 4 tablespoonfuls hot water and then add 1 tablespoonful castor sugar. Whip up $\frac{1}{2}$ pint cream, and when the gelatine mixture has cooled strain it in, mixing it thoroughly. Stir in also 2 tablespoonfuls chopped glacé cherries and half that quantity of chopped glacé pineapple and then turn the mixture into the decorated mould, being careful not to disturb the rings. Leave the whole to set, and then turn it out carefully on to a glass dish.

VIENNA ICING. A good recipe for this soft icing, which can be used for decorating fancy cakes, is 4 oz. fresh butter to 10 oz. icing sugar, black coffee essence or vanilla essence to taste, and $\frac{1}{2}$ gill rum, brandy, liqueur, or sherry. The butter must be the very best and unsalted, and the sugar must be passed through a fine hair sieve. Work the butter to a cream, then add the other ingredients by degrees. When the icing is ready it should look like cream and can be used as a filling for a layer cake or Victoria sandwich. *See Cake; Icing.*

VIEW FINDER. Every camera should be fitted with an attachment by the use of which the photographer can ascertain precisely what part of the view at which he is pointing his camera will be included on the plate or film. This attachment is known as a view finder, and may take one of three forms.

The most common and least useful is that found on the great majority of small hand cameras used by amateurs, called the brilliant view finder. The amateur who wishes to produce anything more than snaps of varying success should discard it.

The image it produces is so small that it is impossible to see any detail in the picture, or to gain any clear idea of its composition, as it would be seen on the film or focussing screen. Again and again the amateur who relies on the brilliant view finder with its tiny image will find that his film is spoilt by some prominent object which he had not noticed, glaringly out of focus in the foreground.

View Finder. Fig. 1. Showing a direct view finder, consisting of a double concave rectangular lens fitted to the top of the camera

Perhaps its most serious fault is that its use entails holding the camera about the level of the waist-line, a position which is hopelessly wrong. If a scene is looked at from the kneeling position, it will have a distinctly different appearance when we stand up and look at it in the normal erect position. In the first case, foreground objects possess undue importance, and the whole perspective is partially falsified. Since things are normally looked at from eye level in the standing position, the camera should be made to look at them in that position, and not as if the photographer were one of those mythical beings found on old maps with eyes in his stomach.

A much better type is the direct vision finder in one or other of its forms. An example of this is seen in Fig. 1. It consists of a double concave rectangular lens fitted to the top of the camera body in a line with the camera lens. It is of the same proportions as the plate or film used. The view at which the camera is pointed is seen in reduced size, but perfectly clearly, on the inner face of the view-finder lens, correct centring being obtained by means of a sighting pin at the proper distance away from the finder.

View Finder. Fig. 2 Use of view finder as shown in Fig. 1. When this type is used the camera must be held at eye level. Fig. 3. Wire frame view finder, with fixed sighting hole.

The camera must be held at eye level, as shown in Fig. 2. When using this type of finder the camera is almost

bound to be held squarely. The complete fitting folds down on top of the camera, and can be purchased separately and added to most types of folding camera.

Another form of the direct vision finder is the open frame (Fig. 3). Here a wire frame of the same size as the plate or film used is attached to the side of the lens mount. In some patterns it is attached to the top. At the back of the camera a sighting hole is fixed, and by placing the eye to it, as demonstrated in Fig. 3, the exact portion of the view which will be included on the film by the lens is seen. Moreover, the view is seen in its full natural size, so that it can be studied and the view point varied as necessary to avoid ugly foreground intrusions or other undesirable features. This pattern has the additional advantage that, as the frame is attached to the lens mount, its distance from the sighting hole varies with the focussing so that the finder is accurate in all positions.

VINAIGRETTE. This refers to a small box, often made of silver and occasionally of gold with an inner perforated lid that is used for holding a sponge soaked in aromatic vinegar. It was carried in the pocket and the vinegar inhaled as a restorative.

VINAIGRETTE SAUCE. This is made by mixing together 6 tablespoonfuls of tarragon vinegar, a teaspoonful of chilli vinegar, and 2 teaspoonfuls each of chopped tarragon and chervil. Stir these well in a basin, and season with salt and pepper. *See Salad.*

Vinca. *See Periwinkle.*

VINES AND HOW THEY ARE GROWN

Hints on Their Cultivation in Greenhouse and Open Air

This article deals first of all with the varieties of the vine and then with the culture of its most useful and popular form, the grape vine. Its fruit is described under the heading Grape.

See also Dessert; Greenhouse; Muscat

Some of the vines are grown for their ornamental leaves, which colour brilliantly in autumn; others, valued for the sake of their fruits, are grown under glass. Although a few varieties of grape vine may be planted on a sunny wall with fair prospect of a crop of small grapes in a favourable summer, large, well-flavoured fruits and a reliable crop are assured only by growing vines of special varieties in a glasshouse. For planting against a sunny wall out of doors the best variety is Royal Muscadine, which bears small pale yellow grapes.

Haphazard methods will not meet with success in the cultivation of the vine. A border must be prepared just outside the glasshouse by excavating the soil to a depth of 2½ feet. A layer of broken bricks is put in the bottom for drainage and the border is then filled with a compost consisting of

three parts of old turf, chopped into pieces about the size of one's fist, and one part of decayed manure, together with a sprinkling of bonemeal or special vine manure. The compost should be trodden firmly. Vines are best planted in autumn. A hole is made low down in the greenhouse wall to allow of the stem of the vine being passed through.

In January the stem is cut back so that it reaches only to the trellis on which the vine is to be trained. In spring two of the fresh shoots are allowed to grow, one being trained vertically up the trellis, the other horizontally along the front of the trellis. No further pruning is required until the following winter, when the past summer's growth is shortened to within 2 ft. of the base. In spring the new shoots at the ends of the two branches are allowed to grow unchecked and a few others are left to form side shoots or laterals, which will produce grapes. The same routine is practised until the available space is filled, the main branches being allowed to progress at the rate of 2 ft. every year and other shoots being left for fruit bearing. These side shoots ought to be about 18 in. apart on each side of the main stems; it is important that they should alternate with, not be opposite to, each other. Most of the side shoots may be expected to bear bunches of grapes; the tips must be inched off when two leaves have developed beyond the bunch. This will cause other small shoots called sublaterals to form and the tips of these must be pinched off beyond the first leaf. This summer pruning is most important; if it is not practised the trellis will become a mass of crowded leaves, and there is the further risk that mildew will set in and the grapes will not ripen properly.

In winter, all side shoots, whether they have borne fruits or not, must be pruned to within two buds of the base of the past summer's growth. If in spring both buds start into growth one of the shoots, the weaker of the two, must be rubbed off. Summer and winter pruning in the way described is an important detail in the cultivation of the vine, and success depends chiefly on its being carried out. As the years pass this hard annual pruning will result in the formation of woody swelling, called spurs, at the base of the side shoots.

Ventilation and Thinning

Other details which need attention are ventilation, the regulation of the temperature and thinning the bunches. If the glasshouse is heated, a night temperature of 45 degrees should be maintained in January and one of 50 degrees in February and during the spring months. As the temperature rises out of doors the ventilators must be opened to prevent the glasshouse becoming excessively hot, the amount of ventilation being increased as the day advances if necessary. In the afternoon, an hour or so before the sun has ceased to shine on the roof, the ventilators ought to be closed; at the same time the floor and walls should be syringed. The vine flourishes in a warm moist air except when the bunches are in flower; then the glasshouse ought to be dry and well aired if the weather is mild.

When the grapes are the size of peas they ought to be thinned; this is done by cutting out all the smallest berries and those in the middle of the bunches with a pair of scissors having long pointed blades. A further thinning will be necessary to give the berries room for full development. When the grapes begin to change colour a dry airy atmosphere is again necessary.

If the vine is grown in an unheated greenhouse it will start into growth later than if the glasshouse is heated and the grapes will ripen later in the summer. During dull wet weather great care must be taken to ventilate correctly and to keep the air of the greenhouse as dry as possible to prevent an attack of mildew; it is most important also to attend to summer pruning in the way advised to prevent overcrowding.

The best grape to grow in an unheated glasshouse is the variety known as Black Hamburg; this variety is also well suited to a heated glasshouse where, however, others may be planted. Those most easily managed are Alicante, Gros Colmar, Madres-field Court and Foster's Seedling (a pale yellow grape). Other first rate grapes which need somewhat skilled attention are Lady Downe's, Muscat Hamburg, Mrs. Pince and Muscat of Alexandria; the last named is a pale yellow grape,

generally regarded as the most delicious of all, which requires rather a higher temperature than most others to bring it to perfection.

Vine. 1. Propagation by "eyes." 2. "Eye" suitably potted with its base in powdered charcoal. 3. Rooting of same. 4. Propagation in piece of turf: the eye is planted with a base of sand and charcoal dust and covered with fine rich soil. 5. Grafting a vine by approach. 6. How to stop shoots; pricking out points shown by thick lines. 7 and 8. Thinning scissors and special stick for thinning. 9. Bunch suitably thinned

Propagation. Vines are propagated by eyes or buds. In January a piece of shoot of the previous year's growth is cut off; it should be about $1\frac{1}{2}$ in. long and contain a bud. If set singly in small pots of light soil, placed in a propagating case in a heated glasshouse and kept moist, these eyes will form roots; they are subsequently potted in small pots and repotted as becomes necessary until they are in 8 in. or 9 in. pots. In late summer when growth is complete they should be placed out of doors so that the wood may become well ripened. In autumn the young vines may be planted in a border or repotted in 12 in. pots in which they will bear fruits; the stems or branches are trained on thick bamboo canes inserted round the edges of the pots. They need similar treatment to that already described. In December all loose bark should be peeled off the vine stems, which must then be treated with a brush dipped in the Gishurst compound preparation; this will help to keep them free from the attacks of pests.

Pests of the Plant. Red spider is a pest which attacks the lower surface of the leaves and disfigures and weakens them; it is most likely to be troublesome in a dry, warm atmosphere. Syringing the lower side of the leaves with salt water, 1 oz. in one gallon of water, is recommended. Mealy bug is the most serious pest; it can be killed by using a brush dipped in methylated spirit, but great care must be taken not to touch leaves or buds or they will be ruined.

Mildew is a troublesome plant disease to which vines in an unheated glasshouse are particularly liable. It spreads most quickly in a damp atmosphere, therefore if mildew appears the greenhouse must be kept dry and airy. Affected leaves should be “dusted” with sulphur. Great care must be taken not to let the trellis become overcrowded with shoots and leaves. Summer pruning should be practised in the way already advised.

Ornamental vines are handsome leafy climbing plants for covering trellises, arbours and pergolas, and the self clinging *Vitis* (ampelopsis) *Veitchii* is invaluable as a wall covering; its small leaves turn crimson in autumn. The best of the large leaved ornamental vines which become beautifully autumn-tinted are *Coignetiae*, *quinquefolia* (Virginian creeper), *Thompsoni*, *Thunbergii*, *Engelmanni* and *Vinifera purpurea* (the purple leaved vine). *Vitis Henryana*, which has small green and white leaves, is suitable for planting on a wall in mild districts. All these vigorous plants thrive in ordinary well tilled soil.

VINEGAR: Its Uses. Vinegar is a solution of acetic acid in water usually darkened by adding colouring matter. It may be prepared from malt, wine, cider, sugar, wood, and other substances. The ordinary brown vinegar is made from malt. Most French vinegar is colourless, being obtained from the fermentation of light wines.

Besides its use as a table condiment, vinegar is employed in cookery for giving a piquant flavour to savouries and sauces, for dressing salads and for pickling. Various dishes are prepared with it, as, for example, herrings cooked and soured in vinegar. Tough meat is made tender by steeping in vinegar and water before cooking. It is not difficult to make herb-flavoured vinegars at home, and it is useful to have various flavours in the store cupboard. Tarragon vinegar is made thus: To $\frac{1}{4}$ peck tarragon leaves add $\frac{1}{2}$ gallon white vinegar. Leave it in a covered jug for two weeks, then strain it through flannel; return it to the jug. Dissolve in it a good pinch of isinglass in order to fine it. Afterwards bottle and cork it down.

For chilli vinegar add 1 oz. ground chillies to 1 quart white wine vinegar, put it in a covered jar, and leave it for two weeks, shaking it each day, then strain and bottle for use. To make horse-radish vinegar scrape 3 oz. horse-radish, add 1 oz. shredded shallot and 1 dram cayenne pepper. Put all into a jar and pour over it 1 quart white wine vinegar. Cover it closely and let it stand for two weeks, shaking it occasionally, then strain and bottle it.

Cayenne vinegar is useful when a hot seasoning is required. Put $\frac{1}{2}$ oz. cayenne pepper into a jar and pour on it 1 pint white wine vinegar. Cover it closely and leave it for three weeks, shaking it every two or three days. When ready, the liquid must be poured off gently into a bottle or strained through a piece of fine muslin.

Orleans vinegar, prepared in considerable quantities in the Orleans district, is a variety of white wine vinegar suitable for table use and for toilet preparations.

Vinegar is considered to help in the digestion of oily or fatty foods. It should, however, be used in strict moderation, as it interferes with digestion, and may set up irritation of the stomach if taken too constantly or too freely. Vinegar is often taken by the ignorant as a remedy for reducing the weight. It should be clearly understood that its use for this purpose is utterly unjustifiable, as the only way in which vinegar can make one thin is by seriously harming the digestion. *See* Acetic Acid; Pickle; Salad; Sauce.

VINEGAR CAKE. Take 1 lb. self-raising flour, 4 oz. each margarine, sugar, raisins, and sultanas, 1 teaspoonful bicarbonate of soda, 1 breakfastcupful milk, and 2 tablespoonfuls vinegar. Rub the margarine into the flour, add the sugar and the dried fruit, and then the bicarbonate of soda dissolved in the milk. To these add the vinegar, mix all together, and then bake in a moderate oven for an hour.

VIOLA: The Flower. This is the botanical name of the group that includes the viola, or tufted pansy, the ordinary pansy and the violet. Some of the violas are charming rock garden flowers, while the larger-flowered sorts are invaluable for filling spring and summer flower beds. The modern race of large-flowered violas originated by cross-breeding between *Viola cornuta*, a Pyrenean plant, and the pansy.

Viola. Fine flowers of this beautiful border plant.

Right. Viola. Tiny yellow flowers of the low growing rockery plant.

Viola Culture. 1. Cutting : *a*, how to prepare ; *b*, depth to plant. 2. Natural plantlet : *a*, root growth ; *b*, depth to plant. 3. Type of cutting to avoid. 4. Violas from seed : *a*, glass ; *b*, cross sticks ; *c*, sandy soil ; *d*, compost ; *e*, leaves ; *f*, corks. 5. Seedlings transferred to shaded cold frame : *a*, ventilating block ; *b*, shading material. 6. Old plant trimmed to provide cuttings. 7. Soil preparation for cuttings : *a*, sand ; *b*, fine loam ; *c*, ashes ; *d*, sub-soil. 8. Dibbed hole with sand at base. 9. Cutting suitably planted

They flourish in ordinary well-tilled soil, and are propagated by cuttings inserted in sandy soil in a cold frame in September; during the winter in mild weather the frame must be ventilated freely. The plants are set out of doors in April, and will bloom throughout many summer weeks if the dead blooms are picked off and the soil is moist. They are also easily raised from seeds sown under glass in spring. Some of the best varieties are: Primrose Dame, pale yellow; Maggie Mott, lavender; The Swan, white; Moseley Perfection, yellow; W. H. Woodgate, pale blue; Archie Grant, purple blue; Mrs. Chichester, white and purple; Red braes, yellow; Arkwright's Ruby, red.

Viola cornuta is a plant of tufted growth which bears small flowers in profusion; there are varieties with blooms of purple, rose, and other colours which are most useful for planting in rose beds.

Of the species or wild types suitable for the rock garden the following are very charming flowers: *calcarata*, lavender-blue; *gracilis*, purple, and its fine variety Purple Robe; and *lutea*, yellow. These should be planted in gritty, loamy soil in slight shade.

VIOLET. This favourite garden flower pays for good cultivation. If the plants are left undisturbed for years the blooms become small.

It must be planted in deeply dug soil enriched with manure in a slightly shaded position; a border facing west is ideal. In May the old plants should be lifted and separated into pieces, the best of these being replanted. Single varieties are set at 15 in. apart, double varieties at 12 in. apart. During the summer months the soil between the plants should be hoed frequently to keep down weeds, and all runners must be cut off.

Violet. Princess of Wales, a large, long-stemmed bloom.

To ensure fine flowers the violet bed ought to be replanted annually, or, at all events, every two years. Some of the best varieties are Princess of Wales, Czar, California, and La France, violet blue; and White Czar, white. These are single flowered. Good double violets are Comte de Brazza, white; de Parme, lavender; Marie Louise, mauve purple; Mrs. Astor, rosy heliotrope; and Neapolitan, lavender. Admiral Avellan, reddish mauve, and Coeur d'Alsace, pink, are two pretty single violets of unusual colouring.

To obtain violets in winter some of the plants should be lifted and planted in a bed of soil in a cold frame in September; the frame must be in a sunny position; it should be ventilated freely in mild weather in winter.

It is an advantage to make up a bed of fresh, dry leaves in the frame beneath the soil in which the violets are. *See Dog's Tooth Violet.*

VIOLET CRESS. The hardy annual that is called violet cress or *Ionopsidium* is of miniature growth, and produces tiny flowers of white tinged with purple. It should be sown in spring where the plants are to bloom in summer, in light soil in partial shade in the rock garden.

VIOLET GROUND BEETLE. This creature is a little friend to the gardener, and therefore should not be destroyed. It is one of a large family of beetles, the parents and larvae of which run about the surface of the soil devouring grubs and other pests. This beetle is about 1 in. long, and may be recognized by its colouring of violet-black.

Violet Ground Beetle, harmless and even useful in the garden.

VIOLETTA. This is a small-flowered viola, of which there are many varieties suitable for the rock garden or the front of the flower border. *See Viola.*

VIOLIN. To the eye the violin presents three principal parts: the body, which is the resonating chamber; the neck, upon which the finger-board is fixed; and the strings, which extend from one end of the instrument to the other. From a constructional point of view it comprises no fewer than 57 distinct pieces of wood, fitted and glued together, in addition to which there are 13 movable fittings, such as strings, pegs, the bridge, etc.

The violin is an instrument which demands not only absolute perfection of workmanship, but also most careful adherence to those principles of measurement and proportion exemplified in the extant specimens of Stradivari, Amati, Guarneri, and the other masters. It is possible for good workmen to turn out excellent modern violins, but the merit of these is always according to the personal care bestowed upon each instrument, a care which is necessarily lacking in the case of the cheap fiddle produced by the thousand.

Details of the Body. An examination of the body will show that the wood employed is not the same throughout. There is a reason for this. The back and the belly exert a mutual influence, and therefore

if the former gives a hard, metallic sound when tested by rapping it with the knuckles, it is necessary to counteract this by choosing for the belly a somewhat softer wood.

Besides the density of the wood, there are other factors which enter into calculation. The harder the wood, the thinner it can be worked to promote freedom of vibration, and this thinning of the plates is an important detail of the workmanship. Though other woods, such as sycamore, can be used, maple is preferably chosen for the back, as also sometimes for the neck and ribs. The belly and the inside fittings, such as the bass bar, the blocks, the sound-post, etc., are of pine. The age, density, and grain are all-important considerations in selecting the wood. The finger-board, the tailpiece, and the pegs are of ebony.

The body of the violin consists of the back and the belly, which are united by the ribs, but it would be too frail to withstand the strain of the strings without some internal adjuncts. These are first of all the blocks, four of which are glued in the corners next to the waist of the violin, with two more at the top and bottom respectively but the most important fitting is the sound-post, which is placed about $\frac{1}{4}$ in. or less behind the right foot of the bridge. This resists the thrust of the bridge upon the belly, and plays an indispensable part in transmitting the vibrations of the strings to the body. Its thickness, density, and exact position are factors which vitally affect the tone.

The linings are narrow strips of pine, which run all round the inside edges of both back and belly, affording a wider surface for glueing to the ribs, and thus strengthening the structure. The last inside fitting is the bass bar, which is fixed longitudinally to the belly close to the left sound-hole. Mention must also be made of the purfling, the thin black lines of stained plane wood which follow the outlines and obviate any possible danger of the edges splitting. Lastly come the *f* or sound holes, which are cut in the belly.

Neck and Varnish. The neck is fixed to the upper end of the body, and terminates in the head or scroll. Immediately below the scroll is the peg-box, the sides of which are pierced with holes to receive the four pegs. The slight projection at the back is called the nut. Upon the upper surface of the neck is fixed the fingerboard, which is slightly convex, and projects over the belly to within an inch or so of the top of the *f* holes. The strings extend from pegs, round which their one end is coiled, and pass over the bridge to the tailpiece, in which the other end is fixed. The bottom of the tailpiece has a loop of stout gut, which passes round the tailpin on bottom rib.

This description of the parts of the instrument may be completed by mentioning the varnish, which is put on after the desired yellow, red, or brown has been applied to the wood in the form of a wash. Spirit varnish is often used for cheap violins. Oil varnish, though slower in drying, is more lasting.

The bridge transmits the vibrations of the strings to the belly, and, speaking generally, a heavily built instrument will take a finer bridge than a lighter one. Its position is of extreme importance. The correct place for its two feet is exactly between the nicks on the inner edges of the *f* holes. The feet must also be adjusted exactly to the curve of the belly. When properly placed, the right foot will be in line with the sound-post, and the left foot immediately over the centre of the bass bar.

Tuning the Strings. The four strings are tuned in fifths as follows:

The second string A is the standard by which the others are regulated. As they are all of the same length, the differences in pitch have to be secured by differences in thickness and density, while the fourth string G is wound round with silver wire. The requisite tension is obtained by turning the pegs so as to stretch the strings. With experienced performers this is done by the left hand, while the right hand is free to test the pitch with the bow, but in the case of beginners the instrument is held by the neck, resting it against the knee, while the pegs are manipulated, the string being twanged from time to time until the pitch is correct. The final test, however, is always made by the bow.

To fix a new string, knot one end, slip it through the proper hole in the tailpiece, and draw it through the slit, where it will be held by the knot. Thread the other end through the small hole in the peg, pass it under itself, and turn the peg, which should be pressed inward as it is turned. The rest of the coil may then be cut off. The G string is sold of the proper length only. The pitch of the A string having been adjusted to the pitch required by circumstances, the D string is tuned with it, and then the G string below that. Finally the first string is tuned with the second string. In each instance make sure that the fifths is absolutely perfect before proceeding.

Holding the Instrument. The violin is held with the left hand encircling its neck, but so that the palm does not touch it. The end of the instrument rests on the left collarbone, where it is kept in place by a sufficient pressure from the performer's chin. In order to induce greater security of tenure, some players either use a chin-rest fixed to the violin or place a pad upon the collarbone; but this latter, at any rate, would seem to militate against resonance.

The neck of the instrument resting in the hollow of the thumb, the fingers are held over the finger board, so that the first finger if pressed down will produce F on the first string, the second finger C on the second, the third finger G on the third, and the fourth finger D on the fourth string.

The bow is held in the right hand. The thumb must touch the raised part of the nut, and the fingers must be rounded slightly over the stick. Possibly, with some hands, the little finger will experience difficulty in doing this, but if it can be managed it will be of great advantage in forte playing. The bow crosses the strings at right angles between the bridge and the end of the fingerboard, and in order to secure an even, steady tone it should preserve that position in every respect. The action of the right arm should be without stiffness, and special attention must be given to the freedom and independence of the wrist, the forearm, and the upper arm.

The Music. Music for the violin is always written on the treble staff with the G clef. Bowing is always indicated exactly, otherwise each note receives a separate bow. The combinations of slur and dot, etc., are too numerous to be treated in detail here, and full information must be sought in violin schools; but the chief thing to be remembered is that all the notes under one slur are to be performed by the same stroke of the bow. A down bow is indicated by  and an up bow by V.

The only other notation that need be mentioned here is that for harmonics. A small O placed above a note means that it is to be played as a natural harmonic. If artificial harmonics are desired, there is a double notation; the notes which have to be pressed down are given in the usual notation, while for the harmonic there is a diamond-shaped note joined to it by the same stem, thus:

VIRGINIAN COWSLIP. This is the popular name of a hardy herbaceous perennial named *Mertensia pulmonarioides*. It grows 18 in. high and bears blue flowers in May. It flourishes in ordinary well-drained soil and is increased by division in February.

VIRGINIAN CREEPER. The botanical name of this favourite hardy climbing plant, so often planted on house walls, is *Vitis (ampelopsis) quinquefolia*; its large lobed leaves colour brilliantly in autumn. The small-leaved *Vitis inconstans (Ampelopsis Veitchii)* is a greater favourite because it is self-clinging, and even more brilliantly tinted. These climbers thrive best on sunny or only slightly shady walls. It is necessary to support the self-clinging kind with a few pea sticks until it has started to cling to the wall. The large-leaved Virginia creeper should be trained to a trellis of wood fixed against the wall. Planting may be done in autumn or spring. Propagation is by cuttings placed in a frame in autumn or by small pieces of growth, each containing a bud, set in a heated greenhouse in early spring.

Virginian Creeper. Small leaves of the self-clinging variety known as Ampelopsis Veitchii, valued by the gardener for its decorative effect and beautiful autumnal colouring.

VIRGINIAN POKE WEED. This vigorous hardy herbaceous perennial is suitable for the wild garden or large border. The stem reaches a height of 6 ft. or more and the small white flowers are followed by deep purplish berries; it is most ornamental in early autumn. Propagation is by seeds sown out of doors in spring. The roots are poisonous.

VIRGINIAN STOCK. This low growing hardy annual blooms in about 6 weeks after the seeds are sown out of doors in March or April. It is a pretty little plant for an edging to a flower border, the blooms being crimson, rose or white according to the variety chosen. Its beauty is rather shortlived, but another sowing may be made to provide blooms in late summer. Its botanical name is *Malcolmia maritima*.

Virginian Stock. Dainty flowers of a popular and pretty edging plant suitable for garden borders.

VIRGIN'S BOWER. This is the popular name of a rampant climbing plant named *Clematis flammula*. It bears a profusion of small white fragrant flowers in late summer and is useful for covering an arbour or trellis. It flourishes in ordinary soil.

VISCARIA. This is a very showy hardy annual with rose, crimson, white, or purple flowers. It reaches a height of about 12 in., thrives in ordinary soil in a sunny position, and blooms in summer from seeds sown out of doors in March and April. As with all annuals it is most necessary to thin out the seedlings to give them room for development.

VISITING: The Etiquette. The usual method of keeping up with friends who live at a distance is to stay with them or have them to stay in one's own home. Few visits exceed a fortnight in length,

and a week-end is the most usual. The invitation naturally depends upon the circumstances both of host and guest, and must be adapted to suit them. People who possess cars often enjoy weekends, which might prove too expensive for a guest to whom the railway fare is a consideration only to be justified by a longer visit.

The hostess will naturally invite people at the time when it is most convenient for her to have them, and if wise will also make the invitation a definite one. She will ask the guest for a week, a week-end, a fortnight, or whatever period may be suitable. The guest should seldom stay on after that period, even if pressed to do so, unless something has intervened since the arrival to make an extra day or two advisable.

If asked for a week-end the guest should assume that he is not expected before lunch time on Saturday. He will also assume that his departure early on the Monday is expected. If asked vaguely for a few days the visit should always stop short of the week.

The time of departure is necessarily varied by circumstances. If the guest is leaving by car, as a rule an hour after breakfast is convenient, but if returning to business after a week-end there may be a specially early train to catch which should be understood before, or soon after, arrival. Other departures may be regulated by convenient trains for cross country journeys, but in any case it is best to have the matter clearly settled in advance wherever this is possible.

At the conclusion of a visit of some days a tip of 5s. is usual to the parlourmaid and also to the housemaid attending on the rooms. The chauffeur would have the same when leaving the guest at the station. Where there is a butler or single-handed manservant instead of a parlourmaid, the same tip would be usual. In the case of a young unmarried guest the tips to women servants are often reduced to 2s. 6d., and tips to manservants may not be expected.

In larger houses the question of tips becomes rather more expensive for a man. He may be expected to give 5s. to 10s. to a footman who acts as valet as well as tipping the housemaid, etc.

VITAMIN. Certain complex substances which exercise a profound influence on the metabolism of the body are known as vitamins. Six are definitely known to exist, and are described as vitamin A, B₁, B₂, C, D and E respectively. Vitamin A and vitamin D, which appears to occur in close association with it, are not soluble in water but dissolve in fats. They are not easily destroyed by heat. The former promotes growth and the latter prevents rickets, and to a lesser extent promotes growth. Vitamins B₁, B₂ and C are soluble in water and are more easily destroyed by heat, especially vitamin C.

The absence of vitamin B₁ from a diet leads to the development of beri-beri, the absence of B₂ to the development of pellagra, while the absence of vitamin C results in scurvy.

The vitamins originate in plant life and are present in the fresh tissues of animals that live on plants, so that they occur in varying proportions in both animal and vegetable foods. Under the heading Diet (q.v.) there appears a list of foods with the vitamins they contain, and the amounts.

It will be understood that vitamin D is included with fat-soluble vitamin A.

VITEX. The only kind of vitex in general cultivation is *Vitex agnus-castus*, a shrub suitable for planting against a sunny wall in mild districts. It bears bunches of white flowers in September, but is not likely to bloom freely in a sunless season. It can be propagated by cuttings in summer and should be hard pruned in February.

VIVARIUM. This is the name given to a receptacle for housing small semi-aquatic animals and insects, or butterflies.

It is generally supplied with a small pond, rockery, ferns and other plants. The construction is on similar lines to that of an aquarium, but it need not be all watertight, the usual form being illustrated in Fig. 1. It is hardly worth while making a vivarium of less than 30 in. by 15 in. with a height of 30 in., as it would be difficult to arrange for a small pond as well as a selection of ferns and other plants. Teak can be used for the upper portion, which forms a frame for the glass, and zinc for the lower portion, either in the form of thick sheet or as a lining to a shallow wooden box.

The case should be made in three parts, as indicated in the section at Fig. 2. The base is a trough measuring 32 in. by 15 in. by 6 in., as at A.

This supports a rectangular framing (B), open top and bottom, filled on the four sides with glass and made to a height of 18 in. The framing is covered with a top (C), with sloping sides, 6 in. high, framed up to match the lower framing and filled in with glass in the same way, but it has an opening at the top 18 in. by 6 in. covered with perforated zinc sheeting.

Fig. 2

Fig. 3

Fig. 4

Fig. 5

Vivarium. Fig. 1. Case in teak, zinc and glass for small semi-aquatic animals. Fig. 2. Sectional view of case. Figs. 3-5. Different methods of making framework

Several ways of making the framework are illustrated in Figs. 3, 4, and 5. The trough is made of either deal or hardwood from $\frac{3}{4}$ in. to 1 in. thick, with the corners butted and nailed, or dovetailed. The lining should be of thin sheet zinc, with the corners soldered. The upper portion should fit on top of the trough with an overlapping half-round bead around the bottom edge if the framing is of wood, or a flange if of metal. The latter material can be used, as at Fig. 3, by folding it over to enclose the glass. The top portion of the frame should be in two strips so that the glass can be slipped between them. The corners of the framework should be soldered together. Another method is to use angle-pieces, as in Fig. 4, the same method of inserting the glass being used. Fig. 5 illustrates how the frame can be made up of wood. A frame is formed of 1 in. square material, a groove being cut for the glass, and the corners joined with mortise and tenon joints. The top portion is made to match the lower portion, the 18 in. by 6 in. ventilating opening being allowed for, the sides filled with glass, and a piece of perforated zinc attached to cover the top. For hints on setting out the angles for the mitre joints of top framework, *see* Mitre.

The pond can be formed with a shallow earthenware dish, the rocks made with coke dipped in cement, and the trough filled with soil. *See* Aquarium.

VOICE: Its Care. The voice is the sound that is produced by the vibration of the vocal cords of the larynx. These are set in motion by waves of air breathed out from the lungs. The pitch of the vocal sounds depends on the rate of vibration. Sounds produced in the larynx are modified by the movements of the lips, tongue, etc. The quality or timbre of the voice depends upon secondary vibrations, overtones or harmonics, superimposed on the primary vibrations. The loudness of the voice depends chiefly on the quantity of air which is employed in order to set the vocal cords vibrating.

Men have deeper or lower pitched voices than women because, as a rule, they have longer vocal cords. The breaking of the voice, which occurs at the change from childhood to adult life in the male, is due to the rapid growth of the larynx at this time, and the temporary lessening of control over the muscles which govern the tension and rigidity of the larynx.

Loss of voice and gruffness of the voice or hoarseness may be brought about by anything which interferes with normal movements of the vocal cords. Paralysis of the nerves supplying the cords, growths on the cords, ulceration, catarrhal inflammation, etc., all may interfere to a greater or less extent with the production or with the quality of the voice. *See* Laryngitis; Larynx; Throat; Tonsillitis.

VOILE. There are both silk and wool voiles, but these are unimportant in comparison with the cotton voiles. All are light in weight and open in texture.

Crispness is a virtue in cotton voiles, plain or fancy; double voiles, as they are sometimes called, crease less easily than the soft, clinging kinds, last longer, and require washing less frequently. Especially when buying self-coloured voile, care should be taken to choose the harder-feeling variety. Patterned or plain coloured cotton voiles make excellent glass curtains for bedroom windows.

VOL-AU-VENT. This refers to a round or oval case of puff pastry which, after baking, is filled with some delicate ragout of chicken, sweetbread, lobster, or other fish. Sometimes quenelles of chicken are mixed with the sweetbread. The sauce used is always rich and usually flavoured with mushrooms and truffles. When served as a sweet, the pastry case is filled with fruit.

To make a good vol-au-vent 1 lb. puff paste will be required. After giving the paste six turns, roll it out $\frac{3}{4}$ in. thick and cut it to an oval shape. Place the case on a baking-sheet rinsed with hot water and brush the top of it with egg, then mark it with a cutter or sharp knife within about $\frac{3}{4}$ in. of the edge all round to form the lid. Put a hoop of white paper 2-3 in. high and a little larger than the case around it. Bake it in a hot oven from $\frac{3}{4}$ to 1 hour.

When baked, remove the lid, scoop out any soft pieces of pastry, brush the inside of the case with egg, take away the paper and return the pastry to the oven for a few minutes. Have the filling ready and well heated, then fill the case and cover with the lid. It is better to dish the vol-au-vent before filling it.

Turbot Vol-au-vent. A vol-au-vent case filled with cold boiled turbot reheated in some white sauce makes a good luncheon dish. Prepare the pastry case as directed, break the fish into flakes, rid it of skin and bone, and then moisten it with the sauce, made from fish stock. Add a few shelled shrimps and seasoning to taste, heat the mixture thoroughly over the fire, and then turn it into prepared case. Serve very hot.

Turkey Vol-au-vent. Small vol-au-vent cases may be filled with a savoury mixture of turkey and ham. While the cases are baking, mince the remains of some cold cooked turkey, add to it about a quarter of its weight of grated ham, a little white sauce and a spoonful of thick cream. Heat these

together in a small pan, season them to taste with salt, pepper, and mace, and then turn them into the hot cases. Serve them at once.

Fruit Vol-au-vent. A good sweet is made by putting 3 dessertspoonfuls Demerara sugar into a saucepan containing $\frac{3}{4}$ gill water, and allowing the two to boil for 5 min. or until a thick syrup is formed. Add 1 lb. damsons, cherries, plums or other suitable fruit, cook them very gently until they are tender, and then leave them to get cold.

Make the vol-au-vent case, as previously directed, take out the inner circle of pastry, and when the case is cold fill it up with the fruit, keeping back some of the juice if too moist.

Mix a few drops of vanilla and a sprinkling of castor sugar with 1 gill of cream, whisk the whole until it thickens, and then shake it on to the fruit, decorating the top with one or two damsons, cherries, or neat pieces of fruit if a larger kind is used. If liked, a teaspoonful of lemon-juice can be added to the flour when it is mixed with water; this counteracts the richness of the pastry. See Pastry; Sauce.

Fruit Vol-au-Vent, an attractive sweet.

VOLT. In electricity the unit of electromotive force or electrical pressure is termed a volt. It is that pressure which will drive a current of one ampere through a resistance of one ohm. See Electric Light.

Voltage. See Electricity.

VOLTMETER: Its Uses. The instrument known as a voltmeter is used for recording the voltage or pressure of an electric current flowing in a circuit. The watch pattern voltmeter is convenient for testing the voltages of accumulators or other sources of small voltage supply. It consists of a metallic casing enclosing the coils, etc., and fitted at its bottom end with a pointed lug which forms one of the connexions. The other connexion is a short length of flexible wire which passes through a hole in the knob to which the ring is fitted. The outside end of the wire is finished off in a sharp-pointed metal end.

To use the instrument it should be inspected to see if it requires connecting to a circuit a definite way round. If this is the case, a plus sign is usually to be found near its appropriate terminal. This terminal should be placed on the positive side of the battery or circuit under test, while the negative side of the battery is joined to the negative side of the instrument. To obtain an accurate reading the voltmeter should be held vertically. Good connexion is made by scraping and pressing the pointed ends of the voltmeter connexions while a reading is being made.

As the voltmeter is required to read the difference of potential between two points in a circuit, it is placed in parallel to the circuit containing the resistance causing the potential drop. In this respect it differs from an ammeter, which is a low-resistance instrument, and, as it measures the total current flow, it is wired in series to the circuit.

Testing H.T. Batteries. Only high resistance instruments should be used for testing the voltages of high-tension batteries, otherwise an unfair load is placed upon the small cells.

In order to obtain an accurate indication of the state of a battery used for a wireless set all voltage readings should be taken with the battery delivering its normal current to the valves. "Open circuit"

readings are misleading, because the cells tend to recover after a period of rest, but when current is consumed the voltage gradually falls to a steady value, depending upon the condition of the battery.

The ordinary high-resistance voltmeter is not suitable for measuring the output voltages of mains H.T. units.

See Accumulator; Battery.

VOLUME CONTROL: In Wireless. The most efficient form of volume control is obtained with the use of one or more “variable mu” valves (q.v.). These are valves in the high frequency amplifying circuits of a set whose amplifying properties can be varied by varying their grid biases. Thus the sensitivity of the receiver is altered as with the different levels of volume required. There is no danger, with this method, of overloading occurring in any of the subsequent amplifying valves up to the maximum output for which the receiver is designed, even in the case of the very powerful stations. The grid bias adjustments are usually effected by means of potentiometers.

Automatic Volume Control. An extension of the “variable mu” principle. Energy from the detector valve is fed back, rectified and smoothed, to the grids of the variable-mu valves so that if the general level of the input to the detector valve rises, the sensitivity of the set is reduced and a substantially constant volume level preserved. In this manner the fading effects in the reception of distant broadcasting stations can be countered. *See Potential Divider.*

VOLUNTEER SNOOKER. This billiard game is a variant of snooker. It can be played by two or more persons either as sides or independently. It is called volunteer snooker because a player is said to volunteer if, when striking, the cue ball hits a pool ball which he is not on, after the first score. In general the game proceeds in almost the same way as snooker pool. The same 22 balls are necessary and there are no cannons. The balls are the white one, known as the cue ball, with which each striker plays, 15 red balls, and one each of the following colours: yellow, green, brown, blue, pink, and black; these six are the pool balls. *See Billiards; Snooker Pool, etc*

VOMITING. The forcible expulsion of the contents of the stomach through the mouth, vomiting is generally preceded by nausea and with this a free flow of saliva. The first thought on the occurrence of vomiting will generally be that it is due to some disturbance of the stomach itself caused by the ingestion of unsuitable food or of some irritant poison, but there is a very large list of possible causes, many of which have no connexion whatever with the digestive apparatus. Those that have such a connexion, apart from gastric affections themselves, include irritation in the pharynx, irritation or obstruction of the intestine, appendicitis, gall-stone, and other affections of the liver and gall-bladder.

On the other hand, vomiting may occur in the eye disorder known as glaucoma, and in some ear disorders in which there is disturbance of the apparatus concerned with preserving balance; it is a common incident in pregnancy; it usually occurs when there is renal colic; it may be an early symptom of meningitis, and is caused by tumours in the brain.

Information regarding the cause of vomiting may often be derived from an examination of the vomitus, or vomited matter. Frequently this will consist of undigested food simply, but when vomiting is caused by corrosive poisons, the vomitus may contain shreds of stomach-lining and blood. In gastric ulcer and cancer there is also blood, but there are other causes for blood vomiting. Bile is often found in the vomit, and sometimes wrongly supposed to be the cause of the vomiting,

when what has happened is that bile has been forced into the stomach by the muscular contractions that cause vomiting.

The treatment of vomiting depends on the cause, and in many of the conditions above mentioned treatment will have to be directed to other things than the vomiting, which is merely incidental and relatively unimportant. When the cause is irritating food or something of the kind, it is desirable to give large draughts of tepid water. This washes the stomach out, and makes the act of vomiting less distressing. Sips of hot water may check vomiting, though sometimes sips of iced soda water are more successful. In persistent vomiting during fevers, sips of iced champagne often prove beneficial when other remedies have failed. Counter-irritation over the pit of the stomach by applying a mustard plaster is another useful measure in some instances.

Many drugs, including bismuth, morphine, dilute hydrocyanic acid, and others are used in treatment. A convenient remedy may be found in a single drop of tincture of iodine in a tablespoonful of water, the dose to be repeated every 15 minutes for five or six doses. *See* Biliousness; Emetic; Gastritis; Indigestion Morning Sickness; Nausea; Poisoning; Sea Sickness.

VOTE: How to Secure. The qualifications for the parliamentary vote were altered by the Act of 1928. At the present day a vote of this kind can be exercised practically by all men and women over 21 years of age, provided they are British subjects. Such persons must have resided for three months at the house in the constituency in which they vote, or must have occupied business premises for that period. This is the qualifying period which ends on June 1 each year.

A person can vote in two constituencies but no more. For instance, a man or woman can vote as resident and also as occupier of business premises, provided the two are in different constituencies. He or she can also vote for one of these, and, if qualified, for a university. In the case of universities the vote can be exercised by those who have taken their degrees. Women can vote for a university that does not admit them to its degrees, provided they have passed the necessary examinations.

Special arrangements are made regarding the rights of soldiers, sailors and airmen to vote. They are registered in the constituencies for which they would be qualified if they were not away on service. This condition applies not only to soldiers and sailors on full pay, but to merchant seamen, pilots and fishermen, and to those engaged on Red Cross and other work of national importance abroad. These persons are allowed to vote by proxy. The Act of 1918 allowed persons in receipt of poor relief to vote: previously they had been disqualified.

The Register of Voters. To exercise the right to vote, the person's name must appear on the register of electors. This is made up in the autumn and comes in force on Oct. 15. The town clerk or clerk of the county council is responsible, under the council, for making up the register for his town or county. He decides whether or not a person is qualified to have his or her name placed on the register. Anyone dissatisfied with his decision can take the case to a county court and from there to a court of appeal. A person desirous of obtaining a vote should therefore first find out whether the name is on the register, and if not should claim a vote before Aug. 7.

Voting for Local Authorities. As regards local authorities, persons, both men and women, are qualified to vote at elections for these bodies if they are 21 years of age and over, and occupy, either as owner or as tenant, any land or premises in a local government electoral area. He or she must have occupied the premises for the qualifying period of three months, and the name must appear on the roll of electors. In this sense a tenant includes a lodger, provided he or she is in the occupation of unfurnished rooms.

VULCANITE. The real difference between vulcanite and ebonite consists in the quantity of sulphur used in the manufacture. Vulcanite is made by incorporating india-rubber or gutta-percha with ordinary sulphur and lampblack in a masticating machine. It is pressed into moulds and heated in a steam oven at a temperature of 315° F. In use and methods of working vulcanite and ebonite are practically identical. *See Ebonite; Polishing.*

WADDING. Cotton wadding, which may be bought cheaply at any draper's, is used for padding such articles as cosies, and also as an interlining for quilting. A layer of wadding, cut to the same dimensions, is laid between the outer fabric and the lining, and the three are quilted together. A special attachment for quilting is sold by sewing machine makers.

Common wadding is usually of a brownish colour. Surgical wadding or cotton should always be employed for wounds or for direct application to the skin, as in making pneumonia jackets. In recovering chairs it is often advisable to lay a sheet of common wadding under the embroidered canvas, cloth or leather. *See Taxidermy; Upholstery.*

WAFER. A wafer usually takes the form of an imitation seal. It is made of glazed paper, gummed at the back, and is affixed to the flap of the envelope in the same way as a seal. At one time they were very popular, and were used by many people, but of recent years they only appear in many colours and designs at Christmastime to decorate letters and parcels of gifts. Occasionally wafers are printed for some charitable purpose, and people buy them and use them on their letters as a means of inducing others to subscribe to the charity.

WAFER BISCUIT. Home-made wafers may be composed of equal quantities of sugar and flour moistened with 1 tablespoonful cream and a quarter that quantity of orange-flower water to each oz. of flour. The mixture is beaten for $\frac{3}{4}$ of an hour and then baked in portions between the wafer irons, somewhat on the same principle as waffles.

An easier and more modern recipe is to beat 1 oz. butter with the white of an egg till mixed, then to add them to 1 lb. flour, together with sufficient cream to form all into a thick paste. It is important to knead the mixture till it is as fine and smooth as glass; roll out into very thin pieces, shape and bake 3 min. in a quick oven. Before rolling, let the paste stand 20 min.

WAFFLE. This American dish is becoming more and more popular in England. It is composed of a thin, rich batter mixture cooked at high temperature in a waffle iron until crisp and brown. A little practice is necessary to achieve the desired degree of crispness, and the amount of batter required for each waffle. The thickness of the batter may vary according to personal taste, a thicker batter requiring a little longer in cooking to crisp it. Plain waffles are served with maple syrup, golden syrup or honey as a rule, or with just a pat of butter on the top.

A good foundation recipe is as follows: 1 heaped breakfastcupful flour, 2 egg yolks and 3 egg whites, $\frac{1}{2}$ teaspoonful salt, 1 teaspoonful sugar, $\frac{1}{2}$ breakfastcupful milk, 2 tablespoonfuls melted butter.

Sieve the flour, salt and sugar together, and milk and egg yolks beaten until light, and the melted butter.

Beat well, and when smooth add the egg whites beaten stiffly. The batter is lighter if allowed to stand a little time.

Heat the waffle iron, sprinkle with a teaspoonful of water, and when the iron stops steaming put in about a quarter of the waffle mixture. This quantity may vary a little with different irons and only experiment will show the right quantity to use. If too much batter is inserted it will ooze out when

the iron is closed; if too little, it will not spread evenly and the thin places will burn. Generally the squares in the iron should be two-thirds full.

Close the iron, and cook until no steam is seen coming from between the two halves. If the waffle is hot, crisp and brown by this time, lower the heat and cook for a minute or so longer, but be careful that it does not burn. Cooking takes 2 to 3 minutes as a rule.

