With any opening of the compasses, as  $ZL$ , describe the two semicircles  $Lfk$  and  $L\mathcal{Q}k$ , upon the centers  $Z$  and  $z$ , where the six o'clock line crosses the double meridian line, and divide each semicircle into 12 equal parts, beginning at  $L$  (though, strictly speaking, only the quadrants from  $L$  to the six o'clock line need be divided;) then connect the divisions which are equidistant from  $L$ , by the parallel lines  $KM$ ,  $IN$ ,  $HO$ ,  $GP$ , and  $F\mathcal{Q}$ . Draw  $VZ$  for the hypotenuse of the stile, making the angle  $VZE$  equal to the latitude of your place; and continue the line  $VZ$  to  $R$ . Draw the line  $Rr$  parallel to the six o'clock line, and set off the distance  $aK$  from  $Z$  to  $T$ , the distance  $bI$  from  $Z$  to  $X$ ,  $cH$  from  $Z$  to  $W$ ,  $dG$  from  $Z$  to  $T$ , and  $eF$  from  $Z$  to  $S$ . Then draw the lines  $Ss$ ,  $Tt$ ,  $Ww$ ,  $Xx$ , and  $Yy$ , each parallel to  $Rr$ . Set off the distance  $yT$  from  $a$  to 11, and from  $s$  to 1; the distance  $xX$  from  $b$  to 10, and from  $g$  to 2;  $wW$  from  $c$  to 9, and from  $h$  to 3;  $tT$  from  $d$  to 8, and from  $i$  to 4;  $sS$  from  $e$  to 7, and from  $n$  to 5. Then laying a ruler to the center  $Z$ , draw the forenoon hour-lines through the points 11, 10, 9, 8, 7; and laying it to the center  $z$ , draw the afternoon lines through the points 1, 2, 3, 4, 5; continuing the forenoon lines of VII and VIII through the center  $Z$ , to the opposite side of the dial, for the like afternoon hours; and the afternoon lines IIII and V through the center  $z$ , to the opposite side, for the like morning hours. Set the hours to these lines as in the figure, and then erect the stile or gnomon, and the horizontal dial will be finished.

To construct a south dial, draw the line  $VZ$ , making an angle with the meridian  $ZL$  equal to the co-latitude of your place; and proceed in all respects as in the above horizontal dial for the same latitude, reverting the hours as in fig. 4. and making the elevation of the gnomon equal to the co-latitude.

Perhaps it may not be unacceptable to explain the method of constructing the dialing lines, and some others; which is as follows.

With any opening of the compasses, (Plate LXX. fig. 1.) as  $EA$ , according to the intended length of the scale, describe the circle  $ADCB$ , and cross it at right angles by the diameters  $CEA$  and  $DEB$ . Divide the quadrant  $AB$  first into 9 equal parts, and then each part into 10; so shall the quadrant be divided into 90 equal parts or de-

grees. Draw the right line  $AFB$  for the chord of this quadrant, and setting one foot of the compasses in the point  $A$ , extend the other to the several divisions of the quadrant, and transfer these divisions to the line  $AFB$  by the arcs 10, 10, 20, 20, &c. and this will be a line of chords, divided into 90 unequal parts; which, if transferred from the line back again to the quadrant, will divide it equally. It is plain by the figure, that the distance from  $A$  to 60 in the line of chords, is just equal to  $AE$ , the radius of the circle from which that line is made; for if the arc 60, 60 be continued, of which  $A$  is the center, it goes exactly through the center  $E$  of the arc  $AB$ .

And therefore, in laying down any number of degrees on a circle, by the line of chords, you must first open the compasses so, as to take in just 60 degrees upon that line, as from  $A$  to 60: and then, with that extent, as a radius, describe a circle, which will be exactly of the same size with that from which the line was divided: which done, set one foot of the compasses in the beginning of the chord line, as at  $A$ , and extend the other to the number of degrees you want upon the line; which extent, applied to the circle, will include the like number of degrees upon it.

Divide the quadrant  $CD$  into 90 equal parts, and from each point of division draw right lines, as  $i$ ,  $k$ ,  $l$ , &c. to the line  $CE$ ; all perpendicular to that line, and parallel to  $DE$ , which will divide  $EC$  into a line of sines; and although these are seldom put among the dialing lines on a scale, yet they assist in drawing the line of latitudes. For if a ruler be laid upon the point  $D$ , and over each division in the line of sines, it will divide the quadrant  $CB$  into 90 unequal parts, as  $Ba$ ,  $Bb$ , &c. shewn by the right line  $10a$ ,  $20b$ ,  $30c$ , &c. drawn along the edge of the ruler. If the right line  $BC$  be drawn, subtending this quadrant, and the nearest distances  $Ba$ ,  $Bb$ ,  $Bc$ , &c. be taken in the compasses from  $B$ , and set upon this line in the same manner as directed for the line of chords, it will make a line of latitudes  $BC$ , equal in length to the line of chords  $AB$ , and of an equal number of divisions, but very unequal as to their lengths.

Draw the right line  $DGA$ , subtending the quadrant  $DA$ ; and parallel to it, draw the right line  $rs$ , touching the quadrant  $DA$  at the numeral figure 3. Divide this quadrant into six equal parts, as 1, 2, 3, &c. and through these points of division draw right lines from the centre  $E$  to the line  $rs$ , which will divide it at the points where the six hours are to be placed, as in the figure. If every sixth part of the quadrant be subdivided into four equal parts, right lines drawn from the centre through these points of division, and continued to the line  $rs$ , will divide each hour upon it into quarters.

In Fig. 2. Plate LXX. we have the representation of a portable dial, which may be easily drawn on a card, and carried in a pocket-book. The lines  $ad$ ,  $ab$ , and  $bc$  of the gnomon must be cut quite through the card; and as the end  $ab$  of the gnomon is raised occasionally above the plane of the dial, it turns upon the uncut line  $cd$  as on a hinge. The line dotted  $AB$  must be slit quite through the card, and the thread behind  $C$  must be put through the slit, and have a knot tied behind, to keep it from being easily drawn out. On the other end of this thread

thread is a small plummet *D*, and on the middle of it a small bead for shewing the hour of the day.

To rectify this dial, set the thread in the slit right against the day of the month, and stretch the thread from the day of the month over the angular point where the curve-lines meet at XII; then shift the bead to that point on the thread, and the dial will be rectified.

To find the hour of the day, raise the gnomon (no matter how much or how little) and hold the edge of the dial next the gnomon towards the sun, so as the uppermost edge of the shadow of the gnomon may just cover the *shadow-line*; and the bead then playing freely on the face of the dial, by the weight of the plummet, will shew the time of the day among the hour-lines, as it is forenoon or afternoon.

To find the time of sun-rising and setting, move the thread among the hour-lines, until it either covers some one of them, or lies parallel betwixt any two; and then it will cut the time of sun-rising among the forenoon hours, and of sun-setting among the afternoon hours, for that day of the year to which the thread is set in the scale of months.

To find the sun's declination, stretch the thread from the day of the month over the angular point at XII, and it will cut the sun's declination, as it is north or south, for that day, in the proper scale.

To find on what days the sun enters the signs: when the bead, as above rectified, moves along any of the curve-lines which have the signs of the zodiac marked upon them, the sun enters those signs on the days pointed out by the thread in the scale of months.

The construction of this dial is very easy, especially if the reader compares it all along with fig. 3. as he reads the following explanation of that figure.

Draw the occult line, (Plate LXX. fig. 9.) *AB* parallel to the top of the card, and cross it at right angles with the fix o'clock line *ECD*; then upon *C*, as a centre, with the radius *CA*, describe the semicircle *AEL*, and divide it into 12 equal parts (beginning at *A*) as *Ar*, *As*, &c. and from these points of division draw the hour-lines *r*, *s*, *t*, *u*, *v*, *E*, *w*, and *x*, all parallel to the fix o'clock line *EG*. If each part of the semicircle be subdivided into four equal parts, they will give the half-hour lines and quarters, as in fig. 2. Draw the right-line *ASD*, making the angle *SAB* equal to the latitude of your place. Upon the centre *A* describe the arch *RST*, and set off upon it the arcs *SR* and *ST*, each equal to  $23\frac{1}{2}$  degrees, for the sun's greatest declination; and divide them into  $23\frac{1}{2}$  equal parts, as in fig. 2. Through the intersection *D* of the lines *ECD* and *AD*, draw the right line *FDG* at right angles to *AD*. Lay a ruler to the points *A* and *R*, and draw the line *ARF* through  $23\frac{1}{2}$  degrees of south declination in the arc *SR*; and then laying the ruler to the points *A* and *T*, draw the line *ATG* through  $23\frac{1}{2}$  degrees of north declination in the arc *ST*: so shall the lines *ARF* and *ATG* cut the line *FDG* in the proper length for the scale of months. Upon the centre *D*, with the radius *DE*, describe the semicircle *FoG*; which divide into six equal parts, *Fm*, *mn*, *no*, &c. and from these points of division draw the right lines *mh*, *ni*, *pk*, and *ql*, each parallel to

*oD*. Then setting one foot of the compasses in the point *F*, extend the other to *A*, and describe the arc *AzH* for the tropic of  $\Psi$ : with the same extent, setting one foot in *G*, describe the arc *AEO* for the tropic of  $\Phi$ . Next setting one foot in the point *b*, and extending the other to *A*, describe the arc *ACI* for the beginnings of the signs  $\Lambda$  and  $\uparrow$ ; and with the same extent, setting one foot in the point *l*, describe the arc *AN* for the beginnings of the signs  $\Pi$  and  $\Omega$ . Set one foot in the point *i*, and having extended the other to *A*, describe the arc *AK* for the beginnings of the signs  $\chi$  and  $\mathfrak{M}$ ; and with the same extent, set on foot in *k*, and describe the arc *HM* for the beginnings of the signs  $\gamma$  and  $\mathfrak{M}$ . Then setting one foot in the point *D*, and extending the other to *A*, describe the curve *AL* for the beginnings of  $\varphi$  and  $\underline{\omega}$ ; and the signs will be finished. This done, lay a ruler from the point *A* over the sun's declination in the arch *RST*; and where the ruler cuts the line *FDG*, make marks; and place the days of the months right against these marks, in the manner shewn by fig. 2. Lastly, draw the shadow-line *PQ* parallel to the occult line *AB*; make the gnomon, and set the hours to their respective lines, as in fig. 2. and the dial will be finished.

There are several kinds of dials, which are called *universal*, because they serve for all latitudes. Of these, the best is Mr Pardie's, (Plate LXX. fig. 4.) which consists of three principal parts; the first whereof is called the horizontal plane (*A*), because in practice it must be parallel to the horizon. In this plane is fixed an upright pin, which enters into the edge of the second part *BD*, called the meridional plane; which is made of two pieces, the lowest whereof (*B*) is called the quadrant, because it contains a quarter of a circle, divided into 90 degrees; and it is only into this part, near *B*, that the pin enters. The other piece is a semicircle (*D*) adjusted to the quadrant, and turning in it by a groove, for raising or depressing the diameter (*EF*) of the semicircle, which diameter is called the axis of the instrument. The third piece is a circle (*G*), divided on both sides into 24 equal parts, which are the hours. This circle is put upon the meridional plane so, that the axis (*EF*) may be perpendicular to the circle, and the point *C* be the common centre of the circle, semicircle, and quadrant. The straight edge of the semicircle is chamfered on both sides to a sharp edge, which passes through the centre of the circle. On one side of the chamfered part, the first six months of the year are laid down, according to the sun's declination for their respective days, and on the other other side the last six months. And against the days on which the sun enters the signs, there are straight lines drawn upon the semicircle, with the characters of the signs marked upon them. There is a black line drawn along the middle of the upright edge of the quadrant, over which hangs a thread (*H*), with its plummet (*I*), for levelling the instrument. *N. B.* From the twenty-third of September to the twentieth of March, the upper surface of the circle must touch both the centre *C* of the semicircle, and the line of  $\varphi$  and  $\underline{\omega}$ ; and from the twentieth of March to the twenty-third of September, the lower surface of the circle must touch that centre and line.

To

To find the time of the day by this dial. Having set it on a level place in sun-shine, and adjusted it by the leveling screws *k* and *l*, until the plumb-line hangs over the black line upon the edge of the quadrant, and parallel to the said edge; move the semicircle in the quadrant, until the line of  $\varphi$  and  $\underline{\alpha}$  (where the circle touches) comes to the latitude of your place in the quadrant: then turn the whole meridional plane *BD*, with its circle *G*, upon the horizontal plane *A*, until the edge of the shadow of the circle falls precisely on the day of the month in the semicircle; and then, the meridional plane will be due north and south, the axis *EF* will be parallel to the axis of the world, and will cast a shadow upon the true time of the day, among the hours on the circle.

*N. B.* As, when the instrument is thus rectified, the quadrant and semicircle are in the plane of the meridian, so the circle is then in the plane of the equinoctial. Therefore, as the sun is above the equinoctial in summer (in northern latitudes) and below it in winter; the axis of the semicircle will cast a shadow on the hour of the day, on the upper surface of the circle, from the twentieth of March to the twenty-third of September: and from the twenty-third of September to the twentieth of March, the hour of the day will be determined by the shadow of the semicircle, upon the lower surface of the circle. In the former case, the shadow of the circle falls upon the day of the month, on the lower part of the diameter of the semicircle; and in the latter case, on the upper part.

The method of laying down the months and signs upon the semicircle is as follows. Draw the right line *ACB*, equal to the diameter of the semicircle *ADB*, and cross it in the middle at right angles with the line *ECD*, equal in length to *ADB*; then *EC* will be the radius of the circle *FCG*, which is the same as that of the semicircle. Upon *E*, as a centre, describe the circle *FCG*, on which set off the arcs *Cb* and *Ct*, each equal to  $23\frac{1}{2}$  degrees, and divide them accordingly into that number, for the sun's declination. Then, laying the edge of a ruler over the centre *E*, and also over the sun's declination for every fifth day of each month (as in the card dial) mark the points on the diameter *AB* of the semicircle from *a* to *g*, which are cut by the ruler; and there place the days of the months accordingly, answering to the sun's declination. This done, setting one foot of the compasses in *C*, and extending the other to *a* or *g*, describe the semicircle *abcdesfg*; which divide into six equal parts, and through the points of division draw right lines, parallel to *CD*, for the beginning of the lines (of which one half are on one side of the semicircle, and the other half on the other) and set the characters of the signs to their proper lines, as in the figure.

Having shewn how to make sun-dials by the assistance of a good globe, or of a dialing-scale, we shall now proceed to the method of constructing dials arithmetically; which will be more agreeable to those who have learned the elements of trigonometry, because globes and scales can never be so accurate as the logarithms in finding the angular distances of the hours. Yet, as a globe may be

found exact enough for some other requisites in dialing, we shall take it in occasionally.

The construction of sun-dials on all planes whatever, may be included in one general rule: intelligible, if that of a horizontal dial for any given latitude be well understood. For there is no plane, however obliquely situated with respect to any given place, but what is parallel to the horizon of some other place; and therefore, if we can find that other place by a problem on the terrestrial globe, or by a trigonometrical calculation, and construct a horizontal dial for it; that dial, applied to the plane where it is to serve, will be a true dial for that place.—Thus, an erect direct south dial in  $51\frac{1}{2}$  degrees north latitude, would be a horizontal dial on the same meridian, 90 degrees southward of  $51\frac{1}{2}$  degrees north latitude; which falls in with  $38\frac{1}{2}$  degrees of south latitude. But if the upright plane declines from facing the south at the given place, it would still be a horizontal plane 90 degrees from that place, but for a different longitude, which would alter the reckoning of the hours accordingly.

### C A S E I.

1. LET us suppose, that an upright plane at London declines 36 degrees westward from facing the south; and that it is required to find a place on the globe, to whose horizon the said plane is parallel; and also the difference of longitude between London and that place.

Rectify the globe to the latitude of London, and bring London to the zenith under the brass meridian, then that point of the globe which lies in the horizon at the given degree of inclination (counted westward from the south point of the horizon) is the place at which the above-mentioned plane would be horizontal.—Now, to find the latitude and longitude of that place, keep your eye upon the place, and turn the globe eastward, until it comes under the graduated edge of the brass meridian; then, the degrees of the brass meridian that stands directly over the place, is its latitude; and the number of degrees in the equator, which are intercepted between the meridian of London and the brass meridian, is the place's difference of longitude.

Thus, as the latitude of London is  $51\frac{1}{2}$  degrees north, and the declination of the place is 36 degrees west; elevate the north pole  $51\frac{1}{2}$  degrees above the horizon, and turn the globe until London comes to the zenith, or under the graduated edge of the meridian; then count 36 degrees on the horizon westward from the south point, and make a mark on that place of the globe over which the reckoning ends, and bringing the mark under the graduated edge of the brass meridian, it will be found to be under  $30\frac{1}{2}$  degrees in south latitude: keeping it there, count in the equator the number of degrees between the meridian of London and the brass meridian (which now becomes the meridian of the required place) and you will find it to be  $42\frac{1}{2}$ . Therefore an upright plane at London, declining 36 degrees westward from the south, would be a horizontal plane at that place, whose latitude is  $30\frac{1}{2}$  degrees south of the equator, and longitude  $42\frac{1}{2}$  degrees west of the meridian of London.

Which difference of longitude being converted into time, is 2 hours 51 minutes.

The vertical dial declining westward 36 degrees at London, is therefore to be drawn in all respects as a horizontal dial for south latitude  $30\frac{1}{2}$  degrees; save only, that the reckoning of the hours is to anticipate the reckoning on the horizontal dial, by 2 hours 51 minutes: for so much sooner will the sun come to the meridian of London, than to the meridian of any place whose longitude is  $42\frac{1}{2}$  degrees west from London.

2. But to be more exact than the globe will shew us, we shall use a little trigonometry.

Let *NE SW* (Plate LXX. fig. 6.) be the horizon of London, whose zenith is *Z*, and *P* the north pole of the sphere; and let *Zb* be the position of a vertical plane at *Z*, declining westward from *S* (the south) by an angle of 36 degrees; on which plane an erect dial for London at *Z* is to be described. Make the semidiameter *ZD* perpendicular to *Zb*, and it will cut the horizon in *D*, 36 degrees west of the south *S*. Then a plane, in the tangent *HD*, touching the sphere in *D*, will be parallel to the plane *Zb*; and the axis of the sphere will be equally inclined to both these planes.

Let *WQE* be the equinoctial, whose elevation above the horizon of *Z* (London) is  $38\frac{1}{2}$  degrees; and *PRD* be the meridian of the place *D*, cutting the equinoctial in *R*. Then it is evident, that the arc *RD* is the latitude of the place *D* (where the plane *Zb* would be horizontal) and the arc *RQ* is the difference of longitude of the planes *Zb* and *DH*.

In the spherical triangle *WDR*, the arc *WD* is given, for it is the complement of the plane's declination from *S* to south; which complement is  $54^\circ$  (viz.  $90^\circ - 36^\circ$ ): the angle at *R*, in which the meridian of the place *D* cuts the equator, is a right angle; and the angle *RWD* measures the elevation of the equinoctial above the horizon of *Z*, namely,  $38\frac{1}{2}$  degrees. Say therefore, as radius is to the co-sine of the plane's declination from the south, so is the co-sine of the latitude of *Z* to the sine of *RD* the latitude of *D*: which is of a different denomination from the latitude of *Z*, because *Z* and *D* are on different sides of the equator.

As radius . . . . . 10.00000  
To co-sine  $36^\circ$  0' = *RQ* 9.90796  
So co-sine  $51^\circ$  30' = *QZ* 9.79415

To sine  $30^\circ$  14' = *DR* (9.70211) = the lat. of *D*, whose horizon is parallel to the vertical plane *Zb* at *Z*.

*N. B.* When radius is made the first term, it may be omitted, and then, by subtracting it mentally from the sum of the other two, the operation will be shortened. Thus, in the present case,

To the logarithmic sine of *WR* =  $54^\circ$  0' 9.90796  
Add the logarithmic sine of *RD* =  $38^\circ$  30' 9.79415

Their sum — radius . . . . . 9.70211

give the same solution as above. And we shall keep to this method in the following part of this article.

To find the difference of longitude of the places *D* and *Z*, say, as radius is to the co-sine of  $38\frac{1}{2}$  degrees, the height of the equinoctial at *Z*, so is the co-tangent of 36 degrees, the plane's declination, to the co-tangent of the difference of longitudes. Thus,

To the logarithmic sine of  $51^\circ$  30' 9.89354  
Add the logarithmic tang. of  $54^\circ$  0' 10.13874

Their sum — radius . . . . . 10.013228  
is the nearest tangent of  $47^\circ$  8' = *WR*; which is the co-tangent of  $42^\circ$  52' = *RQ*, the difference of longitude sought. Which difference, being reduced to time, is two hours 51 $\frac{1}{2}$  minutes.

3. And thus having found the exact latitude and longitude of the place *D*, to whose horizon the vertical plane at *Z* is parallel, we shall proceed to the construction of a horizontal dial for the place *D*, whose latitude is  $30^\circ$  14' south; but anticipating the time at *D* by 2 hours 51 minutes (neglecting the  $\frac{1}{2}$  minute in practice) because *D* is so far westward in longitude from the meridian of London; and this will be a true vertical dial at London, declining westward 36 degrees.

Assume any right line *CSL*, (Plate LXX fig. 7.) for the subtile of the dial, and make the angle *KCP* equal to the latitude of the place (viz.  $30^\circ$  14') To whose horizon the plane of the dial is parallel; then *CRP* will be the axis of the stile, or edge that casts the shadow on the hours of the day, in the dial. This done, draw the co-tangent line *EQ*, cutting the subtilar line at right angles in *K*; and from *K* make *KR* perpendicular to the axis *CRP*. Then *KG* (= *KR*) being made radius, that is, equal to the chord of  $60^\circ$  or tangent of  $45^\circ$  on a good sector, take  $42^\circ$  52' (the difference of longitude of the places *Z* and *D*) from the tangents, and having set it from *K* to *M*, draw *CM* for the hour-line of XII. Take *KN*, equal to the tangent of an angle less by  $15^\circ$  degrees than *KM*; that is, the tangent  $27^\circ$  52'; and through the point *N* draw *CN* for the hour-line of I. The tangent of  $12^\circ$  52' (which is  $15^\circ$  less than  $27^\circ$  52') set off the same way, will give a point between *K* and *N*, through which the hour-line of II is to be drawn. The tangent of  $2^\circ$  8' (the difference between  $45^\circ$  and  $42^\circ$  52') placed on the other side of *CL*, will determine the point through which the hour-line of III is to be drawn: to which  $2^\circ$  8', if the tangent of  $15^\circ$  be added, it will make  $17^\circ$  8'; and this set off from *K* towards *Q* on the line *EQ*, will give a point for the hour-line of IIII: and so of the rest.—The forenoon hour lines are drawn the same way, by the continual addition of the tangents  $15^\circ$ ,  $30^\circ$ ,  $45^\circ$ , &c. to  $42^\circ$  52' (=the tangent of *KM*) for the hours of XI, X, IX, &c. as far as necessary; that is, until there be five hours on each side of the subtile. The sixth hour, accounted from that hour or part of the hour on which the subtile falls, will be always in a line perpendicular to the subtile, and drawn through the center *C*.

4-

\* The co-sine of  $36^\circ$  0. or of *RQ*.  
† The co-sine of  $51^\circ$  30. or of *QZ*.

\* The co-sine of  $38^\circ$  30. or of *WDR*.  
† The co-tangent of  $36^\circ$  0. or of *DR*.

Fig. 6.

Fig. 4.

Fig. 3.

Fig. 7.

Fig. 5.

A. Bell Sc.

4. In all erect dials,  $CM$ , the hour-line of XII, is perpendicular to the horizon of the place for which the dial is to serve: for that line is the intersection of a vertical plane with the plane of the meridian of the place, both which are perpendicular to the plane of the horizon: and any line  $NO$ , or  $ho$ , perpendicular to  $CM$ , will be a horizontal line on the plane of the dial, along which line the hours may be numbered; and  $CM$  being set perpendicular to the horizon, the dial will have its true position.

5. If the plane of the dial had declined by an equal angle toward the east, its description would have differed only in this, that the hour-line of XII would have fallen on the other side of the substile  $GL$ , and the line  $HO$  would have a subcontrary position to what it has in this figure.

6. And these two dials, with the upper points of their stile's turned toward the north pole, will serve for other two planes parallel to them; the one declining from the north toward the east, and the other from the north toward the west, by the same quantity of angle. The like holds true of all dials in general, whatever be their declination and obliquity of their planes to the horizon.

## C A S E II.

7. If the plane of the dial not only declines, but also reclines, or inclines. Suppose its declination from fronting the south  $S$ , (Plate LXXI. fig. 1.) be equal to the arc  $SD$  on the horizon; and its reclination be equal to the arc  $Dd$  of the vertical circle  $DZ$ : then it is plain, that if the quadrant of altitude  $ZdD$  on the globe cuts the point  $D$  in the horizon, and the reclination is counted upon the quadrant from  $D$  to  $d$ ; the intersection of the hour circle  $PRd$ , with the equinoctial  $WQF$ , will determine  $Rd$ , the latitude of the place  $d$ , whose horizon is parallel to the given plane at  $Z$ ; and  $RQ$  will be the difference in longitude of the planes at  $d$  and  $Z$ .

Trigonometrically thus: let a great circle pass through the three points  $W$ ,  $d$ ,  $E$ ; and in the triangle  $Wdd$ , right-angled at  $D$ , the sides  $WD$  and  $Dd$  are given; and thence the angle  $diWd$  is found, and so is the hypotenuse  $Wd$ . Again, the difference, or the sum, of  $diWd$  and  $diWR$ , the elevation of the equinoctial above the horizon of  $Z$ , gives the angle  $diWR$ ; and the hypotenuse of the triangle  $WRd$  was just now found; whence the sides  $Rd$  and  $WR$  are found, the former being the latitude of the place  $d$ , and the latter the complement of  $RQ$ , the difference of longitude sought.

Thus, if the latitude of the place  $Z$  be  $52^{\circ} 10'$  north; the declination  $SD$  of the plane  $Zh$  (which would be horizontal at  $d$ ) be  $36^{\circ}$ , and the reclination be  $15^{\circ}$ , or equal to the arc  $Dd$ ; the south latitude of the place  $d$ , that is, the arc  $Rd$ , will be  $15^{\circ} 9'$ ; and  $RQ$ , the difference of longitude,  $36^{\circ} 2'$ . From these data, therefore, let the dial (fig. 2.) be described, as in the former example.

\* That is, of  $15, 30, 45, 60, 75^{\circ}$ , for the hours of I, II, III, IIII, V in the afternoon; and XI, X, IX, VIII, VII in the afternoon.

† In all horizontal dials, and erect north or south dials, the substile and meridian are the same; but in all declining dials, the substile line makes an angle with the meridian.

‡ In which case, the radius  $CK$  is supposed to be divided into 1000000 equal parts.

9. There are several other things requisite in the practice of dialing; the chief of which shall be given in the form of arithmetical rules, simple and easy to those who have learned the elements of trigonometry. For in practical arts of this kind, arithmetick should be used as far as it can go; and scales never trusted to, except in the final construction, where they are absolutely necessary in laying down the calculated hour-distances on the plain of the dial.

RULE I. To find the angles which the hour-lines on any dial make with the substile.

To the logarithmic line of the given latitude, or of the stile's elevation above the plane of the dial, add the logarithmic tangent of the hour \* distance from the meridian, or from the † substile; and the sum minus radius will be the logarithmic tangent of the angle sought.

For, in fig. 7. Plate LXX.  $KC$  is to  $KM$  in the ratio compounded of the ratio of  $KC$  to  $KG$  ( $=KR$ ) and of  $KG$  to  $KM$ ; which, making  $CK$  the radius 10,000000, or 10,0000, or 10, or 1, are the ratio of 10,000000, or of 10,0000, or of 10, or of 1, to  $KG \times KM$ .

Thus, in a horizontal dial, for latitude  $51^{\circ} 30'$ , to find the angular distance of XI in the forenoon, or I in the afternoon, from XII.

To the logarithmic line of $51^{\circ} 30'$	9.89354 ‡
Add the logarithmic tang. of $15^{\circ} 0'$	9.42595
	<hr/>

The sum — radius is — — — — — 9.32159 = the logarithmic tangent of  $11^{\circ} 50'$ , or of the angle which the hour-line of XI or I makes with the hour of XII.

And by computing in this manner, with the sine of the latitude, and the tangents of  $30, 45, 60$ , and  $75^{\circ}$ , for the hours of II, III, IIII, and V in the afternoon; or of X, IX, VIII, and VII in the forenoon; you will find their angular distances from XII to be  $24^{\circ} 18', 38^{\circ} 3', 53^{\circ} 35'$  and  $71^{\circ} 6'$ ; which are all that there is occasion to compute for. — And these distances may be set off from XII by a line of chords; or rather, by taking 1000 from a scale of equal parts, and setting that extent as a radius from  $C$  to XII; and then, taking 209 of the same parts (which, in the tables, are the natural tangent of  $11^{\circ} 50'$ ) and setting them from XII to XI and to I, on the line  $ho$ , which is perpendicular to  $CXII$ : and so for the rest of the hour-lines, which, in the table of natural tangents, against the above distances, are 451, 782, 1355, and 2920, of such equal parts from XII, as the radius  $CXII$  contains 1000. And lastly, set off 1257 (the natural tangent of  $51^{\circ} 30'$ ) for the angle of the stile's height, which is equal to the latitude of the place.

RULE II. The latitude of the place, the sun's declination, and his hour-distance from the meridian, being given; to find (1.) his altitude; (2.) his azimuth.

1. Let

1. Let  $d$ , (Plate LXXI. fig. 1.) be the sun's place,  $dR$ , his declination; and in the triangle  $PZd$ ,  $Pd$  the sum, or the difference, of  $dR$ , and the quadrant  $PR$ , being given by the supposition, as also the complement of the latitude  $PZ$ , and the angle  $dPZ$ , which measures the horary distance of  $d$  from the meridian; we shall (by Case 4. of Keill's oblique spheric Trigonometry) find the base  $Zd$ , which is the sun's distance from the zenith, or the complement of his altitude.

And (2.) As sine  $Zd$ : sine  $Pd$  ::  $dPZ$  :  $dZP$ , or of its supplement  $DZS$ , the azimuthal distance from the south.

Or, the practical rule may be as follows.

Write  $A$  for the sign of the sun's altitude,  $L$  and  $I$  for the sine and co-sine of the latitude,  $D$  and  $d$  for the sine and co-sine of the sun's declination, and  $H$  for the sine of the horary distance from VI.

Then the relation of  $H$  to  $A$  will have three varieties.

1. When the declination is toward the elevated pole, and the hour of the day is between XII and VI; it is

$$A = LD + Hld, \text{ and } H = \frac{A - LD}{ld}$$

2. When the hour is after VI, it is  $A = LD - Hld$  and  $\frac{LD + A}{ld}$

3. When the declination is toward the depressed pole, we have  $A = Hld - LD$ , and  $H = \frac{A + LD}{ld}$

Which theorems will be found useful, and expeditious enough for solving those problems in geography and dialling, which depend on the relation of the sun's altitude to the hour of the day.

#### EXAMPLE I.

Suppose the latitude of the place to be  $51\frac{1}{2}$  degrees north: the time five hours distant from XII, that is, an hour after VI in the morning, or before VI in the evening; and the sun's declination  $20^\circ$  north. *Required the sun's altitude?*

$$\begin{array}{r} \text{Then to log. } L = \log. \sin. 51^\circ 30' \quad 1.89354^* \\ \text{add log. } D = \log. \sin. 20^\circ 0' \quad 1.53405 \\ \hline \end{array}$$

$$\text{Their sum} \quad 1.42759 \text{ gives}$$

$LD =$  logarithm of 0.267664, in the natural sines.

$$\text{And, to log. } H = \log. \sin. \dagger 15^\circ 0' \quad 1.41300$$

$$\begin{array}{r} \text{add } \left\{ \begin{array}{l} \log. I = \log. \sin. \dagger 38^\circ 0' \quad 1.79415 \\ \log. d = \log. \sin. * 70^\circ 0' \quad 1.97300 \end{array} \right. \\ \hline \end{array}$$

$$\text{Their sum} \quad 1.18015 \text{ gives}$$

$Hld =$  logarithm of 0.151408, in the natural sines.

And these two numbers (0.267664 and 0.151408) make 0.419072 =  $A$ ; which, in the table, is the nearest natural sine of  $24^\circ 47'$ , the sun's altitude sought.

The same hour-distance being assumed on the other side of VI, then  $LD - Hld$  is 0.116256, the sine of  $6^\circ$

$40\frac{1}{2}$ ; which is the sun's altitude at V in the morning, or VII in the evening, when his north declination is  $20^\circ$ .

But when the declination is  $20^\circ$  south (or towards the depressed pole) the difference  $Hld - LD$  becomes negative, and thereby shews that, an hour before VI in the morning, or past VI in the evening, the sun's center is  $6^\circ 40\frac{1}{2}$  below the horizon.

#### EXAMPLE II.

From the same data to find the sun's azimuth.

If  $H$ ,  $L$  and  $D$  are given, then (by par. 2. of Rule II.) from  $H$  having found the altitude and its complement  $Zd$ ; and the arc  $Pd$  (the distance from the pole) being given; say, As the co-sine of the altitude is to the sine of the distance from the pole, so is the sine of the hour-distance from the meridian to the sine of the azimuth distance from the meridian.

Let the latitude be  $51^\circ 30'$  north, the declination  $15^\circ 9'$  south, and the time II h. 24. m. in the afternoon, when the sun begins to illuminate a vertical wall, and it is required to find the position of the wall.

Then, by the foregoing theorems, the complement of the altitude will be  $81^\circ 32\frac{1}{2}'$ , and  $Pd$  the distance from the pole being  $109^\circ 5'$ , and the horary distance from the meridian, or the angle  $dPZ$ ,  $36^\circ$ .

$$\begin{array}{r} \text{To log. sin. } 74^\circ 51' \quad - \quad - \quad - \quad 1.98464 \\ \text{Add log. sin. } 36^\circ 0' \quad - \quad - \quad - \quad 1.76922 \\ \hline \end{array}$$

$$\text{And from the sum} \quad - \quad - \quad - \quad 1.75386$$

$$\text{Take the log. sin. } 81^\circ 32\frac{1}{2}' \quad - \quad - \quad - \quad 1.99525$$

$$\text{Remains} \quad 1.75861 = \log. \sin.$$

$35^\circ$ , the azimuth distance sought.

When the altitude is given, find from thence the hour, and proceed as above.

This praxis is of singular use on many occasions; in finding the declination of vertical planes more exactly than in the common way, especially if the transits of the sun's center is observed by applying a ruler with sights, either plain or telescopic, to the wall or plane, whose declination is required.—In drawing a meridian line, and finding the magnetic variation.—In finding the bearings of places in terrestrial surveys; the transits of the sun over any place, or his horizontal distance from it being observed, together with the altitude and hour.—And thence determining small differences of longitude.—In observing the variation at sea, &c.

*Of the double horizontal dial; and the Babylonian and Italian dials.*

To the *gnomonic* projection, there is sometimes added a *stereographic* projection of the hour-circles, and the parallels of the sun's declination, on the same horizontal plane; the upright side of the gnomon being sloped into an edge, standing perpendicularly over the center of the projection: so that the dial, being in its due position, the shadow

\* Here we consider the radius as unity, and not 10,00000, by which, instead of the index 9, we have—1, as above; which is of no farther use, than making the work a little easier.  
† The distance of one hour from VI.  
‡ The co-latitude of the place.  
\* The co-declination of the sun.

shadow of *that* perpendicular edge is a vertical circle passing through the sun, in the stereographic projection.

The months being duly marked on this dial, the sun's declination, and the length of the day at any time, are had by inspection (as also his altitude, by means of a scale of tangents.) But its chief property is, that it may be placed true, whenever the sun shines, without the help of any other instrument.

Let  $d$  (Plate LXXI. fig. 1.) be the sun's place in the stereographic projection,  $x d y z$  the parallel of the sun's declination.  $Z d$  a vertical circle through the sun's center,  $P d$  the hour-circle; and it is evident, that the diameter  $NS$  of this projection being placed duly north and south, these three circles will pass through the point  $d$ . And therefore, to give the dial its due position, we have only to turn its gnomon toward the sun, on a horizontal plane, until the hour on the common gnomonic projection coincides with that marked by the hour-circle  $P d$ , which passes through the intersection of the shadow  $Z d$  with the circle of the sun's present declination.

The *Babylonian* and *Italian* dials reckon the hours, not from the meridian, as with us, but from the sun's rising and setting. Thus, in *Italy*, an hour before sun-set is reckoned the 23d hour; two hours before sun-set, the 22d hour; and so of the rest. And the shadow that marks them on the hour-lines, is *that* of the point of a stile. This occasions a perpetual variation between their dials and clocks, which they must correct from time to time, before it arises to any sensible quantity, by setting their clocks so much faster or slower. And in *Italy*, they begin their day, and regulate their clocks, not from sun-set, but from about mid-twilight, when the *Ave Maria* is said; which corrects the difference that would otherwise be between the clock and the dial.

The improvements which have been made in all sorts of instruments and machines for measuring time, have rendered such dials of little account. Yet, as the theory of them is ingenious, and they are really, in some respects, the best contrived of any for vulgar use, a general idea of their description may not be unacceptable.

Let fig. 5. represent an erect south wall, on which a *Babylonian dial* is to be drawn, shewing the hours from sun-rising; the latitude of the place, whose horizon is parallel to the wall, being equal to the angle  $\angle ACR$ . Make, as for a common dial,  $KG = KR$  (which is perpendicular to  $CR$ ) the radius of the equinoctial  $AEQ$ , and draw  $RS$  perpendicular to  $CK$  for the stile of the dial; the shadow of whose point  $R$  is to mark the hours, when  $SR$  is set upright on the plane of the dial.

Then it is evident, that, in the contingent line  $AEQ$ , the spaces  $K 1$ ,  $K 2$ ,  $K 3$ , &c. being taken equal to the tangents of the hour-distances from the meridian, to the radius  $KG$ , one, two, three, &c. hours after sun-rising, on the equinoctial day; the shadow of the point  $R$  will be found, at these times, respectively in the points, 1, 2, 3, &c.

Draw, for the like hours after sun-rising, when the sun is in the tropic of Capricorn  $WV$ , the like common lines  $CD$ ,  $CE$ ,  $CF$ , &c. and at these hours the shadow of the point  $R$  will be found in those lines respectively. Find the sun's altitudes above the plane of the dial at these

hours, and with their co-tangents  $Sd$ ,  $Se$ ,  $Sf$ , &c. to radius  $SR$ , describe arcs intersecting the hour-lines in the points  $d$ ,  $e$ ,  $f$ , &c. so shall the right lines 1  $d$ , 2  $e$ , 3  $f$ , &c. be the lines of I, II, III, &c. hours after sun-rising.

The construction is the same in every other case, due regard being had to the difference of longitude of the place at which the dial would be horizontal, and the place for which it is to serve: And likewise, taking care to draw no lines but what are necessary; which may be done partly by the rules already given for determining the time that the sun shines on any plane; and partly from this, that on the tropical days, the hyperbola described by the shadow of the point  $R$  limits the extent of all the hour-lines.

*Of the right placing of dials, and having a true meridian line for the regulating of clocks and watches.*

The plane on which the dial is to rest being duly prepared, and every thing necessary for fixing it, you may find the hour tolerably exact by a large equinoctial ring-dial, and set your watch to it. And then the dial may be fixed by the watch at your leisure.

If you would be more exact, take the sun's altitude by a good quadrant, noting the precise time of observation by a clock or watch. Then compute the time for the altitude observed, and set the watch to agree with that time, according to the sun. A *Hadley's* quadrant is very convenient for this purpose; for, by it you may take the angle between the sun and his image reflected from a basin of water; the half of which angle, subtracting the refraction, is the altitude required. This is best done in summer, and the nearer the sun is to the prime vertical (the east or west azimuth) when the observation is made, so much the better.

Or, in summer, take two equal altitudes of the sun in the same day; one any time between 7 and 10 in the morning, the other between 2 and 5 in the afternoon; noting the moments of these two observations by a clock or watch: and if the watch shews the observations to be at equal distances from noon, it agrees exactly with the sun: if not, the watch must be corrected by half the difference of the forenoon and afternoon intervals; and then the dial may be set true by the watch.

Thus, for example, suppose you had taken the sun's altitude when it was 20 minutes past VIII in the morning by the watch; and found, by observing in the afternoon, that the sun had the same altitude 10 minutes before III; then it is plain, that the watch was 5 minutes too fast for the sun: for 5 minutes after XII is the middle time between VIII h. 20 m. in the morning, and III h. 50 m. in the afternoon; and therefore, to make the watch agree with the sun, it must be set back five minutes.

A good *meridian line*, for regulating clocks or watches, may be had by the following method.

Make a round hole, almost a quarter of an inch diameter, in a thin plate of metal; and fix the plate in the top of a south window, in such a manner, that it may recline from the zenith at an angle equal to the co-latitude of your place, as nearly as you can guess: for then

the plate will face the sun directly at noon on the equinoctial days. Let the sun shine freely through the hole into the room; and hang a plumb-line to the ceiling of the room, at least five or six feet from the window, in such a place as that the sun's rays, transmitted through the hole, may fall upon the line when it is noon by the clock; and having marked the said place on the ceiling, take away the line.

Having adjusted a sliding bar to a dove-tail groove, in a piece of wood about 18 inches long, and fixed a hook into the middle of the bar, nail the wood to the above-mentioned place on the ceiling, parallel to the side of the room in which the window is; the groove and bar being towards the floor. Then, hang the plumb-line upon the hook in the bar, the weight or plummet reaching almost to the floor; and the whole will be prepared for farther and proper adjustment.

This done, find the true solar time by either of the two last methods, and thereby regulate your clock. Then, at the moment of next noon by the clock, when the sun shines, move the sliding-bar in the groove, until the shadow of the plumb-line bisects the image of the sun (made by his rays transmitted through the hole) on the floor, wall, or on a white screen placed on the north side of the line; the plummet or weight at the end of the line hanging freely in a pail of water placed below it on the floor.—But because this may not be quite correct for the first time, on account that the plummet will not settle immediately, even in water; it may be farther corrected on the following days, by the above method, with the sun and clock: and so brought to a very great exactness.

*N. B.* The rays transmitted through the hole, will cast but a faint image of the sun, even on a white screen, unless the room be so darkened that no sunshine may be allowed to enter, but what comes through the small hole in the plate. And always, for some time before the observation is made, the plummet ought to be immersed in a jar of water, where it may hang freely; by which means the line will soon become steady, which otherwise would be apt to continue swinging.

*An universal dial, shewing the hours of the day by a terrestrial globe, and by the shadows of several gnomons, at the same time: together with all the places of the earth which are then enlightened by the sun; and those to which the sun is then rising, or on the meridian, or setting.*

This dial (see Plate LXXII.) is made of a thick square piece of wood, or hollow metal. The sides are cut into semicircular hollows, in which the hours are placed; the stile of each hollow coming out from the bottom thereof, as far as the ends of the hollows project. The corners are cut out into angles, in the insides of which the hours are also marked; and the edge of the end of each side of the angle serves as a stile for casting a shadow on the hours marked on the other side.

In the middle of the uppermost side, or plane, there is an equinoctial dial; in the centre whereof an upright wire is fixed, for casting a shadow on the hours of that dial, and supporting a small terrestrial globe on its top.

The whole dial stands on a pillar, in the middle of a

round horizontal board, in which there is a compass and magnetic needle, for placing the meridian stile toward the south. The pillar has a joint with a quadrant upon it, divided into 90 degrees (supposed to be hid from sight under the dial in the figure) for setting it to the latitude of any given place; the same way as already described in the dial on the cross.

The equator of the globe is divided into 24 equal parts, and the hours are laid down upon it at these parts. The time of the day may be known by these hours, when the sun shines upon the globe.

To rectify and use this dial, set it on a level table, or sole of the window, where the sun shines, placing the meridian stile due south, by means of the needle; which will be, when the needle points as far from the north fleur-de-lis toward the west, as it declines westward, at your place. Then bend the pillar in the joint, till the black line on the pillar comes to the latitude of your place in the quadrant.

The machine being thus rectified, the plane of its dial-part will be parallel to the equator, the wire or axis that supports the globe will be parallel to the earth's axis, and the north pole of the globe will point toward the north pole of the heavens.

The same hour will then be shewn in several of the hollows, by the ends of the shadows of their respective stiles: the axis of the globe will cast a shadow on the same hour of the day, in the equinoctial dial, in the centre of which it is placed, from the 20th of March to the 23d of September; and, if the meridian of your place on the globe be set even with the meridian stile, all the parts of the globe that the sun shines upon, will answer to those places of the real earth which are then enlightened by the sun. The places where the shade is just coming upon the globe, answer to all those places of the earth to which the sun is then setting; as the places where it is going off, and the light coming on, answer to all the places of the earth where the sun is then rising. And lastly, if the hour of VI be marked on the equator in the meridian of your place (as it is marked on the meridian of London in the figure) the division of the light and shade on the globe will shew the time of the day.

The northern stile of the dial (opposite to the southern or meridian one) is hid from sight in the figure, by the axis of the globe. The hours in the hollow to which that stile belongs, are also supposed to be hid by the oblique view of the figure: but they are the same as the hours in the front-hollow. Those also in the right and left hand semicircular hollows are mostly hid from sight; and so also are all those on the sides next the eye of the four acute angles.

The construction of this dial is as follows: (See Plate LXXI. fig. 4.)

On a thick square piece of wood, or metal, draw the lines *ac* and *bd*, as far from each other as you intend for the thickness of the stile *abcd*; and in the same manner, draw the like thickness of the other three stiles, *efgh*, *iklm*, and *nopq*, all standing outright as from the centre.

With any convenient opening of the compasses, as *aA* (so as to leave proper strength of stuff when *KI* is equal

to  $aA$ ) set one foot in  $a$ , as a centre, and with the other foot describe the quadrantal arc  $Ac$ . Then, without altering the compasses, set one foot in  $b$  as a centre, and with the other foot describe the quadrant  $dB$ . All the other quadrants in the figure must be described in the same manner, and with the same opening of the compasses, on their centres  $e, f, i, k$ ; and  $n, o$ : and each quadrant divided into six equal parts, for so many hours, as in the figure; each of which parts must be subdivided into 4, for the half hours and quarters.

At equal distances from each corner, draw the right lines  $Ip$  and  $Kp$ ,  $Lq$  and  $Mq$ ,  $Nr$ , and  $Or$ ,  $Ps$  and  $Qs$ ; to form the four angular hollows  $IpK$ ,  $LqM$ ,  $NrO$ , and  $PsQ$ ; making the distances between the tips of these hollows, as  $IK$ ,  $LM$ ,  $NO$ , and  $PQ$ , each equal to the radius of the quadrants; and leaving sufficient room within the angular points  $pqr$  and  $s$ , for the equinoctial dial in the middle.

To divide the insides of these angles properly, for the hour-spaces thereon; take the following method.

Set one foot of the compasses in the point  $I$ , as a centre, and open the other to  $K$ ; and with that opening describe the arc  $Kt$ : then, without altering the compasses, set one foot in  $K$ , and with the other foot describe the arc  $It$ . Divide each of these arcs, from  $I$  and  $K$  to their intersection at  $t$ , into four equal parts; and from their centres  $I$  and  $K$ , through the points of division, draw the right lines  $I3, I4, I5, I6, I7$ ; and  $K2, K1, K12, K11$ ; and they will meet the sides  $Kp$  and  $Ip$  of the angle  $IpK$  where the hours thereon must be placed. And these hour-spaces in the arcs must be subdivided into four equal parts, for the half-hours and quarters.—Do the like for the other three angles, and draw the dotted lines, and set the hours in the insides where those lines meet them, as in the figure: and the like hour-lines will be parallel to each other in all the quadrants and in all the angles.

Mark points for all these hours on the upper side; and cut out all the angular hollows, and the quadrantal ones quite through the places where their four gnomons must stand; and lay down the hours on their insides, as in Plate LXXII. and then set in their gnomons, which must be as broad as the dial is thick; and this breadth and thickness must be large enough to keep the shadows of the gnomons from ever falling quite out at the sides of the hollows, even when the sun's declination is at the greatest.

Lastly, draw the equinoctial dial in the middle, all the hours of which are equidistant from each other: and the dial will be finished.

As the sun goes round, the broad end of the shadow of the stile  $abcd$  will shew the hours in the quadrant  $Ac$ , from sun-rise till VI in the morning; the shadow from the end  $M$  will shew the hours on the side  $Lq$  from V to IX in the morning; the shadow of the stile  $efsb$  in the quadrant  $Dq$  (in the the long days) will shew the hours from sun-rise till VI in the morning; and the shadow of the end  $N$  will shew the morning hours, on the side  $Or$ , from III to VII.

Just as the shadow of the northern stile  $abcd$  goes off the quadrant  $Ac$ , the shadow of the southern stile  $iklm$

begins to fall within the quadrant  $Fl$ , at VI in the morning; and shews the time, in that quadrant, from VI till XII at noon; and from noon till VI in the evening in the quadrant  $mE$ . And the shadow of the end  $O$ , shews the time from XI in the forenoon till III in the afternoon, on the side  $rN$ ; as the shadow of the end  $P$  shews the time from IX in the morning till I o'clock in the afternoon, on the side  $Qs$ .

At noon, when the shadow of the eastern stile  $efgb$  goes off the quadrant  $hC$  (in which it shewed the time from VI in the morning till noon, as it did in the quadrant  $gD$  from sun rise till VI in the morning) the shadow of the western stile  $nopq$  begins to enter the quadrant  $Hp$ ; and shews the hours thereon from XII at noon till VI in the evening; and after that till sun set, in the quadrant  $qG$ : and the end  $Q$  casts a shadow on the side  $Ps$  from V in the evening till IX at night, if the sun be not set before that time.

The shadow of the end  $I$  shews the time on the side  $Kp$  from III till VII in the afternoon; and the shadow of the stile  $abcd$  shews the time from VI in the evening till the sun sets.

The shadow of the upright central wire, that supports the globe at top, shews the time of the day, in the middle or equinoctial dial, all the summer half year, when the sun is on the north side of the equator.

**DIALECT**, an appellation given to the language of a province, in so far as it differs from that of the whole kingdom. The term, however, is more particularly used in speaking of the ancient Greek, whereof there were four dialects, the Attic, Ionic, Æolic, and Doric, each of which was a perfect language in its kind, that took place in certain countries, and had peculiar beauties.

**DIALOGISM**, in rhetoric, is used for the soliloquy of persons deliberating with themselves. See **SOLILOQUY**.

**DIALOGUE**, in matters of literature, a conversation between two or more persons, either by writing or by word of mouth.

Dialogue appears to be the most ancient form of writing, and is greatly recommended by several authors. The archbishop of Cambray, at the head of his pastoral instruction, gives an account of the advantages of dialogue.

**DIALTHÆA**, in pharmacy, an unguent much used as a resolvent, so called from *althæa*, or marsh-mallows, which is the principal ingredient in it. See **ALTHÆA**.

**DIALYSIS**, in grammar, a mark or character, consisting of two points,  $\cdot\cdot$ , placed over two vowels of a word, in order to separate them, because otherwise they would make a diphthong, as *Mosaic*, &c. See **DIERESIS**.

**DIAMETER**, in geometry, a right line passing through the center of a circle, and terminated at each side by the circumference thereof. See **GEOMETRY**.

**DIAMOND**, in natural history, a genus of precious stones, of a fine pellucid substance, of great hardness, never fouled by any admixture of earthy or any other coarse matter, susceptible of elegant tinges from metal-  
line

fine particles, giving fire with steel, not fermenting with acid menstruums, scarcely calcinable by any degree of fire, and of one simple and permanent appearance in all lights.

This is the most valuable and hardest of all gems; and though found of different shapes, and sometimes accidentally tinged to several colours, yet ever carries the same distinguishing characters, and is very evidently in all those states the same body. It is, when pure, perfectly clear and pellucid as the purest water, and is eminently distinguished from all other substances, by its vivid splendor, and the brightness of its reflections. It is extremely various in shape and size, being found in the greatest quantity very small, and the larger ones extremely seldom met with; the largest diamond certainly known ever to have been found is that in the possession of the Great Mogul, which weighs 279 carats, and is computed to be worth 779,244 l.

The diamond has certainly one proper and determinate figure, into which it naturally mult concrete, when in a state of rest and impeded by no other accident in its formation: the true figure then is an equilateral octohedron; and where-ever it has concreated in a perfect manner, and without any interrupting accidents, it has always formed itself into this figure; and often in this its several surfaces are as bright as if polished by art: but, as in common salt, though its figure be pyramidal, yet very easy accidents can determine it into cubes and parallelopipeds; so the diamond has often, in the state of formation, been thrown into two other figures, both also seeming regular ones; the one a prismatic columnar one of six angles somewhat emulating the figure of crystal, the other an oblong quadrilateral column with two truncated ends: these seem the only regular figures of this gem; but besides these, it is every day found in numberless other mishapen forms, often roundish, emulating the shape of pebbles, but full of small flat planes or faces; frequently oblong, very often flat, and as often tapering, either from one end to the other, or else from the middle to both ends. A diamond bears the force of the strongest fire, except the concentrated solar rays, without hurt; and even that infinitely fiercest of all fires does it no injury, unless directed to its weaker parts.