Cheaper waffles may be made by using 1 egg and 2 teaspoonfuls baking powder to the above quantities, while they can be varied by sprinkling the top of the batter when in the iron with chopped cooked sausage or bacon, cooked chicken or grated cheese.

Waffle Iron. This utensil for cooking waffles can be heated by electricity, gas or fire. The electric ones are the most convenient, requiring no turning in the cooking of the waffles, and many of them have gauges which show when they are heated to the right degree. They are often made in aluminium or on bright metal stands for table use.

A new waffle iron needs burning in for 10 minutes before use. Then with a soft cloth dipped in melted fat the iron plate into which the batter is poured should be coated thinly with the fat, the iron closed and the heating continued for 3 minutes. It is now ready for use and grease should not again be applied, the surface merely requiring a sprinkle of water.

Waffle Iron. An electric waffle iron suitable for table use.

WAGES. Money paid for the services of persons in one's employ is known as wages. In the domestic sphere wages are paid to all indoor and outdoor servants, although in the case of governesses and others of superior status the payment is known as salary. Wages are paid either weekly or monthly. There is no rule on the subject, but in general it may be said that indoor servants are paid by the month and outdoor ones by the week. On the other hand, daily maids are as a general rule paid by the week.

Under English and Scottish law employers have certain legal obligations to those to whom they pay wages. The latter must be insured under the national health insurance and contributory pensions schemes while in the employ of their master. Wages that are not paid when due can be recovered by an action in a court of law, and in the case of an employer going bankrupt unpaid wages must be paid in full before anything is available for the ordinary creditors. *See* Employers' Liability; Insurance; Servant.

WAHLENBERGIA. The most beautiful of all the tufted harebells is a little rock garden plant named *Wahlenbergia serpyllifolia*. It grows only a few inches high and bears large purple blossoms of bellflower shape. It must be planted in gritty soil in slight shade. *Pumilio* has lilac-blue flowers; *Hederacea* is of creeping growth and bears pale blue flowers. The best method of propagation is by sowing seeds in a pot of fine soil in a frame.

WAINSCOT. The form of wall covering applied to the interior of rooms and known as wainscot or wainscoting is sometimes composed of marble or other materials, but is usually of wood. It takes the form of panelling at the height of about 5 ft. from the floor to the top.

In construction, wainscot consists of a series of rails and uprights varying from 1 in. to 2 in. thick, tenoned into each other, the interspaces being filled with panels from $\frac{3}{8}$ in. to 1 in. thick. The edges

of the rails and uprights are moulded or bevelled; the corners are mitred, and are also grooved to take the panels. Wainscots are generally surmounted by a capping moulding and finally finished at the bottom with a skirting board.

In oak wainscot it is a common practice to peg the tenons, no glue being applied to the joints. This was the customary method in early oak wainscoting, in which the lower edges of the rails were left square, the top edges bevelled, and both edges of the uprights moulded. Fig. 1 shows a typical example of a wainscot of oak. Where a very large room is to be fitted, it is made up in sections and the parts secured in position separately.

A cheaper form of wainscot may be made by securing sheets of 3-ply to a rough groundwork nailed or plugged to the wall, and then nailing a series of battens to the surface to give the effect of panelling. It is essential to arrange the joints in the 3-ply so that they come opposite the battens, and are thus hidden. The groundwork also should be arranged in a similar formation to that of the battens, so that there is a solid ground to nail to. Fig. 2 shows the finished wainscot of this type and the under-ground. An effective finish to the work can be obtained by staining the battens a darker colour than the 3-ply.

The term wainscot is also applied to oak boards cut in such a way that the silver grain or medullary rays appear on the surface. To secure this effect it is necessary to cut them radially from the centre. See Panelling.

WAITER. This word is occasionally used for a piece of furniture that serves to hold something needful for the table at meal times. Such pieces are usually known as dumb waiters. The word is also employed for a small tray or salver.

WAKE ROBIN. This common name is applied to the cuckoo pint of the hedgerows (*Arum maculatum*). *See* Arum Lily; Cuckoo Pint; Trillium.

WALDSTEINIA. This is the name given to a small family of hardy herbaceous perennial plants, known as the barren strawberry. They rarely attain to a height of more than 6 in., with yellow flowers in late-spring and early summer. They are propagated by seeds sown at the same period of the year, or by division of the plants in autumn or winter. Waldsteinias flourish in ordinary soil. The most noteworthy kind is *W. fragarioides*; it is useful for planting on a dry bank.

WALK: In the Garden. For convenience of access to various parts of a garden and to facilitate the work of maintenance it is necessary to have a number of paths. Those of gravel should be not less than 5 ft. wide to allow of two persons walking abreast in comfort. Paved paths, which are more expensive to construct, are usually laid only in certain parts, as in the rosery, the little formal garden or the rock garden; a width of 3 ft. is sufficient for these. A wide grass path between borders of hardy flowers is very attractive if kept trim. In making a gravel path the soil should be removed to a depth of at least 18 in. and carefully sifted for stones and other refuse. This refuse, together with bricks, broken flower-pots, and other drainage material, should be placed at the bottom of the walk

trench, which should then be filled up with coarse gravel and further surfaced with a layer of fine gravel and sand. The whole should be rolled, leaving the centre higher than the sides. Stone or brick paths must be laid on a foundation of sifted soil, sifted ashes, or sand. *See* Crazy Paving; Path.

Walk. A richly flowering herbaceous border enhances the beauty of this grass walk, from which, by means of picturesquely curved steps, one descends to a quaint brick path set between grass borders.

WALKING STICK. Sticks have long been used as aids to walking and as a means of defence in case of attack by dogs or men. They are carried, however, by many men merely as an addition to an outdoor outfit, and a present to a man often takes the form of one of these sticks.

There is hardly any limit to the variety in which walking sticks are made. Many woods are used for them, cherry wood and malacca cane being among the most popular, and they can be bought at prices ranging from a few pence to several pounds. The price depends to some extent upon the material, but more upon the mounting, which may be of silver or even of gold. Initials are sometimes engraved on a band of the metal, this being especially the case with presentation sticks.

As regards shape, sticks may be divided into those with crook handles and those that have no handle but only a finished top. The former are perhaps more useful, and a good example is of imitation ebony with silver mountings at the nose of the crook and at the collar. The best are fitted with a horn ferrule. Of sticks without handles, a good example is of ebony fitted with a gold cap. Others are of malacca cane with a silver cap.

A development of the walking stick is now specially designed for sporting men and women, tourists and walkers, its special feature being the addition of a seat. The stick itself has a sharp spike at the bottom so that it can be inserted into the ground, and the seat is made by opening out the handle or head. These sticks are sold in various qualities and designs. The seat may be of mahogany, walnut, or some other wood. The better examples have fittings of aluminium, and the seat is covered with leather. *See Ivory.*

WALKING TOUR. Persons who spend a holiday, either long or short, in walking from place to place need to observe a few simple precautions if the tour is to be a pleasant one. Firstly, there is the choice of footwear. Since everything depends on comfortable feet, this deserves a little care. Stockings or socks should be made of wool, as this is less liable to cause chafing or blisters. Men usually prefer thick ribbed golf stockings.

Boots and Shoes. The boots or shoes should fit well, especially at the heels, but should not be new. If they have been in wear for a few weeks they will have taken the shape of the wearer's foot and cause no discomfort. Square heels are essential. The heels should be inspected beforehand and, if necessary, levelled.

People with tender feet are advised to rub them over with a little methylated spirit before starting, and to put a little boracic or other foot powder in their stockings. Some people recommend soaping the inside of the feet of the stockings with a slightly moistened cake of soap. As far as the other clothing is concerned, so long as it is comfortable all requirements are fulfilled, but the wise traveller carries a raincoat or some sort of light coat to put on if the weather changes or during the pauses for lunch, etc.

In arranging a tour, it is wisest to take easy days at the beginning, unless the walkers are in the pink of condition, and to work up for the longer tramps towards the middle of the week, or whatever the period is. It is also wise, when planning the day's distance, to arrange for a shorter distance the day after an extra long one. Fatigue is often felt more the day after than on the day itself.

Accommodation. The securing of accommodation for the night is an important matter. In the more populous parts of the country, where the villages are not very far apart, it is generally possible for travellers to secure sleeping quarters in an inn, or, if that is full, in a cottage near. Many walkers, however, like to walk over more lonely districts, such as Dartmoor, the Yorkshire moors, the Cheviot Hills or the Black Mountains, where houses are few and often at considerable distances from each other. Such persons should arrange the day's walking so that a village or an inn can be reached before the close of the day. The arrival should not be too late in the evening, so that, if the inn or cottage is full, there is still time and energy to walk a mile or two to another haven.

In 1931 a movement was started to provide hostels for walkers in various parts of the country, and a few were opened during the summer of that year. The idea is to afford shelter for the night at a very low charge. The travellers bring their own blankets and also their food, for which cooking facilities are provided. The movement is directed by a national organization and the opening of a chain of hostels has been planned.

Maps. The walker will find a good map essential. The best are those based on the maps issued by the Ordnance Survey, and the one-inch to a mile will, for the majority, be found the most convenient, although the two-inch can also be recommended. They can be bought from any stationer. *See Holiday.*

WALL: In Brick, Concrete or Stone. A wall is a structure of brick, stone, or other material, generally built for enclosing a piece of ground, or as a shell in which are formed the rooms of a building. There are two main classifications: walls which are built to resist vertical pressure for the support of objects placed upon them, such as floors; and those built to withstand oblique thrusts, such as that of a vaulting or untied roof trusses. Another kind of wall for the latter purpose is the retaining wall for earth.

Walls may be hollow or solid, according to the purpose for which they are required. Brick is the material mostly used in their construction except in districts where stone is available. Concrete, too, is much employed. For light partitions and as walls for small buildings, wood is extensively used, the wooden walls being set on concrete or brick foundations.

The thickness of brick, stone, or concrete walls varies according to the weight or pressure they will be called upon to withstand. For walls not more than 8 ft. high, which are to enclose areas, and will only have to withstand wind pressure, an ordinary 9 in. brick wall should be strong enough; lower walls, not called upon to withstand much weight, could sometimes be 4½ in. wide, or the width of a single brick. Concrete for this purpose consists of blocks about 18 in. long, 9 in. wide, and 2½ in. thick.

Internal walls may be made up of timber studding and with wall board. They are dealt with under the heading Partition.

Rougher kinds of walls, suitable for boundaries, are usually made of random rubble stone. Sometimes a walling material for a small building is simply rammed earth, the method being known as *pisé de terre*. In addition, many other materials are employed in particular districts. Devonshire cob houses and the stone buildings of Gloucestershire and the northern counties are examples. A variety of materials have been experimented with as suitable for walling purposes, notably the mixtures of cement and different aggregates. In this Encyclopedia detailed information about walling is given under the headings of the materials more commonly employed, e.g. Brick; Concrete; Stone.

It is often necessary to protect the surface of a wall so that the porous bricks do not allow water to pass through to the interior or upward. The latter is dealt with in the case of buildings for habitation by means of the damp course (q.v.), while the exterior surface may be covered with a rendering of cement. The inner surface of walls for buildings, if for habitation, are in almost all cases given a coat of plaster. *See* Building; Cement Rendering; Wall Board.

WALLABY. A cheap fur, wallaby is obtained from the smaller kangaroos. The hair is soft, rather long, and of a greyish colour, but it is usually dyed, being then sold as an imitation of skunk.

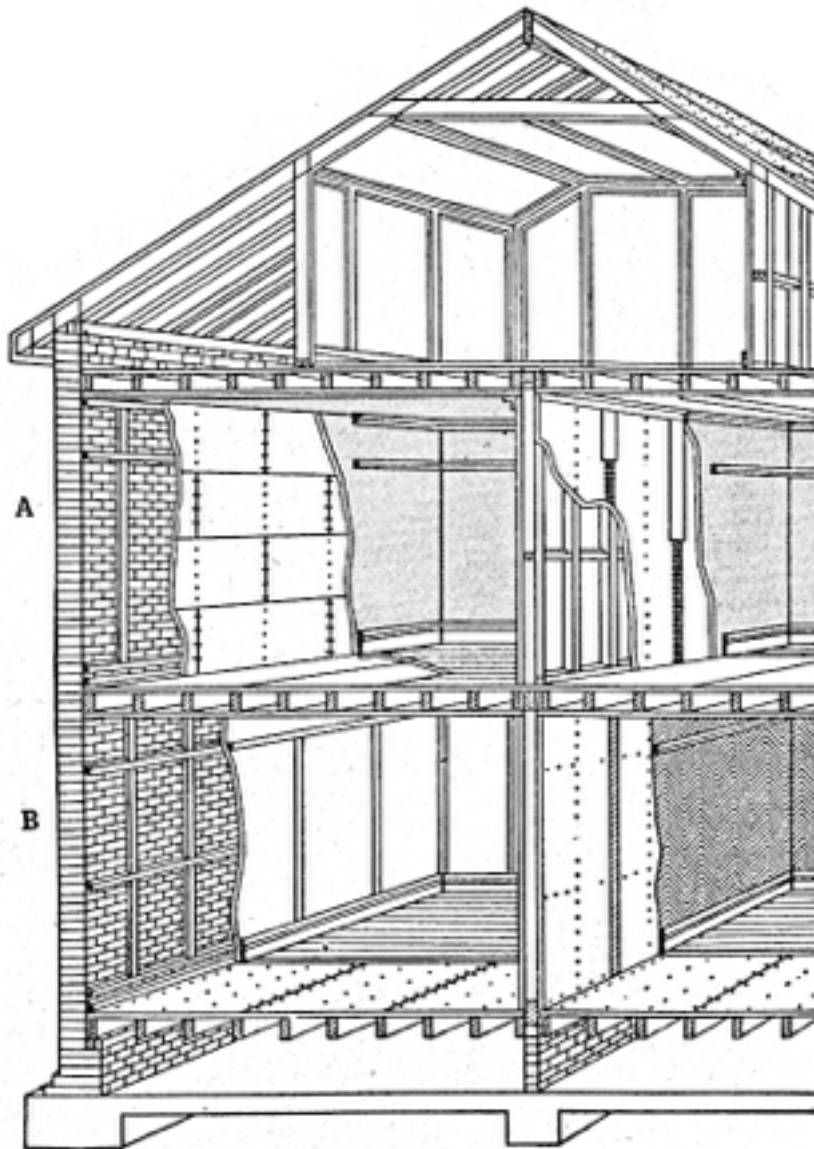

WALL BOARD. Large flat sheeting composed of fibrous or other material known as wall board is employed in the construction or decoration of walls and partitions. For internal work many different materials are used, including highly compressed paper, wood pulp or fibre rolled into sheets, plywood, reed and plaster slabs, asbestos cement. Asbestos cement composition is largely used for exteriors and also for internal panelling and partitions. For external walls the material may be purchased with a rough-cast surface on its outer side.

A common size is 8 ft. by 3 or 4 ft. in width. Larger sizes run up to 12 ft. by 4 ft. Thickness is from 3/16 in. to ¾ in.

As the weight is from 8 oz. to 1 lb. per sq. ft., wall board is a good substitute for wood and plaster ceilings, which average about twice the weight of a good quality wall board.

Many varieties are supplied with a finished surface to take a coating of enamel or paint.

For both internal and external walls in bungalows, garages, or other buildings wall board is much used, owing to its panelled appearance and the rapidity with which it can be put up. The drying-off stages (of plaster are obviated and an advantage is that the building is fit for habitation immediately upon completion.

Wall Board. Fig. 1. Sectional diagram illustrating various methods of utilizing the material, in this case Insulwood, for attic lining, exterior and exterior walls, etc. Wall board forms a roof sheathing, and is laid also under floor boards. See enlarged details of A, B, C, D in Fig. 2.
Patent Impermeable Millboard Co., Ltd.

A useful property of many of the wall boards is that of insulating against heat or cold. Some are made of sound-deadening material. The diagrams in Figs. 1 and 2 illustrate the manufacturers' suggestions for various uses of Insulwood.

In new buildings the wall board is attached directly to the studding or joists of the framework. Short lengths of 2 in. by 2 in. timber are first nailed to the studding and form a means of attachment of the top and bottom ends of the panel. The usual method of fixing wall boards is to nail them in position, using 1 in. or 1½ in. nails spaced about 6 in. apart and ¾ in. from the edge of the panel. The panel is nailed to intermediate joists and studding, the nail space in this case being about 12 in. The nail heads are afterwards covered with plaster-of-Paris stopping, and coated with shellac to prevent the absorption of paint, thus rendering the detection of the nail more difficult.

If the positions of the studding do not conveniently work out to suit the edges of the panels, furring strips or rough grounds must first be nailed in position. This point should be determined before purchasing the material. For studding centred at 16 in. a wall board of 48 in. in width is suitable, while the same width is also used for studding arranged 12 in. apart. For 18 in. studding a panel of 36 in. should be used. A small space of about ⅛ in. to ¼ in. should be left between adjacent sides and ends of the panels to obviate buckling if the panels expand slightly.

The same applies at the ceiling and floor terminations of the panels. If the panel is a few inches shorter than the required height from ceiling to floor, the gap may be covered by a deeper skirting board. The latter should overlap by at least 1 in.

In fixing panels to vertical walls, nailing should be commenced at the top and continued towards the bottom. In the case of a ceiling the centre should be nailed first and then progressively continued to

the outsides. In the latter operation an improvised T square will be found useful in supporting the panel to the ceiling during its erection. The long side of the square should be about the height of the room with the shorter side less than the width of the panel. (See also Board.)

Fig. 2. Diagrams showing varied application of Insulwood. A. Showing plaster-base applied in sheets before plastering. B. How panelled effect is obtained by using large sheets of wall board. C. Treatment of internal wall, showing use of plaster base. D. Internal wall covered with wall board and papered

Patent Impermeable Millboard Co., Ltd.

Where the wall board is to be fixed over brickwork or plaster, battens or furring strips should first be attached to form a frame on which the panels may be nailed. The framework should be spaced to suit the width of the panel. It must be secured to solid material, and to this end it is best to plug the walls before nailing or screwing on the battens. If the plaster is bulging or broken away, or the surface to be covered is found to be uneven, small packing strips made from odd pieces of the wall board may be tacked underneath. It is important, where the wall board is applied to a plastered ceiling, to ascertain that the panel coincides with the joists.

The space between adjacent panels is covered with an ornamental strip of wood, which gives the panelling effect to this class of work. A convenient size for this strip measures 2 in. wide and $\frac{3}{8}$ in. thick. Before nailing the strip over the wall board the latter should first be painted, taking care that all holes not covered by the panelling strip are stopped. In fixing the panelling strips the vertical strips should continue unbroken if a sense of additional height is required.

A useful application of wall board is in dividing a large room into two smaller ones by means of a partition (Fig. 3). Information about this is given in the article on Partition. In the event of a window or ventilator cutting into a sheet of the wall board, the latter may be cut to shape as required with a

cross-cut saw. To cut a straight strip from a length of the wall board it may be heavily scored with a chisel and bent off at the weakened line, the board being supported at the score by placing it against the edge of a bench. Rough-cast wall board is cut in a similar manner with the score on the smooth side. The rough side is then broken off by continued bending. *See Asbestos; Panelling; Partition; Plywood.*

Wall Board. Fig. 3. Showing how the home worker can use wall board to partition off a room. The material shown is Essex board. (Courtesy of Thames Board Mills. Ltd.)

WALL CRESS. This name is often given to the white arabis, a low-growing spreading plant which bears a profusion of flowers in spring. *See Arabis.*

WALLFLOWER. The modern varieties of this favourite plant are invaluable for spring flower beds; there, in association with daffodil, tulip and forget-me-nots they provide charming displays of bloom. The colours of the modern varieties range from white through primrose to yellow, orange and dark crimson. Purple Queen, Faerie Queen, pale lemon yellow, and Primrose Monarch are varieties of unusual colouring. Wallflowers are raised from seeds sown out of doors on a reserve border in May; the seedlings are transplanted at 10 in. apart to give them room for development, and in October they are set out where they are to bloom. When the seedlings are transplanted it is a good plan to pinch off the ends of the taproot and the leading shoot; this will ensure well-branched, sturdy plants. The Siberian wallflower (*Cheiranthus Allionii*) which bears orange-coloured blooms, makes a magnificent display. The seeds should not be sown before the end of May or the plants may bloom prematurely. There is an early flowering strain of wallflowers which blooms in mild weather in autumn and winter, and is in full beauty in spring. Wallflowers are excellent window box plants and will flourish on a dry stone wall.

The double wallflowers are grown in pots for the decoration of the greenhouse in spring. Seeds are sown in a box of soil set in a frame in July and August, the seedlings being potted singly in small pots and subsequently into others 5 in. wide. Some of the wallflowers, e.g. alpinus, light yellow, and Marshallii orange, are pretty plants for the rock garden, where they should be set in light soil in a sunny place.

Wallflower. Flowers of the single variety which is known as Primrose Monarch.

WALL GARDENING. A dry wall, that is, a wall built without mortar or cement in the joints, can be made a very beautiful feature of a garden if planted with snapdragon, wallflower, valerian, aubrietia, arabis, yellow alyssum, silvery Saxifrage, pink, sun rose, stone-crop, dwarf phlox, and other suitable flowers.

If the wall is shady it provides a home for ferns, foxgloves, ivy-leaved toadflax, mossy saxifrage, fumitory, and bellflower. Seeds mixed with a little moist soil may be sown in the chinks of the wall in spring or late summer, or small plants can be set in spring or autumn. A bank provides an excellent site for a dry wall; or a double wall may be constructed in the open garden, space being left in the middle for well drained soil. In building a wall care must be taken that it slopes backwards from the base, so that all the plants receive their share of the rainfall.

Wall Gardening. An old wall provides an ideal home for pink and mauve aubrietia, alyssum, arabis, silvery saxifrage, pinks and other suitable flowers.

Fruit Growing on Walls. On a sunny wall it is possible to grow fruits of the highest possible quality. Fan trained or single or double-stemmed cordon trees are most suitable. Planting should be done in autumn in deeply dug ground enriched with basic slag or bonemeal, and it is beneficial to add old mortar

rubble freely to the soil in which stone fruits are to be planted. Care must be taken to set the stems of the trees about 12 in. away from the wall.

A wall facing south or south-west is suitable for peach, nectarine, apricot, fig and the choicest dessert pears. Plums and pears will thrive on a wall facing west. Sweet cherries are suitable for an east wall, and on a north wall the Morello cherry and cordon gooseberries and currants may be planted. In-cold northern gardens it is worth while planting some of the choice dessert apples against a sunny wall. For a south or south-west wall: peaches, Hale's Early, Peregrine, Bellegarde, Barrington and Waterloo; nectarines, Elruge, Hardwicke and Humboldt; pears, Doyenné du Comice, Bergamot d'Esperen, Beurré Superfin, Fondante d'Automne, Glou Morceau, Marguerite Marillat and Winter Nelis; plums, Coe's Golden Drop, Comte d'Althan's Gage, Early Transparent Gage, Jefferson, and Oullin's Golden Gâge.

For a west wall the pears and plums already mentioned are suitable. A wall facing east will provide excellent crops of sweet cherries, e.g. May Duke, Black Tartarian, Early Rivers, Frogmore Bigarreau, Kentish Bigarreau, and Knight's Early Black.

WALLPAPER. The most important thing to do when wallpapers have to be chosen is to make up one's mind to a definite scheme of treatment. Every room has, by reason of its use, a character which is emphasized by its furnishing and which can be made a key to the problem of its decoration. The personal factor must not be relegated to a secondary place, because decoration should be the expression as well as the environment of personality.

Whatever the purpose of the room, there are certain general considerations which are of importance; aspect, lighting, size and proportions are conditions which must influence choice. Rooms facing north require tints which suggest warmth ; south rooms can be treated with schemes in cool colours.

Effect of Lighting. Window space and the conditions imposed by artificial light should regulate the shade of the wall covering, whether it is to be light and so capable of refraction, or whether shades

which absorb light can be used. Insufficient light, whether natural or artificial, is a fault which, if it cannot be remedied, must be corrected by the colour and texture of mural coverings if possible.

The effect of light can be attained by ensuring such contrasts of colour and shade as will make objects easily seen which would be otherwise indistinguishable. A wallpaper having a light background with well defined pattern will carry out this idea, or a brightly coloured border having distinctive forms and sharp contrasts will perform the same service.

In this connexion it must be remembered, however, that what is easily seen seems to be near at hand, so that easily seen patterns may appear to reduce the size of a room; whilst, on the other hand, if it is desired to make a room appear larger, indefinite patterns in low tones of colours, tending towards greys, will give the effect of space. The principle might be summed up thus: whatever the eye sees clearly is imagined to be near at hand, whilst haziness and indefiniteness are mentally associated with distance. The apparent size of a room is materially affected by the volume of light which enters it, or is provided by the proximity of the colour of the walls to white. Light and spaciousness are closely related, whilst shade and dark colours suggest cosiness and enclosure. The effect of colour is dealt with in the article under that heading, and that of texture of wall coverings in the article on Decoration.

Use of Pattern Papers. It is not surprising that woven and printed fabrics, embossed leather and other materials which have been used for wall coverings are closely imitated in appearance and texture on wallpapers. There are papers having the appearance of canvas and hessian, produced by printing and embossing, which make excellent wall coverings for rooms which are much used. The designs in popular use in the 18th century for printed linens and cotton hangings, and the hand worked embroideries which preceded them, have been followed most successfully on wallpapers, and are satisfying for many bedrooms and sitting rooms where the appearance of brightness is desired. There is a series of such papers known as chintz papers, some based on the designs of Queen Anne embroideries which are most attractive, recalling rooms in country houses with period furniture.

For dining rooms, hall, landings and staircase, patterns based on tapestry designs, have the advantage of traditional associations in their favour, and also of not showing marks. Many are well produced and can be obtained in a wide range of colourings. Soirette is the name given to a type of paper with silky surface which is used for drawing rooms, bedrooms and other rooms where delicate tints are suitable, and the furniture is highly polished and somewhat French in design.

Of the unpatterned papers which are called semi-plains there is sufficient variety in colour, type and texture to suit every kind of room. Here again materials which are used for wall decoration are imitated in wallpaper, notably leather of many kinds, oak and other kinds of wood grain, plaster of rough-cast and trowelled finish. The suitability of this range of papers for particular rooms depends on their colouring and their degree of finish; they are, however, in general use for living-rooms and hall and staircase walls. Effects resembling old parchment are much favoured for modern decorative schemes and other suitable types resemble stippled and mottled paintwork.

The delightful blending of colours found in marbles of many different kinds has given inspiration for a great range of well produced papers in soft tints, but without any attempt at imitative rendering of actual marble. Others represent marble with varying degrees of accuracy, and these papers are excellent where Regency or Empire effects are liked.

Some imitations of marble are popular for bathrooms, while others are used in narrow widths as surrounds for doorways, windows and niches. Recently there has been a revival of the use of marble papers for staircase and landing walls; when hung horizontally and panelled out to represent slabs the result is impressive.

Motifs and Panels. A form of wallpaper decoration which has become increasingly used within the last few years is achieved by the use of appliqué motifs which are made in a great number of types and sizes. There are motifs for corners of panels, pendants for use with cut-out borders, independent ornaments for centres of panels, over mantelpieces, bed heads or other positions where attractive colour is desired. All these present little difficulty in arranging. If there should be doubt they can be separated from the surrounding paper, on which they are printed, and pinned up to judge of their suitability before actually pasting on to the background paper with which they are used. Another type of motif is designed for use above skirting or dado rail and takes the form of groups of flowers of varying height and width. Some of these are very extensive, and are of sufficient height to reach from skirting to picture rail. Their arrangement is not difficult, for with them are generally supplied illustrations showing how they can be adapted. A floral panel and an applied tree motif are illustrated in the article on Decoration.

Corner ornaments are used to enrich panels, which are arranged symmetrically to cover the wall space. Such panels are formed by using a "stile" or "stiling border." These borders are obtainable for use with appliqué motifs, and in several different widths. First the stile is hung under the picture rail and above, the skirting, all round the room, then the stile is hung vertically at angles. If there are large wall spaces the stile can be used to form divisions between angles, the lengths being pinned up before pasting so that the proportions of the panels can be adjusted pleasantly.

It should be remembered that these fancy styles of bordered panels look better if one dimension is considerably greater than the other; if both dimensions are nearly equal the effect is not so pleasant. Square panels of this type are uninteresting. Panels in the proportion of 7 ft. high and 5 ft. wide are pleasing, and the narrower the panels in proportion to their height the greater will be the effect in increasing the apparent height of the room. Panels which are wider than their height will make a room appear lower.

Assistance in connexion with choosing motifs and simulated panelling can be found in the illustrated booklets which are obtainable from most up-to-date decorators. In the article on Hall the attractive use of a landscape motif on a marbled paper is illustrated, and also of a lincrusta panelling. *See* Colour; Decoration; Frieze; Hall; Panelling; Paperhanging; Paste.

WALL PLATE. This phrase is applied generally to almost all types of horizontal timber set upon the top or some other part of a wall to act as a support for joists, rafters, or the like. In a normal two-storey house three principal wall plates might be used. On the ground floor, if the floor were made of boarding, the joists would rest upon a horizontal plate of wood set upon the lower part of the brickwork; this horizontal plate being known as the wall plate.

A somewhat similar arrangement may be adopted for the first-floor joists, except that the wall plate would either be supported on corbels or, preferably, built into the wall itself. On the top of the wall a horizontal member, also known as a wall plate, is provided as a means of fixing the roof rafters and ceiling joists. *See* Joist; Rafter.

WALL RUE FERN. The popular name of the fern which is known botanically as *Asplenium rutamuraria*: it thrives admirably in the crevices of a shady wall. *See* Fern.

WALNUT. The fruit of the hardy, summer-leaving walnut tree is a brown nut enclosed in a green husk, and is ripe in September, when it is thrashed off the trees. It is sometimes removed in summer, for pickling. It is best dried after gathering, so that the husks can be removed without staining the shells, and then stored in jars, with salt placed between each layer.

Walnut trees are raised from seed sown in spring and transplanting the seedlings in autumn, or else by budding or grafting if it is desired to keep a particular form true. The walnut does not thrive in

thin soil over chalk or gravel; it is most successfully grown in a deep loam, with a fairly dry subsoil. The walnut produces separate male and female flowers, and the fruit is borne in terminal clusters. After a young tree has been shaped no pruning is required. The common walnut is *Juglans regia*, of which the wood is in demand for furniture making.

Walnut. Cluster of green-husked nuts.

Walnuts as Food. In addition to their use as dessert, walnuts are added as ingredients to many dishes that need nut flavouring. Usually they are shelled, peeled, and toasted in a cool oven until they are slightly crisped, and then chopped or broken into small pieces.

One of the simplest ways of using walnuts is to make them into a salad. Toast them and break them up as already directed, having removed the brown skin, and then mix them with some cleaned and shredded celery. Only the white portion of the celery should be used, and the quantity should equal that of the nuts. Season the mixture to taste, bind it with some thick mayonnaise sauce, and garnish the top with a few halved walnuts. This salad is a good accompaniment to chicken. (*See Mayonnaise; Salad.*)

Walnut Stains. Of all stains those caused by walnuts are the most difficult to remove. On wool or silk they are best left alone, for the drastic treatment needed to take them out is almost certain to ruin the material. On cotton and linen, however, repeated applications of eau-de-javelle or a warm solution of oxalic acid may be effective.

Uses of Walnut. This wood is fairly hard, heavy, and close in grain, easy to work, and does not warp or shrink much. There is the European variety, the best of which grows in Italy; the American black walnut, which is darker in colour; and another American variety called satin walnut. The Italian and American black walnut are those chiefly used for the better class furniture. Satin walnut is used for cheaper furniture, and is not considered a high-class furniture wood. It is soft and tough, and liable to shrink and warp considerably, but is an easy wood to work. It is a light brown or yellowish colour with darker streaks, and shows a satiny surface when planed. The others range in colour from greyish to purplish brown, often streaked with darker shades. Walnut is not used by builders, as it often becomes worm-eaten and its durability cannot be depended on.

American black walnut looks very well when treated with a wax polish. The polisher should look carefully for light portions of the wood, and, having found them, should take a small pencil brush and carefully stain them to match the surrounding parts. Some workers use a feather to mottle up the work.

The colouring up of the light portions may be done with a water stain, made by mixing dry powdered Vandyke brown with liquid ammonia, and then diluting this mixture to the desired shade; or it may be done with a judicious use of spirit stain, say, walnut crystal, or powdered stain dissolved in methylated spirit. The stain, no matter what variety is used, will raise the grain of the wood, and the usual course of glass-papering down the work must be gone through. Some workers prefer to rub the work over with linseed oil before using a wax polish. If it is first oiled in this way, it should stand for at least 48 hours before the wax compound is applied. For chairs, bedroom suites and sideboards waxed walnut is very effective. Some polishers apply a few rubbers of french polish on the top of the wax after it has been allowed to harden.

Another simple way of finishing walnut is by oil polishing. This is generally used for the tops of dining tables, although it is sometimes seen on chairs. The oil polish is far superior to a wax finish, as neither heat nor moisture will affect it. Either raw linseed oil or boiled linseed oil can be used. American black walnut is frequently french polished. This begins with a preliminary staining, this being done with a water or spirit stain applied to any part of the work that shows signs of light sapwood. No hard and fast rule can be given for the mixing. A good plan is to mix a fairly heavy stain, and to dilute it as required.

The next step is to oil the work. Here again colour must be considered. If the general character of the work appears to border on slate colour, it is necessary to use red oil, otherwise the work when finished will be dull and lifeless. On the other hand, if the walnut has a rich red shade, raw linseed oil should be used. After the oiling some the three successive processes of filling in, bodying up, and spiriting out. These are described in the article on French Polishing.

Walnut Furniture. For articles of furniture walnut was used earlier on the Continent of Europe than it was in England. In the latter half of the 17th century it was in great favour in Holland, and, with the close connexion between that country and England that began about 1660, much walnut furniture was brought over. About the same time the supply of English oak was diminishing, and walnut began to take its place, the Queen Anne period around 1700 being sometimes known as the age of walnut. In addition to its use for the body of the article, it was much used for veneering, walnut on oak being a popular form. It was employed for decorative furniture made in the style of Louis XVI, but in England about the same time its place was taken to a large extent by mahogany. In the middle of the 19th century there was a great revival of walnut furniture, the Italian variety being particularly favoured for fine furniture. *See* Armchair; Bureau; Cabinet; Chair; Dressing Table; Furniture; Graining; Grandfather Clock; Inlaying; Marquetry; Mirror; Queen Anne Style; Stool; Tallboy; Veneering; Wood.

WALNUT BUN. The ingredients for making walnut buns are $\frac{1}{2}$ lb. flour, 2 oz. cornflour, 1 teaspoonful baking-powder, 3 eggs, 2 tablespoonfuls milk or cream, a little jam, and 5 oz. each castor sugar, butter and walnut kernels. Put the walnuts into a moderate oven for a few minutes to crisp, and then chop them finely. Cream the butter and sugar, add nearly all the walnuts, then break in the eggs, beating one in well before adding another. Sieve together flour, cornflour, and baking-powder, and then add them to the mixture, with the milk.

Beat the whole for a few minutes and put the mixture into small greased tins on a baking sheet. Bake in a good oven until they are firm to the touch. Turn them out and allow them to cool; then brush them with a little jam and sprinkle with chopped walnuts.

WALNUT CAKE. The ingredients that are required for a plain walnut cake are $\frac{1}{2}$ lb. each butter, castor sugar, and fine flour, 5 eggs, a good pinch of salt, $\frac{1}{4}$ lb. peeled and chopped walnuts, and 6 bitter almonds peeled and pounded fine. Cream the butter and sugar till very light, add 2 of the eggs, and beat for 5 min. Add 2 more eggs and beat again for 5 min.; then add the remaining egg and give another good beating to the sponge. Sift the flour with the salt, add the nuts, and mix it very lightly but quickly with the eggs, sugar, and butter.

Put all into a shallow cake tin and bake till firm and a golden brown colour. The time required for baking varies according to the depth of the tin, but the oven must be steady and not too hot.

This walnut cake should be iced with white fondant or French icing, and should be decorated with peeled halves of walnuts placed here and there on the surface of the icing.

A rather more spongy cake is made without butter. Beat together for 25 min. the yolks of 3 large eggs with 5 oz. castor sugar, adding a few drops of water from time to time, in all 1 tablespoonful, and flavouring with the grated rind of a lemon. Mix with 2½ oz. ground walnuts, 1½ oz. wheaten flour sifted with 1½ oz. potato flour and a pinch of salt, then whip up the whites of the eggs.

Fold the flour and whites of egg alternately into the sponge, putting in about half of each at one time. Bake about 20 min. in a shallow tin lined with greaseproof paper. The oven should be of a moderate heat, and the cake on no account must be moved while baking until it has set. Ice with white icing or merely dust the top of the cake with icing sugar and sprinkle over chopped walnuts. *See Cake; Fondant; Icing.*

WALNUT PUDDING. A variety of bread and jam pudding, with walnut flavouring, this can be made in the following way: Heat up 3 gills milk, then pour it over 3 oz. fine breadcrumbs mixed with 1½ tablespoonfuls castor sugar and a little grated lemon-rind. While these are soaking, shell some walnuts, weigh out 3 oz. of them and toast them for a few minutes before chopping them finely. Then stir them into the bread and milk mixture, adding also the yolks of two eggs, finally mixing in the stiffly whisked whites.

Grease a small pie-dish, put into the bottom of it 1 or 2 tablespoonfuls of jam, then cover the latter with the pudding mixture, and bake it in a moderately hot oven until it is lightly browned.

WALTZ. There are three fundamental steps of this dance, the natural turn, the reverse turn, and the changes, i.e. changing from the natural turn to the reverse turn and vice versa. In these three main steps there is only one rhythm, a step to every beat. The music and the steps go in threes, and as the first beat of the music is accentuated, the first of each three steps should be a little longer than the second and third. On the third beat in both the natural and the reverse turns and the forward changes the feet must be closed together.

An important point to observe is the rise, which commences at the end of the first step and continues through the second, bringing the dancer right up on to the balls of the feet on the third step. Contrary body movement (C.B.M.) is used on the first step of every three.

The Natural Turn (Fig 1). This is composed of six steps. In the first three the man steps forward with R.F., turning on it to R., to side with L.F., still turning, and closes R.F. to L.F., completing half a turn. He then steps back with L.F., turning on it to R., to side with R.F., still turning, and closes L.F. up to R.F., completing the whole turn. When the man is doing the first three steps the girl is doing the last three, and vice versa. It

Waltz. Fig. 1. Steps of the natural turn for both partners. Fig. 2. Those of the reverse turn

is not always necessary to make half a turn on each three steps, a quarter turn is sometimes used. This depends on the direction in which the man wishes to steer. Contrary body movement is used on the 1st and 4th steps by both man and girl.

Waltz. Diagram showing the various steps and turns. Figs. 3 and 4 show the details of the forward change. Figs. 5 and 6. The backward change

The Reverse Turn (Fig. 2). In the first three steps the man steps forward with L.F., turning on it to L., to side with R.F., still turning, and crosses L.F. up in front of R.F., completing half a turn. He then steps back with R.F., turning on it to L., to side with L.F., still turning, and closes R.F. up to L.F., completing the whole turn. When the man is doing the first three steps the girl is doing the last three, and vice versa. As in the natural turn, it is not always necessary to make half a turn on each three steps; but if less than half a turn is made on the first three steps the man should close his feet together on the third step of the reverse instead of crossing them. The same rule, of course, applies to the girl's step. Contrary body movement is used by both dancers on the 1st and 4th steps.

The Forward Changes (Figs. 3 and 4). 1. After a natural turn the man steps forward with R.F., turning body slightly to R. (C.B.M.), to side with L.F., and closes R.F. up to L.F. The girl steps back with L.F., turning body slightly to R. (C.B.M.), to side with R.F., and closes L.F. up to R.F. 2. After a reverse turn the man steps forward with L.F., turning body slightly to L. (C.B.M.), to side with R.F., and closes L.F. up to R.F. The girl steps back with R.F., turning body slightly to left (C.B.M.), to side with L.F., and closes R.F. up to L.F.

The Backward Changes (Figs. 5 and 6). 1. After the first three steps of his natural turn (1, 2, 3, Fig. 5) the man steps back with L.F., turning body slightly to R. (C.B.M.), back with R.F., back with L.F., only just passing R.F., and finishes with the last three steps of his reverse turn. The girl, after the first three steps of her natural turn, steps forward with R.F., turning body slightly to R. (C.B.M.), forward with L.F., forward with R.F., only just passing L.F., and finishes with the last three steps of her reverse turn.

2. After the first three steps of his reverse (1, 2, 3, Fig. 6), the man steps back with R.F., turning body slightly to left (C.B.M.), back with L.F., back with R.F., only just passing the L.F., and finishes with the last three steps of his natural turn. The girl commences with the first three steps of her reverse turn, steps forward with L.F., turning body slightly to L. (C.B.M.), forward with R.F., forward with L.F., only just passing R.F., and finishes with the last three steps of her natural turn. In the diagrams accompanying this article the right foot is shaded, but the left is shown in outline only. The dotted line indicates the ultimate position of foot. It will be easier to follow the diagrams which are given in this and the previous page if the dancer faces the direction in which the toes are pointing and turns the diagram at the same time. *See Dancing; Fox Trot; Quickstep; Tango.*

WARD: In Chancery. By the theory of English law the king is the guardian of every infant (i.e. person under 21) in the country, but he exercises this guardianship through his judges, and only becomes an active guardian when in some way an infant is brought before the court. Any person under 21 may be made a ward of court by someone paying into court a sum of money in which the infant is declared to be interested. The court will not usually interfere unless the infant has some property.

The position of such a ward is that he or she cannot marry without the consent of the court. It is a contempt of court punishable by imprisonment for anyone to marry such a ward without the judge's leave. Ignorance that the infant was a ward of court is no defence in a case of this kind.

The judge has power to order the infant to be placed in the custody of any person he chooses. He can even take a child out of the custody of one or both of its parents and hand it over to somebody who may or may not be a relative.

The National Society for the Prevention of Cruelty to Children uses this weapon sometimes in order to take children out of the custody of undesirable parents. It is contempt of court for anyone to interfere with such custody or to remove the infant out of the jurisdiction of the court without leave. The wardship ceases when the infant attains the age of 21. *See Guardian.*

WARDROBES: ANTIQUE AND MODERN

With Designs for a Hall Wardrobe and One in Veneered Walnut

After some remarks on the story of this piece of furniture, this contribution gives particulars, aided by diagrams, about making two types of wardrobe. The worker will obtain further assistance by con-sulting the entries Cabinet Making; Joint; Polishing; Stain; and others on woodworking processes. *See also Bedroom; Corner Wardrobe; Cupboard; Fur; Furniture; Hall*

The wardrobe was evolved about the last decade of the 17th century from the hanging cupboard and is a combination of that piece and a chest of drawers. Examples, of Queen Anne period pieces are rare, but there is an interesting child's wardrobe dated 1712 in the Victoria and Albert Museum. It is made in the form of a contemporary house, painted to resemble brickwork. The roof has a gable at either end, a hexagonal chimney and dormer windows. There are three rows of sash windows across the front. The doorway has pilasters and curved steps.

The centre of the front is hinged and forms the door of the cupboard fitted with clothes pegs. There are two wings, one fitted with small drawers and the other with shelves. It is therefore a complete wardrobe in the modern sense.

About the middle of the 18th century a higher standard of comfort was introduced into bedroom furnishing, and accommodation for clothes improved from the usual tallboy to the clothes press and wardrobe. The clothes press is sometimes known as a "gentleman's wardrobe." It consists of a cupboard enclosing sliding trays and mounted on a low chest of drawers. Most of these pieces were

made of plain mahogany, but highly decorative carved pieces were based on a design in Chippendale's "Director."

Hepplewhite also designed and made wardrobes. In one fine example the mahogany piece was inlaid and ornamented with marquetry. The upper part was the wardrobe proper, enclosed by two doors, which were panelled; and below were two small drawers and two larger ones. Contemporary wardrobes were of painted or lacquered wood. The illustration shows a beautiful piece with a Chinese design in lacquer work made for David Garrick.

Wardrobe. This piece of furniture was formerly the property of David Garrick. English, c. 1770. (By permission of the Director, Victoria & Albert Museum, S. Kensington)

Sheraton's designs for wardrobes were usually of mahogany with restrained use of inlay or marquetry in satin wood. The Regency period wardrobes by first-class makers often showed the familiar association of strongly figured woods with brass mountings. By the middle of the 19th century mahogany and walnut wardrobes had reached heavy and vast proportions, and a little later the wardrobe became part of a bedroom suite, including also a washstand and dressing table. Such wardrobes usually have a mirror on one side, in the centre, or inside the cupboard door.

Modern Wardrobes. Apart from pieces included in modern suites, which are to be had in mahogany, weathered oak, Jacobean oak walnut, sycamore and enamelled or painted wood, wardrobes in recent years have again been made as separate pieces either of the compact fitted type or designed to suit a special room. A good example planned for a man's study-bedroom looks like a sideboard-bookcase, but when open the two sides reveal a wardrobe fitment. The size of the hanging cupboard section is sufficiently large to take a number of a man's suits on hangers and is provided with a sliding rod. The other wardrobe section contains shelves and drawers. The central portion is reserved for bookshelves.

The compact fitted wardrobes are usually in oak or mahogany and are made in three or four sections. Some designed particularly for men are provided with hanging space, sliding trays, shelves, an extending fitment on which to hang trousers, bootrack and a mirror. Other compact wardrobes are specially designed for women with more hanging space and good shoe and hat accommodation. The fashion for built-in furniture has extended to wardrobes. The illustration here shows one provided with an electric light which goes on when the door is opened and out after the required garment has been selected and the door is closed.

Built-in wardrobe with electric light fitted to switch on with the opening of the door. The light is switched off when the door is closed.

Quite an excellent wardrobe can be made of two whitewood cupboards, a narrow and a medium-sized one, screwed together to make one piece of furniture and painted or stained to match the walls or woodwork of the room. The wardrobe is provided with brass rods

for the accommodation of hangers. One cupboard is used for heavy coats, the other being reserved for light dresses, etc. Alternatively the narrow cupboard may be fitted with trays or shelves. Ornamental brass drops or ring handles if the wardrobe is stained, or if painted china or coloured glass knobs, and a lining of glazed chintz finish the piece. The lining is attached with drawing pins, a curtain gimp hiding the edges and being caught down with invisible gimp pins.

Making a Wardrobe. The amateur who is desirous of constructing a wardrobe will find it worth while to study such woodworking articles as Cabinet Making; Cupboard, etc. Some proficiency in the use of tools and the making of the principal joints should be acquired before attempting a job such as the hall wardrobe or the veneered walnut article later described.

On the opposite side a shelf for hats at the top and a rail for boots and shoes at the bottom could be contrived, leaving the rest of this compartment for coats and suits, supported on hangers which hook on to a sliding fitting attached to the under side of the hat shelf. A small mirror in a frame can be screwed to the back of one of the doors. The necessary metal fittings can be purchased at an ironmonger's.

Hall Wardrobe in Oak. A length of 30 in. for a hall wardrobe is ample for the small hall. It enables a good many coats to be put away, and does not take up much space. The wardrobe in Fig. 1 is intended to be made in oak. Practically the whole thing can be made up from $\frac{7}{8}$ in. oak for the main framework, and $\frac{3}{16}$ in. oak-veneered plywood. It is possible to obtain ready-grooved oak, the advantage of the use of which is that it saves the somewhat awkward job of grooving. If one has a grooving plane there is no difficulty, but this is not a tool generally found in the amateur's kit.

However, this is a point that the home worker can decide for himself.

Fig. 2 gives the main sizes, and Fig. 3 the general construction. It will be seen that the main carcass consists virtually of

four frames, The two sides, the front, and the back. These are made up independently and fixed together afterwards.

Take the two sides first. Each consists of two uprights, four cross-rails, and three panels. Prepare the uprights and mark on them the positions of the rails. Mortise and tenon joints are used to fix the rails. When marking out the mortises on the uprights the over-all width of the rails should be drawn in, and inside lines squared across just inside these at a distance from them equal to the depth of the groove. These inner lines give the length of the mortises. It will be appreciated that the tenons on the rails cannot extend to the full width of the rails because the grooves automatically reduce them.

Marking Out Rails. When marking out the rails it is a good plan to fix them all together temporarily so that all are marked alike. Allowance must be made, of course, for the tenons when cutting the rails to length. The top outer edges of the rails are chamfered. This should be done after the sides of the tenons have been cut but before the shoulders have been formed. When all joints have been cut and fitted the panels can be prepared. The whole unit is then glued up.

As shown in Fig. 3, the back is a similar framework. There is no need to have oak panels; ordinary birch plywood is good enough. Neither need the rails be of oak. The uprights must be of oak, however, as they show at the sides.

There are no panels in the front framework, because the door is fitted here, and no grooves are needed, of course. Before glueing up it is necessary to work the decorative channels in the front surfaces of the uprights and bottom rail. A plain channel in the form of a wide, shallow groove is worked first and a bead formed at each side afterwards. It should be noted that the over-all size of this front framework must exactly equal that of the back.

The four frames are joined together by means of dowels let into the edges of the sides (Fig. 3). In order to make good joints the sides should be carefully planed and fitted against the front and back. It is a simple matter to mark out the dowels so that they coincide, by fixing the joining parts together with a cramp and squaring lines across with a pencil. Then set a marking gauge and mark each line. Dowels $\frac{3}{8}$ in. thick are suitable. Cramps should be used after jointing up, so as to draw the parts tightly together. For the top a piece of plain plywood can be used. If it is intended to use extending hanger rods a piece of solid wood should be attached beneath it to provide a fixing for the screws. Fig. 4 shows how the bottom rests upon fillets fixed to the rails. The addition of the cornice moulding completes the main carcass. This is mitred at the front corners. Shelves can be added if desired.

Making the Door. Fig. 5 shows how the door is made. The framework is put together with mortise and tenon joints and the inner edges are grooved to hold the panels. A decorative effect is produced by moulding and chamfering the edges. The top rail is moulded at its lower edge. The middle rail is chamfered at the top and has a channel worked along the centre. It is necessary to stop the chamfer on the bottom rail at the centre where the

upright joins it. This is shown clearly in Fig. 5. A moulding similar to that on the top rail is worked at both edges of the centre upright.

The diamond decoration in the top panel is formed by the application of a thin fret with a moulding mitred round the edges. Wrought iron hinges screwed direct to the surface are the most suitable to use. A good finish for the job is a dark oak stain followed by one or two coats of french polish. After this the surface can be well waxed.

Wardrobe. Fig. 6. Veneered walnut wardrobe with three compartments. It can be fitted up inside to suit any requirement.

Veneered Walnut Wardrobe. Present day design favours the use of large unbroken surfaces in which the work relies for its effect upon the main proportions and upon the beauty of the material. The wardrobe shown in Fig. 6 exemplifies this tendency. The doors have no visible framework, the whole surface being flat. The decorative effect is produced by the use of choice veneers. Another feature typical of modern practice is the absence of a cornice. The doors run right through to the top and are shaped.

Working diagrams of the wardrobe illustrated at Fig. 7. Details of the main measurements. Fig. 8. How the principal parts are assembled. Fig. 9. Simple method employed for constructing the doors, showing mirror at back.

The wardrobe gives excellent accommodation. There are three main cupboards, and these can be fitted up in any way the worker pleases. It is advisable to give over one entirely to hanging space, with possibly a boot rack at the bottom. The other two can be arranged to have shelves or drawers as desired. For the main sizes see Fig. 7. Fig. 8 shows how the main parts are made. There are three separate carcasses for the cupboards and a plinth upon which these stand. Each of these four parts is made up as a complete unit. Yellow pine, mahogany, or some other wood suitable to take veneer should be used throughout.

The Carcass. The sides of the centre carcass stand forward beyond the others. The reason is that the centre door must be contained between them, for otherwise it would be impossible to hinge it. The side doors are hinged over their carcasses. In order that the cross-banded effect on the doors may be continued round, the front edges of the centre sides are cross-banded. In this way they appear to be part of the doors themselves.

No attempt is made to follow the top shaping of the doors in the carcasses, except that the centre carcass is taller than the others and lines up with the over-all height of the side doors. One important point to watch in making this job is that all three carcasses must be made perfectly square. Otherwise, when they are assembled they will not stand true on the plinth, which is, of course, straight.

Lap-dovetails are used in the construction of the carcasses, as shown in Fig. 8. Dealing first with those at the sides, note that the top and bottom are narrower than the sides by the thickness of the back ($\frac{7}{8}$ in.). Rebates of this depth are worked in the back edges of the sides to hold the back. This is also true of the centre carcass, but the top and bottom are made narrower still because the door, although it is contained between the sides, closes over the top and bottom.

When the carcasses have been glued up and tested for squareness the backs can be made. These are plain frames mortised together and with grooved-in panels. They are screwed on. If permanent shelves are being introduced these can be either housed in or be supported by fillets. If the former method is adopted the housings should be worked before the carcasses are assembled. It is not practicable to use fillets in the case of drawers, and the rails for them must be housed in.

The Plinth. At this stage the plinth should be made up. Its construction is shown in Fig. 8. It consists of four stout stub feet into which the rails are tenoned. As it has to support a fair weight $1\frac{1}{4}$ in. stuff should be used for the rails. To give additional strength two intermediate rails are dovetailed in between the front and back rails.

After glueing up the joints are levelled and the surface veneered, the grain of the veneer running vertically. A wide, flat moulding is planted on top. Glue blocks should be rubbed in at the angles to reinforce the whole.

A simple method of making the doors is given in Fig. 9. A main framework of $\frac{3}{4}$ in. stuff is made up and a plywood panel glued over the front. The panel should be veneered before being fixed to the framework. Note that the top rails must be sufficiently wide to allow for the shape to be worked in them.

Fixing Mirrors. A useful addition to the side doors are mirrors, fixed inside. A quite light frame mitred at the corners can be used. It is shown in section in Fig. 10. A rebated picture-frame moulding could quite well be used for the purpose. To secure the mirror the framework is laid face downwards on the table and the mirror put in the rebate. The mirror should be about $\frac{1}{16}$ in. smaller all round. Wedges are then glued to the rebate at intervals of 9 in. or so. These hold the mirror

without touching the silver. When the glue has set the whole thing is placed on the door and screwed.

Fig. 10. Details of the method used when mirrors are required in side doors

The necessary information about veneering will be found in the article dealing with that subject. Other helpful hints are available in the articles Cabinet Making and Joint. If an inlaid or marquetry effect is desired reference should be made again to the specific articles earlier in this work.

WAREHOUSING. Persons wishing to warehouse their furniture should first of all obtain an estimate from a good firm, who will, if requested, send a representative to look at the articles. The charge for warehousing usually takes the form of so much per van load per week or per month, and it does not include the cost of conveying the goods to the repository. Neither does it include the cost of insuring them.

The warehousing firm will make out an inventory of the goods that pass into its keeping and hand a copy of this to the owner. The firm is then responsible for the safety and good condition of all the articles mentioned in the inventory, but for nothing else, and can be called upon to make good any loss or damage to them, provided this took place after they had passed into its keeping.

The charges for warehousing should be paid, when due. If they are allowed to fall into arrears and the arrears become considerable, the warehousing firm may sell the furniture to discharge the debt owing to it. Before doing this, however, ample notice should be given to the owner, or, if he cannot be found, the intention to sell the goods should be announced in the daily papers. The warehousing firm may also refuse to part with the furniture until all its charges have been paid.

Certain articles, such as pianos, are sometimes warehoused separately from other articles. Most dealers in musical instruments store pianos, and the arrangements for this are practically the same as for other articles of furniture. The storing firm usually undertakes to tune the piano at regular intervals. *See Removal.*

WARMING PAN. The predecessor of the india-rubber and stoneware hot water bottles was the warming pan, a shallow, circular vessel with a hinged lid, made of stout sheets of copper or brass. It was filled nightly during the cold season with red-hot coals and placed inside the bed. It was provided with a long handle, occasionally of iron, But generally of polished wood turned in the lathe. To avoid creasing the sheets, the top, bottom, and sides were made slightly Convex in form.

Warming pans were in use from the 17th century onward. Early examples often bear a date engraved or embossed on the lid, sometimes with homely proverbs, pious mottoes, or loyal sentiments, such as one dated 1622 which reads "God Save King James." These appliances are now

Warming Pan in embossed brass
Courtesy of Country Homes Supplies

in request by lovers of old brass, and they have not escaped the attention of the counterfeiter. They may be kept bright with dry leathers, preferably without metal pastes, and should not be lacquered.

WARRANT: In Law. A warrant is a direction under the common seal of a competent court or magistrate directed to an officer ordering or authorizing him either to seize the property of a debtor or offender, to arrest an offender, or to search a certain place or the actual effects of a certain person. Warrants for arrest can only be issued by magistrates on sworn information, and will only be issued in the case of serious offences where it may be supposed that the person charged is about to attempt to escape or might run away if only a summons were served upon him. The difference between a warrant and a summons is that a summons is a document that is sent to the offender ordering him to attend the court on a certain day to answer a charge, while a warrant is directed to a police officer ordering him to arrest the offender.

A search warrant is only granted on sworn information and on strong grounds. It is very often applied for in cases of breaches of the liquor licence law. If a mistress wishes to search a servant's box on suspicion of theft, her only legal course is to obtain a warrant and have the search carried out by a police officer.

A prosecutor who goes to a magistrate and gives him information, even though it be false, upon which a warrant is issued by the magistrate is not liable in an action for false imprisonment if the charge turns out to be a false one, though he may be liable in an action for malicious prosecution. Any police officer who arrests an alleged offender without a warrant is not liable to an action for false imprisonment if he can prove he had reasonable cause for suspecting that a felony had been committed and that the person arrested had committed it, or that he made the arrest to prevent a breach of the peace.

A private person, on the other hand, who arrests a suspect without a warrant must be prepared to prove that a felony actually had been committed, and that he had reasonable grounds for suspecting that the person whom he arrested had committed it. *See Summons.*

WART: How to Cure. A wart is a simple growth consisting of over-developed skin papillae. Warts occur most commonly in young people, on the hands, feet, and scalp. They are contagious.

Warts can generally be treated by applying glacial acetic acid every two or three days. This can be done with the end of a match. Care should be taken to keep the acid off the surrounding skin as much as possible. When warts are large in number and widely distributed, the free use of lime water inwardly has been said to be beneficial.

Care should be taken in applying caustics to warts in elderly people, especially those occurring about the face, as the growth may readily become malignant. The so-called butcher's wart is a local infection with tuberculosis.

WART DISEASE. This disease, which is known also as black scab, has been the cause of immense loss to potato growers: the warts, which form in the "eyes" of the potatoes, develop into small, cauliflower-like growths, eventually the whole tuber decays and the soil becomes infected with disease spores.

Fortunately the introduction of a race of potatoes which are immune to wart disease has been raised; these may be planted even on infected land. Some of the best potatoes which are immune to the wart disease are (early) Witch Hill, Immune Ashleaf, and Di-Vernon. (Second early) Arran Comrade, Ben Lomond, Abundance, King George, Arran Banner, and Great Soot. (Maincrop) Ben Cruachan, White City, Arran Consul, The Bishop, and Golden Wonder. Popular varieties of potato which are liable to attack by the wart disease and must not therefore be planted on infected land are King Edward, Duke of York, Sharpe's Express, British Queen, Arran Chief, and Up to Date.

WASHER: For Clothes. Where a good deal of laundry work is done at home, the task is simplified by the use of a reliable clothes washer. These machines are classed as gas, non-gas or electric washers. The gas models are provided with a gas burner, a heat retaining outer cover and constructed with a copper tank. Models are also obtainable which are complete with wringers and table tops. Deferred terms can be arranged for British washers which are fully guaranteed.

There is no complicated mechanism, and in most washers the agitator produces the actions of hand washing by means of which fabrics are stirred, squeezed and rubbed. Embedded dirt is removed by the vigorous swirling of the agitator. A gas model is reckoned to consume about 3d. gas in an hour and to use half a bar of soap in doing the washing for a family of several persons. Some electric models are stated to cost only 1d. an hour to run.

A vacuum electric washer has no moving part. The soapy water is drawn through the weave of the fabric fifty times a minute by the bubble action of the vacuum washer. A tablespoonful of soap flakes are placed in the bottom of the washer tub, the clothes are dropped in and the tub filled with water. The unit cylinder is then dropped into place and the machine is plugged to the nearest electric outlet for 20 minutes. The soapy water is then poured away and the clothes rinsed in a similar manner to that of the washing operation, but only immersed for a few minutes. *See Laundry.*

Washer for Clothes. Complete with wringer; this washer takes up little room, and fits into the legs when not in use. (Press Caps. Ltd.)

Washing. *See Laundry.*

WASHING. In Photography. The importance of washing thoroughly all plates, films, and prints cannot be too strongly emphasized. Prints or negatives which are insufficiently washed will inevitably develop stains and spots, or else the prints, particularly if made on gelatino-chloride paper, will gradually fade until the image disappears altogether. As many prints and negatives are spoiled by insufficient washing as by any other amateur fault. The object of washing is to remove

all traces of hypo (sodium hyposulphite) and free silver.

Washing in Photography. Fig. 1. Washing tank for plates. It is in japanned tin and fitted with a syphon.

By thorough washing is not meant prolonged washing. It is quite possible to wash a print in a deep dish, from which the water overflows only at the top, for 10 to 12 hours, and still find traces of hypo. The reason is that hypo solution is heavier than plain water, and sinks to the bottom. Although various hypo eliminators have been recommended from time to time, there is no doubt that water, properly used, supplies the quickest and best means of removing hypo. Experiment has shown that 10 min. really efficient washing is sufficient.

The amateur must not imagine that he will be safe if he washes his plates or prints in a sink or bath under a stream of running water for so short a period as 10 min. The most efficient method, though rather tedious, is to immerse the negative or print in a dish in successive changes of water. The print is allowed to stay in the water for 7 or 8 min., the dish rinsed out and then filled again with fresh water. If this is repeated eight times the most delicate chemical test will reveal no trace of hypo.

Apart from the use of the commercially made washing apparatus, several methods are open to the amateur photographer. The points to bear in mind are that the water must always be able to run away from underneath; that the water must have free access to both sides of roll films, and these must not be allowed to curl up or to get into violent motion which would cause scratches and other damage; that prints should not be allowed to stick together; and, finally, that postcards and prints on thick paper must be washed for a considerably longer time than other prints, since the hypo is present in the pores of the paper as well as in the film. In practice, if the washing methods are sound, the following times will be sufficient:

Glass plates and bromide and gaslight prints on light-weight paper, $\frac{1}{2}$ hour. Roll films and ordinary P.O.P. prints, $\frac{3}{4}$ hour. P.O.P. postcards and heavy-weight prints, one hour. These times will allow a certain margin of safety. Glass plates may be placed in a clean sink under a gently flowing tap, if means are adopted to prevent them being washed over and blocking up the outlet, so causing the sink to fill and overflow. Adjust the flow of water so that all the plates are sufficiently covered without the stream being so violent as to move them about. Flat films and prints may be washed in a bath with the waste plug nearly closed and the inflow regulated so that the water level remains constant. Each film or print is floated by means of a cork in which a nick has been cut with a sharp knife, the corner of the print being inserted in the nick. A large cork can be cut up into a number of slices about $\frac{1}{4}$ in. thick, each slice being nicked. The water flow will keep the prints on the move, while the corks prevent them sticking.

Roll films can be washed by a similar method if larger pieces of cork are attached at both ends, at one corner and also one or two others along the edge, so that the film is suspended edge downward in the water, while the cork prevents it rolling up. Any risk of damage to the surface of the film while wet is avoided by the use of wooden spring clips to which the corks are attached.

Above. Washing: in photography. Fig. 2. Excellent type of washing tank.

Figs. 3 and 4. Sectional view of tank shown in Fig. 2. Left, syphon shown in full action, hypo laden water (coloured dark grey) being removed, and fresh water (coloured light grey) taken in. Right, when water level reaches bottom of inverted cone on inlet of syphon tube, a hole admits air to syphon and stops water discharging. The whole process is then repeated.

Courtesy of W. Butcher & Sons, Ltd.

Washing tanks for plates in japanned tin or zinc can be obtained in various forms. A simple form is shown in Fig. 1, which holds 12 quarter plates or 6 half plates. It is fitted with a syphon so that the water is removed from the bottom of the tank. A better form is shown in Fig. 2. Here a complete change of water is obtained every minute. The principle is seen in the diagrams Figs. 3 and 4.

An effective print washer is illustrated in Fig. 5. It is connected to the tap by a short length of rubber tubing and so shaped that the water is constantly in a circular motion, carrying the prints with it. This washer can be obtained with a metal rack to take plates.

Fig. 5. Print washer so shaped that, on connecting it to a tap with rubber tubing, the water and the prints are kept in a circular motion. (Courtesy of W. Butcher & Sons, Ltd.)

Where a considerable number of prints have to be washed, special types of washer can be obtained in which the large numbers of prints are kept in constant rotation by means of apparatus resembling a turbine.

A simple test for the presence of hypo, which will indicate whether washing is efficient, is applied by allowing the last drips from the negative or print to fall into a tumbler and adding a little water faintly tinted pink with potassium permanganate. If hypo is present the pink tint will disappear immediately. *See Bromide Paper; Fixing; Negative; P.O.P.; Printing.*

WASHING POWDER. For washing clothes and other domestic purposes special soap preparations are sold in the form of powders. As some are injurious to fine materials only those produced by reliable firms should be used, and the powder should be dissolved in the washing water before the clothes are put in. Washing powders will make a quick lather, and are less wasteful than soap. They may be employed also for dish-washing, and are more satisfactory than solid soap for use with washing machines. *See Laundry; Soap.*

WASHING-UP IN THE HOME

How Modern Methods Lighten this Domestic Labour

This article gives useful hints on the daily cleansing of china, glass, and silverware, and also of cooking utensils. Other entries that may be consulted are Aluminium; Draining Board; Hot Water Supply; Kitchen; Scullery; Sink; Water

There are many devices for lessening the drudgery of washing up after meals and cookery. The most expensive is a dish washing machine and the least costly are mops. In the larger household the former appliance is probably worth while. A combined clothes and dish washer is obtainable in three models, hot water, gas and electric, and converted from one of its cleansing uses to the other by the simple interchange of two fittings. The floor space required is 20 sq. in.; the machine washes and dries all classes of crockery. There are several other types of washing-up machines on the market, the general principle of these being that hot water is sprayed on to the plates, etc., and when the hot water is turned off they are dried by hot air.

Apart from such a machine, the task of washing-up is made less fatiguing by the use of plate racks, draining boards, and various other devices. A plate rack fixed over the sink or draining board does away with the necessity of drying plates and dishes, provided they are thoroughly rinsed. An

improved type of rack is made to hold cups and tumblers in addition to plates. Some are made so that they can either hang on the wall or stand on the draining board. Sinks should, when newly installed, be placed in a good light and at a convenient height to obviate stooping too much while working. Where an existing sink is too low, boards made of wooden slats raise the height of the washing-up basin.

Portable draining boards are made to clip and clamp on the side of the sink. These are useful in sculleries where the sink is immediately next to the door or passage-way, and where a fixed board is not possible.

Inexpensive Aids. Papier mâché or wood pulp bowls are more suitable than those of metal for washing up glass and china, as they save a number of pieces from chipping and breakage during the year. A long-handled mop saves the hands. A plate scraper should be used to remove particles of food and grease from dishes, etc., before putting them into the water. A little pad is obtainable for cleansing and polishing knives.

Bottle brushes are invaluable for decanters and other narrow-necked vessels, whilst fresh tea leaves may be used to remove stains from the inside. A spiral rubber mop can be obtained which is excellent for cleansing glass bottles. Wire-headed brush mops are useful for detaching particles and grease from saucepans, while a scouring glove and a metal scouring pad are both practical aids for the same purpose.

The cleansing of greasy articles is greatly assisted by the use of soap or soap powder in the water, so as to provide a lather. The small pieces of soap that accumulate in a house can be utilized in this way by being put into a wire soap saver. The oddments are placed in the cage of this and boiling water poured on to them, a few whisks with the soap saver quickly producing a lather. To soften the water and to save soap, a little washing soda emulsifies grease and makes it easy to remove. Those who find that soda has a harsh effect on the hands and causes cracks should put a tablespoonful of borax instead of the soda in a medium-sized basin of water. Rubber gloves are suitable in cold weather for anyone whose hands quickly chap and crack. If the insides of the gloves are sprinkled with French chalk before use they do not stick to the hands.

Efficient Procedure. Whether the washing-up is done by hand or machine, plenty of hot water must be available. This is an important matter to be seen to when moving into a new home. For a small amount of washing-up a kettle or large saucepan can be boiled. In a gas oven, after the gas is turned out, there is usually sufficient heat retained in the oven to heat a basinful of water; if it is not quite hot enough a few minutes over a small gasring will bring it to the right temperature.

Where there is no constant supply of hot water from the range or from an independent boiler, a supply is obtainable at a minimum cost by the use of a small gas or electric water heater placed near the sink. In districts where electricity or gas is not available, a rapid water heater may be installed. for use with paraffin oil or an oil stove will supply sufficient hot water.

When the washing-up is actually done in the sink or in a basin standing in the sink, the right-hand draining board or a small table placed against the right side of the sink is the most handy position for the dirty things. Where there is a pantry, finer china, silver and glass ware will be washed at the sink there, the cooking utensils and crockery, etc., being done in the kitchen.

First remove all scraps, remains of food, and grease from plates, spoons, knives, and forks—a piece of newspaper can be used for the purpose if no scraper or rubber squeegee is at hand. Tea cups and milk glasses should be rinsed under the cold tap. If a little trouble is taken with this part of the work the washing-up water will remain comparatively clean.

The things should be washed in the following order: Glass, silver, china, knives and other metal articles, saucepans, and baking tins. A few things only should be washed at a time, and, when there is a good supply of hot water, a better result is obtained and with less effort if the things are rinsed in hot water, drained, and dried at once. The smeary marks frequently noticed on glass and china are due to the fact that water containing soap and soda has been allowed to dry on the articles instead of being removed with a cloth or by rinsing.

When washing china with gilt or hand colouring on it, soda or strong soap powders should not be put in the washing-up water, as the alkali is likely to remove the gilt and spoil the colours. Glass requires special care, particularly when new. The water should not be very hot or the glass cracks, being a poor conductor of heat, and the thicker the glass the more liable it is to fly. A small brush should be used to clean cut and moulded glass.

White marks on water jugs and bottles are often caused by hard water that cannot be removed with soap and water. The best way to deal with these is to allow vinegar to remain in contact with the chalky deposit for a short time, then rub hard with a small piece of cloth moistened in vinegar; the acid in the vinegar dissolves the chalk. A rub with a cut lemon answers equally well.

All knives and forks with handles attached require special care. Whether the handles are riveted or stuck on, they should on no account be put right into the washing-up water, for hot water soon loosens those that are stuck on and cracks and splits ivory. They are best placed upright in a jar or jug partially filled with hot softened water.

To simplify the cleaning of greasy saucepans and baking tins, fill them with warm or cold water immediately the contents have been dished up, add some washing soda, stand them on the stove or in the oven, and when ready to be washed the pans will be found to be practically clean. All saucepans, other than aluminium, in which food has been burnt should be boiled up with a strong solution of soda and allowed to soak, as this saves both the time and labour necessary for hard scouring.

After use, the washing-up bowl, mop, dish cloth, scouring cloth, or saucepan brush should be scalded, and then washed in hot soapy water, rinsed, and hung up. Separate towels are required for drying glass, china, and silver and knives. So that they may be easily distinguished, the glass cloth could be of checked linen of medium texture, the china cloth of coarse white linen, and for knives and tins a thick, unbleached linen towel is suitable.

WASH LEATHER. Wash leather or chamois leather is unrivalled as a cleaner and polisher of glass and silver. It should never be used with anything but cold or tepid water; hot water will cook the fibre and render it perished and brittle. After use, the surplus moisture should be wrung out and the leather hung to dry. When thoroughly dry it will be found somewhat hard, but can be returned to its original softness by pulling and stretching.

Wash leather should always be used in preference to other materials for putting the finish on silver and plated articles, after all plate powder or whiting has been removed. It will not only impart a high polish, but its continued use will remove light surface scratches. The best results are obtained by the aid of a small quantity of jeweller's rouge applied as a final operation with soft, dry wash leather.

Grease marks and other stains on articles made of suède leather or cloth with a velvety pile or nap, soft felt hats, for instance, may be removed by rubbing briskly with a clean, dry piece of wash leather. The linings of men's pockets, especially vest pockets, are sometimes made of wash leather. *See Glove; Window.*

WASHSTAND. Except in houses where the bathroom accommodation is limited for the number of bedrooms, or in rural districts where the water supply has to be economically considered, there is a

tendency towards the disappearance of the movable washstand as a piece of furniture. They can be bought separately or made to match other bedroom pieces, but are not included in many of the more expensive modern suites. Owing to their partial decline in use oak, mahogany and painted wooden washstands can be picked up in reliable secondhand shops at comparatively low prices.

In some of the newer houses and flats hot and cold water fitted washstands are built into the bedrooms. Such washstands are either concealed in a cupboard, or are planned on the same lines as a lavatory basin, in more or less expensive styles, and provided with a pedestal base or supported on plated legs.

Antique mahogany washstands of corner shape are usually more decorative than practical. Many people cover the top with a fitted board, hiding this with a shaped piece of old brocade, damask or tapestry needlework, and thus convert the washstand into an attractive little corner piece for the sitting-room. *See Bathroom; Bedroom.*

WASP. Usually in hot weather numbers of these insects frequently invade the house, especially congregating where there is anything sweet, such as jam or fruit. They are not only a great nuisance, but, owing to their capacity for stinging, may be a positive danger. They can be killed one by one, or trapped and then killed, but a better plan, if it is possible, is to seek out and destroy their nest.

Wasp. Enlarged photograph of this stinging summer insect.

Treating a Sting. When a person is stung by a wasp, the part begins to swell almost before the first acute pain from the wound subsides. This swelling is generally confined to the immediate neighbourhood of the point of entrance of the sting.

Ordinarily the system is not appreciably affected by the poison in the sting, but in rare cases, and particularly when the victim has been stung in a number of different places, the poison may act

directly on the heart. A wasp sting over a vein, where the poison is poured directly into the blood stream and so carried straight to the heart, is more likely to be serious than one in which the poison enters solid tissues underlying the skin.

A wasp sting on the tongue, lips, or inside the cheek may lead to suffocation through rapid swelling of throat tissues, preventing air being drawn into the lungs. Not infrequently, as the result of the wasp poison in the blood, a type of nettlerash, which may persist for several days, may break out over the part affected. In some cases this rash may cover the whole body.

The wound should first be carefully examined to see whether the insect's sting has been left behind. If so, this should be carefully squeezed out or removed with a needle or a fine pair of tweezers. If the pain and swelling are severe, a handkerchief soaked in lead-water and laudanum lotion may be lightly bandaged over the part, or the old-fashioned bluebag may be employed. Another homely but usually efficacious remedy is rubbing the sting with a strong onion.

Destroying a Nest. Found in the ground or on grassy banks, wasps' nests can be destroyed in several ways, an old method being to burn them out with sulphur fumes. This method, however, is attended with some risk, especially to those inexperienced in the use of sulphur. A good plan is to pour some petrol in the opening late in the evening when the wasps are all in their nest, and seal up the hole with some clay. The next morning a little more petrol should be poured in, and then the nest can be dug out and destroyed. Cyanide of potassium can be used in the same way. The latter should be dissolved in water in the proportion of 3 drams to ½ pint, and carefully squirted into the opening of the wasps' nest with a small syringe.

Trap for Wasps. A wasp trap can very easily be made from a flower pot, a jam jar and a saucer. The flower pot should be turned upside down, and raised from the ground on three small blocks of wood. The jam jar is then placed over the hole in the bottom of the flower pot, and underneath the whole is the saucer with some sugar therein. The wasps will enter in the space between the bottom of the flower pot and the earth in order to eat the sugar. When satiated, they will fly up and through the hole in the flower pot into the inverted jam jar, where they will be caught.

To remove the wasps, a card should be placed between the mouth of the jar and the inverted bottom of the flower pot. Keeping the card firmly fixed against the mouth of the jar, this can be removed and immersed in water drowning the wasps.

WASTE PAPER BASKET. Receptacles for holding waste paper and discarded scraps of other materials are necessary in all sitting-rooms and in most bedrooms. They can be bought very cheaply, especially the varieties in wicker, cane, rush, imitation leather and cardboard covered with cretonne. Metal baskets are constructed of interlaced steel hoops and various forms of woven wire work.

Woven cane baskets are enhanced in appearance by barbola decoration (see Gesso Work), the contrasting tones of the gold, silver or other coloured barbola work throwing the ground colour of the basket into harmonious relief. The gilded cane waste paper basket shown in Fig. 1, embroidered in coloured raffia is a variation of the same type. The basket may be bought ready gilded or painted at home with metallic paint. The flowers should be loosely made (see Raffia Work), and two or three shades of pink may be used for each rose, the leaves and stems being worked with green raffia. The basket may be lined with silk and finished at the top with gold galon if desired.

Waste Paper Basket. Fig. 1. Gilded waste paper basket decorated with flowers in brightly coloured raffia. Fig. 2. Waste paper receptacle with wood pulp foundation painted and decorated with old flower print.

Varieties of parchment covered waste paper receptacles can be obtained either plain or ready decorated. The one shown in Fig. 2 has a wood pulp foundation, is painted green, with a gilded rim and base, and lined with marbled paper. A beautiful old flower print has been used to ornament one side and the whole has then been varnished. Stencilled or hand painted designs would be an equally suitable form of decoration. *See Writing Desk Set.*

WATCHES AND THEIR MECHANISM

Simple Explanation of Different Types of Escapement

Aided by diagrams this article first describes the working of a watch, and in a subsequent section gives hints on the selection and care of this delicate apparatus. *See also Clock.*

Watches small enough to be carried in the pocket were first invented in Nuremberg, about the year 1500, by Peter Hele, a clock-maker, who devised the mainspring. In 1658 a step forward was made by the discovery of the balance spring, and in 1695 Tompion, the great London clockmaker, patented a cylinder escapement. In the early part of the 18th century Graham brought out his dead-beat escapement, while John Harrison invented the compensation balance to counteract

irregularities of time-keeping owing to variations in the temperature. The keyless watch appeared during later Regency days, and after 1850 was made in great quantities in, and exported from, Switzerland.

Though watches have usually preserved a round and fairly flat shape, ball and square, oblong and lozenge forms have appeared from time to time. The watch belonging to Mary Queen of Scots, illustrated in this page, was made in the shape of a skull and beautifully wrought.

Watch. Memento Mori watch, belonging to Mary Queen of Scots and given by her to Mary Seaton.

In the 17th century decoration in enamel for watch cases and dials appeared. In the 18th and early 19th centuries pinchbeck (q.v.) was used instead of gold for cases, and was sometimes as richly chased and engraved. Silver was extensively used and other examples had outer cases of shagreen, tortoiseshell, etc.

The mechanism of the watch will be more readily understood if the article on Clock is first referred to. The number of wheels in a watch has always remained the same, variations in the number of teeth in wheels and pinions being made to suit the different escapements that have been used. The mainwheel gears into the centre pinion, which carries the hands. From there the centre wheel gears into the third pinion and the third wheel into the fourth pinion, to which is fitted the seconds hand. The fourth wheel gears into the escape-wheel pinion.

Escapements. Various types of escapement have been devised, the first of these being the cylinder or horizontal. This comprises an escape wheel with wedge-shaped teeth, which stand up from the flat of the wheel on stalks, and work in and out of a steel cylinder, nearly half of which is cut away. On the cylinder is mounted the balance and spring, and in swinging it gets impulse from the inclined plane of the teeth rubbing against the edges of the cylinder. This escapement was never used extensively in England, as it was found that there was a tendency to excessive wear on the working parts. Swiss watchmakers got over the difficulty by making the cylinder and wheel of hardened steel, and this device is still in use in the cheaper grades of both Swiss and French watches.

Fig 1. shows a detached lever escapement, typical in the main of the form found in the great majority of modern watches. The balance has a free swing, the pallets B and lever C interposing between the wheel and the balance. Fitted on to the balance staff E is a steel roller D with a jewelled impulse pin F standing out at right angles to the face; the pallets and lever are fixed together and swing on an axis at K.

When the balance swings, carrying with it the roller, in the direction of the arrow, the impulse pin enters the notch of the lever, striking with sufficient energy to move the lever and pallets far enough to release the wheel tooth from the locking face of the pallet. The wheel, actuated by the force of the mainspring, now moves forward in the direction indicated by the arrow, pushing the pallet out of its path. By the time that the wheel tooth has reached the end of the impulse face the other pallet will be in position to receive another tooth.

When the pallet was pushed aside it carried with it the lever in the same direction as the roller is travelling, and in its passage it imparts a blow to the impulse pin that sends the balance on with renewed energy. The impulse pin has a dual use, unlocking the pallets by giving a blow on one side of the notch of the lever and receiving a blow from the other. The balance in its swing coils up the

balance spring until its energy is expended. Its motion is then reversed by the uncoiling of the spring, when it repeats its operation in the opposite direction.

In the roller a small crescent is cut out, and into this passes the guard pin H to prevent the escapement from unlocking except when the impulse pin is in the notch. There are two banking pins L, set one on each side of the lever to keep the motion of the lever within the desired limits. The locking faces of the pallets are cut back from the radial line, and this causes the teeth to draw the pallets inward towards the centre of the wheel, and the lever is hard up against the banking pins so that the guard pin is clear of the roller. The working faces of the pallets are jewelled, J, and are slightly rounded to lessen the friction.

There are some minor variants of this escapement. The Swiss, for example, have abandoned the pointed teeth and use a wheel with what are called club teeth M, Fig. 2—that is, teeth with the tips formed into an inclined plane dividing the impulse face between the wheel teeth and pallets. Some escapements are made with a double roller, the guard pin working on a smaller roller underneath the impulse roller N. The chronometer escapement is only used on very high-class watches, and clocks for use at sea.

Watch. Typical specimens, 16th to 18th centuries. Top row : 1, Single hand watch, brass, c.1560 ; 2, Claud Viet, 1608, shagreen case ; 3, W. Tomlinson, 1696-1732, silver ; 4, H. Massey, 1692-1707, silver. Middle row : 5, T. Tompion, 1639-1713, gold ; 6, H. Prevost, 1710, gold, with repoussé outer case ; 7, J. Shearwood, 1769, silver ; 8, J. Harrison, 1693-1776, early work, case in Vernis Martin. Bottom row : 9, Robt. Fleetwood, 1760, gold, in shagreen outer, case (back) ; 10, W. Collett, 1789, tortoiseshell painted dial ; 11, Justin Vuillamy, 1739, gold ; 12, Ben. Taylor, 1784, skin

Courtesy of Joseph Pizzala, Esq.

Fig. 1. Lever escapement, invented in the eighteenth century, and still the best to-day. It is known as a detached escapement, the balance having a free swing. An explanation of the lettering is given in the text. Fig. 2. Swiss form of escape teeth, club shaped. Fig. 3. Sectional view showing two methods of jewelling. Fig. 4. Compensating balance for counteracting changes in temperature

Jewelling, two methods of which are shown in Fig. 3, is another important part of a watch, the pivots being run in bearings made from hard stones set into the brass plates and cocks. These tend to a smoother running and diminish wear. Some of the pivots run in holes alone, others have endstones placed over the outside of the jewel hole, the pivots in this case taking a bearing on the ends, and the shoulder of the pivot, which is usually cone-shaped, standing clear of the jewel hole. Balance pivots are always made this way. The jewels of a watch have no value as gems. Their only worth lies in this useful function of making a smooth running for the mechanism.

The Balance. With the ordinary plain steel, brass, or gold balance, changes in temperature cause variations in timekeeping through the metal expanding or contracting. To overcome this the compensating balance is used, as in Fig. 4. The parts A and B

are turned out of one piece of steel, on the outer edge of which is melted a brass band C twice as thick as the steel band B. These two bands are cut through at opposite sides (D), close up to the arm, leaving the balance with two free ends.

With a rise in temperature an ordinary balance expands, and in so doing increases its diameter, which causes it to vibrate more slowly. With a drop in temperature the operation is reversed. The remedy for this is a compensating balance. The compensated balance also expands with a rise in temperature, but as brass expands more than steel the effect is that the brass bends the rim inward at the free ends. This causes the centre of gyration to approach the centre of motion in the opposite direction to which the mass would expand, thus restoring the balance to its former shape. Around the rim are a series of tapped holes, into which screws, E, are fitted, and these can be shifted from one hole to another to vary the compensation. There are also four timing screws F, which can be used for bringing the watch up to time by screwing in or out, thus decreasing or increasing the diameter of the balance.

The balance spring controls the number of vibrations a balance will make in a given time, so that the strength of the spring is in proportion to the weight of the balance. The usual form of spring is the volute or flat spiral. The inner end is pinned to a collar which is fitted friction-tight on the balance staff, and the outer end is pinned to a stud in the balance cock or the plate. An overcoil or Bréguet spring has the outer coil bent upward and carried in a long curve over the flat plane of the spring towards the centre near which it is fixed. The advantage of this type of spring is that it distends in action on each side of the centre, thus relieving the balance pivots of a good deal of side friction.

The regulator of a watch is generally a steel index held down friction-tight by the end-piece on the top of the balance cock. Its axis coincides with the centre of the balance, the index finger pointing to a scale engraved F and S on the top of the balance cock. At the other end of the index there are two fine pins standing out at right angles. Between these pins passes the outer coil of the spring, about a quarter of a turn from the pinning-up stud, and from these pins to the centre is the effective length of the spring. As the regulator is moved the pins pass along the spring, shortening or lengthening its effective length and therefore making the balance vibrate faster or slower.

The Care of Watches. A watch should be purchased from a reputable watchmaker, who can give much useful information on the question of its choice. It is well to consider if the difference between a high grade watch and a cheaper one is of personal importance. The difference, apart from external details, such as the material of the case, etc., is one of service; a cheap article may serve for a time and give tolerably good results for the money paid. While it is uncommon to find a poor movement in an expensive case, it is by no means necessary to have a gold case in order to secure a good timepiece. Reliable movements in silver or other metal cases can be bought at quite moderate prices.

A watch is a delicate piece of apparatus which violence or ill usage will immediately put out of order, causing damage to its finely constructed parts and rendering necessary a visit to a repairer, with its attendant expense. In the average watch there are upwards of 150 parts, some microscopically minute, although for its size it is as robust as well as a most delicate machine. The watch should be wound at regular intervals, night or morning, and should be removed from the garment at night. To throw down a garment with the watch in the pocket is to risk damage to the delicate mechanism.

The mainspring of a watch is enclosed in a drum or barrel, and consists of a finely made steel ribbon. It is the motive force of the remaining wheels, comprising the whole train down to the balance wheel, which latter may make as many as 18,000 vibrations in an hour. Regular or irregular beats of the balance will indicate its condition; many watch troubles will arise from a defect

hereabout, and on the accurate adjustment of the balance wheel and hair spring depends good timekeeping.

The hair spring is so fine and sensitive that it should never be touched by any but an expert; it is most easily damaged and put out of working order, and is usually costly to replace.

The question of periodical cleaning and readjustment is vital to good performance.

If a watch is allowed to run for years without this attention the constant running friction will cause the lubricating oil to dry up, or on the other hand it may become thickened. If the oil dries up the effect on the fine pivots, running in dry bearings, can be imagined.

The regulating of a watch when gaining or losing is a delicate operation and is best performed by a watchmaker. The regulator is in close proximity to the balance wheel and hair spring, and if the alteration is made by an amateur a slip with any instrument that may be used may cause considerable damage to these parts. Further, the regulation is not always effectively made with the index or regulator, but may require to be done by way of alteration to the timing screws, to be seen around the balance wheel, and none but an expert should venture this. On some watches, again, the index is provided with a tiny micrometer screw adjustment.

The watch pocket should be kept free of dust, since a tiny particle of grit in the working parts will cause a stoppage, and necessitate a cleaning job for the watchmaker. If a watch stops for no apparent reason, it may need re-winding. Apart from this, try gentle pressure on the winder, and if it fails to start, do not tamper with it, since a stoppage then indicates something amiss.

Should the user of a wrist watch inadvertently omit to remove it before entering a bath or the sea, the case front and back should be opened at the earliest moment, draining out all the water possible, after which the whole watch should be immersed in oil to prevent the steel parts becoming affected by rust. The watch should then be passed on to the watchmaker to deal with. If a watch keeps erratic time, it may be because it has become magnetized. The watchmaker will possess an instrument for testing and demagnetizing, which will correct this defect.

WATER SUPPLY AND DISTRIBUTION

Methods in Use in Town and Country

The subject of this article is touched upon in a large number of related entries in this work. A selection of these only is named here, but a perusal will suggest others: Cistern; Drains; Filter; Frost; Hot Water Supply; House; Pipe; Pump; Rainwater; Soakaway; Tap; Well.

The water that forms the domestic water supply is obtained in a variety of ways. Houses in towns and populous districts are almost always connected up with a local supply, and this ensures to the house an amount ample for cleansing purposes of all kinds, and of a quality good enough for drinking.

In country districts water for the former purpose is often obtained by the collecting of rainwater, but this will not serve for drinking. A supply of drinking water, therefore, is often secured by sinking a well, but water from shallow wells in the neighbourhood of houses or of land grazed by livestock should be regarded with suspicion. A good plan is to pass all the drinking water through a filter, a process carried out in many homes. When this is done it is of vital importance that the filter be kept scrupulously clean; the filtering medium frequently renewed, or if of the porcelain candle type, washed and sterilized. If this is not carefully attended to, instead of filtering the germs from the water, it will add further germs. Water may be divided into hard and soft, each with its own advantages and defects for washing and drinking purposes. It is quite possible to soften hard water, and this is sometimes done by the company that is in control of the supply. Water softening apparatus for use in the home is dealt with later in this article.

The supply of water for domestic purposes may conveniently be divided into two branches, the external supply to the house and the internal arrangements for distributing. Rainfall constitutes the chief source of all supplies. For the water supply of towns, rivers and lakes are dammed and reservoirs are filled from them. Distribution is effected by means of main pipes. The water is purified by being made to pass through filter beds, which usually consist of concrete receptacles having layers of different filtering material arranged in them. A typical filter bed has at the bottom a layer of large graded gravel, on the top of which is another layer of smaller grade gravel. This again has pea gravel on top of it, and above this a very thick layer of fine washed sand. Distribution from the purifiers to the houses is usually accomplished by gravity, and in many cases the water has first to be pumped to a sufficiently high level to ensure adequate pressure.

With regard to the actual chemical contents of an ordinary public supply, the following analysis may be taken as typical in a rural district in England.

Grains Per Gallon

Total solids	28·00
Chlorine	1·85
Ammonia	0·00112
Albuminoid ammonia	0·00042
Nitrogen as nitrites	Absent
Nitrogen as nitrates	0·017
Lead	Absent

Microscopic examination revealed a little vegetable debris and mineral matter, and there was the faintest trace of iron.

In the case of country houses water supply may present a considerable problem, and the choice of a suitable system for its collection depends entirely on circumstances. Wells are still in use, and care is required to choose a site where the water is pure and free from decayed animal or vegetable matter.

The House Supply. The internal distribution of cold water throughout a house where a town main exists presents no difficulty, as the pressure is always ample to supply all floors. Where there is no main, however, a tank placed at the highest point available is essential, and the distribution to lower parts is accomplished by gravity. A common arrangement is to use a storage tank for the supply to the lavatory basins, bath and hot water system, the main being connected to the ground-floor taps only. Automatic regulation of the water to the tank or cistern is accomplished by a ball valve.

Water from the main supply is carried from the main to the house by a service pipe generally of $\frac{3}{4}$ in. lead pipe, fitted with a stop cock situated below the pavement. The position of this stop cock should be noted and the cover should be examined from time to time to prevent it becoming clogged up. The service pipe is carried through the wall of the house at some convenient position, and is then connected up to the main internal distribution pipe. In the event of a burst pipe or during a severe frost the internal supply should be cut off at the stop cock by means of a T-handled key.

The usual arrangement of the supply main is indicated in Fig. 1, which shows how the pipe is brought into a house provided with a cellar. In addition to a stop cock outside the house (usually in the forecourt), it is an advantage to fit an indoor stop cock at the point of entry into the house, as shown. In districts where the pressure is intermittent it is necessary to use a storage tank at the top

of the building for use when the main supply is not operating, but in this case a tap should be fitted to the internal main supply pipe so that drinking water is obtainable direct.

Storage tanks are also necessary in all buildings possessing modern systems of domestic hot-water services.

The arrangement of the internal distribution of pipes for an intermittent supply is illustrated in Fig. 1; the main supply is shown as a solid line and the supply from the tank as a double line. It will be noted that the main supply pipe is fitted with an emptying cock; this should always be done and it should be at the lowest point of the pipe. In houses where the supply is obtained from a well or surface storage tank, the water should be carried direct to the upper tank, arrangements being made for emptying the tank at the lowest level of the internal piping. For bungalows in cases where the

supply is obtained from rainwater from the roof, a convenient plan is to support a tank as high as possible close under the eaves. The support can be arranged as a cool store for food. Storage tanks should be provided with a cover and must be periodically and frequently cleaned. Supply pipes should be accessible and not bedded in plaster, and internal pipes must be inclined towards the lowest point.