It is a common thing for diamonds to be too thick or deep for the extent of their surface, and there is a certain proportion of depth, beyond which the gem should not be allowed: in this case two diamonds are often made, by the regularly dividing one: this, when the mass is of an angular figure, is done by cutting it through with a wire, wetted with oil, and covered with diamond-powder; but in the flat or more common mass, it is done much more expeditiously by finding the grain of the stone, and introducing the point of a fine flat chisel between them. This is not the only use of the splitting; for when a diamond has a flaw or blemish in it, which greatly debases its value, the plates may be separated at a proper breadth, and the flaw removed; in which case the thinner crust, struck off, is of value in proportion to its size, and the remainder, being now freed from its flaw, is of

much more value than it was at first. The places whence we have the diamonds are the East-Indies, in the island of Borneo, and in the kingdoms of Visapour, Golconda, Bengal; and the Brazils in the West-Indies. They are not unfrequently found yellowish, blueish, and reddish, but more rarely greenish.

*Valuation of DIAMONDS*, among jewellers, is thus calculated: they suppose the value of a rough diamond to be 2 l. per carat; then to find the value of those of greater weight, they multiply the square of their weight by 2, and this last product is the value of the diamonds in their rough state: thus, the value of a rough diamond weighing 4 carats, is equal  $4 \times 4 \times 2 = 16 \times 2 = 32$  l. and so in other cases. Again, to find the value of wrought diamonds, they suppose half their weight lost in the manufacturing them, and therefore multiply the square of double their weight by 2; thus the value of a wrought diamond, weighing 3 carats, is equal  $6 \times 6 \times 2 = 36 \times 2 = 72$  l.

*Rose-DIAMOND* is that quite flat underneath, with its upper part cut in divers little faces, usually triangles, the uppermost of which terminate in a point.

*Table-DIAMOND* is that which has a large square face at top, encompassed with four lesser.

*Brilliant DIAMOND* is that cut in faces both at top and bottom; and whose table, or principal face at top, is flat.

*DIAMOND*, in the glass-trade, an instrument used for squaring the large plates or pieces; and, among glaziers, for cutting their glass.

These sort of diamonds are differently fitted up; that used for large pieces, as looking-glasses, &c. is set in an iron ferril, about two inches long, and a quarter of an inch in diameter; the cavity of the ferril being filled up with lead, to keep the diamond firm: there is also a handle of box, or ebony, fitted to the ferril, for holding it by.

*DIAMOND*, in heraldry, a term used for expressing the black colour in the achievements of peerage.

Guillim does not approve of blazoning the coats of peers by precious stones instead of metals and colours; but the English practice allows it. Morgan says the diamond is an emblem of fortitude.

*DIANÆ ARBOR*, or *ARBOR LUNÆ*, in chemistry, the beautiful crystallizations of silver, dissolved in aqua fortis, to which some quicksilver is added: and so called from their resembling the trunk, branches, leaves, &c. of a tree. See *CHEMISTRY*.

*DIANDRIA*, in the Linnæan system of botany. See *BOTANY*, p. 635.

*DIANO*, a town of the Genoese, about three miles from the sea. The country about produces great numbers of olives.

*DIANTHERA*, in botany, a genus of the diandria monogynia class. The corolla is ringent; and the capsule has two elastic valves. There are two species, both natives of America.

*DIANTHUS*, in botany, a genus of the decandria digynia class. The calix is cylindrical, and consists of one leaf, with four scales at the base; the corolla consists of five clawed petals; and the capsule is cylindrical, and

and has but one call. There are seventeen species, five of which are natives of Britain, *viz.* the armeria, or Deptford pink; the proflifer, or linewort; the deltoides, or maiden pink; the glaucus, or mountain pink; and the arenarius, or stone pink.

**DIAPASON**, in music, a musical interval, by which most authors, who have wrote upon the theory of music, use to express the octave of the Greeks. See OCTAVE.

**DIAPASON**, among the musical-instrument makers, a kind of rule or scale, whereby they adjust the pipes of their organs, and cut the holes in their flutes, hautboys, &c. in due proportion, for performing the tones, semitones, and concords just.

**DAPASON DIAEX**, in music, a kind of compound concord, whereof there are two sorts; the greater, which is in the proportion of 10:3; and the lesser, in that of 16:5.

**DIAPASON DIAPENTE**, in music, a compound consonance in a triple ratio, as 3:9. This interval, says Martianus Capella, consists of nine tones and a semitone, nineteen semitones, and thirty eight dieses. It is a symphony made when the voice proceeds from the first to the twelfth sound.

**DIAPASON DIATESSARON**, in music, a compound concord, founded on the proportion of 8:3. To this interval Martianus Capella allows eight tones and a semitone, seventeen semitones, and thirty-four dieses.

This is when the voice proceeds from its first to its eleventh sound. The moderns would rather call it the eleventh.

**DIAPASON DITONE**, in music, a compound concord, whose terms are as 10:4, or 5:2.

**DIAPASON SEMIDITONE**, in music, a compound concord, whose terms are in the proportion of 12:5.

**DIAPEDESIS**, in medicine, a transfusion of the fluids through the sides of the vessels that contain them, occasioned by the blood's becoming too much attenuated, or the pores becoming too patent.

**DIAPENSIA**, in botany, a genus of the pentandria-monogynia class. The calix consists of five leaves, imbricated with three smaller ones; the stamina arise from the tube of the corolla; and the capsule has three cells; there are three species, none of them natives of Britain.

**DIAPENTE**, in the ancient music, an interval marking the second of the concords; and with the diatessaron, an octave. This is what in the modern music is called a fifth.

**DIAPHANOUS**, an appellation given to all transparent bodies, or such as transmit the rays of light. See OPTICS.

**DIAPHOENICUM**, in pharmacy, a sort of medicine or electuary chiefly made of dates. It purges serosities, and excites the menses. It is also used in dropsies, lethargies, apoplexies, and palsies.

**DIAPHORESIS**, in medicine, an elimination of the humours in any part of the body through the pores of the skin. See PERSPIRATION.

**DIAPHORETICS**, among physicians, all medicines which promote perspiration.

**DIAPHHRAGM**, in anatomy. See Vol. I. p. 213.

**DIAPOROSIS**, in rhetoric, a figure of oratory, expressing the uncertainty of the speaker how he shall proceed in his discourse.

**DIARREC**, or **DIARBECK**, the capital of a province of the same name, answering to the ancient Mesopotamia: it is situated on the river Tigris, near its source, in 42° E. long. and 37° 20' N lat.

**DIARRHOEA**, or **LOOSENESS**, in medicine, is a frequent and copious evacuation of liquid excrement, by stool. See MEDICINE.

**DIARTHROSIS**, in anatomy. See Vol. I. p. 148.

**DIARY**, among traders, denotes a day-book containing the proceedings of one day.

**DIACHISM**, among musicians, denotes the difference between the comma and enharmonic diesis, commonly called the lesser comma.

**DIASCORDIUM**, in pharmacy, a celebrated composition, so called from scordium, one of its ingredients. It is otherwise termed *confectio fracastorii*, and is thus directed by the college.

Take of cinnamon and cassia-wood, of each half an ounce; of true scordium, one ounce; of Cretan dittany, tormentil, bistort, galbanum, and gum-arabic, of each half an ounce; of storax, four drams and an half; of opium, and seeds of sorrel, of each one dram and an half; of gentian, half an ounce; of American bole, one ounce and an half; of Lemnian sealed earth, half an ounce; of long pepper and ginger, of each two drams; of clarified honey, two pounds and an half; of sugar of roses, one pound; of generous canary, eight ounces; make into an electuary. It is excellent in all kinds of fluxes, and a great strengthener both of the stomach and bowels.

**DIASEHESTEN**, in pharmacy, a soft purgative electuary, whereof sebestens are the principal ingredients. The other ingredients are prunes, tamarinds, juices of iris, anguria and mercurialis, penidies, simple diaprurnum, violet seeds, and diagrydium. It is good in remitting and continued fevers, &c.

**DIASENNA**, in pharmacy, the name of a medicine in which fenna is the principal ingredient.

The other ingredients are sugar-candy, cinnamon, lapis lazuli, silk, cloves, galanga-minor, black pepper, nardus indica, seed of basilicum, flowers of cloves, cardamoms, saffron, ginger, zedoary, &c.

This electuary is taken against melancholy and spleen, and against diseases arising from an atrabilis.

**DIASTOLE**, among physicians, signifies the dilatation of the heart, auricles and arteries; and stands opposed to the systole, or contraction of the same parts. See CIRCULATION.

**DIASTOLE**, in grammar, a figure of prosody, whereby a syllable naturally short is made long: such is the first syllable of Priamides, in the following verse of Virgil.

*Atque hic Priamides! nihil tibi, amice, reliquum.*

**DIASYRMUS**, in rhetoric, a kind of hyperbole, being an exaggeration of some low ridiculous thing.

**DIATESSARON**, among ancient musicians, a concord, or harmonical interval, composed of a greater tone, a

less tone, and one greater semi-tone: its proportion in numbers is as 4 : 3.

**DIATESSARON**, in pharmacy, the name of a composition so called, from the four ingredients it comprehends: it is prepared thus.

Take of gentian root, bay-berries, myrrh, and roots of birthwort, of each two ounces; of honey, two pounds; mix them into an electuary. This, with the addition of the shavings of ivory, two ounces, is entitled diapente, or a composition of five ingredients.

**DIATONIC**, an epithet given to music, as it proceeds by tones and semi-tones, both ascending and descending. See **MUSIC**.

**DIATRAGACANTH**, in pharmacy, a name applied to certain powders, whereof gum tragacanth is the principal ingredient; of which there are two kinds, the cold and the hot: the cold is directed thus: take of gum tragacanth, two ounces; of gum arabic, an ounce and two drams; of starch, half an ounce; of liquorice, and the seeds of melons and white poppies, of each two drams; of sugar candy, three ounces; mix them into a powder. This is frequently prescribed in febrile heats, in choleric constitutions, in distempers of the breast, in strangueries, heat of urine, and the pungency of venereal gleets.

Powder of hot diatragacanth is composed of gum tragacanth, cinnamon, hyssop, almonds, linseed, fenugreek, liquorice, and ginger. It is good against asthma, to promote expectoration, strengthen the stomach, and assist digestion.

**DIAUGOPHRAGMIA**, in natural history, a genus of fossils of the order of septaria, whose partitions, or septa, consist of spar with an admixture of crystal. Of this genus there are three species. 1. A red kind, with brownish yellow partitions. 2. A brownish yellow kind, with whitish partitions. 3. A bluish-white kind, with straw-coloured partitions.

**DICE**, among gamblers, certain cubical pieces of bone or ivory, marked with dots on each of their faces, from one to six, according to the number of faces.

Sharps have several ways of falsifying dice. 1. By sticking a hog's bristle in them, so as to make them run high or low, as they please. 2. By drilling and loading them with quicksilver; which cheat is found out by holding them gently by two diagonal corners; for if false, the heavy sides will turn always down. 3. By filling and rounding them. But all these ways fall far short of the art of the dice-makers; some of whom are so dextrous this way, that your sharpening gamblers will give any money for them.

Dice formerly paid 5 s. every pair imported, with an additional duty of 4 s. 9 <sup>1</sup>/<sub>2</sub> d. for every 20 s. value upon oath; but are now prohibited to be imported.

**DICHOTOMY**, a term used by astronomers for that phasis, or appearance of the moon, wherein she is bisected, or shews just half her disk. In this situation the moon is said to be in a quadrate aspect, or to be in her quadrature.

**DICHOTOMY**, in botany. See **BOTANY**, p. 641.

**DICHOTOPHYLLUM**, it botany. See **CERATOPHYLLUM**.

**DICKER**, in old writers, denotes the quantity of ten hides of skins, whereof twenty made a last: also ten pair of gloves, ten bars of iron, and the like, are sometimes expressed by the term dicker.

**DICTAMUS**, **DITTANY**, in botany. a genus of the decandria monogynia class. The calix consists of five leaves, and the corolla of five open petals; the filaments have many glandular points; and the five capsules are united. There is but one species, *viz.* the oblus, a native of Italy. The root is said to be alexipharmic, but is not regarded in practice.

**DICTATOR**, in the policy of the ancient Romans, a magistrate invested with sovereign and even arbitrary power.

He had power of life and death; also to raise and disband troops, make war or peace, and that without the consent either of the senate or people, or being accountable for his proceedings. He was elected by one of the consuls in the night-time, on the frontiers of the commonwealth, and nowhere else; and the ordinary duration of his office was only for six months, during which time all other magistracies ceased, the tribuneship excepted. Whenever he appeared in public, he was attended by twenty-four lictors, or double the number allowed a consul. However, notwithstanding all this power, he could not go out of Italy, or even ride on horseback during a march, without leave from the people.

This office was accounted the safeguard of the commonwealth for four hundred years together, till Sylla and Cæsar, by assuming the title of perpetual dictators, converted it into tyranny, and rendered the very name odious.

**DIC TION**, the phrase, elocution, or style of a writer or speaker. See **COMPOSITION**.

**DICTIONARY**, in its original acceptation, is the arranging all the words of a language according to the order of the alphabet, and annexing a definition or explanation to each word. When arts and sciences began to be improved and extended, the multiplicity of technical terms rendered it necessary to compile dictionaries either of science in general, or of particular sciences, according to the views of the compiler. For further particulars concerning dictionaries of this kind, see the *Preface*.

**DICTIONARY of the English language**. The only attempt which has hitherto been made towards forming a regular dictionary of the English language, is that of the learned Dr Samuel Johnson. But although it is executed in a masterly manner, yet as it cannot be expected that an undertaking of this nature could be brought to perfection by one man, we shall venture to suggest a few circumstances which, if duly attended to, may perhaps be of some utility.

The design of every dictionary of language, is to explain in the most accurate manner, the meaning of every word, and to shew the various ways in which it can be combined with others, in as far as this tends to alter its meaning. The dictionary which does this

this in the most accurate manner, is the most complete. Therefore the principal study of a lexicographer ought to be, to discover a method which will be best adapted for that purpose. Dr Johnson, with great labour, has collected the various meanings of every word, and quoted the authorities: But, would it not have been an improvement if he had given an accurate definition of the precise meaning of every word; pointed out the way in which it ought to be employed with the greatest propriety; shewed the various deviations from that original meaning, which custom had so far established as to render allowable; and fixed the precise limits beyond which it could not be employed without becoming a vicious expression? With this view, it would have been necessary to exhibit the nice distinctions that take place between words which are nearly synonymous. Without this, many words can only be defined in such a manner, as that they must be considered as exactly synonymous. We omit giving any quotations from Johnson to point out these defects; but shall content ourselves with giving a few examples, to shew how, according to our idea, a dictionary of the English language ought to be compiled.

**IMMEDIATELY.** *adv. of time.*

1. Instantly, without delay. Always employed to denote future time, and never past. Thus, we may say, *I will come immediately*; but not, *I am immediately come from such a place*. See **PRESENTLY**.
2. Without the intervention of any cause or event; as opposed to mediately.

**PRESENTLY.** *adj. of time.*

1. Instantly, without delay. Exactly synonymous with *immediately*; being never with propriety employed to denote any thing but future time.
2. Formerly it was employed to express present time: Thus, *The house presently possessed by such a one*, was often used; but this is now become a vicious expression, and we ought to say, *The house possessed at present*. It differs from *immediately*, in this, that even in the most corrupt phrases it never can denote past time.

**FORM.** *subst.* The external appearance of any object when considered only with respect to shape or figure. This term therefore, in the literal sense, can only be applied to the objects of the sight and touch; and is nearly synonymous with figure; but they differ in some respects. *Form* may be employed to denote more rude and unfinished shapes; *figure*, those which are more perfect and regular. *Form* can never be employed without denoting matter; whereas *figure* may be employed in the abstract: Thus, we say a square or a triangular *figure*; but not a square or triangular *form*. And in the same manner we say, the *figure* of a house; but we must denote the substance which forms that figure, if we use the word *form*; as, *a cloud of the form of a house*, &c. See **FIGURE**.

2. In contrast to irregularity, or confusion. As beauty cannot exist without order, it is by a figure of speech employed to denote beauty, order, &c.
3. As *form* regards only the external appearance of

bodies, without regard to their internal qualities, it is, by a figure of speech, employed in contrast to these qualities, to denote empty shew, without essential qualities. In this sense it is often taken when applied to religious ceremonies, &c.

4. As *form* is employed to denote the external appearance of bodies; so, in a figurative sense, it is applied to reasoning, denoting the particular mode or manner in which this is conducted; as, *the form of a syllogism*, &c.
5. In the same manner it is employed to denote the particular mode of procedure established in courts of law; as, *the forms of law, religion*, &c.
6. *Form* is sometimes, although improperly, used to denote the different circumstances of the same body; as, *water in a fluid or a solid form*. But as this phrase regards the internal qualities rather than the external figure, it is improper, and ought to be, *water in a fluid, or a solid state*.
7. But when bodies of different kinds are compared with one another, this term may be employed to denote other circumstances than shape or figure; for we may say, *a juice exuding from a tree in the form of wax or resin*; although, in this case, the consistence, colour, &c. and not the external arrangement of parts, constitutes the resemblance.
8. From the regular appearance of a number of persons arranged in one long seat, such persons so arranged are sometimes called a *form*; as, *a form of students*, &c. And,
9. By an easy transition, the seat itself has also acquired that name.

**GREAT.** *adj.* A relative term, denoting largeness of quantity, number, &c. serving to augment the value of those terms with which it is combined, and opposed to *small* or *little*. The principal circumstances in which this term can be employed, are the following:

1. When merely inanimate objects are considered with regard to quantity, *great* is with propriety employed, to denote that the quantity is considerable; as, *a great mountain, a great house*, &c. and it is here contrasted with *small*. When *great* is thus employed, we have no other word that is exactly synonymous.
2. When inanimate objects are considered with regard to their extent, this term is sometimes employed, although with less propriety; as, *a great plain, a great field*, &c. and in this sense it is nearly synonymous with *large*; and they are often used indiscriminately, but with some difference of meaning: for, as *large* is a term chiefly employed to denote extent of superficies, and as *great* more particularly regards the quantity of matter; therefore, when *large* is applied to any object which is not merely superficial, it denotes that it is the extent of surface that is there meant to be considered, without regard to the other dimensions; whereas when the term *great* is employed, it has a reference to the whole contents. If, therefore, we say, *a large house*, or *a large river*, we express that the house, the river, have

have a surface of great extent, without having any necessary connection with the size in other respects. But if we say, *a great house*, or *a great river*, it at once denotes that they have not only a large surface, but are also of great size in every respect.

3. *Great*, when applied to the human species, never denotes the size or largeness of body, but is applied solely to the qualities of the mind. Thus, when we say, that *Socrates was a great man*, we do not mean that he was a man of great size, but that he was a man who excelled in the endowments of the mind. The terms which denote largeness of size in the human body are, *big*, *bulky*, *huge*, &c.
4. *Great* is sometimes applied to the human species, as denoting high rank. In this case it is oftener used in the plural number than otherwise. Thus we say simply, *the great*, meaning the whole body of men in high station, as opposed to *mean*. It should seldom be employed in this sense, as it tends to confound dignity of rank with elevation of mind.
5. As this is a general term of augmentation, it may be joined with all nouns which denote *quantity*, *quality*, *number*, *excellence*, or *defects*; or such as imply *praise*, *blame*, *anger*, *contempt*, or any other affection of the mind.
6. It is employed to denote every step of ascending or descending consanguinity; as, *great-grandfather*, *great-grandson*, &c.

**HIGH.** *adj.* Exalted in a perpendicular direction at a distance from the surface of the earth. Opposed to *low*.

1. *High* is a term altogether indefinite, and is employed to express the degree of elevation of any inanimate body. Thus, we say, *a high mountain*, *a high house*, *steeple*, *tower*, *pillar*, &c. nor is there any other word that can here be considered as synonymous; *lofty* being employed only to denote a very eminent degree of elevation.
2. To express the perpendicular elevation of vegetables, either *high* or *tall* may be employed, as being in this case nearly synonymous, we may therefore say, *a high* or *tall tree*, *a high* or *tall mast*, &c. but with this difference between these two expressions, that *tall* can be more properly applied to those that are much elevated and of small dimensions; and *high*, to such as are more bulky, and of greater size.
3. The perpendicular height of man can never be expressed by the word *high*; *tall* being here the proper expression. And although *high* is sometimes used to express the height of other animals, yet it seems to be an improper expression. See **TALL**.
4. *High*, when applied to the human species, always refers to the mind; and denotes *haughtiness*, *statefulness*, *pride*, &c.; and, when combined with the expressions of any energy of the mind, it denotes that in a higher degree. In this sense, it is opposed to *meanness*, *abjectness*, and *humility*.
5. As this is an indefinite term, tending to denote any thing that is elevated above us, it may be combined with almost every noun which admits of this

elevation. And as objects high above us are always out of our reach, it is in a metaphorical sense used to denote any thing that seems to be above the ordinary condition of mankind; or those qualities or endowments of mind that are not easily acquired; as, *dignity* or *elevation of sentiment*, *dignity of rank*, *acuteness in reasoning on difficult subjects*; *pride*, *haughtiness*, or any other quality which seems beyond the ordinary level of mankind; *dearness of price*, &c.

6. In the same manner we employ this term to time; which having a metaphorical resemblance to a river, flowing on with an unceasing current through all successive ages, any thing of remote antiquity is denoted by the term *high*.
7. Likewise those degrees of latitude far removed from the line, where the pole becomes more elevated.
8. And to some particular crimes, as being attended with peculiar degrees of guilt; as, *high treason*.

**TALL.** *adj.* Something elevated to a considerable degree in a perpendicular direction. Opposed to *low*.

1. This term is chiefly employed to express the height of man, and other animals; and is applied to denote the height of the body only, without having any reference to the mind. When applied to man, no other word can be substituted in its stead: when applied to other animals, *high* is sometimes considered as nearly synonymous. See **HIGH**.
2. It is likewise employed to denote the perpendicular height of vegetables; and in this case it is nearly synonymous with *high*. See **HIGH**.
3. It can in no case be employed to express the height of merely inanimate objects; as we can never say *a tall steeple*, *tower*, or *pillar*, but *a high steeple*, &c. For the distinctions in these cases, see **HIGH**.

**LONG.** *adj.* A relative term, denoting the distance between the extremes of any body, which is extended more in one of its geometrical dimensions than another. Opposed to *short*.

1. This term may be applied to all inanimate objects, of whatever kind, whose dimensions in one way exceeds the other, and when not in an erect posture, whatever be the other circumstances attending them; whether it relates to superficies alone, or to solid bodies; whether these be bounded or open, straight or crooked, flexible or rigid, or in any other circumstances whatever; thus we say *a long* or *short line*, *a long* or *short ridge*, *street*, *ditch*, *rope*, *chain*, *staff*, &c. But it is to be observed, that although *long* is, in the strict sense only, opposed to *short*; yet as it expresses the extension of matter in one of its geometrical proportions, it is often contrasted by those words which express the other proportions when we mean only to describe the several proportions; as, *a table long and broad*: and as these several dimensions are expressed by different words, according to the various forms, modifications, and circumstances, in which bodies are found; therefore it is in this sense contrasted by a great diversity of terms; as, *a long*  
and

*and broad, or wide, narrow, or strait street or lane, a long and thick, or small rope, chain, staff, &c.* For the distinctions in these cases, see BROAD, WIDE, &c.

2. Objects necessarily fixed in an erect position can never have this term applied to them; and therefore we cannot say *a long*, but *a high tower or steeple*. And for the same reason, while trees are growing and fixed in an erect position, we cannot apply this term to them; but when they are felled and laid upon the ground, it is quite proper and necessary. Thus, we do not say *a long*, but *a tall or high tree*, while it is growing; but we say *a long*, not *a tall log of wood*: and in the same manner we say *a tall mast*, when it is fixed in the ship; but *a long mast*, while it lies upon the beach. See TALL and HIGH.
3. Those vegetables which are of a tender pliant nature, or so weak as not to be able to retain a fixed position, being considered as of a middle nature between erect and prostrate bodies, admit of either of the terms *long*, *tall*, or *high*; as, *a long or tall rush or willow wand*, or *a long, tall, or high stalk of corn*. See HIGH and TALL.
4. The parts of vegetables, when considered as distinct from the whole, even when growing and erect, assume the term *long*: for we do not say *a tall*, but *a long shoot of a tree*; and *a tree with a long stem*, in preference to *a tree with a high stem*.
5. For the same reason, a staff, and pole, even when fixed in a perpendicular direction, assume the word *long*, in preference to *tall or high*.
6. With regard to animals, the general rule is applied, without any exceptions; *tall*, and not *long*, being employed to denote the height of the human body, when in an erect posture; and *long* and not *tall*, to denote its length when in an incumbent situation. *Long*, applied to all other animals which do not walk erect, always denotes their greatest length in a horizontal position from head to tail.
7. In a figurative sense, it denotes, with regard to time, any thing at a great distance from us.
8. As also, any thing that takes up much time before it is finished; as, *a long discourse, a protracted note in music, &c.*

**BROAD.** *adj.* The distance between the two nearest sides of any body, whose geometrical dimensions are larger in one direction than in another; and has a reference to superficies only, and never to the solid contents. Opposed to *narrow*.

1. *Broad*, in the strictest acceptation, is applied to denote those bodies only whose sides are altogether open and unconfined; as, *a broad table, a broad wheel, &c.* and in these cases it is invariably contrasted by the word *narrow*; nor is there any other word which in these cases can be considered as synonymous with it, or used in its stead.
2. When any object is in some sort bounded on the sides, although not quite closed up, as a road, street, ditch, &c. either *broad* or *wide* may be employed, but with some difference of signification; *broad* be-

ing most properly used for those that are more open, and *wide* to those which are more confined; nor can this term be ever applied to such objects as are close bounded all around, as a house, church, &c. *wide* being here employed. For the more accurate distinctions in these cases, see the article WIDE.

**WIDE.** *adj.* A term employed to denote relative extent in certain circumstances. Opposed to *narrow* and *strait*.

1. This term is in its proper sense applied only to denote the space contained within any body closed all round on every side, as a house, gait, &c. and differs from *broad* in this, that it never relates to the superficies of solid objects, but is employed to express the capaciousness of any body which containeth vacant space; nor can capaciousness in this sense be expressed by any other word but *wide*.
2. As many bodies may be considered either with respect to their capaciousness, or superficial extent; in all these cases, either the term *broad* or *wide* may be used; as, *a broad or wide street or ditch, &c.* but with a greater or less degree of propriety, according to the circumstances of the object, or the idea we wish to convey. In a street where the houses are low, and the boundaries open, or in a ditch of small depth and large superficies, as this largeness of superficies bears the principal proportion, *broad* would be more proper; but if the houses are of great height, or the ditch of great depth, and capaciousness is the principal property that affects the mind, we would naturally say *a wide street or ditch*; and the same may be said of all similar cases: but there are some cases in which both these terms are applied, with a greater difference of meaning; thus we say, *a broad, or a wide gate*; but as the gate is employed to denote either the aperture in the wall, or the matter which closes that aperture, these terms are each of them used to denote that particular quality to which they are generally applied: and as the opening itself can never be considered as a superficies, the term *wide*, in this case, denotes the distance between the sides of the aperture; while, on the contrary, *broad* denotes the extent of matter fitted to close that aperture; nor can these two terms in any case be substituted for one another.
3. As a figurative expression, it is used as a cant phrase for a mistake; as, *you are wide of the mark*; that is, not near the truth.

**NARROW.** *adj.* A relative term, denoting a proportional smallness of distance between the sides of the superficies of plain bodies. Opposed to *broad*.

1. As this is only applied to superficies, it is exactly contrasted by *broad*, and is applied in all cases where the term *broad* can be used, (see BROAD); and in no other case but as a contrast to it, except the following.
2. It sometimes is employed to describe the smallness of space circumscribed between certain boundaries, as opposed to *wide*, and nearly synonymous with

*strait*; as we say *a wide* or *a narrow house, church, &c.* For the necessary distinctions here, see the article **STRAIT**.

3. In a figurative sense it denotes *parsimony, poverty, confined sentiments, &c.*

**STRAIT.** *adj.* A relative term, denoting the extent of space in certain circumstances. Opposed to *wide*, see **WIDE**.

1. This term is employed, in its proper sense, to denote only space, as contained between surrounding bodies in such circumstances as to denote some degree of confinement; and is exactly opposed to *wide*; as, *a wide* or *a strait gate, &c.* See **WIDE**.
2. So necessary is it that the idea of confinement should be connected with this word, that in all those cases where the space contained is large, as in a church or house, we cannot express a smaller proportional width by this term. And as we have no other word to express space in these circumstances, we have been obliged to force the word *narrow* from its natural signification, and make it express this. See **NARROW**.
3. In some particular cases *narrow* or *strait* may be employed to the same object; as, *a narrow* or *a strait lane*: but here *strait* is never employed but where an idea of confinement is suggested, and where it is exactly contrasted to *wide*; nor can *narrow* be employed but in such circumstances where *broad* would be a perfect contrast to it. Therefore these two terms may be always employed in the same circumstances as those which contrast them may be. For an account of which, see **WIDE**.
3. The term *strait* is likewise in a peculiar manner used to denote the smallness of the internal diameter of those small bodies which are fitted to receive or contain others as, any kind of bag, tube, body-cloaths, mortoise, and others of the same kind; and in all these cases this term may be employed to denote the smallness of their lesser diameter, and never the term *narrow*. But in certain circumstances the word *tight* may be substituted for it. See **TIGHT**.
4. *Strait*, in a figurative sense, denotes any sort of confinement of sentiment or disposition.

**TIGHT.** *adj.* A term employed in certain circumstances to denote the internal capacity of particular bodies. Nearly synonymous with *strait*.

This term is confined entirely to denote the smallness of the internal dimensions of such objects as are formed to cover or to receive or contain other solid bodies, and can be employed in no other case. And although it agrees with *strait*, in always denoting confinement, and by being applicable to the same species of objects, yet it differs in the the following respects: 1. If there be any difference of the diameter of the objects to which the term *strait* can be employed, it always has reference to the smaller; yet *tight* may be employed to any sort of confinement, whether it regards the length or breadth. 2. *Strait* can be applied to all bodies of capacity when of small diameter, without any sort of reference to the nature of the substance which it may

be capable of containing. For we can say *a strait bag, a strait sleeve, a strait mortoise, a strait gate, &c.* whereas *tight* can only be applied to any body when it is considered as having reference to another body which is intended to be contained in it and is pinched for want of room. Thus, we say, *the sleeve of a coat is too tight for the arm, the mortoise is too tight for the tenon, &c.* but we cannot say, *the bag, or the gate is too tight*, because these are fitted to receive any sort of objects. And hence it happens, that, in many cases, the dimensions of the same body may be expressed by *tight* or *strait* when considered in different circumstances. Thus, we may say, *this sleeve is too strait*, when we look at a coat when lying on the table, and consider its proportions; but it is not till we have tried it upon the arm that it is intended to cover, that we call it *tight*. And we may say, *a gate is too strait, or too tight*; but in the first case we consider it as being too confined for admitting objects to pass through it, and in the last as being too confined with respect to the leaves that are to shut the aperture, not allowing them space to move with freedom.

These examples may serve to give some idea of the plan of an English dictionary composed upon philosophical principles: But, besides the circumstances above enumerated, there are many others which would require particular attention in the execution of a work of this kind. In the English language, a great variety of terms occur, which denote matter under certain general forms or circumstances, without regarding the minute diversities that may take place; as the word *cloth*, which denotes matter as manufactured into a particular form, including under it all the variety of stuffs manufactured in that particular way, of whatever materials, colours, texture, or fineness they may be. The same may be said of *wood, iron, yarn*, and a great variety of terms of the same nature, some of which cannot assume any plural; while others admit of it in all cases; and others admit or refuse it according to the different circumstances in which they are considered. In a dictionary, therefore, all this variety of cases ought to be clearly and distinctly pointed out under each particular article: this is the more necessary, as some of these words have others formed from them, which might be readily mistaken for their plurals, although they have a very different signification; as *cloaths* which does not denote any number of pieces or different kinds of *cloth*, but *wearing apparel*. The following example will illustrate this head.

**WOOD.** *sub.* A solid substance of which the trunks and branches of trees consist.

1. This term is allowed to denote the solid parts of vegetables of all kinds, in whatever form or circumstances they are found. Nor does this term admit of plural with propriety, unless in the circumstances after mentioned: for we say, *many different kinds of wood*, in preference to *many kinds of woods*; or, we say, *oak, ash, or elm wood*; not *woods*.
2. But where we want to contrast *wood* of one quality,

lity or country with that of another, it admits of a plural; for we say, *white woods are in general lighter than red*; or *West-Indian woods are in general of greater specific gravity than the European woods*: But unless where the colour, or some quality which distinguishes it from growing wood, is mentioned, this plural ought as much as possible to be avoided, as it always suggests an idea of growing wood.

3. *Wood* likewise denotes a number of trees growing near one another; being nearly synonymous with *forest*: See *FOREST*. In this sense it always admits of a plural; as, *Ye woods and wilds whose solitary gloom, &c.*

A dictionary cannot be reckoned complete without explaining obsolete words; and if the terms of the several provincial provincial dialects were likewise given, it would be of great utility: nor would this take much time; because a number of these words need no other explanation than to mark along with them the words which had come in their place, when there happened to be one perfectly synonymous: and in these cases where the same idea could not be expressed in modern language without a periphrasis, it would be of use to explain them distinctly; so that, when a writer found himself at a loss for a term, and obliged to search for one beyond the bounds of our own language, he might take one of these, when he found that it was expressive and energetic, in preference to another drawn from a foreign language. This would at least have one good effect: it would make our language more fixed and stable; not to say more accurate and precise, than by borrowing from foreign languages. The following examples may serve to give some idea of the manner of treating this part of the work.

*MOE*, or *MO*. *adj.* An obsolete term still employed in the Scotch dialect, and by them pronounced *mae*: denoting a greater number, and nearly synonymous with *more*; but it differs in this respect, that, in the Scotch dialect, *mae* and *mair* (*English, more*) are each employed in their distinct sphere, without encroaching upon one another; *mae* being employed to denote number, but never quantity or quality; and *mair*, to denote quantity and quality, but never number: thus they say *mae*, not *mair apples, men, &c.* and they say *mair*, not *mae cloth, earth, courage, &c.* See *MAIR*. Both of these terms are supplied by the word *more*; which, in the English language, is applied indiscriminately to denote quantity, quality, and number. See *MORE*.

*THIR*. *pron.* Obsolete; still employed in the Scotch dialect: the plural of *this*; and contrasted to *these*, in the same manner as *that* is to *this*.

As there is no word in the English language equivalent to this, we thus shew the manner in which it is employed. In the English language we say, *that stone or house*, pointing at one at a distance, *is larger or more commodious than this stone or this house*, which is supposed to be at hand. In the same manner, in the Scotch dialect, they say, *these* (or as it is pronounced, *thae*) *stones are whiter than thir*

*stones*; denoting, that the former are at a distance, and the latter at hand. And, in the same manner, it is invariably applied to denote any present object in the plural number, as opposed to *these*; as *these or thir apples*, as at hand or at a distance; *these or thir trees, &c.*; but never in the singular number, as it is always *this* or *that tree, house, &c.*

As the English language is so exceedingly irregular in the pronunciation, the same letter in the same situation often assuming sounds totally different in different words, it is impossible to establish any general rules on this subject, which do not admit of many exceptions: therefore, a dictionary is the best means of ascertaining and pointing out the proper pronunciation of words. For, if the writer first pointed out all the different sounds that the same letter could ever be made to express, and assigned to every particular sound which each letter could be made to assume, a particular mark, which was appropriated to denote that particular sound of the letter whenever it occurred; by placing these particular marks above the letters in the dictionary, the sound of each letter would be pointed out in all cases with the utmost certainty. It would be impossible for us to illustrate this by examples, without first ascertaining all the sounds of each letter; which would lead us into a discussion too long for this place; and this is at present the more unnecessary, as the public have been long in expectation of a dictionary, by a very able hand, in which this particular will be attended to.

We shall only further observe, that, besides having the accented syllable of every word properly distinguished in a dictionary to assist in the pronunciation, the English language requires another essential improvement, *viz.* the use of accents to distinguish the meaning of words and phrases; which, although it is not so properly confined to a lexicographer, yet it is not quite without his sphere. Thus the word *as* admits of two very different sounds, as well as different significations; as in this example, "*Cicero was nearly as eloquent as Demosthenes*:" in which the first *as* is pronounced *afs*, and the last is pronounced *ax*. Now, it often happens, that, in reading, the particular way in which it ought to be understood is not pointed out by the context, till after the word itself is pronounced, which has an equal chance at least of being pronounced wrong; whereas, if it were always accented when employed in the one sense, and not in the other, it would free the reader from this perplexity. There are other cases in which the use of proper accents in writing would be of great consequence; as at the beginning of a sentence, when it was put as a question, or used ironically, &c. the want of which every one must have observed. But as this does not so properly belong to the lexicographer as the grammarian, we shall here take no further notice of it.

The above examples, we hope, will be sufficient to give the reader some idea of the plan that we would propose; and enable him to determine, whether or not a dictionary, executed upon this plan, would convey to his mind a more perfect knowledge of the English language, than those dictionaries that have been hitherto published.

These

These examples were given rather with a view to shew the manner in which a work of this kind might be conducted, than as perfect and unexceptionable explanations of the several articles there enumerated; and therefore we did not think it necessary to produce any authorities, although we are sensible that they would be necessary in a work of this kind.

**DIDACTIC**, in the schools, signifies the manner of speaking, or writing, adapted to teach or explain the nature of things.

**DIDAPPEK**, in ornithology, See **COLYMUS**.

**DIDELPHIS**, in zoology, a genus of quadrupeds belonging to the order of feræ, the characters of which are these: they have ten foreteeth in the upper-jaw, and eight in the under one; the dog-teeth are long; the tongue is somewhat ciliated; and they have a pocket, formed by a duplicature of the skin of the belly, in which the dugs are included. There are five species, *viz.* 1. The marsupialis, with eight dugs inclosed in the abdominal pocket. He is about sixteen inches long from the snout to the root of the tail, which is about twelve inches long: he has five toes on the fore-feet, with crooked claws and five toes on the hind-feet, only four of them furnished with claws; the fifth, which is a kind of thumb, is at a distance from the others, and has no claw; the tail is bare from a little below the root: The ears and legs are likewise bare; the eyes are small, prominent, of a black colour, and very lively. The body is of a greyish colour, with some small tufts of black and white hairs upon the back and sides. Under the belly of the female there is a large bag or pocket, formed by a remarkable duplicature of the skin, in which the dugs are contained. This pocket the animal can shut or open at pleasure, by means of a couple of muscles and two bones which are placed before the os pubis, and are peculiar to the didelphis. The interior side of this pocket is full of small glands, which secrete a yellowish stinking substance, which diffuses its odour through the whole body of the animal: but this substance, when dried, loses its disagreeable odour, and acquires a smell like that of musk.—This animal is originally a native of South America. Most authors affirm that they bring forth five or six young ones at a time. As soon as they are brought forth, they creep into the pocket of the mother, where the dugs are situate, and continue there sucking till they be able to run about. When alarmed or frightened, they run into the mother's pocket, and she makes off with them in this situation. The didelphis is an animal of slow motion; a man can easily out run him; but then, he takes to a tree, which he mounts with great facility, and conceals himself among the leaves, or suspends himself by twirling his tail round a branch. Although a carnivorous animal, he is fond of the sugar cane, potatoes, &c. See Plate LXVIII fig. 3.

The second species is the philander, with four dugs, pendulous ears, and a tail bushy at the base. 3. The opossum, with two dugs, and a less bushy tail. 4. The murina, with six dugs. 5. The dolich-

gera, with the tail bushy at the base, and longer than the body. The females of this species carry their young on their backs, the young having their tails twisted about the tail of the mother. The above four are natives of America.

**DIDUS**, in ornithology, a genus belonging to the order of gallinæ. The bill is contracted in the middle by two transverse rugæ; each mandible is inflected at the point; and the face is bare behind the eyes. The body is blackish and cloudy; the tail is very short; and the upper part of the bill is red. It is a native of India, and is incapable of flying, because the wings are not furnished with feathers sufficient for that purpose.

**DIDYNAMIA**, in the Linnæan system of botany. See **OTANY**, p. 635.

**DIE**, in geography, a town of France, in the province of Dauphiny, situated on the river Drome, twenty-two miles south of Grenoble: E. long. 5° 20', N. lat. 44° 50'.

**DIEGEM**, a town of the Austrian Netherlands, in the province of Brabant, about three miles north of Brussels: E. long. 4° 20', and N. lat. 51°.

**DIEPE**, a port-town of France, situated on the British channel, about thirty miles north of Rouen, and opposite to port Rye in England: E. long. 1° 15', and N. lat. 49° 55'.

**DIEPHOLT**, a city of Westphalia in Germany, situated at the north end of the Dummer-lake, thirty-five miles south of Bremen: E. long. 8°, N. lat. 53°.

It is subject to the king of Great Britain, as elector of Hanover.

**DIERVILLA**, in botany. See **LANICERA**.

**DIES MARCHIÆ**, was the day of congress, or meeting of the English and Scotch, annually appointed to be held on the marches, or borders, in order to adjust all differences between them.

**DIESIS**, in music, is the division of a tone less than a semi-tone; or an interval consisting of a less or imperfect semi-tone.

Diesis is the smallest and softest change or inflexion of the voice imaginable: it is called a faint, expressed thus X, by a St Andrew's cross, or saltier.

**DIET**, in medicine, according to some, comprehends the whole regimen, or rule of life, with regard to the six non-naturals, air, meats and drinks, sleep and watching, motion and rest, passions of the mind, retentions and excretions.

The more accurate writers, however, restrain the term of diet to what regards eating and drinking, or solid aliments and drinks. See **MEDICINE**.

**DIET-DRINKS**, a form in physic, including all the medicated wines, ales, and wheys, used in chronic cases. They require a course or continuation to answer any intention of moment.

**DIET of appearance**, in Scots law, the day to which a defender is cited to appear in court, and every other day to which the court shall afterwards adjourn the consideration of the question.

**DIET**, or **DYET**, in matters of policy, is used for the general

general assembly of the states, or circles of the empire of Germany, and of Poland, to deliberate and concert measures proper to be taken for the good of the public.

The general diet of the empire is usually held at Ratisbon: it consists of the emperor, the nine electors, and the ecclesiastical princes; viz. the archbishops, bishops, abbots, and abbesses; the secular princes, who are dukes, marquises, counts, viscounts, or barons; and the representatives of the imperial cities. It meets on the emperor's summons, and any of the princes may send their deputies thither in their stead. The diet makes laws, raises taxes, determines differences between the several princes and states, and can relieve the subjects from the oppressions of their sovereigns.

The diet of Poland, or the assembly of the states, consists of the senate and deputies, or representative of every palatinate or county and city, and meet usually every two years, and oftener upon extraordinary occasions, if summoned by the king, or, in his absence, by the archbishop of Gnesna. The general diet of Poland sits but six weeks, and often breaks up in a tumult much sooner: for one dissenting voice prevents their passing any laws, or coming to any resolutions on what is proposed to them from the throne. Switzerland has also a general diet, which is usually held every year at Baden, and represents the whole Helvetic body: it seldom lasts longer than a month. Besides this general diet, there are diets of the protestant cantons, and diets of the catholic ones; the first assemble at Araw, and are convoked by the canton of Zurich; the second at Lucern, convoked by the canton of that name.

**DIETETIC**, denotes something belonging to diet, but particularly that part of physic which treats of this subject.

**DIETS**, a town in the circle of the Upper Rhine in Germany, situated on the river Lohn, twenty miles north of Mentz, and subject to the house of Nassau-Orange: E. long.  $7^{\circ} 40'$ , and N. lat.  $50^{\circ} 28'$ .

**DIEU ET MON DROIT**, i. e. *God and my right*, the motto of the royal arms of England, first assumed by king Richard I. to intimate that he did not hold his empire in vassalage of any mortal.

It was afterwards taken up by Edward III. and was continued without interruption to the time of the late king William, who used the motto *Je main-tien-dray*, though the former was still retained upon the great seal. After him queen Anne used the motto *Semper eadem*, which had been before used, by queen Elizabeth; but ever since queen Anne, *Dieu et mon droit* continues to be the royal motto.

**DIEXAHEDRIA**, in natural history, a genus of pellucid and crystalliform spars, composed of two pyramids, joined base to base, without any intermediate column: the diexahedria are dodecahedral, or composed of two hexangular pyramids.

**DIFFUSE**, an epithet applied to such writings as are wrote in a prolix manner. Among historians, Sallust

is reckoned sententious, and Livy diffuse. Thus also among the orators, Demosthenes is close and concise; Cicero, on the other hand, is diffuse.

**DIFFUSION**, the dispersion of the subtle effluvia of bodies into a kind of atmosphere all round them. Thus the light diffused by the rays of the sun, issues all round from that amazing body of fire.

**DIGASTRICUS**, in anatomy. See Vol. I. p. 222.

**DIGEST**, in matters of literature, a collection of the decisions of the Roman lawyers properly digested, or arranged under distinct heads, by order of the emperor Justinian. It constitutes the first part or volume of the civil law.

**DIGESTION**, in medicine, is the dissolution of the aliments into such minute parts as are fit to enter the lacteal vessels, and circulate with the mass of blood.

Various are the systems and hypotheses framed by physicians and philosophers to account for digestion. Some contend, that it is done by a kind of elixation of the solid and grosser parts of the food in the liquid by the heat of the stomach, and of the adjacent parts, the liver, spleen, &c. Others will have it done by attrition, as if the stomach, by those repeated motions, which are the effects of respiration, rubbed off the minuter particles from the grosser matters, and agitating the rest against each other, attenuated and dissolved them.

Others think the bilious juice, others the spirits, chiefly concerned in digestion.

Others will have the food dissolved by a menstruum; but then they are greatly divided as to the nature and origin of this menstruum; some supposing it an acid furnished by the glands of the stomach; others, a nitro-aerial spirit, which, by penetrating the mass of food, breaks the connexion of the most solid parts: and others, a saline juice, which divides and volatilizes the parts of the food. Others, again, suppose digestion to be performed by means of a ferment or leaven, which mixing with the aliment, excites an intestine motion in the parts thereof, by which means the parts are attenuated and dissolved. But these likewise differ in their opinion of this ferment; some taking it to be the remains of the food last digested, which, by its continuance in the stomach, has contracted an acid quality and become a ferment: others take the principles of fermentation to be contained in the aliment itself, which when inclosed in the stomach, heated there, and put in motion, enters on its office of fermentation: others suppose the matter of the ferment supplied by the glands of the stomach; and lastly, others contend for the saliva, and make that the ferment serving principally for the digestion of the food.

Some suppose digestion owing to gentle heat and motion. By this heat and motion, say they, the texture of the nourishment is changed in the bodies of animals; and then the constituent solid parts are indued with peculiar attractive powers of certain magnitudes, by which they draw, out of the fluids moving through them, like parts in certain quantities, and thereby preserve their forms and just magnitudes.

†

4 S

And,

And, to mention no more, Boerhaave ascribes digestion to the joint action of several of the above-mentioned cauces, aided by the expansion of the air contained in the aliments.

*Want of DIGESTION*, a disease attended with pain, and a sense of weight, with eructations and copious flatulences from corrupt humours in the stomach.

**DIGESTIVE**, in medicine, such remedies as strengthen and increase the tone of the stomach, and assist in the digestion of foods. To this class belong all stomachics and strengtheners, or corroborants.

**DIGIT**, in astronomy, the twelfth part of the diameter of the sun or moon, is used to express the quantity of an eclipse. Thus an eclipse is said to be of six digits, when six of these parts are hid.

**DIGITS**, or **MONADES**, in arithmetic, signify any integer under 10; as 1, 2, 3, 4, 5, 6, 7, 8, 9.

**DIGIT** is also a measure taken from the breadth of the finger. It is properly  $\frac{1}{4}$  of an inch, and contains the measure of four barley-corns laid breadth-wise.

**DIGITALIS**, or **FOX-GLOVE**, in botany, a genus of the didynamia angiospermia class. The calix is divided into five segments; the corolla is bell-shaped, ventricose, and has five divisions; and the capsule is oval, and has two cells. There are six species, only one of which, *viz.* the purpurea, or purple fox-glove, is a native of Britain. The leaves are said to be emetic and vulnerary, but are little used.

**DIGITATED**, among botanists. See Vol. I. p. 640.

**DIGITUS**, in anatomy. See Vol. I. p. 181.

**DIGLYPH**, in architecture, a kind of imperfect triglyph, console, or the like, with two channels or engravings, either circular or angular.

**DIGNE**, a city and bishop's see of Provence in France, fifty-five miles north of Toulon: E. long.  $6^{\circ} 5'$ , and N. lat.  $44^{\circ} 6'$ .

**DIGNITARY**, in the canon law, a person who holds a dignity, that is, a benefice which gives him some pre-eminence over mere priests and canons. Such is a bishop, dean, arch-deacon, prebendary, &c.

**DIGNITY**, as applied to the titles of noblemen, signifies honour and authority.

**DIJON**, the capital of the province of Burgundy, in France, situated on the river Ouche, 140 miles south-east of Paris: E. long.  $5^{\circ} 5'$ , and N. lat.  $47^{\circ} 15'$ .

**DILATATION**, in physics, a motion of the parts of any body, by which it is so expanded as to occupy a greater space. This expansive motion depends upon the elastic power of the body, whence it appears that dilatation is different from rarefaction, this last being produced by the means of heat. See **MECHANICS**.

**DILATATOIRES**, in anatomy, a name given to several muscles in the human body. See **ANATOMY**, Part II.

**DILEMMA**, in logic, an argument consisting of two or more propositions, which divides the whole into all its parts, or members, by a disjunctive proposition, and then infers something concerning each part, which is finally referred to concerning the whole. See **LOGIC**.

**DILIGENCE**, in Scots law, signifies either that care

and attention which parties are bound to give, in implementing certain contracts or trusts, and which varies according to the nature of the contract; as to which, see **SCOTS LAW**, title 7. 20. and 28.: Or it signifies certain forms of law, whereby the creditor endeavours to operate his payment, either by affecting the person or estate of the debtor; see title 18.

**DILL**, in botany. See **ANETHUM**.

**DILLEMBURG**, a city of the circle of the Upper Rhine in Germany, about forty miles north of Frankfurt, and subject to the house of Nassau: E. long.  $8^{\circ} 8'$ , and N. lat.  $50^{\circ} 45'$ .

**DILLENGEN**, a city of Swabia, in Germany, situated on the Danube, about twenty miles north-east of Ulm: E. long.  $10^{\circ} 20'$ , and N. lat.  $48^{\circ} 40'$ .

**DILLENIA**, in botany, a genus of the polyandria polygynia class. The calix consists of five leaves, and the corolla of five petals; and the capsule contains many seeds. There is but one species, a native of Malabar.

**DILUTE**. To dilute a body is to render it liquid; or, if it were liquid before, to render it more so, by the addition of a thinner thereto. These things thus added, are called diluents, or dilutors.

**DIMENSION**, in geometry, is either length, breadth, or thickness; hence, a line hath one dimension, *viz.* length; a superficies two, *viz.* length and breadth; and a body, or solid, has three, *viz.* length, breadth, and thickness.

**DIMINUTIVE**, in grammar, a word formed from some other, to soften or diminish the force of it, or to signify a thing is little in its kind. Thus, cellule is a diminutive of cell, globule of globe, hillock of hill.

**DIMORPHOTHECA**, in botany. See **CALENDULA**.

**DINANT**, a town of Germany in the bishopric of Liege, situated on the river Maese, about twelve miles south of Namur: E. long.  $4^{\circ} 50'$ , and N. lat.  $50^{\circ} 18'$ .

**DINGWEL**, or **DINGWAL**, a parliament-town of Scotland, situated at the west end of the Cromarty-bay, in the county of Ross: W. long.  $4^{\circ} 15'$ , and N. lat.  $57^{\circ} 56'$ . It classes with Dornock, Wick, and Kirkwall.

**DINKELSPIEL**, a city of Swabia, about forty miles north of Ulm, E. long.  $10^{\circ} 12'$ , and N. lat.  $49^{\circ}$ .