Water Softening Apparatus. The question of the hardness and softness of water for household purposes is important, and in some districts it is essential that artificial aid be used to render the water soft. The term hard is applied to water which has absorbed mineral compounds from the ground, generally some chemical compound of lime or magnesia.

Water softening plants may be obtained in sizes suitable for any household, and a type of plant in general use for this purpose is the Permutit softener, illustrated in Fig. 2. The water is softened by a chemical compound through which it is made to pass. The cylinder shown in the photograph contains the compound, the upper tank containing a common salt solution which is regulated automatically and regenerates the permutit. If a quantity of dry salt is added at stated intervals the apparatus requires no further attention.

Water. Fig. 2. Permutit water softening plant which softens water by means of a chemical compound.

Below. Fig. 3. Portable softener suitable for a moderate-sized house. (Fig. 2, courtesy of United, Water Softeners, Ltd.; Fig. 3. Silical Water Softeners, Ltd.)

There are a number of reliable apparatus on the market, functioning in somewhat the same manner. Sometimes there are considerations which prevent the installation of a plant for dealing with the entire water supply for the household, in which case it is possible to obtain small supplies of soft water for drinking, toilet, or culinary purposes by using a portable apparatus connected at will to a kitchen, lavatory basin, or bath tap. Fig. 3 illustrates a typical softener of the smaller type. No plumbing is necessary, the appliance being simply fastened to the wall, and the flexible connexion slipped over the nozzle of the tap.

Advantages of Soft Water. While some people claim that a certain degree of hardness makes drinking water more palatable, an excess renders it harmful. Organic purity of water may be attested, and yet inorganic purity may not be attained. The former refers to freedom from harmful bacteria, the latter indicates the absence of chemical compounds which make water hard, as for example, salts of lime and magnesia.

Most housewives know the deposit of “fur” or “scale” which forms on the kettle where water is hard, and can have some idea of the effects of this on the interiors of hot water pipes and boilers. Hard water has been replaced for various household purposes by rain water and distilled water in the past, but the first of these is uncertain in supply and not always possible to obtain and the second is costly.

As soft water effects many economies in the household, the installation of a softening plant is worth consideration, especially as some reliable and effective water softeners are obtainable at very moderate prices. They require no expenses of upkeep beyond the passing of a solution of ordinary salt in water through the appliance at stated intervals, take up little room and are noiseless.

The use of soft water in the kitchen produces immediate benefit and saving both of labour and money. Tea and coffee can be reduced in quantity, as the full value is extracted by soft water. The latter is necessary when cooking vegetables to preserve colour and flavour. The consumption of soaps for toilet and domestic use is reduced almost by half, and soda or powders to soften water are unnecessary. For washing-up, the task is lessened when lime and magnesia have been removed, and no chalky marks are left to polish off glass or silver ware. The insoluble curd of soap which makes laundry work difficult is obviated by soft water, in which a small quantity of flakes produce a copious lather.

WATER BED. In order to lessen friction and pressure and prevent bedsores in cases where from paralysis or other illness patients must be in bed for long periods at a stretch, a water bed is often employed in place of a mattress. It is simply an india-rubber bag of the size of an ordinary mattress. A screw stopper is inserted in one corner of the mattress, through which it is filled.

The patient should not be on the bed while it is filled and should be taken off before it is emptied. The water for filling should be at a temperature of 90° and sufficient should be used to separate properly the two surfaces when the patient is on it. On the other hand, it must not be too full or it will be uncomfortable. A water bed should be covered by a mackintosh sheet, and a blanket beneath the sheet. *See* Bed-making; Bed Sore.

WATER BISCUIT. These plain biscuits are made by rubbing 3 oz. butter into 1 lb. flour, and adding sufficient water to mix the whole to a stiff dough. Knead the latter well, roll it out very thinly, and stamp it into biscuits. Prick each biscuit on top and bake them until they are pale brown in colour.

WATER BOTTLE. Glass bottles for holding water are ordinary household items, but old ones, some of them made before the invention or at least the general use of glass are regarded as curios and are prized accordingly. Some of these are made of skin, but others are of metal, in some cases the precious metals being used for them, and examples may be seen in the various museums.

In the ordinary household the most usual type of water bottle employed is the one which is placed on the washstand. These are bought complete with one or two tumblers, and vary from plain to cut glass or crystal.

Flat-shaped water bottles of glass or aluminium, for carrying when out for a long walk, can be obtained in cases fitted with a long strap. *See* Hot Water Bottle.

WATERBRASH. The regurgitation of a watery acrid or acid material into the mouth from the stomach is a feature of some forms of indigestion, and is popularly known as water-brash. It is usually accompanied by a hot sensation behind the breast-bone and in the throat, which is described as heartburn (q.v.). *See* Indigestion.

WATER CLOSET. Both the construction and the arrangement of water closets are governed by building acts and the regulations of the local sanitary authorities, and when any alteration or addition is contemplated such requirements must be observed.

The usual apparatus comprises a closet pan and a flushing device known as a waste-water preventer. This consists of a tank or cistern holding two or three gallons of water. When the water is released, it is forced down a vertical pipe and flushes out the pan. The amount of water in the cistern is regulated by a ball cock, which is generally made of thin copper and should be airtight, so that the ball floats on the surface of the water. Its function is automatically to raise a lever, which closes a valve and cuts off the supply of water to the cistern when it has reached a certain level.

Should this ball be punctured, it becomes partly filled with water and is no longer sufficiently buoyant to close the valve with the result that the water continues to run into the cistern and escapes by the overflow pipe. The remedy is to turn off the water at the source of supply, or else temporarily to fasten up the valve and then remove the ball and lever. The water is expelled by enlarging the puncture and by warming the ball; then the surface is scraped clean and a small patch of thin copper soldered over the aperture.

If the ball is immersed in water, air bubbles will show at once if there is another leak, which can be remedied in a similar manner. If no air bubbles are visible, the ball may be considered watertight and can be replaced. Another cause of the cistern overflowing may be found in the lever gradually bending and not rising sufficiently. This is remedied by bending the lever to its proper shape with the aid of pliers and spanners. When the valve is the cause of the trouble, the remedy is to replace the worn washer with a new one.

The cleansing of a water closet should be carried out regularly, using a long-handled, stiff-bristled brush and one of the branded preparations or disinfectants which are put up for that purpose, failing which a few drops of hydrochloric acid may be dropped into the pan, which should be thoroughly flushed two or three times in succession. *See* Ball Cock; Drains; Pipe; Sanitation.

WATER COLOUR. Damp is the worst enemy of water colour drawings, because its presence is often unsuspected before the damage has been done. Common effects of damp are the crinkling up of the drawing and the appearance of mildew spots on its surface. Initial care in seeing that the drawing is properly set in its mount—the slightly sunk variety is preferable—helps to prevent crinkling, but where doubt exists as to the dryness of a particular waif the frame should be kept clear with strips of cork glued at or near its points of contact with the wall. Cork studs about $\frac{1}{2}$ in. thick make a perfect nonconductor of damp. Mildew is very difficult to remove without injuring the drawing, but, if its presence is detected at an early stage, light rubbing with breadcrumbs may prevent its development. *See* Picture; Print.

WATERCRESS. Watercress is a hardy perennial herb, and is a true nasturtium. It can be cultivated in gardens without a waterway so long as it is given a moist, shaded position. It will thrive in still water, but steps must be taken periodically to renew it, otherwise it may become foul.

Table Uses. Watercress is an adjunct to salad and is also useful for sandwiches to be served for afternoon tea, or may be eaten with bread and butter at breakfast. It has medicinal qualities as a blood purifier. The cress must be very thoroughly cleansed and picked before being served at table, and the thick stalks removed. When added to salads it is divided into sprays, but the leaves are always allowed to remain whole.

Many dishes are garnished with watercress, notably those which are egged and crumbed and fried. As a garnish for ducks, chickens, pigeons, or game it is, after washing and picking, heated over steam or in a cool oven and seasoned with pepper and salt.

WATER GARDEN. The simplest form of water garden is a small pool of which the sides and bottom have been made watertight with layers of cement. On clay land the pool may be rendered watertight by puddling, but it is safer to use cement.

Water lilies, set in shallow baskets filled with loamy soil and planted in April or May, are the best plants for a garden pool. There are many varieties suitable for deep or shallow water. Other attractive aquatic plants are the bog bean, Cape pondweed, and flowering rush (*hottonia*).

Those who possess some kind of waterway, be it shallow water, ditch, stream, or even bogland, can transform it into a charming adjunct of the garden proper. The mud of the water-edge will accommodate bold groups of Japanese irises in company with *Spirea palmata*. Then one may select the marsh marigold in single and double forms, together with the vivid orange globe flowers. Space may also be found for the sweet flag, funkia, and Japanese primulas. The reed mace will find a home, but its growth must be kept under control. Where space is ample, gunneras, rodgersias and giant reeds are available for use. *See Arrowhead.*

WATERGLASS: For Eggs. As used for preserving eggs, this is a strong solution of silicate of soda and water, varying in specific gravity according to the amount of silicate that is dissolved. The strongest solution usually found has a specific gravity of 1·7, and contains about equal parts by weight of sodium silicate and water.

In preparing the waterglass for use, five or 10 times its bulk of clean boiling water should be added, to the concentrated solution, the amount varying with its strength. The preparation should be quite cold before it is used. Experiments have shown that a 3 per cent solution, i.e. 3 parts by measure of the concentrated solution to 97 parts of water, yields as good results as the one of 10 per cent that is often recommended. A 5 per cent solution can be used with safety.

When the waterglass is added to the water, the two must be very carefully and thoroughly mixed. The eggs may be dipped in the water-glass and dried off, leaving a film on the shells and then stored upon shelves, or they may be kept in the liquid until wanted. The latter method is preferable. When taken out of the solution they should be washed. *See Egg.*

WATER JUG. Water jugs were made in the 18th century, and some of these are beautiful specimens of cut glass. Others were of pottery or china, made in plain, fancy and sometimes grotesque shapes. Most of those in use to-day are based on 18th century patterns, or else are of coloured glass, modern in form, and sold to match sets of tumblers. *See Glass Ware.*

WATER LILY. The *nymphaea* or water lily makes a charming display in the summer months in a garden pool or even in tubs sunk in the ground. It must be planted in still water open to the sunshine: running water is too cold and it does not flourish in the shade. The larger kinds need 2 to 3 ft. depth of water but the smaller kinds flourish in a pool 18 in. deep, and the miniature water lilies are happy in 12 in. depth of water. The way to plant them is to place the roots in a basket filled with loamy (turfy) soil and manure, weight them with stones, and sink them to the bottom of the pool in April or May. The baskets will gradually decay. The smallest of all water lilies suitable for tubs or for a shallow pool are *pygmaea*, white; *pygmaea helvola*, yellow; *odorata alba*, white; and *Luciana*, rose.

One of the loveliest of the water lilies suitable for cultivation in a tank or large tub in a heated glasshouse is the blue *Nymphaea stellata*. If this water lily is started into growth under glass in a tub of water it may be placed out of doors for the summer months. *See Lily; Victoria Water Lily.*

Water Lily. Soft pink flower of the variety Colossea, which blooms throughout the summer. (Courtesy of Amateur Gardening)

WATER MELON. The water melon, which is one of the two chief varieties of melon, the other being known as the musk melon, is a popular dessert fruit and is also sometimes served as hors d'oeuvres. Several different kinds are grown, three of the best being known as the Spanish, apple-seeded, and the citron water melon. *See Cantaloup; Melon.*

Water on the Brain. *See Hydrocephalus.*

WATERPROOF. The name waterproof is given to mackintoshes and any other coats which have been so treated in manufacture as to be impervious to wet. Oilskins and cloth raincoats are in this category, and coats made of material that will not in itself withstand the rain are often lined with rubber. All such garments should have ventilation holes.

WATERPROOFING. Rubber is the most reliable substance for rendering fabrics impervious to water. There are other commercial processes which are used in the manufacture of rainproof cloths, and they depend mainly on the reaction between two or more substances which causes a substance insoluble in water to be deposited in the fibres of the material.

The process of treating calico and other thin materials with both raw and boiled linseed oil forms another method of waterproofing. It can be carried out by the amateur. The oil should be brushed very sparingly and dried in a current of air. If the material can be placed out of doors in a position free from dust, it will dry quicker, but the best method is to place it in a room near an open window, which should be covered with fine muslin. Three or four thin coats of oil will be necessary; raw linseed oil makes the material more flexible, but it takes much longer to dry. A little gold size is sometimes added to the oil, in the proportions of 1 oz. to 16 oz. of oil, to assist the drying. If it is desired to make the material black, the method is to thin some black paint with turps and apply it when the last coat of oil is dry.

Coarse canvas for use as awnings, covers, and tents can be waterproofed by applying a solution made by mixing 1 part of sulphate of zinc and parts of sulphate of iron with 18 parts of linseed oil and boiling it for two hours. When cool, add 15 parts of oil of turpentine and any colouring matter desired. The canvas should be left to dry for a week and a second application will complete the process.

Methods of rendering brick work and concrete resistant to damp and the action of driving rain or falling water are described in the article on Damp.

WATER RATE. This describes the charge made for the use of water by the municipalities and public companies that provide it. It is payable by all householders to whose premises the water is laid on, and is calculated at 5 or some other percentage on the rateable value, the amount being

fixed by Act of Parliament. It is usually payable every quarter, but in London every half year, and landlords who themselves pay the rates on the houses they let pay also the water rate.

Water companies make an extra charge to persons who require water for other than strictly household purposes, e.g. those who have a garden hose or a garage or stables. If the water rate is not paid when it becomes due, the supply may be cut off and the occupier of the premises summoned. *See Rates.*

WATT. In electricity a watt is the unit of electrical power. It is the power exerted by a current of one ampere flowing under a pressure of one volt. A horse power is 746 watts. *See Electric Light.*

WATTEAU STYLE. Paintings or decorative designs imitated from the work of Antoine Watteau, a French artist of the early 18th century, are said to be in the Watteau style.

Graceful fantasies of figures, in the court or pierrot costume of the period, set in a landscape of park or garden, the subjects are sentimental comedy or romance, the colouring is delicate, and the figures dainty, but at the same time realistic and beautifully drawn. Statues of nymphs, musical instruments, and garlands appear in many of the compositions.

The style is used in mural and ceiling decorations for rooms to be furnished in imitation of this period. The ornamentation is often arranged in medallions connected by garlands. Designs for tapestry to upholster the gilt furniture of his time, for paintings on screens, on cabinet panels, on china and on fans are also often in so-called Watteau style.

Watteau style in dress usually refers to the *sacque* or overdress in which he painted so many of his court ladies, and particularly to the pleated fold at the back of the neck which flutes out into the skirt and is known as the Watteau pleat. *See Fan.*

WATTLE. This word is employed in two main senses. It refers to various Australian species of the acacia. This wattle has become closely associated with that country, and one of the principal Australian holidays is called Wattle Day. The name is sometimes given to the twigs or rods of the willow. *See Mimosa.*

WAVELENGTH: In Wireless. The measurement of the wave produced in the ether by a wireless transmitting station. The ether is presumed to be a substance which permeates the whole of space soaking through the interstices of the atoms of all gases, liquids and solids, in the same way that water soaks through a sponge. Therefore, ether waves are independent of the atmosphere and can travel equally well through a vacuum. Their form is similar to that of sea waves in so far as they possess crests and troughs. The distance between the crests of two successive waves is the wavelength. The measurement is normally given in metres. The number of waves which are produced by a transmitting station in one second denotes the frequency of that transmission.

The velocity of an ether wave (its speed of travel) always remains constant at 300 million metres per second. Therefore, if this velocity is divided by the wavelength in metres of a transmission the result is the frequency of that transmission. The unit of frequency is the cycle. A kilocycle is one thousand cycles and a megacycle is one million cycles. Usually the transmissions of medium and long wave broadcasting stations are listed in wavelengths and the short-wave and ultra-short-wave stations in frequencies.

WAX FLOWER. This is the popular name of an evergreen plant of slender climbing growth, with wax-like flowers, suitable only for cultivation under glass. The commonest kind is *Hoya carnosa*, which needs a minimum temperature of about 55 degrees and bears white flowers tinged with pink.

It should be planted in a tub, well drained, and filled with a compost of loam, peat and sand. Propagation is by cuttings inserted in sandy soil beneath a propagating case in spring.

WEAK MIXTURE: In Motoring. This fault in carburation may be due to the jets being too small or the choke tube too large. At one time it was thought that a uniform mixture was necessary at all engine speeds; but it has now been ascertained that a somewhat richer mixture is best for running at high engine speeds with the throttle wide open. A weak mixture contains about 17 parts of air to 1 of fuel.

The following rough tests will assist in determining the condition of the mixture. First shut off the fuel supply to the carburetter float chamber, then open the throttle wide enough to cut out the slow-running jet. Fix the throttle so that the engine runs at a fair speed, but do not race it. If the engine speed increases as the fuel in the float chamber is consumed, the mixture is too rich. If speed is unaffected, turn on the fuel and flood the jet while the engine is running on the same throttle setting. If engine speed increases, the mixture is too weak. *See Carburetter; Motor Car; etc.*

WEANING. An infant at the breast should be weaned gradually when it is nine months old. A meal of cornflour, arrowroot, barley jelly or something similar, with cow's milk, is substituted for a breast feed, and in the course of a few weeks the child should have all its meals of the latter description. Should the time for weaning fall in hot weather, or when the child's health is disturbed by teething or some other cause, weaning should be postponed till the circumstances are more favourable. *See Baby.*

WEATHERBOARD. The particular class of timber known as weatherboard is used extensively in the construction of small buildings. It is commonly made with a feather edge and is wedge-shaped in section, being 1 in. thick on one side and $\frac{1}{4}$ in. on the other, averaging in width 5 to 6 in.

The boards are weather-tight in virtue of their characteristic overlap, the lower edge of one plank overlapping by about an inch the upper edge of the plank beneath it.

It would be undesirable to expose the end grain of the weatherboard to the full force of the weather, and for this reason vertical timbers, or cover strips, should be employed at all external angles. These strips are erected first, and the weatherboard fitted into the space between them when the timber is of sufficient length to reach from one side of the wall to the other side.

In addition to the ordinary form it is possible to get rebated weatherboard, the use of which permits of a flat surface on the inside. For good work T. and G. matched weatherboard should be used. *See Board; Draught; House.*

WEAVING IN THE HOME

With Descriptions of Various Kinds of Loom

This article deals with a domestic industry that is becoming increasingly popular. After a clear description of a typical loom and its mechanism the reader is told how to weave a piece of material suitable for covering chairs, settee, etc. The article loom may also be profitably consulted.

It is not necessary to provide a large loom in order to gain some practical experience of weaving in its simplest form; narrow materials, braids, trimming, and ties can be made on a board loom of quite simple construction. The material produced is weaving in its simplest form, depending on colour for its effect; but it thoroughly illustrates the essentials of the craft. The proportions of this simple appliance can be increased, but for anything but the simplest work the table loom shown in the same

page is recommended. It is not expensive to purchase, and can be obtained in widths from 18 in. to 33 in., made either as a simple loom, as illustrated, or with four heddles, manipulated by cords.

In a pedal loom the heddles are operated by the feet, and four or more can readily be manipulated, the hands being left free for passing the shuttle and beating the weft.

Greater speed is possible, and more intricate patterns can be undertaken.

In this page we illustrate a heavier loom of the conventional type, useful especially to the weaver who goes in thoroughly for the craft and can devote a room to the loom with its associated appliances. While the table loom will probably be preferred by the beginner on account of its compactness and ease of manipulation, there is a great deal to be said for the pedal loom, especially the simple type, for which we give working drawings and full constructional details.

In order to describe the basic principles of the craft, the setting up of a piece of weaving on the large loom will be described in detail. The first thing is to decide on both fibre and colour for the foundation, or what is called the warp of the weave, that is, the thread which forms the basis of the fabric, passing from roller to roller in the loom, as in Fig. 1.

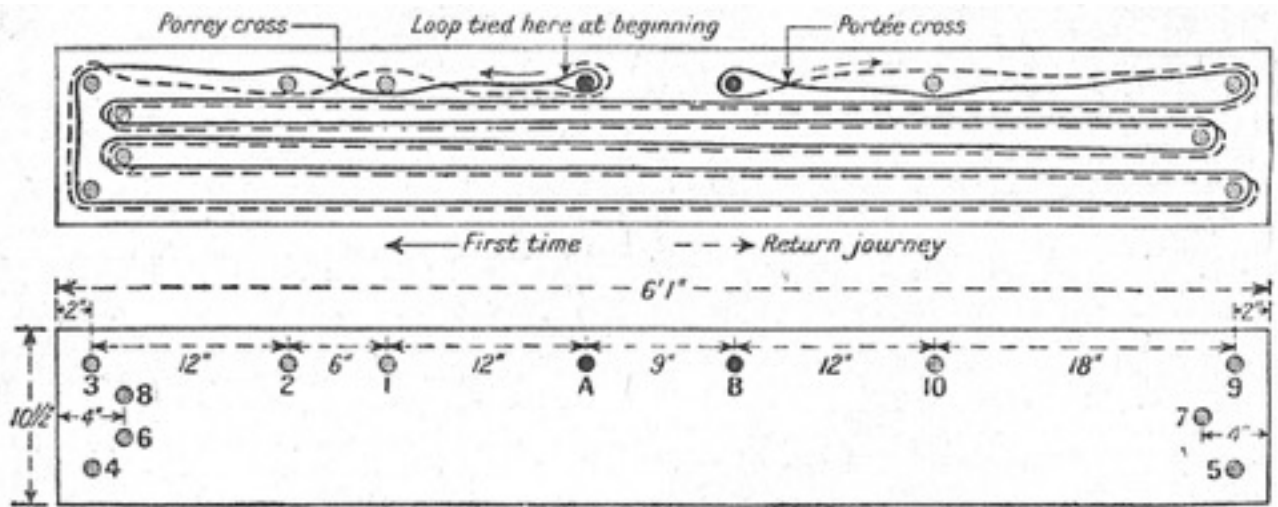

Weaving. Fig. 1. Hand loom. A, warp stretching from roller to roller. B, lease rods. C, porrey cross. D, heddles. E, reed. F, sleigh. G, breast roller. H, treadles. K, grooves in roller. L, pawl and ratchet wheel. M, groove in roller. N, friction brake. O, weight beam. P, beam warp or cane roller. Q, weaver's seat

Having selected the warp yarn, decide on the length of material to be made. In calculating the length, at least 18 in. or 2 ft. extra of warp thread must be allowed, as it is impossible to weave right up to the end of the threads. The desired width of the material must also be settled, and number of warp threads to the inch ascertained. A very good warp for a beginner is thick cotton. This can be used at twenty ends or threads to the inch, and is recommended because its strength and durability render it less liable to break.

Laying a Plain Warp. The chief thing to bear in mind in making a warp is that all the warp threads must be of equal length. A simple method of getting a series of cords the same length is by fixing in a board hung on the wall a number of wooden pegs, arranged more or less after the manner in Fig.

2. A dimensioned drawing of the warping board is given in Fig. 3. The pegs (A. B), shown in solid black, are loose and may be withdrawn from the board, the other pegs being firmly fixed. With the warp thread reeled or spooled, and resting on a thick 1 wire supported on a frame (Fig 7), so that the reel or spool will rotate, begin by looping the end of the warp to the peg of the warping board marked A.

Weaving. Figs. 2 (above) and 3. Showing a simple warping board, together with the necessary constructional dimensions. For further details see text

Proceed in the direction marked by the arrow to the left, under the first peg, over the second, over the corner pegs 3, 4 and 5; then round 6 and back to 7; thence to 8 and round 9: under 10. Next the thread goes over and round B, over 10, thence to 9, and so back to peg 3, passing over 8, 7, 6, 5 and 4 in turn. From 3 the thread is continued under 2, over 1, and under A. This must be repeated until the number of threads on the pegs A and B corresponds with those required for the width of the material. Each forward and each backward run of the thread equals one warp thread a complete course from A to B and back again to A equalling two warp threads. Both ends of the warp A to B must now be secured with cords, tightly fastened. Similar cords must be tied at the porrey cross, between 2 and 1, and the portée cross, between B and 10, but in these two instances the cords must be long, tied tightly at the ends, and looped near to the cross. These instructions apply to a plain warp. Instructions for laying a striped warp are given in a later section dealing with the weaving of an upholstery material.

Weaving. Fig. 4. Raddle and stand with warp ready for distributing in dents of raddle. Below, raddle shown with cap lifted.

The required number of threads having been made, take off warp at peg B and loop warp as if making a crochet chain (Fig. 9) until peg A is reached. Insert a smooth stick or iron rod $\frac{3}{8}$ in. or $\frac{1}{2}$ in. diameter through loop.

Beaming the Warp. The raddle is illustrated in Fig. 4, and is a simple framework of wood. The cap, or upper part of the frame, lifts off, displaying a series of strong wires fixed into the lower part of frame, in this case spaced five to the inch. It is between these wires or dents that the warp threads

are now to be distributed. The suggested warp had twenty threads to the inch, so in order to spread the threads evenly across the loom it will be necessary to put four warp ends together in a space or dent of the raddle. On some looms the raddle can be inserted temporarily in the frame of the batten in place of the reed.

Having spread the warp, return the cap to its place, seeing that all the wires are settled in the groove of the cap. Then make it secure by tying cords at either end of the raddle, so that there is no possibility of the cap becoming detached. All is now ready for the warp to be wound or turned or beamed to the warp roller at the back of the loom, as shown in Fig. 1, and it is important to spread the warp as evenly as possible on the warp or cane roller. This can be done by first lifting the iron rod over which the warp is spread and placing it in the groove of the back roller, where it is cured with cords. The triangle (Fig. 5) is heavily weighted and placed as far away as possible from the loom, keeping the point to the middle of the loom. Next proceed carefully to turn the warp on to the roller.

This is accomplished by means of the turning stick, which is passed through a hole in the end of the roller. Turn the roller until ail but a foot or two are on, or until the cross in the warp nearest A on the warping board has been nearly reached. Two round, smooth sticks about $\frac{1}{2}$ in. or $\frac{3}{8}$ in. in diameter will now be wanted. These are the lease rods, and take the place of the loop of cord between 1 and 2 in the warp called the porrey cross. They will require some support and can be looped up with two cords attached to back and front rollers of loom, as at Fig. 1, B. To prevent confusion, tie the warps in groups with a loop.

Making the Heddles. The heddles, which carry the warp, are composed of groups of leashes set on shafts or frames of wood. Each eye in the leash has a warp thread passed through it, and the action or treadling causes the warp threads to rise or fall, making a space between the warps which is technically known as the rising or lowering shed. These leashes can be purchased or may be made on a small board formed as shown in Fig. 8 It is made of a piece of $\frac{3}{4}$ in. board having four pieces of dowel stick fixed firmly in it, as shown in the illustration.

Cut a number of cords of the correct length. Measure one by hooking around first peg and taking the double cord down to the pointed end of heddle board, where it can be cut. This gives the length of cord required. Test one leash to make sure.

In order to make the process clear we may call the pegs A, B, C and D, commencing with the left-hand one. Begin with a piece of cord by looping it round A and tying off firmly at B, leaving both ends the same length. Then, without cutting, loop round C and tie again; finally tie around D and leave the ends uncut. Simple reef knots should be made, and below B and C the cord can be twisted. Fig. 4 shows very clearly how the loops are made. The loop around C is the "eye" of the leash.

Having made sufficient leashes, one for each warp thread, hang them on two thin laths of wood, suspended by cords, and the heddle is ready to hang in its place in the loom, as at Fig. 1, D. Two sets of these will be required, that is to say, if 100 ends of warp have been warped up, it will be necessary to have 50 leashes on each heddle. The heddle laths should be so arranged in the loom that the eye in the leash is on a level with the tops of the rollers.

Fig. 5. The triangle together with diagram showing measurements and method of construction

The next process consists in picking up the warp threads and entering each, that is, passing the end through an eye of the leash. The warp must take a straight course, and not get twisted round the eye or through the lower or upper loop of the leash. First a back leash is entered, then a front, and so on alternately across the loom, the work being done from left to right.

The batten or sleigh, Fig. 1, F, contains the comb or reed, E. This is made with steel wire, which furnishes spaces of various sizes according to the requirements of the particular work in hand. Some have ten spaces or dents to the inch, some twelve or twenty. For ordinary work a ten or twenty reed will be found very useful. We will assume that a twenty gauge reed is being employed in the work now being described. In arranging the work, as stated above, twenty warp ends were allowed to every inch, so that warp thread will be entered or passed through each dent or space in the reed; in the case of ten warp ends to the inch, every other dent would have been left empty; or in the case of forty warp ends to the inch, two threads would be entered together in each dent or space. Although a reed can be made with almost any number of dents, coarse or fine work can be done in a twenty reed. For very coarse work, such as thick canvas or rugs, ten or even five dents to the inch would be considerably more suitable.

To prevent confusion at this stage in gaiting or entering the loom, loop the warps into groups. Take two iron rods, $\frac{1}{2}$ in. in diameter, and two long pieces of strong cord. Loop the double ends of each cord round the ends of the first rod, and drop it into the groove in the cloth or front roller. Fig. 1, G, and Fig. 6, O; secure firmly with cords, and wind the ends of the cords round the roller until only 6 or 7 in. of the cord hang over. These ends are now to be secured to the ends of the second iron rod, which has been fastened in the same manner to beam warp or cane roller P, Fig. 1, and with two small weights attached to the ends, is supported by the reed immediately in front.

For the purpose of tying the ends of the warps firmly to the second iron rod several methods can be employed. Take a group of warp threads and pass them over the second iron rod; turn them under,

and in the process divide them so that as they come up on the other side of the iron rod half will be on the right of the original group of threads, and half on the left. Tie first a knot, then a double bow. The point to aim at is that the warp threads shall be securely held at about the same tension right across the loom. This completes what is called the tie-up of the warp threads.

It now remains to tie up the heddles and treadles, Fig. 6. In order to prevent the sagging of the warp, a friction brake is applied to the beam warp. This consists of a rope wound once or twice round it and tightened with weights, as shown at O, Fig. 1.

The shuttle. Fig. 10, is the wooden instrument or tool which carries the quill containing the weft to and fro across the loom. The correct way of threading the shuttle is shown in the illustration.

First Steps in Weaving. One method of making a pass is to depress the right treadle H, pressing the batten back with the left hand, while the right hand has the shuttle ready to throw across the loom through the shed caused by the lowering of the warp threads in the first heddle D. The shuttle having passed from the right hand to the left, the right is now free to press back the batten or sleigh. The left foot must now depress the other treadle, when all the warp threads attached to the second heddle will be lowered, leaving an opening or shed in the warp through which the shuttle is thrown to the right hand.

Beat up the weft with the batten by pulling it forward, and by repeating this sequence of operations the fabric will begin to appear, the kind of weaving produced being what is known as plain weaving or tabby.

A glance at Fig. 6 will show a plan and sectional elevation of the warp and draft or pattern on squared paper; also the tie-up of the threads, entering through heddles and reed, and a piece of the fabric woven. Many variations of form and colour are possible with this simple setting up of the loom. There is no limit to the variety of patterns known as weft stripes, formed by a certain number of passes to represent the width of the band.

Weaving a Chair Cover. Fig. 11 illustrates a portion of a piece of material woven on a table loom, for the purpose of covering chairs or a settee. Its application is wider, however, for it can be used for window curtains and other hangings. The warp is of linen in various colours so arranged as to produce a striped effect. The weft is of blue spun silk, a material which, on account of its relatively lighter weight, is less expensive to use than artificial silks. The piece is 12 yd. long and 33 in. wide. The following instructions apply specifically to a table loom of the type illustrated under the heading Looms.

The Warp. In the warp there are 24 strands to the inch, and since the width is 33 in., the latter number multiplied by 24 (=792), gives us the total number of warp threads needed. In laying the warp a spool-holder (Fig. 7) is used to hold bobbins or spools. Place 2 spools of brown cotton on spool-holder, knot ends of threads together, and place on peg A of warping board. Continue round peg 1 to 2 (forming crossing), thence to numbers 3, 4, 5, 6, 7, 8 and 9, finishing at 10 and B, taking threads round peg B and back the same way to peg 2, crossing threads reverse way to 1 round peg A.

Continue laying the threads as follows: 22 brown, making in all * 24, 8 fawn, 4 brown, 2 orange, 2 yellow, 4 green, 2 mauve, 2 blue, 2 mauve, 2 blue, 4 green, 2 orange, 12 fawn, 2 orange, 4 green, 2 blue, 2 mauve, 2 blue, 2 mauve, 4 green, 2 yellow, 2 orange, 4 brown, 8 fawn, 2 brown, 2 fawn, 2 brown, 2 fawn, 2 orange. [1 brown, 1 fawn; repeat four times.] 2 orange, 2 blue, 2 yellow, 2 fawn, 2 brown, 2 fawn, 2 brown**, *** [42 fawn, 2 brown, 2 fawn, 2 brown, 2 fawn, 1 brown, 1 fawn, 8 times; 2 fawn, 2 brown, 4 times; 42 threads fawn.] Repeat from *** (42 fawn, etc.) four times in all. This forms one complete unit of design. Next repeat pattern backwards starting from ** (2 brown, 2 fawn, etc.) until 24 brown are reached.

This finishes the laying of the warp. When only two threads are needed it is best to leave at peg B until required again, or if at peg B, leave at peg A. Do not take the same 2 threads back, as otherwise there would be 4 threads instead of 2. Knot threads same way to finish as detailed for the beginning. Tie each side of peg A, 1, 2 and B, making 8 ties in all.

Take off warp at peg B, and loop warp as if making a crochet chain until peg A is reached (see Fig. 9). Insert a smooth stick through loop and tie this on to front beam of table loom. Place crossing sticks through tie-ups of pegs 1 and 2, making sure warp is not twisted. Tie string across sticks to keep in place. Then cut through top ties made at peg A, and take out the crossing. It will be seen that two strands are under one crossing stick and two over, alternately all the way.

Threading the Warp. Tie a twelve gauge reed in position so that it will not move while threading, then turn handle at side, so that one line of heddles is up and one down; make sure that eye is seen

from back of loom. Pass reed hook through first eyelet and then through first dent of reed; take first pair of threads from crossing and, hooking one on reed hook, draw through to back of loom. Place hook in lower eyelet and through same dent, drawing thread through in a similar way. Continue thus until all the threads are entered, two in each dent, up to the entire width of the warp. It is best to thread an inch at a time and tie up separately, also to have instruction paper in front of the worker so as to check stripes in warp.

Fasten loom firmly on to a table, so that it can resist the pull of the warp in beaming on. Place triangle, heavily weighted, on the floor as far away as possible, keeping point of triangle to the middle of loom.

It is very important to see that eyelets are closed in one line before warping up. Do not take out crossing sticks. Undo chain as far as triangle. Next take first bunch of threads and pull up tight (leaving no loose ones), and tie on stick at back roller, half under and half over. The stick passes through a number of loops at back of loom. It is best to tie one inch at each end and one in the middle, and continue until all bunches are tied, at an even tension.

Take crossing sticks down through the warp to triangle, making sure that there are no loose threads or ends. The end of the warp chain is looped over the post of triangle and secured by the peg. This keeps the un beamed portion of the warp taut and even while winding on is in progress. Place a sheet of paper over the layer of threads on back roller and turn roller, so winding on the warp, until triangle is pulled up to loom. Now take triangle down again (away from loom) and proceed in a similar manner until warp is finished. It must be noted that each time the triangle is pulled up close to the loom by the winding on and consequent shortening of the chain of warp, a number of loops of warp chain are to be freed, and the chain secured again. When warp is finished, cut through ties B, take out crossing sticks, open harness and tie on to front stick in the same manner as at the back of loom, but putting the "unders" under the stick, and tie to tops. Continue until finished, when the loom is ready for weaving.

Weaving. Fig. 11. Hand woven material for chair cover (part width only shown). Border is repeated at right margin, with brown stripes on a fawn ground between.

The Weaving. Blue spun silk is used for the weft, but a linen could be utilized, and would make a stronger fabric. Place a spool in shuttle, clamp loom on a table about 25 in. high so that a comfortable sitting position is obtained. Turn the handle at side of loom, which will operate the heddle roller and cause one set of heddles to fall and one to rise, thus forming a "shed" or opening of the threads. Throw the shuttle through "shed" from right to left, catch the shuttle on the left side, bring batten forward as far as it will come. Hold the batten in the centre with the left hand, at the same time turning the handle in the opposite direction to that first used. Push batten back, throw shuttle through shed from left to right, catch the shuttle with the right hand, and pull the batten forward to beat as before. Now change the shed by turning the handle opposite way.

Continue weaving until there is insufficient opening to pass shuttle through, when the batten can be set further back by lifting up and moving over one or two notches, so that a good opening is obtained again. Continue weaving further until shed becomes too small for shuttle, when some of the woven material must be wound on to roller. Release the back roller, wind the material round the front roller, placing a sheet of paper between layers to keep the material clean and even. It is

important to leave sufficient of the material unwound for the batten to press up firmly when beating the weft between each pass. It is necessary to keep the edges of the warp thread and woven material even when winding up, and also to maintain an equal tension all through the piece. After winding on the woven material as described, lift the batten nearer to the front in the first notch and continue weaving again. This sequence of operations is carried out at intervals until the entire warp is finished.

The quantities of linen needed for the warp in the various colours are as follows: Brown, 8 oz.; fawn, 2 lb. 8 oz.; orange, 4 oz.; yellow, 2 oz.; green, 2 oz.; mauve, 2 oz.; blue, 2 oz. Blue spun silk is suggested for the weft and 1½ oz. per yard will be needed. The colour could be varied to give a banded effect, if desired. Linen might be used for the weft, instead of silk, if a stronger and more durable fabric is required. The piece of cloth from which our illustration was made was woven for the purpose by the Alston Weaving Studios, from whom suitable yarns may be obtained. The material would also make curtains, table runners, and cushions. By using three complete widths it might be employed for a bedspread; the widths could be joined either by a handwoven braid or trimming of narrow width, by a knitted insertion in silk to tone, or by faggoting (q.v.). Handwoven materials for upholstery and furnishing require little trimming as their decorative value lies in colour and texture. Heavy tassels, plain cords, narrow silk fringes, gimps and tinsel galons are suitable finishes for cushions, curtains and runners.

WEBBING: In Upholstery. In upholstery, webbing in the form of a wide tape is used for supporting the stuffing and springs of chairs. There are two kinds, the best being English, which is recognized by its black and white diagonal pattern. Its strength is known by numbers. Nos. 10, 12, and 14 being in general use. English web is put up in pieces of 18 yd. A cheaper quality is woven in stripes, and the sizes are known by the number of stripes of colour in the width. It is usually put up in pieces of 36 yd.

Although webbing is a closely woven material, it stretches in use, and when it is attached to a chair frame it is necessary to stretch it as much as possible. The upholsterer uses special pliers for this purpose, but it is generally possible to use a short length of wood as a lever.

WEDDING ARRANGEMENTS AND ETIQUETTE

How to Plan the Reception and the Refreshments

This contribution deals with the ceremonial and social observances for the occasion. References should be made to the article on Marriage. See also the entries on At Home; Banns; Best Man; Bouquet; Bride; Bridegroom; Bridesmaid; Cake; Ice; Luncheon; Sandwich; Supper.

Wedding invitations should be issued from three weeks to a fortnight before the wedding day. They are sent out in the names of the bride's parents or near relative, by either of whom a luncheon or reception is usually given after the ceremony. In the case of a young widow living with her parents, the invitations would be sent out in their names, but if she is living in her own home, in her own.

People invited to a wedding send wedding presents either to the bride or bridegroom. Sometimes this is done as soon as the engagement is announced, and in that case an invitation should be sent to anyone who has given a present, even if there is little chance that he or she will be able to attend the ceremony. Presents are always displayed at the reception, and a special afternoon tea is sometimes given, also for this purpose, previous to the wedding day. They should be attractively arranged, and a card bearing the name of the giver placed on or close to each present.

Wedding Expenses. The chief expenses of a wedding fall on the bride's parents, or relative who stands in their place. The cost of the trousseau, dinners, and at homes given to introduce the bridegroom to the bride's family, the reception, whether given at the house or at an hotel, are all defrayed by them. A choral service, the fees of the organist, choirmaster, and choir, also the printing of leaflets for the special hymns to be sung on the occasion, and the newspaper announcements of the wedding, all floral decorations, the hire of the awning and felt at the church doors, and wedding buttonholes are paid for by them.

The bridegroom provides the ring, and bouquets for bride and bridesmaids, and it is usual for him to make a present to each of the bridesmaids. He also provides the car to take himself and the bride from the church to the reception and away to the honeymoon destination or railway station for this afterwards. Should the bride's father have a car of his own, it is sometimes lent for the latter purpose. The bridegroom also pays the fees connected with the ceremony. It is also customary for him to provide the furniture and accessories for the new home, though these are often supplemented by the wedding presents.

The Ceremony. Afternoon weddings are usually at 2.30 o'clock. Quieter weddings take place in the mornings, the hours when marriages can be solemnised being from 8 a.m. to 3 p.m. The best man, usually a bachelor, should either accompany the bridegroom to the church or meet him there. They both await the bride at the right-hand side of the chancel gates. The best man stands on the right of the bridegroom during the wedding ceremony; he should sign the register in the vestry afterwards and pay the fees if the bridegroom does not do so on arrival.

The bride is driven to church with either her father or mother. Should the father be dead, the bride is given away by a near male relative, who meets her at the church door. Should there be sisters who are acting as bridesmaids, the mother often precedes the bride to church and with the bridesmaids awaits her inside the doors. When the bride and her father arrive she takes his right arm while walking up to the chancel. At choral weddings the clergy and choir head the bridal procession to the chancel, singing a hymn. The bridesmaids follow the bride, and her mother walks next with a near male relative.

The relatives in either family seat themselves in pews, the bridegroom's relatives on the right-hand side of the nave, the bride's on the left. The bride stands at the bridegroom's left hand, with the person who is to give her away on her left. The bridesmaids stand immediately behind the bride, and the chief bridesmaid holds her gloves, if she has these, and bouquet from the commencement of the service. After the service is over the bride takes the bridegroom's left arm, and, preceded by the officiating clergyman, and followed by the chief bridesmaid, best man, father, mother, and most distinguished guests present, they enter the vestry to sign the register. After this the bride takes the bridegroom's left arm and passes down the aisle, followed by the bridesmaids. The married couple should leave the church without shaking hands, etc., with friends, if a reception is to follow. The bride's mother should be the next to leave the church, in order that she may reach home to receive her guests.

In the case of a widow, it is optional whether she is given away or not. She does not have bridesmaids, but may have pages, should the wedding be a fashionable one. She may have a wedding cake, but it should not be decorated with orange blossoms.

Wedding Reception. Wedding luncheons are usually given at receptions only when the party is comparatively a small one, and the wedding has been held in the morning, or at country weddings. The menu is that of a seasonable luncheon. It is usual to begin the actual meal about half an hour after the guests have assembled at the bride's house or where-ever the reception is being held

Cocktails and appetizers are offered first and afterwards the luncheon is served. Wedding cake and champagne are included on the menu.

Plate for service, a wedding cake knife, and decorative accessories such as a bouquet holder, flower vases, and a wedding cake stand can be hired inexpensively from a firm of caterers. Floral decorations are of first importance, and should tone with the colour scheme of the bridesmaids' dresses, or may be of all white flowers. China, glass, and silver ware and also the embroidered or lace runner or lace trimmed cloth on the buffet or dining table should all be chosen with regard to the occasion. If white flowers are used, amber or green glasses will look well. A background of palms, ferns, flowering plants and arrangements of cut flowers to tone with the other floral decorations is usually made in one part of the reception-room where the bridal pair will stand to receive congratulations before luncheon is served in the dining room, or the cake is cut and light refreshments provided.

When only a reception is given at an afternoon wedding, such refreshments are much the same as those at an At Home or supper party, with the exception of the wedding cake and champagne. Orangeade or lemonade should be provided for guests who do not drink wine. Whatever the nature of the entertainment the bride should put the knife into the cake, of which a wedge should have been previously cut and tied with a bow of satin ribbon to simplify the operation. While more cake is cut, either the chief bridesmaid or the hostess slices the wedge and the cake is handed round with champagne in glasses, so that the guests may drink the bride's health.

On the buffet all kinds of sandwiches, lobster patties, fancy pastries, small cakes, fruit, tea and coffee should be set out. Trifles, sundaes, and other ice creams may be also provided. About 4 sandwiches, 1 pastry, and several small cakes can be allowed for each person, while 1 bottle of champagne is usual for 4 persons and 1 quart ice-cream will be sufficient for 12 persons. The buffet should be placed so that the maids who are helping to serve refreshments can pass easily behind it and also have access to the kitchen for supplies. Where there is a service hatch the buffet should be placed in front of this.

Wedding Cake. Bridal cakes are always rich both in their ingredients and decoration. Small silver bells and symbols of good luck are usually added, and occasionally a greeting is written across the top of the cake in icing of a contrasting shade. Many cake shops specialize in making them, but the following is a good recipe for a home-made wedding cake. Cream 1 lb. butter and $\frac{3}{4}$ lb. castor sugar till they are quite smooth; then add 6 eggs, one at a time, and beat thoroughly. Stir in 1 lb. flour, and gradually add 3 lb. currants, $1\frac{1}{4}$ lb. sultanas, $1\frac{1}{2}$ lb. finely cut mixed peel, $\frac{1}{4}$ lb. almonds blanchd and chopped, $\frac{1}{4}$ oz. mixed spice, a few drops of almond essence, $\frac{1}{2}$ gill rum, and 1 tablespoonful dark treacle. Beat well all the time to mix the ingredients thoroughly, and then put the mixture into a well-greased cake ring surrounded outside with several thicknesses of brown paper. The cake underneath must be well protected also. Use a very thick baking sheet covered with sand under the tin on which the cake stands. Bake the cake for five or six hours in graduated heat and keep it for a month at least before icing. See heading for Icing directions and also the entries on Almond Paste and Icing.

To provide a cake of more imposing appearance increase the ingredients in the same proportions to four times the quantities given. Provide two tins, one about 10 in. and the other 6 in. in diameter, prepare them as already directed, and fill them with cake mixture, 3 parts full. Bake the smaller tin for about 4 and the larger for 5 hours on the sand-covered sheet. When cooked allow the cakes to cool and wrap them in white paper for storage in a tin. Ice the cakes when required with almond paste and then with royal icing. Place the smaller cake on the larger before decorating with fancy icing by means of a forcing bag, or forcing pipe, and completing the whole with the silver

ornaments and satin ribbon. On the two ends of the bow the bride's initials can be worked on the left, the bridegroom's on the right, and a spray of white heather passed through the knot.

Wedding Ring. In Great Britain the wedding ring is worn on the third finger of the left hand. For legal purposes the bride has the ring put on her finger by the bridegroom during the ceremony. A widow remarrying usually removes her first wedding ring when she is about to go to the church or register office.

WEDGWOOD: The Chinaware. While old Wedgwood pottery, especially in its more characteristic forms, is not easy to procure, the Etruria factory, established in 1768-9 by Josiah Wedgwood, still produces as vigorously as ever, in some instances from the original moulds, wares which legitimately bear the Wedgwood name.

The term "old Wedgwood," may usually be taken to mean pieces produced before 1800. These productions are more perfect in finish than those made during the 19th century, or even to-day, though an excellent quality marks the present output of fine pieces.

The many wares which Josiah Wedgwood invented or improved include the fine cream-ware which achieved world-wide renown as Queen's ware, the famous jasper ware, black basalts or Egyptian black, several forms of variegated and pebble ware, besides fine red pottery and silver and gold lustre.

The dinner service made for Catherine II of Russia was in Queen's ware. Each of the 952 pieces was hand-painted with a different view of rural England. The black basalt ware, which was solidly black throughout and lent itself to fine incised or raised decoration owing to its beautiful texture, is another ware which has been extensively reproduced for flower bowls and vases.

The distinctive qualities of old Wedgwood are its perfect potting and its fastidious accuracy of detail, extending to the fitting of the lids and the shapes of the spouts. The applied decorations are always sharply defined, the edges being undercut and the whole polished on the wheel, resulting in an unmistakable velvety feel. Queen's ware and pearl ware set new standards of technical excellence which drove out of the market both saltglaze and delft. The early tea and coffee sets in these styles, as well as in basalts and other clay fabrics, are highly prized.

Wedgwood. Pieces from tea and dinner services of modern Queen's ware. (Courtesy of Josiah, Wedgwood & Sons, Ltd.)

Distinguishing Marks. During Josiah's lifetime the mark was impressed in the clay. At first the name Wedgwood appeared alone, but for twelve years after 1768 the partnership mark Wedgwood & Bentley was used on jasper and crystalline vases except blue jasper, and also upon blue plaques and medallions, on some of which portraits were carried out in

relief with exquisite precision of detail. Etruria was added for a brief period after 1840, England being added to meet American requirements in 1891. In 1879 a device of a vase was placed above the name. A three-character mark, used since 1846, was definitely established in 1907, when the figure 3 denoted the third alphabetical cycle, and J the letter for that year, preceded by the workman's initial.

The name Wedgwood & Co. denotes the productions of Ralph Wedgwood, a cousin of Josiah, produced 1796-1800. Wedgwood was used deceptively by Smith, of Stockton, for some years, until stopped by a perpetual injunction granted in 1848. Apart from unscrupulous imitations, several pupils and rivals of Wedgwood have produced under their own marks styles of ware created by him, which are also in demand by collectors.

Porcelain made for about ten years after 1805 is distinguished from that produced since 1878 by the plain name Wedgwood, stencilled usually in red over the glaze. In 1848 Etruria took up the manufacture of Parian ware; after 1850 jasper was made with the well-known lavender ground; in 1860 reproductions of Italian majolica were introduced, and some painted ware was done. *See* China; Jasper Ware; Lustre Ware; Pebble Ware; Pottery; Queen's Ware; Staffordshire Ware.

WEEDS: Their Treatment. Every gardener has to deal from time to time with weeds of various kinds. They may be annual, biennial, or perennial, and must therefore be combated by different methods according to their habit of growth.

Hand pulling, digging with fork or spade, and the total removal of the weeds are efficient methods of destruction. In every case the weeds collected should be burned. If these methods are too laborious, owing to the accumulation of weeds, spraying may be tried. Poppies, groundsel, dandelions, and certain other weeds can be more or less crippled and prevented from seeding by spraying them with 25 per cent solution of copper sulphate or a 15 per cent solution of sulphate of iron.

When hand weeding of lawns becomes essential it must be systematically carried out, and clearance should be made square yard by square yard, the labourer kneeling on a pad and spudding out every available weed. Where tap-rooted weeds, or others with large crowns, are rampant, a skewer dipped into a bottle of sulphuric acid will be found a simple eradicator; when using the acid a pair of leather gloves should be worn. To deal with weeds in beds and borders the hoe should be in constant use.

The weeding of paths should be taken in hand during early spring. Hand-picking for such purpose is an antiquated business, whilst the old remedy of applying salt or brine is only effectual up to a point, and sometimes actually encourages a fresh crop of weeds. Proprietary weed-killers, poisonous and non-poisonous, are far more effective, especially when applied on dry, windless, and sunless days. It must be understood, however, that such preparations can only be used for weeds on paths and walks; if the liquid falls on grass or plants these may be destroyed.

Implements Used. Common implements for weeding, usually contained in the average gardener's equipment, are the hand-fork, Dutch hoe, rake, and spud. There are other articles for special purposes, including the daisy rake and certain proprietary tools known as weed extractors. The latter have forks to insert under the crown of a weed, which, by pressure, lift the root stock bodily from the soil. Some instruments are designed for the use of liquid weed-killer. Lawn sand is a preparation made to keep down weeds on lawns. *See* Dandelion; Dibber; Groundsel; Hoe; Poppy; Spud.

WEeping ROSE. A rambler or climbing rose, when budded on a brier 5 ft. or more high, is called a weeping rose; such a specimen makes a handsome lawn tree. Weeping roses should be pruned as soon as the flowers have faded by cutting out parts of the old branches to make room for the new shoots. All brier shoots must be cut off; they may develop not only on the stem but among the branches. Each tree must be supported securely by a strong stake. Roses which make beautiful weeping standards are Alberic Barbier, Fraicheur, Lady Godiva, Hiawatha, Purity, and Dorothy Perkins. *See* Rose.

WEEVIL. This is the popular name given to a large number of beetles that have the anterior part of the head prolonged into a beak. They feed upon plants and are injurious to grain. Three types that should be noted by the gardener are the clay-coloured, the black, and the plum weevil; they appear in late spring and early summer, attacking leaves, shoots, and bark, and causing much damage.

The clay-coloured, or raspberry, weevil is the most harmful of the three and is also the smallest. In habit it is mainly nocturnal, crawling out from its hiding place at night to feed. It damages fruit blossoms and buds and the tender shoots of raspberries.

The black, or vine, weevil is more troublesome under glass than in the open. In the beetle stages, it is chiefly injurious to vine shoots and to the shoots and foliage of fruit trees or shrubs grown under glass. The larva is very injurious to plants in pots, notably to ferns, primulas, and cyclamens. It is not unusual to find six or eight grubs in one pot. The grub is injurious to many garden plants and also to strawberries. The red-legged, or the plum, weevil is a black, shining insect, $\frac{1}{2}$ in. long. It is very injurious to plums and also attacks peaches, nectarines, and apricots.

These weevils are extremely difficult to eradicate once they have become established, and it is therefore of great importance to prevent them from obtaining a foothold. The weevils cannot fly, and can therefore only reach fresh ground by crawling or being carried in soil when in the grub stage.

In greenhouses devoted to growing ferns or primulas, the first stock should be carefully watched, and if the plants do not thrive the roots of the least healthy should be searched for the white grubs. Potting soil should be examined, and if grub-infested soil has to be used it should first be sterilized by heat.

Young trees and grafted stock can be protected from the adult weevils by banding, since the weevils spend the day in the soil and only crawl up at night. Apart from this, the only treatment is to catch the weevils at night by shaking them on to tarred trays or boards. Vast numbers can be caught in this way, but care is necessary, as the insects fall off readily when alarmed. No insecticide has proved of any use against them. *See Apple Blossom; Gall Weevil; Grease; Plum.*

WEIGELA. The bush honeysuckle, called the weigela, is a beautiful, hardy leaf-losing shrub, 5 ft. or more high, which blooms in early summer and thrives in ordinary well-tilled land. The typical kind is rosea, with rose-coloured blooms. Improved varieties are Eva Rathké, crimson; Abel Carrière, rose crimson; Mont Blanc, white, and Van Houtten, rose and white. Propagation is by cuttings of young shoots under glass in May or by inserting woody cuttings out of doors in autumn and covering them with a handlight.

WEIGHT. The weight of an individual depends on the height, age, and sex. The ratio of weight to height varies considerably in healthy people. The average weight for a man and woman about 25 years of age, and of a height of 5 ft. and over, is as follows:

A few lb. must be added for every additional 10 years of age, more for a woman than for a man. If the weight of an individual is $1\frac{1}{2}$ or 2 st. below the average for his height, and more particularly if there is a progressive loss of weight, there is need for a thorough overhaul by a doctor.

HEIGHT		WEIGHT			
		Man		Woman

6	2	12	10		
6	3	13	1		

WEIGHTS AND MEASURES. In English law all weights and measures are based upon the pound and the yard, which are the only independent standards. The gallon, which is the standard of all measures of capacity, is based upon the pound. It is defined as the volume of ten standard pounds of distilled water weighed in air against brass weights, both water and air at the temperature of 62° F. with the barometer at 30 in.

Legal Points. Certain commodities have conditions about their sale. Coal must be sold by weight for domestic use. Where the quantity exceeds 2 cwt., the seller must deliver to the purchaser a weight ticket showing the net weight of the coal delivered before any part is unloaded. The sale of coal in quantities not exceeding 2 cwt. is governed in most towns by the by-laws.

In selling any article of food by weight, measure or number, it is an offence to deliver a less weight, measure or number than is purported to be sold. Tea, coffee beans, cocoa and potatoes must be sold by net weight. Certain other articles of food may be sold with the wrapper included, provided the weight of the wrapper does not exceed certain specified amounts. In the case of meat it is an offence to deliver to a purchaser any butcher's meat without a legible statement of weight upon which the purchase price is based, unless the delivery is made to the buyer on the premises of the seller immediately after the purchase has been made.

If the meat is boned or trimmed and such bones and trimmings are not delivered with the meat, the delivery note should then contain two statements of weight, (1) the weight on which the purchase price is based, i.e. before boning and trimming, (2) the net weight as sent out. All bread, excluding fancy bread, must be sold by net weight and must be made in weights of 1 lb. or an integral number of lbs.

No milk must be sold in bottles or containers except in quantities of $\frac{1}{2}$ pint or multiples of $\frac{1}{2}$ pint. This does not apply to dried or condensed milk. *See* Avoirdupois Weight; Bushel; Decimal System; Dry Measure; Gas; Liquid Measure; Measurement; Metre; Ruler; Therm; T Square, etc.

WELDING. A simplified process of welding or uniting ferrous metals consists in heating the parts to a white heat, placing them one upon the other, and hammering them into union. Autogenous welding has to a large extent taken the place of the older method, especially for small work. The apparatus consists of a blow pipe with oxygen and acetylene gas under high pressure. These gases are mixed within the blow pipe, and emerge at a high velocity from a small nozzle. Ordinary welding can be carried out by the amateur, but considerable practice is required. Success depends on the proper heating of the metal, the direction of the hammer blows, and often the use of a suitable flux placed between the joint faces in order to assist adhesion.

While the practice of welding is generally limited to the ferrous metals, it can be employed with modifications for some others. Autogenous welding is particularly applicable to articles made of cast iron, which, by their nature, cannot be united by hammering. *See* Brazing; Flux; Forge; Metal Work; Soldering.

WELL: For Water Supply. In country districts the water well is vitally important, and it is necessary to give much attention to the subject when considering the purchase or renting of a country property.

There are several methods of ascertaining whether water is present beneath the surface. One is to employ a water diviner, who, with the aid of a hazel twig, is able to locate running water with considerable accuracy. A more scientific method is to use a regular water-divining instrument or to call in a geological expert.

Although the diviner is able to say that water is present, it is impossible to know whether it will be fit to drink until it is actually reached. Consequently, before incurring the expense of making a well, the surroundings should be carefully studied. If stables or cowsheds are in the vicinity and on land slightly higher than the site of the well, there is risk that the water may be contaminated, and it is better to find another site.

When there is any choice in the matter, the most convenient site will be that which is highest in respect to the building to be supplied with water, and also nearest to it, if about the same level. In hilly districts there is often no need for pumping water, the spring being at a sufficient altitude above the house. Such ideal conditions, however, are seldom realized in the more level parts of the country, and some means of mechanically raising the water from the well is necessary.

The plan commonly adopted is to employ the local well-digger to dig the well and to brick it up on the inside. An alternative plan is to use well-boring tools, boring only a small hole, perhaps 4 to 6 in. in diameter, and sinking an iron pipe into the earth, but this is only practicable when the pipe would terminate in a stratum yielding a sufficiently voluminous supply, or when an artesian well can be made. *See Pump; Ram; Water.*

WELSH CAKE. This refers to a currant cake mixture made as stiff as short crust, rolled out into a sheet, and then cut into rounds with a cutter or the lid of a tin. These rounds are baked on a lightly greased girdle or bake-stone.

Take 1 lb. flour, a good teaspoonful of baking powder, a pinch of salt, 6 oz. lard or lard and butter mixed, 4 oz. castor sugar, 3 oz. currants and sufficient milk to mix all to a stiff dough. Sift the salt, baking powder, and flour together, rub in the fat, add the sugar and currants, and moisten with the milk.

Roll out about $\frac{1}{4}$ in. thick, cut into cakes, and bake on the bake-stone. Turn the cakes when browned one side and brown the other side. 1 or 2 eggs may be added if a superior cake is required, but less milk would be needed in that case. Sour milk or butter milk improves these cakes. They are generally eaten hot for tea. *See Girdle.*

WELSH CORGI. This dog is regarded as having two centres of origin, namely, Pembrokeshire and Cardiganshire. The distinctive feature of the two is whilst the former have long tails the latter have short ones. Moreover, the Pembrokeshire variety are either red or red and white, whereas the Cardiganshire dogs are any colour excepting white, and the latter are slightly heavier. The weight of the corgi is from 18 to 25 lb. The head is foxy and the

ears erect or semi-erect. The contour of body is also foxy, but the limbs are of sturdier build than that of the fox. The coat is smooth but harsh. Corgis make excellent workers for sheep and are good tempered and hardy.

Welsh Corgi, a breed of dog used by shepherds in the uplands of Wales (Pembroke type). (Photo, Thos. Fall)

WELSH DRESSER. This name is given to a piece of furniture that was made in Wales, the reason presumably being the abundance there of oak. This type of dresser is made of oak, frequently with a simple inlay of mahogany. It is polished dark, has plain rectangular mouldings, and also plain brass droppers for the drawers.

Pieces labelled by the name Welsh dresser are often spurious. A useful test is the condition of the brass. If the piece is a genuine antique, time will have browned the handles: consequently those that look new should be suspected. *See Dresser.*

WELSH OMELETTE. Wash three small leeks, taking care to free them from grit: trim off the root ends and most of the green portion, and then cook them in stock or water until they are tender. Drain them, cut them into thin slices, and mix with a little butter, and dust with pepper. Keep hot while making a plain omelette, and put leeks on one half and fold over. Sometimes a little grated cheese is added. *See Leek; Omelette.*

WELSH RAREBIT. A rich cheese such as Cheshire or Cheddar should be employed when making a rarebit. Gloucester cheese is sometimes substituted for Cheddar. Cut up 4 or 5 oz. cheese in thin slices and place them in a saucepan with 1 oz. butter, 1 small mustard-spoonful made mustard, 3 tablespoonfuls draught mild ale, and seasoning of cayenne pepper and salt.

Stir the cheese over gentle heat until it is melted and the whole has the appearance of a creamy mixture, then dish it immediately on hot buttered toast. The toast must be freshly made and the crust cut off, also it should be crisp and evenly browned, although not hard. Rarebit requires speedy preparation, and it must be served immediately it is cooked. Malt vinegar may be added instead of ale.

A second method consists of flaking into a small pan 5 oz. cheese, adding 1½ oz. butter, a good pinch pepper, salt, and a small quantity of dry mustard. Stir these together and melt them in the oven, then serve on toast. Sometimes 2 tablespoonfuls milk are added to these ingredients before putting them in the oven.

WELSH TERRIER. Probably similar in origin to the wire-haired fox terrier, the Welsh terrier has the same sporting instincts and the desire to exterminate all four-footed vermin. But, as in the case of the fox terriers, this does not unfit him for human companionship, and he will be found to be a good house dog, of affectionate disposition, and not apt to quarrel with his own kind.

In many respects similar to the wire-haired terrier, his head is rather wider and the muzzle more powerful. He has a very close and abundant coat of hard, wiry hair of black and tan or grizzle and tan, without any black pencilling on the toes. The height at the shoulders should be about 15 in., and weight about 20 lb.; less in each case for the bitch. *See Dog.*

Welsh Terrier, an alert and companionable dog.

WEST HIGHLAND TERRIER. This rather small but strongly built, hard-coated dog is often regarded as a white variety of the Scottish terrier, but it is a distinct and ancient breed, kept up for routing the fox, otter, and badger from their lairs in rocky ground. To indomitable courage are added great intelligence and devotion to his owner.

For the show bench he must be wholly white with the exception of his nose, his footpads and nails, which are black, yet he may be quite true to type even if he has a little red or yellow on his back or ears.

He stands from 8 in. to 12 in. at the shoulder, and weighs not more than 18 lb., the bitch 2 lb. less. There is a soft, close, furry undercoat, impervious to wet. *See* Aberdeen Terrier; Dog.

West Highland Terrier, a breed of small sporting dog which combines great courage with affection. (Photo, Thos. Fall)

WHAT-NOT. This term is used for a piece of furniture, something resembling a cabinet without doors, that was very frequently seen in English houses in the 19th century. It is made usually of slender pillars or uprights that support a number of shelves, suitable for displaying china. What-nots are made chiefly of walnut and mahogany, but the most decorative examples were of papier mâché japanned

black, painted in floral designs and often inlaid with mother-of-pearl.

WHEAT. Most of the flour which is used in cookery is produced from wheat, though cornflour, rice flour and maize flour are also employed. Flour varies in quantity, wheat that possesses a low percentage of gluten yielding soft flour, and that with a high proportion, a hard, strong flour that develops elasticity when mixed into dough. The colour of flour also depends upon the wheat from which it is obtained. White wheat produces a pure white flour and red wheat a flour that has a yellowish tinge. *See* Flour.

WHEATMEAL BISCUIT. To make these, sieve $\frac{1}{2}$ lb. wheatmeal and one teaspoonful ground ginger into a clean, dry basin, rub in a lump of butter about twice the size of a hen's egg, and then add two tablespoonfuls sugar. Stir in first a beaten egg and then enough milk to form the whole into a stiff paste; roll the mixture out on a floured board until it is about $\frac{1}{2}$ in. thick, and cut it into biscuits, baking these in a moderate oven until cooked through, and lightly browned.

WHEEL. In this Encyclopedia differing types of wheel are dealt with under such headings as Bicycle; Gear; Mangle; Perambulator; and Sewing Machine. Change wheels used on the screw cutting lathe are described in the articles Lathe and Metal Turning. For hints on repairing wheels of toys see the article Toys.

The road wheels of the motor vehicle are dealt with in the contribution immediately following, and other information will be found in the articles on Cotter; Motor Car; Motor Cycle; Sprocket; Tire.

WHEELS FOR MOTOR VEHICLES

Modern Tendencies in Design and Construction

Other articles in this work that are of interest to the motorist include Motor Car; Motor Cycle and Motoring. See also Brake; Gear; Tire; Transmission.

Considerable changes in wheel construction have occurred during the last decade as the result largely of the introduction of large-section low-pressure tires, the use of wired or straight-sided tires

instead of beaded tires, and the substitution of pneumatic tires for solid tires on commercial vehicles. Overall diameters of tires have not increased; the tendency is in fact in the reverse direction, and wheels have become smaller and lighter.

Motor-car wheels carrying pneumatic tires may be classified broadly as spoke, wire and disk. Further, the design depends upon whether the wheel is detachable as a whole or whether only the rim with the tire is detachable from the wheel. A complete fixed wheel with detachable rim is heavier than a detachable wheel carrying the same size of tire. Also in the event of accident such as a wheel striking the kerb, a fixed wheel, if broken, will disable the car completely, whereas a detachable wheel may bend or collapse without damaging the axle, so that it is only necessary to fit the spare wheel. The detachable wheel is generally used in Great Britain, while the detachable rim has been used largely in America, but has now yielded place to the detachable wire or disk wheel.

The steel spoke wheel after many years of popularity has to some extent yielded precedence to the wire wheel with a well-type rim on ordinary motor cars and on the lighter commercial vehicles, but special disk wheels with flat base rims are largely used on the heavier commercial vehicles. Such wheels have now replaced cast steel wheels with solid tires. In the ordinary motor-car industry changes in the popularity of different types of wheel are often due to fashion rather than to technical superiority.

Wooden wheels with detachable steel rims were largely used on American cars, these wheels being of the artillery type; that is, the inner ends of the spokes are clamped between two circular steel plates forming the boss or nave.

The circular rim or felloe (pronounced felly) is of wood, with a light metal rim which supports the steel rim carrying the tire. This type of wheel was long ago superseded in Great Britain by detachable steel wheels of similar appearance but of radically different construction.

In its latest form this type of wheel, now in use on nearly every modern car, is constructed from a single steel pressing. It has the advantages of great strength, ease of cleaning and simplicity in manufacture. Known as the spoked disk type, it is secured to the hub by a number of studs and is retained by the usual lock nuts.

Bolts and nuts are concealed with a large central shell which is enclosed by a plated cover, as shown in Fig. 1. The earlier type of steel wheel was constructed from two stampings welded together to form a hollow shell. It is retained to the hub by studs in the same way as the spoked disk type.

Wheel. Fig. 1. Spoked disk type, now used on most motor vehicles. Made from single steel pressing.

Wire wheels have for many years been used on cars, and give a very satisfactory combination of strength and lightness.

The well-known Rudge-Whitworth wheel, shown in Fig. 2, consists of a steel hub or shell serrated on its interior to engage similar serrations F on the rotating axle, the driving and braking efforts being transmitted through the serrations.

The inner end of the hub is enlarged to receive the inner wire spokes and is also coned to bear against a cone G on the axle. The coned surfaces are pressed into engagement by a lock nut H with two ears, which may be tightened up by a lead or raw hide hammer or a wooden mallet, but not by a metal hammer. The lock nut screws on to the axle and is formed with a double conical recess J

which engages the end of the hub and is thereby locked securely against rotation, no other locking arrangements being necessary.

A modified type of wire wheel which has recently attained considerable popularity is secured to the axle by a number of studs and nuts as in the Sankey wheel described above, but the nuts are located inside the hub and are concealed by a large plated cap. A Rudge-Whitworth construction is shown in Fig. 3. The large steel hub K, although very strong, is made of comparatively thin metal and is secured by wire spokes to the rim, many of these spokes being arranged tangentially to the hub so as to transmit the driving and braking forces. The inner face of the hub is secured by studs and nuts against the outside L of the brake drum, the nuts M being rotated by the usual wheel brace. The opening on the outside of the hub is large enough to give proper access to the nuts and is closed by a light sheet-metal plated cap N with a flanged edge entering the recess. Spring-pressed plungers O on flange retain the cap in position.

Detachable disk wheels consisting of a steel rim riveted to a slightly coned disk are much less used to-day than the other types on ordinary cars, but a similar appearance has been obtained by securing light conical disks on the outside and inside of wire wheels. Apart from the matter of appearance, these disks

Wheel, Fig. 2. Detachable wire wheel with central locking nut. Fig. 3. Detachable wire wheel with studs and securing nuts concealed within the hollow hub by a covering disk

reduce the labour of washing the many wire spokes and thus remove the most serious disadvantage from which wire wheels suffer in comparison with other types. Modern wire wheels are, however, constructed with a smaller number of thicker spokes more widely spaced, so that the cleaning difficulty is thereby reduced.

Fig. 4. Heavy disk wheel as used with giant pneumatic tire on commercial vehicles

Although not very popular on passenger cars and light vehicles, specially designed disk wheels are widely employed on the heavier commercial vehicles, a Sankey wheel being shown in Fig. 4. The rim of this wheel is of the flat-base type as distinct from the well-base type, but it carries similar wired or straight-sided tires of large size known commercially as giant pneumatics. A disk P is secured to the end of the axle by a number of studs and its outer edge is flanged and is riveted to a rim having an integral flange Q on one side. The other flange R by which the tire is retained in position, is formed by a detachable rim held in place by a spring ring S.

With all types of wheels care should be taken, when placing them in position, that the engaging surfaces are clean and free from mud or grit which might prevent them from being clamped up firmly.

WHEELBARROW. The wheelbarrow is extremely handy for conveying all sorts of garden material. As it is easily tipped either sideways or on end, its contents may be shot at any point desired without the necessity of handling them.

A hand barrow is also useful, but needs two persons to carry it. In its simplest form (Fig. 1) the hand barrow is a flat, shallow tray fixed to two lengths of wood which are formed with handles at each end, where they project beyond the tray. Four legs

enable the barrow to rest conveniently on the ground. The wooden barrow shown at Fig. 2 can be easily made. The wheel, generally a stumbling point with the novice, is not difficult to construct, and when hooped it is quite satisfactory. The strines, or handles, should be of ash or oak; the mortise holes are bored

out and then cut with the chisel to the sizes shown at Fig. 3. The sloats, or cross rails, made of oak, ash, or elm, are 3 in. wide in the centre, tapering to 2 $\frac{3}{4}$ in. at the ends. They thus form a wheelwright's self-wedging tenon.

Begin by making the barrow frame, as shown at Fig. 3; then fix the two legs F, by securing them with a long $\frac{3}{8}$ in. or $\frac{1}{2}$ in. bolt, which should run right through the frame and be secured with a washer and nut at the other side. This bolt and the hoop and axle will be all the metal work required from the local smithy, as all other portions are of timber.

Fix in the bottom of the barrow out of $\frac{5}{8}$ in. tongued and grooved boarding. This bottom portion is nailed on to the sloats; it hangs over the wheel about $\frac{1}{2}$ in. and over the handle sloat 1 in. Select suitable boarding for the barrow bottom before setting out for the mortise holes. The worker will then be able to arrange for the sloats to stand down below the top edge of the strines exactly the correct thickness of the bottom boarding.

The two brackets B are now fixed in position by skew-nailing them from the top, as shown in the detail drawing, and putting a good nail or screw from the under side of the strine.

The front piece H is planed slightly on the bevel at its bottom edge and nailed on to the brackets B. Next take the sides G, bevel the bottom edge so that it beds on the strine, whilst its side leans outwards and beds on the leg F. When the sides are fitted in a satisfactory manner, nail them to the leg F from the inside of the barrow, and nail their ends which engage with the front board H by nailing from the front of the barrow. Fit the piece J, and nail it to the ends H, after which fix the brackets C. The piece D, which steadies the legs, is now nailed in position.

To fit L, take a piece of wood, about 6 in. longer than you think will be required, and plane its edges so as to bed against the side G and the front board H. When neatly fitted to the required angle, sketch a line with your pencil to what appears to be the correct angle that will fit the strine. Saw the piece L to the sketched line, and, holding it to bed against the barrow side and the front, slide it down and see if it makes a good joint with the strine. It will probably be slightly out, but it will enable one to see the exact part that requires paring off with the chisel. Repeat this "cut-and-try" method until the desired joint is obtained, then cut off the surplus portion at the top of piece L, and nail L in position to the strine, front, and the side. Ease off the corners of H and G, as shown.

Fig. 1. Hand barrow consisting of a flat shallow tray with four handles and legs

Making the Wheel. The wood for the wheel should be of ash or oak. Plane up the two crosspieces and halve them, as shown at Fig. 4. Find the centre and mark out the diameter of the wheel; the circumference of the circle will coincide with the angle point on the cross rails. Set out the ends of the cross rails and cut the tenons with bevelled shoulders, as shown at Fig. 4. The bevelled shoulders make an angle of 45° with the edges of the cross rails. The next step is to slot mortise the rim rails A to fit the tenons, knock them up in their positions, and again mark out the complete

circle. Take the rails A off the cross rails and saw and spokeshave them to the required line. Fix the wheel together by smearing the joints with thick paint and put a fine nail in the joints, so as to hold all together until the blacksmith hoops the wheel. A square hole is cut through the centre of the wheel after it is hooped; the axle is driven into this mortise and the wheel secured by a washer and nut.

Fig. 2

Fig. 4

Wheelbarrow. Fig. 2. Useful garden barrow which can be made at home. Fig. 3. Plan of frame and dimensions of the detail parts which are necessary for constructing the wheelbarrow shown in Fig. 2. Fig. 4. Showing method of constructing the wheel.

The small axle brackets K are bored only half-way through their thickness, and this hole receives the axle. These brackets should be of hardwood, such as ash. The brackets B and K are held at the front with a $\frac{3}{8}$ in. bolt and nut, which goes through the strine.

The other end of bracket K is secured with two wrought-iron rails. Finish barrow with three coats of dark green paint.

The following particulars will assist the worker:

Wheel, all of ash, 2 in. thick,

or, say, $1\frac{7}{8}$ in. finish; legs, ash or oak, $2\frac{1}{4}$ in. square at bottom.

Brackets, B, C, and D, English elm, $1\frac{1}{2}$ in. thick.

Sides (G), front (H) and back (J) of elm or other wood, such as white deal, 1 in. thick.

Brackets (K), ash, $1\frac{3}{4}$ in. thick.

Strines, English ash, size as drawing.

Piece L, ash or red deal, $1\frac{3}{4}$ in. by $1\frac{3}{4}$ in.

Barrow bottom, elm, ash, oak, or deal, about $\frac{5}{8}$ in. or $\frac{3}{4}$ in. thick, made in one piece or tongue-and-groove jointed.

Many workers leave the sides, back and front boards roughly sawn with their ends square, until they are fitting their work. The overhanging portions of H and J are afterwards cut off to the required bevel, which will be proved by nailing on the sides. *See* Chisel; Joint; Mortise; Plane, etc.

WHELK. The small shellfish known as a whelk has a twisted shell of a conical shape. There are several varieties, the ribbon, the red, and the dog whelk, all equally indigestible. Nevertheless, the whelk is eaten in the same way as a winkle. *See* Shellfish.

WHETSTONE. Used for sharpening scythes, hooks, axes, and other cutting tools, whetstones are made from stone, emery and carborundum, and in shape are either round or flat, the former being smaller at the ends than in the centre. Generally a coarse stone is employed without a lubricant; those with a fine grain, especially if made of carborundum, should be used with a thin mineral oil.

To sharpen a tool, the side of the stone is placed flat on the blade and moved along with a spiral motion, keeping it flat against the blade and placing the correct amount of pressure on the down stroke; the up stroke should be as light as possible to prevent the formation of a wire edge. The whetstone should be kept quite dry when not in use. *See* Grindstone; Hone; Oilstone.

WHEY. The watery liquid that is known as whey, which remains in milk after the separation of the curd by coagulation, is composed of water and lactic acid with a small proportion of casein and butter and sometimes cream. It is used for making certain drinks, and is valuable also in inflammatory complaints. Rennet is used in producing whey, but there are several other methods which can be employed.

For whey with curds soak a small piece of rennet in $\frac{1}{2}$ teacupful warm water and let it stand 2 hours. Pour 1 dessertspoonful of this liquid into 2 pints boiling milk and keep it warm but not hot until the whey begins to separate and looks clear. This dish is the old-fashioned curds and whey and usually is eaten with cream and sugar. Prepared rennet may be used in place of soaking a piece of rennet from the calf.

To make lemon whey, pour as much of the strained juice of a lemon into $\frac{1}{2}$ pint boiling milk as will produce a curd. The whey is then strained off and sweetened. Whey is sometimes flavoured with mint or other aromatic herbs and taken as a summer drink. It is not lowering like some of the acid preparations. Pigs are fed occasionally on food mixed with whey and are then termed whey pigs. *See* Cheese; Junket; Rennet.

‘V’ AND ‘W’ RECIPES: A SELECTION SHOWN IN COLOUR

Walnut Meringue: Take 1 lb. breadcrumbs, 2 oz. sugar, 1pt. milk, 1oz. butter, 2 eggs and a little jam, 1 oz. chopped walnuts, 1 oz. whole walnuts. Mix together the breadcrumbs, sugar and chopped walnuts. Boil milk and butter together and pour them over. Add beaten yolks of eggs and mix all together. Put layer of jam at bottom of pie-dish and pour mixture over. Whip whites of eggs to stiff froth and spread over pudding. Bake in moderate oven and decorate with walnuts.

Vermicelli: Put $\frac{3}{4}$ lb. ground almonds in a basin and by degrees pour over them 1 pt. cold water. Turn all into a pan and bring slowly to boil. Strain almonds out of liquor. Boil 3 oz. vermicelli in this liquor (almond milk), add a pinch salt; beat up 3 eggs with 2 oz. sugar. Cool milk a little, add sugar and eggs, and mix in 1 gill whipped cream. Decorate a plain, buttered mould with crystallized fruits and steam pudding from 1 to $1\frac{1}{4}$ hr. Serve with almond sauce.

WHIELDON: The Ware. The Staffordshire earthenware produced at Fenton by Thomas Whieldon for about 40 years after 1740 is in demand by collectors. It is of interest in association with that of Spode, Wedgwood, and other 18th century potters.

Whieldon ware consists largely of the variegated or clouded pottery which preceded the great developments of creamware and jasper, especially imitations of agate and tortoiseshell, as well as those based upon the forms and colours of cauliflowers, maize, pineapples, and melons. Especially prized are handsome octagonal plates finely mottled, with purplish browns, yellows, and greens, and old Staffordshire pieces of this type, when not otherwise identified, are usually classed as Whieldon. His earliest pieces were agate knife-handles and snuff boxes, now rarely met with, except in spurious imitations. Other classes comprised tea, chocolate and coffee pots in a fine black ware which was the precursor of black basalt ware.

Although the greater part of Whieldon's output consisted of useful articles, he also turned out image toys and chimney ornaments after the style of the example illustrated. Whieldon's saltglaze pieces of this type are often called Astbury figures, the confusion being aided by the circumstance that neither potter made a systematic practice of marking his name. The two makes can be distinguished

by the fact that Whieldon did not use red or brown clays, and his bodies are usually harder than Astbury's.

Much so-called Whieldon ware probably includes pieces actually made by Wedgwood, Booth, Warburton, Ralph Wood, and others. He was especially fond of modelling animals, including elephants, squirrels, parakeets, and poultry; in addition, groups of musicians and mounted soldiers are found in his pieces. *See Pottery; Wedgwood.*

Whieldon Ware. Delightful piece consisting of two small seated figures against a background representing an arbour, c. 1755. (British Museum)

WHIPPET. Although this breed was brought into existence by the colliers in the N. of England especially for the purpose of coursing rabbits, the whippet, or snap dog, has always been accustomed to a domestic life, and is an affectionate companion. The coat may be of almost any colour—black, white, red, fawn, brindle, blue, or a mixture of any of them. In size he is variable, but should be about 17 lb. in weight, the bitch a pound or so less. *See Dog.*

Whippet. Champion of this sporting breed.

WHISKY. Whisky is a spirit distilled from grain. It is made from malt, malted barley, or from a mixed grist of barley malt and dried barley and oats or from a mixture of other malted and unmalted cereals.

Pure malt whisky is made almost exclusively in Scotland. Irish whisky is made of about $\frac{1}{3}$ malt to $\frac{2}{3}$ oats and maize; it needs longer keeping than Scotch whisky and should be at least 10 years old. Blending and diluting take place in the bonded warehouses. Whisky, like brandy, is naturally white, and takes its colour and, to a certain extent, its flavour, from the sherry casks in which it is matured.

It is also coloured by the addition of caramel (burnt sugar) or adding a matured wine. The older whiskies were darker in colour from being kept in golden sherry or Madeira casks, and rather heavier in texture. The newer whiskies are lighter and drier in taste.

Medicinal Value. Whisky has medicinal value principally for chills, fevers, colds, influenza, and malaria. As a beverage, diluted with plain water or with mineral water, it can be taken by gouty and rheumatic people when wine is not advisable. It is important to note that whisky should not be drunk with oysters or any kind of shellfish. *See* Alcohol; Brandy; Stimulant.

WHIST. The game of whist is played by four persons, two against two, although there are variants of the game suitable for two or three. Two packs of cards are desirable, one being used in dealing by each side. The players cut for partners, the two who cut lowest playing against the two highest, and the lowest of all deals first. In these cuts the ace counts as the lowest, not as the highest, card. If two players draw cards of equal value, not being the two highest or the two lowest, they must draw again.

The cards should then be shuffled, cut, and dealt, the shuffling being done by an opponent of the dealer and the cutting, by the opponent on his right. The deal begins with the player who cuts the lowest card, afterwards passing to the one on his left, and so on until the end of a rubber, when the procedure begins all over again. In case of a misdeal the cards must be shuffled and dealt again. The full pack is used, and all the cards are dealt out, 13 to each player.

The four cards that are played out in a single round form a trick, and this is taken for his side by the player who plays the highest of its four cards. Players must follow the suit led, whenever possible, and the highest card of that suit wins, provided it is not trumped. The trump suit is decided for each game by the last card dealt out, this indicating the trump suit. This should be laid upon the table, face upward, by the dealer and left there until the first round has been played, when he takes it up.

Scoring. A game consists of five points and a rubber of three games. A point is scored for every trick made in excess of six. Thus if two players win nine tricks they score three points. If the same players win the first two games it is unnecessary to play the third. Honours may be scored. They are ace, king, queen and knave, but not ten, as at bridge. If two players hold in one hand or in two the four honours they score four points; if they hold three they score two. Those players who, at the beginning of a deal, have a score of four cannot score honours.

The winners score two points, in addition to the value of their games, for winning the rubber. They also score a treble, or game of three points, when their opponents have made no score; a double, or game of two points, when their opponents have scored one or two; and a single, or game of one point when their opponents have scored three or four. If the rubber has gone to the full three games, the final score is made by deducting the value of the game won by the losers from the gross number of points made by the winners.

For revoking, or playing a card of a different suit when holding one or more of the suit led, the penalties are: The opponents, at the end of the hand, may either take three tricks from the revoking player and add them to their own tricks, or deduct three points from the opponents' score, or add three to their own score. This penalty can be claimed for as many revokes as occur during the hand, and a different one may be exacted for each revoke. The penalty, however, cannot be divided.

Cards must be placed on the table, or exposed, under the following conditions: If two or more have been played face upward at one time; if a card has been dropped, face upward, in any way on the table, even though it has been picked up again so quickly that no one has really seen it; and any card that the player holding it has named. The exposed cards must be left on the table and can be called, or played, by the opponents at any time. If two or more cards are played at once, the opponents have

the right to call the remainder. It should be noted that a card does not become an exposed card if it is dropped on the floor or elsewhere beneath the table.

Whist Drive. Although bridge has supplanted whist as the popular card game, a whist party or drive on the progressive principle is sometimes held in connexion with clubs of all kinds, and sometimes as a means of raising money for charitable purposes. In the latter case persons buy tickets in order to attend. At all kinds of whist drives it is usual to give prizes to those who score the greatest number of points. There may be one, two, or more prizes for men, and the same for women.

The hostess should first decide how many persons she can accommodate or proposes to ask, and should then send out the invitations. The number invited must be a multiple of four, and if any persons refuse their places must be filled, unless the refusals happen to number exactly four or eight. Women and men should if possible be equal in number. Sometimes the hostess does not include herself in the number of players, and so is able to fill a vacancy if one arises at the last minute.

On entering, each guest is given a card, on which the scores will be entered. This bears also a number indicating the table at which the player will play first. The four players at each table cut for partners. One game only is played before the players move on. Each player puts down on his or her card the number of tricks scored, and has it initialled by his or her partner.

The usual plan is for the winning lady to go forward, that is, to go from table 4 to table 5, for example, and the winning man to go backward, i.e. from table 3 to table 2. Other arrangements, however, are sometimes made, this matter being decided by the hostess beforehand. Half-way through the programme refreshments should be served. Thus, if an evening's play consists of 24 games, refreshments will be taken after the completion of the twelfth. At the end of the play each player adds up his or her score, and the host or someone else asks for high figures, say, in excess of 100. Eventually he gets to know the highest scores, and, having examined the cards, announces the winners. The prizes, provided by the hostess, are then given away. At some whist drives a booby prize is given for the lowest score, for instance, a wooden spoon.

In order to break the monotony of the scoring, various devices are introduced into the programme, and these are usually indicated on the scoring cards; if not, they can be announced by the host. For instance, in one round, instead of trumps being decided by a turned-up card, they are fixed at a certain suit all over the room, e.g. clubs. Again, the winners in one round are allowed to score double, or for a change each pair is credited with the score of the opponents, thus making the particular game one in which each aims at making as few tricks as possible. *See Bridge Party; Evening Party; Progressive Party.*

WHITEBAIT. When in good condition, whitebait, which are the fry of sprats and herring, have a silvery sheen. They must be eaten soon after they are caught. They should be kept on ice until time for cooking. White-bait are in season from March till September.

The fish must be handled as little as possible and the fat used must be at the exact heat necessary to crisp them. Drain the whitebait in a clean cloth and see that all the water is absorbed, then turn them on to a floured sieve, dredge them with flour, and shake them gently.

Have the fat heating ready for the white-bait, and when it reaches 400° turn the prepared fish into a frying basket and plunge them into the boiling fat. Fry for 2 or 3 min., turn the fish on to a sieve to drain and serve very hot. They should be dished on a folded fish napkin and sprinkled well with salt. Cut brown bread and butter, quarters of lemon, and cayenne pepper should be handed round.

To devil whitebait prepare as above, then season with cayenne pepper, raise the temperature of the fat rather higher than it was for the first time of frying, and plunge the fish into the fat, and after 1 min. drain, season, and serve very hot. *See Fish.*

WHITE CURRANT. The white or pale yellow currant is less commonly planted than the red varieties of this popular bush fruit. It needs exactly the same treatment as the red currant. Some of the best varieties are White Dutch, White Transparent, and White Versailles. *See Red Currant.*

White Currant. Ripe fruit of the variety known as White Dutch.

White Lead. *See Paint.*

WHITE MICE. The albino and the black-eyed white mice thrive in captivity if kept in a clean, dry cage and fed once or twice daily.

Apart from a little vegetable food and bread soaked in milk, the stock food is composed of equal quantities of canary seed, millet seed, and oats, the daily allowance being a small teaspoonful per head. The cage must be cleaned very thoroughly three times a week and food pans must be kept scrupulously clean.

Mice should always be kept in couples, as they do not thrive singly. If several are kept in one cage, care should be taken that there is only one male. If a litter is expected, a small supply of clean hay should be provided and the doe removed to a separate cage. Mice should be lifted up by grasping the tail firmly about half-way up. The best covering for the floor of the cages is dry sawdust mixed with a little sanitas powder.

WHITENING. The name of whitening or whiting is usually given to the well-washed residue of chalk. It should form, when crushed, a fine powder and when placed in water should separate into fine particles at the bottom of the vessel and is not soluble. It is used for many purposes in the workshop and the home. In making whitewash it is mixed with size; it is used for polishing and it forms the basis of several kinds of wood-filler.

White Sauce. *See Sauce.*

WHITEWASH. Whitewash is usually a mixture of slaked lime and water. Whitening is also used. The ingredients that are required for internal work are the whitening, some size, and a little ivory black or blue to keep the colour white.

To prepare the whitewash, break up a quantity of the whitening, say, about 6 lb., in the pail, which should contain sufficient water to cover it. Allow the whitening to become thoroughly soaked or dissolved, and pour off any surplus water. Having stirred it, add a quart of hot double size, previously prepared. The mixture is then given a thorough stirring, and set aside to cool, when it will form a jelly-like compound. Blue or other material should be added at the same time as the size.

When required for use, the mixture is diluted with cold water and applied immediately. For exterior work ordinary lime may be used as paste, and sufficient of this used with water to form a thick liquid. The paste is best kept in a box or pail sunk in a hole in the ground and covered with water to keep it from drying. When required for use, the water is poured off and the lime, a smooth, white mixture, is employed.

Whitewash or limewash made in this way can be applied directly to the exterior surface of brickwork with a large, old whitewash or distemper brush, one good coat being usually sufficient. It should not be applied too thickly or it will be liable to flake off, nor should the mixture be too weak or it will not dry with a clear surface. If the brickwork has not previously been whitewashed, it

should be brushed down with a stiff bristled brush. If the surface has already been whitewashed, it is desirable to wash it down with copious supplies of water and brush it thoroughly.

Ceilings. To whitewash a ceiling more preliminary preparation is necessary, either covering the floor with old newspaper or dust sheets, or entirely removing the floor covering. All small furniture should be placed in another room, the larger pieces being assembled in the centre of the room or in any other convenient position and covered with dust sheets. To keep the whitewash from spattering over the floor and the walls, it is a good plan to fix a dust sheet or other covering over the walls, or at least those portions where whitewashing is in progress.

The whitewash is then prepared as already described. Another pail or bucket filled with clear water will be needed for the preliminary washing down, which simply consists of brushing the ceiling vigorously with a disused whitewash brush. This removes the bulk of the previous coat of whitewash. The ceiling is allowed to dry, and if very good results are required it may be covered with clearcole, a thin liquid obtained by dissolving some size and a small quantity of alum in hot water and adding a little whiting. When brushed over the ceiling, this stops the suction and makes the whitewash take better, but it is often omitted on ceilings in good condition.

As soon as the clearcole or the washing off is dry, any cracks are made good with Keen's cement or a plaster, and the whitewashing proper is commenced. It ought to be continued uninterruptedly until the whole of the ceiling is finished. The work should commence at one corner of the room and may include the cornice and frieze, if desired. The whitewash can probably be applied by the amateur to the cornice and mouldings with a small brush, but the bulk of the ceiling is best dealt with by the large distemper brush.

There is a knack in applying whitewash which it is not easy to describe. The essential thing is to charge the brush with sufficient colour to enable the largest area to be covered without refilling the brush. To do this the brush must be immersed fully in the whitewash; any surplus is wiped off by stroking the brush on the edge of the pail, any surplus at the tip being similarly wiped off on the edge of the pail or on a bar placed across it. Under these conditions, the brush will be found to hold a considerable quantity of whitewash, which may be applied to the ceiling with a kind of slapping and stroking motion. In a sense, the whitewash is flicked on the ceiling on the first part of the stroke, and the other part of the stroke is a smoothing operation.

Whitewash is practically transparent while it is wet. The quantity that is applied can be judged by the feel of the brush while it is being wiped over the surface of the ceiling. At the first application of the brush the feeling is that there is too much of the fluid, whereas towards the end of the stroke there is a drag. The correct quantity is that which is applied when the brush is about half full. The manner in which the brush works then should be taken as the standard to be adhered to throughout.

WHITEWOOD. The timber that is known as whitewood is really spruce. It is less strong and durable, and therefore less suited for outdoor work, than is red timber, but has a number of indoor uses. When employed for joinery purposes it requires keen tools for its proper manipulation, but when it is finished it presents a fine lustrous surface with a creamy colour. It thus forms an excellent material for table tops, dressers, cupboards and other fitments of a house; also for floor boards, as it will keep its clean appearance. The name whitewood is also given to bass (q.v.).