**DIOCESE**, denotes a particular district, or division, under the direction and government of a bishop.

**DIOCTAHEDRIA**, in natural history, a genus of pelucid and crystalliform spars, composed of two octangular pyramids, joined base to base, without any intermediate column. Of these some have long pyramids, others short and sharp-pointed ones, and others short and obtuse pointed ones; the two former species being found in the hartz-forest, and the last in the mines of Cornwall.

**DIODIA**, in botany, a genus of the tetrandria monogynia class. The corolla consists of one tunnel-shaped petal; and the capsule has two cells, containing as many seeds. There is but one species, a native of Virginia.

**DIODON**, in ichthyology, a genus belonging to the order of amphibia nantes. The jaws are bony, stretched out, and undivided; the aperture or mouth is a transverse

transverse line. The body is every way beset with sharp moveable prickles. It has no belly-fins. There are two species, *viz.* 1. The atringa, which is spherical, and has triangular prickles. It is a native of India. 2. The trylrix, which is oblong, with cylindrical prickles, and is a native of the Cape of Good Hope.

**DIOMEDEA**, in ornithology, a genus belonging to the order of anseres. The bill is strait; the superior mandible is crooked at the point, and the lower one is truncated; the nostrils are oval, open, a little prominent, and placed on the sides. There are two species, *viz.* 1. The exulans, has pennated wings, and three toes on each foot. It is the abbatros of Edwards, and is found in the ocean betwixt the tropics, and at the Cape of Good Hope. It flies pretty high, feeds upon flying fish, and is about the size of a pelican. 2. The demersa, has no quill-feathers on the wings; and the feet have four toes, connected together by a membrane. It is the black penguin of Edwards, about the size of a goose, and is found at the Cape of Good Hope.

**DIONYSIA**, in Grecian antiquity, solemnities in honour of Bacchus, sometimes called by the general name of orgia; and by the Romans bacchanalia, and liberalia. See **BACCHANALIA**.

**DIOECIA**, in the Linnæan system of botany. See Vol. I. p. 635.

**DIOMEDIS AVIS**, in ornithology. See **PROCELLARIA**.

**DIOPTRICS**, the science of refractive vision. See **OPTICS**.

**DIOSCOREA**, in botany, a genus of the dioecia hexandria class. The calix both of the male and female consists of six segments, and they have no corolla. The female has three styli; the capsule is compressed, has three cells, and contains two membranaceous seeds. There are eight species, none of them natives of Britain.

**DIOSMA**, in botany, a genus of the pentandria monogynia class. The corolla has five petals; and the nectarium is shaped like a crown, is divided into five segments, and situate above the germen; it has five united capsules; and the seeds are furnished with calyptræ. There are nine species, none of them natives of Britain.

**DIOSPYROS**, in botany, a genus of the polygamia dioecia class. The calix of the hermaphrodite has four segments, and the corolla is uncelated, and has four segments; it has eight stamina, and a quadrifid stylus; and the berry contains eight seeds. The calix, &c. of the male are the same with the above. There are two species, none of them natives of Britain.

**DIOTOTHECA**, in botany. See **MORINA**.

**DIPHTHONG**, in grammar, a double vowel, or the mixture of two vowels pronounced together, so as to make one syllable. See **GRAMMAR**.

**DIPHYES**, among natural historians, an appellation given to stones resembling the male and female parts of generation in mankind.

**DIPLOE**, in anatomy, the soft medullium, or medul-

lary substance, which lies between the two laminae of the bones of the cranium. See **ANATOMY**, Part I.

**DIPLOMA**, an instrument or licence given by colleges, societies, &c. to a clergyman to exercise the ministerial function, or to a physician to practise the profession, &c. after passing examination, or admitting him to a degree.

**DIPLOMA**, in chemistry, &c. a double vessel. To boil in diplomate, is to set one vessel, containing the ingredients intended to be acted upon, in another larger vessel full of water, and to this last the fire is to be applied.

**DIPONDIUS**, in the scripture-language, is used by St Luke to signify a certain coin, which was of very little value: our translation of the passage is, *Are not two sparrows sold for two farthings?* In St Matthew, who relates the same thing, we read, *Are not two sparrows sold for a farthing?*

**DIPPING**, among miners, signifies the interruption, or breaking off, of the veins of ore; an accident that gives them a great deal of trouble before they can discover the ore again.

**DIPSACUS**, or **TEASEL**, in botany, a genus of the tetrandria monogynia class. The common calix consists of many leaves, and the proper one is above the fruit; and the receptacle is paleaceous. There are three species, all natives of Britain, *viz.* the sulonium, or manured teasel; the sylvestris, or wild teasel; and the pilosus, or small wild teasel.

**DIPSAS**, in zoology. See **COLUBER**.

**DIPTOTES**, in grammar, are such nouns as have only two cases, as *suppetia*, *suppetias*, &c.

**DIPTYCHS**, in antiquity, a public register, in which were written the names of the consuls and other magistrates among the heathens; and among the Christians, they were a sort of tablets, on one of which were written the names of the deceased, and on the other those of the living patriarchs, bishops, &c. or those who had done any service to the church, for whom prayers were offered, the deacon reading the names at mass.

**DIRECTION**, in mechanics, signifies the line or path of a body's motion, along which it endeavours to proceed, according to the force impressed upon it. See **MECHANICS**.

**DIRECTOR**, in commercial polity, a person who has the management of the affairs of a trading company: thus we say, the directors of the India company, South-sea company, &c. See **COMPANY**.

The directors are considerable proprietors in the stocks of their respective companies, being chosen by plurality of votes from among the body of proprietors. The Dutch East-India company have sixty such directors; that of France, twenty one; the British East-India company has twenty-four, including the chairman, who may be re-elected for four years successively. These last have salaries of 150l. a-year each, and the chairman 200l. They meet at least once a week, and commonly oftener, being summoned as occasion requires.

**DIRECTOR**, in surgery, a grooved probe, to direct the edge

edge of the knife or scissors, in opening sinuses, or fistulæ, that by this means the adjacent vessels, nerves, and tendons may remain unhurt. See SURGERY.

**DIRIGENT**, or **DIRECTRIX**, a term in geometry, signifying the line of motion, along which the describent line or surface is carried in the genesis of any plane or solid figure.

**DIS**, an inseparable article prefixed to divers words, the effect whereof is either to give them a signification contrary to what the simple words have, as *disoblige*, *disobey*, &c. or to signify a separation, detachment, &c. as *disposing*, *distributing*.

**DISC**, in antiquity, a quoit made of stone, iron, or copper, five or six fingers broad, and more than a foot long, inclining to an oval figure, which they hurled in form of a bowl, to a vast distance, by the help of a leathern thong tied round the person's hand who threw it, and put through a hole in the middle. Homer has made Ajax and Ulysses great artists at this sport.

**DISC**, in astronomy, the body and face of the sun and moon, such as it appears to us on the earth; or the body or face of the earth, such as it appears to a spectator in the moon.

**DISC**, in optics, is the width of the aperture of telescopic glasses, whatever their form be, whether plain, convex, concave, &c.

**DISCERNING**, or **DISCERNMENT**, among logicians, a faculty of the mind, whereby it distinguishes between ideas.

**DISCIPLE**, one who learns any thing from another: thus, the followers of any teacher, philosopher, &c. are called disciples. In the Christian sense, they were followers of Jesus Christ, in general; but in a more restrained sense, the disciples denote those alone who were the immediate followers and attendants on his person, of which there were seventy or seventy-two. The names *disciple* and *apostle* are often synonymously used in the gospel-history; but sometimes the apostles are distinguished from disciples, as persons selected out of the number of disciples, to be the principal ministers of his religion; of these there were only twelve. The Latins kept the festival of the seventy or seventy-two disciples on July 15th, and the Greeks on January 4th.

**DISCIPLINE**, in a general sense, denotes instruction and government; as military discipline, ecclesiastical discipline, &c.

**DISCLAMATION**, in Scots law, is that casualty whereby a vassal forfeited his feu to his superior, by disowning or disclaiming him as such without sufficient reason. See SCOTS LAW, title 12.

**DISCORD**, in music, the relation of two sounds which are always and of themselves disagreeable, whether applied in succession or consonance.

**DISCOUNT**, in commerce, a term among traders, merchants, and bankers. It is used by the two former on occasion of their buying commodities on the usual time of credit, with a condition that the seller shall allow the buyer a certain discount at the rate of so much *per cent. per annum*, for the time for which the credit is

generally given, upon condition that the buyer pays ready money for such commodities, instead of taking the time of credit.

**DISCRETE**, or **DISJUNCT PROPORTION**, is when the ratio of two or more pairs of numbers or quantities is the same, but there is not the same proportion between all the four numbers. Thus if the numbers 3 : 6 :: 8 : 16 be considered, the ratio between 3 : 6, is the same as that between 8 : 16, and therefore the numbers are proportional; but it is only discretely or disjunctly, for 3 is not to 6 as 6 to 8; that is, the proportion is broken off between 8 and 3, and is not continued as in the following continual proportionals, 3 : 6 :: 12 : 24.

**DISCUS**, in antiquity. See **DISC**.

**DISCUSSION**, in matters of literature, signifies the clear treating or handling of any particular point, or problem, so as to shake off the difficulties with which it is embarrassed: thus we say, such a point was well discussed, when it was well treated of and cleared up.

**DISCUTIENTS**, in medicine, are such remedies, as, by their subtilty, dissolve a stagnating or coagulated fluid, and dissipate the same without an external solution of continuity.

**DISDIAPASON**, or **BISDIAPASON**, in music, a compound concord, described by F. Parran, in the quadruple ratio of 4 : 1, or 8 : 2.

**DISDIAPASON-DIAPENTE**, a concord in a sextuple ratio of 1 : 6.

**DISDIAPASON-SEMI-DIAPENTE**, a compound concord in the proportion of 16 : 3.

**DISDIAPASON-DITONE**, a compound consonance in the proportion of 10 : 2.

**DISDIAPASON-SEMI-DITONE**, a compound concord in the proportion of 24 : 5.

**DISEASE**, in medicine, that state of a living body, wherein it is deprived of the exercise of any of its functions, whether vital, natural, or animal. See MEDICINE.

**DISFRANCHISING**, among civilians, signifies the depriving a person of the rights and privileges of a free citizen or subject.

**DISJUNCTIVE**, something that separates or disjoins. Thus, *or*, *neither*, &c. which in connecting a discourse yet separates the parts of it, are called disjunctive conjunctions.

**DISLOCATION**, in surgery. See **LUXATION**.

**DISMA**, a town of Japan, separated from Nanquesacque, only by a narrow canal. The Dutch have a very fine magazine there.

**DISPENSARY**, or **DISPENSATORY**, denotes a book containing the method of preparing the various kinds of medicines used in pharmacy. Such are those of Bauderon, Quercetan, Zwelfer, Charas, Bates, Mesue, Salmon, Lemery, Quincy, &c. but the latest and most esteemed are the Edinburgh and London Dispensatories.

**DISPENSARY**, or **DISPENSATORY**, is likewise a magazine or office for selling medicines at prime cost to the poor.

DIS-

**DISPENSATION**, in law, the granting a license of doing some certain action that otherwise is not permitted.

**DISPLAYED**, in heraldry, is understood of the position of an eagle, or any other bird, when it is erect, with its wings expanded or spread forth. See Plate LXVIII fig. 8.

**DISPONDEE**, in the Greek and Latin poetry, a double spondee or foot, consisting of four long syllables, as *māēcēnātēs cōclūdētēs*.

**DISPOSITION**, in Scots law, is that deed or writing which contains the sale or grant of any subject: when applied to heritable subjects, it in some cases gets the name of charter, which differs from a disposition in nothing else than a few immaterial forms. See **CHARTER**.

**DISPOSITION**, in rhetoric, the placing words in such an order as contributes most to the beauty and sometimes even to the strength of a discourse.

**DISQUISITION**, a serious and exact examination into the circumstances of any affair, in order to discourse clearly about it.

**DISS**, a market-town of Norfolk, on the river Waveney, sixteen miles south of Norwich.

**DISSECTION**, in anatomy, the cutting up a body, with a view of examining the structure and use of the parts. See **ANATOMY**.

**DISSEISIN**, in law, an unlawful dispossessing a person of his lands or tenements.

**DISSENTERS**, separatists from the service and worship of any established church.

**DISSIPATION**, in physics, an insensible loss or consumption of the minute parts of the body; or, that flux whereby they fly off, and are lost.

*Circle of DISSIPATION*, in optics, is used for that circular space upon the retina, which is taken up by one of the extreme pencils or rays issuing from an object. See **OPTICS**.

**DISSOLVENT**, in general, whatever dissolves or reduces a solid body into such minute parts as to be sustained in a fluid. See **CHEMISTRY**.

**DISSONANCE**, in music. See **DISCORD**.

**DISSYLLABLE**, among grammarians, a word consisting only of two syllables: such are nature, science, &c.

**DISTAFF**, an instrument about which flax is tied in order to be spun.

**DISTANCE**, in general, an interval between two things, either with regard to time or place.

*Accessible DISTANCES*, in geometry, are such as may be measured by the chain, &c. See **GEOMETRY**.

*Inaccessible DISTANCES*, are such as cannot be measured by the chain, &c. by reason of some river, or the like, which obstructs our passing from one object to another. See **GEOMETRY**.

**DISTASTE** properly signifies an aversion or dislike to certain foods; and may be either constitutional, or owing to some disorder of the stomach.

**DISTEMPER**, among physicians, the same with distaste. See **DISEASE**.

**DISTEMPER**, in painting, a term used for the working up of colours with something besides water or oil. If the colours are prepared with water, that kind of painting is called limning; and if with oil, it is called painting in oil, and simply painting. If the colours are mixed with size, whites of eggs, or any such proper glutinous or unctuous matter, and not with oil, then they say it is done in distemper.

**DISTENSION**, in general, signifies the stretching or extending a thing to its full length or breadth.

**DISTICH**, a couplet of verses making a complete sense. Thus hexameter and pentameter verses are disposed in distichs.

**DISTICHIASIS**, in surgery, a disease of the eye-lids, when under the ordinary eye-lashes there grows another extraordinary row of hair, which frequently eradicates the former, and pricking the membrane of the eye, excites pain, and brings on a defluxion.

**DISTILLATION**, in chemistry, the act of drawing off the spiritous, aqueous, oleaginous, or saline parts of a mixed body from the grosser and more terrestrial parts by means of fire, and collecting and condensing them again by cold. The end of distillation is of two kinds: the first, and by far the most general, is for the separation of some acquired bodies from others with which they were mixed, as in the case of vinous and volatile spirits, and essential oils: the other is for the quicker and more effectual combination of such bodies, whose mixture is assisted by a boiling heat, as in the case of spir. nitr. dulc. See **CHEMISTRY**.

*The method of distilling malt-wash, or a fermented mixture of meal and malt, for spirit.* Fill two thirds of a still, first moistened by the steam of boiling water, with malt-wash; immediately clap on the head, and lute it down; there will soon run a spirituous inflammable liquor. Thus is obtained what the malt-distillers call a malt low-wine; what comes over after the spirit falls off from being proof, is called faints. This experiment may be rendered general, with slight variation; for if any wine, beer, or fermented liquor from sugar, treacle, or fruits, &c. be thus treated, it affords a spirit differing only according to the nature of the subject; but none of them will afford the least inflammable spirit without a previous fermentation. The requisite cautions for success are, 1. That the fermentation be well performed. 2. That it be gently distilled, with a soft well regulated fire. 3. That the grosser oil, apt to rise along with the spirit, be let out by flannel under the nose of the worm. These cautions observed, the low-wines will be pure and vinous.

*The method of distilling the lower wines into proof spirits for sale.* The lower wines of the last process, distilled in a bath-heat, give a higher rectified spirit than before, which being let down with fair water to a certain size or standard, called proof, is what the malt-distillers understand by proof-goods, or their rectified malt-spirit.

The inconveniencies of this art, on account of the many large vessels required, which increase the labour and price of the commodity, might perhaps be remedied by the introduction of a new art, subservient to the malt-distillers, and confined to the boiling down the malt-wort to a rob; wherefore it were to be wished, that those who were skilled in this branch of distillation

lation would try whether a spirit superior to that of treacle may not be procured from the rob of malt, prudently prepared and fermented. See **CHEMISTRY**.

**DISTINCT BASE**, in optics, is that distance from the pole of a convex glass, in which objects beheld through it appear distinct and well described; so that it is the same with the focus. See **OPTICS**.

**DISTINCTION**, in logic, is an assemblage of two or more words, whereby disparate things, or their conceptions, are denoted.

**DISTORTION**, in medicine, a contraction of one side of the mouth, occasioned by a convulsion of the muscles of one side of the face: and it is likewise used to denote any part of an animal body when it is ill placed or ill favoured.

**DISTRESS**, in Scots law. When a person makes payment of a debt not voluntarily, but in obedience to legal diligence, he is said to have paid in distress.

**DISTRIBUTION**, in printing, the taking a form asunder, separating the letters, and disposing them in the cases again, each in its proper box. See **PRINTING**.

**DISTRICT**, in geography, a part of a province, distinguished by peculiar magistracies, or certain privileges, in which sense it is synonymous with hundred. See **HUNDRED**.

**DISTRINGAS**, in law, a writ commanding the sheriff, or other officer, that he distrain a person for debt to the king, &c. or for his appearance at a certain day.

**DISTRINGAS JURATORES**, a writ directed to the sheriff, whereby he is commanded to distrain upon a jury to appear, and to return issues on their lands, &c. for non-appearance. This writ of distringas juratores issues for the sheriff to have their bodies in court, &c. at the return of the writ.

**DITHYRAMBUS**, in ancient poetry, a hymn in honour of Bacchus, full of transport and poetical rage.

**DITONE**, in music, an interval comprehending two tones. The proportion of the sounds that form the ditone is 4 : 5, and that of the semiditone is 5 : 6.

**DITRIHEDRIA**, in mineralogy, a genus of spars with twice three sides, or six planes, being formed of two trigonal pyramids joined base to base, without any intermediate column. See **SPAR**.

The species of ditrihedria are distinguished by the different figures of these pyramids.

**DITTANY**, in botany. See **DICTAMNUS**.

**DITTO**, usually written D<sup>o</sup>, in books of accounts, an Italian word, signifying *the aforementioned*.

**DIVAL**, in heraldry, the herb nightshade, used by such as blazon by flowers and herbs, instead of colours and metals, for sable, or black.

**DIVALLIA**. See **ANGERONALIA**.

**DIU**, a little island and town on the coast of Guzurat, in the hither India, and subject to Portugal: E. long. 69°, N. lat. 21° 15'.

**DIU** is also a town of Bulgaria, upon the Danube.

**DIVAN**, a council-chamber, or court of justice, among the eastern nations, particularly the Turks.

**DIVAN-BEGHI**, the superintendent of justice in Persia,

whose place is the last of the six ministers of the second rank, who are all under the athemadauler, or first minister. To this tribunal of the divan-beghi he appeals from sentences passed by the governors: he has a fixed stipend of 50,000 crowns for administering justice: all the serjeants, ushers, &c. of the court, are in his service: he takes cognizance of the criminal causes of the chams, governors, and other great lords of Persia, when accused of any fault. There are divan-beghis not only at court and in the capital, but also in the provinces and other cities of the empire. The alcoran is the sole rule of his administration of justice, which also he interprets at pleasure. He takes no cognizance of civil causes, but all differences arising between the officers of the king's household, and between foreign ministers, are determined by him.

**DIVANDUROW**, the name of seven islands which lie a league north of the Maldives, and twenty-four from the coast of Malabar, almost opposite to Cananor.

**DIVER**, in ornithology. See **COLYMBUS**.

**DIVERGENT**, or **DIVERGING LINES**, in geometry, are those which constantly recede from each other.

**DIVERGENT RAYS**, in optics, are those which going from a point of the visible object, are dispersed, and continually depart one from another, in proportion as they are removed from the object: in which sense it is opposed to convergent. See **OPTICS**.

**DIVERSION**, in military affairs, is, when an enemy is attacked in one place where they are weak and unprovided, in order to draw off their forces from another place where they have made or intend to make an irruption. Thus the Romans had no other way in their power of driving Hanibal out of Italy, but by making a diversion in attacking Carthage.

**DIVESTING**, or **DIVESTITURE**, in law, is used for the act of surrendering one's effects.

**DIVIDEND**, in arithmetic, the number proposed to be divided into equal parts. See **ARITHMETIC**.

**DIVIDEND of stocks**, is a share or proportion of the interest of stocks erected on public funds, as the South-sea, &c. divided among and paid to the adventurers half yearly.

**DIVINATION**, the knowledge of things obscure, or future, which cannot be attained by any natural means.

It was a received opinion among the heathens, that the gods were wont to converse familiarly with some men, whom they endowed with extraordinary powers, and admitted to the knowledge of their councils and designs. Plato, Aristotle, Plutarch, Cicero, and others, divide divination into two sorts or species, *viz.* natural and artificial. The former was so called, because not attained by any rules or precepts of art, but infused or inspired into the diviner, without his taking any further care about it, than to purify and prepare himself for the reception of the divine afflatus. Of this kind were all those who delivered oracles, and foretold future events by inspiration, without observing external signs or accidents. The second species of divination was called artificial, because it was not obtained by immediate inspiration, but was the effect of experience and observation.

observation. Such was southsaying, as depending upon human art and invention, which however was supposed not to be altogether destitute of divine direction and concurrence, and such was divination by lots. Of this sort there were various kinds, as by sacrifices, entrails, flame, cakes, flour, wine, water, augury, birds, lots, verses, omens, &c.

**DIVINE**, something relating to God.

**DIVING**, the art of descending under water, to considerable depths, and abiding there a competent time; the uses of which are considerable, particularly in fishing for pearls, corals, sponges, wrecks of ships, &c. See **PNEUMATICS**.

**DIVINITY**, properly signifies the nature, quality, and essence of God.

**DIVINITY** is also used in the same sense with theology.

**DIVISIBILITY**, that property by which the particles of matter in all bodies are capable of separation or disunion from each other. See **MECHANICS**.

**DIVISION**, in general, is the separating a thing into two or more parts.

**DIVISION**, in arithmetic. See Vol. I. p. 376.

**DIVISION**, in algebra. See Vol. I. p. 82.

**DIVISOR**, in arithmetic. See Vol. I. p. 376.

**DIUL**, a port-town of Asia, situated on the Indian ocean, westward of the river Indus, and sixty miles west of the city of Tatta: E. long. 67°, and N. lat. 25° 15'.

**DIVORCE**, is the legal dissolution of a marriage which can be obtained at the suit of the injured party, upon the grounds of adultery or wilful desertion proved against the other. See **SCOTS LAW**, title 6.

**DIURESIS**, in medicine, an excretion of urine: whence,

**DIURETICS**, in pharmacy, such simples as increase the discharge of urine; or which are supposed to have a power of removing obstructions in the urinary passages.

**DIURNAL**, in astronomy, something relating to the day; in opposition to nocturnal, which regards the night.

**DIZIER**, or **St Dizier**, a city of Champaign in France, situated on the river Marne, about forty-five miles north-east of Troyes: E. long. 5°, and N. lat. 48° 32'.

**DIZOSTOS**, in botany. See **EUPHORBIA**.

**DIZZINESS**, in medicine. See **VERTIGO**.

**DO**, in music, a note of the Italian scale, corresponding to *ut* of the common gamut. See **MUSIC**.

**DOB-CHICK**, in ornithology. See **COLYMBUS**.

**DOHLAC**, a town of the Tyrolese, in Germany, situated at the foot of the Alps, about two miles north of the frontiers of the state of Venice.

**DOCIMASIA**, in Greek antiquity, a probation of the magistrates and persons employed in public business at Athens. It was performed publicly in the forum, where they were obliged to give account of themselves and their past life before certain judges. Among several questions proposed to them, we find the following, whether they had been dutiful to their parents, had served in the wars, and had a competent estate.

**DOCK**, in botany. See **LAPATHUM**.

**Dock**, in maritime affairs, is a pit, great pond, or creek, by the side of an harbour, made convenient either for the building or repairing of ships.

**Dock-YARDS**, in ship-building, are magazines of all sorts of naval stores. The principal ones in England are those of Chatham, Portsmouth, Plymouth, Woolwich, Deptford, and Sheerness. In time of peace, ships of war are laid up in these docks; those of the first-rates mostly at Chatham, where, and at other yards, they receive from time to time such repairs as are necessary. These yards are generally supplied from the northern crowns with hemp, pitch, tar, rosin, &c. but as for masts, particularly those of the larger size, they are brought from New England.

**DOCTOR**, a person who has passed all the degrees of a faculty, and is empowered to teach or practise the same: thus we say, doctor in divinity, doctor in physics, doctor of laws.

The title of doctor seems to have been created in the XIIth century, instead of *master*, and established with the other scholastic degrees of bachelors and licentiates, by Peter Lombard and Gilbert Porreus, then the chief divines of the university of Paris. Gratian did the same thing, at the same time, in the university of Bologna.

**Doctor of the law**, a title of honour among the Jews. The investiture, if we may so say, of this order was performed by putting a key and table book in their hands, which is what some authors imagine our Saviour had in view, Luke xi. 52. when speaking of the doctors of the law, he says, "Wo unto you, doctors of the law, for you have taken away the key of knowledge: you entered not in yourselves, and them that were entering you hindered."

**DOCTORS-COMMONS**. See **COLLEGE of civilians**.

**DOCUMENT**, in law, some written monument produced in proof of any thing asserted.

**DODARTIA**, in botany, a genus of the didynamia angiospermia class. The calix has five teeth; the inferior labium is much less than the superior; and the capsule is roundish, and has two cells. There are two species, none of them natives of Britain.

**DODDER**, in botany. See **CUSCUTA**.

**DODECAGON**, in geometry, a regular polygon consisting of twelve equal sides and angles.

**DODECAHEDRON**, in geometry, one of the platonic bodies, or regular solids, contained under twelve equal and regular pentagons.

**DODECANDRIA**, in the Linnæan system of botany. See Vol. I. p. 635.

**DODO**, in ornithology. See **DIDUS**.

**DODONÆA**, in botany. See **PTELEA**.

**DODRANS**, in antiquity, three fourths of the as. See **AS**.

**DOESBURG**, a town of the United Netherlands, in the province of Guelderland, situated on the river Yssel, about nine miles south of Zutphen: E. long. 6°, and N. lat. 52°.

**DOG**, in zoology. See **CANIS**.

**DOG'S BANE**, in botany. See **APOCYNUM**.

Dog.

**DOG-DAYS.** See **CANICULAR**.

**DOG'S FENNEL**, in botany. See **COTULA**.

**DOG'S MERCURY**, in botany. See **MERCURIALIS**.

**DOG'S ROSE.** See **ROSA**.

**DOG'S STONES**, in botany. See **ORCHIS**.

**DOG'S TAIL**, in botany. See **CYNOSURUS**.

**DOG'S TONGUE**, in botany. See **CYNOGLOSSUM**.

**DOG'S TOOTH**, in botany. See **ERYTHRONIUM**.

**DOGE**, the chief magistrate in the republics of Venice and Genoa.

This dignity is elective in both places; at Venice it continues for life; at Genoa, it is only for two years. His title is Serenity: he is chief of the council, and mouth of the republic, he being to answer for her. The Venetians do not go into mourning at his death, being only the phantom of majesty, as all the authority is vested in the republic; the doge only lends his name to the senate; the power is diffused through the whole body; though answers to foreign ambassadors, &c. are made in the name of the doge. The money is struck in his name, but does not bear his arms. All the magistrates rise and salute him when he comes into the council: but he rises to none but foreign ambassadors. He must not stir out of Venice, without leave of the counsellors, &c.

**DOGGERS**, a name used for fishing vessels; whence, in some of our old statutes, we meet with dogger-men, denoting the fishermen of those vessels.

**DOGMA**, a principle, maxim, tenet, or settled opinion, particularly with regard to matters of faith and philosophy.

**DOGMATICAL**, something belonging to a doctrine or opinion. A dogmatical philosopher is one who asserts things positively; in opposition to a sceptic, who doubts of every thing.

**DOGMATISTS**, a sect of ancient physicians, of which Hippocrates was the first author. They are also called *logici*, logicians, from their using the rules of logic in subjects of their profession. They laid down definitions and divisions reducing diseases to certain genera, and those genera to species, and furnishing remedies for them all; supposing principles, drawing conclusions, and applying those principles and conclusions to particular diseases under consideration: in which sense the dogmatists stand contradistinguished from empirics and methodists. They reject all medicinal virtues that they think not reducible to manifest qualities: but Galen hath long ago observed of such men, that they must either deny plain matter of fact, or assign but very poor reasons and causes of many effects they pretend to explain.

**DOLE**, in our ancient customs, signified a part or portion, most commonly of a meadow, where several persons have shares. It also still signifies a distribution or dealing of alms, or a liberal gift made by a great man to the people.

**DOLF**, in Scots law, signifies a malevolent intention. It is essential in all crimes that it be committed intentionally, or by an act of the will; hence the rule, *Crimen doli contrahitur*. See **SCOTS LAW**, title 35.

**DOLICHOS**, in botany, a genus of the diadelphia decandria class of plants, the corolla of which is papilionaceous; the vexillum is roundish, large, emarginated, and wholly reflected; the fruit is a large, acuminate, oblong pod, composed of two valves, and containing two cells; the seeds are numerous, elliptical, and frequently compressed. There are twenty-five species, none of them natives of Britain.

**DOLLAR**, a silver coin current in several parts of Germany and Holland. There are various species of dollars, as the rix-dollar, the semi-dollar, the quarter-dollar, &c.

**DOLPHIN**, in ichthyology. See **DELPHINUS**.

**DOM**, or **DON**, a title of honour, invented and chiefly used by the Spaniards, signifying, sir, or lord.

This title, it seems, was first given to Pelayo, in the beginning of the VIIIth century. In Portugal no person can assume the title of don, without the permission of the king, since it is looked upon as a mark of honour and nobility.

**DOMAIN**, the inheritance, estate, or possession of any one. See **DEMESNE**.

**DOVE**, in architecture, a spherical roof, or a roof of a spherical form, raised over the middle of a building, as a church, hall, pavilion, vestibule, stair-case, &c. by way of crowning.

**DOVE**, or **DOOM**, signifies also a sentence, judgment, or decree.

**DOMESDAY**, or **DOOMSDAY-BOOK**, a very ancient record made in the time of William the Conqueror, which now remains in the exchequer, and consists of two volumes, a greater and a less; the greater contains a survey of all the lands in most of the counties in England, and the less comprehends some counties that were then surveyed. The book of domesday was begun by five justices, assigned for that purpose in each county, in the year 1081, and finished in 1086. It was of that authority, that the conqueror himself submitted, in some cases wherein he was concerned, to be determined by it. Camden calls this book the tax-book of king William; and it was farther called *Magna rolla*.

There is likewise a third book of Domesday, made by command of the conqueror; and also a fourth, being an abridgment of the other books.

**DOMESTIC**, any man who acts under another, serving to compose his family; in which he lives, or is supposed to live, as a chaplain, secretary, &c. Sometimes domestic is applied to the wife and children, but very seldom to servants, such as footmen, lacquies, porters, &c.

**DOMICILE**, in Scots law, is the dwelling place where a person lives with an intention to remain. See **SCOTS LAW**, title 2.

**DOMIFYING**, in astrology, the dividing or distributing the heavens into twelve houses, in order to erect a theme, or horoscope, by means of six great circles, called circles of position.

There are various ways of domifying: that of regiomontanus, which is the most common, makes the circles

circles of position pass through the intersections of the meridian and the horizon: others make them pass through the poles of the zodiac.

**DOMINATION**, in theology, the fourth order of angels, or blessed spirits, in the hierarchy, reckoning from the seraphim.

**DOMINGO**, or **ST DOMINGO**, the capital of the island of Hispaniola, the see of an archbishop, and the most ancient royal audience in America: W. long. 70°, N. lat. 18° 20'.

**DOMINICA**, one of the Caribbee islands, subject to Britain: W. long. 61° 20', N. lat. 16°.

**DOMINICAL LETTER**. See **ASTRONOMY**, p. 495.

**DOMINICANS**, an order of religious, called in France Jacobins, and in England Black friars, or preaching-friars. This order founded by St Dominic, a native of Spain, was approved of by Innocent III. in 1215, and confirmed by a bull of Honorius III. in 1216. The design of their institution was to preach the gospel, convert heretics, defend the faith, and propagate Christianity. They embraced the rule of St Augustine, to which they added statutes and constitutions, which had formerly been observed either by the Carthusian or Præmonstratenses. The principal articles enjoined perpetual silence, abstinence from flesh at all times, wearing of woollen, rigorous poverty, and several other austerities. This order has spread into all the parts of the world. It has produced a great number of martyrs, confessors, bishops; and they reckon three popes, sixty cardinals, 150 archbishops, and 800 bishops of their order, besides the masters of the sacred palace, who have always been Dominicans. They are inquisitors in many places:

**DOMINION**, in the civil law, signifies the power to use or dispose of a thing as we please.

**DOMINIUM *eminens***, in Scots law, that power which the state or sovereign has over private property, by which the proprietor may be compelled to sell it for an adequate price where public utility requires. See **SCOTS LAW**, title 8.

**DOMINIUM *directum***, in Scots law, the right which a superior retains in the lands, notwithstanding the feudal grant to his vassal. See **SCOTS LAW**, title 12.

**DOMINIUM *utile***, in Scots law, the right which the vassal acquires in the lands by the feudal grant from his superior. See **SCOTS LAW**, title 13.

**DON**, the name of two rivers; one very large, which, after dividing Asia from Europe, falls into the Palus Meotis; the other in the county of Aberdeen in Scotland.

**DONATION**, in Scots law, signifies a voluntary gift. Donation betwixt husband and wife; see **SCOTS LAW**, title 6—When revocable; Not presumed *in dubio*;—Donations *mortis causa*: See title 22.

**DONATISTS**, Christian schismatics in Africa, who took their name from their leader Donatus. A secret hatred against Cæcilian, elected bishop of Carthage about the year 311, excited Donatus to form this sect. He accused Cæcilian of having delivered up the sacred books to the Pagans, and pretended that his election

was void, and all his adherents heretics. He taught that baptism administered by heretics was null, that every church but the African was become profaned, and that he was to be the restorer of religion. Some accuse the Donatists of Arianism. Constantius and Honorius made laws for their banishment, and Theodosius and Honorius condemned them to grievous mulcts.

**DONATIVE**, a gratuity, or present made to any person.

Donative among the Romans was properly a gift made to the soldiers, as *congiarium* was that made to the people.

**DONATORY**, in Scots law, that person to whom the king bestows his right to any forfeiture that has fallen to the crown.

**DONAWERT**, a city of Bavaria in Germany, forty miles north-west of Ulm: E. long. 10° 40', N. lat. 48° 40'.

**DONAX**, a genus of insects belonging to the order of vermes testacea. It is an animal of the oyster kind; and the shell has two valves, with a very obtuse margin in the fore-part. There are ten species, principally distinguished by the figure of their shells.

**DONCASTER** a market-town of Yorkshire, thirty miles south of York. See **YORK**.

**DONOR**, in law, the person who gives lands or tenements to another in tail, &c. as he to whom such lands, &c. are given is the donee.

**DONZY**, a town of France in the Orleannois: E. long. 3° 16', N. lat. 47° 17'.

**DOOR**, in architecture. See **ARCHITECTURE**, p. 356.

**DORCHESTER**, the capital of Dorsetshire, situated on the river Frome, six miles north of Weymouth: W. long. 2° 35', and N. lat. 50° 40'. It gives the title of marquis to the noble family of Pierpoint, dukes of Kingston, and sends two members to parliament.

**DORDONNE**, a river of France, which runs through the province of Guienne, and falls into the Garonne, twelve miles below Bourdeaux.

**DOREE**, or **JOHN DOREE**, in ichthyology. See **ZEUS**.

**DORIA**, in botany. See **SOLIDAGO**.

**DORIC**, in general, any thing belonging to the Dorians, an ancient people of Greece, inhabiting near mount Parnassus.

**DORIC ORDER** in architecture. See Vol. I. p. 351.

**DORIC DIALECT**, one of the five dialects, or manners of speaking which were principally in use among the Greeks.

It was first used by the Lacedæmonians, particularly those of Argos; afterwards it passed into Epirus, Lybia, Sicily, and the islands of Rhodes, Crete, &c.

**DORIC MODE**, in music, the first of the authentic modes of the ancients; its character is to be severe, tempered with gravity and joy; and is proper upon religious occasions, as also to be used in war. It begins *D, la, sol, re*. Plato admires the music of the doric mode, and judges it proper to preserve good manners, as be-

- ing masculine; and on this account allows it in his commonwealth. The ancients had likewise their sub-doric or hypodoric mode, which was one of the plagal modes. Its character was to be very grave and solemn: it began with *re*, a fourth lower than the doric.
- DORMANT**, in heraldry, is used for the posture of a lion, or any other beast, lying along in a sleeping attitude, with the head on the fore-paws; by which it is distinguished from the couchant, where though the beast be lying, yet he holds up his head.
- DORMER**, in architecture, signifies a window made in the roof of an house, or above the entablature, being raised upon the rafters.
- DORMITORY**, a gallery in convents or religious houses, divided into several cells, in which the religious sleep or lodge.
- DORONICIS AFFINIS**, in botany. See **GERBERA**.
- DORONICUM**, **LEOPARD'S BANE**, in botany, a genus of the syngenesia polygamia superflua class. The receptacle is naked; the pappus is simple; the scales of the calix are equal, and longer than the disc; and the seeds in the radius are naked, and have no pappus. There are three species, none of them natives of Britain.
- DORPT**, or **DORPAT**, a city of Livonia, about fifty miles south of Narva: E. long.  $27^{\circ} 25'$ , and N. lat.  $58^{\circ}$ .
- DORSAL**, an appellation given to whatever belongs to the back. See **DORSUM**.
- DORSAL MUSCLES**. See **ANAT. PART. II.**
- DORSIFEROUS PLANTS**, among botanists, such as are of the capillary kind, without stalks, and which bear their seeds on the back-side of their leaves.
- DORSTENIA**, in botany, a genus of the tetrandria monogynia class. The common receptacle consists of one fleshy leaf, in which the solitary seeds are contained. There are four species, none of them natives of Britain.
- DORSUM**, **BACK**, in anatomy, comprehends all the posterior part of the trunk of the body, from the neck to the buttocks. See **ANATOMY**.
- DORT**, a city of the United Provinces, situated in that of Holland, on an island in the river Maele, about ten miles east of Rotterdam: E. long.  $4^{\circ} 40'$ , and N. lat.  $51^{\circ} 47'$ .
- DORTMONT**, a city of Westphalia in Germany, about thirty miles north-east of Dusseldorp: E. long  $6^{\circ} 50'$ , and N. lat.  $51^{\circ} 25'$ . It is an imperial city, and constitutes a sovereign state.
- DORTMANNA**, in botany. See **LOBELIA**.
- DORYCNium**, in botany. See **CONVOLVULUS**.
- DORYPHORI**, in antiquity, an appellation given to the life guard men of the Roman emperors.
- DOSITHEANS**, in church-history, a sect among the Hebrews, being one of the branches of the Samaritans. See **SAMARITANS**.
- They abstained from eating any creature that had life, and were so superstitious in keeping the sabbath, that they remained in the same place and posture wherein that day surpris'd them, without stirring till the next day. They married but once, and a great number ne-
- ver married. Dositheus, their founder, being dissatisfied among the Jews, retired to the Samaritans, who were reputed heretics, and invented another sect; and to make it more authentic, he went into a cave, where, by too long abstinence, he killed himself. The name of Dositheans was also given to some of the disciples of Simon Magus.
- DOTTEREL**, in ornithology. See **CHARADRIUS**.
- DOUAY**, a fortified city of the French Netherlands, situated on the river Scrape, about fifteen miles south of Lisle: E. lon.  $3^{\circ}$ , and N. lat.  $50^{\circ} 25'$ .
- DOUBLE FICHY**, or **FICHE'**, in heraldry, the denomination of a cross, when the extremity has two points, in contradistinction to fiché, where the extremity is sharpened away to one point. See Plate LXVIII. fig. 8.
- DOUBLET**S, a game on dice within tables: the men, which are only fifteen, being placed thus; upon the six, cinque, and quater points, there stand three men a-piece; and upon the trey, duce, and ace, only two. He that throws highest hath the benefit of throwing first, and what he throws he lays down, and so doth the other: what the one throws, and hath not, the other lays down for him, but on his own account; and thus they do till all the men are down, and then they bear. He that is down first bears first, and will doubtless win the game, if the other throws not doublets to overtake him; which he is sure to do, since he advances or bears as many as the doublets make, viz. eight for two fours.
- DOUBLING**, in the military art, is the putting two ranks or files of soldiers into one. Thus, when the word of command is, *double your ranks*, the second, fourth, and sixth ranks march into the first, third, and fifth, so that the six ranks are reduced to three, and the intervals between the ranks become double what they were before.
- DOUBLING**, among hunters, who say that a hare doubles, when she keeps in plain fields, and winds about to deceive the hounds.
- DOUBLING**, in the menage, a term used of a horse, who is said to double his reins, when he leaps several times together, to throw his rider: thus we say, the ramingue doubles his reins, and makes pontlevis.
- DOUBLING a cape or point**, in navigation, signifies the coming up with it, passing by it, and leaving it behind the ship.
- DOUBLINGS**, in heraldry, the linings of robes and mantles of state, or of the mantlings in achievements.
- DOUBLON**, or **DUBLOON**, a Spanish and Portuguese coin, being the double of a pistole. See **PISTOLE**.
- DOUBTING**, the act of withholding our assent from any proposition, on suspicion that we are not thoroughly apprised of the merits thereof; or from not being able peremptorily to decide between the reasons for and against it.
- DOUCINE**, in architecture, a moulding concave above and convex below, serving commonly as a cymatium to a delicate cornice. It is likewise called gula.
- DOVE**, in ornithology. See **COLUMBA**.
- DOVE**, in geography, the name of a river dividing Derbyshire

byshire from Staffordshire : also of a town of the Orleans, in France, about twenty miles south-east of Angers.

**DOVE-TAILING**, in carpentry, is the manner of fastening boards together by letting one piece into another, in the form of the tail of a dove. The dove-tail is the strongest of the assemblages or jointings, because the tenon, or piece of wood which is put into the other, goes widening to the extreme, so that it cannot be drawn out again, by reason the extreme or tip is bigger than the hole.

**DOVER**, a borough and port-town of Kent, situated on a rock, opposite to Calais in France, with a strong castle: E. long. 25', and N. lat. 51° 10'.

Dover gives the title of duke to the dukes of Queenbury, a branch of the noble family of Douglas; and sends two members to parliament, styled barons of the cinque ports, whereof Dover is the chief.

**DOUGLAS**, a port-town, and the best harbour in the Isle of Man: W. long. 4° 25', and N. lat. 54° 7'.

**DOWAGER**, a widow endowed, is a title applied to the widows of princes, dukes, earls, and persons of high rank only.

**DOWER**, that portion which the law allows a widow out of the lands of her husband, after his decease.

**DOWN**, in geography, the capital of a county of the same name in the province of Ulster, in Ireland: W. long. 5° 50', and N. lat. 54° 23'.

**DOWNETON**, or **DUNKTON**, a borough-town of Wiltshire, five miles south of Salisbury. It sends two members to parliament.

**DOWNHAM**, a market-town of Norfolk, ten miles south of Lynn, famous for its good butter; there being a thousand, and sometimes two thousand sirkins bought here every Monday, and sent up the river Ouse to Cambridge, from whence it is conveyed to London, in the Cambridge waggons.

**DOWNS**, a famous road near Deal, in Kent, where both the outward and homeward bound ships frequently make some stay; and squadrons of men of war rendezvous in time of war.

It affords excellent anchorage, and is defended by the castles of Deal, Dover, and Sandwich.

**DOWRY**, the money or fortune which the wife brings her husband in marriage: It is otherwise called *maritagium*, marriage-goods, and differs from dower.

**DOXOLOGY**, an hymn used in praise of the Almighty, distinguished by the title of greater and lesser.

The lesser doxology was anciently only a single sentence, without response, running in these words, *Glory be to the Father, and to the Son, and to the Holy Ghost, world without end. amen.* Part of the latter clause, *As it was in the beginning, is now, and ever shall be*, was inserted some time after the first composition. Some read this ancient hymn, *Glory be to the Father, and to the Son with the Holy Ghost.* Others, *Glory be to the Father in or by the Son, and by the Holy Ghost.* This difference of expression occasioned no disputes in the church, till the rise of the Arian heresy; but when the followers of Arius began to make

use of the latter as a distinguishing character of their party, it was entirely laid aside by the catholics, and the use of it was enough to bring any one under suspicion of heterodoxy. The doxology was used at the close of every solemn office. The western church repeated it at the end of every psalm, and the eastern church at the end of the last psalm. Many of their prayers were also concluded with it, particularly the solemn thanksgiving, or consecration prayer at the eucharist. It was also the ordinary conclusion of their sermons.

The greater doxology, or angelic hymn, was likewise of great note in the ancient church. It began with these words, which the angels sung at our Saviour's birth, *Glory be to God on high, &c.* It was chiefly used in communion service, and in mens private devotions. Both the doxologies have a place in the church of England, the former being repeated after every psalm, and the latter used in the communion service.

**DRABA**, in botany, a genus of the tetradynamia siliculosa class. The pod is entire and somewhat oval, with plain valves, and a parallel dissepimentum; it has no stylus. There are six species, three of them natives of Britain, viz. the verna, or common whitlow-grass; the muralis, or speedwell-leaved whitlow-grass; and the incana, or wreathen-podded whitlow-grass.

**DRABS**, in the salt-works, a kind of wooden boxes for holding the salt when taken out of the boiling pan, the bottoms of which are made shelving or inclining forwards, that the briny moisture of the salt may drain off.

**DRACHM**, a Grecian coin of the value of seven pence three-farthings.

**DRACO**, the **DRAGON**, in zoology, a genus belonging to the order of amphibia reptilia. The characters of which are these: It has four legs, a cylindrical tail, and two membranaceous wings, radiated like the fins of a fish, by which he is enabled to fly, but not to any great distance at a time. There are two species, 1. The volans, or flying dragon, with the wings entirely distinct from the fore-legs; it is found in Africa and the East Indies. 2. The præpos, with the wings fixed to the fore-legs; it is a native of America. They are both harmless creatures, and feed upon flies, ants, and small insects.

**DRACO VOLANS**, in meteorology, a fiery exhalation, frequent in marshy and cold countries.

It is most common in summer, and though principally seen playing near the banks of rivers, or in boggy places, yet sometimes mounts up to a considerable height in the air, to the no small terror of the amazed beholders; its appearance being that of an oblong, sometimes roundish, fiery body, with a long tail. It is entirely harmless, frequently sticking to the hands and cloaths of people without injuring them in the least.

**DRACO**, in astronomy, a constellation of the northern hemisphere. See **ASTRONOMY**, p. 486.

**DRACOCEPHALUM**, **DRAGON'S HEAD**, in botany, a genus of the didynamia gymnospermia class. The

faux

base of the corolla is inflated, and the superior labium is concave. There are 13 species, none of them natives of Britain.

**DRACONTIC MONTH**, the time of one revolution of the moon, from her ascending node, called caput draconis, to her return thither.

**DRACONTIUM**, **DRAGONS**, in botany, a genus of the gynandria polyandria class. The spathe is shaped like a boat; the spadix is covered; it has no calix; the corolla consists of five petals; and the berry contains many seeds. There are five species, all natives of the Indus.

**DRACUNCULI**, in medicine, small long worms, which breed in the muscular parts of the arms and legs, called Guinea worms. See **MEDICINE**.

**DRACUNCULUS**, in botany. See **ARUM**.

**DRACUNCULUS**, in ichthyology. See **CALLIONYMUS**.

**DRAGOMAN**, **DROGMAN**, or **DRUGGERMAN**, a name given in the Levant to the interpreters kept by the ambassadors of Christian nations, residing at the Porte, to assist them in treating of their master's affairs.

**DRAGON**, in zoology. See **DRACO**.

**DRAGON'S BLOOD**, in pharmacy, a resin brought from the East-Indies, either in oval drops, wrapped up in flag leaves, or in large masses composed of smaller tears. The fine dragon's blood of either sort breaks smooth, free from any visible impurities, of a dark red colour, which changes upon being powdered into an elegant bright crimson. It dissolves in pure spirit, and tinges a large quantity of the menstruum of a deep red colour; it is also soluble in oils. It is usually looked upon as a gentle astringent, and is sometimes prescribed against femoral gleets, the fluor albus, and other fluxes.

**DRAGON-FLY**. See **LIBELLA**.

**DRAGON-SHELL**. See **PATELLA**.

**DRAGONS**, in botany. See **DRACONTIUM**.

**DRAGONNE'E**, in heraldry; a lion dragonnée is where the upper half resembles a lion, the other half going off like the hinder part of a dragon. The same may be said of any other beast as well as a lion.

**DRAGOON**, in military affairs, a musqueteer, mounted on horseback, who sometimes fights or marches on foot, as occasion requires.

Dragoons are divided into brigades, as the cavalry, and each regiment into troops; each troop having a captain, lieutenant, cornet, quarter-master, two sergeants, three corporals, and two drums. Some regiments have hautboys: they are very useful on any expedition that requires dispatch, for they can keep pace with the cavalry, and do the duty of infantry: they encamp generally on the wings of the army, or at the passes leading to the camp; and sometimes they are brought to cover the general's quarters: they do duty on the generals of horse and dragoons, and march in the front and rear of the army.

**DRAGS**, in the sea-language, are whatever hangs over the ship in the sea, as shirts, coats, or the like; and boats, when towed, or whatever else that, after this manner, may hinder the ship's way when she sails, are called drags.

**DRAINS**, a name given, in the fen countries, to certain large cuts or ditches of twenty, thirty, nay sometimes forty foot wide, carried through the marshy ground to some river or other place capable of discharging the water they carry out of the fen-lands. See **AGRICULTURE**.

**DRAKE**, in ornithology, the male of the duck-kind. See **ANAS**.

**DRAMA**, a poem containing some certain action, and representing a true picture of human life, for the delight and improvement of mankind.

The principal species of the drama are two, comedy and tragedy. Some others there are of less note, as pastoral, satire, tragi-comedy, opera, &c. See **COMPOSITION**.

**DRAMATIC**, an epithet given to pieces written for the stage. See **COMPOSITION**.

**DRANK**, among farmers, a term used to denote wild oats, which never fail to infect worn-out lands; so that when plowed lands run to these weeds and thistles, the farmer knows it is high time to fallow them, or else to sow them with hay-seed, and make pasture of them.

**DRAPERY**, in sculpture and painting, signifies the representation of the clothing of human figures, and also hangings, tapestry, curtains, and most other things that are not carnations or landscapes. See **PAINTING**.

**DRAUGHT**, in trade, called also **CLOFF** or **CLOUCH**, is a small allowance on weighable goods, made by the king to the importer, or by the seller to the buyer, that the weight may hold out when the goods are weighed again.

The king allows 1 lb draught for goods weighing no less than 1 Cwt. 2 lb for goods weighing between 1 and 2 Cwt. 3 lb for goods weighing between 2 and 3 Cwt. 4 lb from 3 to 10 cwt. 7 lb from 10 to 18 Cwt. 9 lb from 18 to 30, or upwards.

**DRAUGHT HOOKS**, are large hooks of iron, fixed on the cheeks of a cannon-carriage, two on each side, one near the trunnion hole, and the other at the train, distinguished by the name of fore and hind draught-hooks. Large guns have draught-hooks near the middle trunnion, to which are fixed the chains that serve to keep the shafts of the limbers on a march. The fore and hind hooks are used for drawing a gun backwards or forwards, by men with strong ropes, called draught-ropes, fixed to these hooks.

**DRAUGHT-HORSE**, in farming, a sort of coarse-made horse, declined for the service of a cart or plough. See **EQUUS**.

**DRAW**, in the sea-language. A ship is said to draw so much water, according to the number of feet she sinks into it; so that if a ship sink into the water eighteen feet perpendicularly, she is said to draw eighteen feet water; and according as she draws more or less, she is said to be of more or less draught.

**DRAW-BACK**, in commerce, certain duties, either of the customs or of the excise, allowed upon the exportation of some of our own manufactures; or upon certain foreign merchandise, that have paid duty on importation.

The

The oaths of the merchants importing and exporting are required to obtain the drawback of foreign goods, affirming the truth of the officer's certificate of the entry, and the due payment of the duties: and these may be made by the agent or husband of any corporation or company, or by the known servant of any merchant usually employed in making his entries and paying his customs. In regard to foreign goods entered outward, if less quantity or value be fraudulently shipped out than is expressed in the exporter's certificate, the goods therein mentioned, or their value, are forfeited, and no drawback to be allowed for the same. Foreign goods exported by certificate, in order to obtain the drawback, not shipped or exported, or re-landed in Great Britain, unless in case of distress, to save them from perishing, are to lose the benefit of the drawback, and are forfeited, or their value, with the vessels, horses, carriages, &c. employed in the re-landing thereof; and the persons employed in the re-landing them, or by whose privity they are re-landed, or into whose hands they shall knowingly come, are to forfeit double the amount of the drawback. Officers of the customs conniving at, or assisting in any fraud relating to certificate-goods, besides other penalties, are to forfeit their office, and to suffer six months imprisonment, without bail or mainprize; as are also masters, or persons belonging to the ships employed therein. Bonds given for the exportation of certificate-goods to Ireland, must not be delivered up, nor drawback allowed for any goods, till a certificate under the hands and seals of the collector or comptroller, &c. of the customs be produced, testifying the landing.

The computation of what is to be drawn back upon the exportation of foreign goods, may be seen under their respective heads.

**DRAW-BRIDGE**, a bridge made after the manner of a floor, to draw up, or let down, as occasion serves, before the gate of a town or castle.

**DRAWING**, in general, denotes the action of pulling out, or haling along: thus, we read of tooth-drawing, wire-drawing, &c.

**DRAWING**, the art of representing the appearances of objects by imitation, or copying without the assistance of mathematical rules.

The general precepts for drawing are as follow:

1. Begin with plain geometrical figures, as lines, angles, triangles, polygons, arches, circles, ovals, cones, cylinders, and the like, being the foundation of all other proportions. The circle is of use in the several orbicular forms, as the sun, moon, globes, &c. the oval, in giving a just proportion to the face and mouth; and the square confines a picture you are to copy, &c. the triangle is of use in drawing a side or half face; angles and arches, in perspective; and the polygon, in ground-plots, fortifications, &c. the cone, in spires, steeples, tops of towers, &c. the cylinder, in columns, pillars, pilasters, &c. See PERSPECTIVE.

2. Having brought your hand to be fit and ready in general proportions, accustom yourself to give every object its due shade, according to its concavity or

VOL. II. No. 45.

3

convexity, and to elevate or depress the same, as the object appears either nearer or farther off the light.

3. The second practice of drawing, consists in forming fruits, as apples, pears, cherries, &c. with their leaves; the imitation of flowers, as roses, tulips, carnations, &c. herbs, trees, &c. of different kinds.

4. The third, in the imitation of beasts, fowls, fishes, &c.

5. The fourth practice of drawing consists in the imitation of the body of man, with all its lineaments, as head, nose, eyes, ears, cheeks, arms, and shadows, all exactly proportioned both to the whole and to one another.

6. The fifth is in the drapery, in the imitation of cloathing, and artificially setting off the outward coverings, habit, and ornaments of the body, either of cloth, stuff, silk, or linen, in their natural and proper folds.

7. In drawing of all the forms before-mentioned, it is requisite to be first perfect in the laying down the exact proportions; secondly, in the general or outward lines, before you proceed to shadowing, or trimming the work within.

8. In mixed and uncertain forms, where the circle, square, &c. will be of no use, but only in the idea thereof in your own fancy, as horses, oxen, and the like, you must do it by judgment, and so gain the true proportions by assiduous practice: thus having the shape of the thing in your mind, first draw it rudely with a coal; then, with more exactness, with a lead or pencil; then peruse it well, and mend it in those parts you have erred in, according to the idea you carry in your mind. When it is mended by your own judgment, compare it with some good pattern of the same kind, and amend it by that.

9. Having good copies to draw after, learn to reduce them to other proportions, either larger or smaller; and this by frequent practice.

10. Let a perfection in drawing be attained by diligent exercise, and the instruction of a good master, before there be any attempts as to colouring and painting; for the former being attained, the rest will be easily understood, and gained by frequent practice.

*Particular observations with regard to DRAWING, are as follows.*

1. If you draw after a print or picture, place it in such a light, that the gloss of the colours may not interrupt your light, and that the light and your eye may equally and obliquely fall upon the piece, which should be placed at such a distance, that, upon opening your eye, you may view it at once: the larger the picture is, the greater distance off it should be placed: it should also be right before you, and a little reclining.

2. Draw your out-lines at first very faint, and with a coal; and let them be drawn agreeable to the pattern, before you begin to shadow any part of it. When you have drawn one feature, it should, in some measure, be a direction for you to draw the other, by observing the distance from that to the next feature; making a small mark at the place with your coal, then draw it, and so to the next, till you have drawn the whole figure.

†

4 X

3. Then

3. Then observe the middle of the picture you would copy, and touch upon the paper with the point of your coal: afterwards, observe the more conspicuous and uppermost figures, if there are more than one, which you are to touch lightly in their proper places: thus, running over the whole draught, you will see, as it were, the skeleton of the piece to draw.

4. Having made out these sketches, view them diligently, if they answer your pattern or not; for the gestures of the life ought to shew themselves eminently in the first and rudest draughts thereof: correct and mend whatever you perceive amiss, adding and diminishing as it varies from the pattern; by which method it will be brought nearer and nearer to the life.

5. Observe the distance of one limb, joint, or muscle, from another, and the same in all other accidents of the figure, their length, breadth, turnings, &c. shadow next to the light very faintly; and where you see bold and free touches, be not timorous in expressing the same. In drawing a head by the life, or otherwise, take care to place the features exactly right upon the cross-lines, whether it be a full face, or three-quarter face. In fore-shortening you must make the cross-lines to fly upwards, where they look upwards; but where the aspect is downwards, they must be made downwards, in a circular manner. Having drawn the out-lines true, with a coal, you are to proceed to trace the same lines again with a pen, Indian ink, &c. drawing them with more exactness, and by imitating all the hatches with their exact distances one from another, their crossings, turnings and windings, with more boldness and freedom perfect your design.

6. In drawing after a naked body, all the muscles are not to be so plainly expressed as in anatomical figures: but that side whose parts are most apparent, and of signification in the performance of any action, must be made to appear more or less, according to the force of that action.

7. In drawing young persons, the muscles must not appear manifestly so hard as in older and full-grown persons: the same is to be observed as to fat and fleshy persons, and such as are very delicate and beautiful; and in women, scarce any muscles at all are to be expressed, or but very little, unless it be in some very terrible action, and then too they are to be represented very faintly; the like is also to be observed as to little children.

8. The motion of the whole body must be considered in drawing of the muscles; as in the rising and falling of the arms, the muscles of the breast do appear more or less; the hips do the like according as they are bent outward or inward; and it is the same chiefly in the shoulders, sides, and neck, according to the several actions of the body.

9. The proportion of the figure ought to be multiplied by degrees. in proportion of one to two, three, four, &c. for herein the chief skill consists: the diameter of the biggest place, between the knee and the foot, is double to the least; and the largest part of the thigh, triple.

**DRAY**, a kind of cart used by brewers, for carrying barrels of beer, or ale; also a sledge drawn without wheels.

**DRAY**, among sportsmen, denotes squirrel-nests, built in the tops of trees.

**DRYATON**, a market-town of Shropshire, fourteen miles north-east of Shrewsbury.

**DREDGE**, or **DREG**, among farmers, denotes oats and barley mingled together.

**DREDGERS**, the term used in the admiralty-court for the oiler-fishers.

**DREIN**, in the military art, a trench made to draw the water out of a moat, which is afterwards filled with hurdles and earth, or with fascines or bundles of rushes and planks, to facilitate the passage over the mud. See **TRENCH**.

**DRENCH**, among farriers, a physical potion for horses. The ingredients for this purpose are to be beat coarsely, and either mingled with a decoction, or with wine. Then let all infuse about a quarter of an hour, and give it to the horse with a horn, after he has been tied up two hours to the rack.

**DRESDEN**, the capital of Upper Saxony, in Germany, situated on the river Elbe, sixty-five miles north-west of Prague, and eighty-five south of Berlin: E. long. 13° 36', N. lat. 51°.

It is one of the largest and strongest towns in Germany, and is the usual residence of the elector of Saxony.

**DREUX**, a town of Orleanois, in France, seventeen miles north of Chartres, and thirty-five west of Paris.

**DRIFT**, a term used at sea. Thus, any thing that floats upon the water, is said to run a-drift.

**DRIFT-SAIL**, a sail used under water, veered out right a-head by sheets, as other sails are. It serves to keep the ship's head right upon the sea in a storm, and to hinder her driving too fast in a current.

**DRILL**, in mechanics, a small instrument for making such holes as punches will not conveniently serve for. Drills are of various sizes, and are chiefly used by smiths and turners.

**DRILL**, or **DRILL-BOX**, a name given to an instrument for sowing land in the new method of horse-hoeing husbandry. See **ARICULTURE**.

**DRINK**, a part of our ordinary food in a liquid form, serving to dilute and moisten the dry meat.

The drinks in different countries are different. The common drink in England is either water, malt-liquor, wine, or mixtures of these.

The first drinks of mankind were certainly water and milk, but the love of luxury and debauchery soon introduced the art of preparing intoxicating and inebriating drinks out of vegetables. The vine gave the first of these liquors; after this, wheat, barley, millet, oats, rice, apples, pears, and pomegranates; and after those the juices drained from the pine, sycamore, and mapple, were brought to this use: in latter times, roots, berries, and the pith of the sugar-cane, have been employed for the same purposes.

**DRIVERS**, among sportsmen, a machine for driving pheasant-powts, consisting of good strong ozier-wands, such

such as the basket-makers use; these are to be set in a handle, and twisted or bound with small ozers in two or three places.

With this instrument, the sportsman drives whole eyes of young powns into his nets. See the next article.

**DRIVING**, among sportsmen, a method of taking pheasant-powns. It is thus: the sportsman finds out the haunts of these birds; and having fixed his nets there, he calls them together by a pheasant-call, imitating the voice of the dam: after this he makes a noise with his driver, which will make them run a little way forward in a cluster; and this he is to repeat till he has made sure of them, which an expert sportsman never fails to do, by driving them into his nets.

**DRIVING**, in metallurgy, is said of silver, when in the operation of refining, the lead being burnt away, the remaining copper rises upon its surface in red fiery bubbles.

**DRIVING**, in the sea-language, is said of a ship when an anchor being let fall will not hold her fast, nor prevent her sailing away with the tide or wind. The best help in this case is to let fall more anchors, or to veer out more cable; for the more cable she has out, the safer she rides. When a ship is a-hull, or a-try, they say she drives to leeward.

**DROGHEDA**, a port-town of Ireland, twenty-three miles north of Dublin.

**DROGMAN**. See **DRAGOMAN**.

**DROITWICH**, a borough six miles north of Worcester, which sends two members to parliament.

**DROMEDARY**. See **CAMELUS**.

**DRONE**, in the history of insects. See **APIS**.

**DRONE-FLY**, a two-winged insect, extremely like the common drone-bee, whence also the name.

**DROPS**, in meteorology, small spherical bodies which the particles of fluids spontaneously form themselves into when let fall from any height.

**DROPS**, in medicine, a liquid remedy, the dose of which is estimated by a certain number of drops.

**DROPSY**, in medicine, an unnatural collection of watry humours in any part of the body. See **MEDICINE**.

**DROP-WORT**, in botany. See **FILIPENDULA**.

**Water DROP-WORT**, in botany. See **OENANTHE**.

**DROSERA**, **SUN-DEW**, in botany, a genus of the pentandria pentagynia class of plants, with a funnel-fashioned flower, consisting of five obtusely-ovated petals: the fruit is an unilocular suboval capsule, containing a great many very small seeds.

**DROWNING**, the act of suffocating, or being suffocated, by water.

Naturalists and physicians furnish us with divers well attested instances of surprising recoveries of persons drowned. It is certain from repeated dissections made on persons drowned, that they generally have less water in their stomachs than if they had voluntarily drunk a considerable quantity: whence it does not seem expedient to hang the drowned person by the heels, a position that must prove uneasy as soon as the humours of the body should resume their ordinary motion. In order to know whether the person has swallowed too

much water or not, and to make him vomit it up if he has, it is proper to put him in a tun, open at both ends, which is to be rolled in different directions: or the bearded end of a feather should be introduced into the œsophagus. After taking off the cloaths of the drowned person, we ought, with the utmost expedition, to shelter him from the impressions of the cold air, and begin to warm him, by wrapping him up with cloaths and coverings: to do this more effectually, he is afterwards to be put into a pretty warm bed, applying also to his body hot napkins and cloths. A hot scorching sun, to which drowned persons have been exposed, and hot baths, have produced the same happy effects.

The great intention to be pursued is, to put the solid parts of the machine in action, that thus they may restore the motion of the fluids: in order to this, the drowned person should be agitated in various directions, in a bed, in the arms of persons of sufficient strength.

Spirituous liquors should be poured into his mouth, or warm urine; and some persons prescribe a decoction of pepper and vinegar, as a gargarism: we must also attempt to irritate the internal fibres of the nose, either by volatile spirits, and by the liquors used in apoplectic cases; or by tickling the nerves of the nostrils with a bearded feather; or by blowing, through a quill, snuff, or some other more powerful sternutatory. One of the means frequently used with success, is to blow warm air, by means of a pipe, into their mouths; or to introduce it by a pair of bellows; or, by injecting warm clysters, to irritate the intestines: the smoke of tobacco conveyed into the intestines, by means of a tobacco pipe, is much recommended. Venæsection is by no means to be neglected; and perhaps most successfully in the jugular vein.

**DRUG**, a general term for goods of the druggist and grocery kinds, especially for those used in medicine and dying.

**DRUGGET**, in commerce, a stuff sometimes all wool, and sometimes half wool half thread, sometimes corded, but usually plain.

Those that have the woof of wool, and the warp of thread, are called threaded-druggets; and those wrought with the shuttle on a loom of four marches, as the serges of Moui, Beauvois, and other like stuffs corded, are called corded druggets. As to the plain, they are wrought on a loom of two marches, with the shuttle, in the same manner as cloth, camlets, and other like stuffs not corded.

**DRUIDS**, the priests or ministers of religion of the ancient Britons and Gauls. The druids were chosen out of the best families; and were held, both by the honours of their birth, and their office, in the greatest veneration. They are said to have understood astrology, geometry, natural history, politics, and geography: they had the administration of all sacred things, were the interpreters of religion, and the judges of all affairs indifferently.

Whoever refused obedience to them, was declared impious and accursed: they held the immortality of the

the soul, and the transmigration of souls. They are divided by some into several classes, as the *vaceni*, *bardi*, *bubagis*, *semothii*. They had a chief, or arch-druid, in every nation: he was a sort of high-priest, having an absolute authority over the rest, and was succeeded by the most considerable among his survivors. The youth used to be instructed by them, retiring with them to caves and desolate forests, where they were sometimes kept twenty years. They preserved the memory and actions of great men by their verses; but are said to have sacrificed men to Mercury. Cæsar imagined that the druids came from Britain into Gaul, but several among the modern writers are of a different opinion.

**DRUM**, is a martial musical instrument in form of a cylinder, hollow within, and covered at the two ends with vellum, which is stretched or slackened at pleasure by the means of small cords or sliding knots: It is beat upon with sticks. Some drums are made of brass, but they are commonly of wood.

**Kettle Drums**, are two sorts of large basons of copper or brass, rounded in the bottom, and covered with vellum, or goat-skin, which is kept fast by a circle of iron, and several holes fastened to the body of the drum, and a like number screws to screw up and down. They are much used among the horse, as also in operas, oratorios, concerts, &c.

**DRUM**, or **DRUMMER**, he that beats the drum; of whom each company of foot has one, and sometimes two. Every regiment has a drum-major, who has the command over the other drums. They are distinguished from the soldiers, by cloaths of a different fashion: their post, when a battalion is drawn up, is on the flanks, and on a march it is betwixt the divisions.

**DRUM of the ear**, in anatomy. See Vol. I. p. 299.

**DRUMLANERK**, a town of Scotland, fifteen miles north of Dumfries.

**DRUNKENNESS**, a well known disorder in the brain, occasioned by drinking too freely of spirituous liquors. Drunkenness appears in different shapes, in different constitutions: some it makes gay, some sullen, and some furious.

**DRUPE**, among botanists. See Vol. I. p. 637.

**DRUSENHEIM**, a town of Alsace, in Germany, four miles south-east of Hagenau.

**DRYADÆA**, in botany. See **DRYAS**.

**DRYADS**, in the heathen theology, a sort of deities, or nymphs, which the ancients thought inhabited groves and woods. They differed from the Hamadryades, these latter being attached to some particular tree, with which they were born, and with which they died; whereas the Dryades were goddesses of trees and woods in general.

**DRYAS**, in botany, a genus of the icofandria polygynia class. The calix consists of eight segments, and the corolla of eight petals; and the seeds are tailed and hairy. There are two species, both natives of Britain, viz. the pentapetala, or cinquefoil avens; and the octopetala, or mountain avens.

**DUBLIN**, the capital of the province of Leinster, and of all Ireland, situated at the mouth of the river Lif-

fee, sixty miles west of Holyhead in Wales: W. lon. 6° 25', N. lat. 53° 16'.

It is a large and beautiful city, pleasantly situated; having a view of the sea on one side, and of a fine country on the other. It is the seat of the courts of justice, and an archbishop's see; and has a noble college, which is an university of itself.

**DUCAL**, in general, something belonging to a duke. See **DUKE**.

**DUCAT**, a coin current in Germany and other countries abroad, of different values.

**DUCATOON**, a silver coin, likewise frequent in several parts of Europe.

**DUCENARIUS**, in Roman antiquity, a military office, who had the command of two hundred men.

**DUCK**, in ornithology. See **ANAS**.

**DUCKER**. See **COLYMBUS**.

**DUCKING**, plunging in water, a diversion anciently practised among the Goths, by way of exercise; but among the Celts, Franks, and ancient Germans, it was a sort of punishment for persons of scandalous lives.

They were shut up, naked to the shift, in an iron cage, fastened to the yard of a shallop, and ducked several times.

**DUCKING at the main-yard**, among seamen, is a way of punishing offenders on board a ship; and is performed by binding the malefactor, by a rope, to the end of the yard, from whence he is violently let down into the sea, once, twice, or three times, according to his offence: and if the offence be very great, he is drawn underneath the keel of the ship, which they call keel-haling.

**DUCKUP**, at sea, is a term used by the steer's-man, when the main-sail, fore-sail, or sprit-sail, hinders his seeing to steer by a land-mark: upon which he calls out, *Duckup the clew-lines of these sails*, that is, hale the sails out of the way. Also when a shot is made by a chace-piece, if the clew of the sprit-sail hinders the sight, they call out, *Duckup*, &c.

**DUCT**, in general, denotes any tube or canal. It is a term much used by anatomists.

**Air-DUCT**, among ichthyologists, a canal reaching from the air-bladder in fishes to their stomach.

**DUCTILITY**, in physics, a property of certain bodies, whereby they are capable of being expanded, or stretched forth, by means of a hammer, press, &c. See **CHEMISTRY**, and **MECHANICS**.

**DUDERSTAT**, a town of Upper Saxony, thirty-five miles north-east of Cassel.

**DUEL**, a single combat, at a time and place appointed, in consequence of a challenge. This custom came originally from the northern nations, among whom it was usual to decide all their controversies by arms. Both the accuser and the accused gave pledges to the judges on their respective behalf; and the custom prevailed so far amongst the Germans, Danes, and Franks, that none were excused from it but women, sick people, cripples, and such as were under twenty-one years of age, or above sixty. Even ecclesiastics, priests, and monks, were obliged to find champions

to

to fight in their stead. The punishment of the vanquished was either death, by hanging or beheading; or, mutilation of members, according to the circumstances of the case. Duels were at first admitted not only on criminal occasions, but on some civil ones for the maintenance of rights to estates, and the like: in latter times, however, before they were intirely abolished, they were restrained to these four cases. 1. That the crime should be capital. 2. That it should be certain the crime was perpetrated. 3. The accused must, by common fame, be supposed guilty. And, 4. The matter not capable of proof by witnesses. At present it is used for a single combat on some private quarrel, and must be premeditated, otherwise it is called a rencounter. If a person be killed in a duel, both the principals and seconds are guilty of murder, whether the seconds engage or not. It is also a very high offence to challenge a person, either by word or letter, or to be the messenger of a challenge. The severe edicts made by Lewis XIV. against duels have, in a great measure, put a stop to the custom in France.

**DUELING**, in Scots law. See title 33.

**DUERO**, or **DURO**, a large river, which, rising in Old Castile in Spain, runs from east to west, crosses the province of Leon, and, after dividing Portugal from Spain by a southerly course, turns westward, crosses Portugal, and falls into the Atlantic Ocean at Porto-Port.

**DUKE** is either the title of a sovereign prince, as the duke of Savoy, Parma, &c. the grand duke of Tuscany, Muscovy, &c. or it is the title of honour and nobility next below princes. The commanders of armies in time of war, the governors of provinces and wardens of marches in times of peace, were called *duces* under the later emperors. The Goths and Vandals divided all Gaul into dutchies and counties, the governors of which they sometimes call *duces*, and sometimes *comites*. In France, under the second race of kings, though they retained the name and form of ducal government, there were scarce any dukes except those of Burgundy, Aquitain, and France. In England, among the Saxons, the commanders of armies, &c. were called dukes, *duces*, without any addition, till Edward III. made his son, the Black Prince, duke of Cornwall; after whom there were more made in the same manner, the title descending to their posterity. Duke then, at present, is a mere title of dignity, without giving any domain, territory, or jurisdiction over the place from whence the title is taken. A duke is created by patent, cincture of sword, mantle of state, imposition of a cap and coronet of gold on his head, and a verge of gold put into his hand. His title is Grace; and, in the style of the heralds, Most high, potent, high-born, and noble prince.

**DULCIFYING**, in chemistry, is the sweetening any matter impregnated with salts, by frequently washing it in pure water.

**DULL**, in the menage. The marks of a dull horse, called by the French *marquis de ladre*, are white spots round the eye and on the tip of the nose, upon

any general colour whatsoever. Though the vulgar take these spots for signs of stupidity, it is certain they are great marks of the goodness of a horse; and the horses that have them are very sensible and quick upon the spur.

**DULWICH**, a village near London, remarkable for its mineral waters, which are said to contain a bitter cathartic salt, but no iron.

**DUMBLAIN**, a town of Scotland, about five miles north of Stirling.

**DUMBNESS**, the privation of the faculty of speech. The most general, or rather the sole cause of dumbness, is the want of the sense of hearing. The use of language is originally acquired by imitating articulate sounds. From this source of intelligence, deaf people are intirely excluded: they cannot acquire articulate sounds by the ear: unless, therefore, articulation be communicated to them by some other medium, these unhappy people must forever be deprived of the use of language; and as language is the principal source of knowledge, whoever has the misfortune to want the sense of hearing, must remain in a state little superior to that of the brute creation. Deafness has in all ages been considered as such a total obstruction to speech, or written language, that an attempt to teach the deaf to speak or read has been uniformly regarded as impracticable, till Dr Wallis and some others have of late shewn, that although deaf people cannot learn to speak or read by the direction of the ear, there are other sources of imitation, by which the same effect may be produced. The organs of hearing and of speech have little or no connection. Persons deprived of the former generally possess the latter in such perfection, that nothing further is necessary, in order to make them articulate, than to teach them how to use these organs. This indeed is no easy task; but experience shews that it is practicable. Mr THOMAS BRAIDWOOD, of Edinburgh, is perhaps the first who ever brought this surprising art to any degree of perfection. For these some years past, he has taught many people born deaf, to speak distinctly, to read, to write, to understand figures, the principles of religion and morality, &c. This, at first sight, may appear to be altogether incredible; but the fact is certain. Mr Braidwood has, at present, ten or a dozen of deaf pupils, some of them above twenty years of age, all making a rapid and amazing progress in those useful branches of education.

Mr Braidwood's principal difficulty, after he had discovered this art, was to make people believe in the practicability of it. He advertised in the public papers; he exhibited his pupils to many noblemen and gentlemen; till he found the generality of mankind unwilling to believe him. A remarkable instance of this incredulity occurred some years ago. A gentleman in England sent a deaf girl of his to Mr Braidwood's care. A year or two afterwards, Mr Braidwood wrote to the father, that his daughter could speak, read, and write distinctly. The father returned an answer, begging Mr Braidwood's excuse, as he could not believe it; however, he desired a friend of his, who was oc-

casionally going to Edinburgh, to call at Mr Braidwood, and inquire into the truth of what he had wrote him: he did so; conversed with Mr Braidwood, saw the young lady, heard her read, speak, and answer any questions he put to her. On his return, he told the father the surprising progress his child had made; but still the father thought the whole an imposition: the girl herself wrote to her father, but he looked upon the letter as a forgery. About this time the father died, and the mother sent an uncle and cousin of the deaf lady's from Shrewsbury, in order to be satisfied of the truth. When they arrived, Mr Braidwood told the girl her uncle and cousin were in the parlour, and desired her to go and ask them how they did, and how her mother and other friends did. The friends were astonished, and could hardly credit their own ears and eyes.

We have conversed with Mr Braidwood, concerning the nature and method of teaching this wonderful art: he seems to be very desirous of communicating and transmitting his discovery to posterity: but says, and, from the nature of the thing, we believe it to be true, that he cannot communicate it so fully in writing as to enable any other person to teach it. The first thing in the method is, to teach the pupil to pronounce the simple sounds of the vowels and consonants. We have even seen him performing this operation; but are unable to give a clear idea of it. He pronounces the sound of *a* slowly, pointing out the figure of the letter at the same time; makes his pupil observe the motion of his mouth and throat; he then puts his finger into the pupil's mouth, depresses or elevates the tongue, and makes him keep the parts in that position; then he lays hold of the outside of the wind-pipe, and gives it some kind of squeeze, which it is impossible to describe: all the while he is pronouncing *a*, the pupil is anxiously imitating him, but at first seems not to understand what he would have him to do. In this manner he proceeds, till the pupil has learned to pronounce the sounds of the letters. He goes on in the same manner to join a vowel and a consonant, till at length the pupil is enabled both to speak and read.

It is altogether in vain for us to attempt to say any more concerning the mode of operation. Mr Braidwood undertakes every deaf person, who is not at the same time foolish or idiotical. The greatest misfortune is, that this art is confined to a single man, and that his pupils must live in the house with him for some years. The expence necessarily attending education of this kind, excludes all but people in opulent circumstances from deriving any advantage from it. Mr Braidwood says, that the only way for preserving the art, and communicating it to a number, is to take people in the way of apprentices: this he is unable to do at his own expence. What a pity, that such a curious and useful art should live and die with a single man! There are many sums mortified in this kingdom, both by government and private persons, for less important purposes, than the preservation and ex-

tenion of the art of raising a great number of our fellow-creatures from the rank of brutes, to that of reasonable beings, and useful members of society.

**DUMFERMLINE**, a parliament-town of Scotland, situated in the county of Fife, fifteen miles north-west of Edinburgh: W. long.  $30^{\circ} 20'$ , and N. lat.  $56^{\circ} 15'$ . Here was formerly a magnificent abbey and palace of the kings of Scotland, in which the princess Elizabeth, daughter of king James VI. and mother of the princess Sophia, from whom the present royal family are descended, was born.

**DUMFRIES**, the capital of a county of the same name, in Scotland, lying northwards of the Solway frith: W. long.  $3^{\circ} 20'$ , and N. lat.  $54^{\circ} 45'$ .

**DUNBAR**, a parliament and port-town of Scotland, about twenty-five miles east of Edinburgh.

**DUNBARTON**, the capital of a county of the same name in Scotland, called by some Lenox: it is a parliament town, situated at the confluence of the rivers Clyde and Leven; sixteen miles north-west of Glasgow.

**DUNCANNON**, a town of the county of Wexford, in Ireland, six miles east of Waterford.

**DUNDALK**, a port-town of Ireland, eighteen miles north of Drogheda.

**DUNDEE**, a large parliament-town of Angus, in Scotland, situated on the north side of the frith of Tay, fourteen miles north-west of St Andrews: W. lon.  $2^{\circ} 42'$ , and N. lat.  $56^{\circ} 32'$ .

**DUNG**, in husbandry, is of several sorts, as that of horses, cows, sheep, hogs, pigeons, geese, hens, &c. See **AGRICULTURE**.

**DUNGANNON**, a town of Ireland, eleven miles north of Armaugh.

**DUNGING** of lands. See **AGRICULTURE**.

**DUNKELD**, a town of Perthshire in Scotland, formerly a bishop's see, situated about twelve miles north of Perth.

**DUNG MEERS**, in husbandry, places where soils and dungs are mixed and digested together. For this purpose it is usual to dig a pit sufficient to hold the stock of soil the husbandman is capable of making; and to prepare it at the bottom with stone and clay, that it may hold water, or the moisture of the dung; and besides, it should be so situated that the sinks and drips of the houses and barns may run into it. Into this pit they cast refuse fodder, litter, dung, weeds, &c. where they lie and rot together, till the farmer have occasion for it.

**DUNKIRK**, a port-town of the French Netherlands: E. lon.  $2^{\circ} 28'$ , and N. lat.  $51^{\circ}$ .

**DUNNEGAL**, the capital of a county of the same name in Ireland, situated on a bay, to which it likewise gives name: W. lon.  $8^{\circ} 22'$ , and N. lat.  $54^{\circ} 35'$ .

**DUNNINGTON**, a market-town of Lincolnshire, about twenty-three miles south-east of Lincoln.

**DUNS**, a market-town of Scotland, twelve miles west of Berwick upon Tweed.

**DUNSTABLE**, a market-town, fifteen miles south of Bedford, and thirty north-west of London.

DUN-

**DUNWICH**, a borough of Suffolk, forty miles east of Bury. It sends two members to parliament.

**DUO**, in music, a song or composition to be performed in two parts only, one sung, the other played on an instrument, or by two voices.

**Duo** is also when two voices sing different parts, as accompanied with a third, which is a thorough base. It is seldom that unisons and octaves are used in duos, except at the beginning and end.

**DUODECIMA**, in music, is the twelfth or the fifth doubled. See **FIFTH**.

**DUODENUM**, in anatomy. See Vol. I. p. 259.

**DUPLE**, among mathematicians, denotes the ratio of 2 to 1. Thus the ratio of 8 to 4 is duple, or as 2 to 1.

**Sub-DUPLE RATIO** is just the reverse of the former, or as 1 to 2. Such is 4 to 8, or 6 to 12.

**DUPLICATE**, among lawyers, denotes a copy of any deed, writing, or account. It is also used for the second letters patent, granted by the lord chancellor in a case wherein he had before done the same. Also a second letter written and sent to the same party and purpose as a former, for fear of the first's miscarrying, is called a duplicate.

**DUPLICATE PROPORTION, OR RATIO**. See **ALGEBRA** and **ARITHMETIC**.

**DUPLICATION**, in general, signifies the doubling of any thing, or multiplying of it by 2: also the folding of any thing back again on itself.

**DUPLICATURE**, among anatomists, a term used to denote the folds of any membrane, or vessel: thus we say, the duplicatures of the intestines, peritonæum, &c.

**DUPONDUS**, in antiquity, the weight of two pounds: also a piece of money equal to two as in value.

**DURA MATER**, in anatomy. See Vol. I. p. 284.

**DURANCE**, a river of France, which falls into the Rhone, a little below Avignon.

**DURANTA**, in botany, a genus of the didynamia angiospermia class. The calix is above the fruit, and divided into five segments; and the berry contains four seeds. There are two species, both natives of America.

**DURATION**, an idea which we get by attending to the fleeting and perpetually perishing part of succession; the idea of succession being acquired by reflecting on that train of ideas which constantly follow one another in our minds, as long as we are awake. The simple modes of duration are any different lengths of it whereof we have distinct ideas, as hours, days, years, time, eternity, &c.

**DURATION**, as marked by certain periods and measures, is what we most properly call time. See **TIME**.

**DURATION of action**, according to Aristotle, is confined to a natural day in tragedy; but the epopee, according to the same critic, has no fixed time.

**DURESSE**, in law, is where a person is wrongfully imprisoned, or restrained of his liberty, contrary to law; or is threatened to be killed, wounded,

or beaten, till he executes a bond, or other writing.

**DURHAM**, a city and county, in the north of England, situated on the river Wère, fourteen miles south of Newcastle: W. lon.  $1^{\circ} 12'$ , and N. lat.  $54^{\circ} 50'$ . It is the see of a bishop, and sends two members to parliament.

**DUSSELDORP**, a city of Germany, situated on the eastern shore of the Rhine, twenty miles north of Cologne: E. lon.  $6^{\circ} 20'$ , and N. lat.  $51^{\circ} 15'$ .

**DUTCHY**, in geography, an appellation given to the dominions of a duke.

**DUTCHY-COURT**, a court of the dutchy chamber of Lancaster, held at Westminster, before the chancellor of the same, for matters concerning the lands and franchises of that dutchy.

**DUTY**, in general, denotes any thing that one is obliged to perform.

**DUTY**, in polity and commerce, signifies the impost laid on merchandizes, at importation or exportation, commonly called the duties of customs; also the taxes of excise, stamp-duties, &c. See **CUSTOMS**, **EXCISE**, &c.

The principles on which all duties and customs should be laid on foreign merchandizes, which are imported into these kingdoms, are such as tend to cement a mutual friendship and traffic between one nation and another; and therefore due care should be taken in the laying of them, that they may answer so good an end, and be reciprocal in both countries: they should be so laid as to make the exports of this nation at least equal to our imports from those nations wherewith we trade, so that a balance in money should not be issued out of Great Britain, to pay for the goods and merchandizes of other countries: to the end that no greater number of our landholders and manufacturers should be deprived of their revenues arising from the product of the lands, and the labour of the people, by foreign importations, than are maintained by exportations to such countries. These are the national principles on which all our treaties of commerce with other countries are to be grounded.

**DUTY**, in the military art, is the exercise of those functions that belong to a soldier; with this distinction, that mounting guards and the like, where there is no enemy directly to be engaged, is called duty; but their marching to meet and fight an enemy is called going on service.

**DUUMVIRATE**, the office or dignity of the duumviri. See the next article.

The duumvirate lasted till the year of Rome 399, when it was changed into a decemvirate.

**DUUMVIRI**, in Roman antiquity, a general appellation given to magistrates, commissioners, and officers, where two were joined together in the same functions.

**DUUMVIRI CAPITALIS** were the judges in criminal causes: from their sentence it was lawful to appeal to the people, who only had the power of condemning a citizen to death. These judges were taken from the body of

of the decuriones; they had great power and authority, were members of the public council, and had two lictors to walk before them.

**DUUMVIRI MUNICIPALES**, were two magistrates in some cities of the empire, answering to what the consuls were at Rome: they were chosen out of the body of the decuriones; their office lasted commonly five years, upon which account they were frequently termed *quinquinales magistratus*. Their jurisdiction was of great extent: they had officers walking before them, carrying a small switch in their hands; and some of them assumed the privilege of having lictors, carrying axes and the fasces, or bundles of rods, before them.

**DUUMVIRI NAVALES** were the commissaries of the fleet, first created at the request of M. Decius, tribune of the people, in the time of the war with the Samnites. The duty of their office consisted in giving orders for the fitting of ships, and giving their commissions to the marine officers, &c.

**DUUMVIRI SACRORUM** were magistrates created by Tarquinius Superbus, for the performance of the sacrifice, and keeping of the sybils books. They were chosen from among the patricians, and held their office for life: they were exempted from serving in the wars, and from the offices imposed on the other citizens, and without them the oracles of the sybils could not be consulted.

**DUYVELAND**, or **DIVELAND**, one of the islands of Zealand, in the United Provinces, lying eastward of Schonen, from which it is only separated by a narrow channel.

**DWAL**, in heraldry, the herb nightshade used by such as blazon with flowers and herbs, instead of metals and colours, for sable or black.

**DWARF**, in general, an appellation given to things greatly inferior in size to that which is usual in their several kinds: thus there are dwarfs of the human species, dwarf-dogs, dwarf-trees, &c.

The Romans were so passionately fond of dwarfs, that they often used artificial methods to prevent the growth of boys designed for dwarfs, by inclosing them in boxes, or by the use of tight bandages. In Italy, even at present, they wash young puppies every day with astringent liquors, in order to prevent their growth by hardening the parts.

**DWINA**, the name of two large rivers, one of which rises in Lithuania, and, dividing Livonia from Courland, falls into the Baltic sea a little below Riga: the other gives name to the province of Dwina, in Russia, discharging itself into the White sea, a little below Archangel.

**DYE**, in architecture, any square body, as the trunk or notched part of a pedestal: or it is the middle of the pedestal, or that part included between the base and the cornice, so called because it is often made in the form of a cube or dye. See **ARCHITECTURE**.

**DYER**, a person who professes the art of dyeing all manner of colours. See **DYEING**.

**DYER'S WEED**, in botany. See **RESEDA**.

**DYEING**, the art of giving a lasting colour to silks,

cloths, and other substances, whereby their beauty is much improved, and value enhanced.

This art depends chiefly on three things, *viz.* 1. Disposing the surface of the stuffs to receive and retain the colours; which is performed by washing them in different lyes, digesting, beating them, &c. in which human urine putrified, a sharp salt of ashes, divers soaps, and galls of animals, are of principal use; by means whereof the viscous gluten of the silk-worms naturally adhering to their threads, is washed and cleansed from them, and thus they become fitted gradually to imbibe the colours. By these also the greasy foulness adhering to wool and flax is scoured off.

2. To grind the colours, as that they may enter the body duly prepared, and preserve their brightness undiminished.

3. The third consists in having beautiful colours.

According to Sir W. Petty's account of what is done in particular trades by the art of dyeing, 1. There is a whitening of wax, and several sorts of linen and cotton cloths, by the sun, air, and reciprocal effusions of water. 2. Colouring of wood and leather, by lime, salt and liquors, as in stoves, canes, and marble leathers. 3. Colouring of paper, *viz.* the marbled paper, by distempering the colours with ox-gall, and applying them upon a stiff gummed liquor. 4. Colouring, or rather discolouring, the colours of silks, tiffanies, &c. by brimstone. 5. Colouring of several iron and copper-works into black with oil. 6. Colouring of leather into gold-colour, or rather silver-leaves into gold by varnishes, and in other cases by urine and sulphur. 7. Dyeing of marble and alabaster, with heat and coloured oils. 8. Colouring silver into the brass-colour, with brimstone or urine. 9. Colouring the barrels and locks of guns into blue and purple, with the temper of small-coal heat. 10. Colouring of glass (made of sands, flints, &c.) as also of crystals and earthen ware, with the rufts and solutions of metals. 11. The colouring of live hair, as in Poland, horse and man's hair: as also the colouring of furs. 12. Enameling and annealing. 13. Applying colours, as in the printing of books and pictures, and as in making of playing cards, being each of them performed in a different way. 14. Gilding and tinning with mercury, block-tin, sal armoniac. 15. Colouring of metals, as copper with calamy, into brass, and with zinc or spelter into a golden colour, or into a silver one with arsenic; and of iron into a resemblance of copper with Hungarian vitriol. 16. Making painters colours by preparing of earth, chalk, and slates; as in umber, ochre, cullen-earth, &c. as also out of calces of lead, as ceruse and minium; by sublimates of mercury and brimstone, as in vermilion; by tinging whole earths variously, as in verdeter, and some of the lakes; by concrete juices, or sæculæ, as in gambogium, indigo, pinks, sap-green, and lakes; as also by rufts, as in verdigrease, &c. 17. The applying these colours by the adhesion of ox-gall, as in the marbled paper aforesaid; or by gum-water, as by limning; or by clammy drying oils, such as the oils of lintseed, nuts, &c. 18. The watering of tabbies. 19. The colouring of wool, linen, cotton, silk, hair, feathers, horn, leather, and the threads

threads and webs of them with woods, roots, herbs, seeds, leaves, salts, limes, lixiviums, waters, heats, fermentations, macerations, and other great variety of management: an account of all which is a short history of dyeing.

*The materials used in the art of DYEING*, are iron and steel, or what is produced from them in all true blacks, called Spanish blacks, though not in Flanders blacks, *viz.* they use copperas, steel-slings, and slippe; they also use pewter for Bow-dye scarlet, *viz.* they dissolve bars of pewter in aquafortis; litharge is also used by some, though acknowledged by few to add weight to dyed silk. Antimony is much used to the same purpose. Arsenic is used in crimson upon pretence of giving lustre, although those who pretend not to be wanting in giving lustre to their silks disown its use. Verdigreale is also used by linen-dyers in their yellow and greenish colours; though, of itself, it strikes no deeper colour than that of a pale straw. Of mineral salts used in dyeing, the chief is alum; the true use whereof seems to be in regard to the fixation of colours. The next mineral salt is saltpetre, not used by ancient dyers, and but by few of the modern: nor is it yet used but to brighten colours, by back-boiling of them, for which argol is more commonly used: lime is much used in working blue vats.

Of the animal tribes are used cochineal, urine of labouring men kept till it be stale and stinking, honey, yolks of eggs, and ox-gall; the use of the urine is to scour, and help the fermenting and heating of woad; and is used also in blue-vats instead of lime: it discharges the yellow, and therefore is used to spend woad withal.

Dyers use two sorts of water, *viz.* river and well-water; the last, which is harsh, they use in reds and other colours wanting restraining, and in dyeing materials of the flacker contextures, as in callicoe, fustian, and the several species of cotton-works; but is not good for blues, and makes yellows and greens look rusty. River-water is more fat and oily, and is therefore used in most cases, and must be had in great quantities for washing and rinsing their cloths after dyeing. Water is called by dyers white liquor; but a mixture of one part bran, and five of river-water, boiled an hour and put into leaden cisterns to settle, is what they call liquor absolutely.

Gums have been used by dyers about silk, *viz.* gum arabic, tragacanth, mastic, dragon's blood. These tend little to the tincture, any more than gum in writing-ink, which only gives it a consistence; so gum may give the silk a glossiness; and, lastly, to increase the weight.

The three peculiar ingredients for black are copperas, slings of steel, and slippe: the restraining binding materials are alder-bark, pomegranate-peels, walnut-rinds and roots, oaken-sapling bark, and saw-dust of the same, crab-tree bark, galls, and sumac.

The salts are alum, salt-petre, sal armoniac, pot-ashes, and stone-lime; among which urine may be enumerated as a liquid salt.

The liquors are well and river water, urine, aquavi-

VOL. II. N<sup>o</sup> 45.

2

tz, vinegar, lemon juice, aquafortis, honey, and molasses.

Ingredients of another class are bran, wheaten-flour, yokes of eggs, leaven, cummin seed, fenugreek seed, agaric, and fenna.

The snectics, or absterfives, are fuller's earth, soap, linseed-oil, and ox-gall.

The metals and minerals are pewter, verdigreale, antimony, litharge, and arsenic.

The colourings are of three sorts, *viz.* blue, yellow, and red; of which logwood, old fustic, indigo, and madder, are the chief.

#### *General observations upon DYEING.*

1. All materials which of themselves do give colour are either red, yellow, or blue; so that out of them, and the primitive fundamental colour white, all that great variety which we see in dyed stuffs doth arise.

2. That few of the colouring materials, as cochineal, foot, wood-wax, woad, &c. are in their outward and first appearance of the same colour, which by the slightest distempers and solutions in the weakest menstrua, they dye upon cloth, silk, &c.

3. That many of them will not yield their colours without much grinding, steeping, boiling and fermenting, or corrosion by powerful menstrua, as redwood, weld, woad, arnotto, &c.

4. That many of them will of themselves give no colouring at all, as copperas or galls, or with much disadvantage, unless the cloth or other stuff to be dyed be as it were first covered, or incrustated with some other matter, though colourless beforehand, as madder, weld, brazil, with alum.

5. That some of them, by the help of other colourless ingredients, do strike different colours from what they would of themselves, as cochineal, brazil, &c.

6. That some colours, as madder, indigo, and woad, by reiterated tinctures, will at last become black.

7. That although green be the most frequent and the most common of natural colours, yet there is no simple ingredient now used alone to dye green with upon any material; sap-green being the nearest, which is used by country people.

8. There is no black thing in use which dyes black, though both the coal and foot of most things burnt or scorched be of that colour, and the blacker, by how much the matter before being burnt was whiter, as in ivory black.

9. The tincture of some dyeing stuffs will fade even with lying, or with the air, or will stain with water only, but very much with urine, vinegar, &c.

10. Some of the dyeing materials are used to bind and strengthen a colour; some to brighten it; some to give lustre to the stuff; some to discharge and take off the colour, either in whole or in part; and some out of fraud, to made the material dyed, if costly, heavier.

11. That some dyeing ingredients, or drugs, by the coarseness of their bodies, make the thread of the dyed stuff seem coarser; and some, by shrinking them, smaller; and some, by smoothing them, finer.

†

4 Z

12.

12. Many of the same colours are dyed upon several stuffs with several materials, as red-wood is used in cloth, not in silks; arnetto in silks, not in cloth, and may be dyed at several prices.

13. That scouring and washing of stuffs to be dyed, is done with special materials, as sometimes with ox-galls, sometimes with fullers-earth, and sometimes soap; this latter being, in some cases, pernicious, where pot-ashes will stain, or alter the colour.

14. Where great quantities of stuffs are to be dyed together, or where they are to be done with any speed, and where the pieces are very long, broad, thick, or otherwise, they are to be differently handled, both in respect to the vessels and ingredients.

15. In some colours and stuffs the tingent liquor must be boiling, in other cases blood-warm, and in some it may be cold.

16. Some tingent liquors are fitted for use by long keeping, and in some the virtues wear away by the keeping.

17. Some colours or stuffs are best dyed by reiterated dippings in the same liquor, some by continuing longer, and others a lesser time therein.

18. In some cases, the matter of the vessel wherein the liquors are heated, and the tincture prepared, must be regarded, as the kettles must be pewter for Bow-dye.

19. There is little reckoning made how much liquor is used in proportion to the dyeing drugs, it being rather adjusted to the bulk of the stuffs, as the vessels are to their breadth; the quantity of dyeing drugs being proportioned both to the colour, higher or lower, and to the stuffs; as likewise the salts are to the dyeing drugs. Concerning the weight that colours give to silk, (in which it is most taken notice of, being sold by weight, and a commodity of great price) it is observed, that one pound of raw silk loseth four ounces by washing out the gums and the natural fordes; that the same scoured silk may be raised to above thirty ounces from the remaining twelve, if it be dyed black with some materials.

Of a thing very useful in dyeing, especially of black, nothing increases weight so much as galls, by which black silks are restored to as much weight as they lost by washing out their gum: nor is it counted extraordinary that blacks should gain about four or six ounces in the dyeing upon each pound. Next to the galls, old fustic increases the weight about  $1\frac{1}{2}$  in 12; madder, about one ounce; weld, half an ounce. The blue vars in deep blues of the fifth stall, give no considerable weight; neither doth logwood, cochineal, nor even copperas, where galls are not: slippe adds much to the weight, and giveth a deeper black than copperas itself, which is a good excuse for the dyers that use it.

#### *DYEING of wooll and woollen manufactures.*

For black in woollen manufactures, it is begun with a strong decoction of woad and indigo, that communicate a deep blue; after which the stuffs being boiled with alum and tartar, or pot-ash, are to be

maddered with common madder, then dyed black with Aleppo galls, copperas, and sumac, and finished by back-boiling in weld. Woolis for tapettry are only to be woaded, and then put in black. For scarlet, woad and woollen manufactures are dyed with kermes and cochineal, with which may also be used agaric and arsenic. Crimson scarlet is dyed with cochineal, mastic, aquafortis, sal armoniac, sublimat, and spirit of wine. Violet scarlet, purple, amaranth, and pansy-scarlets, are given with woad, cochineal, indigo, braziletto, brazil, and orchal. Common reds are given with pure madder, without any other ingredient. Crimson reds, carnations, flame and peach-colours, are given, according to their several hues, with cochineal, mastic, without madder, or the like. Crimson red is prepared with Roman alum, with cochineal. Orange aurora, brick-colour, and onion-peel colour, are dyed with woad and madder, mixed according to their several shades. For blues, the dark are dyed with a strong tincture of woad; the brighter with the same liquor, as it weakens in working. Dark browns, minims, and tan colours, are given with woad, weaker in decoction than for black, with alum and pot-ashes, after which they are maddered higher than black: for tan-colours, a little cochineal is added. Pearl-colours are given with galls and copperas; some are begun with walnut-tree roots, and finished with the former; though to make them more useful, they generally dip them in a weak tincture of cochineal. Greens are begun with woad, and finished with weld. Pale-yellows, lemon-colour, and sulphur colour, are given with weld alone. Olive colours of all degrees are first put in green, and taken down with foot, more or less, according to the shade that is required. Feulemott, hair-colour, musk, and cinnamon colour, are dyed with weld and madder. Nacaret, or bright orange, is given with weld and goats-hair boiled with pot-ashes.

*DYEING of silks*, is begun by boiling them in soap, &c. then scouring and washing them in water, and steeping them in cold alum-water. For crimson, they are scoured a second time, before they are put into the cochineal-vat. Red crimson is given with pure cochineal, mastic, adding galls, turmeric, arsenic, and tartar, all mixed in a copper of fair water, almost boiling: with these the silk is to be boiled an hour and a half, after which it is allowed to stand in the liquor till next day. Violet crimson is given with pure cochineal, arsenic, tartar, and galls; but the galls in less proportion than in the former: when taken out, it is washed and put in a vat of indigo. Cinnamon crimson is begun like the violet, but finished by back-boiling; if too bright, with copperas; and if dark, with a dip of indigo. Light blues are given in a bath of indigo. Sky-blues are begun with orchal, and finished with indigo. For citron colours, the silk is first alumed, then welded with indigo. Pale yellows, after aluming, are dyed in weld alone. Pale and brown aurora's, after aluming are welded strongly, then taken down with rocou and dissolved with pot-ashes. Flame-colour is begun with rocou, then alumed, and afterwards dipped

ped in a vat or two of brazil. Carnation and rose colours are first alumed, then dipt in brazil. Cinnamon colour, after aluming, is dipt in brazil and braziletto. Lead colour is given with fustic, or with weld, braziletto, galls and copperas. Black silks of the coarser sort, are begun by scouring them with soap, as for other colours; after which they are washed out, wrung, and boiled an hour in old galls, where they are suffered to stand a day or two: then they are washed again with fair water, wrung, and put into another vat of new galls: afterwards washed again, and wrung, and finished in a vat of black. Fine black silks are only put once into galls of the new and fine sort, that has only boiled an hour: then the silks are washed, wrung out, and dipped thrice in black, and afterwards taken down by back-boiling with soap.

The dyeing of thread is begun by scouring it in a lye of good ashes: afterwards it is wrung, rinsed out in river water, and wrung again. A bright blue is given with braziletto and indigo: bright green is first dyed blue, then back-boiled with braziletto and verdeter, and lastly woaded. A dark green is given like the former, only darkening more before woaded. Lemon and pale yellow is given with weld mixed with rocou. Orange isabella, with fustic, weld, and rocou. Red, both bright and dark, with flame-colour, &c. are given with brazil, either alone, or with a mixture of rocou. Violet, dry-rose, and amaranth, are given with brazil, taken down with indigo. Feulemort and olive colour are given with galls and copperas, taken down with weld, rocou, or fustic. Black is given with galls and copperas, taken down and finished with braziletto wood.

**DYNASTY**, among ancient historians, signifies a race or succession of kings of the same line or family: such were the dynasties of Egypt.

The Egyptians reckon thirty dynasties within the space of 36525 years; but the generality of chronologers look upon them as fabulous. And it is very certain, that these dynasties are not continually successive, but collateral.

**DYSCRACY**, among physicians denotes an ill habit or state of the humours, as in the scurvy, jaundice, &c.

**DYSENTERY**, in medicine, a diarrhoea or flux, wherein the stools are mixed with blood, and the bowels miserably tormented with gripes. See **MEDICINE**.

**DYSERT**, a parliament-town of Scotland, in the county of Fife, situated on the northern shore of the frith of Forth, about eleven miles north of Edinburgh.

**DYSOREXY**, among physicians, denotes a want of appetite, proceeding from a weakly stomach.

**DYSPEPSY**, a difficulty of digestion.

**DYSPNOEA**, a difficulty of breathing, usually called asthma.

**DYSURY**, in medicine, a difficulty of making urine, attended with a sensation of heat and pain. See **MEDICINE**.

**DYTISCUS**, **WATER-BEETLE**, in zoology, a genus of insects of the order of the coleoptera; the antennæ of which are slender and setaceous, and the hind feet are hairy, and formed for swimming. There are twenty-three species, distinguished by their antennæ, the colour of the elytra, &c.

**DYVOUR'S HABIT**, in Scots law, a party-coloured habit which fraudulent bankrupts, or bankrupts who have been dealers in illicit trades, are directed to wear, as a mark of ignominy, upon their being liberated from prison on a cessior bonorum. See **SCOTS LAW**, title 32.

## E

### E A G

**EAGLE**, in ornithology. See **FALCO**.

**EAGLE**, in heraldry, is accounted one of the most noble bearings in armoury, and, according to the learned in this science, ought to be given to none but such as greatly excel in the virtues of generosity and courage, or for having done singular services to their sovereigns; in which cases they may be allowed a whole eagle, or an eagle naissant, or only the head or other parts thereof, as may be most agreeable to their exploits.