WHITING: How to Cook. Small haddocks are sometimes substituted for this fish, but they do not possess its delicate flavour. When unskinned, the haddock may be easily distinguished by its dark markings and the barbule on the chin. The whiting when skinned looks compact, and the head is small. Rock whiting is the best kind.

For frying, the whiting should be skinned after being gutted; the head should be turned round and the tail thrust through the eyes so that a circle is formed. When trussed, dip each fish into seasoned flour. Then brush with beaten egg and cover with breadcrumbs.

It is better to use a frying basket when cooking whiting, as the shape will be preserved intact. Fry the fish, according to size, from 5 to 7 min., then drain and dish it on a folded fish napkin or paper. If three or four whiting are to be served, stand them up on the dish with the tails and heads uppermost, and garnish with pieces of lemon and fried parsley. Serve with shrimp or anchovy sauce. To bake whiting, prepare three fish, skin and fillet them, making two fillets out of each whiting. Dry the pieces well, and arrange them in a well-buttered baking or gratin dish. Season them with salt and cayenne, and add a little ground mace. Work together $\frac{1}{2}$ oz. butter with the same quantity of flour into a paste and distribute this over the fish. Then pour on to them $\frac{1}{2}$ a wineglassful port, the juice of $\frac{1}{2}$ a lemon, and $\frac{1}{2}$ a teaspoonful chilli vinegar. Cover them entirely with a thick buttered paper and bake them in a moderate oven for 15 min. When cooked, remove the paper and serve in the gratin dish. While the fish is baking, baste it once or twice.

Whiting can be fried, dipped in batter instead of egg and crumbs. Fillet three fish and place the pieces in a deep dish with three shallots peeled and chopped, a bouquet garni, seasoning, $\frac{1}{2}$ gill vinegar, and rather more of salad oil. Steep the fish in this mixture for 3 hours, turning it two or three times. Then drain the fillets, dip each in a fritter batter, and fry till a good golden brown colour. Garnish the dish with fried parsley and serve with parsley and butter sauce.

WHITLOW. The term whitlow is applied to inflammation of the fingers or toes, caused by the entrance of septic microbes. These may make their way into the tissues through scratches or punctures.

The septic poisoning may extend from the finger up the hand and forearm, along the lymphatic vessels to the lymphatic glands in the armpit. The infection may now extend into the blood vessels, giving rise to blood poisoning. In other cases there is a formation of pus or matter in the fingers. It should be let out at once, otherwise serious danger threatens the usefulness of the hand.

Rest in bed, with a splint on the front of the forearm and reaching from the elbow to beyond the tips of the fingers, and poulticing, help to make the patient more comfortable.

WHITLOW GRASS. This is the name of a group of small early-flowering evergreen rock garden plants. They must be planted in gritty well-drained soil and a sunny place. The botanical name is *draba*. *Draba aizoides*, 3 in., which bears yellow flowers in April, is a favourite kind; others are *bruniaefolia*, 3 in., yellow; and *pyrenaica*, 3 in., lilac-rose: the last-named is usually grown in a mixture of stone chips and soil. These plants are best propagated by seeds sown in spring; they should be protected by raised pieces of glass in winter to throw off excessive rain.

WHOLEMEAL. Wholemeal differs from ordinary flour in that it retains the bran removed from flour in the course of milling. It is consequently darker and does not keep so well, but, on the other hand, it is more nourishing because the bran contains a large proportion of cellulose and salts.

Wholemeal bread is an ideal food for growing children, because it supplies them with certain indispensable organic phosphates. *See* Bread; Diet; Flour; Wheatmeal Biscuit.

WHOOPIING COUGH. Pertussis, or whooping cough, is an acute infectious disease, in which there is catarrh of the respiratory tract and a characteristic cough. This comes on in spasms of 10 to 20 short coughs, succeeded by a long, deep breath which is accompanied by a whooping sound, caused by spasm of the vocal cords.

It is a dangerous disease when it occurs in infancy, or in older children who are debilitated from any cause. The disease is infectious from the beginning of signs of irritation of the bronchial tubes. The incubation period lasts usually about 10 days, and then the child may appear simply to have a bad cold.

The cough may assume its spasmodic form in from a few days to three weeks from the onset. During the cough the child's face may become blue and the eyes may bulge and become bloodshot. The cough may bring up some thick mucus and often causes vomiting. If vomiting is very frequent, the child's nutrition will suffer. Someone should always be at hand to help the child during a paroxysm and to reassure it.

It often happens that a child suffering from measles develops whooping cough, and the converse is also true. The most serious complication is broncho-pneumonia.

Immediately a child who has not already suffered from whooping cough shows signs of catarrh of the nose and bronchial tubes, during an epidemic of the disease, it should be isolated. If confined in bed it is of the greatest importance that the sick room should be kept ventilated day and night. The doctor will advise upon the use of drugs and fumigations.

The patient should be fed with easily digested food, and if there is much tendency to vomit should have frequent meals of milk. When convalescing, malt and cod-liver oil will be beneficial, and a tonic may also be given. Children who have suffered from whooping cough are not supposed to go back to school till the end of five weeks at least, and only then if the characteristic cough has been gone for two weeks. *See Cough.*

WHORTLEBERRY. This belongs to a group of dwarf shrubs, known botanically as *vaccinium*. Known also as bilberry and blaeberry, it bears blue berries valued for cooking purposes. The cowberry (*Vaccinium vitis-idaea*), with red berries, is another British shrub. One of the best of the exotic kinds is the American blueberry (*Vaccinium corym-bosum*), which grows 2 ft. high and bears pale rose-coloured blooms in early summer. All need moist, peaty soil and slight shade, and can be propagated by cuttings or seeds.

WICKERWORK. This is another name for basketwork made with osiers, and is applied to baskets, stands, tables and chairs. Wickerwork repairs are often not worth troubling about, owing to the limitations of the material. After being in use for some time, the osiers become very dry and brittle, and if replaced with new material there is always a risk that the new stuff will prove too strong for the old portions left in. This is particularly noticeable when new lengths are woven between the old stakes.

If wicker chairs are damaged, the better plan is to effect repairs with a suitable thickness of pith cane rather than with osier rods. The material can be rendered quite pliable by soaking it in water just before use, and it will dry out without straining the existing portions.

White wickerwork should be washed with a strong cold solution of salt and water, then wiped as dry as possible and left in the sun to bleach. Hot water, which destroys the natural polish of the wood, should not be used; neither should soap nor soda, both of which have a detrimental effect. Brown wicker furniture is best cleaned by rubbing it with a rag dipped in paraffin. *See Basket; Cane; Osier.*

WIDGEON. The season for the widgeon is from early autumn till March. The birds should be selected by pressing the pinions; if these are pliable the flesh is tender. To prepare them for table, pluck, draw, and truss as for ducks, but do not stuff them.

To roast widgeon, brush the bird well over with butter and roast it in front of the fire, if possible basting frequently. A Dutch oven (q.v.) may be used with advantage. From 15 to 25 min. is considered sufficient to cook widgeon, as they are supposed to be of superior flavour if underdone. When ready, score the breast lightly and sprinkle over it lemon-juice and seasoning. Serve very hot with a made gravy, and garnish with watercress. The gravy should be rich, and flavoured with port wine and red currant jelly. When carving, remove the whole of each side of the breast in the slice. *See Game.*

WIFE: Legal Position. As against her husband, a wife has a right to be maintained according to the husband's rank and means, and for this purpose, unless the husband is making her an adequate allowance, she may pledge his credit for necessities. The word necessities in this connexion is interpreted very widely.

What is necessary for one wife would be a mere luxury for another. For instance, the wife of an earl would be entitled to order evening dresses at an expensive dressmaker's; but not so the wife of a small tradesman or agricultural labourer. If a husband and wife are living apart, the wife, unless she has an adequate allowance, can support herself in this way so long as she can find tradespeople who will supply her with goods on her husband's credit. She forfeits this right, however, if she commits misconduct.

With regard to the guardianship and custody of children, when a husband and wife are living together the husband is the guardian, and if they separate he has a prima facie right to the custody of the infants; but this right is more nominal than real, because on the application of the wife the court will, unless she is an unfit person, invariably order that she have the custody of very young children and all girls of any age. At the same time the husband remains, in law, the guardian of the children.

A wife cannot compel her husband, whether living with her or not, to grant her an allowance. Where a husband dies on or after July 13, 1939, his wife may apply to the court for an allowance from his property if he has not made proper provision for her. A husband has a like right. If he dies intestate, whether there are children or not, she has the right to take all the personal chattels, i.e. the household furniture and effects, including such things as motor cars which are not used for business, and the sum of £1,000 free of all death duties and costs. If there is no issue, she also takes a life interest in the rest of his estate; and if there is issue, then a life interest in half of the estate. A husband possesses a similar right in the property of his deceased wife. *See Child; Divorce; Guardian; Husband; Marriage.*

WILD DUCK. Probably the best way to choose a wild duck is to examine the feet and press the pinions. The feet should be supple and the legs limber, and the pinions when pressed should not be rigid. These birds are in season from August to February. The only objection is a slight fishy taste, which is easily removed if the bird is put into the oven in a tin of salted water and cooked for 10 min. The tin should be covered. After this the duck is trussed and roasted in the same manner as tame duck. *See Duck.*

WILD GARDEN. Many gardens of fair size have a portion where aspect, soil, and other conditions are not favourable for the choicer plants. Such positions will accommodate a host of shrubs and plants of somewhat grosser habit at small cost and with comparatively little labour. However rough the spot may be, there is opportunity for planting bulbs, perennials, and shrubs, and, as bold grouping is of the essence of this form of natural gardening, it follows that the greater the space that is available the more effective will be the result.

Spring-flowering bulbs may be naturalized among the trees and shrubs, and some of the lilies are suitable for planting in partially-shaded places, where also the Japanese primrose and the common primrose still flourish. Some of the shrub roses are splendid plants for the wild garden, especially the musk roses named Felicia, Penelope, Prosperity and Pax; *Rosa Moyesii*, which bears rose-red single flowers and large red hips, and the Japanese briar (*Rosa rugosa*), valued both for its flowers and fruits. Other shrubs suitable for planting in the wild garden are *Berberis Darwinii*, *Berberis stenophylla*, mock orange, Spanish broom (*Genista hispanica*), the common broom (*Spartium junceum*), double gorse, the common *Rhododendron ponticum*, heather, Mahonia (*Berberis aquifolium*) and the pheasant berry (*Leycesteria*). *See* Rock Garden; Water Garden, etc.

WILL: How to Make. A will is a declaration of the person making it with regard to matters which he wishes to take effect upon, or immediately after, his death. It need not necessarily be a disposition of property, be cause a man may make a will merely to appoint guardians of his children, or to appoint an executor. But as a rule a will is a document by which the person making it, who is called the testator, disposes of his property after his death.

In England anybody of the age of 21 years and upward may make a will, and by it he may dispose of any property he has, or to which he is entitled, or over which he has a power of appointment. Except as to the wills of soldiers on actual military service or mariners actually at sea, every will must be in writing and signed by or on behalf of the testator. Such signature must be either made or acknowledged in the presence of two witnesses who are both present at the same time and both affix their signatures in each other's presence as well as in the presence of the testator. A will may be written on anything which is capable of receiving writing, and either in pencil, ink, chalk, or any other substance that can make a mark. A testator who cannot write may make his mark, which will be accepted if it is duly witnessed.

Valid and Invalid Wills. It is essential to the validity of a will that the testator should act voluntarily, i.e. of his own free will, and be of sound disposing mind, which means that he must know he is making a will and know what the effect of the will is. For this reason a lunatic cannot make a will unless in a lucid interval. Further, if it be proved that a will was made under undue pressure, either physical or mental, the court will upset it. At the same time there is nothing to prevent, for instance, a wife requesting her husband to make proper provision for her or her children in his will.

The kind of case where a will is upset owing to undue influence is where some person very old or feeble in mind or body is more or less compelled by someone who has great influence over him to make a will in that person's favour, or to give favour to someone through whom that person derives some benefit. A will induced by fraud will also be avoided, e.g. where a man made a will in favour of X, X having fraudulently told him that his, the testator's, only son, who was on a voyage, had been drowned.

Until 1926 a will was revoked by the marriage of the testator, but now a will which is made in contemplation of marriage is not avoided by that marriage taking place. A young man about to marry, and wishing to make a will to provide for his future wife before the ceremony, should begin somewhat in this form: This is the last will of me, John Jones, of 490, High Street, Peckham. Whereas I have arranged to marry Annie Robinson, now I make this will in contemplation of such marriage. He should then go on to dispose of his property according to his wishes and responsibilities.

A gift by will which is illegal, or against public policy or morality, is not good, e.g. where a man left a fortune to his son on condition that the son separated from his wife; or a gift for some superstitious purpose, as where someone left money for the education of spiritualistic mediums.

Everyone who makes a will should take great care to begin by appointing an executor, or even more than one, because if no executor is appointed a great deal of extra trouble and expense is incurred in proving the will.

A will is, by the law of England, always revocable, even though it is expressed to be irrevocable. It can always be revoked by a later will or codicil which purposes to revoke the former, and, indeed, most wills begin with the words, "I revoke all former wills and testamentary dispositions by me made." It can also be revoked by cancellation or destruction; but the mere destruction of a will, if it is done without the intention of revoking it, does not revoke it, and it can be proved by evidence, such as a solicitor's draft or even a verbal recollection of anyone who has seen it, as was done in the famous case of the will of Lord St. Leonards. In the same way, if the testator tears up his will when he is insane or drunk, it is no revocation. As a will can only be revoked by the testator himself, it follows that he cannot delegate to somebody else the power of revoking after his death.

Alterations in Wills. If it is desired to make an alteration in some of the dispositions of a will already made, it is not necessary to make an entirely fresh will. The testator can execute what is called a codicil, which ought to begin with the words: This is a codicil to my will dated the X day of X. He can then, for instance, revoke a particular legacy or appoint a fresh executor or give an additional gift.

If he intends to make an additional gift to someone who already benefits, he should be careful to make it quite clear that it is additional. Thus, if he has left £500 to his son John and wishes to increase it to £1,000, he should say: Instead of the £500 given to my son John, I bequeath the sum of £1,000. Or he should say: In addition to the £500 bequeathed by my will I give him another £500. If he simply says: I give my son John £1,000, the question will arise whether he means John to have the original £500 and the £1,000 as well. Clearness is the very essence of making a will, and technical terms are not at all necessary.

The ordinary family man who makes a will to divide his property amongst his children will generally find it best to divide it in proportion rather than in sums of money, because sometimes investments diminish or increase in value, and although the testator may think that his investments are worth £5,000, and that he is safe in saying that he gives £1,000 to each of his sons, it may turn out that the investments cannot be sold for more than £4,000, and very often complications arise.

If a testator intends that a business which he has shall be carried on for the benefit of his wife or family he should make it very clear that his trustees are to have that power. He should also make it quite clear if he intends his money to remain in any particular kind of investment, e.g. colliery shares, otherwise the executors and trustees will be bound to convert all the shares into money and invest it in trustee funds.

Scots Law. As in other matters the law of Scotland on the subject of wills differs in some respects from that of England. Mutual wills, or wills made by two persons jointly, are permissible in Scotland although not in England. More important is the provision of Scots law by which a will is valid, although it is not witnessed, provided the testator has written it wholly in his own hand. *See* Administration; Executor; Estate Duty; Intestacy; Legacy.

WILLIAM AND MARY STYLE. It has been said that the decorative arts in the reign of William and Mary reached a gorgeousness and beauty that has never been surpassed. The style was the culmination of the baroque period in English decoration, marked by a development of the lavish ornament in fashion during the later Stuart times, and also of the Dutch influence, which had already been seen in the furniture of the reign of Charles II, made after 1670 when a number of Dutch craftsmen, particularly cabinet makers, were employed in England by rich patrons.

Architectural changes also showed Dutch design or inspiration. In some of the earlier houses built in the reign of William III the characteristic feature of the scrolled outlines to the gables at each end of the roof is found, while towards the close of the reign, and during that of Queen Anne, Dutch architects had considerable influence on English house planning.

Reception rooms in the great houses were spacious and magnificent. Wall panels were large, with richly carved mouldings surmounted by applied swags of flowers, fruit and foliage, after the manner of the Grinling Gibbons carvings. Pilasters flanking doors, windows and chimney pieces, also pediments to these, and the ceiling cornices were decorated with carving. Oak, walnut and pine were used for panelling, the last wood being sometimes painted green and the carved enrichments gilded. Cedar, pear and lime were the woods chiefly employed for the applied carvings on oak or walnut. Fireplaces were smaller than in the Jacobean period and usually had marble rectangular surrounds. The hearths were provided with large fire dogs, as logs were still the fuel employed.

Floors were of parquet, often inlaid and partially covered with small carpets. These were usually imported, but at the Wilton factory English carpets had begun to be woven. Lighting fittings included central chandeliers of metal or painted wood and candle sconces with reflectors of bright metal or mirror glass.

William and Mary Style. Fig. 1; Chair of carved walnut, an early piece of this period. (By permission of the Director, Victoria and Albert Museum, S. Kensington.)

Characteristic Furniture Chinese lacquer was fashionable at this period, beautiful cabinets being mounted on gilt or silvered stands after the style of the somewhat earlier piece illustrated in Fig. 1 of the article on Lacquer Work. Lacquer cabinets were imported from Japan, done in the Chinese manner, and though the finest examples were not allowed to be exported from the Imperial factory in Japan, some good pieces were made there for the foreign market. The carved wooden stands were made in England, later pieces of the 17th century showing the ornate stretcher work which is such a feature of the William and Mary style. A beautiful writing table in black and gold lacquer is illustrated in Fig. 2. The flat, shaped stretcher is most characteristic, as also are the heavy bun feet.

William and Mary. Fig. 2. Writing table in black and gold lacquer. About 1700. (Courtesy of Gill & Reigate)

Dutch influence is noted in the furniture by the more extensive use of upholstery and costly textiles, and by the introduction of the cabriole leg, although this latter was not the typical furniture leg of the earlier pieces of this period, a good example of which is here illustrated on the chair of beautifully carved walnut. This chair is 4 ft. 3 in. high and is upholstered in green figured velvet. Twisted spiral, baluster and spindle legs are also found on the earlier chairs, tables and stands. In some of the chairs the backs were entirely upholstered, while in others the framing was exposed. Some had cane

panels. Beech or walnut was used for frames, the former being often painted or gilded. Fringe and galons were employed to trim both chair and settee coverings of damask brocade, velvet and needlework.

The cabriole leg seen at the end of this period was pronounced in curve, and usually terminated in a heavy bun foot. The idea of these feet originated in the blocks of wood placed by Dutch housewives to save the legs of their furniture from being rotted by the constant damp arising from well-washed tiled floors.

Cabriole legs were united by hooped or curved stretchers, often with a turned finish in the centre. This system of under-framing chairs replaced the carved deep rail below the seat directly connecting the two front legs, with simple turned rails running at the sides and back. Completely upholstered settees had high arched backs and six or eight legs braced by crossed serpentine stretchers.

During the later period of the style carving gave way to marquetry for the decoration of cabinets, secretaires, table tops and chests of drawers. Such ornamentation was helped by the arrival of fine woods from the Dutch Indies. Entire surfaces were covered with thin veneer, the pattern and background being fretted out by cutting through two or more sheets of wood at a time and interchanging pattern and background. The carcasses were of pinewood. In cases where the geometrical design was relieved by floral work the motif is frequently seen to be the jasmine, treated conventionally, a form of decoration which dates a piece fairly accurately as belonging to this period.

Oyster veneering is typical of this style, and so is the finest arabesque marquetry. *See* Jacobean Style; Marquetry; Oyster Grain; Queen Anne Style.

WILLOW. This is one of the best trees for planting in damp or even wet land; the weeping willow (*Salix babylonica*) is a most beautiful waterside tree. The blue willow (*Salix coerulea*) provides the wood from which cricket bats are made. Several of the willows have coloured bark which is most ornamental in winter; the best of these are *vitellina*, which has yellow, and *cardinalis*, which has red bark; these must be hard pruned each spring. Willows are largely grown for the purpose of basket-making, and one kind, *Salix fragilis*, is used in the manufacture of riddles or sieves. *Salix alba* is one of the best willows for general planting. The catkins of two British willows (*Salix caprea* and *cinerea*) provide the popular “palm” in spring. Willows are easily propagated by cuttings 12 inches long inserted out of doors in autumn.

Uses of the Wood. Willow is a soft, light wood with smooth, lustrous surface, tough and pliable, brownish or yellowish white in colour; it may be bruised by a blow but is not likely to split. Its most important use is for cricket bats, gold lacquer. About 1700 but only the best parts of the tree are good enough for this purpose, and it is cleft instead of sawn. Willow as flooring wears well and has a smooth surface susceptible of a fine polish, besides being non-inflammable. It is employed for hurdles, poles, cutting boards, knife boards, and by the cooper and turner; scrap willow is used in toymaking. Sometimes spade and shovel handles are of willow, and next to alder it is the best wood for clogs.

The chief varieties are known as white and red willow; the latter, which has a red tinge is generally preferred, but it is not plentiful. The willow is much cultivated for wickerwork and basket making and is not allowed to grow beyond the stage of osier or withy rods. With this are used the twigs and small branches which are cut periodically from growing pollard willows. Another way in which young willow is used is by splitting it into thin slices for making woven crates, hampers, baskets, and hats. *See* Osier; Wood.

WILLOW HERB. The common name of a group of hardy plants, of which the most familiar is the rose bay (*Epilobium angustifolium*), which grows wild in many parts of this country; it reaches a height of 4 feet and bears rose-purple flowers in early summer.

WILLOW PATTERN. Based on several Chinese originals, the willow pattern was evolved by Thomas Minton, the engraver, for use on china dinner ware. In the earliest version, dated 1780, there were only two figures on the bridge, no flying doves, and no cedar trees bearing the so-called apples. It was introduced at Caughley by Thomas Turner, who printed it under the glaze, generally with a blue crescent mark, and also with C and S, or even the crossed swords device.

The engraver and his assistants supplied copper-plates of the pattern to other works, after varying the details and introducing the doves and the fruit. Josiah Spode, who printed his willow pattern by transfer in 1784, had a design with a pagoda on the left and a butterfly border, and another with a dagger border. The willow pattern sprang into favour from the first and was applied to a wide range of wares. Davenport plates have 25 apples, with a special fret pattern round the rise. Spode has 32 and Wedgwood 34, while Adams plates have 32 and the dishes 50. Both Spode and Wedgwood did the Caughley pattern as well as their own. Differences are observable in the depth of the blue tint in the printing, the Adams cobalt being especially sought after. During the early 19th century the pattern was produced on various bodies, often marked with the Staffordshire knot, and not always in blue. It remains one of the standard designs of the modern potter and is still made by Mintons and other historic factories in the traditional form. *See* China; Davenport Ware; Pottery; Spode, etc.

Willow Pattern. Plate decorated with this quaint pattern derived from China and now a standard English design.

WINCEY. This fabric is a wool and cotton mixture. It is obtainable in white, some colours and stripes, and is especially suitable for children's light-weight pyjamas. The little wool that it contains makes it warmer than cotton of equal substance and less perilous than flannelette.

WINCH. The use of a winch is for winding up rope, etc. on a revolving drum in various kinds of apparatus used in hauling. It comprises a crank with a handle and geared by means of cogged wheels to a drum. A

winch is commonly seen in the apparatus used to draw water from a well; it is used for winding the rope on a crane and is generally provided with a pawl to prevent unwinding.

Wind: In the Body. *See* Flatulence.

Windflower. This name is given to plants of the genus *anemone* (q.v.).

WINDOW. The form of a window depends chiefly upon its position in the building and the room which it is to light. Its proportion necessarily varies, and the type will be chosen to suit the design of the building.

The various types of window include the bay, which may be square, angular, or curved, the casement, plain and transomed in both metal and wood, the dormer, the French, also made in metal

and wood, the gable, the jut, the mullion, and the oriel. The sash window is more commonly fitted than any other, but in modern construction it is being superseded by the more convenient casement. The mullioned window with transoms, the bay with latticed casements and the oriel in a simple form are all adapted to Tudor styles in building.

Typical examples of most of the above types have been fully described and illustrated in this Encyclopedia under their respective headings. (*See Glass and Glazing; Leaded Lights; Stained Glass.*)

An inexpensive glass is obtainable through local glaziers or builders which transmits the vital ultra-violet rays shut out by ordinary window glass. Many people have this glass fitted to the windows of nursery and living-rooms. It is made up in clear sheet, plate and cathedral forms for sash windows or leaded lights. This glass is helpful in counteracting the ill effects of a badly lighted basement flat. Windows may be recessed, flush, or may project; in all cases they should fit into a rebate in the wall, which may be formed by a depression in the brickwork or by an iron bar fixed into the mortar joints. For recessed windows the rebate is in the interior side of the wall and in flush windows on the outside.

All wood window frames should be kept in good condition by applying periodical coats of paint to make them weatherproof. Certain forms of metal frame are provided with small grooves or troughs in which the rainwater is caught, and this prevents it from collecting at the bottom of the window.

Properly constructed windows should not rattle. If the meeting rails are made such a width that the sash fastener, on pulling them tightly together, also pulls them tightly to the parting beads, the window sashes will not rattle. If, however, when the meeting rails are close together, there is a space of $\frac{1}{2}$ in. between the stile of the top sash and the fin of the stile of the bottom sash and the parting bead is only $\frac{3}{8}$ in. thick, the window will shake considerably in the slightest wind. On the other hand, if the stiles of the sashes are within $\frac{3}{8}$ in. of each other, the fastener will pull all tight together, and so, no matter how high the wind, the windows will be silent.

Window Cleaning. In most towns there are window cleaners who will do the windows of the whole house at a moderate charge, and who are usually called in, at any rate, for the less accessible ones. Those that can be done by the ordinary domestic staff should be cleaned on a dull day, or at least when the sun is off the window; they should not be cleaned in cold or frosty weather. The materials required are a pail of clean warm water with a little paraffin in it, a wash-leather or cloth for applying the water to the window; a soft cloth, preferably linen, for drying, and a dry selvet, soft duster, or wash-leather for polishing. Before starting, the frames should be brushed.

The water should be sluiced over lightly, so as not to scratch the panes with any dirt that has adhered to them, but care should be taken that all dirt is removed before they are wiped over with the drying cloth. When all the wet has been dried off with clean, sweeping movements, the panes may be polished with the polishing cloth, and any smears left by the damp cloth removed. A little methylated spirit on the cloth will ensure a fine polish, but the paraffin in the washing water is also excellent for this purpose, and it keeps flies away. When no suitable cloth or selvet is available for polishing, a piece of clean newspaper rolled up into a loose pad will be found to make an excellent substitute. *See Bay Window; Blinds; Burglar Alarm; Casement; Curtain; French Window; Glass; House; Lead Art Craft; Pelmet; Sash; Transom, etc.*

WINDOW BOX. Plants may be grown upon the window-sills of flats, town houses and other buildings by the use of window boxes. Such a box may be made of wood, about 1 in. thick; it should be the length of the sill upon which it is to stand, and about 1 in. wider. A depth of 9 in. is sufficient.

Ridges or runners of wood should be placed at each end in order that the box may not rest directly upon the sill. A few holes should be bored in the bottom, and shallow tins or trays, such as the lids of discarded biscuit boxes, may be slid under the bottoms of the boxes to catch any superfluous moisture. Before being placed in position, window boxes should be burned or charred inside so as to present a resisting surface to the decaying qualities of moisture.

A simple form of window box is made with 9 in. by $\frac{3}{4}$ in. boards cut out to the size of the sill and nailed together, with due allowance for the slope of the sill. The latter adjustment can be made by making the front board wider than the back one, or by fitting wedges underneath. If flower pots only are placed in the box there will be no need to do more than bore a few holes for drainage, but if the box is filled with soil the inside can be lined with sheet zinc. Metal flower boxes can be bought which are inexpensive and require no lining, but such boxes are ugly unless it is intended completely to cover their outer sides with trailing creepers.

Preparation and Planting. In preparing the box to receive plants, the bottom is first filled to a depth of about 1 in. with broken brick, crock, or other material in order to form a drainage. On this is placed a layer of turf or rough soil and the remaining space is filled with a compost of loam leaf-mould and sand.

In the spring, nasturtiums may be planted to droop over the front of the box, or creeping jenny, or canary creeper. Behind these, yellow or brown calceolarias, white daisies, or heliotrope Lord Roberts may be planted. Combinations of colour must be carefully thought out. White, yellow and bronze or mauve look well together, while pink geraniums will be charming with either lobelia, catmint or mauve violas in front. Begonia Lloydii is most attractive, as it droops over the front of the box and has double flowers in yellow, scarlet or pink.

When the summer flowering subjects are over, the boxes should be cleaned out and refilled for the winter display, consisting of plain and variegated euonymus and other small evergreens.

WINDOW SEAT. A window seat generally takes the form of a flat board fitted to the shape of the window recess, supported on a suitable framework, and fitted with cushions or upholstered.

In a simple form of construction the seat board, measuring from 15 in. to 18 in. wide, is supported on two fillets screwed to the wall with the aid of plugs at a height of about 16 in. The fillets should be at least 1 in. thick, and chamfered on the front and lower edges. If the recess is a long one, one or two bracket supports will be required for the seat, and in making them due allowance must be made for the skirting board as shown in Fig. 1. Having fitted the end fillets, as at A, from 2 in. by 1 in. wood, a length of similar wood B, which can be obtained machine planed, should be fitted between and secured to the wall, great care being taken that the back strip is exactly equal in thickness to the skirting; otherwise it will have a faulty appearance.

Fig. 5. In the old-world hall of a converted farmhouse a suitable window seat has been constructed with paneled back and solid shaped brackets. (Humphrey & Vera Joel)

The brackets as shown in side elevation in Fig. 2 should be framed up from 2 in. by 1 in. wood on a back piece C, which should be the same height as the top of the fillets. The horizontal piece D forming the top of the bracket is

dovetailed to the top of the back piece, as in the plan in Fig. 3; it should be cut to a length that will bring the end 1 in. from the front edge of the seat board. The strut is fitted as at E. The brackets are screwed to the back fillet, as in Fig. 1.

If it is not desired to make the seat a fixture, a light framework as in Fig. 4 can support the seat board, the wood used being at least 2 in. by 1 in.; corners and rail can be jointed with the lapped halving joint or the frame mortised and tenoned. For long seats it is better to use 1½ in. square material, the joints being mortised and tenoned. To prevent the supports from moving, one or two rails are tenoned into them and further secured by pinning or fox wedging. The top board in all cases should be 1 in. thick, and as the width of the seat will be greater than the average width of the material, two lengths must be glued together. Information on seats of a similar type will be found in the articles in this work on Corner Seat and Ingle Nook.

Window Seat. Fig. 6. The most convenient way of furnishing a window seat in a modern living-room is with a long fitted cushion and two fancy cushions to suit the general colour scheme. (Humphrey & Vera Joel)

A window seat intended for an old world Tudor or Jacobean type of hall or living-room is effective when constructed of natural oak, wax polished and having a simple panelled back and solid shaped brackets, as shown in Fig. 5. Any form of upholstery would be out of place in such a setting, though one or two flat velvet cushions, edged with cord and trimmed with heavy tassels, would be permissible.

For a more up-to-date style the most convenient covering for a window seat is a fitted cushion like the one illustrated in Fig. 6. Velvet has been selected as the fabric for the cushion in this ease to

match the upholstered chairs, but tapestry, damask, printed linens, cretonne or chintz would all be equally suitable in correct relation to the curtains and chairs of the particular room. *See Bay Window.*

WINDSOR CHAIR. This type of chair, a real English production, was first made in the 17th century, and good examples are much valued. The characteristic features are the hollowed wooden seat and the complete separation between the uprights forming the back and those forming the legs. The method of putting it together also was new. This was the boring of circular holes by means of a bit, and the fitting in of cylindrical spars, fastened by wedges and glue.

In the oldest form, the backs are composed of simple turned spindles, or spars, that run into a curved top rail. The arms are continuations of the back centre rail. Another type has a stretcher back in the form of a V. This is fixed by two extra spindles fitted in the back for additional strength. These are put in behind the others, which they cross transversely, and are fixed in a tailpiece to the seat.

The fiddle splat back type was seen early in the 18th century, the splat probably having been copied from that in the ordinary Queen Anne chair. In these cabriole front legs are often seen and they possess stretchers. About 1750 the Windsor chair with an arch back was made. In this the cabriole leg is used, and the front stretcher is curved away towards the back legs, being connected therewith by two turned stretchers. The back is in the form of an arch and is usually supported by six spars with a centre splat laid on, which may or may not be pierced. The arms are often horseshoe in shape.

A variation of the splat in the arch back is the wheel back. The centre has a circular pierced ornament in the form of a wheel made by fretting out six triangular holes. The legs of the ordinary Windsor chair were made of beech or birch. The seat was made of elm, which was cut up into rough planks. An adze was used for the hollowing process and the seat made smooth with a spokeshave. Each plank was then cut up into the required number of chair seats and each seat shaped with a band saw. A bit bored the holes that received the rungs. The pieces were allowed to dry before they were put together with glue.

These chairs were also made of yew, walnut, and cherry wood. Yew ones are very valuable, as age gives the wood a beautiful tortoiseshell colour and a fine patina. *See Chair.*

WINE. All wines possess a peculiar aroma or perfume which constitutes one of their most valued properties. The way to tell good wine is by its appearance, its smell, and its taste. Be the wine young or old, it should be clear and brilliant in colour, not dull or thick. It should be clean-smelling and of a pleasant aroma. Its taste should also be clean and pleasant.

Wines are often classified into natural and made or manufactured and fortified wines, but these classifications are not absolute. The white and still wines of France, Germany and Italy are matured generally according to natural processes, and untouched thereafter. Made wines are all sparkling wines, such as champagnes, which have added a liqueur composed of fine wine-brandy and sugar.

Port and sherry are very often fortified by an addition of alcohol, but the finest vintage port is a natural wine free from added alcohol, thereby enabling the wine to keep and rendering it wholesome. Well-made wine improves with age. Port or sherry will last for 80 or 90 years or more, a good burgundy or claret for 40 or even 50 years. Champagne is at its best at from 12 to 15 years after bottling.

The Wine Cellar. Every lover of wine should keep a wine cellar. It need not be an elaborate affair. A good-sized cupboard will do provided it is dry, or any underground cellar that has not outside walls. The temperature should be from 53° to 58° F., and this can be obtained by means of a gas jet.

The great thing is to keep the temperature uniform.

Bins made of iron and wood in two-dozen units for holding the bottles can be obtained inexpensively at any ironmonger's.

The bottles should be placed in the bin on their sides and, once binned, should be left undisturbed until required. On port bottles is a splash mark, and the bottles should be binned with this mark uppermost. Sparkling wines soon become flat if they are stood on end.

The Decanting of Wine. Great care should be taken in decanting old wines, especially old vintage wines. First of all the sealing wax should be removed carefully. Then a brush should be used to remove any dust, wax, or cork. A good corkscrew is necessary. For difficult corks a double-liner extractor is useful. When drawing a cork, a guard should always be used consisting of a piece of cloth or a leather guard which is slipped over the neck of the bottle. In the case of old wines, it is wise to decant through a decanting funnel or a piece of muslin. If a funnel is used, it should be warmed to the temperature of the wine.

When opening champagne, the wire and string should be entirely removed before uncorking. The wine may be spoilt easily if poured out over string and rusty wire. Do not put more than one bottle of wine into a decanter. Each bottle of wine has its own character and individuality. Do not decant more wine than you think will be consumed.

Temperature for Serving. As for the temperature, white wines should be a few degrees colder than the room, and in hot weather full-bodied wines may even be iced. Red wines, on the other hand, should have had time to take the temperature of the room, a matter of two or three hours, and there is no objection to their being a degree or two above it. But it must be remembered that if wine is at too high a temperature all its finer qualities will disappear, and the particles which it gives off will be so loaded with alcohol that perfume, bouquet, and aroma will become indistinguishable. The wine glass should be as thin as possible so that the wine may be affected by the heat of the hand without delay, and it should be of a bulging shape, with its opening smaller than its body, so that the perfumed particles given off by the wine may be inhaled, as it were, concentrated through a funnel. At small, informal dinner parties it is now usually the practice to serve only one or two wines throughout, claret, burgundy, or champagne. But at big dinner parties and banquets there is a recognized order, as follows: With oysters, graves or chablis; with soup, sherry, marsala, or madeira; with fish, a glass of sauterne or chablis; with the entrée and roast, claret or burgundy; with game, champagne; with pastry, madeira; with cheese and fruit, port should be served. *See Burgundy; Champagne; Dinner; Port Wine; Sherry, etc.*

WINE BISCUIT. To make, sift 8 oz. fine flour with a pinch of salt, then rub in 2 oz. butter, add the same amount of castor sugar, and make all up into a dough with 1 small egg and about 1 tablespoonful cream. Add to the dough, mixing in lightly 2 oz. currants cleaned and picked or ½ oz. caraway seeds. Lay aside for 1 hour to stiffen the dough. Cut it into shape with a fluted cutter and bake it on a greased and floured baking tin in a moderate oven.

WINE COOLER. This article, now mainly valued as an antique, developed from the tub or vat in which bottles of wine were placed for cooling. It was also known as the ice pail. These coolers or pails are often found in pairs, and the fact that their usual place was beneath the centre of the sideboard was not without influence on the design of that piece of furniture.

Silver bowls were used for cooling wine in Italy in the 16th century and something of the kind was used in England in the 17th, but the best examples, both in silver and in Sheffield plate, date from

the 18th. Pieces were made in the shape of an urn or vase, and some of them are remarkably graceful in design. Some are provided with a lid and others with a handle or both lid and handles, but there are examples without either.

In some cases ring handles have lion mask supports and lie flat to the sides; in others, as in the one here illustrated, the handles are high and ornamented with twisted snakes or with vine branches. Bases were square, round or oval, and some of the earlier examples were on scrolled feet.

Probably the finest existing examples are those copied from the Warwick vase. One beautiful specimen stands on a square base and is decorated with bead edging and acanthus leaves on the body and a band of leaves round the top and along the sides of the base. *See Sheffield Plate; Sideboard.*

Wine Cooler. Antique silver wine cooler having a lid with a knob formed of vine leaves. Period of George III.

WINE GLASS. Convention has decreed that each wine shall have its particular pattern of glass. Claret glasses should have the sides sloping slightly outward and should hold about a third of a pint. For burgundy the glass should be slightly bevel shaped on a short stem; it should hold nearly half a pint.

Certain white wines, such as chablis and sauterne, should be drunk from glasses of the ordinary goblet shape with straight sides. The champagne glass had a very wide, shallow bowl, the idea being that this keeps the wine fresh by retaining its effervescence; modern champagne glasses are often unconventional in shape, the same type being used for hock or moselle. These glasses are sometimes gilded at the rims, decorated with black or coloured stems, or made in delicate colours with cut stems. Sherry glasses are tall and pyramidal in shape, and port is usually drunk from a somewhat smaller glass shaped like a cup. *See Glass Ware.*

WINKLE. The winkle or periwinkle is a small shellfish which has little food value. The horny excrescence which surmounts the head should always be removed. Winkles are usually eaten with vinegar and seasoning and accompanied by bread and butter. *See Shellfish.*

WINTER: In the Garden. Winter is chiefly a period for repairing past errors and planning new schemes in the garden. Dead stems, leaves, and all sorts of rubbish may be cleared away and burned, but it is always desirable to establish the identity of each plant before removing the top hamper, otherwise the label may be lost, or illegible, and doubt may arise in the future.

Roses and fruit trees may be planted when the weather is open, and other operations carried out according to the calendar for the various months of the season.

Quite a number of shrubs and plants are in full beauty during the winter months. The yellow winter jasmine is charming on a house wall or fence, and the pink buds and white flowers of the evergreen laurustinus are cheerful. The Chinese witch hazel (*Hamamelis mollis*) bears fragrant yellow blooms in midwinter and the heather named *Erica darleyensis* is also in flower. The spring heather (*Erica carnea*) shows colour early in the new year, and on a sunny wall the old red *Pyrus japonica* and the fragrant winter sweet (*calycanthus*) then begin to flower. The earliest and best of the Christmas roses (*Helleborus altifolius*), the winter-flowering *Iris stylosa*, stray blooms from the winter-flowering pansies and poppy anemones, snowdrop and winter aconite—all these help to invest the

garden with interest in the depth of winter. Then also the trees and shrubs grown for the sake of their coloured bark or showy fruits are in full beauty.

Systematic gardeners will prepare and map out on paper new plans for beds and borders to be established in the spring, or note corrections to be made in doubtful blendings of heights or colours. *See* Autumn; December; January; Spring.

WINTER ACONITE. This is a charming low-growing, spring-flowering bulb, the first to open in the new year. The yellow blooms surrounded by a ruff of green are on stalks about 2 in. high. It looks well in grass, or may be set among shrubs where it will spread and provide a carpet of colour early in the year. The bulbs should be set 2 or 3 in. deep in August and September.

The botanical name of the common kind of winter aconite is *Eranthis hyemalis*.

WINTER CHERRY. A hardy herbaceous plant, known also as Chinese lantern, the winter cherry is prized for its large orange-yellow “fruits” which are so popular for room decoration in autumn and winter. These “fruits” are really enlarged calyces. The two best kinds are *Physalis Franchetti* and *Bunyardii*; they grow 2 ft. or more high, may be planted in autumn or spring, and thrive in ordinary well-drained soil. Propagation is by division in autumn. *See* Solanum.

WINTER GARDEN. In the ordinary acceptance of the term this is simply an elaborate and large conservatory attached to a house, with sufficient space for indoor beds and borders, and roof-room of an altitude that will accommodate the loftiest palms. The winter garden is usually heated by hot water pipes, and is often utilized as an after-dinner lounge. An outdoor winter garden suitably arranged would include such flowering shrubs as winter sweet, winter-flowering jasmine, heaths, dogwood, hamamelis, laurustinus and the earliest bulbs. *See* Conservatory; Dogwood; Lounge.

WINTER GREEN: The Plant. Two useful evergreen shrubs are known by the name of winter green—*Gaultheria shallon* and *green procumbens*. The former grows 2 to 3 ft. high, bears blush-coloured flowers in spring and purplish-black fruits in autumn; it is often planted as an undergrowth beneath trees. The partridge berry (*Gaultheria procumbens*) is a creeping shrub suitable for planting in shade; it has white flowers and red berries; the latter provide the winter green oil used in the treatment of rheumatism. Propagation is by seeds and cuttings.

Oil of winter green consists mainly of methyl salicylate, and has the same effects on rheumatism as other salicylates. It is chiefly used as an external application.

WINTER GREENS. In the vegetable garden it is very important to provide for winter use a supply of greenstuff or winter greens, such as cabbages, Brussels sprouts, broccoli, kale, savoys, and sprouting broccoli. To avoid any glut, sowings should be made in small lots in March and April. A fresh sowing can be made when plants sown previously are just showing through the soil, thus providing plants which will mature in succession instead of all coming to harvest at one time. As a rule amateurs will not sow in this way, and consequently huge quantities of green vegetables either rot or run to seed every winter. *See* Brussels Sprouts; Kitchen Garden, etc.

WINTER JASMINE. This charming hardy winter-flowering, climbing shrub of slender growth is suitable for training on a house wall, fence or trellis. It flourishes in ordinary soil, and should be pruned as soon as the flowers have faded. The flowers of the winter jasmine are yellow and open well in water, if sprays bearing buds are cut and brought indoors. *See Jasmine.*

Winter Jasmine. A beautiful winter-flowering shrub.

WINTER MOTH. One of the worst pests of fruit trees is the winter moth, its caterpillars devouring leaves and blossom. Grease banding in autumn is necessary to trap the wingless females, which crawl up the stems of trees to deposit their eggs in crevices of branches and shoots, these hatching out into destructive larvae as buds begin to burst. In addition to grease-banding, trees may be sprayed with a tar-oil wash in winter, and the poisonous arsenate of lead wash as soon as the fruits are set. *See Grease; Spraying.*

Winter Moth, the caterpillars of which destroy the leaves and blossom of fruit trees.

WIRE: Its Uses. Wire can be obtained in many different shapes and sizes, and is produced commercially by means of powerful machinery which draws the heated metal through a series of holes of gradually diminishing size in a metal plate. Wire is employed for innumerable purposes in the home. It can be used for binding and repairing, for clothes lines, for supports for flowers in the garden or in pots and for hanging pictures and curtains. It can be kept straight for the latter purpose by using wire strainers, and it is also obtainable in coiled spiral form for the same purpose. It is made up in the form of nails, pins, hooks, staples, and tacks. Wire is found in the form of gauze, netting, fencing and is also made up into many household utensils.

In the Garden. Wire is useful for supporting climbing plants and trained fruit trees, and for binding joints or pergolas and arches. Ordinary wire is liable, however, to become sun-hot during summer, scorching shoots and tender growth. In high winds, too, it is apt to tear tendrils and young branches. Multi-stranded wire with a composition covering is best suited for garden use.

Wire Gauges. Gauges for measuring the thickness of wire are made in several shapes, and there are a number of different systems employed in measuring. The thickness of the wire is denoted by numbers, except in the case of the Lancashire steel wire gauge, in which letters are used. In most gauges the lowest number indicates the thickest wire, but in the Whitworth gauge the reverse is the case. The Whitworth gauge ranges from $\bullet 5$ in. (No. 500) to $\bullet 001$ (No. 1), and it has the advantage that the number of the gauge is a key to the dimension. In the other gauges in ordinary use the number is no indication of the size of the wire. The British imperial standard gauge, indicated by the letters S.W.G., is the English legal standard for measurement, and its graduations extend from $7/0 = \bullet 5$ in. to $36 = \bullet 0076$ in., and include 43 numbers. The Birmingham wire gauge is still in general use, and many wires are quoted as B.W.G. Its numbers range from 0000 $4/0$ to 18, and with slight

differences in the second and third decimal point from 19 to 36. Wire from the United States is measured by the Brown and Sharpe (B. & S.W.G.). The disk gauge is generally used, being more convenient than those of oblong shape. *See* Fence; Gauge; Micrometer.

WIRELESS RECEPTION FOR HOME PURPOSES

Types of Service Available in this Universal Entertainment

The component apparatus are severally dealt with in this work under numerous specific headings, e.g. Valve, and the complete receiver is discussed in detail under Broadcast Receiving Sets, Portable, Superheterodyne, Television etc. Other contributions describe the accessories, e.g. Accumulator; Rectifier. *See* also High Tension; Reaction; Selectivity.

The sources of entertainment and instruction available through the medium of a wireless set can be divided into four groups: 1. Speech and music broadcast on medium and long waves by the British Broadcasting Corporation and other European broadcasting organisations. 2. Speech and music transmitted by short-wave stations, most of which are designed to disseminate advertising or propaganda to other countries. 3. Television (sound and vision) transmitted on ultra short waves from the Alexandra Palace, London, and receivable only in London and parts of the "home" counties. 4. Records electrically reproduced (in the case of a "radio gramophone").