**EAGLE**, in astronomy. Vol. I. p. 487.

**EAGLE-OWL**. See **BUBO**.

**EAGLE-STONE**. See **ÆTITES**.

**Black EAGLE**, an order of knighthood, instituted by the

### E A R

elector of Brandenburg, in 1701, on his being crowned king of Prussia.

The knights of this order wear an orange-coloured ribband suspending a black eagle.

**White EAGLE**, a like order in Poland, instituted in 1325, by Uladislaus V. on occasion of the marriage of his son Calimir to the daughter of the great duke of Lithuania.

The knights of this order wear a chain of gold, suspending a silver eagle crowned.

**EAGLET**, a diminutive of eagle, properly signifying a young eagle. In heraldry, when there are several eagles on the same escutcheon, they are termed eaglets.

**EAR**,

**EAR**, in anatomy. See Vol. I. p. 295.

**EAR-WIG**, in zoology. See **FORFICULA**.

**EARING**, in the sea language, is that part of the bolt-rope which at the four corners of the sail is left open, in the shape of a ring. The two uppermost parts are put over the ends of the yard-arms, and so the sail is made fast to the yard; and into the lowermost earings, the sheets and tacks are seized or bent at the clew.

**EARL**, a British title of nobility, next below a marquis, and above a viscount. Earls were anciently called *comites*, because they were wont *comitari regem*, to wait upon the king for council and advice. The Germans call them graves, as landgrave, margrave, palsgrave, rheingrave; the Saxons ealdormen, unless that title might be more properly applied to our dukes; the Danes, eolras; and the English, earls. The title, originally, died with the man. William the conqueror first made it hereditary, giving it in fee to his nobles, and allotting them for the support of their state the third penny out of the sheriff's court, issuing out of all pleas of the shire whence they had their title. But now the matter is quite otherwise; for whereas heretofore *comes* and *comitatus* were correlatives, and there was no *comes* or *earl* but had a county or shire for his earldom, of later years the number of earls increasing, and no more counties being left, divers have made choice of some eminent part of a county, as Lindsey, Holland, Cleveland, &c. some of a lesser part, as Stafford, &c. others have chosen for their title some eminent town, as Marlborough, Exeter, Bristol, &c. and some have taken for their title the name of a small village; their own seat or park, as Godolphin, Clarendon, &c. An earl is created by cincture of sword, mantle of state put upon him by the king himself, a cap and a coronet put upon his head, and a charter in his hand. All the earls of England are denominated from some shire, town or place, except three; two of whom, *viz.* earl Rivers, and earl Paulet, take their denomination from illustrious families: the third is not only honorary, as all the rest, but also officary, as the earl-marshal of England.

**EARL-marshal of England**, is a great officer who had anciently several courts under his jurisdiction, as the court of chivalry, and the court of honour. Under him is also the herald's office or college of arms. He hath some pre-eminence in the court of Marshalsea, where he may sit in judgment against those who offend within the verge of the king's court. This office is of great antiquity in England, and anciently of greater power than now; and has been for several ages hereditary in the most noble family of Howard.

**EARNEST**, in Scots law, a piece of money sometimes given by a buyer, in evidence that the sale or contract is completed. See tit. 22.

**EARTH**, a fossile, or terrestrial matter, whereof our globe partly consists. See Vol. I. p. 67.

**EARTH**, in astronomy and geography, one of the primary planets, being this terraqueous globe whereon we inhabit. See **ASTRONOMY** and **GEOGRAPHY**.

**EARTHQUAKE**, in natural history, a violent agitati-

on or trembling of some considerable part of the earth generally attended with a terrible noise like thunder, and sometimes with an eruption of fire, water, wind, &c. See **PNEUMATICS**.

**EASEL-PIECES**, a denomination given by painters to such pieces as are contained in frames, in contradistinction from those painted on cielings, &c.

**EASEMENT**, in law, a privilege or convenience which one neighbour has of another, whether by charter or prescription, without profit: such are a way through his lands, a sink, or the like. These, in many cases, may be claimed.

**EASING**, in the sea-language, signifies the slackening a rope, or the like: thus, to ease the bow-line or sheet, is to let them go slacker; to ease the helm, is to let the ship go more large, more before the wind, or more larboard.

**EASLOW**, a borough of Cornwall, twenty-two miles south of Launceston, which sends two members to parliament.

**EAST**, one of the four cardinal points of the world; being that point of the horizon, where the sun is seen to rise when in the equinoctial.

**EASTER**, a festival of the christian church, observed in memory of our Saviour's resurrection.

The Greeks call it *pascha*, the Latins *pascha*, an Hebrew word signifying *passage*, applied to the Jewish feast of the passover. It is called easter in the English, from the goddess Eostre, worshipped by the Saxons with peculiar ceremonies in the month of April.

The Asiatic churches kept their easter upon the very same day the Jews observed their passover; and others, on the first Sunday after the first full moon in the new year. This controversy was determined in the council of Nice, when it was ordained that easter should be kept upon one and the same day, which should always be a Sunday, in all christian Churches in the world. For the method of finding easter by calculation, see Vol. I. p. 492.

**EASTERN**, an appellation given to whatever relates to the east: thus we say, eastern amplitude, eastern church, &c.

**EATON**, a town of Buckinghamshire, situated on the north side of the Thames, opposite to Windsor, and famous for its collegial school, founded by king Henry VI. being a seminary for king's college Cambridge, the fellows of which are all from this school.

**EAVES**, in architecture, the margin or edge of the roof of an house; being the lowest tiles, slates, or the like, that hang over the walls, to throw off water to a distance from the wall.

**EBBING of the tides**. See Vol. I. p. 473.

**EBDOMARIUS**, in ecclesiastical writers, an officer formerly appointed weekly to superintend the performance of divine service in cathedrals, and prescribe the duties of each person attending in the choir, as to reading, singing, praying, &c.

**EBENUS**, the **EBONY-TREE**, in botany, a genus of the diadelphia decandria class. The calix has a number of small hairy teeth, as long as the corolla; the corolla

corolla has hardly any wings; and the pod is hairy, and contains but one seed. There is but one species, a native of Crete.

**EBIONITES**, in church-history, heretics of the first century, so called from their leader Ebion.

They held the same errors with the Nazarenes, united the ceremony of the Mosaic institution with the precepts of the gospel, observed both the Jewish sabbath and Christian Sunday, and in celebrating the eucharist made use of unleavened bread. They abstained from the flesh of animals, and even from milk. In relation to Jesus Christ, some of them held, that he was born like other men, of Joseph and Mary, and acquired sanctification only by his good works. Others of them allowed, that he was born of a virgin, but denied that he was the Word of God, or had any existence before his human generation. They said, he was indeed the only true Prophet; but yet a mere man, who, by his virtue, had arrived at being called Christ, and the Son of God. They also supposed, that Christ and the devil were two principles, which God had opposed to each other. Of the New Testament they only received the gospel of St Matthew, which they called the gospel according to the Hebrews.

**EBRO**, anciently **IBERUS**, a large river of Spain, which taking its rise in Old Castile, runs through Biscay and Arragon, passes by Saragosa, and, continuing its course through Catalonia, discharges itself with great rapidity into the Mediterranean, about twenty miles below the city of Tortosa.

**EBULLITION**. See **BOILING**.

**EBULUS**, in botany. See **SYMBUCUS**.

**ECBOLIUM**, in botany. See **ADHATODA**.

**ECCHYMOISIS**, in surgery, an extravasation of the blood from a vein in the arm betwixt the flesh and skin.

**ECCLESIASTES**, a canonical book of the Old Testament, the design of which is to shew the vanity of all sublunary things.

It was composed by Solomon, who enumerates the several objects on which men place their happiness, and then shews the insufficiency of all worldly enjoyments.

The Talmudists make king Hezekiah to be the author of it; Grotius ascribes it to Zorobabel, and others to Isaiah; but the generality of commentators believe this book to be the produce of Solomon's repentance, after having experienced all the follies and pleasures of life.

**ECCLESIASTICAL**, an appellation given to whatever belongs to the church: thus we say, ecclesiastical polity, jurisdiction, history, &c.

**ECCLESIASTICUS**, an apocryphal book, generally bound up with the scriptures, so called, from its being read in the church, *ecclesiis*, as a book of piety and instruction, but not of infallible authority.

The author of this book was a Jew, called Jesus the son of Sirach. The Greeks call it the wisdom of the son of Sirach.

**ECCOPE**, in surgery. See **AMPUTATION**.

**ECCOPROTICS**, in pharmacy. See **CATHARTICS**, and **EVACUANTS**.

VOL. II. No. 46.

2

**ECHAPE**, in the menage, a horse begot between a stallion and a mare of different breeds and countries.

**ECHAPER**, in the menage, a gallicism used in the academics, implying to give a horse head, or to put on at full speed.

**ECHENEIS**, in ichthyology, a genus belonging to the order of thoracici. The head is fat, naked, depressed, and marked with a number of transverse ridges: it has ten rays in the branchiostegic membrane; and the body is naked. There are two species, *viz.* 1. the remora, with a forked tail, and eighteen stripes on the head. It is found in the Indian ocean. 2. The pycrates, with an undivided tail, and twenty-four stripes on the head. It is likewise a native of the Indian ocean.

**ECHEVIN**, in the French and Dutch polity, a magistrate elected by the inhabitants of a city or town, to take care of their common concerns, and the decoration and cleanliness of the city.

At Paris, there is a prévôt, and four echevins; in other towns, a mayor and echevins. At Amsterdam, there are nine echevins; and, at Rotterdam, seven.

In France, the echevins take cognizance of rents, taxes, and the navigation of rivers, &c. In Holland, they judge of civil and criminal causes; and if the criminal confesses himself guilty, they can see their sentence executed without appeal.

**ECHINATE**, or **ECHINATED**, an appellation given to whatever is prickly, thereby resembling the hedgehog.

**ECHINITES**, in natural history, the name by which authors call the fossil centronia, frequently found in our chalk-pits. See **CENTRONIA**.

**ECHINOPHORA**, in botany, a genus of the pentandria digynia class. The fruit has sunk peduncles. There are two species, one of which, *viz.* the spinosa, or prickly samphire, is a native of Britain.

**ECHINOPS**, **GLOVE-TWISTLE**, in botany, a genus of the syngenesia polygamia segregata class. The proper calix is erect, imbricated, and contains but a single flower. There are three species, none of them natives of Britain.

**ECHINUS**, in zoology, a genus of insects belonging to the order of vermes mollusca. The body is roundish, covered with a bony crust, and often beset with moveable prickles; and the mouth is below, and consists of five valves. There are seventeen species, all natives of the sea.

**ECHINUS**, in architecture, a member or ornament near the bottom of the Ionic, Corinthian, and composite capitals.

**ECHIUM**, **VIPER'S BUGLOSS**, in botany, a genus of the pentandria monogynia class. The corolla is irregular, with a naked faux. There are seven species, three of which are natives of Britain, *viz.* the vulgare, or viper's bugloss; the anglicum, or English viper's bugloss; and the italicum, or wall-viper's bugloss.

**ECHIO**, a sound reverberated or reflected to the ear from some solid body. See **PNEUMATICS**.

**ECHO**, in architecture, a term applied to certain kinds

†

5 A

of

of vaults and arches, most commonly of elliptical and parabolical figures, used to redouble sounds, and produce artificial echos.

**ECHOMETER**, among musicians, a kind of scale or rule, with several lines thereon, serving to measure the duration and length of sounds, and to find their intervals and ratios.

**ECLECTICS**, ancient philosophers, who, without attaching themselves to any particular sect, selected whatever appeared to them the best and most rational, from each.

Potamon of Alexandria was the first of the eclectics: he lived in the reigns of Augustus and Tiberius; and being tired with the scepticism of the Pyrrhonians, he resolved upon a scheme that would allow him to believe something, but without being so implicit as to swallow any entire hypothesis.

**ECLECTOS**. See **LINCTUS**.

**ECLIPSE**, in astronomy, the deprivation of the light of the sun, or of some heavenly body, by the interposition of another heavenly body between our sight and it. See Vol. I. p. 476.

**ECLIPTIC**, in astronomy, a great circle of the sphere, supposed to be drawn through the middle of the zodiac, making an angle with the equinoctial of about  $23^{\circ} 30'$ , which is the sun's greatest declination; or, more strictly speaking, it is that path or way among the fixed stars, that the earth appears to describe to an eye placed in the sun. See **ASTRONOMY**, and **GEOGRAPHY**.

**ECLOGUE**, in poetry, a kind of pastoral composition, or a small elegant poem, in a natural simple style.

The models in this sort of poetry are Theocritus and Virgil.

**ECOUTER**, in the menage, a pace or motion of a horse, when he rides well upon the hands and the heels, is compactly put upon his haunches, and hears or listens to the heels or spurs, and continues duly balanced between the heels, without throwing to either side. This happens when a horse has a fine sense of the aids of the hand and heel.

**ECPHRACTICS**, in medicine, remedies which attenuate and remove obstructions. See **ATTENUANTS**, and **DEOBSTRUENTS**.

**ECPIESMA**, in surgery, a sort of fracture of the cranium, when the bones are much shattered, and, pressing inwardly, affect the membranes of the brain.

**ECPIESMA**, in pharmacy, signifies the mass remaining after the juices of vegetables have been pressed out: and, in this sense is the same as magma. It sometimes further imports the juice pressed out.

**ECPIESMUS**, in the ancient writers of medicine, a word used to express a distemperature of the eye, consisting in a very great prominence of the entire globe of the eye, which is, as it were, thrust out of its socket or orbit, by a great flux of humours, or an inflammation.

**ECTUCTICA**, in pharmacy. See **INCRASSANTS**.

**ECTHESIS**, in church-history, a confession of faith, in the form of an edict, published in the year 639, by the emperor Heraclius, with a view to pacify the troubles

occasioned by the Eutychian heresy in the eastern church. However, the same prince revoked it, on being informed that pope Severinus had condemned it, as favouring the Monothelites; declaring at the same time, that Sergius, patriarch of Constantinople, was the author of it.

**ECTHILIPSIS**, among Latin grammarians a figure of prosody whereby the *m* at the end of a word, when the following word begins with a vowel, is elided, or cut off, together with the vowel preceding it, for the sake of the measure of the verse: thus they read *mult' illz*, for *multum ille*.

**ECTROPIUM**, in surgery, is when the eye-lids are inverted, or retracted so as to shew their internal or red surface, and cannot sufficiently cover the eye.

**ECTYLOICS**, in pharmacy, remedies proper for consuming callosities.

**ECU**, or **ESCU**, a French crown, for the value of which, see **MONEY**.

**EDDISH**, or **EADISH**, the latter pasture, or grafs that comes after mowing or reaping; otherwise called *ca-grafs*, or *earfh*, and *etch*.

**EDDY TIDE**, or **EDDY WATER**, among seamen, is where the water runs back contrary to the tide; or that which hinders the free passage of the stream, and so causes it to return again.

**EDDY-WIND** is that which returns, or is beat back from a sail, mountain, or any thing that may hinder its passage.

**EDESSA**. See **ORFA**.

**EDICT**, in matters of polity, an order or instrument, signed and sealed by a prince, to serve as a law to his subjects. We find frequent mention of the edicts of the prætor, the ordinances of that officer in the Roman law. In the French law, the edicts are of several kinds: some importing a new law or regulation; others, the erection of new offices; establishments of duties, rents, &c. and sometimes articles of pacification. In France, edicts are much the same as a proclamation is with us; but with this difference, that the former have the authority of a law in themselves, from the power which issues them forth, whereas the latter are only declarations of a law, to which they refer, and have no power in themselves.

**EDINBURGH**, the capital city of the kingdom of Scotland, situated W. long.  $3^{\circ}$ , and N. lat.  $56^{\circ}$ .

We shall not spend time in fruitless inquiries into the antiquity of this city, or the etymology of its name; both of which seem to be fabulous and uncertain. It is conjectured by some to have owed its origin and name to Edwin king of Northumberland, about the year 600: is taken notice of by authors in the 854 as a small and inconsiderable village, and only about the middle of the 14th century as the capital of Scotland.

Edinburgh is situated upon a steep hill rising from east to west, and terminating in a high and inaccessible rock, upon which the castle stands. At the east end, or lower extremity of this hill, stands the abbey of Holyrood-house, or king's palace, distant from the castle upwards of a mile; and betwixt which, along the top of the ridge, and almost in a straight line, runs the high-street of Edinburgh. On each side, and parallel

parallel to this ridge or hill, is another ridge of ground lower than that in the middle, and which does not extend so far to the east; that on the south being intercepted by Salisbury-rocks, and Arthur's-seat, a hill of about 650 feet of perpendicular height; and that on the north by the Calton-hill, considerably lower than Arthur's-seat: so that the situation of this city is most singular and romantic; the east or lower part of the town lying between two high hills; and the west or higher part rising up towards a third hill, little inferior in height to the highest of the other two, upon which, as has been observed, the castle is built, and overlooks the town.

The buildings of the town terminate at the distance of about 200 yards from the castle-gate; which space affords a most delightful as well as convenient and healthful walk to the inhabitants. The prospect from this spot is perhaps the finest any where to be met with, for extent, beauty, and variety.

In the valley or hollow betwixt the mid and south ridge, and nearly parallel to the high-street, is another street called the Cowgate; and the town has now extended itself over most part of that south ridge also. Betwixt the mid and north ridge was a loch, which, till of very late, terminated the town on that side. From the high street towards the loch on the north, and Cowgate on the south, run narrow cross streets or lanes, called wynds and lasses, which grow steeper and steeper the farther west or nearer the castle; so that, were it not for the closeness and great height of the buildings, this city, from its situation and plan, might naturally be expected to be the best aired as well as the cleanliest in Europe. The first, notwithstanding these disadvantages, it enjoys in an eminent degree; but we cannot compliment it upon the latter, notwithstanding every possible means has been used by the magistrates for that purpose.

The steepness of the ascent makes the access to the high street from the north and south very difficult; and has no doubt greatly retarded the enlargement of this city. To remedy this inconvenience on the north, and with a view to extend the town on that quarter, a most elegant bridge is presently throwing over the north loch, which will join the north ridge to the middle of the high-street, by so easy an ascent as one in sixteen; and in pursuance of this design a plan of a new town to the north is fixed upon, and is actually carrying into execution with surprising rapidity, and with an elegance and taste that does honour to this country.

The principal public buildings in Edinburgh may be reduced to four *viz.* St Giles's church, the palace of Holyrood-house, Herriot's hospital, and the Royal Infirmary.—St Giles's church is the most ancient church in Edinburgh, in so much that it is not known when or by whom it was founded. It stands on the south-side of the high street, about a quarter of a mile below the castle. It is a very large, irregular, and heavy building, except the steeple, which rises with a square stalk from the middle of the structure, and terminates in the form of an imperial crown,

and is reckoned the finest in Britain for elegance and symmetry.

The abbey of Holyrood-house was erected by David I. *anno* 1128, in memory, as is said, of his deliverance from the horns of an enraged hart, by the interposition of heaven in the form of a cross. It was first made a royal palace by James V. about the year 1528, who built the north wing of the present front, which evidently appears older than the rest. It was completed in the present form by Charles II. in the year 1673; and is justly reckoned a most magnificent and elegant building.

Herriot's hospital was founded, July 1. 1628, by the magistrates of Edinburgh, in virtue of a donation of L. 43 608 : 11 : 5, bequeathed to them by George Herriot, goldsmith and jeweller to James VI. "for the maintenance, relief, bringing up, and education of so many poor fatherless boys, freemen's sons of the town of Edinburgh," as the above sum should be sufficient for. This hospital contains at present about a hundred and forty boys, who are well educated and taken care of. It has, notwithstanding the large sum laid out in building the house, a great annual revenue; which, as it consists mostly of lands, must always keep pace with the nominal value of money. This hospital is finely situated on the west end of the south ridge, almost opposite to the castle; and is perhaps the most magnificent building of that kind in Britain.

The Royal Infirmary was founded in August 1738, by the magistrates of Edinburgh, in virtue of a charter from the crown, for the reception of poor diseased persons; and by conduct in the management of its funds, which arose mostly from the public contributions, and were but very scanty, has proved an inestimable blessing to this country. This hospital stands near the east end of the south ridge; and is thought by some to be rather too magnificent, considering the purpose for which it is designed, and the narrowness of the original funds.

Edinburgh, as not being properly a sea-port town, has never been remarkable for trade. The chief advantages it enjoys arise from the supreme courts of justice, which are there held; and from its college, which has become famous over Europe, particularly for physic.

**EDITOR.** a person of learning, who has the care of an impression of any work, particularly that of an ancient author: thus Erasmus was a great editor; the Louvain doctors, Scaliger, Petavius, F. Sirmond, bishop Walton, Mr Hearn, Mr Ruddiman, &c. are likewise famous editors.

**EDUCATION.** the instructing children, and youth in general, in such branches of knowledge and polite exercises, as are suitable to their genius and station.

Education is a very extensive subject, that has employed the thoughts and pens of the greatest men: Locke, the archbishop of Cambray, Tanaquil Faber, M. Crousaz, Rollin, and Rousseau, may be consulted on this head.

The principal aim of parents should be, to know what sphere of life their children are designed to act in;

in; what education is really suitable to them; what will be the consequence of neglecting that; and what chance a superior education will give them, for their advancement in the world. Their chief study should be to give their children such a degree of knowledge, as will qualify them to fill some certain post or station in life: in short, to fit them for an employment suited to their condition and capacity, such as will make them happy in themselves and useful to society.

**EDULCORATION**, in chemistry, the separating, by a washing or solution in water, the salt that anybody may be impregnated with, or those that may be left adhering to a body after any operation. See **CHEMISTRY**.

**EEL**, in ichthyology, a species of *muræna*. See **MURÆNA**.

**EEL-SPEAR**, a forked instrument with three or four jagged teeth, used for catching of eels: that with the four teeth is best, which they strike into the mud at the bottom of the river, and if it strike against any eels it never fails to bring them up.

**EFFARE**, or **EFFRAYE**, in heraldry, a term applied to a beast rearing on its hind-legs, as if it were frightened or provoked.

**EFFECT**, in a general sense, is that which results from, or is produced by, any cause. See **CAUSE**.

**EFFECTS**, in commerce, law, &c. the goods possessed by any person, whether moveable or immoveable.

**EFFERDING**, a town of Upper Austria, about ten miles west of Linz.

**EFFERVESCENCE**, in a general sense, signifies a slight degree of ebullition in liquors exposed to a due degree of heat: but the chemists apply it to that intestine motion excited in various fluids, either by the mixture of fluids with others of a different nature; or by dropping salts or powders of various kinds into fluids. See **POWDERS**.

**EFFIGY**, the portrait, figure, or exact representation of a person.

**EFFLORESCENCE**, among physicians, the same with exanthema. See **EXANTHEMA**.

**EFFLUVIUM**, in physiology, a term much used by philosophers and physicians, to express the minute particles which exhale from most, if not all, terrestrial bodies in form of insensible vapours.

**EFFUSION**, in a general sense, the pouring out of any thing liquid, and that with some violence.

**EFT**, in zoology, the English name of the common lizard. See **LACERTUS**.

**EGERMOND**, a market-town of Cumberland, ten miles south of Cockermouth.

**EGG**, in physiology, a body formed in certain females, in which is contained an embryo, or fœtus of the same species, under a cortical surface or shell. The exterior part of an egg is the shell, which in a hen, for instance, is a white, thin, and friable cortex, including all the other parts. The shell becomes more brittle by being exposed to a dry heat. It is lined every where with a very thin but a pretty tough membrane, which dividing at, or very near, the obtuse end of the egg, forms a small bag, where only air is contain-

ed. In new laid eggs this folliculus appears very little, but becomes larger when the egg is kept.

Within this are contained the albumen or white, and the vitellus or yolk; each of which have their different virtues.

The albumen is a cold, viscous, white liquor in the egg, different in consistence in its different parts. It is observed, that there are two distinct albumens, each of which are inclosed in its proper membrane; of these, one is very thin and liquid, and the other more dense and viscous, and of a somewhat whiter colour; but, in old and stale eggs, after some days incubation, inclining to a yellow. As this second albumen covers the yolk on all sides, so it is itself surrounded by the other external liquid. The albumen of a fecundated egg, is as sweet and free from corruption, during all the time of incubation, as it is in new-laid eggs; as is also the vitellus. As the eggs of hens consist of two liquors separated one from another, and distinguished by two branches of umbilical veins, one of which goes to the vitellus, and the other to the albumen; so it is very probable that they are of different natures, and consequently appointed for different purposes.

When the vitellus grows warm with incubation, it becomes more humid, and like melting wax, or fat; whence it takes up more space; for as the fœtus increases, the albumen insensibly wastes away, and condenses: the vitellus, on the contrary, seems to lose little or nothing of its bulk when the fœtus is perfected, and only appears more liquid and humid when the abdomen of the fœtus begins to be formed.

The chick in the egg is first nourished by the albumen; and when this is consumed, by the vitellus, as with milk. If we compare the chalazæ to the extremities of an axis passing through the vitellus, which is of a spherical form, this sphere will be composed of two unequal portions, its axis not passing through its centre; consequently, since it is heavier than the white, its smaller portion must always be uppermost in all positions of the egg.

The yellowish white round spot, called cicatricula, is placed on the middle of the smaller portion of the yolk; and therefore, from what has been said in the last paragraph, must always appear on the superior part of the vitellus.

Not long before the exclusion of the chick, the whole yolk is taken into its abdomen; and the shell, at the obtuse end of the egg, frequently appears cracked some time before the exclusion of the chick. The chick is sometimes observed to perforate the shell with its beak. After exclusion, the yolk is gradually wasted, being conveyed into the small guts by a small duct.

Eggs differ very much according to the birds that lay them, according to their colour, form, bigness, age, and the different way of dressing them: those most used in food are hens eggs: of these, such as are new-laid are best.

As to the preservation of eggs, it is observed that the

the egg is always quite full when it is first laid by the hen, but from that time it gradually becomes less and less so, to its decay; and however compact and close its shell may appear, it is nevertheless perforated with a multitude of small holes, though too minute for the discernment of our eyes, the effect of which is a daily decrease of matter within the egg, from the time of its being laid; and the perspiration is much quicker in hot weather than in cold.

To preserve the egg fresh, there needs no more than to preserve it full, and stop its transpiration; the method of doing which is, by stopping up those pores with matter which is not soluble in watery fluids; and on this principle it is, that all kinds of varnish, prepared with spirit of wine, will preserve eggs fresh for a long time, if they are carefully rubbed all over the shell: tallow, or mutton fat, is also good for this purpose, for such as are rubbed over with this will keep as long as those coated over with varnish.

*Artificial method of hatching eggs.* See HATCHING.  
EGLANTINE, in botany. See ROSA.

EGRA, a city of Bohemia, situated on a river of the same name, about seventy-five miles west of Prague: E. long.  $12^{\circ} 22'$ , N. lat.  $50^{\circ} 10'$ .

EGYPT, an extensive country of Africa, lying between  $30^{\circ}$  and  $36^{\circ}$  of east longitude, and between  $21^{\circ}$  and  $31^{\circ}$  of north latitude; and bounded by the Mediterranean on the north; by the Red-sea and Isthmus of Suez, which divide it from Arabia, on the east; by Abyssinia or Ethiopia, on the south; and by the deserts of Barca and Nubia, on the west; being six hundred miles in length from north to south, and from one hundred to two hundred in breadth from east to west. Egypt is subject to the grand signior, and governed by a bashaw, or viceroy. It owes its fertility to the annual overflowing of the Nile, which it begins to do in the months of May and June, and is usually at its height in September, from which time the waters decrease till May or June again. By this supply of water, Egypt is rendered so fruitful, as to serve Constantinople and other places with corn, as it did Rome and Italy of old. They only harrow their grain into the mud, on the retiring of the water, and in March following usually have a plentiful harvest; and the lands, not sown, yield good crops of grass for the use of the cattle. According to Mr. Sandys, no country in the world is better furnished with grain, flesh, fish, sugar, fruits, melons, roots, and other garden stuff, than the lower Egypt.

EGYPTEN, a town of Courlapd, seventy miles south-east of Mittau.

EGYPTIANS, or GYPSIES, in Scots law, a band of robbers originally from Egypt, which infested Scotland about the end of the 16th century.

EJACULATOR, a muscle of the penis. See Vol. I. p. 170.

EICHTERNAC, a town of Luxemburg, seven miles north-west of Treves.

EJECTA, a term used, by lawyers, for a woman deflowered, or cast from the virtuous.

EJECTION, in the animal oeconomy, evacuation, or

the discharging any thing through some of the emunctories, as by stool, vomit, &c.

EJECTION, in Scots law, is the turning out the possessor of any heritable subject by force; and is either *legal* or *illegal*.—Legal ejection is where a person having no title to possess, is turned out by the authority of law: See REMOVING. Illegal ejection, is one person's violently turning another out of possession without lawful authority. See LAW, title 29.

EIENHOVEN, a town of Dutch Brabant, fifteen miles south of Boisleduc.

EIFIELD, or ELFIELD, a town of lower Saxony, six miles north-west of Mentz.

EIGHT, or PIECE OF EIGHT. See MONEY.

EIMBECK, a town of lower Saxony, belonging to the elector of Hanover, twenty-five miles south of Hildesheim.

EISLEBEA, a town of Upper Saxony, five miles east of Mansfield, remarkable for being the birth-place of Luther.

ELÆAGNUS, DUTCH MYRTLE, in botany, a genus of the tetrandria-monogynia class. It has no corolla; the calix is bell-shaped above the fruit, and has four segments; and the drupa is bell-shaped, and below the calix. There are three species, none of them natives of Britain.

ELÆOTHESIUM, in antiquity, the anointing room, or place where those who were to wrestle, or had bathed, anointed themselves. See GYMNASIUM.

ELAPHEBOLIUM, in Grecian antiquity, the ninth month of the Athenian year, answering to the latter part of February and beginning of March. It consisted of thirty days, and took its name from the festival elaphebolia, kept in this month, in honour of Diana the huntress; on which occasion, a cake made in the form of a deer, was offered to her.

ELASMIS, in natural history, a genus of tales, composed of small plates in form of spangles; and either single, and not farther fissile; or, if complex, only fissile to a certain degree, and that in somewhat thick lamina.

Of these tales there are several varieties, some with large and others with small spangles, which differ also in colour and other peculiarities.

ELASTIC, in natural philosophy, an appellation given to all bodies endowed with the property of elasticity. See the next article.

ELASTICITY, or ELASTIC FORCE, that property of bodies wherewith they restore themselves to their former figure, after any external pressure. See MECHANICS.

ELATER, in zoology, a genus of insects belonging to the order of coleoptera. The feelers are setaceous. There are 38 species, distinguished by their colour, &c.

ELATERIUM, in pharmacy, imports, in general, any purging medicine; but is particularly applied to those which operate with violence.

ELATINÉ, in botany, a genus of the octandria-tetragynia class. The calix consists of four leaves, and the corolla of four petals; the capsule has four cells and

four depressed valves. There are two species, one of which, *viz.* the *almustrum* or water-wort, is a native of Britain.

**ELBE**, a large river in Germany, which, rising on the confines of Silesia, runs through Bohemia, Saxony, and Brandenburg; and afterwards dividing the dutchy of Lunenburg from that of Mecklenburg, as also the dutchy of Bremen from Holstein, it falls into the German ocean, about seventy miles below Hamburg.

It is navigable for great ships higher than any river in Europe.

**ELBOW**, in anatomy, the juncture of the cubitus and radius; or the outer angle made by the flexure or bend of the arm. See **ANATOMY**.

**ELCESAITES**, in church-history, ancient heretics, who made their appearance in the reign of the emperor Trajan, and took their name from their leader Elcesai. The elcesaites kept a mean between the Jews, Christians, and Pagans; they worshipped but one God, observed the Jewish sabbath, circumcision, and the other ceremonies of the law. They rejected the pentateuch, and the prophets; nor had they more respect for the writings of the apostles, particularly those of St. Paul.

**ELDERS** or **SENIORS**, in Jewish history, were persons the most considerable for age, experience, and wisdom. Of this sort were the seventy men whom Moses associated to himself in the government of his people; such, likewise, afterwards were those who held the first rank in the synagogue, as presidents.

In the first assemblies of the primitive Christians, those who held the first place were called elders. The word presbyter, often used in the New Testament, is of the same signification: hence the first councils of Christians were called presbyteria, or councils of elders.

**ELDER** is also a denomination still preserved in the presbyterian discipline. See **PRESBYTERIAN**.

**ELDER**, or **ALDER**, in botany. See **ALNUS**.

**ELECAMPANE**, in botany. See **INULA**.

**ELECT**, among ecclesiastical writers, those whom God has chosen, or predestinated to be saved.

**ELECTION**, the choice that is made of a person, or thing, in preference of any other; as in the election of an emperor, of a pope, of a bishop, of members of parliament, &c.

**ELECTION**, in theology, signifies the choice which God makes of angels and men for the objects of his grace and mercy. See **GRACE**, and **PREDESTINATION**.

**ELECTOR**, a person who has a right to elect or chuse another to an office, honour, &c.

Electors are particularly, and by way of eminence, applied to those princes of Germany in whom lies the right of electing the emperor: being all sovereign princes, and the principal members of the empire.

The electoral college, consisting of all the electors of the empire, is the most illustrious and august body in Europe. Bellarmine and Baronius attribute the institution of it to pope Gregory V. and the emperor Otto III. in the tenth century; of which opinion are

the generality of historians, and particularly the canonists: however, the number of electors was unsettled, at least, till the thirteenth century. In 1356 Charles IV. by the golden bull, fixed the number of electors to seven; three ecclesiastics, *viz.* the archbishops of Mentz, Treves, and Cologne; and four seculars, *viz.* the king of Bohemia, count Palatine of the Rhine, duke of Saxony, and marquis of Brandenburg. In 1648 this order was changed, the duke of Bavaria being put in the place of the count Palatine, who having accepted the crown of Bohemia was outlawed by the emperor; but being at length restored, an eighth electorate was erected for the duke of Bavaria. In 1692, a ninth electorate was created, by the emperor Leopold, in favour of the duke of Hanover, of the house of Brunswick Lunenburg.

There is this difference between the secular and ecclesiastical electors, that the first have an active and passive voice, that is, may chuse and be chosen; the last, an active only. The three archbishops are to be thirty years old, before they can be advanced to the dignity; the seculars, eighteen, before they can perform the office themselves. These last have each their vicars, who officiate in their absence.

Besides the power of chusing an emperor, the electors have also that of capitulating with, and deposing him; so that, if there be one suffrage wanting, a protest may be entered against the proceedings. By the right of capitulation, they attribute to themselves great privileges, as making of war, coining, and taking care of the public interest and security of the states; and the emperor promises, upon oath, to receive the empire upon these conditions.

The electors have precedence of all other princes of the empire, even of cardinals and kings; and are addressed under the title of electoral highness.

Their several functions are as follow: the elector of Mentz is chancellor of Germany, convokes the states, and gives his vote before any of the rest. The elector of Cologne is grand chancellor of Italy, and consecrates the emperor. The elector of Treves is chancellor of the Gauls, and confers imposition of hands upon the emperor. The count Palatine of the Rhine is great treasurer of the empire, and presents the emperor with a globe at his coronation. The elector of Bavaria is great master of the imperial palace, and carries the golden apple. The marquis of Brandenburg is grand chamberlain, and puts the ring on the emperor's finger. The elector of Saxony is grand marshal, and gives the sword to the emperor. The king of Bohemia is grand butler, and puts Charlemaign's crown on the emperor's head. Lastly, the elector of Hanover, now king of Great Britain, is arch-treasurer, though first erected under the title of standard-bearer of the empire.

**ELECTORATE**, a term used as well to signify the dignity of, as the territories belonging to, any of the electors of Germany; such are Bavaria, Saxony, &c.

**ELEC-**

# E L E C T R I C I T Y.

**T**HE word ELECTRICITY signifies, in general, the effects of a very subtile fluid matter, different in its properties from every other fluid we are acquainted with. This fluid is capable of uniting with almost every body, but unites more readily with some particular bodies than with others: its motion is amazingly quick, is regulated by peculiar laws, and produces a vast variety of singular phenomena, the principal of which shall be enumerated in this article.

As we are entirely ignorant of the nature of the electrical fluid, it is impossible to define it but by its principal properties: that of repelling and attracting light bodies, is one of the most remarkable. The ancients were only acquainted with this property in amber. William Gilbert, a native of Colchester, and physician at London, in his treatise *De Magnete*, in the year 1600, was the first person who discovered, that sulphur, wax, resinous substances, glass, and precious stones, when dried and rubbed a little, were endowed with the same property of attracting and repelling straws and other light substances. Sir Francis Bacon, in his physiological remains, gives a catalogue of electrical bodies; but it differs in nothing worth mentioning from that of Gilbert. Mr Boyle, about the year 1670, made some addition to the catalogue of electric substances; but all his experiments on this subject relate only to a few circumstances attending the simple property of electric attraction: he had never seen the electric light, and little imagined what astonishing effects would be afterwards produced by this wonderful power.

Cotemporary with Mr Boyle was Otto Guericke, burgo-master of Magdeburg, and inventor of the air-pump, who was likewise one of the first improvers of electricity. He made his experiments with a globe of sulphur, which he mounted on an axis, and whirled it in a wooden frame, rubbing it at the same time with his hand. He first discovered, that a body once attracted by an excited electric was repelled by it, and not attracted again till it had been touched by some other body: that bodies immersed in electric atmospheres are themselves electrified: that threads suspended within a small distance of his excited globe, were often repelled by his finger brought near them: that a feather, repelled by the globe, always turned the same face towards it, like the moon with respect to the earth: and that the excitation of his globe produced both light and sound, though in a very inconsiderable degree. A much finer electric light was afterwards observed by Dr Wall, and an account of it was published in the Philosophical Transactions: Dr Wall likewise compares the light and the crackling of his excited amber to thunder and lightening.

Sir Isaac Newton, in 1675, was the first who discovered that excited glass attracted light bodies on the side opposite to that on which it was rubbed.

After Gilbert, Boyle, and Otto Guericke, Mr Hawke-

bee, in his Physico-mechanical Experiments, published in the year 1709, distinguished himself by his experiments and discoveries in electricity. He first discovered the electric power of glass, the light proceeding from it, and the noise occasioned by it, together with a variety of phenomena relating to electric attraction and repulsion: Indeed little was added to his observations, till the discovery of a plus and minus electricity by Dr Watson and Dr Franklin about the year 1746, and the farther illustration of that doctrine by Mr Canton.

From the year 1730 to the 1746, the writers on electricity are so numerous, and their experiments so many and various, that a volume would be insufficient for their history. We shall therefore endeavour, in the *first* place, To give a short and connected view of the nature and principles of electricity, so far as they have hitherto been unfolded, without mentioning the persons to whom we are indebted for any particular discovery: And, in the *second* place, Give a description of electrical machines; with a selection of a few of the most curious and useful experiments, which the reader may easily understand after having made himself acquainted with the general principles.

It has been asserted, that all bodies, provided they be heated to a certain degree, and rubbed for a long time, will discover themselves to be possessed of the property of attracting and repelling light substances. However, metals of all kinds, although ever so much heated, or rubbed, or polished, never discover the least signs of electrical attraction; and consequently are excepted from the general rule, as well as water and other fluids, which cannot be subjected to the necessary treatment. Although most bodies, by being heated and rubbed, discover more or less of electrical attraction; yet, as some of them possess this property in a more eminent degree, and with less labour, this circumstance has suggested a division of bodies into two classes, according as they are more or less susceptible of electricity.

The first class comprehends those bodies which receive and collect the electrical matter most easily, and in greatest quantity, after being a little rubbed and heated: these bodies are called *electrics*, or *non conductors*; such as,

1. Diamonds of all kinds; the ruby, the sapphire, the emerald, the opal, the amethyst, the topaz, the beryl, the garnet, rock crystal, &c.

2. Glass, and all vitrified bodies, enamels of all colours, porcelain, glass of antimony, of lead, &c.

3. Balsams, resins of all kinds, wax, &c.

4. Bituminous bodies, sulphur, amber, asphaltum, &c.

5. Certain animal productions; as silk, feathers, wool, hairs, and bristles, &c.

The second class comprehends these bodies which either do not at all collect the electrical matter by friction,

or

or in a very inconsiderable degree: such bodies are called *non-electrics*, or *conductors*, viz.

1. Water, and all aqueous and spirituous liquors, which are incapable of being thickened, and subjected to friction

2 All metals, perfect and imperfect, and the greatest part of minerals; as, the load-stone, antimony, zinc, bismuth, the agat, the jasper, marble, free-stone, slate, &c.

3. All living creatures, excepting their hair. To which may be added most animal-sustances; as leather, parchment, bone, ivory, horn, shells, &c.

4. Trees and plants of all kinds; thread, ropes, linen-cloth, paper, &c.

These two classes of bodies have been called by the name of *electrics* and *non-electrics*: but as the electrical matter is not contained in the electrical bodies themselves, but collected by them from the earth; and as non-electric allow the electrical matter to penetrate and flow through them, or to spread equally on their surfaces, the terms *conductor* and *non conductor* are more proper. Metals and water are the only perfect conductors; other bodies conducting only as they contain a mixture of these, without more or less of which they will not conduct at all.

Although conductors cannot be electrified by heat or friction, they may be charged with electricity, or made non-conductors, by an easy operation; but then they retain this property no longer than they are kept from communicating with other conductors. A bar of iron will become an electric or non-conductor, by being suspended by a silk cord, or laid upon a piece of rosin or other non-conductor, and at the same time having one end of it in contact with a well-rubbed glass tube, or globe. In the same manner, water and metals of all kinds may be charged with electricity.

It is absolutely necessary, in exciting electricity by friction, that the glass, or other body, be perfectly dry; the least moisture destroys, or at least diminishes the effect. A moist atmosphere, a burning candle, &c. are extremely unfavourable in making electrical experiments.

Hollow glass globes, of about a foot diameter, and the 16th part of an inch thick, are now used in place of tubes, because it lessens the labour of friction, and accumulates a greater quantity of electrical matter. This globe is turned rapidly by a large wheel like those used by the cutlers. When the globe is rubbed, it soon acquires a considerable degree of electrical virtue, which is discovered by light bodies, at the distance of two or three feet, flying towards it. In approaching the globe with the hand or face, you will likewise feel the electric matter surrounding it like a gentle breeze of wind. These subtle emanations continue to be diffused round the globe as long as the friction is continued; and, when the friction is stopped, they gradually diminish, till they are no longer perceptible. The application of non-conductors to the globe does not diminish the electrical matter: on the contrary, the application of conductors almost instantly annihilates the whole quantity previously collected by the friction. But this effect is not produced, unless when the

conductor at the same time has a communication with the floor or earth where the machine stands. For, as above observed, if the conductor has no communication with the earth, it charges with electricity, and becomes a non-conductor. But non-conductors, as a piece of glass, sulphur, or wax, though they do not diminish the virtue of the globe, yet they do not acquire, like iron, &c. the property of attraction or repulsion. Hence it appears, that the electrical matter passes freely along conductors, and dissipates in the earth; but, on the contrary, that non conductors do not receive any matter from the globe, and are incapable of transmitting it. The following experiments will make this more plain.

1. If a piece of iron be placed on a glass standard, and unconnected with any other body, as soon as the electrical matter is communicated to it, it attracts and repels pieces of gold leaf or other light bodies, and preserves this virtue even for some minutes after its communication with the globe is cut off. But, if a piece of glass, rosin, or any other non-conductor, be placed in the same circumstances, they do not discover any such effect.

2. If a person touches the piece of iron above mentioned with his hand, no friction is capable of making it attract or repel, or exhibit any marks of electricity. The same thing happens, if a chain of any metal touch the iron, and at the same time has a communication with the ground. In both these cases, the electrical matter passes along the iron, and dissipates in the earth.

3. In place of touching the piece of iron with the finger, if a piece of amber, wax, or any other non-conductor be applied to it, the communication with the earth being interrupted by the non-conductor, the iron, in that case, retains the electrical matter as before.

From these experiments we learn, that metals and other conductors receive the electrical matter, and transmit it to other conductors till it diffuses and is lost in the earth; but that, if wax, glass, or any other non-conductor, be applied to the conductor, the motions of the matter is instantly stopt, and accumulates and charges the conductor, at the same time that the non-conductor itself is not all affected. It is for this reason that conductors, as silk-cords, hair-ropes, &c. are always employed to suspend or support such bodies as we want to charge with electricity.

The following experiments will throw further light on this subject.

1. If a man stands upon a piece of rosin about five inches in diameter, and seven or eight inches thick, touching softly the globe, while the operator is rubbing it, his whole body, in a few seconds, will be charged with electrical matter; and the following phenomena will take place.

1. His loose hand, and indeed every part of his body, will mutually attract and repel light bodies at the distance of three or four feet.

2. All conductors which he takes in his hand, will become electrified in the same manner with himself, provided they touch nothing else, or be supported upon non-conductors: and this communication to other conductors, let

let their number and extension be ever so great, instead of diminishing the electrical virtue in the body of the man, will rather augment its strength and quantity.

3. If this person gives his hand to another likewise standing on a similar piece of rosin, he too will be charged with electrical matter; and the same thing will happen to any number of persons, provided they stand upon rosin, and communicate with one another by an iron chain or other conductor. But the whole company will instantaneously lose the whole of their electrical virtue, if any non-electrified person touch a single man, or if there be any communication between one of them and a conducting substance.

4. If the first man removes his hand from the globe, and at the same time keep his former station, he and all the rest will preserve the power of attracting and repelling light substances for some time; but it gradually diminishes, till its effects totally disappear.

5. If a non-electrified person puts his hand near the first man's face, he will feel a kind of atmosphere surrounding the electrified person; if he advances his hand still nearer any part of the face, for example the nose, both the point of the finger and the nose will appear luminous in the dark: Lastly, if he touches the nose, a spark of fire instantly explodes with a crack, and strikes both parties equally with a shock more or less painful in proportion as the electrified person was charged. It is by the explosion of this spark, that the electrical matter instantly transmits itself from one body to another.

6. When we approach near an electrified person, we perceive an extraordinary smell proceeding from his body, similar to that of the phosphorus of urine.

II. An iron wire, 12,000 feet in length, was suspended about five feet from the ground by silk cords; one end of it was connected to the globe of an electrical machine, and at the other a lead ball was hung in order to perceive when the matter reached it.

1. After five or six turns of the wheel, the matter had passed along the whole wire, and communicated its virtue to the ball, which instantly attracted and repelled light bodies.

2. As this ball was equally electrified with every part of the wire, it is probable that the electric matter would instantly pervade a wire of a still greater length, provided we had a proper apparatus for the purpose.

3. Several metals and other conductors were substituted in place of the ball, and all received the electricity in the same manner.

4. The ball and other non-conductors, when touched with the finger, gave a luminous spark and as smart a shock, as when the end of the wire next the globe was touched.

5. All these effects instantly ceased whenever any person not electrified touched any part of the wire, and commenced again a few seconds after his hand was withdrawn.

6. The same effects are produced, though with more difficulty, when hair or woolen ropes were substituted in place of the silk ones: But they were entirely stopped by hemp-ropes, or when the silk ones were wetted.

7. When a hempen rope was substituted in place of

the wire, the ball at the end of it was electrified with greater difficulty than when it hung at the wire, especially when the rope was dry; but when the rope was wet, the matter passed with more ease.

8. When, in place of the wire, a dry silk cord, or long glass tube, were used, they received but a very small quantity of the matter, which was not perceivable in the glass tube above 12 feet, nor in the cord above 25, beyond the globe.

9. When the wire was cut in several places, and the cut ends kept at the distance of somewhat less than a foot from each, the electrical matter darted through all these interruptions, and appeared in the ball at the furthest end. A strong blast made by a bellows across one of the interruptions, did not obstruct the passage of the matter; neither did the interposition of a piece of glass, wax, and other non-conductors: but all conductors, as the hand of a man, the point of a sword, and even a moist vapour, obstructed its course towards the ball.

10. When a man stood on a piece of rosin, and put a point of a sword in one of the interruptions, he was instantly filled with the matter, although neither he nor the sword touched the wire: neither was the course of the matter towards the ball obstructed by the interposition of the sword.

11. When a ring of brass wire, about three feet in diameter, was suspended in a vertical direction, and the iron wire was made to pass nearly through its centre, without touching any part of the circumference, the ring, in whatever part of the wire it was tried, was sensibly electrified. This shows that the electrical matter expands to a considerable distance on all sides of the electrified body.

12. The same iron wire suspended by silk cords was extended 6000 feet, (just one half of its length), in a straight line; the other half was turned back in a parallel direction towards the globe, leaving about nine or ten inches of interval between the two halves of the wire: Each extremity of the wire was supported by a dry silk cord about seven or eight feet from the globe, and the lead ball was hung at one of them. An iron chain was then fixed with another ~~silk~~ cord above the globe, in order to receive the matter at one of its extremities; the other end of the chain was fixed to a rod of glass about five feet long, in such a manner that the matter received from the globe might be transmitted at pleasure to the wire, by applying the end of the fixed chain to the glass rod. Matters being thus prepared, after five or six turns of the wheel, the chain was applied to one end of the wire; at the same instant the ball at the other end attracted and repelled bits of gold-leaf. The same experiment was repeated, and a finger applied to the ball, and a spark issued out, and a shock was received at the very instant that the chain was applied to the other end of the wire: A spark likewise proceeded from the chain, which afforded an easy opportunity of discovering that the two sparks were perfectly synchronous.

From these experiments it appears,

1. That the electrical matter communicates itself to all non-electrics, or conductors, whatever be their bulk or extension.

2. That the quantity of this matter diffused is always in proportion to the magnitude and extension of the bodies into which it passes; and that it is uniformly diffused, no part of the body retaining more than any other part.

3. That, after being thus communicated to any body, it escapes with equal facility, as soon as it finds a communication with the earth.

4. That small interruptions in the continuity of electrified bodies do not interrupt the motion of the electrical matter.

5. That the motion of the electrical matter is so amazingly swift, that it runs over a space of 12,000 feet in an undefinable instant of time.

6. That it moves with equal rapidity either backward or forward, upon the application of a conductor.

7. Lastly, That an indefinitely large quantity of this matter may be accumulated by applying the globe or tube to conducting bodies of very large dimensions. Of late other methods of condensing a large quantity of electrical matter into a small space have been invented, as will afterwards appear when we come to treat of the Leyden phial.

The attraction and repulsion of light bodies, is the first thing that discovers to us the presence of the electrical matter. This motion is always reciprocal: If the electrified body be lighter than the conductor, and both are at liberty, the motion of the former is quicker than that of the latter; if the one be fixed, and the other at liberty, the unfixed one constantly goes to the one that is fixed, and, at the same, takes the shortest road. The following experiments will illustrate these motions.

1. Present an electrified tube to small pieces of gold-leaf placed on a well-polished plate of copper, they will instantly fly towards the tube.

2. Suspend an electrified tube by two silk cords; take a piece of gold-leaf, and, holding it firm betwixt your fingers, bring it near the tube; and the tube will be attracted and move toward the leaf.

3. If an electrified person, standing on a piece of rosin, holds in his hand a plate of copper, upon which pieces of gold-leaf are placed; and another person, who is not electrified, holds his finger above the plate; the gold-leaf will instantly rise from the plate, and fly towards his finger.

4. Lastly, If two balls of gilt paper be suspended six inches asunder, the one by a silk thread three feet in length, and the other by a small silver wire of the same length; when the ball suspended by the silk thread is electrified by the tube, both balls advance with equal quickness towards one another, though only one of them was electrified.

The most favourable circumstances for exhibiting the attraction of light bodies are the following:

1. They should be perfect conductors.
2. They ought to be of a small size.
3. They should be supported by a non-conductor, and raised four or five feet from the ground.
4. No other non-conductor should be nearer the bodies than the tube with which the experiments are making; otherwise the attraction will be disturbed.

Repulsion generally succeeds attraction; that is, a piece of gold leaf is no sooner attracted by the tube than it is repelled and driven off from it. This repulsion is not very perceptible when the tube is slightly electrified; but, when the electricity is brisk, the gold leaf never fails to be repelled as soon as it has touched the tube. Again, if the electricity be very strong, the gold-leaf, though strongly attracted by the tube, never touches it; the repulsive power beginning to operate two or three inches before the leaf reaches the tube: from that instant the leaf is electrified; and, when it begins to be repelled, it has acquired as dense an electrical atmosphere as the tube: it then flies off, and remains suspended above the tube until it loses the electric virtue it had acquired, either by the moist vapours in the air, or till it loses it suddenly by touching some conductor. Hence it appears, that attraction precedes repulsion, only because it is necessary that the pieces of gold-leaf should acquire as dense an atmosphere as that of the globe before they can be repelled by it.

When the tube has repelled a piece of gold leaf, if another tube, nearly equally electrified, be suddenly substituted in place of the former tube, the leaf will continue to be repelled at an equal distance. But if the substituted tube be much less electrified than the original one, the leaf will be attracted by that tube.