Fig. 1. Car Radio. Philips 4-valve superhet MotoRadio. Built-in speaker; new type control head, for instrument panel or steering column mounting, shown inset.

For practical purposes, reception of medium and long wavelength broadcasting, which comprises the domestic mechanism of the broadcasting services of all countries, is restricted in this country to the stations situated in Europe. Of these, only the nearer and more powerful ones can be heard in daylight. At night many more become audible since darkness extends their ranges.

The short waves (q.v.) are not normally used to provide local or national services, but are employed for programmes intended to be received in other countries. Short-wave stations are able to cover great distances using relatively low power, and it is possible with these to receive programmes originating in America, Australia, and other distant continents when conditions are favourable. Turbulent conditions of the ether are liable to cause interference and fading and, therefore, short waves cannot give a completely consistent service, even when compensating systems of Automatic Volume Control are used.

Listeners who have not experienced reception on these bands should bear in mind that commercial advertising and political propaganda prominently figure in a large proportion of the short-wave programmes from other countries. For a time they may find this an interesting novelty, but ultimately it often tends to become somewhat irritating, in many cases.

In regard to television it can be noted that there is only one television station in Great Britain, and this is situated at the Alexandra Palace, London. Programmes in vision and sound are sent out on ultra short wavelengths (approximately six metres). These ultra short television waves are

receivable only over a limited range. Fifty miles represents an extreme limit of reception, and this cannot normally be exceeded even with a very sensitive set.

Fig. 2. Motor-driven automatic tuning system, designed and built as integral part of receiver, on chassis of Philips Model 753. Fig. 3 (lower illustration) ; back view of selector drum assembly of Philips Press-Button Tuning Mechanism. A-H, individual drums. J, friction clutch spring. K, flexible drive coupling. L, swivelling guide arm. M, motor switch, forward and reverse contacts

The so-called radio-gramophone is fitted with a turn-table so that gramophone records can be played electrically through the loud speaker; alternatively, separate “playing units” are made for coupling to sets equipped with “pick up” terminals. In choosing a set from catalogue descriptions it should be remembered that the term “radiogram” (an abbreviation of radio-gramophone) is often somewhat loosely used, and it may be applied to a set that is not in fact a complete combination of radio receiving set and electric gramophone, but one which requires the addition of the independent turntable and pick-up unit before records can be played. Complete all-electric types of radio-gramophones are usually though not invariably fitted with electrically-driven turntables. Clockwork drives are sometimes found on the cheaper models and necessarily in sets designed for battery operation (*see* Gramophone).

It is advisable always to test a radio-gramophone for the direct emission of sound from its pick-up. This is heard at its worst when the lid has to remain open while the record is being played. A substantial, close-fitting and preferably felt-lined lid is needed for its complete suppression.

Fig. 4. "Push-Button Control" as it appears from the outside, on a Cossor A.C. Mains Model (398) with "De Monge" Interference Suppression Circuit. Note simplicity of controls and of the calibrated station-log

Buying a Set. In deciding exactly what type of set to buy, the main consideration is obviously its performance. Almost equally important is its appearance. A radio set is a piece of furniture, and can be either an eyesore or an attractive asset in the furnishing of a room. Listeners often tend to look at a set while they are listening, even when it has no television screen on it. Therefore, a wireless set can well be the most looked at object in a room, and so a wide variety of makes and models is now available.

Potential buyers of wireless sets should bear another point in

mind: a set ought not to possess a "tone" of its own. To say of any particular instrument that it has a "nice tone" is tacitly to ascribe to it the introduction of false sound values. Actually, the highest compliment which can be paid to a set is that in fact it has no tone of its own, but that it reproduces speech and music with fidelity. The nearer the approach to a faithful reconstruction of the original sound values as created in the broadcasting studio, the nearer to perfection does the instrument go towards perfection in quality of reproduction.

Obviously, one fundamental factor cannot be re-created under domestic conditions; the full volume of the original sounds cannot comfortably be reproduced. The listener does not in fact want the equivalent of, for example, a full-sized brass band playing in his parlour! Nevertheless, a balance of tone is maintained at lower volumes by an efficient receiver.

The size of room in which a receiver is to be used need not therefore affect its choice to any considerable extent so long as there is an ample reserve of power; but a set having a fairly large power output is as much to be desired in a small room as in a large one. Not because the ability to emit sounds at a considerable volume is necessarily desired, but "peaks" occur even in "quiet" levels of volume which can be handled without distortion only when there is a comparatively large output maximum.

A certain amount of distortion is inevitable in wireless reception. Generally speaking, it is only from the National and Regional B.B.C. stations serving a particular area that the highest quality can be obtained on any set with the minimum of interference. For this reason there is a tendency for many listeners to confine their listening to their "local" stations after the novelty of listening to distant stations has worn off. Nevertheless, that a sensitive modern set can pick up distant programmes is indisputably an advantage. Fading can be overcome to a considerable extent by Automatic Volume Control, although there is yet no successful method of combating interference from atmospherics.

Electrical interference is even more serious, as it is liable to intrude on the reception of local stations. It may be caused by domestic electrical appliances, lifts, machinery, electric signs and many other such things. When it reaches a radio set through the mains, a suitable suppressor device connected to the power point serving the instrument may be effective. Electrical interference which arrives through the ether is much more difficult to deal with.

However, special forms of “anti-interference” aerials are obtainable and these sometimes prove completely effective.

Tuning. Probably the greatest advances in radio receiver design during the past few years are to be seen in the controls. Whereas the earlier sets had to be tuned by means of dials calibrated in degrees, the modern set has its dial marked with both wavelengths and station names, thus enabling anyone without any technical knowledge whatever to select the required programmes. The operation has been still further simplified by “pushbutton” tuning. With this method any one of a pre-selected number of stations is selected merely by pressing a marked button.

Push-Button Tuning

There are two systems employed. In the one an electric motor drives the tuning condenser round to a point determined by the particular button pressed. In the other a number of small condensers are each initially adjusted to such values as will tune the-circuits of the set to the required series of wavelengths. The push-buttons with which the programmes are selected switch the required condensers in circuit. It is important that tuning should be exact in the case of a set employing the super-heterodyne principle. Any deviation from this exact tuning is liable to introduce distortion. To ensure exact tuning some of the more expensive sets include in their circuits a system of automatic tuning which “pulls” the tuning into precise line directly a station has been brought up to a certain minimum of volume by the listener. There are also various forms of visual tuning indicators to point out precision of tuning. Extensive aerial systems are not needed with modern radio receivers. In fact, a long aerial may often be a disadvantage in that it will be more sensitive to electrical interference. A good earth connexion is frequently desirable.

Car Radio. Owing to the fact that many cars are manufactured with all-metal bodies, it is generally necessary to position the aerial outside the body of the car. It can sometimes be run along the underside of the running boards. Alternatively, it can be neatly disposed outside the roof. If the set is to be operated while the engine is running all the wiring in the ignition system may have to be encased in metal tubing, and, in any event, “suppressors” usually have to be fitted to the plugs. The set itself is normally built into or behind the dashboard; the controls by being connected to the set with Bowden cables can be fixed to the steering wheel if desired.

Wireless Licence. A licence costing ten shillings per year must be obtained before a wireless receiving set of any kind can be used in Great Britain. Licences can be purchased at any Post Office, and each one will cover the use of a stationary set in the house and a portable receiver used by the licensee or any other person living on his premises. A separate licence must be purchased for each car radio.

WIRE NETTING: Its Uses. Galvanized wire netting is useful for a variety of purposes.

It is obtainable in rolls of 50 ft. length in widths from 1 ft. to 6 ft., increasing by 6 in., and with meshes varying from $\frac{3}{8}$ in., increasing by $\frac{1}{8}$ in. to $\frac{3}{4}$ in., by $\frac{1}{4}$ in. to $1\frac{1}{2}$ in., with additional sizes of $1\frac{5}{8}$ in., 2 in., 3 in., and 4 in. In the large mesh the selvages are 3-ply, otherwise it is usual to have 2-ply twisted selvages. Netting of 3 and 4 in. mesh can be obtained in widths of 3 ft., 3 ft. 6 in., and 4

ft., with a 3-ply twisted selvage at the top and bottom and a 3-ply strand woven in the centre. Mixed mesh wire netting is made up of two widths laced together and afterwards galvanized.

The gauge of the wire used in the netting depends on the size of the mesh; except the smallest mesh, which is generally No. 21, all sizes can be obtained in several gauges.

The best quality should always be purchased.

In securing wire netting to framing, it is generally advisable to fasten one of the selvage edges first, straining it as tightly as possible. The opposite edge is similarly secured, leaving the ends to be neatly turned in and secured at frequent intervals.

In using wire netting for fencing, it can be attached to stakes of wood or iron, the latter being generally more convenient and lasting.

Stakes should be placed at intervals of from 6 ft. to 9 ft. apart. Wooden stakes should be round for preference, pointed, and entirely creosoted; failing this the cut wood should be coated with tar and the exposed portion treated with a wood preservative. Sawn stakes, unless of stout material, are liable to snap. Iron stakes of circular section are obtainable provided with an extra prong for fixing in the ground. They are made in several lengths, giving a height above ground ranging from 18 in. by 6 in. to 6 ft. and 7 ft., with thicknesses varying from $\frac{3}{8}$ in. to $\frac{3}{4}$ in. diameter. For strong fences 1 in. angle iron is obtainable in lengths of 4 ft. or 4 ft. 6 in., and 5 ft., with riveted plate for pressing into the ground with the foot, and a hook top and bottom for holding the netting in position. *See* Aviary; Chicken; Fence; Poultry; Tennis Court, etc.

WIRE WORM. This word is employed somewhat loosely for pests that attack crops. True wireworms, however, are the young of certain species of the click beetle or skipjack, and are easily distinguished by their yellow colouring. They are common and very widely distributed.

To combat this pest the following hints are given in Leaflet 10 issued by the Ministry of Agriculture. If it is not desired to use a proprietary compound, experiments may be made in the use of naphthalene alone. This substance in the crude or semi-refined form can be obtained from gasworks or makers of insecticides. The naphthalene in powder, at the rate of from 1 to 2 oz. per sq. yd., should be worked into the soil as thoroughly as possible, and its effects seem to be much greater if the application is followed by a heavy rainfall or drenching by artificial means.

If the land is not badly infested, or if soil insecticides are considered unsatisfactory, wireworms may be either trapped or dealt with by poisoned baits. In the former case pieces of potato, beet, or carrot should be spitted on short sticks, buried in the ground, and examined every few days, if it is desired to poison the wire worms, the shoes of root, or preferably small pieces of rape cake, may be dipped in a mixture of Paris green in water (1 oz. in 2 gallons) and then buried.

The adult beetles may be trapped in spring and summer by means of small heaps of cut clover, sainfoin, or broken rape cake covered with a tile. *See* Insecticide; Tomato.

Wireworm. Top. Larvae of the click beetle. Below, adult beetle.

WIRING DIAGRAM. This piece of mechanism is a pictorial or practical representation of the connexions to the various component parts of a circuit, as distinct from a circuit diagram, which latter is simply a theoretical conception. In wireless the wiring diagram may take the form of a blue print, or alternatively a black and white drawing to scale, the panel and baseboard usually being shown in plan and the components in their correct relative positions. The circuit connexions are

then indicated by means of lines joining the terminals on the various components. *See* Circuit Diagram.

WISTARIA. This is one of the most beautiful of all hardy climbing plants. It is seen to the best advantage on an arch or pergola, though it may be planted against a wall: it is very striking when trained on a circular trellis in the open garden. This shrub thrives in ordinary soil; it is rather slow growing for the first year or two. The way to prune is to allow sufficient shoots to develop to form the main branches and to shorten the side shoots in summer and again in winter to ensure the development of blossom buds.

The common kind is *Wistaria sinensis*. One with longer flower bunches is *Wistaria multijuga*; this provides a remarkable display when trained on a pergola. Both have lilac-mauve blooms in early summer. The white variety of *multijuga* is particularly beautiful. *Wistarias* grown in pots can be forced into bloom in the greenhouse in spring. *See* Climbing Plant; Japanese Garden; Roof Garden.

Wistaria. Beautiful drooping racemes of the species sinensis, one of the most valuable of all climbing shrubs.

WITCH HAZEL. This is the popular name of a group of leaf-losing, autumn, winter and spring-flowering shrubs of which the botanical name is *hamamelis*. They are slow growing, but eventually form large bushes. Ordinary soil suits them, and they need very little pruning; it is necessary merely to thin them out occasionally. The best is *Hamamelis mollis*, which bears fragrant pale yellow flowers in mid-winter; *arborea* has deep yellow flowers in February and *virginica* bears pale yellow blooms in late autumn. They are most interesting and easily managed hardy shrubs. Layering is the best method of propagation.

Medicinal Uses. Witch hazel is an active haemostatic much used for controlling bleeding. A few drops of the liquid extract in water snuffed up the nose is an excellent treatment for nose bleeding. *Hamamelis*, on account of its astringent action, is a useful home remedy for haemorrhoids.

WOLF. The fur of the wolf is longer and coarser than fox, but it is also cheaper. The wool is soft and very liable to felt, but on the whole wolf wears fairly well and is less fragile than many of the more expensive pelts. The colour varies from yellowish grey to blue, but some skins are so dark that they almost appear to be black. The general directions given for the care of long-haired furs may be applied to wolf. *See* Fur.

WOLFHOUND. The three varieties of this dog that are most usually seen in Great Britain are the Alsatian, the Irish and the Borzoi. *See* Alsatian; Borzoi; Dog; Irish Wolfhound; Kennel, etc.

WOLVERINE. The fur known as wolverine is obtained from the carcajou or skunk-bear. It is soft and thick, and of a dark-brown colour, a whole skin usually measuring 3 to 4 ft. in length. A patch of dark fur in the centre of the back is known as the saddle. Around it there is a band of lighter fur, and then another dark ring, the latter is not quite so dark, however, as the saddle, which resembles fine sable tail, and is usually cut out and used for the same purposes. After the saddle has been removed, the gap is filled with bearskin, and the whole used for rugmaking.

WOOD. Wood as used by the cabinet maker and the woodworker in general is the seasoned product of the timber tree, and as such is divided into two classes, softwoods and hardwoods. It is usual to describe as softwoods those obtained from trees bearing needle-pointed leaves, and to classify as hardwoods those from trees bearing broad leaves. Only a very small quantity of the wood used in this country is home grown; the main supplies come from all parts of the world, generally cut into recognized sizes and partly seasoned.

The principle varieties of timber are dealt with in this work under specific headings. Other information is given under such headings as Grain; Timber, etc. Surface treatment is described in Paint; Stain; and Varnish.

The most commonly used wood is known as deal, but this is the name of the size into which several varieties of pine or fir are cut. Under the one species of pine there are several entirely different woods, ranging from one of the softest to one of the hardest. The same difference is found among the hardwoods; for example, lime is soft and even textured, and lignum vitae is exceedingly hard and difficult to work.

The matter of shrinkage is of importance in all forms of cabinet making, and it can be taken as a general rule that the softer the wood the more liable it is to shrink. There are other faults which generally go with a liability to excessive shrinkage. Among them are shakes. These are splits in the direction of the grain at right and other angles to the annual rings as well as along the line of the rings, the latter being known as cup shakes. The pines are liable to knots, and it is rarely possible to obtain a board of yellow deal without knots, but if they are only small it does not matter very much; large knots, however, are liable to fall out, especially in thin boards.

The difference between heartwood and sap-wood can generally be noted by a difference in colour and in the brilliancy of the planed wood. The heartwood is the fully developed portion of the tree, and the sapwood is only partly lignified. Satin walnut is a case in point, for the tree produces very wide sapwood, which is imported under the name of hazel pine. The heartwood of yellow deal is of a bright golden colour and has a distinct lustre, while the sapwood is of a bluish shade and planes up to a rough spongy surface.

Timber for Carpentry. The timbers used for carpentry are mostly softwoods, such as red deal, white deal or spruce, and red or yellow pine. Red deal is in general use for window frames, cold frames, doors, and similar outside work which is to be finished by painting. White deal is used principally for flooring boards, tongued and grooved partition work, and common inside fixings, such as shelving. The better type of work, such as table tops, the ends of cupboards, panels, etc., calls for a medium quality of yellow pine. Tongued and grooved matchboarding and flooring boards are sold by the square, a square being nominally 100 sq. ft.; but smaller quantities may be purchased at per sq. yd. White deal shelving, machine-planed on both sides and both edges, can be obtained in varying widths from 9 to 11 in. wide at per foot super.

There is a large variety of ready-made mouldings for picture rails, hat and coat rails, cornices, sash bars and skirtings; these are obtainable at the rate of per 100 ft. For small quantities of mixed woods, such as mahogany, walnut and canary, the amateur is advised to purchase what are called cuttings at the local manufacturing cabinet shop. Some kinds of wood are obtainable in wider widths than others. For example, oak is not generally obtainable in wider widths than 11 in. and averages 8 in. wide; satin walnut averages 9 in., but can be obtained 14 in. wide. Black walnut averages 7 in., and is obtainable up to 11 in., while American whitewood and mahogany, with an average width of 10 in., are available up to 23 and 24 in. wide. Yellow deal does not run more than 11 in., but Oregon pine is easily obtainable in widths up to 24 in. It does not follow, however, that

the wider widths are more suitable for all wide work, for it is often an advantage to glue up several narrow widths as they are then much less liable to warp.

Colour and Grain. The colour of the wood is another consideration in the choice of wood, and in this respect there is great variety. A choice can be made from the almost pure white woods such as sycamore, spruce, and holly, to the black of ebony. Yellow woods are numerous in both soft and hard varieties, e.g. yellow deal and boxwood. Red woods include red pine, sequoia, radouk, mahogany, and rosewood. Brown woods are obtainable in the form of satin walnut, chestnut, and snake-wood, while walnut is of a purplish tint.

In addition to the actual colour of the wood, the peculiarities of the grain enter into considerations of choice, not only the distinguishing grain of the wood, but the accidental formations and malformations. As a rule, any wood cut parallel with the diameter is even in grain, and when there is a difference between spring and autumn growth, as exemplified in yellow deal, this contrast of colour can be accentuated by cutting the wood at various angles. The commonest example of the cross grain cutting of wood is seen in the silver grain of oak, which owes its effect to the method of sawing the wood diagonally to the medullary rays, those lines of hard cells which radiate from the centre of the tree.

The burr effect in such woods as walnut, amboyna, and thuya is produced by the growth of small branches on the lower portion of the trunk, which do not pierce the bark. A type of figuring known as the curl is caused by the natural flow of the grain, which originates at the commencing growth of a branch. The grain effect in the pollard oak and other woods, as well as in bird's-eye maple, is due to malformation; in the former case it is due to a fungus growth, and also by cutting the branches close to the trunk, and in the latter to the ravages of a boring insect. It will be seen, then, that the figuring of wood is due either to the method of conversion, which is often wasteful, or to malformations, which are rare.

Surface Treatment. Owing to the comparatively porous nature of the grain, the untreated surface of wood is liable to disease, especially when exposed to damp. External constructional work should be either painted or coated with a wood preservative, and all internal woodwork, in cases where it is not usual to treat in this way, should be kept dry and surrounded with a current of air.

Wood Ash. *See* Fertilizer.

Woodbine. *See* Honeysuckle.

WOOD CARVING: PRINCIPLES AND PRACTICE

With Some Beautiful Examples of this Decorative Work

The amateur, whether man or woman, will find much scope in this handicraft for manual dexterity, skill and artistic expression, while it can be carried out with an inexpensive equipment. Further assistance can be obtained from perusing such entries as Gouge; Grindstone; Tools; Wood.

See also Chip Carving.

Wood carving is the one branch of sculpture that the amateur craftsman can follow with little expense and considerable chance of success. It is not, however, generally considered as an end in itself, but as a means of decorating wood. Chip carving is a simple method of decoration. In this article the methods of dealing with carving in the round or in high relief from the simplest beginnings will be dealt with.

The beginner will be well advised to purchase tools as they are required, and, although most of the tools illustrated at Fig. 1 are essential for advanced work, there is no need to purchase them all at once. Much preliminary practice can be obtained by the use of a firmer gouge and a veiner, and with the former tool a series of cuts should be made on a piece of even-grained wood, as shown at Fig. 2. It does not matter very much what the size is, anything from $\frac{3}{8}$ in. to $\frac{3}{4}$ in. will do, but lines should be made on the wood as a guide before the cutting is commenced by the worker. The simplest cuts are made by pressing the gouge into the wood in a vertical position. The gouge is now set back $\frac{1}{8}$ in. and inclined slightly backward, this having the effect of removing a chip of wood of segmental shape. This is followed by a similar commencing cut a little farther back, with the distance of the second cut increased. Several cuts should be made thus, each time increasing the distance until it is possible to scoop out a space of 1 in. long up to the first vertical cut taken. On slowly turning the gouge round on its own curve, a circular cut can be made, and when this is accomplished the scooped cuts can be made each side, as at A and B, Fig. 2. A pattern combining the first and second methods is shown at C and D.

Wood Carving. Fig. 1. Selection of tools which are necessary to the wood carver. (Courtesy of The Manual Training Tool Co. (Sheffield))

The next stage is to cut a circular space and combine it with the cuts at D to form the patterns at E and F. The use of the veiner in conjunction with the first practised cuts enables a variety of patterns to be formed, as indicated at G. This provides an effective method of wood decoration.

Another form of pattern is shown at H, and is more difficult, but with a perfectly sharp gouge the cuts can be made quite clean. It should be noted at this stage that a considerable amount of early carved decoration was effected by the above means, and numerous examples can be seen on old chests, settles, and other furniture. Most of the cuts illustrated at Fig. 2 are done in the direction of the grain, but practice in other directions of the grain must be acquired when some confidence has been gained in the use of the gouge.

The keen edge of the tool soon becomes dull, even when working with softwood, and unless the keenness is frequently renewed it will be impossible to obtain clean cuts.

Fig. 2. Preliminary cuts with gouge and veiner, showing method of forming a simple pattern. Explanations of the lettering will be found in the text.

Owing to the extra keenness required, a leather strop or two should be provided, so that the sharpened edge can be stropped. Leather belting is useful, one piece being thick, and the other thin enough to fold so that it can conform with the inner curve of the tool.

A Simple Panel. Having become proficient in making simple gouge cuts in all directions, a simple pattern form, as at Fig. 3, may be attempted, and for this purpose a parting tool and a flat gouge will be required. The shape of the centre diamond space with the triangular corners should be drawn out first, and the work can be screwed to a small block of wood so that it can be placed in the vice. Generally the height of the bench is too low for convenient carving, and it will be convenient to make a stand with 1 in. or 1¼ in. wood.

The first stage in working out the pattern at Fig. 3 is to outline the inner parallel with a parting tool. The wood should be cut away to the centre boss with the flat gouge, and then the boss can be

shaped with the latter tool. The leaf formation is indicated with the parting tool, and with the addition of the veiner the whole of the work can be effectively done.

Wood Carving. Fig. 3. Simple panel which will give the amateur practice in the use of a flat gouge and parting tool.

Fig. 4. Cutting out ground to leave pattern.

Fig. 5. Carved panel with punched background.

It is a good plan to endeavour to do as much cutting as possible with the fewest number of tools, and if the pattern can be effectively done with the above mentioned tools much valuable practice will have been accomplished. A further example of simple carving is shown at Fig. 4. This is a spray of oak leaves with a few acorns.

The first stage after the drawing has been transferred to the wood is to cut out the background and leave the pattern standing out.

In the first place, the outline should be cut down with a vertical cut, and the waste removed with a flat gouge. It will be seen that the stalk of the lower acorn is missing. This is the result of careless outlining. In approaching a thin stalk, the first cut should be at least $\frac{1}{8}$ in. away from the required line, and the ground should be removed before the wood is cut back to the correct line. If this is omitted, it is quite possible for the gouge to slip and entirely remove all across grain stalks, or, if it does not actually cut into them, the grain may be sufficiently raised to cause them to break off in the subsequent finishing.

The leaves should be finished with a veiner, and a slight amount of modelling effected with a flat gouge. A development of this form of work is shown at Fig. 5, which is an adaptation of a piece of early wood-carved ornament. The design is quite straightforward, but a gouge or two with quicker curves should be utilized. The ground is stamped with a punch to provide a suitable finish, but this should not be overdone, as it detracts from the general effect in some kinds of work.

Bold work with broader cuts should now be attempted, and a good example is shown at Fig. 6. The wood should be of even grain about 12 in. by 9 in. or 10 in. by 7 in., and $1\frac{1}{2}$ in. thick at least. The pattern should be marked out and then cut down, leaving the pattern standing out. The first stage is to cut the inner portion down and then the top and bottom portions, leaving the two side leaves to be roughly shaped with suitable gouges and flat chisels. In work of this description each portion should

be roughed out in turn, making no attempt to obtain any finish until the general shape of the curves has been worked. A certain amount of undercutting at the top of the curves will be necessary, but the finishing of these portions should be left until the top rounded portions of the work are practically finished.

Fig. 6. Simple design for bold work.

This exercise is to gain command over the tools, and not primarily to produce a piece of ornament. The left hand should be used just as much as the right, for the latter will hold the tool and give the necessary guidance to it, but the left hand is essential for purposes of resistance. Sweeping cuts with both gouge and chisel should be practised, and considerable skill will be required to enable the tool to be stopped before the cut becomes deep and perhaps begins to pull the grain apart. This must be avoided or infinite trouble may be caused. It is in the latter that the left hand will be most helpful, and it can be taken as a general rule that the tool should never be driven forward with one hand without applying the counter-resistance of the other.

Another important point which experience will teach is not to put too much force on the tool when working in the direction of the grain, or near a delicate piece of cutting, the method being to remove the material by a series of small cuts. Another use of the exercise is in enabling the carver to give texture to the surface.

The finishing cuts on the rounds should conform to the main direction. This is not so evident in the photograph at Fig. 6, except in the sweep of the hollows, but the main idea of the finishing marks should be to convey to the eye the main form of the shape.

Wood Carving. Fig. 7. Method of using a flat gouge in shaping natural forms, such as a leaf.

Preliminary practice in the formation of curved surfaces can hardly be carried to excess. It is the best means of obtaining a command over the tools and gaining an intimate knowledge of the material. The shaping of leaves, as shown at Fig. 7, indicates a line of work which provides invaluable experience. The general method of tackling the outlining is the same as in the previous example, but the great variety of curves,

running in all directions of the grain, should provide opportunities for the use of all the tools in the suggested outfit.

In dealing with the carving of natural forms, much depends on the position of the finished work, and as the carver is limited by the grain of the wood in exactly imitating many forms, it becomes necessary to utilize the effect of light and shade. It is impossible to represent exactly any natural form in wood by means of carving tools. Some slight alteration here or there must be made to conform with the limitations of the material and with the effect of light and shade, so that the representation must be conventional. The beginner, modelling leaf and flower shapes, need not conventionalize to any extent until the difficulties of technique have been overcome. The laurel leaf, shown in Fig. 7, is capable of providing unlimited surface modelling.

In working out the shape, the first stage consists in forming the main shape and cutting away to form the background. The main direction of the curves should be roughed out with suitable gouges, and the final shaving effected with suitable flat gouges and chisels. The lightest possible touch should be used, and the tool held in complete restraint as shown. This is particularly required when approaching the edges of the leaves, and as far as possible the shape should be completed on the top surface before the undercutting is attempted. The exact position of the tool cannot be stated, as it should be changed cut by cut to conform with the direction of the grain, but in the main the fibres of the wood should be sliced.

All cuts should be made entirely with the hands directing the tool, the mallet being reserved for such work as outlining and cutting out large outer surfaces. Some very hard woods may require such pressure that is beyond hand power to perform; but, generally, if the tool is kept perfectly sharp, and small, thin cuts are made, there will be no need for mallet work.

Figs. 8 and 9. Methods of treating conventional forms. Fig. 10. Shield with low relief border carried out in a conventional design. Fig. 11. Showing the method of treating the classic form of the acanthus leaf in wood.

Where necessary the left hand should hold the chisel and continually restrain it, while the mallet is used to give a number of light taps. Nothing in the way of heavy blows should be allowed, even with the hardest woods. It is far better to attend carefully to the keenness of the cutting edges of the carving tools. The conventionalized treatment of leaf forms is shown at Fig. 8, and work of this sort makes an excellent exercise for the beginner. It will be seen that the main line of the continuous curve on which the ornament is based is retained as a fine edge, and the test of good craftsmanship lies in the ability of retaining the edge throughout. The first stage in carving the ornament is to cut out the out-line and the straight sides with a veiner, and then to work each side to the approximate depth. The beginner, unless thoroughly conversant with the formation of the leaf, should work from an actual cast, or at least a photograph of a finished piece of work. Failing this, a pencil drawing can be used if the effect of light and shade is shown.

An elaborated form of the same kind of leaf is shown at Fig. 9; it introduces animal forms treated in the more or less grotesque manner so often seen in medieval work. In this example the curvature of the leaves renders the carving much more difficult, and incidentally provides excellent practice in the control of the tools in finishing the surface.

The best method of dealing with the panel is to form the main curves without attempting to do any of the actual shaping, either on the surface or on the edges. As much of the ground as possible should be removed, keeping it flat, and in this connexion it is an advantage to use a strip of thin wood to rest across the panel from side to side, and to drive a wire nail through it, to project when filed off flat, to the required depth. This rough depth gauge can be used in all positions, and will help in obtaining an even surface. The curves leading to the tips of the serrations of the leaves should be made as flowing as possible, and although a distinct depth is necessary, it should not be overdone. The raised portions of the edges should be slightly undercut, in order to emphasize them, but generally the amount should not exceed $\frac{1}{8}$ in.

It should not be necessary in continuing the exercises in carving to use a plaster model, and, with a view of training originality of treatment, the better plan is to work from a drawing shaded with charcoal or crayon. Assistance can be gained by studying carvings in museums, and by making pencil sketches of details.

The shield at Fig. 10 is an example of finished surface modelling, and the craftsmanship involved forms a valuable training. The leaf border should be done first and carried to not more than $\frac{3}{16}$ in. deep, as the whole effect is one of low relief. The border is well filled without an excess of ornamentation, and the lowness of the relief does not detract from the shield, which is the main object.

The surface finishing of all parts should be carried out as smoothly as possible, and, however carefully the shield itself is finished and curved, with the use of scraper and possibly glass paper, the tool marks on the foliage should not be obliterated.

Decoration of Furniture. The application of carving to furniture will be the main object of the home craftsman in learning the craft, and some appreciation of the particular form required is necessary. The florid decoration of the so-called dark oak antique furniture should be avoided. Many examples of excessive carving can often be seen, and in these cases the furniture in question has been made with the idea of providing as much carving surface as possible.

The piece of furniture on which it is desired to execute carved ornamentation should be designed primarily for its correct purpose, and the carved decoration should be secondary and not prominent. Small carved panels in a framed door may be made entirely decorative, and yet, on the other hand, by the use of unsuitable designs, the eye will not be able to take in the proportions and lines of the framing, but is attracted by the weight of the decoration. It is difficult to say exactly what proportion of the space should be decorated in any article of furniture; this is a matter of training in the laws of design and the appreciation of good form, but the first essential is restraint, the second being proportion.

Many beautiful examples of wood-carving can be seen in old oak chests where the stiles and rails only are carved with a simple pattern in gouge cuts; in other chests the panels only are carved, the rails and stiles giving an idea of solidity and strength. The classic style of ornament is valued by many woodcarvers as providing a subdued form of decoration, and the example of acanthus-leaf ornamentation at Fig. 11 is a type of what can be done.

Animal and figure forms in the round should not be attempted by the amateur craftsman without some considerable preliminary work in modelling. A sculptor finds it necessary to use clay to enable him to appreciate form, and, apart from the technique of dealing with the materials, there is very little difference between the stone and wood sculptor. The stonecarver works on similar lines to the

woodcarver, and generally would be unable to tackle the figure, although a head, particularly a grotesque head, may be attempted.

Many woods are suitable for carving, but they should be of even and uniform grain, free from knots and shakes, and have been thoroughly seasoned. The grain should be as close as possible and free from strong markings. Of the softer woods more suitable to the beginner, but still useful for many forms of carving, are yellow pine, American whitewood, basswood, lime, and Kauri pine, and of these yellow pine will be found the best for preliminary work. Of slightly harder woods there are sycamore, satin walnut, beech, and holly, and of hardwoods, oak, walnut, and sometimes mahogany can be used.

It is generally easier to obtain suitably seasoned yellow pine, and if used in at least 1 in. thickness no trouble should be experienced in working it, but it is not suitable for high relief. American whitewood and basswood are good for preliminary practice, but tools require more sharpening than is necessary with yellow pine. Lime is not so easily procurable, but if it is properly sawn and thoroughly seasoned it forms an ideal material for the beginner, especially when working out such examples as shown at Fig. 3. The intermediate woods can be used for the examples given in Figs. 4 and 5.

The kind of walnut known as Italian is more suitable than the home-grown variety. Much of the walnut supplied by timber merchants is sawn so as to show the figured grain, and this is especially evident in the English wood. The grain should be as close and as straight as possible, and wood for carving must be cut from the heartwood, sapwood being distinguished by light streaks or markings. The wood is more suited to low-relief carving, but with selected specimens it is possible to obtain effective high relief.

As a rule carving should not be polished; the only treatment allowable is that of oiling or waxing, and these are used to protect the surface and not for polishing.

WOODCOCK. The season for woodcock extends from August to March. In choosing a bird press the breast and pinions; the feet, also, will be supple if the bird is fresh and in good condition, the head and throat clean and the flesh firm. The bird does not usually weigh more than 1lb. It is prepared and trussed like the snipe, with the head left on and the long beak thrust through the legs and body in place of a skewer. The pinions should always be cut off at the first joint, and the feet crossed after the legs have been secured in place. The bird is cooked undrawn and must never be overdone.

Roasting is the usual method of cooking woodcock. After trussing, brush the bird all over with oiled butter, then tie over the breast a slice of bacon, and roast from 10 to 15 min., basting frequently. Woodcocks should hang when roasting with the feet downwards, and a piece of toasted bread should be placed underneath for the purpose of catching the trails. If hanging the birds to roast is not possible let them rest on bars in a baking-tin, and in the bottom of the tin underneath the bars lay toast. The birds are served on this toast with a good brown gravy and a garnish of hot seasoned watercress and cut lemon. To carve, split the bird right in half through the centre, cutting from neck to tail, and with each portion give a piece of the toast. *See Game.*

WOODLOUSE. Because of its slaty colour the woodlouse is often called a slater. Nocturnal in habit, it feeds upon plants and seedlings and may do considerable damage.

When its presence is suspected all rubbish and crevices of dry wood should be searched in the neighbourhood of the plants affected, and if necessary treated with boiling water. Traps may be prepared with hay-filled flower pots, the sides being smeared with treacle.

Borax or beetle poison may be used, and there are also proprietary preparations.

WOODRUFF. This is a pretty low growing plant which spreads very quickly and is suitable for planting in odd corners, whether shady or sunny. It becomes smothered in small white flowers Woodruff, in spring, and if planted with forget-me-nots provides a charming display. It should not be set among choice plants owing to the rapidity with which it spreads. Any little rooted piece pulled off and replanted will grow. Its botanical name is *Asperula odorata*; the leaves have a haylike scent when dry. The blue woodruff (*Asperula azurea*) is a hardy annual 9 in. high with pale blue flowers in summer; seeds are sown out of doors in spring. *Asperula suberosa*, with greyish leaves and pink flowers, is a charming little spring flowering plant, excellent for the rock garden, where it should be set in very gritty soil.

Woodruff. Fragrant clumps of the pink Asperula suberosa, a favourite spring flowering rockery plant.

WOODSIA. The hardy kinds of this fern require a leafy or peaty soil, and a position in shady borders or banks. Greenhouse species are best grown in pots of peat, loam and silver sand. The plants should be placed in a shaded position, and watered freely from March till October. The maximum height of the plants is about 12 in. The hardy sorts are all suitable for greenhouse cultivation. Propagation is by division. *See Fern.*

WOOD SORREL. This is a pretty, low growing plant suitable for the rock garden and for sunny corners. One of them (*Oxalis acetosella*), which grows wild in woods in Britain, bears white flowers in spring and is suitable for planting in the rock garden. It is however, less attractive than two kinds from the Falkland Islands, *adenophylla* and *eneaphylla*, which have grey leaves, and pink and blush-coloured blooms respectively, and thrive in a compost of sandy loam and leaf-mould among the rocks. A popular wood sorrel which is often seen in cottage gardens is that known as *Corniculata rubra*. It is a low growing spreading plant with copper coloured leaves and yellow flowers. The wood sorrel is propagated by division during the spring.

WOOD TURNING FOR THE BEGINNER

The Use of the Tools and the Results Produced

The important operation of Turning is described in this work under two main headings, each corresponding to one of its branches. Thus the manipulation of metal is dealt with in the article Metal Turning. See also Lathe; Mandrel, and the many articles that describe items of furniture, etc., the component members of which are turned, e.g. Candlestick; Chair; Table.

Wood turning consists chiefly in fashioning wood to circular shapes by devolving it in a lathe and applying cutting tools to the surface. It has many and varied applications in the home, being the only practical method of producing chair and table legs, little columns with turned bases, candlesticks and a host of other articles which are circular in section.

The amateur should commence by practising on such material as boxwood or beech. To avoid accidents he must always see that the material is properly fixed in the lathe, so that there is no risk of its flying out. He should hold the tool firmly, and bring it near the revolving wood with caution. The turning tools are provided with a long handle very securely attached to the shank. They must be kept absolutely keen and sharp. A blunt tool is a danger.

A gouge, chisel, and V-point or veiner are the principal tools required. A gouge about $\frac{5}{8}$ in. wide is suitable, although it is an advantage to have one rather smaller, and also a thicker one. The gouges are ground on the outside of the curved part. The cutting end of the chisel is inclined and the edge comes in the middle of the thickness of the blade, both sides being ground off to a taper and sharpened on an oilstone. The veiner or parting-off tool is V-pointed and ground and sharpened on the outside of the V.

Using the Gouge. The method of holding the gouge is illustrated in Fig. 1, the blade being grasped in the left hand near to the cutting end of the tool. The outer part of the first finger of the left hand is pressed against the back of the T-rest, while the fingers of the left hand hold the gouge firmly to the top of the rest. The right hand grasps and manipulates the handle. To use the gouge, the piece of work is first fixed and the lathe started.

Wood Turning. Fig. 1. Correct way to hold the gouge. Fig. 2. Gouge shown cutting off high spots or corners of the rough material. Fig. 3. Working downward in order to avoid splitting the grain. Fig. 4. Applying scratch gauge to show points where hollows or curves are to be turned. Fig. 5. Turning a concave surface. Fig. 6. Parting off with chisel held vertically. Fig. 7. Hollowing a bowl.

WOOD: DISTINCTIVE COLOURS AND MARKINGS OF VARIOUS KINDS

 see under heading Wood.

It is necessary to remember that as the wood revolves it appears to the eye to be solid and circular, but as a matter of fact it will be more or less square and running out of truth. Consequently, by approaching the gouge to the imaginary face of the material, it will, in fact, only cut off the high spots or corners, as in Fig. 2, and it is at this stage that the utmost care must be exercised. The tool should be pointed towards the work and held with the blade pointing at a small angle towards the headstock. A peculiar half-twist is given to the blade directly it commences its cut, and the tool is traversed bodily towards the headstock, taking care to maintain full control over its movements.

It is usual to terminate the cut at some distance from the chuck or face plate, except in those cases where the end of the wood is overhanging and there will be no risk of the tool catching up on the chuck. The same operation is repeated with the same caution until the general diameter of the material has been reduced to its proper size, when it will be circular in section and more or less cylindrical in shape from end to end. From this stage the pattern of the object can be turned.

Turning with the Grain. To ensure turning with the grain of the wood, always work downward, as in Fig. 3, traversing the tool from the larger diameter towards the smaller. When the material has been reduced to a cylindrical shape it may be smoothed with a chisel. This should be held in the same way as the gouge, but the left thumb should be interposed between the underside of the chisel blade and the upper surface of the T-rest, so that the part of the chisel which will actually cut the wood is about the middle part of the cutting edge. The chisel is traversed along the work in a similar manner to the gouge.

The shavings soon tell whether the chisel is cutting properly or not. They should come away clean cut, and not look as if they had been scraped or rubbed off. In the latter event, it is almost certain that the tool is not sufficiently sharp, that the speed of rotation is not high enough, or the tool itself is not being held in the proper manner. Quite slight variations in the position will make a big difference in the turning.

Supposing that the work is comparatively long and slender—for example, a small leg for a footstool—a good plan is to prepare a full-size drawing of the desired shape. Then take a lath of wood and drive sharp-pointed nails through it at those places where the shape of the object changes. When this is applied to the revolving cylinder the points of the nails scratch a series of rings, as in Fig. 4, which indicate the points where hollows or curves are to be turned. In order to turn a hollow, as in Fig. 5, the gouge is used first from one side towards the valley and then from the other side; working downward, and compelling the cutting edge of the gouge to describe an arc of the circle or follow a curved part by moving the handle of the tool sideways while resting the major portion of the weight on the hand rest. Flats are usually shaped with a chisel, and part's at right angles to the axis of rotation by holding the chisel with its narrow edge resting on the hand rest, as in Fig. 6. The breadth of the blade is vertical, the cutting edge thus inclining backward. It has to be worked very carefully, and a little cut made on each side of the valley so that the tool will not jam in the grooves. Fine lines and beadings are often turned with the point of the chisel.

If it is desired to turn to dimensions, calipers should be used in the ordinary way. It is assumed that the work is mounted between centres on the usual prong or fork centre or on a small face plate with a taper screw centre, screwing it to the latter or driving it on to the prong chuck with a few strokes of a mallet. The opposite end is then supported with the point centre of the tailstock, the latter being forced into the end grain of the wood and locked firmly in that position. When a piece of flat material is to be turned into a disk to form a base or support, the best method is to secure it by screws to a suitable metal face plate, which screws on to the mandrel nose. A similar mode of chucking can be used for various sorts of bowls and similar work.

Internal work is carried out in much the same manner as external wood turning. With a small bowl, for example, such as that illustrated in Fig. 7, the best plan is to turn up the centre first and work

outward. The testing of the size of the work is accomplished by the use of inside calipers, but with intricate or important shapes a simple template may be used and applied to the work from time to time (Fig. 8), as a check to the eye. The work should be finished with glass paper, a small piece being grasped between the finger and thumb and worked over the curved surfaces, as in Fig. 9. In the case of flat work the paper should be wrapped around a flat wooden block or rubber and used with a slight forward and backward motion while the work is being rotated at the highest possible speed. When designing parts to be turned, and it is necessary to join two or more pieces together, the best plan to ensure keeping them all in line is to turn a small projecting peg on the end of one part, and to bore a similar sized hole centrally in the other part. This will serve to centre both parts and keep them in their proper relative axial line.

Wood Turning. Fig. 8. Use of template consisting of a piece of card or zinc cut to the correct profile. Fig. 9. Smoothing the work with glass paper before the final operation of polishing.

Choice of Lathe. The article on Lathe discusses the principles governing the design and construction of this appliance, as modified by the specific purpose for which it is intended.

The main considerations in a lathe for wood turning are a good headstock with bearings suitable for prolonged working at high speeds, an adjustable tailstock, and a suitable rest for the turning tools.

Fig. 10. Example of a simple lathe, suitable for the amateur woodworker. (Courtesy of J. Sagar & Co., Ltd.)

An example is given in Fig. 10. The bed, which is flat topped, is accurately machined and bolted to two massive supports. On the left is the headstock, which is bolted to the bed by plates passing underneath. The spindle is fitted with a four-speed cone pulley for flat belt drive. Bearings of heavy phosphor bronze are used, adjustable for wear, while lubricators are attached. The hand rest is adjustable in every direction, and can be fixed in any position along the whole length of the bed. The T portion is sufficiently long to allow of a good sweep of the turning tool. The tailstock is of the pattern fitted to many metal turning lathes. It is adjustable as regards disposition along the bed, and has a spindle capable of adjustment by the hand wheel provided. A locking screw is also fitted. The chucks enable all classes of wood turning to be accomplished. In the main, most chucks consist of a flat disk or plate, to the centre of which is attached a steel wood screw. The chucks screw on to the mandrel nose, as is usual.

Such lathes may be driven by treadle or power, and with the latter a countershaft of the type illustrated is necessary. This is fitted with a fast and loose pulley mechanism, and a cone pulley similar to that on the lathe itself. The countershaft should be arranged on staging above the lathe, and the belt should be inclined away from the operator. The striking gear will normally come with its handle or chain within easy reach of the operator's hands thus making his task easier.

Woodworm. *See* Worm.

WOOL. There are numerous grades of wool, but, generally speaking, it comes under two great divisions, merino and cross-bred. The merino sheep is bred in Australia chiefly for its wool, while the crossbred sheep is largely bred in New Zealand, partly for its fleece and partly for its carcass. The two different kinds of yarn produced from wool are known as woollen and worsted, and, generally speaking, all woven goods made from wool come under one of these two classes. For woollen cloths the yarn is not so fine, strong or elastic as for worsteds, which require the longest fibres of wool spun into smooth yarn. Melton and pilot cloths, saxonies, tweeds, cheviots and blankets are examples of woollen piece goods, while worsteds include Botany serges, suitings, gabardines, Bedford cords and hopsacks.

For some yarns hair is used in combination with worsteds, as, for instance, camel's hair, goat's hair and alpaca. Owing to the greater length of fibre in the formation of worsted yarns, worsted fabrics wash better than woollens. The latter have a tendency to felt, and bleaching powders should not be used, as they eventually dissolve the yarn.

Knitting wool bought in skeins is best left in that form until wanted. When winding it into balls the thread should not be wound too tight. The softer kinds of wool are warmest in wear, but the harder sorts of worsted yarns last longer and shrink less. Three-ply and four-ply wools are bulkier than two-ply.

Mending wools may be bought by the skein or on cards. Special wools are sold for tapestry needlework. Berlin wools are a softer, coarser kind. Very durable and heavy wools are manufactured for rug-making. *See* Crochet; Knitting; Rug; Shawl; Stocking, etc.

Woolly Aphis. *See* American Blight.

WOOLWORK AND WOOL EMBROIDERY

Quick and Effective Methods in Ornamental Needlecraft

This article deals chiefly with pictorial and conventional designs worked in wools on linen fabrics.

Solid embroidery on canvas is dealt with in the contribution on Tapestry Needlework, and other special forms of woolwork are described under the headings Croche ; Knitting; Rug. *See also* Appliqué Work; Embroidery; Laid Work; Needlework Picture.

Used in its broader sense, the term woolwork includes all work done with wool yarn and needles, or special hooks, from darning and knitting to crochet and knotted rug-making. In particular it is applied to pictorial designs and needlework pictures carried out partly or wholly in coloured wools.

The term wool embroidery is also a broad one, covering any decorative stitchery in wools, but in particular the term is employed for fancy work in which naturalistic or conventional designs are partially embroidered in wools leaving portions of the background fabric exposed.

Woolwork pictures as carried out in the 17th and 18th centuries would be too tedious for most needlewomen of to-day, although smaller pictorial designs are still exquisitely worked in petit point for bags.

Materials and Designs. Very effective woolwork or embroidery can, however, be quickly achieved on rather coarse linen, coloured or of an unbleached shade, using skeins of tapestry wools, or penny balls of embroidery wools with crewel needles.

Woolwork. Fig. 1. Pictorial design of polyanthus grouped in a bowl worked in natural colours on grey linen.

An embroidery frame will be needed by most workers for a solid pictorial design such as that illustrated in Fig. 1, which could be charmingly adapted and worked in natural colours on linen for a cushion, screen or blotter panel, or framed and glazed for wall decoration. An embroidery frame consisting of two wooden hoops would be a suitable one on which to work a panel of small size, but if the panel is a large one the regulation embroidery frame with rollers, on which the work can be evenly stretched, will be needed. For work of less solid design, a frame is not necessary, but to prevent puckering a good method is to pass the needle up and down through the embroidery as if on a frame.

A great variety of transfer designs can be bought either for flowers, figure or geometrical embroidery or many different ideas can be utilized. Flower, bird, animal or Japanese prints can be traced and transferred by means of carbon paper to the material to be embroidered.

Interesting conventional designs can be worked out by pencilling the outlines or coins to mark rounds for flowers and evenly spacing a number of these on a piece of paper the size of the work, then transferring the drawing to the material.

Larger flowers can be worked in buttonhole stitch with an inner ring of chain stitch and centre of French knots. Smaller ones in lazy-daisy stitch and rose stitch. The intervening spaces can be filled in with trellis (q.v.) stitch, or with diamond or diaper stitch. Instead of working these designs all over a cushion, bedspread or duchesse set, they may be enclosed in a circle made by drawing round a plate of the size required and outlining the edge of the circle with chain stitch in black wool bordered with back stitch. The rest of the work can be speedily carried out in Berlin wools in Victorian shades of bright blue, grass green, magenta and foxglove pink, and can be done on felt or hessian, crash, rattine or linen.

Fig. 2. Details for working flowers and leaves. The flower on the right is embroidered in satin stitch, that on the left partly in long and short stitch and partly in satin stitch.

Most of the stitches used for woolwork are given in the page of stitches illustrated in the article on Embroidery. When starting a piece of work it is a good plan to select

the stitches which will be most useful for the various portions of the design. Fig. 2 shows the stitches which may be used for the polyanthus flowers and leaves in Fig. 1. The flower on the right can be worked in satin stitch, as shown, and then outlined in back stitch; that on the left in long and short stitch on the outer portion of the petals, and with satin stitch in different shades for the inner portion and centre. The leaves can also be worked in satin stitch, with the veins in stem stitch, back stitch or crewel stitch, in a darker shade of green. The bowl may be outlined in crewel stitch with one or two lines of shading. Each group of flowers is worked in one of two ways; a glance at Fig. 1 will show which method is applied to each.

Fig. 3. Corner design in Jacobean style suitable for cushion, bedspread, or other square piece of house-linen.

Jacobean Designs. A big selection of effective designs are obtainable in which conventional flower, leaf and fruit forms are partially worked with tapestry wools in solid embroidery, and partially with outlining and light filling stitches. These designs are copied and adapted from old Jacobean needlework. Fig. 3 shows a typical corner piece of such conventional form for a cushion or runner, while Fig. 4 gives the outlines to be transferred, tilling stitches being left to the taste of the worker. Suitable transfers are obtainable for cosies and other accessories in this style of embroidery.

Fig. 4. Design enlarged. By omitting the left-hand spray an effective medallion is obtained.

Jacobean designs are worked in strong colours, but not too brilliant in tone, as they should look mellowed by age. The large leaf at lower corner of design is first worked in green chain stitch and a greenish-blue outline stitch just outside the chain stitch. The veining and stem of leaf, fruit, and flower are all worked in old

gold and brown stem stitch. The small leaf to the right is filled in with two rows of green herringbone stitch, the stitches lengthening towards the centre of leaf and tapering at point. The sprays of grass at each side of the design are represented by fish-bone stitch, and the round dots are covered with satin stitch, with an outline of black back stitches. The large centre blossom has the four-pointed petals worked in long and short stitch in deep crimson round the tip and a rose-red below. The other four petals are worked in two shades of greenish-blue sloping satin stitch, dark blue at the centre of each leaf and medium blue buttonhole stitch all round, with the stitches about

one-eighth of an inch apart. The centre has a cluster of dark-red French knots surrounded with two rows of black chain stitch set square. The solid work at the base of the fruit is carried out in two medium shades of red long and short stitch, while the sides are buttonholed and the centre filled in with a couched pattern, such as diamond couching or diaper couching, and in each little division is a French knot. The shades of red used should be intermediate between the crimson and rose-red of the flower petals. The three leaves at top of left-hand fruit are worked in outline stitch, while the right-hand one has the leaves in chain stitch, with fish-bone on the centre veining.

Wool embroidery may be used to ornament woven raffia table-mats or on raffia cloth. Small electric light shades or shields made of linen stretched on wire frames suitable for wall brackets can also be decorated in wool. Care should be taken that the stitchery is neat on the reverse side. Directions for making-up are given under Lampshade.

WORCESTER CHINA. Both useful and decorative porcelain has been produced at Worcester continuously since the middle of the 18th century. Although china figures are virtually absent from the range of early Worcester, the number of the patterns of tea and coffee services and other useful pieces far exceeded that of any contemporary factory in England. In recent years figures and vases have predominated.

The dominant mark until 1793 was the crescent, although down to 1783 many pieces bore a cursive W, and others a square mark, some pseudo-Chinese devices, and even the Dresden crossed-swords. The square mark frequently appears on spurious blue-scale Worcester. The second period is mostly recognizable by the initials or names of the Flights and Barrs, with a crown after 1788. The words Chamberlain's, Worcester, with various devices, serve to identify that factory's output. Grainger used G & Co. in a shield, with Royal China Works, Worcester. The company mark is a crowned circlet enclosing a central crescent or C surrounded by four W's.

Worcester China. Coffee cup and saucer painted with Watteau figure-subjects, exotic birds, and insects in colours in shaped panels. (Courtesy of Law. Foulsham & Cole. Ltd.)

Wall's copies of Chinese blue-and-white, as well as his egg-shell, were supreme. The mugs had vertical sides, and the early cups usually no handles. Caughley mugs in imitation of Worcester, with a C simulating the crescent mark, are recognizable by having splayed instead of straight bases.

Vases and jugs with scale-blue grounds have been prized at all times. Hancock's line-engraved prints, which reached their highest level when done on Worcester bodies, were often signed by him, but have no factory mark.

The latter part of the first period coincided with the arrival of artists from Chelsea, and the adoption of marone, canary, apple-green and other grounds, with panels of exotic flowers and birds, or Watteau scenes. There were also wild roses in relief on white, and open-work borders. This early ware usually contained steatite in the body, and appears greenish when held to the light. The standard English bone porcelain was not established at Worcester until after the year 1840. *See China.*

WORK BASKET AND BOX. Obtainable in a large variety of shapes and prices, work baskets are made in osier, cane, plaited rush and raffia. Generally they are fitted with the necessary articles used for plain needlework; these are attached directly to the lining, which is provided with pockets to hold cottons, etc.

The large wooden work box fitted with trays and compartments is less in use to-day than some form of work basket or a work table, which is really a work box on legs. Another type of work box which is useful in a sitting-room is the fitted box pouffe with a strip for holding scissors, etc., and a pincushion attached to the lining of the lid and pockets for reels, skeins of silk and other accessories in the lower part.

In the 18th century a great deal of care and time was spent in producing beautiful work-boxes, and some examples of that period are very fine pieces of craftsmanship. Their beauty was enhanced by the costly woods used for them. Work tables were also made with a receptacle in the shape of a bag under them for holding materials. Such tables were designed by Sheraton and others and were known as pouch tables.

Work Box in wood, covered with red morocco, with gilt brass mounts. Early 19th century. (By permission of the Director, Victoria & Albert Museum. S. Kensington)

Our illustration shows a work box made in the early part of the 19th century. It is of wood covered with red morocco and fitted with

brass mounts and feet. Some of these antique work boxes are of wood with glass tops surrounded by metal mounts and lined with quilted satin.

A Woven Work Basket. A circular basket can be made with round cane and raffia, after the manner of Indian basketry, by forming a circular mat, building up the sides and attaching a cover similarly made to the bottom. The method is illustrated in Fig. 1, the materials used being ordinary round cane, plain or coloured raffia, and a needle having a long eye to take the raffia. The bottom is commenced by forming a small spiral with the tapered end of a length of cane, tying the cane together as the sides join. Two complete rounds are formed, and then the work is continued, as in Fig. 2, by threading the raffia first round the cane and then carrying it across the cane adjoining, and between it and the one beyond it nearer the centre.

Fig. 3 shows the third round completed, and the commencement of the fourth round. As the work progresses it is necessary to bind the raffia twice round the cane in order to cover it in the spaces between the connecting stitches, which should not be too far apart. Having completed a flat circular mat of the desired size, say 8 in. to 10 in., for the bottom of the work basket, the cane is continued, but it is placed on the top of the outside ring instead of on the sides, and continued in the same way, each round being placed on the top of the one below to form the sides of the basket, as in Fig. 4.

Having reached the required height, from 4 in. to 6 in., the cane should be sliced to a long taper and gradually worked out so that the top of the sides is flat. A lid is made in the same way as the bottom, and, when the diameter is sufficiently large to fit on top of the sides and slightly overlap them, the end of the cane is tapered and finished off, the raffia being continued for a complete round to give a neat and strong edge. A raffia-covered ring or bunch of raffia flowers for a handle, or one after the

style illustrated on the raffia cosy, is secured to the top of the lid, which can be hinged with raffia to the side. The inside of the basket should be lined and padded; if the exterior is to be varnished this should be done before the interior is fitted. The lining may be of silk or a good printed sateen over a layer of wadding. Separate pockets may be added for reels, tapes, needles and buttons.

Wool embroidery can be effectively used to ornament the cheap rush baskets sold for shopping bags. The handle is removed and the basket, when embroidered, is lined with sateen, allowing sufficient depth of material to draw up into bag shape at the top after a slot has been made in the sateen to take a ribbon or cord. Buttonhole the lining to the top of the rush basket to keep both together neatly. Any bold flower design may be worked effectively in bright, rather coarse wools.

A rush or cane waste paper basket makes an excellent mending basket, lined in the same way with a bag top and trimmed with raffia flowers, wool embroidery or appliqué of linen, felt or cretonne flowers. *See Mending; Needlework; Osier; Raffia Work; Rush Work; Scissors; Woolwork.*

WORKMEN'S COMPENSATION. All householders should insure against liability to pay workmen's compensation to servants. The term servants includes not only those who are employed permanently in and about the household, but also anyone who has regular engagement, e.g. the washerwoman who comes once a week. There is no liability towards a merely casual person employed otherwise than in the way of the employer's trade.

The amount of compensation payable depends upon the remuneration of the servant. Tips and any board supplied are taken into account. The compensation is 50 per cent of the remuneration for total incapacity with a maximum of 30s. a week, and a smaller sum fixed either by agreement or by the county court judge for partial incapacity; but there are certain percentages which are to be added in the case of both total and partial incapacity where the half wages do not amount to 25s. a week. If a servant is injured or makes a claim for compensation, the employer should at once forward it to the insurance company, and should take great care not to make any admissions which can be used by the servant in support of his or her case should it come into court. *See Employers' Liability.*

WORKSHOP. The home worker may be confronted with the problem of finding a place wherein he can do his work with some measure of convenience. He will need a shed or room where he can work at odd moments and, more important still, where his partly completed job can be left in safety. A bench is a necessity, and unless one of the collapsible structures is used, this demands a room or building set aside for its accommodation. Work which has been glued up must be left to set and

harden in a place where it will not be interfered with, or be subject to chance knocks. Tools must be housed where they are out of the way of children.

Of course, a sectional building of some sort, as illustrated under the heading Shed, can be purchased, but the home worker will derive pleasure, experience and profit from making his own workshop. Those who decide to follow this latter course could well use a lean-to construction, built into the corner of two walls, as illustrated and described.

Much helpful information about the framing, joints, etc., will be found in such other articles of our Encyclopedia as Garage; Roof; etc., and, of course, the appropriate woodworking contributions can be referred to.

WORM: In Furniture. Old furniture is very liable to attack by the woodworm, a tiny insect that burrows into the material. Beech, birch and walnut are, perhaps, the most liable to attack, but it is also found in mahogany and other hardwoods.

A good remedy for the worm is a 40 per cent solution of formalin injected into the holes with a small glass syringe. Paraffin is also used and there are a number of patent preparations. Another remedy is to swab the worm-eaten wood with perchloride of mercury or corrosive sublimate. This deadly poison must not be allowed to come into contact with the skin. Other remedies include alternative applications of carbolic acid and paraffin applied to the backs of wardrobes, the insides of chests of drawers, and other places where any ill effects from the acid will not be noticed. Another recommended remedy is paraffin and thymol.

Fumigation is another preventive method. Carbon bisulphide is a good fumigant. One way of using this, only suitable, however, for small pieces, is to make an airtight box, to put the article inside this, and to leave it exposed to the fumes for two or three days. The whole surface of the piece is then painted over with a solution of sodium arsenate, a poison which prevents the insects from entering again.

Large pieces of furniture, such as sideboards and wardrobes, can be fumigated inside a tent made of closely woven cotton sheeting, the porousness of which can be reduced by applying to it a linseed oil varnish. *See Furniture Beetle.*

WORM: In the Garden. Worms do good by aerating the soil of garden beds and borders, and their presence should be regarded as beneficial. On lawns, however, their casts are a nuisance, disfiguring the grass and giving it a dull, muddy appearance. They can be destroyed by purchasing a worm killer powder from seedsmen.

WORMS: In Human Beings. A great variety of worms infest human beings and domestic and other animals, as well as birds.

Intestinal worms are found in children far more frequently than in adults, and especially in weakly children. Parasitic worms come from many sources; thus one species of tapeworm is swallowed in measly pork.

For the prevention of worm infestation, people should avoid underdone or raw meat, water whose purity is doubtful, and raw vegetables, particularly watercress, unless beyond suspicion. Intestinal worms are got rid of by means of vermicide drugs, such as oil of male fern and santonin.

WORMWOOD. This is an attractive herbaceous plant or small shrub which has fragrant foliage. It prefers light soil and a sunny place. The favourite kind is the southernwood or Old Man (*Artemisia abrotanum*), 2-3 ft. high, with grey, scented leaves and yellow flowers in summer; it is a common plant in cottage gardens. *Artemisia absinthium* is the wormwood and *dracunculoides* is the tarragon. *Lactiflora* is an excellent plant for the herbaceous border; it grows 4-5 ft. high and bears cream-

white flowers in September. *Stelleriana*, which has grey-white leaves and yellow flowers, is a trailing plant suitable for the rock garden.

Worsted. *See* Wool.

Wound. *See* Antiseptic; Bandage; Bleeding; Cut; Dressing; First Aid; Shock; Tourniquet.

WREATH. Funeral or commemoration wreaths are composed generally of natural flowers and foliage. Occasionally everlasting flowers are used, or a mixture of artificial flowers such as Flanders poppies with evergreens, or a wreath is carried out in porcelain. A special wire foundation is used in the making of floral wreaths. It is packed with moss, and the flowers are secured through this to the framework by means of stub wires, which pierce the blossoms.

A withered wreath may be renewed by removing flowers and moss, packing the framework with fresh moss over which trails of evergreens may be secured with fine reel wire. On one side a bunch of flowers and foliage can be arranged. If flowers with firm stalks, such as daffodils, hyacinths, carnations, or chrysanthemums, are chosen stub wiring will not be needed. The bouquet can be arranged and secured to the wreath with wire. Sometimes a bow of ribbon is used to finish off the wreath, or to add a touch of colour to a laurel or palm wreath. The latter are sometimes silvered with metallic paint.

An Easter commemoration wreath may be made on a stout wire ring, bound round with strips of green crêpe paper to which palm leaves are wired; a trimming is provided by a bunch of flowering willow, fir cones on twigs, and purple ribbon artistically arranged. Christmas wreaths of holly can be made in the same manner and completed by bunches of mistletoe and scarlet ribbon.

Wreath designs are popular in all forms of decorative art. Success depends on a sense of balance and colour. Wreaths are composed of every kind of artificial flower, leaves and many fruits; and are carried out in appliqué, leather, raffia, ribbon, barbola and woolwork.

Wrench. Fig. 1. Tap wrench. Fig. 2. Pipe wrench. Fig. 3. Monkey wrench, adjustable to nuts of all sizes.

WRENCH. The form of lever known as a wrench is made in many patterns. The screw wrench or adjustable spanner employed to turn a nut on a bolt varies in size from 8 in. to 18 in. and upward, and is either made entirely of steel or fitted with a wooden handle.

Pipe wrenches are made in several forms, the simplest being similar to a flat spanner, but

provided with a V-shaped opening with it is a common serrated edges. For heavy work the form in general use is composed of a stout handle with a curved and serrated end, to which is attached a movable clip of circular form. Similar wrenches are made for use with large tubing.

Tap wrenches for operating screw taps are generally provided with two square holes; the smaller sizes have holes differing by $\frac{1}{10}$ in., and the larger ones by $\frac{1}{8}$ in., and in some cases there are four holes varying in size. There is also an adjustable form in which a pinching screw is turned to close up the aperture and grip the shank of the tap in use. *See* Nut; Pipe; Spanner; Stocks and Dies.

WRINGER. This is an instrument made for forcing water out of wet clothes during laundering operations. It is practically the same as the one known as the mangle, although, strictly speaking, there are slight differences between the two.

The wringer proper does not roll out the garments or articles washed, as the mangle does. There are combined wringers and mangles obtainable, and also washing machines with wringers attached.

Wringer. Combined table and rubber wringer. The resilient rollers squeeze out moisture efficiently, and at the same time break no buttons or fasteners. (Ewbank Rubber Wringer and Table)

Rollers of rubber are desirable, one advantage of this material being that it is less likely than wood to break the buttons of the garments. A model of the type illustrated is easy to use for heavy washing, being perfectly rigid and at the same time constructed to deal gently with light articles. It is convertible into a table.

A smaller type of rubber wringer is manufactured which can be kept on a shelf. A patent reversible drain keeps all water from the floor, and the machine possesses an attachment which converts it into a table mangle. Special fittings are made for sink, draining board and bath. Large wringers, like mangles, can be driven electrically. This saving of labour is often economically justified where there is a great deal of home laundering. A wringer, whether electrically or hand operated, not only saves time and labour, but also wrings out the moisture more effectively than could be done without its aid, and thus enables the clothes to dry more quickly. Wringers need no special care to keep them in good condition, but, to avoid straining the rollers, thick materials should be folded only once or twice before passing through. *See Laundry; Mangle; Washer.*

WRIST. The carpus, or wrist, connecting the hand and forearm, contains eight small bones, called the carpal bones, which above form joints with the lower ends of the two forearm bones, the radius and ulna, and below with the five metacarpal bones. The wrist joint is capable of a wide range of movement, and from its position and structure is very liable to sprains. In Colles fracture (q.v.) the whole wrist is more or less dislocated backward.

Dropped Wrist. Loss of power in the muscles at the back of the forearm is the cause of dropped wrist; it may follow any injury to the musculo-spinal nerve which supplies the muscles. It may also be due to the pressure of the head of a crutch. Treatment is by support, massage, electricity, etc.

WRITING DESK AND TABLE. The name writing desk is employed sometimes as if synonymous with writing table. The differences between the two, although these are now somewhat obliterated, are that the desk is a sloping piece of furniture, while the table is not, and that the desk is also a receptacle.

The early writing desk was just a plain piece of carpentry made to slope towards the writer and to stand on the top of a table. It was therefore portable, but lost this advantage when someone formed the idea of fitting legs to it and so making it the writing desk of modern times. The space beneath the top was utilized as a receptacle for papers, and the desk was also a box; the expression desk box was sometimes used.

In time desks became more elaborate, and some are fine examples of the cabinet maker's art. A beautiful specimen of what may be called the writing desk proper is illustrated in Fig. 1. Made of oak early in the 17th century, it is notable for its magnificent carving.

Writing Desk and Table. Fig. 1. Writing desk in carved oak, dating from the 17th century. Fig. 2. Beautiful Hepplewhite writing table in mahogany, with tambour top. (Fig. 1, by permission of the Director, Victoria and Albert Museum. S. Kensington)

Tables specially designed for writing have been made for centuries in the form of an ordinary table of medium size with drawers or additions for requisites.

The first writing tables had a drawer or two in the underframing, and the tops were covered with a coarsely woven cloth known as bure in France. This was something like a baize and was at first blue in colour but afterwards green. From the word bure developed the word bureau. Morocco was employed for covering the tops of writing tables in the 17th century.

Beautiful kneehole tables were made of walnut early in the 18th century, and other writing tables were decorated in Chinese lacquer. An example of the latter is illustrated in the article on William and Mary Style. From the kneehole table developed the pedestal writing table. Such tables were designed by William Kent, and came into general use about 1735 and onwards for libraries. They were enriched by carving, sometimes by gilding and intended for a central position in the room. In some cases the pedestals on which the table portion rests are panelled as drawers, but actually open as cupboards.

Writing tables of the pedestal type were made by Chippendale. Sometimes their angles were rounded and occasionally they had serpentine fronts. In elaborate examples engaged columns are seen at the angles. Hepplewhite made writing tables on the lines of the roll-top desk. An example of his work is illustrated in Fig. 2, notable both for the elegance of its line and its compact usefulness. Known as tambour writing tables, these were fitted with a sliding shutter to slip down when the article was out of use. Inlaid satinwood was much used for small writing tables of this period, some of these being made with folding tops and fitted with drawers underneath, while others are circular with a hinged drawer that swings out and contains writing materials.

Tambour writing tables continued to be in fashion during the Regency period, made in rosewood with ormolu mounts. Other early 19th century tables were also of rosewood, with bronzed legs and leather tops, sometimes brass rimmed and with mouldings of gilt wood.

To-day good writing tables are leather topped and made of mahogany, walnut, sycamore, weathered oak, and lacquered woods. Some are decorated with carving, while others have cross-banded fronts. Convenient sizes are 3 ft. and 4 ft. long. *See Bureau; Davenport Table; Study.*

WRITING DESK SET. Accessories for the writing desk or table are more likely to add a decorative finishing touch to a room when chosen as a set than when selected as odd pieces without relation to each other or to their surroundings. Sets may be comprised of a blotter, inkstand, pen tray and notepaper rack, or they may also include one or a pair of candlesticks, paper-weight, ash tray and waste paper basket. If the telephone stands on the desk a screen and pad might be added. Sometimes there is a combined fountain pen stand and ash tray.

Writing Desk Set. Fig. 1. Set decorated in modern lacquer work, adapted from an old Indian design in delicate colouring.

The various types of writing table will suggest certain styles of accessories. Coloured glass, in an amber or green shade, looks particularly well on a walnut or mahogany table, for such details as pen and ash trays, candle-sticks and inkstands in combination with lacquered wood for the stationery rack and blotter cover.

Gesso and barbola work on gilded or silvered whitewood articles would be most attractive in

a prettily furnished sitting-room, while leather in a bright or rich colour would be suitable for most of the articles on a man's desk, with attractive ash tray and ink or pen stand in modern style of marble or in metal.

A whitewood set painted in soft colouring, and adapting an old Cashmere design, is illustrated in Fig. 1, and executed in poster colours on a brush lacquer foundation.

Writing Desk Set. Fig. 2. Inexpensive accessories covered in imitation parchment which can be bought ready for painting or ornamenting by means of coloured prints.

Fig. 2 shows a group of inexpensive accessories ready for painting, which can be bought covered with imitation parchment and decorated with coloured prints, with stencilled designs, or by painting them with waterproof inks, which can be bought cheaply and used as described for parchment shades in the article on Lampshade. When decorated the accessories should be varnished with clear white

varnish. If these imitation parchment articles seem too greasy to be easily painted, this can be remedied by rubbing the surface with tissue paper and also by stroking the paintbrush lightly on a piece of damp yellow soap before dipping the brush into the ink. *See Gesso; Lacquer Work; Lampshade; Leather; Stencilling; Telephone Cover; Waste Paper Basket.*

WROUGHT IRON WORK

The Making of Articles both Decorative and Useful

Other metal working processes are dealt with in our work under the headings Bent Iron Work; Metal Work; Silver Work; Tinplate. See further the entries on the associated processes employed, e.g. Brazing; Drilling; Forging; Riveting; Soldering

The manipulation of iron in bar and sheet to make objects of utility and beauty has been superseded by cast iron and machine presswork to a considerable degree. Generally wrought iron work requires the provision of a forge and an anvil as well as a vice, together with suitable hammers, tongs, pliers, and other tools belonging to the metal-worker. Information about forging, together with details of the construction of a simple portable forge, is given in the article Forge.

The particular processes in the manipulation and treatment of wrought iron are forging, welding, flattening, upsetting, bending, embossing, impressing, and punching. Forging is done when the iron is heated to a bright red. Welding consists in forging two separate pieces into one when the iron is at white heat. The parts to be joined are cleaned and sprinkled with borax or sal-ammoniac to prevent oxidization. The striking should be light at first and gradually heavier. Flattening consists of lengthening or widening a piece of bar. This is done with the narrow edge of the hamper, and the grooves so wrought are smoothed out with the large end.

Upsetting consists of thickening the bar and is the opposite of flattening. The method is to strike the red-hot iron on the anvil or to hammer the end. Bending can be done cold as well as when the metal is hot; right-angle bends are done over the edge of the anvil or the square part of the beak, while curves are done on the round end of the beak or on a conical mandrel or stake fitted in the vice. Embossing is the process of making bosses by hammering the hot metal into suitable cavities or by using a ball-faced hammer on a piece of hardwood when the metal is cold. Impressing is a means of arriving at similar shapes by pressure either with the vice or a press. Punching is used for marking points for drilling and cutting as well as for providing decoration.

Welding and Brazing. There are several methods of joining ironwork, welding being the principal and most generally used in large work, but brazing can be carried out with material of small size.

Riveting is necessary in places where welding is not practicable.

There are various ways of joining with rivets, the simplest being where two pieces are to be attached, as at Fig. 1. In dealing with curves, another method of riveting is shown at Fig. 2, and consists of cutting away sufficient material to allow the second piece to fit flush. Intersections of bars are carried out as shown at Fig. 3; in this case the top piece is shaped, while hot, between two projecting blocks. A neat method of intersecting is shown at Fig. 4, and consists of filing out half the thickness of each piece, as at A, so that they may fit flush.

The methods followed in passing one bar through another are shown at Figs. 5, 6, 7, and 8. In the first two the metal is punched and widened out each side; in the latter examples the hole is drilled and filed to take the bar. When several lengths of bar are to be held, the method used (Fig. 9) consists of forming a collar to bind them together. The collar can be of flat bar or half-round, as at Fig. 10; a combination of the two, shown at Fig. 11, is effected by placing a collar of half-round bar on a wider flat collar. Round bars are held together with a collar, as at Figs. 12 and 13.

Straight bar can be decorated by simple means by using a file and a punch, as at Fig. 14. An elaboration is shown at Fig. 15. Another method suitable for square bar is shown at Fig. 16; the angle cuts are made with a three-cornered file and the curves with a half-round file. Simple twists (Fig. 17) can be done while the metal is red hot, by placing one end in the vice and turning it with the tongs. Square bar can also be twisted, but it is heavier work and requires the help of a screw

wrench. Slitting and opening out, as at Fig. 18, is effective. The simplest method is to cut the rod to the centre from three sides, upset it to open out, and then twist. It is, however, a difficult operation for the beginner. Interfacings are fairly simple, as at Fig. 19, but in Fig. 20 the main rod is split and opened out with the ends forged to a knob form.

The spear shape at Fig. 21 is indicative of flattening and welding in the case of the side pieces, otherwise the lower portion would require considerable cutting away. This form of treatment is used with square bar in railings and similar work, and it can be worked out in many different forms. The formation of the volute, at Fig. 22, is termed scrolling, and is one of the main effects obtainable in wrought iron work. It can be done cold or while the metal is hot, either on the anvil or (usually) with a scroll wrench or round a scrolling iron, which enables an even curve to be formed; these are obtainable in several shapes and sizes. The end of the volute can be flattened, as at Fig. 23, or the widened end can be slit and formed into separate volutes, as at Fig. 24.

Wrought Iron Work. Figs. 1 and 2. Two simple rivet joints. Figs. 3 and 4. Methods of intersecting. Figs. 5-8. Methods of passing one bar through another. Fig. 9. Forming a collar to bind several lengths together. Fig. 10. Collar of half-round bar. Fig. 11. Another method of forming a collar. Figs. 12 and 13. Round bars held together by collar

A simple piece of work for the beginner in scrolling is shown at Fig. 25, and consists of a stand for a hot plate, flat iron, or teapot. It is formed with a circular ring which is bent and the ends welded to form an even length, and then the interior pieces are shaped and fitted in.

They can be made in the form of three separate pieces, and then riveted with two rivets, or one length can be welded on to each end of the centre piece.

An example of welding in the formation of several scrolls is shown at Fig. 26, and, although it is sometimes possible to do the welding after the volute has been formed it is usual to weld straight lengths and then form the ends to the required shapes.

An example of welding, intersecting, and riveting is shown at Fig. 27 in the form of a portion of a grill. The curves are made as flowing as possible, and the aim of the designer of a grill should be to fill the space as decoratively as possible without crowding. Spaces should be well balanced, and the riveted joints just sufficient to hold the work together.

As a rule, wrought iron designs should be highly conventional, and suggest strength. A good finish for wrought iron is to heat the metal and then rub on linseed oil; a black finish can be obtained by covering thoroughly with linseed oil and burning it off over a fire.

Fig. 23. End flattened. Fig. 24. End slit. Fig. 25. Teapot stand. Fig. 26. Use of welding in formation of scrolls. Fig. 27. Example of welding, intersecting, and riveting.

WYANDOTTE. Amongst exhibitors of poultry the Wyandotte is without doubt the most popular of all the American breeds. There are 13 varieties, namely: white, black, blue, buff, Columbian, blue-laced, buff-laced, black-laced, gold-laced, silver-laced, pile, silver-pencilled and partridge. The favourites are the white, black, silver-laced, gold-laced and the Columbian.

Amongst many utility breeders the white and the Columbian are the most extensively bred, and as winners of laying competitions no heavy breed has won more distinction than these.

On the average cocks weigh 7 lb. to 8½ lb., hens 5 lb. to 7 lb. The partridge, white, and Columbians are the heaviest, the laced the lightest. The whites are the best layers, as far as numbers of eggs are concerned, the gold-laced being the poorest. The eggs average about 2 oz. in weight and are brown-shelled. All the birds have yellow legs, red combs, faces, wattles, and lobes. They are all rose-combed. *See Fowl; Poultry.*

Wyandotte. Pullet of the white variety of this American breed.

XERANTHEMUM. This is the name of an annual everlasting flower or immortelle which is useful for indoor decoration in winter. It is grown from seeds sown out of doors in spring. Of this flower the chief kind is *Xeranthemum annum*, 18 in. high, of which there are several varieties.

X-RAY: The Röntgen rays, which are more commonly known as the X-rays, have some very important uses in diagnosis, and also in the cure or relief of certain diseases. For the purpose of diagnosis, they are employed to reveal the presence and situation of foreign bodies, for fractures, dislocations and for various diseased conditions.

What is shown on a photograph is not the actual object or tissue, but the shadows of these thrown on the photographic plate. The interpretation of these photographs requires special skill and experience.

On the cells of the body the rays have a stimulating effect, which becomes irritating and destructive when the application is prolonged. A large number of affections are successfully treated by X-rays. These include ringworm and many other skin diseases. With regard to cancer, apart from rodent ulcer, X-rays should not be used if an operation is possible; but when it is too late for a successful operation they often give great relief and prolong the life of the patient.

XYLONITE. A manufactured form of celluloid, xylonite is made in various colours and in imitation of ivory, tortoiseshell, etc. It is manufactured in sheets of various thicknesses and can be used for many purposes. Owing to its inflammable nature it should never be placed near a flame nor exposed to heat. *See Celluloid.*

YACHT: How to Make. The design of a model sailing yacht must follow certain definite rules too numerous to include in this short description, but they are followed in the design shown in the side elevation at Fig. 1. The hull is shaped from a 36 in. by 9 in. by 3½ in. block of sound well-seasoned wood planed to the dimensions given, yellow pine, spruce or cedar being suitable.

The first thing to do is to prepare templates of the sections indicated by the lines on the deck plan at Fig. 2, the section at Fig. 3, and the section lines at Fig. 4, the latter being drawn out full size, together with the sheer plan outlined at Fig. 1, and deck plan at Fig. 2. The templates can be of stiff

paper, as at Fig. 5, and represent the shape of the hull at intervals of 6 in., being marked B, C, D, E, and F. In order to hold the wood securely in the vice, a 2 in. by 2 in. by 12 in. block should be screwed to the top so that the jaws of the vice can grip it and allow the whole of the hull to be worked. The plane, spokeshave and chisel should be used to cut away the waste, and great care must be taken to fit the templates at the correct places, as shown.

The surface, when correctly shaped, must be thoroughly smoothed, first with a scraper and finally with glass paper. The most suitable wood for the keel is beech; it should be prepared to the shape shown from $\frac{1}{2}$ in. board with a length of 25 in. and a depth of $6\frac{3}{4}$ in. The lower edges are rounded off to a sharp edge except that portion at the bottom which is covered with lead. A horizontal groove is now cut along the centre of the hull to a centre depth of $1\frac{1}{4}$ in., so that the keel will fit tightly and can be glued in position. The top is now curved with a drop of $\frac{3}{4}$ in. in the centre and the inside of the hull is removed, by boring a number of holes with a large centre bit and then using one or two sizes of firmer gouges; the sides should be left to a thickness of $\frac{1}{2}$ in. until the inside is neatly shaped, and in order not to cut down too deep, three or four inside templates should be used. The greatest thickness at the bottom should be $1\frac{1}{2}$ in. to allow for the depth of the groove; in any case, this should not be less than $1\frac{3}{8}$ in.

When the shaping is finished, a $\frac{3}{8}$ in. line should be gauged from the top and a $\frac{1}{4}$ in. line from the outside to enable the rebate to be cut for the deck; the latter being shaped from $\frac{1}{8}$ in. wood. The keel is now further secured with screws driven in from the inside of the hull and the two lead weights made and screwed to the bottom of the keel. The easiest way of providing the pieces of lead is to model the shape with a piece of plasticine and make a plaster of Paris mould; two separate castings can be made and fastened to the sides of the keel.

An alternative method is to cast the bulb with a groove in the top so that the planed off keel can be fitted and the lead attached with screws driven in from the bottom. The approximate weight of the lead should be 11 lb.

The hull should be painted inside and out with several coats of good oil paint, rubbing down the outside coats and finishing with enamel or varnish. The spars should be made from a close and straight grained wood, and generally pitch pine is used. The mast is 58 in. long, $\frac{5}{8}$ in. diameter at deck level, squared at the bottom to $\frac{1}{2}$ in. side and tapered to $\frac{3}{8}$ in. at the top. The surface should be carefully finished and made perfectly smooth. A block of wood is placed inside for the heel of the mast to fit in, and a hole bored in the deck and surrounded on both sides as at H with a 2 in. by $1\frac{1}{2}$ in. by $\frac{1}{4}$ in. strip of wood.

The centre of the hole in the deck should be 13 in. from the bow of the boat; the centre of the hole in the block inside should be stepped back to allow a rake of 2 in. in all. However tightly the mast is fitted through the deck it is hardly possible to keep the inside quite watertight: it is therefore necessary to fit a brass screw cap, as used in gas fitting, at the stern as at K, so that any accumulation of water can be emptied out.

A shallow deck house, composed of a $3\frac{1}{2}$ in. by $2\frac{1}{4}$ in. by 1 in., and a $1\frac{3}{4}$ in. by 1 in. by $\frac{1}{2}$ in. piece of wood glued together, is secured to the deck as shown at L in Figs. 1 and 2. Cleats measuring $2\frac{1}{2}$ in. long and made from $\frac{1}{2}$ in. by $\frac{1}{4}$ in. wood are fastened on as at M, N, and P, but the thickness of the deck is increased by $\frac{1}{8}$ in. at the bow by a shaped piece glued and bradded to it.

The deck can now be attached to the hull and the remaining spars and rigging completed. The bowsprit is 13 in. long, tapering from $\frac{1}{2}$ in. to $\frac{3}{8}$ in., and secured to the deck by fitting the heel in a screw eye and binding wire round it and fastening to a small screw eye at Q. The boom is 26 in. by $\frac{5}{8}$ in. diameter and is attached to the mast by two screw eyes.

The mainsheet is secured to the end, run through a block attached as at R, with a closed S hook to a horse made of wire, and through another block as at S, and then through a screw eye in front of the horse direct to the cleat at M. The mainsail measures 25 in. at the foot, 31 in. along the leach, 18 in. at the head, and 18½ in. along the luff. Three brass rings are slipped on the mast and the sail is then sewn to them.

The gaff is shaped to ¾ in. by ½ in. by 20 in.

It is provided with small screw eyes, one at the throat, another 8 in., and another 6 in. further on.

It is held in position as shown at Fig. 1, the screw eye at T being 21 in. up the mast and those at U being 2½ in. above. The lines securing the gaff are threaded through the gaff side at U and T and carried through the first of three small eyes at V, and secured to the cleats at P and N respectively.

The topsail measures 30 in. by 24 in. by 15 in. ; it is secured to an eye at the top of the mast, to a ring 11 in. down and by a line to an eye situated close by the mast on deck and also to the head of the gaff.

The jib is 25 in. along the luff, 21 in. along the leach, and 13 in. along the foot, with the jibboom 14½ in. by 5/16 in. diameter, the latter being secured to a wire horse 10 in. from the bow. Shrouds should be attached to the mast from a point just above U and fastened to the eyes at V2 and V3. The jib is fastened to a line secured to the bowsprit, threaded through the eye at U, carried through V1 on the opposite side and fastened to the cleat at N. The bowsprit is stiffened by the line running to X, and also by two lines secured to rings at W. All spars should be finished with a polished surface, shellac varnish being suitable for the purpose.

The yacht has a fixed rudder and does not require anything else; all necessary movements can be made by the adjustment of the sails. It will be found that the free movements of the booms on the wire horses will provide for sailing motion.

Sails should not be folded up while wet, they should be spread out flat and thoroughly dried. Always remove water from the hold and keep the cap, or hatch, uncovered when the yacht is not being used. It is advisable to have a spare set of spars, and the wise yachtsman will carry a length of cord, some wire and a pair of pliers, so that repairs can be carried out on the spot when urgent. *See Boat.*

YARD: The Measure. The yard is the standard English measure of length. A yard is divided into 3 ft. or 36 in. A square yard contains 9 square feet and a cubic yard contains 27 cubic feet. There are 220 yards in a furlong and 1,760 in a mile; 4,840 square yards make an acre.

YEAST. Yeast is a plant of the fungus order which is formed in fermenting liquids and plays an important part in brewing and also in baking. Fermentation takes place when yeast is added to sugar, alcohol and carbonic acid gas being given off. Yeast is added to dough in baking in order to make the bread light and porous, the gas causing it to swell up into the consistency of a sponge. A tepid liquid must be used, as yeast is inactive when dry and cold, while too great heat kills it.

Yeast has various uses in medicine. It is sometimes given to patients suffering from boils, acne, and tuberculosis, as it appears to increase the number of white corpuscles in the blood. The dose is about 2 teaspoonfuls in a little milk once or twice a day. Yeast cells are rich in anti-neuritic vitamin, as are also extracts of yeast. The latter resemble meat extract in their properties, and are used in diet.

Yeast Cake. This cake is made with 3 lb. flour, 4 oz. each lard, margarine, dried currants and sultanas, 4 oz. moist sugar, 2 oz. chopped lemon peel, ¾ pint each of milk and water, ½ oz. yeast, a little brown sugar and a pinch of salt. Put the flour into a basin, add the salt, and rub in the lard and margarine. Put in the fruit, sugar and peel, mix the yeast with a little warm water and brown sugar, pour this into the centre of the mixture and leave it for 10 min. Then pour in the milk and water and beat all well together. Put it in a warm place to rise for 2 hours, and then bake it in a hot oven.

YEW. This is a most valuable evergreen suitable for hedges, for planting as specimen trees on the lawn and for topiary work, for it bears clipping well. It flourishes in ordinary soil that is not waterlogged. The common yew is *Taxus baccata*: it lives to a great age— 1,000 years or more. The branches and leaves, especially when withered, are poisonous to cattle.

Yew is largely planted as a hedge though it grows slowly for the first few years. The Irish yew (*Taxus baccata fastigiata*) is a popular evergreen tree of upright conical habit of growth and is often

planted on lawns; the variety aurea has golden yellow leaves. The yew named Douastonii is of graceful drooping growth. The best time to transplant yew trees is in May or September.

Yew trees ought to be clipped early in May and again in August. If an old, overgrown hedge has to be cut back the work should be done in April.

Uses of the Wood. This wood is very hard and lasting. Susceptible of a high polish, it is insect proof. It is not greatly used for furniture to-day, but is sometimes employed for marquetry. *See* Hedge; Topiary.

YOGHOURT. Curdled milk has long been largely used in the diet of many countries in south-eastern Europe. The best known preparation is Bulgarian yoghurt or yohourth, in which the souring is produced by the bacillus named bacillus Bulgaricus. Metchnikoff suggested the use of this preparation in the treatment of disease, the acclimatisation of the Bulgarian bacillus lessening intestinal putrefaction. Since its introduction this method of treatment has attained high popularity, and it has been recommended in cases of chronic ill-health without obvious cause, neurasthenia, and certain intestinal affections such as colitis, diarrhoea and constipation. *See* Sour Milk.

YORKSHIRE PUDDING. There are several methods of preparing this batter, which is a usual accompaniment of hot roast beef. The tin or dish must be prepared by melting in it plenty of good dripping, which should be well heated before the batter is poured into it. Before serving, the pudding should be turned out and cut into neat pieces, which are arranged on a hot dish. For an economical Yorkshire pudding sift 8 oz. flour with $\frac{1}{2}$ teaspoonful salt into a basin, make a well in the centre and break in two eggs. Beat these with a portion of flour till light. Then add by degrees 1 pint milk and water, beating all the while. Let the batter stand 1 hour, then pour it into a heated and greased tin. It should be baked 30 to 40 minutes.

Occasionally the pudding is cooked in the same tin in which a joint is being baked. If so, the meat must be raised on a trivet and the batter should not be poured in until the meat has been partly cooked. The objection to this method is that much of the gravy and dripping from the meat is absorbed by the batter. A portion of dripping may be poured off before batter is put in. *See* Batter.

YORKSHIRE TERRIER. This is the name of a pretty little toy dog. It possesses a vigorous and well-proportioned body, and carries it completely hidden beneath the close straight veils of silky hair that fall from the parting along the middle of the back to the ground on either side. The coat should be uniformly of a bright steel blue without a fawn or tan hair, but the long and abundant hair on the head ears and under the chin should be tan. The nose should be perfectly black. *See* Dog; Terrier.

Yorkshire Terrier. Champion of this long and silkyhaired breed of toy dog.

YUCCA. This is an evergreen shrub of striking appearance with long leaves and upright panicles of white or cream white flowers. They like well drained soil and are propagated by offsets in spring: these are taken off the old plants, potted and kept in a frame until rooted.

Yuccas flourish in town as well as in country gardens.

Yucca. Beautiful flower spikes of this decorative plant.

The favourite kind is Adam's needle (*yucca gloriosa*), which has stiff leaves and an immense spike of bloom. *Yucca recurvifolia* and *yucca filamentosa*, the latter almost stemless, are among the other kinds.

ZEPHYR CLOTH. Zephyr cloth is a cotton fabric somewhat resembling gingham in texture, and of light or medium weight; it usually contains two or more colours, woven in a variety of patterns.

ZINC. A bluish-white metal, zinc is harder than aluminium and softer than silver. It is stronger than lead or tin, and has a bright lustre when polished. Being malleable, it can be hammered and rolled into thin sheets. Commercial zinc, which is called spelter, is brittle, but it is malleable when heated to a temperature between 100° C. and 150° C.; when it is heated above that temperature it again becomes brittle.

Zinc is scarcely affected by dry air; in damp air the exposed surface is converted into a basic carbonate of zinc, owing to the presence of carbonic acid gas, and this effectively protects the metal from further change. On account of this property zinc is employed for roofing and also for tanks. It is used to a much greater extent in "galvanizing" iron and steel; the metal is cleaned with acid to remove the scale, and is dipped into the molten zinc. The result is to protect the iron, which is quickly oxidized by exposure to air and water, and provides a rustless surface. *See Boat; Dutch Metal; German Silver; Ice Safe; Ormolu; Soldering.*

Medicinal Uses. Numerous compounds of zinc are used in medicine. Zinc chloride is a powerful caustic, and at one time was commonly used as an antiseptic. The acetate, carbonate, oxide, and sulphate of zinc all act as astringents when applied to raw or ulcerated surfaces, and are therefore often of value in solution as astringent lotions. Lotions of zinc sulphate or other zinc salts provide the best remedy for one form of conjunctivitis.

Powdered oxide of zinc and powdered carbonate of zinc are commonly used as dusting powders where a mild astringent effect is required. Calamine ointment, much used in skin diseases, is made with native zinc carbonate, otherwise known as calamine. Internally, zinc sulphate is a prompt and Valuable emetic in certain cases of poisoning.

ZINNIA. The zinnia is a half-hardy annual bearing flowers of rich colours, some of double form, including crimson, scarlet, bronze, white, buff, violet, and mauve. The plant is prolific and long-lasting, but demands all the sunshine possible and well-enriched soil. Seed should be sown in heat during March, transplanting seedlings once or twice to make good stocky plants.

Zinnia. Gaily coloured blossoms.

ZITHER. As a stringed instrument the zither stands in a class by itself, for the strings are plucked both with the fingers and with a plectrum. It consists of a

wooden body, about 1 ft. 8 in. long, 10 in. wide, and 3 in. deep, which, when played, is placed upon a table. Upon the side farthest from the performer the body has a very pronounced bulge beyond the strings, the object being to increase the resonance of the instrument. In the upper table of the body there is a large, circular sound-hole. The 30 strings, which run from left to right, fall into three distinct classes, namely, the melody, the accompaniment, and the bass strings.