When two or more pieces of gold leaf are presented at the same time to a well electrified tube, they are all equally attracted and repelled; but then they mutually repel one another, so that it is impossible to make any two of them join; and the distance at which they repel one another is equal to the distance to which each of them were repelled from the tube.

If a circular piece of gold-leaf, cut into small fringes to near the centre of the leaf, be presented to an electrified tube, it will first be attracted, and then repelled: in the time of repulsion, all the fringes repel each other, and diverge more or less in proportion to the strength of electricity in the tube.

If a small metal vessel filled with water, and furnished with a capillary siphon, having the longer leg hanging over the outside of the vessel, be touched with an electrified iron rod; the water, which could not run out of the siphon but drop by drop, will instantly fly out a tone jet, and divide itself into very fine threads; and these threads continue sometimes suspended in the air, repelled from each other to a considerable distance.

From these instances of attraction and repulsion it appears,

1. That light bodies are attracted by electrified substances until they be equally electrified by communication, and until they acquire as dense an atmosphere as the electrified substances themselves.
2. That, from the moment they acquire this atmosphere, attraction ceases and repulsion begins.
3. That no repulsion takes place but betwixt bodies electrified.
4. That repulsion continues only as long as the density of the two atmospheres are equal; that it ceases whenever the one or the other is diminished; that a new attraction

*Fig. 1.* ELECTRICAL APPARATUS

*Fig. 2.*  
PRIESTLY'S ELECTRICAL MACHINE

*Fig. 3.*  
THE BATTERY

*A. Bell & Co.*

traction commences, and continues till an equality in the atmospheres is again restored; and that, immediately upon this, a new repulsion takes place.

5. That repulsion may subsist betwixt two bodies which have never mutually been attracted, provided their atmospheres be equally dense.

6. That the distance to which bodies are repelled is always in proportion to the strength of the electricity they contain. This fact first suggested the notion of an electrometer, or a machine for measuring the different degrees of electricity.

#### *Of Electrical Machines and Apparatus.*

THE improvement of electrical machines has kept pace with the improvements in the science. While nothing more than electrical attraction and repulsion was known, every phenomenon might be exhibited by means of a piece of amber, sealing wax, or glass, which the philosopher rubbed against his coat, and presented to bits of paper, feathers, and other light bodies.

To give a greater degree of friction to electric substances, Otto Guericke and Mr Hawkesbee contrived to whirl sulphur and glass in a spherical form. The first conductors were nothing more than hempen-cords supported by silken lines. In place of these, bars of metal, or gun barrels, were soon substituted; and a rubber was employed to supply the place of a human hand. The discovery of the Leyden bottle, (to be afterwards described) occasioned more additions to the electrical apparatus; and the discoveries of Dr Franklin have made proportional additions necessary. No philosopher can now be satisfied, if he be not able to supply a conductor from the clouds, as well as from the friction of his glass globes or tubes.

Although globes or cylinders are now of the most extensive use in electrical experiments, glass tubes are still most convenient for several purposes; they should be about three feet long, and as wide as a person can conveniently grasp, (Plate LXXIII. fig. 1 a.) The thickness of the glass is not material; perhaps the thinner they are the better, if they can bear sufficient friction.

The best rubber for a smooth glass is the rough side of black oiled silk, especially when a little amalgam of mercury or other metal is put upon it.

Glass-globes are in general preferable to cylinders. The globe should have its neck inclosed in a pretty deep brass cap, ending in a dilated brim, of about half an inch broad, if the globe be a large one. It has not been determined what kind of glass is the best; but flint is commonly used. Perhaps globes of twelve or thirteen inches diameter are the best size.

The best rubbers for globes are made of red basil skins, particularly the neck-part of them, where the grain is more open, and the surface somewhat rougher. That the rubber may press the globe equally, it should be put upon a plate of metal bent to the shape of the globe, and stuffed with any thing that is pretty soft: bran is good; and if the stuffing be a conductor, as flax, it will be better than if it be a non-conductor, as hair or wooll. It should rest upon a spring, to favour any inequality there may be in the form of the globe. There should

be no sharp edges or angles about the rubber; for that would make the insulation of it ineffectual. By the insulation of the rubber every electrical experiment may be performed with the twofold variety of *positive* and *negative*, and a conductor be made to give and take fire at pleasure. This insulation is best made by means of baked wood, in the form of a plate, five or six inches in diameter, (y, fig. 2) interpolated between the metallic part of the rubber and the steel spring that supports it. When positive electricity is intended to be produced, a chain (n, fig. 2.) must connect the rubber with the floor; but, when negative electricity is wanted, the chain must be removed, and hung upon the common conductor, while another prime conductor must be connected with the rubber; which will therefore be electrified negatively.

The best method of collecting the electric fire from the globe seems to be by three or four pointed wires, (m, fig. 2.) two or three inches long, hanging lightly upon the globe, and suspended on an open metallic ring.

The prime conductor should be fixed very steady: Whatever be the size of the prime conductor, the extremity of it, or that part which is most remote from the globe, should be much larger and rounder than the rest, (t, fig. 2); for the effort of the electric matter to fly off is always greatest at the greatest distance from the globe.

The electrician should be provided with METALLIC RODS (r, fig. 1.) to take sparks from his conductor for various uses. These should have knobs, larger or smaller in proportion to the curvature of the conductor. If the knob be too small, it will not discharge the conductor at once, but by degrees, and with a less sensible effect; whereas the spark between broad surfaces is thick and strong.

The most formidable part of an electrical apparatus consists in the COATED GLASS that is used for the Leyden experiment. The form of the plate is immaterial with respect to the thickness; and, for different experiments, both plates of glass, and jars of various forms and sizes, must be used. For common uses, the most commodious form is that of a jar, as wide as a person can conveniently hold in his hand by grasping, and as tall as it will stand without any danger of falling; perhaps about  $3\frac{1}{2}$  inches in diameter, and 8 inches in height. The mouth should be pretty open, that it may be the more conveniently coated on the inside, as well as the outside, with tinfoil. A considerable variety of these jars may be seen in the above Plate, fig. 1. c, d, e, f, g, h, i, j, k.

The method of coating is much preferable to that of putting water or brass-shavings into the jars, which both makes them heavy, and likewise incapable of being inverted, which is requisite in many experiments. Brass-dust, however, or leaden-shot, is very convenient for small phials. The tinfoil may be put on either with paste, gum water, or bees-wax. To coat the insides of vessels which have narrow mouths, moisten the inside with gum water, and then pour some brass dust upon it: Enough will stick to make an exceeding good coating.

In the construction of an ELECTRICAL BATTERY, a  
number

number of small jars are preferable to large ones. If one of them should break by an explosion or any other accident, the loss is less considerable; besides, by means of narrow jars, a greater force (that is, a greater quantity of coated surface) may be contained in less room. The largest jars are about 17 inches in height, and should not be more than 3 in diameter, and of the same width throughout. Thus they may be easily coated both within and without, and a box of a moderate size will contain a prodigious force; for the jars being coated within two inches of the top, each will contain a square foot of coated glass. The battery (Plate LXXIII. fig. 3.) consists of 64 jars, each 8 inches long, and  $2\frac{1}{4}$  in diameter, coated within an inch and a half of the top. The coated part of each is half a square foot; so that the whole battery contains 32 square feet. The wire of each jar has a piece of very small wire twisted about the lower end of it, to touch the inside coating in several places; and it is put through a pretty large piece of cork within the jar, to prevent any part of it from touching the side, which would tend to promote a spontaneous discharge. Each wire is turned round, so as to make a hole or ring at the upper end; and through these rings a pretty thick brass rod with knobs is put, one rod serving for one row of the jars. The communication between these rods is made by laying a chain over them all: this chain is not represented in the plate, lest the figure should appear confused. When only a part of the battery is to be used, the chain should be laid over as many rods as you want rows of jars. The bottom of the box in which all the jars stand is covered with tinfoil and brass-dust; and a bent wire touching this tinfoil is put through the box, and appears on the outside, as in the plate. To this wire is fastened whatever is intended to communicate with the outside of the battery, as the piece of small wire in the figure; and the discharge is made by bringing the brass knob to any of the knobs of the battery.

To discover the kind and degree of electricity, many forms of ELECTROMETERS have been thought of. Mr Canton's balls *A*, represented on a glass standing on the stool *c*, (Plate LXXIII. fig. 1.) serve to discover small degrees of electricity, to observe the changes of it from positive to negative, and to estimate the force of a shock before the discharge. These balls are two pieces of cork, or pith of elder, nicely turned in a lathe to about the size of a small pea, and suspended on small linen threads. These balls repel one another to distances exactly proportioned to the quantity of electricity contained in the vessel or other substance with which they are connected; and by this work the operator knows pretty exactly the force of the charge, and the shock that will be given.

In order to repeat the experiment tending to shew that the electric fluid is the same with the matter of lightning, and to make observations on the electricity of the atmosphere, the electrician should be provided with A MACHINE FOR DRAWING ELECTRICITY FROM THE CLOUDS. The best construction of which is the following: On the top of any building erect a pole *a*, (Plate LXXIV. fig. 2.) as tall as a man can well manage, having on the top of it a solid piece of glass, or baked

wood, a foot in length. Let this be covered with a tin or copper vessel (*b*) shaped like a funnel, to prevent its ever being wetted; above this, let there rise a long slender rod *c*, terminating in a pointed wire, and having a small wire twisted round its whole length, the better to conduct the electricity to the funnel. From the funnel make a wire (*d*) descend along the building, about a foot distance from it, and conducted through an open fast into any room that shall be most convenient for making the experiment. In this room, let a proper conductor be insulated, and connected with the wire coming in at the window. This wire and conductor, being completely insulated, will be electrified whenever there is a considerable quantity of electricity in the air. And notice will be given when it is properly charged, either by Mr Canton's balls hung to it, or by a set of bells disposed in the following manner. Take three bells; suspend the two outermost from the conductor by chains, and that in the middle by a silken string, while a chain connects it with the floor; and hang two small knobs of brass by silken strings, one between each two bells, to serve instead of clappers. In consequence of this disposition, when the two outermost bells, communicating with the conductor, are electrified, they will attract the clappers, and be struck by them. The clappers being thus loaded with electricity, will be repelled, and fly to discharge themselves upon the middle bell. After this, the clappers will be again attracted by the outermost bells; and thus, by striking the bells alternately, a continual ringing may be kept up as long as the operator pleases. In the dark a continual flashing of light will be seen between the clappers and the bells. But when the electrification is very strong, these flashes of light will be so large, that they will be transmitted by the clapper from one bell to the other, without its ever coming to actual contact with either of them, and the ringing will consequently cease.

With regard to the construction of machines for electrical experiments in general, that of Dr Priestly, represented on Plate LXXIII. fig. 2. is perhaps the best. The FRAME consists of two strong boards of mahogany, (*aa*), of the same length, parallel to one another, about four inches asunder, and the lower one is an inch on each side broader than the upper: in the upper board is a groove reaching almost its whole length. One of the pillars *b*, which are of baked wood, is immovable, being let through the upper board, and firmly fixed in the lower; while the other pillar slides in the groove above-mentioned, in order to receive globes or cylinders of different sizes; but it is only wanted when an axis is used. Both the pillars are perforated with holes at equal distances from the top to the bottom; by means of which, globes may be mounted higher or lower according to their size; and they are made tall, to admit the use of two or more globes at a time, one above another. Four of a moderate size may be used, if two be fixed on one axis; and the wheel has several grooves for that purpose.

If a globe with only one neck be used, as in the Plate, a brass arm, with an open socket *c*, is necessary to support the axis beyond the pulley; and this part is also contrived to be put higher or lower, together with the brass socket in which the axis stands. The axis *d* let

*Fig. 6.* ERINACEUS or HEDGEHOG

*Fig. 8.* ERMINE

is made to come quite through the pillar, that it may be turned by another handle without the wheel, if the operator chuses. The frame, being screwed to the table, may be placed nearer to, or farther from, the wheel, as the length of the string requires in different states of the weather. The WHEEL is fixed in a frame by itself *e*, by which it may have any situation with respect to the pulley, and be turned to one side, so as to prevent the string from cutting itself.

The RUBBER (*f*) consists of a hollow piece of copper, filled with horse-hair, and covered with a bازل-skin. It is supported by a socket, which receives the cylindrical axis, of a round and flat piece of baked wood *g*, the opposite part of which is inserted into the socket of a bent steel-spring *h*. These parts are easily separated; so that the rubber, or piece of wood that serves to insulate it, may be changed at pleasure. The spring may be either slipped along the groove, or moved in the contrary direction, so as to give it every desirable position with respect to the globe. It is besides furnished with a screw *i*, which makes it press harder or lighter on the globe, as the operator chuses.

The PRIME CONDUCTOR (*k*) is a hollow vessel of polished copper in the form of a pear, supported by a pillar and a firm basis of baked wood; and it receives the electrical matter by means of a long arched wire or rod of very soft brass *l*, easily bent into any shape, and raised higher or lower as the globe requires. It is terminated by an open ring, in which are hung some sharp-pointed wires *m*, playing lightly on the globe when it is in motion. The body of the conductor is furnished with holes and sockets for the insertion of metallic rods to convey the fire where-ever it is wanted.

When positive electricity is required, a wire or chain, as represented in the plate (*n*), connects the rubber with the table or the floor. When negative electricity is wanted, that wire is connected with another conductor, such as that represented, in fig. 1. *s*; where the conductor in fig. 2. is connected with the table by another wire or chain. If the rubber be made tolerably free from points, the negative power will be as strong as the positive.

The machine, represented Plate LXXV. fig. 1. was a contrivance of Dr Watson's, to whirl four large globes at a time, and unite the power of them all. The construction is so simple, that we need not give any particular description of it, especially after having so fully described that of Dr Priestly.

*Of positive and negative Electricity, and the Leyden Phial.*

DR WATSON and Dr Franklin first suggested the notion of *positive* and *negative*, or *plus* and *minus* electricity: several experiments led them to conclude, that every body in nature, and particularly all conducting bodies, possessed a certain quantity of electric matter, and that this natural quantity might be augmented or diminished by being placed in particular circumstances. When a body receives a larger quantity than the natural one, it is said to be electrified *plus*, or *positively*; when the natural quantity is diminished, it is said to be electrified *mi-*

*nus*, or *negatively*. The following experiments will shew the different circumstances requisite to produce these two kinds of electricity.

1. A person standing on wax, and rubbing the tube, and another person on wax drawing the fire, they will both appear to be electrified by a person standing on the floor; that is, he will perceive a spark on approaching each of them with his knuckle.

2. But, if the persons on wax touch one another during the exciting of the tube, neither of them will appear to be electrified.

3. If they touch one another after exciting the tube, and drawing the fire as before, there will be a stronger spark between them, than happens between either of them and the person on the floor.

4. After such strong spark, neither of them discover any electricity.

These appearances are explained in the following manner: the electrical fire is supposed to be a common element, of which each of the three persons above-mentioned has his equal share, before any operation is begun with the tube. A, who stands on wax and rubs the tube, collects the electrical fire from himself into the glass; and his communication with all conductors being cut off by the wax, his body is not again immediately supplied. B, who stands likewise on wax, passing his knuckle along near the tube, receives the fire which was collected by the glass from A; and his communication with conductors, or the common stock of electrical matter, being likewise cut off, he retains the additional quantity received. To C, standing on the floor, both appear to be electrified: for he having only the middle quantity of electrical fire, receives a spark upon approaching B who has an over quantity, but gives one to A who has an under quantity. If A and B approach to touch each other, the spark is stronger, because the distance betwixt them is greater: after such touch, there is no spark between either of them and C, because the electrical fire in all is reduced to the original equality. If they touch while electrifying, the equality is never destroyed, the fire only circulating. Hence we say, B is electrified *positively*, A *negatively*; or rather B is electrified *plus*, A *minus*: and in experimenting, it is common to electrify bodies *plus* or *minus* at pleasure. To electrify *plus* or *minus*, it is sufficient to know, that the parts of the tube or sphere that are rubbed, do, in the instant of the friction, attract the electrical fire, and therefore take it from the thing rubbing: the same parts immediately, as the friction upon them ceases, are disposed to give the fire they have received to any body that has left. Thus you may circulate it or accumulate it upon, or subtract it from any body, as you connect that body with the rubber, or the receiver, the communication in the common stock being cut off.

The great shock from what is called the LEYDEN PHIAL, was first discovered by Mr CUNRUS, a native of Leyden; but was never so thoroughly understood till Dr Franklin published his experiments with regard to it. A glass phial or jar, filled, till within an inch of the top, with water, brals dust, or other non conducting substances, was first used; but coating the vessel with tin foil,

or brads-duft, as mentioned above in the section concerning the electrical apparatus, was found to answer better.

We shall here give Dr Franklin's account of this phial nearly in his own words, together with the experiments confirming it.

1. While the wire and inside of the bottle are electrified *positively* or *plus*, the outside of the bottle is electrified *negatively* or *minus*, in exact proportion; *i. e.* whatever quantity of electrical fire is thrown into the inside, an equal quantity goes out of the outside. To understand this, suppose the natural quantity of electricity in the whole bottle, before the operation begins, is equal to 20; and, at every stroke of the tube, or turn of the globe, suppose a quantity equal to 1 is thrown in; then, after the first stroke, the quantity contained in the wire and inside of the bottle will be 21, and in the outside 19; after the second stroke, the inside will have 22. and the outside 18; and so on, till, after 20 strokes, the inside will have a quantity of electrical fire equal to 40, and the outside none at all; and then the operation ends: for no more can be thrown into the inside, when no more can be driven out of the outside. If more is attempted to be thrown in, it is spued back through the wire, or flies out in loud cracks through the sides of the bottle.

2. The equilibrium of electric matter in the bottle being thus lost, it cannot be restored by any *inward* communication or contact of the parts: but this must be done by a communication formed *without* the bottle between the inside and the outside, by some conductor touching or approaching both sides at the same time; in which case the equilibrium is restored with an inexpressible violence and quickness: or, it may be done by touching each side alternately; in which case, the equilibrium is restored by degrees.

3. As no more electrical fire can be thrown into the inside of the bottle, when all is driven from the outside; so, in a bottle not yet electrified, none can be thrown into the inside, when none can get out at the outside; which happens, either when the glass is too thick or when the bottle is placed in a non-conductor. Again, when the bottle is electrified, but little of the electrical fire can be drawn out from the inside by touching the wire, unless an equal quantity can, at the same time, get in at the outside. Thus, place an electrified bottle on clean glass, or dry wax, and you will not, by touching the wire, get out the fire from the inside: place it on a conductor, and touch the wire, then you will get it out in a short time; but soonest when you form a direct communication as above.

4. The shock to the nerves, or rather convulsion, is occasioned by the sudden passage of the fire through the body, in its way from the inside to the outside of the bottle. The fire takes the shortest course; but it does not appear, that, in order to receive a shock, a communication with the floor is necessary; for he that holds the bottle with one hand, and touches the wire with the other, will be shocked as much, though his shoes be dry, or even standing on wax. And on the touch of the wire (or of the prime conductor, which is the same thing,) the fire does not proceed from the touching finger to the wire, but from the wire to the finger, and passes

through the body to the other hand, and so into the outside of the bottle.

The following experiments will confirm this account of the Leyden phial.

1. Place an electrified phial on wax; a small cork-ball held in your hand, suspended by a dry silk thread, and brought near to the wire, will first be attracted and then repelled: When in a repelled state, sink your hand, that the ball may be brought towards the outside of the bottle; it will be instantly attracted till it has parted with its fire.

If the outside of the bottle had a positive electrical atmosphere, as well as the inside and the wire, an electrified cork would be repelled from the one as well as the other.

2. From a bent wire sticking in the table, let a small linen thread hang down within half an inch of the electrified phial; touch the wire of the phial repeatedly with your finger; and, at every touch, you will see the thread instantly attracted by the outside of the bottle. As soon as you draw any fire from the inside by touching the wire, the outside draws in an equal quantity by the thread.

3. Fix a wire in the outside coating of the bottle, so as that bending upwards its ring-end may be level with the top or ring-end of the wire in the cork of the bottle, and at three or four inches distance. Then electrify the bottle, and place it on wax. If a cork, suspended by a silk thread, hang between these two wires, it will play incessantly from the one to the other, till the equilibrium between the inside and the outside of the bottle is restored.

4. Place a man on a cake of wax, and present him the wire of the electrified phial to touch, you standing on the floor and holding it in your hand. As often as he touches it, he will be electrified *plus*; and any one standing on the floor may draw a spark from him. The fire, in this experiment, passes out of the wire into him; and, at the same time, out of your hand into the outside of the bottle. Give him the electrical phial to hold, and touch the wire; as often as you touch it, he will be electrified *minus*, and may draw a spark from any one standing in the floor. The fire in this case passes from the wire to you, and from him into the outside of the bottle.

5. Lay two books, or two glasses, back to back, two two or three inches distant, place the electrified phial; on one of them, and then touch the wire; that book will be electrified *minus*, the electrical fire being drawn out of it by the outside of the bottle. Take off the bottle, and, holding it in your hand, touch the other with the wire; that book will be electrified *plus*, the fire passing into it from the wire, and the outside of the bottle is at the same time supplied from your hand.

The same explosion and shock happens, if the electrified phial is held in one hand by the hook of the wire, and the coating touched with the other, as when held by the coating and touched at the hook. To take the charged phial safely by the hook, and not at the same time diminish its force; it must first be set down on a non-conductor. The phial will be electrified as strongly, if held by the hook, and the coating applied to the globe or tube,

tube, as when held by the coating and the hook applied: but the *direction* of the electrical fire, being different in the charging, will also be different in the explosion; the bottle charged through the hook will be discharged thro' the hook; the bottle charged thro' the coating will be discharged thro' the coating; because the fire must come out the same way it went in.

6. To prove this, take two bottles that were equally charged thro' the hooks, one in each hand; bring their hooks near each other, and no spark or shock will follow; because each hook is disposed to give fire, and neither to receive it. Set one of the bottles on glass, take it up by the hook, and apply its coating to the hook of the other; then there will be an explosion and shock, and both bottles will be discharged. [*N B.* To charge a bottle commodiously thro' the coating; place it on a glass stand; form a communication from the prime conductor to the coating, and another from the hook to the wall or floor; when it is charged, remove the latter communication before you take hold of the bottle, otherwise great part of the fire will escape by it.]

When the terms of *charging* or *discharging* the phial are used, it is in compliance with custom, and for want of better ones; since there is really no *more* electrical fire in the phial after what is called its *charging* than before, nor *less* after its *discharging*. Besides, the phial will not suffer what is called a *charging*, unless as much fire can go out of it one way as is thrown in by another. A phial cannot be charged standing on wax or glass, or hanging on the prime conductor, unless a communication be formed between its coating and the floor. But suspend two or more phials on the prime conductor, one hanging to the tail of the other, and a wire from the last to the floor, an equal number of turns of the wheel will charge them all equally, and each as strongly as a single one would have been.

When a bottle is charged in the common way, its *inside* and *outside* surfaces stand ready, the one to give fire by the hook, the other to receive it by the coating: yet as the first will not give out, unless the other can at the same instant receive in; so neither will the latter receive in, unless the first can at the same instant give out. When both can be done at once, it is done with inconceivable quickness and violence.

Glass has within its substance the same quantity of electrical fire at all times, and that quantity is very great in proportion to the mass of glass. This quantity it obstinately retains; and will have neither more nor less, though it will allow a change to be made in its parts and situation; that is, we may take away part from one of the sides, provided we throw an equal quantity into the other. Yet when the situation of the electrical fire is thus altered in the glass, it will not be at rest, or in its natural state, till it be restored to its original equality; and this restitution cannot be made through the substance of the glass, but must be done by a conducting communication formed without from surface to surface. Thus the whole force of the bottle, and power of giving a shock, resides in the GLASS itself; the coatings, or conducting substances in contact with the two surfaces, ser-

ving only to give and receive to and from the several parts of the glass; that is, to give in one side, and take away from the other. This was discovered by Dr Franklin, and proved by the following experiment: ' Purposing, (says he,) to analyze the electrified bottle, in order to find wherein its strength lay, we placed it on glass; and drew out the cork and wire, which for that purpose had been loosely put in. Then taking the bottle in one hand, and bringing a finger of the other near its mouth, a strong spark came from the water, and the shock was as violent as if the wire had remained in it, which shewed that the force did not lie in the wire. Then to find if it resided in the water, being crowded into and condensed in it, as confined by the glass, which had been our former opinion, we electrified the bottle again, and placing it on glass drew out the wire and cork as before; then taking up the bottle, we decanted all its water into an empty bottle, which likewise stood on glass; and taking up that other bottle, we expected, if the force resided in the water, to find a shock from it; but there was none. We judged then that it must either be lost in decanting, or remain in the first bottle. The latter we found to be true; for that bottle on trial gave the shock, though filled up as it stood with fresh unelectrified water from a tea-pot — To find, then, whether glass had this property merely as glass, or whether the form contributed any thing to it; we took a pane of sash-glass, and laying it on the hand, placed a plate of lead on its upper surface; then electrified that plate, and bringing a finger to it, there was a spark and shock. We then took two plates of lead of equal dimensions, but less than the glass by two inches every way, and electrified the glass between them, by electrifying the uppermost lead; then separated the glass from the lead; in doing which, what little fire might be in the lead was taken out, and the glass being touched in the electrified parts with a finger, afforded only very small pricking sparks, but a great number of them might be taken from different places. Then dexterously placing it again between the leaden plates, and completing a circle between the two surfaces, a violent shock ensued. — Which demonstrated the power to reside in glass as glass; and that the non-electrics in contact served only, like the armature of a loadstone, to unite the force of the several parts, and bring them at once to any point desired: it being the property of a non-electric, that the whole body instantly receives or gives what electrical fire is given to or taken from any one of its parts. —

' It is amazing to observe in how small a portion of glass a great electrical force may lie. A thin glass bubble about an inch diameter, weighing only six grains, being half filled with water, partly gilt on the outside, and furnished with a wire hook, gives, when electrified, as great a shock as a man can well bear. As the glass is thickest near the orifice, I suppose the lower half, which being gilt was electrified and gave the shock, did not exceed two grains; for it appeared, when broke, much thinner than the upper half. — If one of these thin bottles be electrified by the coating, and the spark taken

' taken out through the gilding, it will break the glass inwards, at the same time that it breaks the gilding outwards. And since there is no more electrical fire in a bottle after charging than before, how great must be the quantity in this small portion of glass! It seems as if it were of its very substance and essence. Perhaps if that due quantity of electrical fire so obstinately retained by glass, could be separated from it, it would no longer be glass; it might lose its transparency, or its brittleness, or its elasticity.—Experiments may possibly be invented hereafter to discover this.'

*Of the Similarity between Lightning and Electricity.*

1. Flashes of lightning are generally seen crooked, and waving in the air. The electric spark has always the same direction when it is drawn from an irregular body at some distance, or through a space in which the best conductors are disposed in an irregular manner, which is always the case in the heterogeneous atmosphere of our globe.

2. Lightning strikes the highest and most pointed objects in its way preferable to others, as high hills, and trees, towers, spires, masts of ships, points of spears, &c. In like manner, all pointed conductors receive or throw off the electric fluid more readily than those which are terminated by flat surfaces.

3. Lightning is observed to take the readiest and best conductor. So does electricity in the discharge of the Leyden phial. For this reason, it would be safer, during a thunder-storm, to have one's cloaths wet than dry, as the lightning might then, in a great measure, be transmitted to the ground, by the water, on the outside of the body. It is found, that a wet rat cannot be killed by the explosion of the electrical bottle, but that a dry rat may.

4. Lightning burns. So does electricity. It will kindle hard dry rosin, spirits unwarmed, and even wood. It will fire gunpowder, by only ramming it hard in a cartridge, into each end of which pointed wires are introduced, and brought within half an inch of one another, and discharging a shock through them.

5. Lightning sometimes dissolves metals. So does electricity. The method in which Dr Franklin made electricity melt metals, was by putting thin pieces of them between two panes of glass, bound fast together, and sending an electric shock through them. Sometimes the pieces of glass, by which they were confined, would be shattered to pieces by the discharge, and be broken into a kind of coarse sand, which once happened with pieces of thick looking-glass; but if they remained whole, the pieces of metal would be missing in several places where it had lain between them, and instead of it a metallic stain would be seen on both the glasses, the stains on the under and upper glass being exactly similar in the minutest stroke.

6. Lightning rends some bodies. So does electricity. The electric spark will strike a hole through a quire of paper.—When wood, bricks, stone, &c. are rent by lightning, the splinters will fly off on that side where

there is the least resistance. In like manner, when a hole is struck through a piece of pasteboard by an electrified jar, if the surfaces of the pasteboard are not confined and compressed, there will be a bur raised all round the hole on both sides of the pasteboard; but if one side be confined, so that the bur cannot be raised on that side, it will all be raised on the other side, which way soever the fluid was directed. For the bur round the outside of the hole is the effect of the explosion, which is made every way from the center of the electric stream, and not an effect of its direction.

7. Lightning has often been known to strike people blind. And a pigeon, after a violent shock of electricity, by which it was intended to be killed, was struck blind likewise.

8. In a thunder-storm at Stretham, described by Dr Miles, the lightning stripped off some paint which had covered a gilded moulding of a pannel of wainscot, without hurting the rest of the paint. Dr Franklin imitated this, by passing a slip of paper over the filleting of gold on the cover of a book, and sending an electric flash through it. The paper was torn off from end to end, with such force, that it was broken in several places; and in others there was brought away part of the grain of the Turkey leather in which the book was bound. This convinced the doctor, that if it had been paint, it would have been stripped off in the same manner with that on the wainscot at Stretham.

9. Lightning destroys animal-life. Animals have likewise been killed by the shock of electricity. The largest animals which Dr Franklin and his friends had been able to kill were a hen, and a turkey which weighed about ten pounds.

10. Magnets have been observed to lose their virtue, or to have their poles reversed, by lightning. Dr Franklin did the same by electricity. By electricity he frequently gave polarity to needles, and reversed them at pleasure. A shock from four large jars, sent through a fine sewing needle, gave it polarity, so that it would traverse when laid on water. What is most remarkable in these electrical experiments upon magnets is, that if the needle, when it was struck, lay east and west, the end which was entered by the electric blast pointed north; but that if it lay north and south, the end which lay towards the north would continue to point north, whether the fire entered at that end or the contrary. He also observed, that the polarity was strongest when the needle was struck lying north and south, and weakest when it lay east and west. He takes notice, that, in these experiments, the needle, in some cases, would be finely blued, like the spring of a watch, by the electric flame; in which case the colour given by a flash from two jars only might be wiped off, but that a flash from four jars fixed it, and frequently melted the needles. The jars which the doctor used held seven or eight gallons, and were coated and lined with tinfoil.

To demonstrate, in the completest manner possible, the sameness of the electric fluid with the matter of lightning, Dr Franklin contrived to bring lightning from the heavens, by means of an electrical kite, which he raised when a storm of thunder was perceived to be coming on. This kite

kite had a pointed wire fixed upon it, by which it drew the lightning from the clouds. This lightning descended by the hempen string, and was received by a key tied to the extremity of it; that part of the string which was held in the hand being of silk, that the electric virtue might stop when it came to the key. He found that the string would conduct electricity even when nearly dry, but that when it was wet it would conduct it quite freely; so that it would stream out plentifully from the key at the approach of a person's finger.

At this key he charged phials, and from electric fire thus obtained he kindled spirits, and performed all other electrical experiments which are usually exhibited by an excited globe or tube.

The first appearance of a thunder-storm (which generally happens when there is little or no wind) is one dense cloud, or more, increasing very fast in size, and rising into the higher regions of the air. The lower surface is black, and nearly level; but the upper finely arched, and well defined. Many of these clouds often seem piled one upon another, all arched in the same manner; but they keep continually uniting, swelling, and extending their arches.

At the time of the rising of this cloud, the atmosphere is generally full of a great number of separate clouds, motionless, and of odd and whimsical shapes. All these, upon the appearance of the thunder-cloud, draw towards it, and become more uniform in their shapes as they approach; till, coming very near the thunder-cloud, their limbs mutually stretch towards one another; they immediately coalesce, and together make one uniform mass. These are called *adscitious* clouds, from their coming in, to enlarge the size of the thunder-cloud. But, sometimes the thunder-cloud will swell, and increase very fast without the conjunction of any adscitious clouds, the vapours in the atmosphere forming themselves into clouds where-ever it passes. Some of the adscitious clouds appear like white fringes, at the skirts of the thunder-cloud, or under the body of it; but they keep continually growing darker and darker, as they approach to unite with it.

When the thunder-cloud is grown to a great size, its lower surface is often ragged, particular parts being detached towards the earth, but still connected with the rest. Sometimes the lower surface swells into various large protuberances, bending uniformly towards the earth. And sometimes one whole side of the cloud will have an inclination to the earth and the extremity of it will nearly touch the earth. When the eye is under the thunder-cloud, after it is grown large, and well formed, it is seen to sink lower, and to darken prodigiously; at the same time that a number of small adscitious clouds (the origin of which can never be perceived) are seen in a rapid motion, driving about in very uncertain directions under it. While these clouds are agitated with the most rapid motions, the rain generally falls in the greatest plenty; and if the agitation be exceeding great, it commonly hails.

When the thunder-cloud is swelling, and extending its branches over a large tract of country, the lightning is seen to dart from one part of it to another, and often

to illuminate its whole mass. When the cloud has acquired a sufficient extent, the lightning strikes between the cloud and the earth, in two opposite places, the path of the lightning lying through the whole body of the cloud and its branches. The longer this lightning continues, the rarer does the cloud grow, and the less dark is its appearance; till, at length, it breaks in different places, and shows a clear sky. When the thunder-cloud is thus dispersed, those parts which occupy the upper regions of the atmosphere are equally spread, and very thin; and those that are underneath are black, but thin too; and they vanish gradually, without being driven away with any wind.

That thunder-clouds were sometimes in a positive as well as negative state of electricity, Signior Beccaria had discovered, before he heard of its having been observed by Dr Franklin or any other person. The same cloud, in passing over his observatory, electrified his apparatus sometimes positively, and sometimes negatively. The electricity continued longer of the same kind, in proportion as the thunder-cloud was simple, and uniform in its direction; but when the lightning changed its place, there commonly happened a change in the electricity of his apparatus. It would change suddenly after a very violent flash of lightning, but the change would be gradual when the lightning was moderate, and the progress of the thunder-cloud slow.

It was an immediate inference from his observations of the lightning abroad, and his apparatus within, that the quantity of electric matter, in an usual storm of thunder, is almost inconceivably great; considering how many pointed bodies, as trees, spires, &c. are perpetually drawing it off, and what a prodigious quantity is repeatedly discharged to or from the earth.

Considering the vast quantity of electric fire that appears in the most simple thunder-storms, he thinks it impossible that any cloud, or number of clouds, should ever contain it all, so as either to discharge or receive it. Besides, during the progress and increase of the storm, though the lightning frequently struck to the earth, the same clouds were the next moment ready to make a still greater discharge, and his apparatus continued to be as much affected as ever. The clouds must, consequently, have received at one place the moment that a discharge was made from them in another. In many cases, the electricity of his apparatus, and consequently of the clouds, would instantly change from one kind to another several times; an effect which cannot be accounted for by any simple discharge or recruit. Both must have taken place in a very quick succession.

The extent of the clouds doth not lessen this difficulty: for, be it ever so great, still the quantity ought to be lessened by every discharge: and besides, the points by which the silent discharges are made are in proportion to the extent of the clouds. Nor is the difficulty lessened by supposing that fresh clouds bring recruits; for besides that the clouds are not ripe for the principal storm, till all the clouds, to a great distance, have actually coalesced, and formed one uniform mass, those recruits bear no sort of proportion to the discharge, and whatever it was, it would soon be exhausted.

The fact, therefore, must be, that the electric matter is continually darting from the clouds in one place, at the same time that it is discharged from the earth in another. And it is a necessary consequence from the whole, that the clouds serve as conductors to convey the electric fluid from those places of the earth which are overloaded with it, to those which are exhausted of it.

That great quantities of electric matter do sometimes rush out of particular parts of the earth, and rise through the air into the higher regions of the atmosphere, he thinks is evident from the great quantities of sand, ashes, and other light substances, which have often been carried up into the air, and scattered uniformly over a large tract of country. No other known efficient cause of this phenomenon can be assigned, except the wind; and it has been observed when there was no wind stirring; and the light bodies have even been carried against the wind. He supposes, therefore, that these light bodies are raised by a large quantity of electric matter, issuing out of the earth, where it was overcharged with it, and attracting and carrying with it every substance that could serve as a conductor in its passage. All these bodies, being possessed of an equal quantity of the electric fluid, will be dispersed equally in the air, and consequently over that part of the earth where the fluid was wanting, and whither they serve to convey it. Had these bodies been raised by the wind, they would have been dispersed at random, and in heaps.

This comparatively rare phenomenon, he thinks, exhibits both a perfect image, and demonstration, of the manner in which the vapours of the atmosphere are raised to form thunder-clouds. The same electric matter, wherever it issues, attracts to it, and carries up into the higher regions of the air, the watery particles that are dispersed in the atmosphere. The electric matter ascends to the higher regions of the atmosphere, being solicited by the less resistance it finds there than in the common mass of the earth; which, at those times, is generally very dry, and consequently highly electric. The uniformity with which thunder-clouds spread themselves, and swell into arches, must be owing to their being affected by some cause which, like the electric matter, diffuses itself uniformly wherever it acts, and to the resistance they meet with in ascending through the air. As a proof of this, steam, rising from an electrified eolipile, diffuses itself with the same uniformity, and in similar arches, extending itself towards any conducting substance.

The same cause which first raised a cloud, from vapours dispersed in the atmosphere, draws it to those that are already formed, and continues to form new ones; till the whole collected mass extends so far, as to reach a part of the earth where there is a deficiency of the electric fluid. Thither too, will those clouds, replete with electricity, be strongly attracted, and there will the electric matter discharge itself upon the earth. A channel of communication being, in this manner, found, a fresh supply of electric matter will be raised from the overloaded part, and will continue to be conveyed by the medium of the clouds, till the equilibrium of the fluid, between the two places of the earth be restored. When

the clouds are attracted in their passage by those parts of the earth where there is a deficiency of the fluid, those detached fragments are formed, and also those uniform depending protuberances, which, in some cases, are the cause of water-spouts, and hurricanes.

That the electric matter, which forms and animates the thunder-clouds, issues from places far below the surface of the earth; and that it buries itself there, is probable from the deep holes that have, in many places, been made by lightning. Flashes of lightning have, also, been seen to arise from subterraneous cavities, and from wells. Violent inundations have accompanied thunder-storms, not occasioned by rain, but by water bursting from the bowels of the earth, from which it must have been dislodged by some internal concussion. Deep wells have been known to fill faster in thunder-storms, and others have constantly grown turbid at the approach of thunder.

This very rise, as well as the whole progress of thunder-clouds, has sometimes been in a manner visible. Exhalations have been frequently seen to rise from particular caverns, attended with a rumbling noise, and to ascend into the higher regions of the air, with all the phenomena of thunder-storms described above, according to the description of persons who lived long before the connection between electricity and lightning was suspected.

The greatest difficulty attending this theory of the origin of thunder-storms relates to the collection and insulation of electric matter within the body of the earth. With respect to the former, he has nothing particular to say. Some operations in nature are certainly attended with a loss of the equilibrium in the electric fluid, but no person has yet assigned a more probable cause of the redundancy of electric matter which, in fact, often abounds in the clouds, than what we may suppose possible to take place in the bowels of the earth. And supposing the loss of the equilibrium possible, the same cause that produced the effect would prevent the restoring of it; so that not being able to force a way, at least one sufficiently ready, through the body of the earth, it would issue at the most convenient vent into the higher regions of the air, as the better passage. His electrical apparatus, though communicating with the earth, has frequently, in violent thunder-storms, given evident sparks to his finger.

In the enumeration of the effects of thunder-storms, he observes that a wind always blows from the place from which the thunder-cloud proceeds; that this is agreeable to the observations of all mariners, and that the wind is more or less violent in proportion to the suddenness of the appearance of the thunder-cloud, the rapidity of its expansion, and the velocity with which the adscitious clouds join it. The sudden condensation of such a prodigious quantity of vapours must displace the air, and repel it on all sides.

He, in some measure, imitated even this effect of thunder, at least produced a circulation of all the air in his room, by the continued electrification of his chain.

Among other effects of lightning, he mentions the case of a man rendered exceeding stiff, presently after he was struck dead in a storm of thunder. But the most remarkable circumstance, in this case, was the lightning (ch-  
line

sing the best conductor) having struck one particular vein, near his neck, and followed it through its minutest ramifications; so that the figure of it appeared through the skin, finer than any pencil could have drawn it.

He cautions persons not to depend upon the neighbourhood of a higher, or, in all cases, a better conductor than their own body; since, according to his repeated observations, the lightning by no means descends in one undivided track, but bodies of various kinds conduct their share of it, at the same time, in proportion to their quantity and conducting power.

A great number of observations, relating to the descent of lightning, confirm his theory of the manner of its ascent: for, in many cases, it throws before it the parts of conducting bodies, and distributes them along the resisting medium through which it must force its passage.

Upon this principle it is, that the longest flashes of lightning seem to be made by its forcing into its way part of the vapours in the air. One of the principal reasons why those flashes make so long a rumbling, is their being occasioned by the vast length of a vacuum, made by the passage of the electric matter. For though the air collapses the moment after it has passed, and the vibration (on which the sound depends) commences at the same moment, through the whole length of the track; yet, if the flash was directed towards the person who hears the report, the vibrations excited at the nearer end of the track will reach his ear much sooner than those excited at the more remote end; and the sound will, without any repercussion or echo, continue till all the vibrations have successively reached him.

He thinks that the Aurora Borealis may be this electric matter performing its circulation, in such a state of the atmosphere as renders it visible, or approaching nearer to the earth than usual.

Stones and bricks struck by lightning are often vitrified. He supposes that some stones in the earth having been struck in this manner first gave occasion to the vulgar opinion of the thunder-bolt.

Signior Beccaria was very sensible that heat contributes much to the phenomena of thunder, lightning, and rain; but he could not find, by any experiment, that it tended to promote electricity. He therefore rather thought that heat operated, in this case, by exhaling the moisture of the air, and thereby cutting off the communication of the electric fluid between one place and another, particularly between the earth and the higher regions of the air, whereby its effects were more visible.

*Method of securing buildings and persons from the effects of lightning.*

EXPERIMENTS made in electricity first gave philosophers a suspicion that the matter of lightning was the same with the electric matter. Experiments afterwards made on lightning obtained from the clouds by pointed rods, received into bottles, and subjected to every trial, have since proved this suspicion to be perfectly well founded; and that whatever properties we find in electricity, are also the properties of lightning.

This matter of lightning, or of electricity, is an extreme subtle fluid, penetrating other bodies, and subtilizing in them equally diffused.

When by any operation of art or nature, there happens to be a greater proportion of this fluid in one body than in another, the body which has most, will communicate to that which has least, till the proportion becomes equal; provided the distance between them be not too great; or, if it is too great, till there be proper conductors to convey it from one to the other.

If the communication be through the air without any conductor, a bright light is seen between the bodies, and a sound is heard. In our small experiments we call this light and sound the electric spark and snap; but in the great operations of nature, the light is what we call *lightning*, and the sound (produced at the same time, though generally arriving later at our ears than the light does to our eyes) is, with its echoes, called *thunder*.

If the communication of this fluid is by a conductor, it may be without either light or sound, the subtle fluid passing in the substance of the conductor.

If the conductor be good and of sufficient bigness, the fluid passes through it without hurting it. If otherwise, it is damaged or destroyed.

All metals, and water, are good conductors.—Other bodies may become conductors by having some quantity of water in them, as wood, and other materials used in building, but not having much water in them, they are not good conductors, and therefore are often damaged in the operation by lightning.

Glass, wax, silk, wool, hair, feathers, and even wood, perfectly dry, are non-conductors: that is, they resist instead of facilitating the passage of this subtle fluid.

When this fluid has an opportunity of passing through two conductors, one good and sufficient, as of metal, the other not so good, it passes in the best, and will follow it in any direction.

The distance at which a body charged with this fluid will discharge itself suddenly, striking through the air into another body that is not charged, or not so highly charged, is different according to the quantity of the fluid, the dimensions and form of the bodies themselves, and the state of the air between them.—This distance, whatever it happens to be between any two bodies, is called their *striking distance*, as till they come within that distance of each other, no stroke will be made.

The clouds have often more of this fluid in proportion than the earth; in which case as soon as they come near enough (that is, within the striking distance) or meet with a conductor, the fluid quits them and strikes into the earth. A cloud fully charged with this fluid, if so high as to be beyond the striking distance from the earth, passes quietly without making any noise or giving light; unless it meets with other clouds that have less.

Tall trees, and lofty buildings, as the towers and spires of churches, become sometimes conductors between the clouds and the earth; but not being good ones, that is, nor conveying the fluid freely, they are often damaged.

Buildings that have their roofs covered with lead, or other metal, and spouts of metal continued from the roof into

in to the ground to carry off the water, are never hurt by lightning, as whenever it falls on such a building, it passes in the metals and not in the walls.

When other buildings happen to be within the striking distance from such clouds, the fluid passes in the walls, whether of wood, brick or stone, quitting the walls only when it can find better conductors near them, as metal rods, bolts, and hinges of windows or doors, gilding on wainscot, or frames of pictures; the silvering on the backs of looking-glasses; the wires for bells; and the bodies of animals, as containing watry fluids. And in passing thro' the house it follows the direction of these conductors, taking as many in its way as can assist it in its passage, whether in a strait or crooked line, leaping from one to the other, if not far distant from each other, only rending the wall in the spaces where these partial good conductors are too distant from each other.

An iron rod being placed on the outside of a building, from the highest part continued down into the moist earth, in any direction strait or crooked, following the form of the roof or other parts of the building, will receive the lightning at its upper end, attracting it so as to prevent its striking any other part; and, affording it a good conveyance into the earth, will prevent its damaging any part of the building.

A small quantity of metal is found able to conduct a great quantity of this fluid. A wire no bigger than a goose quill has been known to conduct (with safety to the building as far as the wire was continued) a quantity of lightning that did prodigious damage both above and below it; and probably larger rods are not necessary, tho' it is common to make them of half an inch, some of three quarters, or an inch diameter.

The rod may be fastened to the wall, chimney, &c. with staples of iron.—The lightning will not leave the rod (a good conductor) to pass into the wall (a bad conductor) through those staples.—It would rather, if any were in the wall, pass out of it into the rod to get more readily by that conductor into the earth.

If the building be very large and extensive, two or more rods may be placed at different parts, for greater security.

Small ragged parts of clouds suspended in the air between the great body of clouds and the earth (like leaf-gold in electrical experiments), often serve as partial conductors for the lightning, which proceeds from one of them to another, and by their help comes within the striking distance to the earth or a building. It therefore strikes through those conductors a building that would otherwise be out of the striking distance.

Long sharp points communicating with the earth, and presented to such parts of clouds, drawing silently from them the fluid they are charged with, they are then attracted to the cloud, and may leave the distance so great as to be beyond the reach of striking.

It is therefore that we elevate the upper end of the rod six or eight feet above the highest part of the building, tapering it gradually to a fine sharp point, which is gilt to prevent its rusting.

Thus the pointed rod either prevents a stroke from the

cloud, or, if a stroke is made, conducts it to the earth with safety to the building.

The lower end of the rod should enter the earth so deep as to come at the moist part, perhaps two or three feet; and if bent when under the surface so as to go in a horizontal line six or eight feet from the wall, and then bent again downwards three or four feet, it will prevent damage to any of the stones of the foundation.

A person apprehensive of danger from lightning, happening during the time of thunder to be in a house not so secured, will do well to avoid sitting near the chimney, near a looking-glass, or any gilt pictures or wainscot; the safest place is in the middle of the room, (so it be not under a metal lustre suspended by a chain), sitting in one chair and laying the feet up in another. It is still safer to bring two or three mattresses or beds into the middle of the room, and folding them up double, place the chair upon them; for they not being so good conductors as the walls, the lightning will not chuse an interrupted course through the air of the room and the bedding, when it can go thro' a continued better conductor, the wall. But where it can be had, a hammock or swinging bed, suspended by silk cords equally distant from the walls on every side, and from the ceiling and floor above and below, affords the safest situation a person can have in any room whatever; and what indeed may be deemed quite free from danger of any stroke by lightning.

In order to secure ships from sustaining damage by lightning, a copper rod, about the thickness of a goose quill, should be connected with the spindles and iron work of the masts continued down to the deck, and from thence, in the most convenient direction, till the end of the rod be always in contact with the sea-water.

With regard to powder-mills and magazines, the apparatus to conduct the lightning from them should be detached from the buildings themselves, and conveyed to the nearest water.

#### *Of Medical Electricity.*

THE first application of electricity to the cure of diseases was made by M. Jallabert, professor of philosophy at Geneva, on a locksmith whose right arm had been paralytic fifteen years. He was brought to M. Jallabert on the 26th of December 1747, and was completely cured by the 28th of February 1748. In this interval he was frequently electrified, sparks being taken from the arm, and sometimes the electrical shock sent through it.

The report of this cure at Geneva, engaged Mr Sauvages of the academy in Montpellier to attempt the cure of paralytics, in which he had considerable success.

In the year 1757, Mr Patrick Bryden, in a few days, performed a complete cure of a hemiplegia, and indeed an almost universal paralytic affection of two years continuance.

Dr Hart, Dr Wilson, Mr Lover, Mr Wesley, and many others, relate a number of cases wherein the palsy was either cured or mitigated by electricity.

Dr Watson cured an universal tetanus, in the year 1762, by electrifying the patient, at proper intervals, for three months.

Dr

Dr Franklin and others mention some paralytic cases, in which electricity seemed rather to make the patient worse than better.

Mr Wilson cured a woman of a deafness of seventeen years standing.—And Mr Lovet considers electricity as a specific in all cases of violent pains, obstinate headaches, the sciatica, and the cramp. The toothach, he says, is generally cured by it in an instant. He relates a case, from Mr Floyer surgeon at Dorchester, of a complete cure of a gutta serena; and another of obstinate obstructions in two young women.

De Haen says, that he never failed to cure St Vitus's dance by electricity; and found it of use in some cases of deafness.

Hitherto electricity has been generally applied to the human body either in the method of drawing sparks, as it

is called, or of giving shocks. But these operations are both violent, and though the strong concussion may suit some cases, it may be of disservice in others, where a moderate simple electrification might have been of use.

The great objection to this method is the tediousness and expence of the application. But an electrical machine might be contrived to go by wind or water, and a convenient room might be annexed to it; in which a floor might be raised upon electrics, a person might sit down, read, sleep, or even walk about during the electrification. It were to be wished, that some physician of understanding and spirit would provide himself with such a machine and room. No harm could possibly be apprehended from electricity, applied in this gentle and insensible manner, and good effects are at least possible, if not highly probable.

## E L E

**ELECTRUM**, in natural history. See **AMBER**.

**ELECTUARY**, in pharmacy, a form in which both official and extemporaneous medicines are frequently made.

It may be considered as a number of boluses united together, but is made somewhat softer by an addition of a due proportion of preserves or syrups. When the consistence is very soft, it is called sometimes by the name of opiata.

The principal consideration in prescribing official electuaries is, that such things only be put together as will not, by any opposite qualities, destroy one another, or lose their natural properties by lying long in this manner; and likewise that the whole be of a consistence that will hold ingredients of different gravities in equal mixture.

**ELEEMOSYNÆ**, and **ELEEMOSYNARIUS**. See **ALMS**, and **ALMONER**.

**ELEGANCE**, or **ELEGANCY**, an ornament of politeness and agreeableness shewn in any discourse, with such a choice of rich and happy expressions, as to rise politely above the common manners, so as to strike people of a delicate taste.

It is observed that elegance, though irregular, is preferable to regularity without elegance: that is, by being so scrupulous of grammatical construction, we lose certain licences wherein the elegance of language consists.

**ELEGIAC**, in ancient poetry, any thing belonging to elegy. See **ELEGY**.

Elegiac verses are alternately hexameter and pentameter, as in the following verses of Ovid. See **HEXAMETER**.

*Flebilis indignas, elegia, solve capillis:  
Ab nimis ex vero nunc tibi nomen erit.*

Who was the inventor of elegiac poetry is not known. Horace professes himself quite ignorant of it. The principal writers of elegiac verse, among the Latins, were Propertius, Ovid, and Tibullus, the latter whereof Quintilian esteems the best elegiac poet; but Pliny the younger gives the preference to the first: the  
Vol. II. No 46.

2

## E L E

chief writers of elegy among the Greeks were Callimachus, Parthenius, and Euphoriion.

**ELEGIT**, in law, a writ of execution, which lies for a person who has recovered debt or damages; or upon a recognizance in any court, against a defendant that is not able to satisfy the same in his goods.

**ELEGY**, a mournful and plaintive kind of poem. See **ELEGIAC**.

As elegy, at its first institution, was intended for tears, it expressed no other sentiments, it breathed no other accents but those of sorrow: with the negligence natural to affliction, it sought less to please than to move; and aimed at exciting pity, not admiration. By degrees, however, elegy degenerated from its original intention, and was employed upon all sorts of subjects, gay or sad, and especially upon love. Ovid's book of Love, the poems of Tibullus and Propertius, notwithstanding they are termed elegies, are sometimes so far from being sad, that they are scarce serious. The chief subjects then to which elegy owes its rise, are death and love: that elegy therefore ought to be esteemed the most perfect in its kind which has somewhat of both at once; such, for instance, where the poet bewails the death of some youth or damsel falling a martyr to love.

**ELEMENT**, a term used by philosophers to denote the original component parts of bodies, or those into which they are ultimately resolvable. See **CHEMISTRY**, Vol. II. p. 66.

**ELEMENT**, in a figurative sense, is used for the principles and foundations of any art or science, as Euclid's Elements, &c.

**ELEMI**, or **ELEMV**, in the materia medica, a kind of resin, very improperly called gum elemi. There are two sorts of it kept in the shops; the one genuine, and brought from Ethiopia; the other spurious, and the produce of America. The true kind is a yellowish resin, with a cast of green and white; its smell is acrid and pleasant, and its taste acrid and bitter. It is very inflammable, and readily dissolves in oil and other fat substances over the fire; which two characters alone

†

; F

lone

lone sufficiently distinguish it from the gums: but this genuine elemi is very rare in Europe.

The spurious elemi is a whitish resin, produced from a tall tree, with pinnated leaves, not unlike those of the pear-tree. It is in some degree pellucid, and of a fragrant smell. It is only used externally, being greatly recommended for resolving tumours, deterring ulcers, wounds, &c.

**ELENCHUS**, in logic, a sophism, or fallacious argument, which deceives the hearer under the appearance of truth. See **SOPHISM**.

**ELEPHANT**, in zoology. See **ELEPHAS**.

*Knights of the ELEPHANT*, an order of knighthood in Denmark, conferred upon none but persons of the first quality and merit. It is also called the order of St Mary. Its institution is said to have been owing to a gentleman among the Danish croisees having killed an elephant, in an expedition against the Saracens, in 1184; in memory of which king Canutus instituted this order, the badge of which is a towered elephant, with an image of the holy virgin encircled with rays, and hung on a watered sky-coloured ribbon, like the George in England.

**ELEPHANTIASIS**, called also the lepra of the Arabians, in medicine, a chronical disease, one of the two species of leprosy, which affects the whole body, where even the bones as well as the skin are covered with spots and tumours, which being red, at last turn black. See **MEDICINE**.

**ELEPHANTINE**, in Roman antiquity, an appellation given to the books wherein were registered the transactions of the senate and magistrates of Rome, of the emperors or generals of armies and even of the provincial magistrates; the births and classes of the people, and other things relating to the census.

They are supposed to have been so called as being made of ivory; though some will have them to have been written on the intestines of elephants.

**ELEPHANTOPUS**, in botany, a genus of the syngenesia polygamia segregata class. The receptacle is naked; the corolla is divided into five segments; the calix is imbricated; and the pappus has several aristæ. There are two species, both natives of the Indies.

**ELEPHAS**, or the **ELEPHANT**, in zoology, a genus of quadrupeds belonging to the order of bruta. The characters are these: The elephant has no fore-teeth in either jaw, and the dog-teeth are very long: The proboscis, or trunk, is long, and capable of laying hold of any thing; and the body is somewhat naked.

The elephant is the largest of all land-animals. From the front to the origin of the tail he is generally about 16 feet long, from the end of the trunk 25 feet, and about 14 feet high. The circumference of the neck is 17 feet, and the circumference of the body at the grossest part 25 feet 10 inches; the tail is about 6 feet long, and 2½ in circumference. The circumference of the legs is about 6 feet. The eyes are small in proportion to the size of the animal. The muzzle is very different from that of any other quadruped; it is nothing but the origin of a long trunk which hangs

between the two large tusks; the mouth appears behind the trunk, which serves in place of an upper lip and the under lip terminates in a point. The tail is short, and small in comparison of the trunk, which has the appearance of a long thick tail placed before. The feet are short, round, clumsy, and only distinguishable by the toes. The trunk is, properly speaking, the nose extended, and terminated by a couple of nostrils. But, besides serving as an organ of smell, the trunk performs all the functions of a strong and dextrous arm. The trunk of an elephant is about 8 feet long, 5½ feet in circumference near the mouth, and one foot and a half near the extremity: It is a pipe of an irregular conical figure, and widened at the end: The superior side of the trunk is convex, and furrowed transversely; and the inferior side is flat, and has two longitudinal rows of small protuberances resembling the tentacula of the silk-worm and most other caterpillars. The upper part of the trunk corresponds with the extremity of the nose in other quadrupeds, and answers the same intention; the inferior part serves as an upper lip, including the nostrils at the same time; for the trunk is a continued canal, divided into two cavities by a longitudinal partition; these cavities ascend along the forepart of the upper jaw, where they make a turn inward and descend into the palate, and then terminate in two separate orifices; they have likewise each a separate orifice at the end of the trunk. At the place where these cavities make a turn, and before they enter into the bones of the head, there is a moveable cartilaginous plate situate in such a manner as enables the elephant to shut the canal, and to prevent the water with which it occasionally fills the trunk from entering into the passage of the nose where the organs serving for the sensation of smell are placed. The elephant can move the trunk in all directions; he can extend or shorten it at pleasure, without altering the diameters of the two canals within. By this means respiration is not interrupted, whatever be the situation of the trunk; and the water is allowed to remain till the animal chuses to throw it out by an expiration. Each canal is lined with a smooth strong membrane, and the surface of the trunk is covered with another strong membrane or skin. The substance contained between the exterior and interior membranes, is a composition of longitudinal and transverse muscles, which serve to extend and contract the length of the trunk. At the extremity of the trunk there is a concave protuberance, in the bottom of which are the two passages of the nostrils. The inferior part of the protuberance is thicker than the sides, and the superior part is stretched out like a finger about five inches long; which, together with the edges of the whole extremity of the trunk, takes on different figures according to the necessities of the animal. It is by this organ that the animal lays hold of food, or other substances, which he manages with as much dexterity as a man does his hand, taking up grains of corn, or the smallest piles of grass, and conveying them to his mouth. When he drinks, he thrusts his trunk into the water, and fills it by drawing in his breath, and exhausting the air: When

When the trunk is thus filled with water, he can either throw it out to a great distance, or drink it by putting the end of the trunk in his mouth.

The two large tusks, which some call the horns of the elephant, are of a yellowish colour, and extremely hard. The bony substance of which they are composed is known by the name of ivory, and much used in different branches of manufacture.

The ears are very large, and resemble those of an ape. The skin of the elephant has but few hairs on it, and placed at great distances from each other. It is full of wrinkles, like those on the palm of a man's hand, besides many chaped and grealy ridges. The female has two dugs, one on each side of the breast. The parts of generation are small in proportion to those of other animals. The penis resembles that of a horse. The female organ is situate near the middle of the belly, more than two feet distant from the usual situation in other quadrupeds: When they copulate, the female lies down on her back.

Elephants, even in a savage state, are peaceable and gentle creatures. They never use their weapons but in defence of themselves or companions. Their social dispositions are so strong, that they are seldom found alone, but march always in large troops; the oldest and most experienced lead the van; the younger, or lame ones, keep in the middle; and those of a second rate, as to age, walk in the rear. The females carry their young on their tusks, embracing them at the same time with their trunk. They seldom march in this regular order but when they reckon the journey dangerous, such as an expedition to cultivated lands, where they expect to meet with resistance. On other occasions they are less cautious. Some of them falling behind or separating from the rest, but seldom so far as to be without the reach of assistance by alarming and assembling their companions. It is only these wanderers that the hunters dare attack; for it would require a whole army to assail a troop of them; and even an army would be unable to conquer them without losing a number of lives. It is dangerous to offer them the least injury; for they run straight upon the offender; and, although the weight of their body be great, their steps are so large, that they easily outrun the swiftest man, whom they either pierce with their tusks or seize with their trunk, dart him in the air like a stone, and then trample him under their feet. But they never attack any person, unless when provoked. However, as they are extremely sensible and delicate with regard to injuries, it is always prudent to keep out of their way. Travellers who frequent these countries kindle large fires, and beat drums during the night, in order to prevent their approach. After being once attacked by men, or falling into any ambush, they are said never to forget the injury, but search for every opportunity of getting revenge. As they are endowed perhaps with a more exquisite sensation of smell than any other animal, owing to the great extent of their nose, they can scent a man at a very great distance, and trace him by his footsteps.

Elephants are peculiarly fond of the banks of rivers,

deep valleys, and marshy grounds, especially when well shaded with trees. They delight in drawing up water into their trunks, even when they do not drink it, and amuse themselves in dashing the water around. They cannot endure cold, and are equally averse to an excess of heat: In order to avoid the scorching heat of the sun, they retire to the thickest and most shady parts of the forest. The bulk of their bodies is so enormous, that they do not chuse to go into deep waters so frequently as some other quadrupeds; although the length of their trunk, which they raise straight up, and by which they respire, is a great advantage in swimming.

The ordinary food of elephants is roots, herbs, leaves, the tender branches of trees, fruits, and grains: but they abhor flesh or fish. When any of them discovers a fine pasture, he immediately calls and invites his companions to come and eat with him. As they devour a large quantity of food in a short time, they are always shifting their pasture; when they meet with cultivated grounds, they make a prodigious desolation, and destroy more plants by their feet than they use for nourishment, which is very considerable, amounting to 150 pounds of herbage every day: by this means, as they constantly graze in large troops, they lay waste whole fields in an hour. The Indians and negroes employ every art to prevent them from visiting their cultivated lands, making great noise, and burning large fires round their fields. However, these precautions are not always sufficient to prevent the elephants from visiting them. They chase away the domestic animals, put the men to flight, and sometimes even throw down their limber huts. Elephants are hardly susceptible of fear; the only things which can surprise them, or stop their course, are artificial fires, such as squibs, crackers, &c the effects of which are so sudden and so quickly repeated, that the elephants frequently turn back; and when one runs, all the rest instantly follow his example.

Although the social disposition in the elephant be exceeding strong; yet whenever the females come in season, it immediately gives place to the stronger and more interesting passion of love. They observe the greatest delicacy in their amours, abhorring nothing so much as to be seen by their companions. The troop divide themselves into couples. steal off into the most secret places of the forest, and then give way to all the impulses of nature, which are lively and lasting in proportion to the long period of abstinence; for the female goes with young two years, and it is only once in three years that the season of love returns. They bring forth but one at a time, which, as soon as it comes into the world, is as large as a wild boar, and is furnished with teeth; however, the large tusks do not make their appearance till some time after, and at the age of six months they are several inches long. Elephants of this age are as large as an ox, when in a natural state. But it is incredible how they degenerate when enslaved and under the management of men. Their disgust and chagrine for the loss of liberty seems never to depart from their minds. In this state, though they feel, at the proper seasons, the

the strongest desires for the sex, no art can allure them to copulate: but the natural passion, restrained by an excess of modesty, bursts out into such violent fits of fury and resentment, that the strongest chains are hardly sufficient to command them. This is a striking difference betwixt the elephant and most other tamed animals. It is only the individual that we can enslave; the species, in spite of all our endeavours, still retain their original freedom and independence.

The manner of taking and taming the elephant, therefore, merits our attention. In forests and such places as are frequented by elephants, the Indians chuse a spot and inclose it with strong pallisades; they use the largest trees as the principal stakes, to which are fixed smaller ones in a transverse direction. These cross-trees are fixed so as to allow a man to pass easily through. There is likewise a large port left for the elephant, over which is suspended a strong barrier, which is let down as soon as he enters. In order to decoy him into the inclosure, the hunters take along with them a tame female in season, and travel about till they come so near as that the cry of the female can reach a male, whom they previously observe in the forest; then the guide of the female makes her give the cry peculiar to the season of love: the male instantly replies, and sets out in quest of her. The guide then makes the female proceed toward the artificial inclosure, repeating her cries from time to time as she goes along. She enters into the inclosure, the male follows her, and the Indians immediately shut the port behind him. He no sooner discovers the hunters, and that he is inclosed, than his passion for the sex is converted into rage and fury. The hunters entangle him with strong ropes; they fetter his legs and trunk; they bring two or three tame elephants in order to pacify and reconcile him to his condition. In a word, they reduce them to obedience in a few days, by a proper application of torture, and caresses. There are many other methods of catching elephants. Instead of making large inclosures with pallisades, like the kings of Siam, and other monarchs, the poor Indians content themselves with a very simple apparatus: they dig deep pits in the roads frequented by elephants, covering them over with branches of trees, turf, &c. When an elephant falls into one of these pits, he is unable to get out again.

The elephant, when tamed, is the most friendly and obedient of all animals: he is entirely attached to the person who feeds and takes care of him. In a short time he understands signs, and the sound of his master's voice. He distinguishes the language of passion, of command, of satisfaction, and acts accordingly. He receives his orders with attention, and executes them with prudence and alacrity, but without precipitation. He easily learns to bow his knees and lower his body, for the convenience of those who mount him. He caresses his friends with his trunk. He lifts burdens with his trunk, and assists those who are loading him in laying them on his back. He delights in shining harness and trappings. When yoked in a cart or waggon, he pulls equally and cheerfully, unless he be a-

bused by injudicious chastisements. His guide is generally mounted on his neck, with a small rod of iron sharp at the point in his hand; he directs his motion by pricking him on the ears and head; but, for the most part, a word is sufficient.

A tame elephant will do more labour than six horses; but then he requires a proportional quantity of food. They are the principal beasts of burden in many parts of Africa and the East Indies. They carry sacks and bundles of all kinds on their neck, back, and tusks. They never lose or damage any thing committed to their care: They will stand on the edge of a river, take bundles off their necks and tusks, lay them carefully in a boat wherever they are desired, and try with their trunk whether they are properly situate; if they be loaded with casks, they go in quest of stones to prop them and prevent them from rolling.

From the earliest accounts in history, the eastern nations have employed elephants in war; Alexander the Great was the first European who ever mounted an elephant. He carried a number of them into Greece, which Pyrrhus employed some years after against the Romans at the battle of Tarentum. Both the Greeks and Romans soon learnt to get the better of these monstrous animals, they opened their ranks and allowed them to pass through; neither did they attempt to hurt them, but threw darts, &c. at their guides. Now that fire-arms are the principal instruments of war, elephants, who are terrified at the noise and flame, instead of being useful, would only tend to embarrass and confuse an army. However, in Cochin and other parts of Malabar, as also in Tonquin, Siam, and Pegu, where fire-arms are little understood, they are still used in battle. The guide sits astride upon the neck, and the combatants sit or stand upon the other parts of the body.

When the elephant is properly managed, he lives very long even in a state of slavery and labour. That some have lived in this state 120 years, is pretty well authenticated. In a natural state, they often exceed 200 years, and propagate their species till they be 120: It is 30 years before they come to their full growth. [Plate LXXIV. fig. 3.]

ELEVATION, the same with altitude or height. See ALTITUDE.

ELEVATION of the host, in the church of Rome, that part of the mass where the priest raises the host above his head for the people to adore. See MASS and HOST.

ELEVATOR, in anatomy, the name of several muscles, so called from their serving to raise the parts of the body to which they belong. See ANATOMY, Part II.

ELEVATORY, in surgery, an instrument for raising depressed or fractured parts of the skull, to be applied after the integuments and periosteum are removed. See SURGERY.

ELEUSINIA, in Grecian antiquity, a festival kept in honour of Ceres, every fourth year by some states, but by others every fifth. The Athenians celebrated it at Eleusis, a town of Attica, whence the name.

It was celebrated with a world of ceremony, and persons of both sexes were initiated in it; it being deemed

deemed impious to neglect doing so. The mysteries were of two sorts, the lesser, and the greater; whereof the former were sacred to Proserpine, Ceres's daughter, and the latter to Ceres herself. According to Lactantius, they consisted in a mythical representation of what mythologists teach of Ceres; though some of the Christian fathers will have the great mystery, or secret, which they were forbidden by law, upon pain of death, to divulge, to have been the representation or figures of both male and female privities, which were handed about and exposed to the company.

**ELEUTHERIA**, another festival celebrated at Platæa, by delegates from almost all the cities of Greece, in honour of Jupiter Eleutherius, or the assertor of liberty.

It was instituted in memory of the victory obtained by the Grecians, in the territories of Platæa, over Mardonius, the Persian general, left by Xerxes with a mighty army to subdue Greece.

**ELF**, a term now almost obsolete, formerly used to denote a fairy, or hobgoblin, an imaginary being, the creature of ignorance, superstition, and craft. See **FAIRY**.

**ELF-ARROWS**, in natural history, a name given to the flints, anciently fashioned into arrow-heads, and still found fossil in Scotland, America, and several other parts of the world; they are believed by the vulgar to be shot by fairies, and that cattle are sometimes killed by them.

**ELGIN**, the capital of the county of Murray, in Scotland, situated on the river Lossy, about six miles north of the Spey: W. long.  $2^{\circ} 25'$ , N. lat.  $57^{\circ} 40'$ .

**ELIQUATION**, in metallurgy, a separation of the different parts of mixed bodies, by the different degrees of fire required to melt them. See **CHEMISTRY**.

**ELISION**, in grammar, the cutting off, or suppressing a vowel at the end of a word, for the sake of sound, or measure, the next word beginning with a vowel.

Elisions are pretty frequently met with in English poetry, but more frequently in the Latin, French, &c. They chiefly consist in suppressions of the *a*, *e*, and *i*, though an elision suppresses any of the other vowels.

**ELIXATION**, in pharmacy, the extracting the virtues of ingredients by boiling or stewing.

**ELIXIR**, in medicine, a compound tincture extracted from many efficacious ingredients. Hence the difference between a tincture and an elixir seems to be this, that a tincture is drawn from one ingredient, sometimes with an addition of another to open it, and to dispose it to yield to the menstruum; whereas an elixir is a tincture extracted from several ingredients at the same time. See **TINCTURE**.

**ELK**, in zoology. See **CERVUS**.

**ELKHOLM**, a port-town of Gothland, in Sweden, twenty-four miles west of Carelskroon.

**ELL**, a measure of length, different in different countries; but those mostly used, are the English and Flemish ells; whereof the former is three feet nine inches, or one yard and a quarter; and the latter only twenty-seven inches, or three quarters of a yard. In Scotland, the ell contains  $37 \frac{1}{8}$  English inches.

**ELLERENA**, a town of Estremadura, in Spain, fifty miles south east of Merida.

**ELLIPSIS**, in geometry. See **CONIC SECTIONS**.

**ELLIPSIS**, in grammar, a figure of syntax, wherein one or more words are not expressed; and from this deficiency, it has got the name ellipsis.

The ellipsis, properly so called, is when the deficient word or words must be supplied from elsewhere; as *Hectoris Andromache*, where *uxor* is understood; that is, Andromache, Hector's wife.

**ELLIPTIC**, or **ELLIPTICAL**, something belonging to an ellipsis.

**ELLIPOMACHROSTYLA**, in natural history, a genus of imperfect crystals, with single pyramids; one end of their column being affixed to some solid body. They are dodecahedral, with thinner hexangular columns and hexangular pyramids.

Of these crystals, authors enumerate a great many species; among which are the whitish pellucid sprig crystal, a bright brown kind, a dull brown kind, and a bright yellow kind, all which are farther distinguished according to the different lengths of their pyramids.

**ELLIPOPACHYSTYLA**, in natural history, a genus of imperfect crystals, composed of twelve planes, in an hexangular column, terminated by an hexangular pyramid at one end, and irregularly affixed to some other body at the other, with shorter columns.

There are two species of these crystals, one short, bright and colourless, found in great plenty in New Spain and other parts of America; the other, a short, dull, and dusky brown one, found in Germany, and sometimes in England.

**ELM**, in botany. See **ULMUS**.

**ELNA**, a town of Catalonia in Spain, but subject to France, situated ten miles south of Perpignan.

**ELOCUTION**, in rhetoric, the adapting words and sentences to the things or sentiments to be expressed. It consists of elegance, composition, and dignity. The first comprehending the purity and perspicuity of a language, is the foundation of elocution; the second ranges the words in proper order; and the last adds the ornaments of tropes and figures to give strength and dignity to the whole.

**ELODES**, in botany. See **HYPERICUM**.

**ELOGY**, a praise or panegyric bestowed on any person or thing, in consideration of its merit. The beauty of elogy consists in an expressive brevity. Eulogiums should not have so much as one epithet, properly so called, nor two words synonymous; they should strictly adhere to truth; for extravagant and improbable eulogies rather lessen the character of the person or thing they would extol.

**ELOINED**, in law, signifies restrained or hindered from doing something: thus it is said, that if those within age be eloined, so that they cannot sue personally, their next friend shall sue for them.

**ELONGATION**, in astronomy, the digression or recess of a planet from the sun, with respect to an eye placed on our earth. See **ASTRONOMY**.

**ELONGATION**, in surgery, is an imperfect luxation, occasioned by the stretching or lengthening of the ligaments of any joint.

**ELOPEMENT**, in law, is where a married woman de-

parts from her husband, and cohabits with an adulterer; in which case the husband is not obliged to allow her any alimony out of his estate, nor is he chargeable for necessaries for her of any kind.

**ELOPS**, in ichthyology a genus of the order of abdominales. The head is smooth, and the teeth are in the margin of the jaws and the palate; there are thirty rays in the branchiostegic membrane. There is but one species, *viz.* the favrus, with a tail armed both above and below. It is a native of Carolina.

**ELOQUENCE**, the art of speaking well, so as to affect and persuade.

Cicero defines it, the art of speaking with copiousness and embellishment.

Eloquence and rhetoric differ from each other, as the theory from the practice; rhetoric being the art which describes the rules of eloquence, and eloquence that art which uses them to advantage.

**ELSINORE**, a port-town of Denmark, about twenty-two miles north of Copenhagen, and situated on the Sound or the entrance into the Baltic sea.

**ELVAS**, a city and bishop's see of Alentejo, in Portugal, situated near the frontiers of Spanish Estremadura: W. long.  $7^{\circ} 35'$ , and N. lat.  $38^{\circ} 45'$ .

It is one of the strongest fortresses in Portugal.

**ELUL**, in ancient chronology, the twelfth month of the Jewish civil year, and the sixth of the ecclesiastical: it consisted of only twenty-nine days, and answered pretty nearly to our August.

**ELUTRIATION**, the separating the lighter matters from the mixt ores of metals, by means of great quantities of fair water. See **CHEMISTRY**.

**ELY**, a city and bishop's see of Cambridgeshire, situated about twelve miles north of Cambridge: E. long.  $15'$ , and N. lat.  $52^{\circ} 24'$ .

It is a county of itself, including the territory around, and has a judge who determines all causes civil and criminal within its limits.

**ELYMUS**, in botany, a genus of the tetrandria digynia class. The involucre consists of two leaves; and the spiculae are double. There are eight species, only one of which, *viz.* the arenarius, or sea lyme-grass, is a native of Britain.

**ELYSIUM**, or **ELYSIAN FIELDS**, in heathen mythology, certain plains abounding with woods, fountains, verdure, and every delightful object; supposed to be the habitation of heroes and good men after death.

According to some, the fable of Elysium is of Phœnician extraction, or rather founded upon the account of paradise delivered in the Scriptures.

**ELYTROIDES**, or **VAGINALES**, in anatomy. See Vol. I. p. 270.

**EMANATION**, the act of flowing or proceeding from some source or origin; or, the thing that proceeds from that action.

**EMANCIPATION**, in the Roman law, the setting free a son from the subjection of his father; so that whatever moveables he acquires belong in property to him, and not to his father as before emancipation.

Emancipation puts the son in capacity of managing his own affairs, and of marrying without his father's

consent, though a minor. Emancipation differs from manumission, as the latter was the act of a master in favour of a slave, whereas the former was that of a father in favour of his son.

There were two kinds of emancipation; the one tacit, which was by the sons being promoted to some dignity, by his coming of age, or by his marrying, in all which cases he became his own master of course.

The other, express; where the father declared before a judge, that he emancipated his son. In performing this, the father was first to sell his son imaginarily to another, whom they called *pater fiduciarius*, father in trust, of whom being bought back again by the natural father, he manumitted him before the judge by a verbal declaration.

Emancipation still obtains in France with regard to minors or pupils, who are hereby set at liberty to manage their own effects, without the advice or direction of their parents or tutors.

**EMARGINATED**, amongst botanists. See Vol. I. p. 640.

**EMASCULATION**, the act of castrating or depriving a male of those parts which characterise his sex. See **CASTRATION**.

**EMBALMING**, is the opening a dead body, taking out the intestines, and filling the place with odoriferous and desiccative drugs and spices, to prevent its putrifying. The Egyptians excelled all other nations in the art of preserving bodies from corruption; for some that they have embalmed upwards of two thousand years ago, remain whole to this day, and are often brought into other countries as great curiosities. Their manner of embalming was thus: they scooped out the brains with an iron scoop, out at the nostrils, and threw in medicaments to fill up the vacuum: they also took out the entrails, and, having filled the body with myrrh, cassia, and other spices, except frankincense, proper to dry up the humours, they pickled it in nitre, where it lay soaking for seventy days. The body was then wrapped up in bandages of fine linen and gums, to make it stick like glue, and so was delivered to the kindred of the deceased, entire in all its features, the very hairs of the eye-lids being preserved. They used to keep the bodies of their ancestors, thus embalmed, in little houses magnificently adorned, and took great pleasure in beholding them, alive as it were, without any change in their size, features, or complexion. The Egyptians also embalmed birds, &c. The prices for embalming were different; the highest was a talent, the next twenty minæ, and so decreasing to a very small matter: but they who had not wherewithal to answer this expence, contented themselves with infusing, by means of a syringe, thro' the fundament, a certain liquor extracted from the cedar, and leaving it there wrapped up the body in salt of nitre: the oil thus preyed upon the intestines, so that when they took it out, the intestines came away with it, dried, and not in the least putrified: the body being inclosed in nitre, grew dry, and nothing remained besides the skin glued upon the bones.

**EMBARGO**, in commerce, in arrest on ships, or merchandise,

chandise, by public authority; or a prohibition of state, commonly on foreign ships, in time of war, to prevent their going out of port, sometimes to prevent their coming in, and sometimes both, for a limited time.

The king may lay embargoes on ships, or employ those of his subjects, in time of danger, for service and defence of the nation; but they must not be for the private advantage of a particular trader, or company; and therefore a warrant to stay a single ship is no legal embargo. No inference can be made from embargoes which are only in war time; and are a prohibition by advice of council, and not at prosecution of parties. If goods be laden on board, and after an embargo or restraint from the prince or state comes forth, and then the master of the ship breaks ground, or endeavours to sail, if any damage accrues, he must be responsible for the same; the reason is, because his freight is due, and must be paid, nay though the goods be seized as contraband.

Embargo differs from quarantine, inasmuch as this last is always for the term of forty days, in which persons from foreign parts, infected with the plague, are not permitted to come on shore. See *QUARANTINE*.

**EMBASSADOR, or AMBASSADOR**, a public minister sent from one sovereign prince, as a representative of his person, to another.

Embassadors are either ordinary or extraordinary. Ambassador in ordinary, is he who constantly resides in the court of another prince, to maintain a good understanding, and look to the interest of his master. Till about two hundred years ago, ambassadors in ordinary were not heard of; all, till then, were ambassadors extraordinary, that is, such as are sent on some particular occasion, and who retire as soon as the affair is dispatched.

By the law of nations, none under the quality of a sovereign prince can send or receive an ambassador. At Athens, ambassadors mounted the pulpit of the public orators, and there opened their commission, acquainting the people with their errand. At Rome, they were introduced to the senate, and delivered their commissions to them.

Embassadors should never attend any public solemnities, as marriages, funerals, &c. unless their masters have some interest therein: nor must they go into mourning on any occasions of their own, because they represent the persons of their prince. By the civil law, the moveable goods of an ambassador, which are accounted an accession to his person, cannot be seized on, neither as a pledge, nor for payment of a debt, nor by order or execution of judgment, nor by the king's or state's leave where he resides, as some conceive; for all actions ought to be far from an ambassador, as well that which toucheth his necessities, as his person: if, therefore, he hath contracted any debt, he is to be called upon kindly, and if he refuses, then letters of request are to go to his master. Nor can any of the ambassador's domestic servants that are registered in the secretaries of state's office be arrested in person or goods: if they are, the process shall be void, and the parties suing out and executing it shall

suffer and be liable to such penalties and corporal punishment as the lord chancellor or either of the chief justices shall think fit to inflict. Yet ambassadors cannot be defended when they commit any thing against that state, or the person of the prince, with whom they reside; and if they are guilty of treason, felony, &c. or any other crime against the law of nations, they lose the privilege of an ambassador, and may be subject to punishment as private aliens.

**EMBASSY**, the office or function of an ambassador. See the preceding article.

**EMBDEN**, a port-town and city of Germany, capital of a county of the same name, now in possession of the king of Prussia; it is situated at the mouth of the river Ems: E. long. 6° 45', and N. lat. 53° 50'.

**EMBER-WEEKS, or DAYS**, in the episcopal church, are certain seasons of the year, set apart for the imploring God's blessing, by prayer and fasting, upon the ordinations performed in the church at such times.

These ordination-fasts are observed four times in the year, viz. the Wednesday, Friday, and Saturday after the first Sunday in lent, after Whitsunday, after the fourteenth of September and the thirteenth of December; it being enjoined, by a canon of the church, that deacons and ministers be ordained, or made, only upon the Sundays immediately following these ember-fasts.

**EMBERIZA**, in ornithology, a genus of birds, belonging to the order of passeræ. The bill is conical, and the mandibles recede from each other towards the base; the inferior mandible has the sides narrowed inwards, but the upper one is still narrower. There are twenty-four species, viz. The nivalis, or great pyed mountain-finch of Ray, and the snow-bird of Edwards, has white-wings; but the outer edge of the prime-feathers are black; the tail is black, with three white feathers on each side. They inhabit Lapland and Hudson's bay, and in hard winters they come into Sweden, when they are totally white. 2. The hyemalis, or snow sparrow of Catesby, is black above, and the belly is white. It is a native of North America. 3. The miliaris, or grey emberiza, is of a greyish colour, spotted with black in the belly, and the orbits are redish. It is the bunting of English authors, and a bird of Europe. 4. The hortulana, or ortolan, has black wings; the first three feathers on the tail are white on the edges, only the two lateral are black outwardly. The orbits of the eyes are naked and yellow; the head is greenish, and yellow towards the inferior mandible. It feeds principally upon the panick-grass; grows very fat, and is reckoned a delicate morsel by certain epicures. It is a bird of Europe. 5. The citrinella, or yellow hammer, has a blackish tail, only the two outward side-feathers are marked on the inner edge with a sharp white spot. It is a bird of Europe, and comes about houses in winter: it builds its nest on the ground in meadows. 6. The olivacea, or olive emberiza, is of an olive colour above, whiter below; the rump of the neck is orange-coloured, and it has a black belt across the breast. It is a native of Dominica. 7. The crix, or grenadier

of Edwards, is greyish, with the front and belly black, a tawny neck and rump, and a black bill. It is a native of Africa. 8. The *quelea*, has a grey back, a black front, and a red bill. It is a native of Africa. 9. The *capensis*, or ortolon of the cape of Good Hope, is greyish, with a white nape of the neck, and a black belt round the orbits and mandibles. It inhabits the Cape of Good Hope. 10. The *ludoviciana* is greyish above, and pale below; the breast is reddish, and there is a black circle on the head. 11. The *cia*, is reddish, with white eye-brows, and black lines on the head. It is a bird of Europe. 12. The *cirlus*, is a bird of Europe; it has a greyish back, a spotted breast, and yellowish eye-brows. 13. The *familiaris* is greyish and spotted; the tips of the tail-feathers are white, and hind part of the back yellow. It is a native of Asia. 14. The *slaveola*, is greyish, with a yellow face; it is about the size of a sparrow, and is a native of warm countries. 15. The *amazona* is of a tawny colour, with the crown of the head yellow, and the base of the wings white underneath. It is a native of Surinam. 16. The *orizivora*, or ortolan of Carolina, is brownish, with a tawny head, and a black belly. It is properly a native of Cuba, but migrates to Carolina about the autumn after the rice is reaped. 17. The *schoeniclas*, or reed-sparrow, has a black head, a blackish-grey body, and a white spot on the quill-feathers. It is a bird of Europe. 18. The *psittacus*, is of a tawny ash-colour, with yellow wings, and two of the tail-feathers remarkably long. 19. The *paradisæa* is brownish, with a red breast, and two long sharp-pointed feathers in the tail, and a black bill. It is a native of Africa, and sheds the long feathers of the tail every year, like the peacock. 20. The *serena*, has a red bill, a black fillet, a red vertex, and a wedge-shaped tail. 21. The *vidua*, or Indian sparrow of Aldrovandus, is blackish above, and white below, with four very long feathers in the tail, and a red bill. It is a native of India. 22. The *principalis*, is spotted, with the breast, bill, and legs red. It is a bird of Argola. 23. The *regia*, has a red bill, four long equal feathers in the tail, and red legs. It is a native of Africa. 24. The *ciris*, has a blueish head, a yellow belly, and a green back. It is a native of North America.

**EMBLEM**, a kind of painted enigma, or certain figures painted or cut, metaphorically expressing some action, with reflections underneath, which in some measure explain the sense of the device, and at the same time instruct us in some moral truth, or other matter of knowledge.

**EMBLEMENTS**, among lawyers, denote the profits of fown lands; but are sometimes used, more largely, for any products that naturally arise from the ground.

**EMBOLISMIC**, or **INTERCALARY**. See **INTERCALARY**.

**EMBOLUS**, the moveable part of a pump, or syringe, called also the piston, or sucker.

**EMBOSSING**, or **IMBOSSING**, in architecture and sculpture, the forming or fashioning works in relief, whether cut with a chisel or otherwise.

**EMBRASURE**, in architecture, the enlargement made of the aperture of a door or window, on the inside of the wall; its use being to give the greater play for the opening of the door or casement, or to admit the more light.

**EMBROCCATION**, in surgery and pharmacy, an external kind of remedy, which consists in an irrigation of the part affected, with some proper liquor, as oils, spirits, &c. by means of a woollen or linen cloth, or a sponge, dipped in the same.

**EMBROIDERY**, a work in gold, or silver, or silk thread, wrought by the needle upon cloth, stuffs, or muslin, into various figures. In embroidering stuffs, the work is performed in a kind of loom, because the more the piece is stretched, the easier it is worked. As to muslin, they spread it upon a pattern ready designed; and sometimes, before it is stretched upon the pattern, it is starched, to make it more easy to handle. Embroidery on the loom is less tedious than the other, in which, while they work flowers, all the threads of the muslin, both lengthwise and breadthwise, must be continually counted; but, on the other hand, this last is much richer in points, and susceptible of greater variety. Cloths too much milled are scarce susceptible of this ornament, and in effect we seldom see them embroidered. The thinnest muslins are left for this purpose; and they are embroidered to the greatest perfection in Saxony: in other parts of Europe, however, they embroider very prettily, and especially in France.

There are several kinds of embroidery; as, 1. Embroidery on the stamp, where the figures are raised and rounded, having cotton or parchment put under them to support them. 2. Low embroidery, where the gold and silver lie low upon the sketch, and are stitched with silk of the same colour. 3. Guimped embroidery: this is performed either in gold or silver; they first make a sketch upon the cloth, then put on cut vellum, and afterwards sew on the gold and silver with silk thread: in this kind of embroidery they often put gold and silver cord, tinsel, and spangles. 4. Embroidery on both sides, that which appears on both sides of the stuff. 5. Plain embroidery, where the figures are flat and even, without cords, spangles, or other ornaments.

**EMBRUN**, or **AMBRUN**, a city of Dauphiny, in France, near the confines of Piedmont: E. long. 6° 6', and N. lat. 44° 35'.

**EMBRIO**, in physiology, the first rudiments of an animal in the womb, before the several members are distinctly formed; after which period it is denominated a *fœtus*.

**EMBRYOTHLASTES**, in midwifery, an instrument contrived for breaking the bones, for the more easy extraction of the *fœtus* in difficult labours.

**EMBRYOTOMY**, the cutting a *fœtus* to pieces whilst in the womb, practised in cases of necessity, when there is no other way of saving the mother.

**EMBRYULCUS**, a hook for extracting the child in difficult labours. See **MIDWIFERY**.

**EMERALD**, in natural history, a genus of precious stone, of a green colour, and next in hardness to the ruby. Our jewelers distinguish emeralds into two kinds, the oriental

oriental and occidental: the emeralds of the East-Indies are evidently finer than those of any other part of the world; but our jewellers, seldom meeting with these, call the American emeralds the oriental, and usually sell crystal accidentally tinged with green, under the name of the occidental emerald: these being also the most common, there has grown an opinion among the lapidaries, that the emerald is no harder than the crystal; because what they take to be emeralds, are in general only crystals.

The genuine emerald, in its most perfect state, is perhaps the most beautiful of all the gems; it is found of various sizes, but usually small; a great number of them are met with of about the sixteenth part of an inch in diameter, and they are found from this to the size of a walnut.

The emerald is of different figures like the diamond and many of the other gems, being sometimes found in a roundish or pebble-like form, but much more frequently in a columnar one, resembling common crystal: the pebble-emeralds are always the hardest and brightest, but are seldom found exceeding the size of a pea: the crystalliform ones grow several together, and are often larger: the pebble-kind are found loose in the earths of mountains, and sands of rivers; the columnar are found usually bedded in, or adhering to, a white, opaque, and coarse crystalline mass, and sometimes to the jasper, or the pralus.

The oriental emerald is of the hardness of the sapphire and ruby, and is second only to the diamond in lustre and brightness: the American is of the hardness of the garnet, and the European somewhat softer than that, yet considerably harder than crystal: It loses its colour in the fire, and becomes undistinguishable from the white sapphire.

The oriental emeralds are very scarce, and at present found only in the kingdom of Cambay; very few of them have of late been imported into Europe, inasmuch that it has been supposed there were no oriental emeralds; but within these ten years, some few have been brought from Cambay into Italy, that greatly excel the American ones. The American, being what our jewelers call oriental emeralds, are found principally about Peru; and the European are principally from Silesia.

**To counterfeit EMERALDS:** Take of natural crystal, four ounces; of red-lead, four ounces; verdegrease, forty-eight grains; crocus martis, prepared with vinegar, eight grains; let the whole be finely pulverized and sifted; put this into a crucible, leaving one inch empty: lute it well, and put it into a potter's furnace, and let it stand there as long as they do their pots. When cold, break the crucible, and you will find a matter of a fine emerald colour, which, after it is cut and set in gold, will surpass in beauty an oriental emerald.

**EMERY,** in natural history, a rich iron-ore found in large masses of no determinate shape or size, extremely hard, and very heavy. It is usually of a dusky brownish red on the surface; but when broken, is of a fine bright iron-grey, but not without some tinge of red-

VOL. II. NO. 46.

†

ness; and is spangled all over with shining specks, which are small flakes of a foliaceous talc, highly impregnated with iron. It is also sometimes very red, and then usually contains veins of gold. It makes no effervescence with any of the acid menstruums, and is found in the island of Guernsey, in Tuscany, and many parts of Germany.

**EMETIC,** a medicine which induces vomiting.

**EMINENCE,** a title of honour peculiar to cardinals. See **CARDINAL**.

**EMIR,** a title of dignity among the Turks, signifying a prince.

This title was first given to the caliphs; but when they assumed the title of sultans, that of emir remained to their children; as that of Cæsar among the Romans. At length the title became attributed to all who were judged to descend from Mahomet by his daughter Fatimah, and who wear the green turban instead of the white. The Turks make an observation, that the emirs, before their fortieth year, are men of the greatest gravity, learning and wisdom; but after this, if they are not great fools, they discover some signs of levity and stupidity. This is interpreted by the Turks as a sort of divine impulse in token of their birth and sanctity. The Turks also call the vizirs, bashaws, or governors of provinces, by this name.

**EMISSARY,** in a political sense, a person employed by another to sound the opinions of people, spread certain reports, or act as a spy over other peoples actions.

**EMMENAGOGUES,** in pharmacy, medicines which promote the menses, either by giving a greater force to the blood in its circulation, whereby its momentum against the vessels is increased; or by making it thinner, whereby it will more easily pass through any outlet.

**EMMERIC,** a city of Westphalia, in Germany, subject to Prussia: E. long. 5° 45', N. lat. 51° 48'.

**EMOLLIENTS,** in medicine and pharmacy, are such remedies as sheath and soften the asperity of the humours, and relax and supple the solids at the same time.

**EMPALEMENT,** an ancient kind of punishment, which consisted in thrusting a stake up the fundament.

**EMPALEMENT of a flower,** the same with calix. See **CALIX**.

**EMPEROR,** a title of honour among the ancient Romans, conferred on a general who had been victorious, and now made to signify a sovereign prince, or supreme ruler of an empire.

The title of emperor adds nothing to the rights of sovereignty; it only gives preeminence above other sovereigns. The emperors, however, pretend, that the imperial dignity is more eminent than the regal. It is disputed whether emperors have the power of disposing of the regal title; however this may be, they have sometimes taken upon them to erect kingdoms: thus it is that Bohemia, Prussia, and Poland, are said to have been raised to that dignity. In the east, the title of emperor is more frequent than with us; thus the sovereign princes of China, Mogul, &c. are called emperors.

2

5 H

perors. In the west, the title has been a long time restrained to the emperors of Germany. The first who bore it was Charlemagne, who was crowned by Pope Leo III. in 800. And it is to be observed, that there was not a foot of land or territory annexed to the emperor's title.

In the year 1723, the Czar of Muscovy assumed the title of emperor of all the Russias. The kings of France were also called emperors, when they reigned with their sons, whom they associated in the crown: thus Hugh Caput was called emperor, and his son Robert king. The kings of England were anciently styled emperors, as appears from a charter of king Edgar.

The emperor of Germany is a limited monarch in regard to the empire, though he is an absolute sovereign in most of his hereditary dominions; the late emperors of the Austrian family, having hereditary dominions, enumerated all of them in their title. Charles VI. was styled emperor of the Romans, always august, king Bohemian and Hungary, archduke of Austria, &c.; but the present emperors inheriting those countries, her consort enjoys only the title of emperor of the Romans, duke of Lorraine and Tuscany. The emperor creates dukes, marquises, and other noblemen; and he appoints most of the officers, civil and military, in the empire: he is elected by the nine electors; and he summons the general diet of the empire.

**EMPETRUM**, BERRY BEARING HEATH, in botany, a genus of the diœcia triandria class. The calix of both male and female consists of three segments, and the corolla of three petals. The female has nine styli; and the berry contains nine seeds. There are two species, one of which, viz. the nigrum, black-berried heath, crow or crane berries, is a native of Britain.

**EMPHASIS**, in rhetoric, a particular stress of the voice and action, laid on such parts or words of the oration as the orator wants to enforce upon his audience.

**EMPHYSEMA**, in surgery, a tumour generally occasioned in a fracture of the ribs. See **SURGERY**, and **MEDICINE**.

**EMPIRE**, a large extent of land, under the jurisdiction or government of an emperor. See **EMPEROR**.

**EMPIRIC**, an appellation given to those physicians who conduct themselves wholly by their own experience, without studying physic in a regular way. Some even use the term, in a still worse sense, for a quack who prescribes at random, without being at all acquainted with the principles of the art.

**EMPIS**, in zoology, a genus of insects belonging to the order of diptera. The beak is horny, inflected, consists of two valves, and is longer than the thorax. There are five species, principally distinguished by their colour.

**EMPRESS**, the spouse of an emperor, or a woman who governs an empire. See **EMPEROR**.

**EMPROSTHOTONOS**, a species of convulsion, wherein the head bends forward. See **MEDICINE**.

**EMPYREMA**, in medicine, a disorder wherein purulent matter is contained in the thorax or breast, after an in-

flammation and suppuration of the lungs and pleura. See **MEDICINE**, and **SURGERY**.

**EMPYREUM**, a term used by divines for the highest heaven, where the blessed enjoy the beatific vision.

**EMPYREUMA**, among chemists and physicians, the fiery taste or offensive smell which brandies, and other bodies prepared by fire, are impregnated with. See **CHEMISTRY**.

**EMRODS**. See **HÆMORRHOIDS**.

**EMULGENT**, or **RENAL ARTERIES**. See **ANATOMY**, Part III.

**EMULSION**, a soft liquid remedy, of a colour and consistence resembling milk. See **CHEMISTRY**.

**EMUNCTORY**, in anatomy, a general term for all those parts which serve to carry off the excrementitious parts of the blood and other humours of the body. Such more especially are the kidneys, bladder, and most of the glands. See **ANATOMY**.

**ENÆMON**, in medicine, an epithet often applied by Hippocrates and Galen, to such topical medicines as are appropriated to a wound newly inflicted, before the blood be stopped.

**ENÆOREMA**, in medicine, that pendulous substance which floats in the urine. It is also called sublimamentum and nubeculæ, from its resemblance to little clouds.

**ENALLAGE**, in grammar, is when one word is substituted for another of the same part of speech: a substantive for an adjective, as *exercitus victor*, for *victoriosus*; *scelus*, for *sceleratus*.

**ENAMEL**, a kind of coloured glass, used in enamelling and painting in enamel.

Enamels have for their basis a pure crystal glass or frit, ground up with a fine calx of lead and tin prepared for the purpose, with the addition usually of white salt of tartar. These ingredients baked together, are the matter of all enamels, which are made by adding colours of this or that kind in powder to this matter, and melting or incorporating them together in a furnace.

For white enamel, Neri (*De Arte Vitriar.*) directs only manganese to be added to the matter which constitutes the basis. For azure, zaffer mixed with calx of brass. For green, calx of brass with scales of iron, or with crocus martis. For black, zaffer with manganese, or with crocus martis; or manganese with tartar. For red, manganese, or calx of copper and red tartar. For purple, manganese with calx of brass. For yellow, tartar and manganese. And for violet-coloured enamel, manganese with thrice-calcined brass.

In making these enamels, the following general cautions are necessary to be observed. 1. That the pots must be glazed with white glass, and must be such as will bear the fire. 2. That the matter of enamels must be very nicely mixed with the colours. 3. When the enamel is good, and the colour well incorporated, it must be taken from the fire with a pair of tongs. 4. The general way of making the coloured enamel is this: powder, sift, and grind all the colours very nicely, and first mix them with one another, and then with the common matter of enamels; then set them in pots in a furnace, and when they are well mixed and incorporated,

incorporated, cast them into water; and when dry, set them in a furnace again to melt; and when melted, take a proof of it. If too deep-coloured, add more of the common matter of enamels; and if too pale, add more of the colours.

Enamels are used either in counterfeiting or imitating precious stones, in painting in enamel; or by enamellers, jewellers, and goldsmiths, in gold, silver, and other metals. The two first kinds are usually prepared by the workmen themselves who are employed in these arts. That used by jewellers, &c. is brought to us chiefly from Venice or Holland, in little cakes of different sizes, commonly about four inches diameter, having the mark of the maker struck upon it with a puncheon. It pays the pound 1s. 7  $\frac{4}{5}$  d. on importation, and draws back 1s. 5  $\frac{7}{8}$  d. at the rate of 4s. per pound.

**ENAMELLING**, the art of laying enamel upon metals, as gold, silver, copper, &c. and of melting it at the fire, or of making divers curious works in it at a lamp. It signifies also to paint in enamel.

*The method of painting in ENAMEL.* This is performed on plates of gold or silver, and most commonly of copper, enamelled with the white enamel; whereon they paint with colours which are melted in the fire, where they take a brightness and lustre like that of glass. This painting is the most prized of all for its peculiar brightness and vivacity, which is very permanent, the force of its colours not being effaced or sullied with time, as in other painting, and continuing always as fresh as when it came out of the workman's hands. It is usual in miniature, it being the more difficult the larger it is, by reason of certain accidents it is liable to in the operation. Enamelling should only be practised on plates of gold, the other metals being less pure: copper, for instance, scales with the application, and yields fumes; and silver turns the yellows white. Nor must the plate be made flat; for in such case, the enamel cracks; to avoid which, they usually forge them a little round or oval, and not too thick. The plate being well and evenly forged, they usually begin the operation by laying on a couch of white enamel (as we observed above) on both sides, which prevents the metal from swelling and blistering; and this first lay serves for the ground of all the other colours. The plate being thus prepared, they begin at first by drawing out exactly the subject to be painted with red vitriol, mixed with oil of spike, marking all parts of the design very lightly with a small pencil. After this, the colours (which are to be before ground with water in a mortar of agate extremely fine, and mixed with oil of spike somewhat thick) are to be laid on, observing the mixtures and colours that agree to the different parts of the subject; for which it is necessary to understand painting in miniature. But here the workman must be very cautious of the good or bad qualities of the oil of spike he employs to mix his colours with, for it is very subject to adulterations. See **OIL**.

Great care must likewise be taken, that the least dust imaginable come not to your colours while you are

either painting or grinding them; for the least speck, when it is worked up with it, and when the work comes to be put into the reverberatory to be red-hot, will leave a hole, and so deface the work.

When the colours are all laid, the painting must be gently dried over a slow fire to evaporate the oil, and the colours afterwards melted to incorporate them with the enamel, making the plate red-hot in a fire like what the enamellers use. Afterwards that part of the painting must be passed over again which the fire hath any thing effaced, strengthening the shades and colours, and committing it again to the fire, observing the same method as before, which is to be repeated till the work be finished.

*Method of ENAMELLING by the lamp.* Most enamelled works are wrought at the fire of a lamp, in which, instead of oil, they put melted horse-grease, which they call caballine oil. The lamp, which is of copper or white iron, consists of two pieces, in one of which is a kind of oval plate, six inches long, and two high, in which they put the oil and the cotton. The other part, called the box, in which the lamp is inclosed, serves only to receive the oil which boils over by the force of the fire. This lamp, or, where several artists work together, two or three more lamps are placed on a table of proper height. Under the table, about the middle of its height, is a double pair of organ-bellows, which one of the workmen moves up and down with his foot, to quicken the flame of the lamps, which are by this means excited to an incredible degree of vehemence. Grooves made with a gauge in the upper part of the table, and covered with parchment, convey the wind of the bellows to a pipe of glass before each lamp; and that the enamellers may not be incommoded with the heat of the lamp, every pipe is covered at six inches distance with a little tin plate, fixed into the table by a wooden handle. When the works do not require a long blast, they only use a glass pipe, into which they blow with their mouth.

It is incredible to what a degree of fineness and delicacy the threads of enamel may be drawn at the lamp. Those which are used in making false tufts of feathers are so fine, that they may be wound on the reel like silk or thread. The fictitious jets of all colours, used in embroideries, are also made of enamel; and that with so much art, that every small piece hath its hole to pass the thread through wherewith it is sewed. These holes are made by blowing them into long pieces, which they afterwards cut with a proper tool.

It is seldom that the Venetian or Dutch enamels are used alone; they commonly melt them in an iron-ladle, with an equal part glass or crystal; and when the two matters are in perfect fusion, they draw it out into threads of different sizes, according to the nature of the work. They take it out of the ladle while liquid, with two pieces of broken tobacco pipes, which they extend from each other at arm's length. If the thread is required still longer, then another workman holds one end, and continues to draw it out, while the first holds the enamel to the flame. Those threads, when cold,

cold, are cut into what lengths the workman thinks fit, but commonly from ten to twelve inches; and as they are all round, if they are required to be flat, they must be drawn through a pair of pincers while yet hot. They have also another iron instrument in form of pincers, to draw out the enamel by the lamp when it is to be worked and disposed in figures. Lastly, they have glass-tubes of various sizes, serving to blow the enamel into various figures, and preserve the necessary vacancies therein; as also to spare the stuff, and form the contours. When the enameller is at work, he sits before his lamp with his foot on the step that moves on the bellows; and holding in his left hand the work to be enamelled, or the brads or iron-wires the figures are to be formed on, he directs with his right the enamel thread, which he holds to the flame with a management and patience equally surprising. There are few things they cannot make or represent with enamel; and some figures are as well finished, as if done by the most skilful carvers.

**ENARTHROSIS**, in anatomy, a species of diarthrosis. See **ANATOMY**, Part I.

**ENCÆNIA**, the name of three several feasts celebrated by the Jews in memory of the dedication, or rather purification, of the temple, by Judas Maccabæus, Solomon, and Zorobabel.

This term is likewise used in church-history for the dedication of Christian churches.

**ENCAMPMENT**, the pitching of a camp. See **CAMP**.

**ENCANTHIS**, in surgery, a tubercle arising either from the caruncula lacrymalis, or from the adjacent red skin; sometimes so large, as to obstruct not only the puncta lacrymalia, but also part of the sight, or pupil itself. See **SURGERY**.

**ENCAUSTIC** and **ENCAUSTUM**, the same with enamelling and enamel. See **ENAMELLING**, and **ENAMEL**.

**ENCEINTE**, in fortification, is the wall or rampart which surrounds a place, sometimes composed of bastions or curtains, either faced or lined with brick or stone, or only made of earth. The enceinte is sometimes only flanked by round or square towers, which is called a Roman wall.

**ENCEPHALI**, in medicine, worms generated in the head, where they cause so great a pain, as sometimes to occasion distraction.

**ENCEPPE'**, in heraldry, denotes fettered, chained, or girt about the middle, as is usual with monkeys.

**ENCHANTER**, a person supposed to practise enchantment or fascination. See **FASCINATION**, **WITCHCRAFT**, &c.

**ENCHANTER'S NIGHTSHADE**, in botany. See **CIRCÆA**.

**ENCHASING**, **INCHASING**, or **CHASING**, the art of enriching and beautifying gold, silver, and other metal-work, by some design or figures represented thereon in low relief.

Enchasing is practised only on hollow thin works, as watch-cases, cane-heads, tweezer cases, or the like. It is performed by punching or driving out the metal, to form a figure, from with-inside, so as to stand out pro-

minent from the plane or surface of the metal. In order to this, they provide a number of fine steel blocks, or puncheons, of divers sizes; and the design being drawn on the surface of the metal, they apply the inside upon the heads or tops of these blocks, directly under the lines or parts of the figures; then, with a fine hammer, striking on the metal, sustained by the block, the metal yields, and the block makes an indentation or cavity on the inside, corresponding to which there is a prominence on the outside, which is to stand for that part of the figure.

Thus the workmen proceeds to chafe and finish all the parts by successive application of the block and hammer to the several parts of the design. And it is wonderful to consider with what beauty and justness, by this simple piece of mechanism, the artists in this kind will represent foliages, grotesques, animals, histories, &c.

**ENCHYSMA**, in medicine, the same with enema. See **ENEMA**.

**ENCLITICA**, in grammar, particles which are so closely united with other words, as to seem part of them, as in *virumque*, &c.

There are three enclitic particles in Latin, viz. *que*, *ne*, *ve*.

**ENCRATITES**, in church-history, heretics who appeared towards the end of the second century: they were called Encratites, or Continentes, because they gloried in abstaining from marriage and the use of wine and animal-food.

**ENCYCLOPÆDIA**. See **CYCLOPÆDIA**, and **DICTIONARY**.

**ENCERIS**, in antiquity, denotes a vessel or galley with eleven tires of oars.

**ENDEMIC**, or **ENDEMICAL DISEASES**, those to which the inhabitants of particular countries are subject more than others, on account of the air, water, situation, and manner of living.

**ENDIVE**, in botany. See **CICORIUM**.

**ENDLESS**, something without an end: thus authors mention endless rolls, the endless screw, &c.

**ENDORSE**, in heraldry, an ordinary, containing the eighth part of a pale, which Leigh says is only used when a pale is between two of them.

**ENDORSED**, in heraldry, is said of things borne back to back, more usually called *adosé*. See **ADOSÉ**.

**ENDOWMENT**, in law, denotes the settling a dower on a woman; though sometimes it is used figuratively, for settling a provision upon a parson, on the building of a church; or the severing a sufficient portion of tithes for a vicar, when the benefice is appropriated.

**ENEMA**, in medicine. See **CLYSTER**.

**ENEMY**, in law, an alien or foreigner, who publicly invades the kingdom.

**ENERGUMENS**, in church history, persons supposed to be possessed by the devil, concerning whom there were many regulations among the primitive Christians. They were denied baptism, and the eucharist; at least, this was the practice of some churches: and though they were under the care of exorcists, yet it was thought

thought a becoming act of charity to let them have the public prayers of the church, at which they were permitted to be present. See EXORCISM.

**ENERGY**, a term of Greek origin, signifying the power, virtue, or efficacy of a thing. It is also used, figuratively, to denote emphasis of speech.

**ENFILADE**, in the art of war, is used in speaking of trenches, or other places, which may be scoured by the enemy's shot along their whole length. In conducting the approaches at a siege, care must be taken that the trenches be not enfiladed from any work of the place. See TRENCHES.

**ENFRANCHISEMENT**, in law, the incorporating a person into any society or body politic.

**ENGASTRIMYTHI**, in Pagan theology, the Pythians, or priestesses of Apollo, who delivered oracles from within, without any action of the mouth or lips.

The ancient philosophers, &c. are divided upon the subject of the engastrimythi. Hippocrates mentions it as a disease. Others will have it a kind of divination. Others attribute it to the operation or possession of an evil spirit. And others to art and mechanism. M. Scottus maintains that the engastrimythi of the ancients were poets, who, when the priests could not speak, supplied the defect by explaining in verse what Apollo dictated in the cavity of the bason on the sacred tripod.

**ENGENDERING**, a term sometimes used for the act of producing or forming any thing: thus meteors are said to be engendered in the middle region of the atmosphere, and worms in the belly. See GENERATION.

**ENGERS**, the capital of a county of the same name, in Germany, situated on the river Rhine, about seven miles north of Coblenz.

**ENGHIEN**, a city of Hainalt, about fourteen miles south-west of Brussels.

**ENGINA**, an island on the north-east of the Morea, about fifty miles east of Corinth.

**ENGINE**, in mechanics, is a compound machine, made of one or more mechanical powers, as levers, pulleys, screws, &c. in order to raise, cast, or sustain any weight, or produce any effect which could not be easily effected otherwise. See MECHANICS.

**ENGINE for extinguishing fires**. See HYDROSTATICS, and HYDRAULICS.

**Pile-ENGINE**, one contrived for driving piles. See MECHANICS.

**Steam-ENGINE**, a machine to raise water by fire, or rather by the force of water turned into steam. See HYDROSTATICS, and HYDRAULICS.

**ENGINEER**, in the military art, an able expert man, who, by a perfect knowledge in mathematics, delineates upon paper, or marks upon the ground, all sorts of forts, and other works proper for offence and defence. He should understand the art of fortification, so as to be able, not only to discover the defects of a place, but to find a remedy proper for them; as also how to make an attack upon, as well as to defend, the place. Engineers are extremely necessary for these purposes: wherefore it is requisite that, besides being ingenious,

VOL. II. No. 46.

†

they should be brave in proportion. When at a siege the engineers have narrowly surveyed the place, they are to make their report to the general, by acquainting him which part they judge the weakest, and where approaches may be made with most success. Their business is also to delineate the lines of circumvallation and contravallation, taking all the advantages of the ground; to mark out the trenches, places of arms, batteries, and lodgments, taking care that none of their works be flanked or discovered from the place. After making a faithful report to the general of what is a-doing, the engineers are to demand a sufficient number of workmen and utensils, and whatever else is necessary.

**ENGLAND**, the southern division of Great Britain, situated in the Atlantic ocean, between 2° E. and 6° W. longitude, and between 49° 55' and 55° 55' N. latitude.

There are in England, including Wales, fifty-two counties, two archbishoprics, twenty-four bishoprics, two universities, twenty-nine cities, upwards of eight hundred towns, and near ten thousand parishes; supposed to contain about 7,000,000 of people.

**New ENGLAND**, comprehending the colonies of Massachusetts, New Hampshire, Connecticut, Rhode-island, and Providence-Plantation, is situated between 67° and 73° W. longitude, and between 41° and 45° N. latitude.

**ENGLISH**, or the **ENGLISH TONGUE**, the language spoken by the people of England, and, with some variation, by those of Scotland, as well as part of Ireland, and the rest of the British dominions.

The ancient language of Britain is generally allowed to have been the same with the Gaulic, or French; this island, in all probability, having been first peopled from Gallia, as both Cæsar and Tacitus affirm, and prove by many strong and conclusive arguments, as by their religion, manners, customs, and the nearness of their situation. But now we have very small remains of the ancient British tongue, except in Wales, Cornwall, the islands and highlands of Scotland, part of Ireland, and some provinces of France; which will not appear strange, when what follows is considered.

Julius Cæsar, sometime before the birth of our Saviour, made a descent upon Britain, though he may be said rather to have discovered than conquered it; but, about the year of Christ 45, in the time of Claudius, Aulus Plautius was sent over with some Roman forces, by whom two kings of the Britons, Cogidunus and Caractacus, were both overcome in battle: whereupon a Roman colony was planted at Malden in Essex, and the southern parts of the island were reduced to the form of a Roman province: after that, the island was conquered as far north as the friths of Dumbarton and Edinburgh, by Agricola, in the time of Domitian; whereupon, a great number of the Britons, in the conquered part of the island, retired to the west part called Wales, carrying their language with them.

The greatest part of Britain being thus become a Roman province, the Roman legions, who resided in Britain for above two hundred years, undoubtedly dis-

2

5 I

seminated

feminated the Latin tongue; and the people being afterwards governed by laws written in Latin, must necessarily make a mixture of languages. This seems to have been the first mutation the language of Britain suffered.

Thus the British tongue continued, for some time, mixed with the provincial Latin, till, the Roman legions being called home, the Scots and Picts took the opportunity to attack and harrafs England: upon which, K. Vortigen, about the year 440, called the Saxons to his assistance, who came over with several of their neighbours, and having repulsed the Scots and Picts, were rewarded for their services with the isle of Thanet, and the whole county of Kent; but growing too powerful, and not being contented with their allotment, dispossessed the inhabitants of all the country on this side of the Severn: thus the British tongue was in a great measure destroyed, and the Saxon introduced in its stead.

What the Saxon tongue was long before the conquest, about the year 700, we may observe in the most ancient manuscripts of that language, which is a gloss on the Evangelists, by bishop Edfrid, in which the three first articles of the Lord's prayer runs thus.

" Uren fader thic arth in heofnas, sic gehalgud thin  
" noma, so cymeth thin ric. Sic thin willa sue is  
" heofnas, and in eorþo, &c."

In the beginning of the ninth century the Danes invaded England; and getting a footing in the northern and eastern part of the country, their power gradually increased, and they became sole masters of it in about two hundred years. By this means the ancient British obtained a tincture of the Danish language: but their government being of no long continuance, did not make so great an alteration in the Anglo-Saxon, as the next revolution, when the whole land, *A. D.* 1067, was subdued by William the Conqueror, duke of Normandy in France: for the Normans, as a monument of their conquest, endeavoured to make their language as generally received as their commands, and thereby rendered the British language an entire medley.

About the year 900, the Lord's prayer, in the ancient Anglo-Saxon, ran thus:

" Thuc ur fader the eart on heofenum, si thin nama gehalgod; cume thin rice si thin willa on eorþan  
" swa, swa on heofenum, &c."

About the year 1160, under Henry II. it was rendered thus by pope Adrian, an Englishman, in rhyme:

" Ure fader in heaven riche,  
" Thy name be halyed ever lich,  
" Thou bring us thy michell blisse:  
" Als hit in heaven y-doe,  
" Evar in yearth beene it also, &c."

Dr Hicks gives us an extraordinary specimen of the English as spoken in the year 1385, upon the very subject of the English tongue.

" As it is knowe how meny maner peple beeth in  
" this lond; ther beeth also so many dyvers longages  
" and tonges. Nothelefs Walschemen and Scots that  
" beeth nought medled with other nation, holdeth wel

" nyh hir firste longage and speche; but yif the Scottes,  
" that were sometime confederate and woned with the  
" Pictes, drawe somewhat after hir speche; but the  
" Flemynge, that woneth on the weste side of Wales,  
" haveth lost her strange spech, and spekeþ Sexon-  
" liche now. Also Englisshemen, they had from the  
" bygynnyng thre maner speche: northerne, sou-  
" therne, and middel speche in the middel of the  
" lond, as they come of thre maner of pepþe of Ger-  
" mania: nothelefs by commyxtion and mellyng first  
" with Danes, and afterwards with Normans, in meny  
" the contrary longage is apayrcd (*corrupted*.)

" This apayryng of the burth of the tynge is bycause  
" of tweie thinges; oon is for children in scole: gentl-  
" the usuaige and maner of all other nation; beeth  
" compelled for to leve hire own longage, and for to  
" construe hir lessons and here thynges in French, and  
" so they haveth sethe Normans come first into Eng-  
" lond. Also gentlemen children beeth taught to  
" speke Frensche from the tyme that they beeth rok-  
" ked in here cradel, and kunneth speke and play  
" with a childe broche; and uplondische men will  
" lykne hymself to gentilmen, and fondeth with great  
" besynesse for to speak Frensche to be told of.—Hit  
" seemeth a greet wonder how Englisshemen and her  
" own longage and tonge is so dyverse of fown in this  
" oon ilond: and the longage of Normandie is com-  
" lynge of another lond, and hath oon maner soun  
" amonge alle men that spekeþ hit ariht in Engeland.  
" Also of the foresaid Saxon tonge that is deled (*di-  
" vided*) a three, and is abide scarceliche with fewe  
" uplondische men is greet wonder. For men of the  
" est, with men of the west, is, as it were, undir  
" the same partie of hevене acordeth more in fown-  
" ynge of speche, than men of the north, with men  
" of the south. Therefore it is that Mercii, that  
" beeth men of myddel Engeland, as it were, par-  
" teners of the endes, understondeþ better the side  
" longages northerne and southerne, than northerne or  
" southerne understondeþ either other.—All the lon-  
" gage of the Northumbers and spechialliche at York,  
" is so scharp, slitting and froynge, and unschape, that  
" we southerne men may that longage unnethen un-  
" derstonde, &c." *Hicks's Thesaur. liter sept.*

In the year 1537, the Lord's prayer was printed as follows: " O oure Father which arte in heven, ha-  
" lowed be thy name: let thy kingdome come, thy  
" will be fulfilled as well in erth as it is in heven;  
" geve us this daye in dayly bred, &c." Where it  
" may be observed that the diction is brought almost to  
" the present standard, the chief variations being only  
" in the orthography. By these instances, and many o-  
" thers that might be given, it appears, that the English  
" Saxon language, of which the Normans despoiled us  
" in a great measure, had its beauties, was significant and  
" emphatical, and preferable to what they imposed on us.  
" Great, verily," says Camden, " was the glory of our  
" tongue before the Norman conquest, in this, that the  
" old English could exprefs, most aptly, all the concep-  
" tions of the mind in their own tongue, without bor-  
" rowing from any." Of this he gives several examples.

Having

Having thus shewn how the ancient British language was in a manner extirpated by the Romans, Danes, and Saxons, and succeeded by the Saxon, and after that the Saxon blended with the Norman French, we shall now mention two other causes of change in the language: the first of these is owing to the Britons having been a long time a trading nation, whereby offices, dignities, names of wares, and terms of traffic are introduced, which we take with the wares from the persons of whom we have them, and form them new, according to the genius of our own tongue; and besides this change in the language, arising from commerce, Britain's having been a considerable time subject to the see of Rome, in ecclesiastical affairs, must unavoidably introduce some Italian words among us. Secondly, as to the particular properties of a language, our tongue has undergone no small mutation, or rather has received no small improvement upon that account: for, as to the Greek and Latin, the learned have, together with the arts and sciences now rendered familiar among us, introduced abundance; nay, almost all the terms of art in the mathematics, philosophy, physic, and anatomy; and we have entertained many more from the Latin, French, &c. for the sake of neatness and elegance: so that, at this day, our language, which about 1800 years ago, was the ancient British, or Welch, &c. is now a mixture of Saxon, Teutonic, Dutch, Danish, Norman, and modern French, embellished with the Greek and Latin. Yet this, in our opinion, is so far from being a disadvantage to the English tongue, as now spoke (for all languages have undergone changes, and do continually participate with each other) that it has so enriched it, as now to become the most copious, significant, fluent, courteous, and masculine language in Europe, if not in the world.

**ENGRAFTING, or GRAFTING**, in gardening. See **GARDENING**.

**ENGRAILED, or INGRAILED**, in heraldry, a term derived from the French *greffy*, hail; and signifying a thing the hail has fallen upon and broke off the edges, leaving them ragged, or with half-rounds, or semicircles, struck out of their edges.

**ENGRAVING**, the art of cutting metals and precious stones, and representing thereon figures, letters, or whatever device, or design, the artist fancies.

Engraving, properly a branch of sculpture, is divided into several other branches, according to the matter whereon it is employed, and the manner of performing it.

The original way of engraving on wood is denominated at present, with us, by cutting in wood; that on metals with aquafortis, is named etching; that by the knife, burnisher, punch, and scraper, is called mezzotinto; that on stones for tombs, &c. stone-cutting; and that performed with the graver on metals or precious stones, keeps alone the primitive name of engraving, being that which we shall at present attend to.

**ENGRAVING on copper**, is employed in representing portraits, histories, landscapes, foliages, figures, build-

ings, &c. either after paintings, or designs for that purpose.

It is performed with the graver on a plate of copper, which, being well polished, is covered over thinly with virgin-wax, and then smoothed, while warm, with a feather, so that the wax be of an equal thickness on the plate; and on this the draught or design, done in black lead, red chalk, or ungummed ink, is laid with the face of the drawing on the wax: then they rub the backside, which will cause the whole design of the drawing to appear on the wax. The design, thus transferred, is traced through on the copper, with a point, or needle; then heating the plate, and taking off the wax, the strokes remain to be followed, heightened, &c. according to the tenor of the design, with the graver, which must be very sharp and well pointed.

In the conduct of the graver consists almost all the art, which depends not so much upon rules as upon practice, the habitude, disposition, and genius of the artist, the principles of engraving being the same with those of painting; for if an engraver be not a perfect master of design, he can never hope to arrive at a degree of perfection in this art. In conducting the strokes, or cuts, of the graver, he must observe the action of the fingers, and of all their parts, with their outlines; and remark how they advance towards, or fall back from his sight, and then conduct his graver according to the risings or cavities of the muscles, or folds, widening the strokes in the light, and contracting them in the shades; as also at the extremity of the outlines, to which he ought to conduct the cuts of the graver, that the figures or objects represented may not appear as if they gnawn, and lightening his hand, that the outlines may be perfectly found, without appearing cut or slit: and, although his strokes necessarily break off where a muscle begins, yet they ought always to have a certain connection with each other, so that the first stroke should often serve to make the second, because this will shew the freedom of the graver.

If hair be the subject, let the engraver begin his work by making the outlines of the principal locks, and sketch them out in a careless manner, which may be finished, at leisure, with finer and thinner strokes to the very extremities.

The engraver must avoid making very acute angles, especially in representing flesh, when he crosses the first strokes with the second, because it will form a very disagreeable piece of tabby-like lattice-work except in the representation of some clouds, in tempests, the waves of the sea, and in representations of skins of hairy animals, and leaves of trees. So that the medium between square and acute seems to be the best and most agreeable to the eye. He that would represent sculpture, must remember, that as statues, &c. are most commonly made of white marble, or stone, whose colour does not produce such dark shades as other matters do, they have no black to their eyes, nor hair of the head and beard lying in the air. If the engraver would

would preserve one quality and harmony in his works, he should always sketch out the principal objects of his piece before any part of them are finished.

The instruments necessary for this sort of engraving are, besides a graver, a cushion, or sand bag, made of leather, to lay the plate on, in order to give it the necessary turns and motions; a burnisher made of iron, or steel, round at one end, and usually flattish at the other, to rub out slips and failures, soften the strokes, &c.; a scraper, to pare off the surface, on occasion; and a rubber, of a black hat, or cloth rolled up, to fill up the strokes that they may appear the more visible.

*In ENGRAVING precious stones*, they use either the diamond, or the emery. The diamond, which is the hardest of all stones, is only cut by itself, or with its own matter. The first thing to be done in this branch of engraving, is to cement two rough diamonds to the ends of two sticks big enough to hold them steady in the hand, and to rub or grind them against each other till they be brought to the form desired. The dust or powder that is rubbed off serves afterwards to polish them, which is performed with a kind of mill that turns a wheel of soft iron. The diamond is fixed in a brass dish, and, thus applied to the wheel, is covered with diamond-dust, mixt up with oil of olives; and when the diamond is to be cut facet-wise, they apply first one face, then another, to the wheel. Rubies, sapphires, and topazes, are cut and formed the same way on a copper wheel, and polished with tripoli diluted in water. As to agates, amethysts, emeralds, hyacinths, granates, rubies, and others of the softer stones, they are cut on a leaden wheel, moistened with emery and water, and polished with tripoli, on a pewter wheel. Lapis-lazuli, opal, &c. are polished on a wooden wheel. To fashion and engrave vases of agate, crystal, lapis-lazuli, or the like, they make use of a kind of lathe, like that used by pewterers to hold the vessels, which are to be wrought with proper tools; that of the engraver generally holds the tools, which are turned by a wheel; and the vessel is held to them to be cut and engraved, either in relievo or otherwise; the tools being moistened, from time to time, with diamond dust and oil, or at least emery and water. To engrave figures or devices on any of these stones, when polished, such as medals, seals, &c. they use a little iron wheel, the ends of whose axis are received within two pieces of iron, placed upright, as in the turner's lathe; and to be brought closer, or set further apart, at pleasure: at one end of the axis are fitted the proper tools, being kept tight by a screw. Lastly. The wheel is turned by the foot, and the stone applied by the hand to the tool, and is shifted and conducted as occasion requires.

The tools are generally of iron, and sometimes of brass; their form is various, but it generally bears some resemblance to chisels, gouges, &c. Some have small round heads, like buttons, others like ferrels, to take the pieces out, and others flat, &c. when the stone has been engraved, it is polished on wheels of hair-brushes and tripoli.

*ENGRAVING on steel* is chiefly employed in cutting seals, punches, matrices, and dyes proper for striking coins, medals, and counters. The method of engraving with the instruments, &c. is the same for coins as for medals and counters: All the difference consists in their greater or less relievo, the relievo of coins being much less considerable than that of medals, and that of counters still less than that of coins.

Engravers in steel commonly begin with punches, which are in relievo, and serve for making the creux, or cavities, of the matrices and dyes: though sometimes they begin with the creux, or hollowness, but then it is only when the intended work is to be cut very shallow. The first thing done, is that of designing the figures; the next is the moulding them in wax, of the size and depth they are to lie, and from this wax the punch is engraved. When the punch is finished, they give it a very high temper, that it may the better bear the blows of the hammer with which it is struck to give the impression to the matrix.

The steel is made hot to soften it, that it may the more readily take the impression of the punch; and after striking the punch on it, in this state, they proceed to touch up or finish the strokes and lines, where by reason of their fineness or the too great relievo they are any thing defective, with steel gravers of different kinds, chisels, flatters, &c. being the principal instruments used in graving on steel.

The figure being thus finished, they proceed to engrave the rest of the medal, as the mouldings of the border, the engrailed ring, letters, &c. with little steel punches, well tempered, and very sharp.

*ENGUICHE'*, in heraldry, is said of the great mouth of a hunting horn, when its rim is of a different colour from that of the horn itself.

*ENGYSCOPE*, the same with microscope. See *MICROSCOPE*.

*ENHARMONIC*, in the ancient music, one of their genera or kinds of music, so called from its superior excellence; though wherein it consisted, says Mr Malcom, is hard to say: it was allowed by all to be so very difficult, that few could ever practise it.

*ENHYDRUS*, in natural history, a genus of siderochita or crustated ferrugineous bodies, formed in large and in great part empty cases, inclosing a small quantity of an aqueous fluid.

Of this genus there are only two species: 1. The thick-shelled enhydrus, with black, reddish-brown, and yellow crusts. 2. The thinner-shelled kind, with yellowish-brown and purple crusts; neither of which ferments with aqua fortis, or gives fire with steel.

*ENIXUM*, among chemists, a kind of neutral salt, generated of an acid and an alkali.

The sal enixum of Paracelsus, is the caput mortuum of spirits of nitre with oil of vitriol, or what remains in the retort after the distillation of this spirit; being of a white colour, and pleasing acid taste.

*ENMANCHE'*, in heraldry, is when lines are drawn from the centre of the upper edge of the chief to the sides, to about half the breadth of the chief; signifying

lying sleeved, or resembling a sieve, from the French *manche*.

**ENNEAGON**, in geometry, a polygon with nine sides. See **POLYGON**.

**ENNEAHEDRIA**, in natural history, a genus of columnar, crystalliform, and double-pointed spars, composed of a trigonal column, terminated at each end by a trigonal pyramid.

Of this genus there are several species, distinguished by the length or shortness of the column and pyramids, none of which will give fire with steel, but all of them ferment with aqua fortis. See **SPAR**.

**ENNEANDRIA**, in botany. See **BOTANY**, p. 635. and Plate LIII. fig. 9.

**ENS**, among metaphysicians, denotes entity, being, or existence: this the schools call *ens reale*, and *ens positivum*, to distinguish it from their *ens rationis*, which is only an imaginary thing, or exists only in the imagination.

**Ens**, among chemists, imports the power, virtue, and efficacy which certain substances exert upon our bodies.

**ENS**, in geography, a city of Germany, situated at the confluence of the Danube and the river Ens, about eighty miles south of Vienna: E. long. 14° 20', N. lat. 48° 16'.

**ENSEELED**, in falconry, is said of a hawk that has a thread drawn through her upper eye-lid, and made fast under her beak, to take away the sight.

**ENSIGN**, in the military art, a banner under which the soldiers are ranged according to the different companies or parties they belong to.

**ENSIGN** is also the officer that carries the colours, being the lowest commissioned officer in a company of foot, subordinate to the captain and lieutenant.

**ENSISHEIM**, a town of Germany, in the landgraviate of Alsace, about fifty miles south of Strasburg: E. long. 7° 30', N. lat. 47° 50'.

**ENSKIRKEN**, a town of Germany, fifteen miles south-west of Cologne.

**ENTABLATURE**, or **ENTABLEMENT**, in architecture, is that part of an order of a column which is over the capital, and comprehends the architrave, frieze, and cornice. See **ARCHITECTURE**.

**ENTABLER**, in the menage, the fault of a horse whose croupe goes before his shoulders in working upon volts; which may be prevented by taking hold of the right rein, keeping your right leg near, and removing your left leg as far from the horse's shoulder as possible.

This is always accompanied with another fault called *aculer*. See **ACULER**.

**ENTAIL**. See **TAILZIE**.

**ENTE'**, in heraldry, a method of marshalling more frequent abroad than with us, and signifying grafted or ingrafted.

We have, indeed, one instance of *enté* in the fourth grand quarter of his majesty's royal ensign, whose blazon is Brunswick and Lunenburg impaled with ancient Saxony, *enté en pointé*, grafted in point.

**ENTELECHIA**, a word used by Aristotle to express

Vol. II. No. 47.

†

the soul, and which, not occurring in any other author, has given the commentators upon that philosopher great trouble to discover its true meaning.

**ENTEROCÆLE**, in surgery, a tumor formed by a prolapsion of the intestines through the rings of the abdomen, and processes of the peritonæum, into the scrotum. See **SURGERY**.

**ENTEROLOGY**, a term used by physicians, for a discourse or treatise on the contents of the head, breast, and abdomen.

**ENTEROMPHALUS**, the same with a hernia umbilicalis, or rupture at the navel.

**ENTERSOLE**, in architecture, a kind of little story, sometimes called a mezzanine, contrived occasionally at the top of the first story, for the convenience of a wardrobe, &c.

**ENTHUSIASM**, a transport of the mind, whereby it is led to think and imagine things in a sublime, surprising, yet probable manner. This is the enthusiasm felt in poetry, oratory, music, painting, sculpture, &c.

**ENTHUSIASM**, in a religious sense, implies a transport of the mind, whereby it fancies itself inspired with some revelation, impulse, &c. from heaven.

**ENTHUSIAST**, a person possessed with enthusiasm. See the preceding article.

**ENTHYMEME**, among logicians, denotes a syllogism, perfect in the mind, but imperfect in the expression, by reason one of the propositions is suppressed, as being easily supplied by the understanding of those with whom we discourse.

**ENTOMON**, in zoology. See **ONISCUS**.

**ENTREPAS**, in the manege, a broken pace or going, that is neither walk nor trot, but has somewhat of an amble.

This is a pace or gait of such horses as have no reins or back, and go upon their shoulders; or, of such as are spoiled in their limbs.

**ENTRING-LADDERS**, in a ship, are of two sorts; one used by the vessel's sides, in a harbour, or in fair weather, for persons to go in and out of the ship: the other is made of ropes, with small staves for steps; and is hung out of the gallery to enter into the boat, or to come aboard the ship, when the sea runs so high that they dare not bring the boat to the ship's side for fear of staving it.

**ENTROCHUS**, in natural history. See **ISIS**.

**ENTRY of an heir**, in Scots law, that form of law by which an heir vests in himself a proper title to his predecessor's estate. See *Precept of CLARE CONSTAT*.

**Bill of ENTRY**, in commerce. See **BILL**.

In making entries inwards, it is usual for merchants to include all the goods they have on board the same ship in one bill, though sometimes they may happen to be upwards of twenty several kinds; and in case the goods are short entered, additional or post entries are now allowed; though formerly the goods, so entered, were forfeited. As to bills of entry outwards, or including goods to be exported, upon delivering them, and paying the customs, you will receive a small piece

2

5 K

of

of parchment called a cocker, which testifies your payment thereof, and all duties for such goods.

If several sorts of goods are exported at once, of which some are free, and others pay customs; the exporter must have two cockets, and therefore must make two entries; one for the goods that pay, and the other for the goods that do not pay custom.

Entries of goods, on which a drawback is allowed, must likewise contain the name of the ship in which the goods were imported, the importer's name, and time of entry inwards. The entry being thus made, and an oath taken that the customs for those goods were paid as the law directs, you must carry it to the collector and comptroller, or their deputies; who, after examining their books, will grant warrant, which must be given to the surveyor, searcher, or land-waiter, for them to certify the quantity of goods; after which the certificate must be brought back to the collector and comptroller, or their deputies, and oath made that the said goods are really shipped, and not landed again in any part of Great Britain.

**ENVELOPE**, in fortification, a work of earth, sometimes in form of a simple parapet, and at others like a small rampart with a parapet: it is raised sometimes on the ditch, and sometimes beyond it.

**ENVIRONNE'**, in heraldry, signifies surrounded with other things: thus, they say, a lion environné with so many bezants. See **BEZANT**.

**ENUMERATION**, an account of several things, in which mention is made of every particular article.

**ENVOY**, a person deputed to negotiate some affair with any foreign prince or state. Those sent from the courts of France, Britain, Spain, &c. to any petty prince or state, such as the princes of Germany, the republics of Venice, Genoa, &c. go in quality of envoys, not ambassadors; and such a character only do those persons bear, who go from any of the principal courts of Europe to another, when the affair they go upon is not very solemn or important. There are envoys ordinary and extraordinary, as well as ambassadors; they are equally the same under the protection of the law of nations, and enjoy all the privileges of ambassadors, only differing from them in this, that the same ceremonies are not performed to them.

**ENVY**, in ethics, an uneasiness of the mind, caused by the consideration of a good we desire, obtained by one we think less worthy of it than ourselves. See **PASSION**, and **MORALS**.

**EPACT**. See **ASTRONOMY**, *Of the Division of Time*.

**EPANORTHOSIS**, in rhetoric, a figure by which a person corrects, or ingeniously revokes, what he just before alledged, as being too weakly expressed, in order to add something stronger, and more conformable to the passion with which he is agitated.

The epanorthosis is distinguished into two kinds. The one is when we correct or revoke the word, as in the following example of the apostle, *But I laboured more abundantly than they all: yet not I, but the grace of God, which was with me*, 1 Cor. xv. 10. where, what he first attributed to his own merit, he chuses afterwards to call the work of grace, as being

the principal cause. The second kind of epanorthosis, is when we correct or revoke the sentiment, as in the following of Cicero: *Italiam ornare, quam domum suam, militat: quarequam, Italia ornata, domus ipsa mihi videtur ornatio.*

**EPARER**, in the menage, signifies the flinging of a horse, or his jerking and striking with his hind-legs.

**EPAULEMENT**, in fortification, a work raised to cover sidewise, is either of earth, gabions, or fascines loaded with earth. The epaulements of the places of arms for the cavalry, at the entrance of the trenches, are generally of fascines mixed with earth.

**EPENTHESIS**, in grammar, the interposition or insertion of a letter or syllable in the middle of a word; as *aliturum*, for *aliturum*; *relligio*, for *religio*; *induprator*, for *imperator*, &c.

**EPERLANUS**, in ichthyology. See **SALMO**.

**EPHA**, or **EPHAN**, in Jewish antiquity, a measure for things dry, containing 1.0961 of a bushel.

**EPHÆTUM**, in botany. See **RANUNCULUS**.

**EPHEDRA**, the **SEA-GRAPE**, or **SHRUB HORSE TAIL**, in botany, a genus of the dioecia monadelphia class. The calix of the amentum of the male and female is divided into segments; the corolla is wanting in both; the stamina are seven; there are two pithils, and two seeds covered with a kind of cup-berry. There are two species, none of them natives of Britain.

**EPHEMERY**, in medicine, the name of a species of fever continuing the space of one day, or sometimes more; for the medical writers express themselves by *ephemera simplex. vel plurium dierum*. See **MEDICINE**.

**EPHEMERA**, the **DAY-FLY**, in zoology, a genus belonging to the order of neuroptera. It has no teeth or palpi; there are two large protuberances above the eyes; the wings are erect, the two hind ones being largest; and the tail is bristly. There are eleven species, distinguished by their colour and the number of bristles in their tail. This fly derives its name from the circumstance of its living but one day.

**EPHEMERIDES**, in literary history, an appellation given to those books or journals, which shew the motions and places of the planets for every day of the year.

It is from the tables contained in these ephemerides that eclipses, and all the variety of aspects of the planets, are found.

**EPHEMERUM**, in botany. See **TRADESCANTIA**.

**EPHIALTES**, in medicine, the same with the incubus, or night-mare. See **INCUBUS**.

**EPHIPPUIM**, in anatomy. See **ANATOMY**, Part I.

**EPHOD**, in Jewish antiquity, one part of the priestly habit; being a kind of girdle, which, brought from behind the neck over the two shoulders, and hanging down before, was put cross the stomach, then carried round the waist, and made use of as a girdle to the tunic.

There were two sorts of ephods, one of plain linen for the priests, and the other embroidered for the high priest.

**EPHORI**, in Grecian antiquity, magistrates established in

in ancient Sparta to balance the regal power. The authority of the ephori was very great. They sometimes expelled and even put to death the kings, and abolished or suspended the power of the other magistrates, calling them to account at pleasure. There were five of them, others say nine. They presided in the public shows and festivals. They were entrusted with the public treasure, made war and peace, and were so absolute, that Aristotle makes their government equal to the prerogative of a monarchy. They were established by Lycurgus.

**EPHYDRUM**, in botany. See **EQUISETUM**.

**EPIC**, or **HEROIC POEM**. See **COMPOSITION**.

**EPICEDIUM**, in ancient poetry, a poem rehearsed during the funeral solemnity of persons of distinction.

**EPICOENE**, in grammar, a term applied to nouns, which, under the same gender and termination, mark indifferently the male and female species.

**EPICUREAN PHILOSOPHY**, the doctrine or system of philosophy maintained by Epicurus and his followers.

His philosophy consisted of three parts, canonical, physical, and ethereal. The first was about the canons, or rules of judging. The censure which Tully passes upon him for his despising logic, will hold true only with regard to the logic of the stoics, which he could not approve of, as being too full of nicety and quirk. Epicurus was not acquainted with the analytical method of division and argumentation, nor was he so curious in modes and formation as the stoics. Soundness and simplicity of sense, assisted with some natural reflections, was all his art. His search after truth proceeded only by the senses, to the evidence of which he gave so great a certainty, that he considered them as an infallible rule of truth, and termed them the first natural light of mankind.

In the second part of this philosophy he laid down atoms, space, and gravity, as the first principles of all things: he did not deny the existence of God, but thought it beneath his majesty to concern himself with human affairs: he held him a blessed immortal being, having no affairs of his own to take care of, and above meddling with those of others.

As to his ethics, he made the supreme good of man to consist in pleasure, and consequently supreme evil in pain. Nature itself, says he, teaches us this truth, and prompts us from our birth to procure whatever gives us pleasure, and avoid what gives us pain. To this end he proposes a remedy against the sharpness of pain: this was to divert the mind from it, by turning our whole attention upon the pleasures we have formerly enjoyed: he held that the wise man must be happy, as long as he is wise; that pain, not depriving him of his wisdom, cannot deprive him of his happiness.

There is nothing that has a fairer shew of honesty than the moral doctrine of Epicurus. Gassendus pretends, that the pleasure in which this philosopher has fixed the sovereign good, was nothing else but the highest tranquillity of mind in conjunction with the most perfect health of body: but Tully, Horace, and

Plurarch, as well as almost all the fathers of the church, give us a very different representation: indeed the nature of this pleasure, in which the chief happiness is supposed to be fixed, is a grand problem in the morals of Epicurus. Hence there were two kinds of Epicureans, the rigid and the remiss: the first were those who understood Epicurus's notion of pleasure in the best sense, and placed all their happiness in the pure pleasures of the mind, resulting from the practice of virtue: the loose or remiss Epicureans, taking the words of that philosopher in a gross sense, placed all their happiness in bodily pleasures or debauchery.

**EPICYCLE**, in the ancient astronomy, a little circle whose centre is in the circumference of a greater circle; or it is a small orb, or sphere, which being fixed in the deferent of a planet, is carried along with it; and yet, by its own peculiar motion, carries the planet fastened to it round its proper centre.

It was by means of epicycles, that Ptolemy and his followers solved the various phenomena of the planets, but more especially their stations and retrogradations.

**EPICYCLOID**, in geometry, a curve generated by the revolution of the periphery of a circle, along the convex or concave side of the periphery of another circle.

**EPICYEMA**, among physicians, denotes a superfluousness; being a false conception or mole happening after the birth of a regular fœtus.

**EPIDEMIA**, in Grecian antiquity, festivals kept in honour of Apollo and Diana, at the stated seasons when these deities, who could not be present every where, were supposed to visit different places, in order to receive the vows of their adorers.

**EPIDEMIC**, among physicians, an epithet of diseases which at certain times are popular; attacking great numbers at or near the same time. See **MEDICINE**.

**EPIDENDRUM**, in botany, a genus of the gynandria diandria class. The nectarium is oblique, reflected, and shaped like a turban. There are thirty species, none of them natives of Britain.

**EPIDERMIS**, in anatomy. See **ANATOMY**, p. 255.

**EPIDIDYMIS**, in anatomy. See **ANATOMY**, p. 171.

**EPIGASTRIC REGION**, a part or subdivision of the abdomen. See **ANATOMY**, p. 256.

**EPIGLOTTIS**, in anatomy, one of the cartilages of the larynx, or wind-pipe. See **ANATOMY**, p. 281.

**EPIGRAM**, in poetry, a short poem in verse, treating only of one thing, and ending with some lively, ingenious, and natural thought or point.

**EPIGRAPHE**, among antiquarians, denotes the inscription of a building, pointing out the time when, the persons by whom, the uses, and the like, for which it was erected.

**EPILEPSY**, in medicine, the same with what is otherwise called the falling-sickness, from the patient's falling suddenly to the ground. See **MEDICINE**.

**EPILOBIUM**, in botany, the **WILLOW HERB**, a genus of the octandria monogynia class. The calix is divided into four segments, and the corolla consists of four petals; the capsule is oblong and below the flower; and the seeds are pappous. There are seven species, all of them natives of Britain, viz. the angustifolium, or rosbay

- rosebay willow herb; the hirsutum, or small flowered hairy willow herb; the ramosum, great flowered willow herb, or codlings and cream; the montanum, or smooth-leaved willow herb; the tetragonum, or narrow-leaved willow herb; the palustre, or marsh willow herb; and the alpinum, or mountain willow herb.
- EPILOGUE**, in oratory, the end or conclusion of a discourse, ordinarily containing a recapitulation of the principal matters delivered.
- EPilogue**, in dramatic poetry, a speech addressed to the audience after the play is over, by one of the principal actors therein, usually containing some reflections on certain incidents in the play, especially those in the part of the person that speaks it.
- EPIEDIUM**, **BARREN-WORT**, in botany, a genus of the tetrandia monogynia class. It has four cap-shaped nectaria lying upon the petals; the corolla consists of four petals; and the calix is caducous. There is but one species, a native of Germany.
- EPIPHANY**, a Christian festival, otherwise called the Manifestation of Christ to the Gentiles, observed on the sixth of January, in honour of the appearance of our Saviour to the three magi, or wise-men, who came to adore him and bring him presents. The feast of epiphany was not originally a distinct festival, but made a part of that of the nativity of Christ, which being celebrated twelve days, the first and last of which were high or chief days of solemnity, either of these might properly be called epiphany, as that word signifies the appearance of Christ in the world.
- EPIPHONEMA**, in rhetoric, a sententious exclamation containing a lively remark placed at the end of a discourse or narration.
- EPIPHORA**, in medicine, a preternatural defluxion of the eyes, when they continually discharge a sharp serous humour, which excoriates the cheeks. See **MEDICINE**.
- EPIPHYSIS**, in anatomy. See **ANATOMY**, Part I.
- EPIPLOCELE**, in medicine, is a kind of hernia, or rupture, in which the omentum subsides into the scrotum.
- EPIPLOOMPHALON**, in medicine, an hernia umbilicalis, proceeding from the omentum falling into the region of the umbilicus or navel.
- EPIPLOON**. See **OMENTUM**.
- EPISCOPACY**, the quality of episcopal government, or that form of church-discipline, wherein diocesan bishops are established distinct from and superior to priests or presbyters. See **BISHOP**.
- EPISCOPAL**, something belonging to bishops.
- EPISCOPALIANS**, in church history, an appellation given to those who prefer the episcopal government and discipline to all others.
- By the test act, none but episcopalians, or members of the church of England, are qualified to enjoy any office civil or military.
- EPISCOPUS**. See **BISHOP**.
- EPISODE**, in poetry, a separate incident, story, or action, which a poet invents, and connects with his principal action, that his work may abound with a greater diversity of events; though, in a more limited sense, all the particular incidents whereof the action or narration is compounded, are called episodes. See **COMPOSITION**.
- EPISPASTIC**, in medicine, a topical remedy, which being applied to the external parts of the body, attracts the humours to that part.
- EPISTATES**, in the Athenian government, was the president of the proedri. See **PROEDRI**.
- EPISTEMONARCH**, in the ancient Greek church, an officer of great dignity, who had the care of every thing relating to faith, in the quality of censor. His office answered pretty nearly to that of master of the sacred palace at Rome.
- EPISTLE**, denotes the same with a missive letter; but is now chiefly used in speaking of ancient writings, as the epistles of St Paul, epistles of Cicero, epistles of Pliny, &c.
- EPISTOLARY**, something belonging to an epistle. See **EPISTLE**.
- EPISTROPHE**, in rhetoric, a figure, wherein that which is supposed of one thing, is strongly affirmed of another: thus, *Are they Hebrews? so am I. Are they Israelites? so am I. Are they of the seed of Abraham? so am I, &c.*
- EPISTYLE**, in the ancient architecture, a term used by the Greeks for what we call architrave, viz. a massive piece of stone or wood, laid immediately over the capital of a column.
- EPITAPH**, a monumental inscription in honour or memory of a person deceased, or an inscription engraven or cut on a tomb, to mark the time of a person's decease, his name, family; and, usually, some eulogium of his virtues, or good qualities.
- EPITASIS**, in ancient poetry, the second part or division of a dramatic poem, wherein the plot, entered upon in the first part, or protasis, was carried on, heightened, and worked up, till it arrived at its state, or height, called catastasis.
- EPITASIS**, in medicine, the increase of a disease, or beginning of a paroxysm, particularly in a fever.
- EPITHALAMIUM**, in poetry, a nuptial song, or composition, in praise of the bride and bridegroom, praying for their prosperity, for a happy offspring, &c.
- Among the Greeks, the married couple were no sooner bedded, than the young men and maids gathered round the door, dancing and singing the epithalamium, shouting and stamping with their feet, with intention to drown the maid's cries.
- EPITHEM**, in pharmacy, a kind of fomentation, or remedy of a spirituous or aromatic kind, applied externally to the regions of the heart, liver, &c. to strengthen and comfort the same, or to correct some intemperate thercof. See **FOMENTATION**.
- EPITHET**, in poetry and rhetoric, an adjective expressing some quality of a substantive to which it is joined; or such an adjective as is annexed to substantives by way of ornament and illustration, not to make up an essential part of the description. Nothing, says Aristotle, tires the reader more than too great a redundancy of epithets, or epithets placed improperly; and yet nothing

nothing is so essential in poetry as a proper use of them. The writings of the best poets are full of them, especially Virgil.

**EPITHOME**, in literary history. See **ABRIDGEMENT**.

**EPITRITUS**, in prosody, a foot consisting of three long syllables and one short.

**EPIZEUXIS**, in rhetoric, a figure which repeats the same word, without any other intervening; such is that of Virgil, *Nunc, nunc, insurgite remis*.

**EPOCH**, in chronology, a term or fixed point of time, whence the succeeding years are numbered or accounted. See **ASTRONOMY**, p. 487.

**EPODE**, in lyric poetry, the third or last part of the ode; the ancient ode being divided into strophe, antistrophe, and epode. See **ODE**.

**EPOPOEIA**, in poetry, the story, fable, or subject treated of in an epic poem.

**EPOTIDES**, in the naval architecture of the ancients, two thick blocks of wood, one on each side the prow of a galley, for warding off the blows of the rostra of the enemy's vessels.

**EPPINGEN**, a town of Germany, situated about ten miles north of Halibron.

**EPSOM**, a town of Surry, about fifteen miles south-west of London; much resorted to on account of its medicinal waters; from which the bitter purging salt being first extracted, got the name of Epsom-salt. At present, however, the bitter purging salt is procured from the bitters, remaining after the crystallization of common salt; and this is found to answer all the purposes of that first obtained from Epsom-waters, and goes by its name. See **CHEMISTRY**.

**EPULONES**, in Roman antiquity, ministers who assisted at the sacrifices, and had the care of the sacred banquet committed to them.

**EQUABLE**, an appellation given to such motions as always continue the same in degree of velocity, without being either accelerated or retarded. See **MECHANICS**.

**EQUAL**, a term of relation between two or more things of the same magnitude, quantity, or quality.

Mathematicians speak of equal lines, angles, figures, circles, ratios, solids.

**EQUALITY**, that agreement between two or more things, whereby they are denominated equal.

**EQUANIMITY**, in ethics, denotes that even and calm frame of mind and temper, under good or bad fortune, whereby a man appears to be neither puffed up nor overjoyed with prosperity, nor dispirited, soured, or rendered uneasy by adversity.

**EQUATION**, in algebra. See **ALGEBRA**, p. 100.

**EQUATION of time**, in astronomy and chronology, the reduction of the apparent time or motion of the sun, to equable, mean, or true time. See **ASTRONOMY**, p. 459.

**EQUATOR**, in geography, a great circle of the terrestrial globe, equidistant from its poles, and dividing it into two equal hemispheres; one north, and the other south. See **GEOGRAPHY**.

**EQUERRY**, in the British customs, an officer of state, under the master of the horse.

VOL. II. No. 47.

2

There are five equerries, who ride abroad with his majesty: for which purpose they give their attendance monthly, one at a time, and are allowed a table.

As to the equerries of the crown stable, they have this distinct appellation, as being employed in mounting, managing, and breaking the saddle-horses for his majesty's use, and holding his stirrup.

**EQUES AUGATUS**, is used for a knight batchelor, called *auratus*, q. d. *gilt*, because anciently none but knights were allowed to beautify their armour, or other habiliments for war, with gold.

**EQUESTRIAN STATUE**, signifies the statue of a person mounted on horseback.

**EQUESTRIAN ORDER**, among the Romans, signified their knights, or equites; as also their troopers, or horsemen in the field; the first of which orders stood in contradistinction to the senators, as the last did to the foot, military, or infantry: each of these distinctions was introduced into the state by Romulus.

**EQUIANGULAR**, in geometry, an epithet given to figures, whose angles are all equal: such are a square, an equilateral triangle, &c.

**EQUICRURAL**, in geometry. See **ISOSCELES**.

**EQUIDISTANT**, an appellation given to things placed at equal distance from some fixed point, or place, to which they are referred.

**EQUILATERAL**, in general, something that hath equal sides, as an equilateral angle.

**EQUILIBRIUM**, in mechanics, is when the two ends of a lever or balance hang so exactly even and level, that neither doth ascend or descend, but keep in a position parallel to the horizon; which is occasioned by their being both charged with an equal weight.

**EQUIMULTIPLES**, in arithmetic and geometry, are numbers or quantities multiplied by one and the same number or quantity. Hence, equimultiples are always in the same ratio to each other, as the simple quantities before multiplication: thus, if 6 and 8 are multiplied by 4, the equimultiples 24 and 32 will be to each other as 6 to 8.

**EQUINOCTIAL**, in astronomy, a great circle of the celestial globe, whose poles are the poles of the world. See **ASTRONOMY**, and **GEOGRAPHY**.

**EQUINOX**, the time when the sun enters either of the equinoctial points, where the ecliptic intersects the equinoctial. See **ASTRONOMY**.

*Precession of the EQUINOXES.* See **ASTRONOMY**.

**EQUISETUM**, or **HORSE-TAIL**, in botany, a genus of the cryptogamia filices class. The fructification is disposed on an oblong spike, and of an orbicular figure. There are seven species, six of which are natives of Britain, viz. the sylvaticum, or wood horse-tail; the arvense, or corn horse-tail; the palustre, or marsh horse tail; the fluviatile, or river horse-tail; the limosum, or smooth horse-tail; and the hyemale, or rough horse-tail.

**EQUITY**, in a general sense, the virtue of treating all other men according to common reason and justice, or as we would be gladly treated ourselves, when we understand aright what is our due. See **JUSTICE**.

**EQUIVALENT**, an appellation given to things which

†

5 L

agree

agree in nature, or other circumstances, as force, virtue, &c.

**EQUIVOCAL TERMS** or **WORDS**, among logicians, are these which have a doubtful or double meaning.

According to Mr Locke, the doubtfulness and uncertainty of words has its cause more in the ideas themselves, than in any incapacity of the words to signify them; and might be avoided, would people always use the same term to denote the same idea, or collection of ideas: but, adds he, it is hard to find a discourse on any subject where this is the case; a practice which can only be imputed to folly, or great dishonesty; since a man, in making up his accounts, might with as much fairness use the numeral characters sometimes for one, sometimes for another collection of unities.

**EQUIVOCAL GENERATION**, the production of animals, without the intercourse between the sexes, by the influence of the sun or stars, &c.

This kind of generation is now quite exploded by the learned.

**EQUULEUS**, or **ECUULEUS**, in antiquity, a kind of rack used for extorting a confession, at first chiefly practised on slaves, but afterwards made use of against the Christians.

The equuleus was made of wood, having holes at certain distances, with a screw, by which the criminal was stretched to the third, sometimes to the fourth, or fifth holes, his arms and legs being fastened on the equuleus with cords; and thus was hoisted aloft, and extended in such a manner, that all his bones were dislocated. In this state red-hot plates were applied to his body, and he was goaded in the sides with an instrument called ungula.

**EQUULUS**, in astronomy. See **ASTRONOMY**, p. 487.

**EQUUS**, the **HORSE**, in zoology, a genus of quadrupeds belonging to the order of belluæ. This genus comprehends the horse, the ass, and the zebra; they have six erect and parallel fore-teeth in the upper jaw, and six somewhat prominent ones in the under jaw; the dog-teeth are solitary, and at a considerable distance from the rest; and the feet consist of an undivided hoof. The horse is a domestic animal, and the figure and dimensions of his body are so well known, that a general description is altogether unnecessary. We shall therefore confine ourselves to the natural history of this noble animal.

The horse, in a domestic state, is a bold and fiery animal; equally intrepid as his master, he faces danger and death with ardour and magnanimity. He delights in the noise and tumult of arms, and seems to feel the glory of victory: he exults in the chase; his eyes sparkle with emulation in the course. But though bold and intrepid, he is docile and tractable: he knows how to govern and check the natural vivacity and fire of his temper. He not only yields to the hand, but seems to consult the inclination of his rider. Constantly obedient to the impressions he receives, his motions are entirely regulated by the will of his master. He in some measure resigns his very existence to the pleasure of man. He delivers up his whole powers; he reserves

nothing; he will rather die than disobey. Who could endure to see a character so noble abused! Who could be guilty of such gross barbarity!

This character, though natural to the animal, is in some measure the effect of education. His education commences with the loss of liberty, and it is finished by constraint. The slavery of the horse is so ancient and so universal, that he is but rarely seen in a natural state. Several ancient writers talk of wild horses, and even mention the places where they were to be found. Herodotus takes notice of white savage horses in Scythia; Aristotle says, they are to be found in Syria; Pliny, in the northern regions; and Strabo, in Spain and the Alps. Among the moderns, Leardon says, that wild horses are to be found in the Highlands of Scotland, and the Orkney Isles; Olaus, in Muscovy; Dapper, in the island of Cyprus; Leo and Marmol, in Arabia and Africa, &c. But, as Europe is almost equally inhabited, wild horses are not to be met with in any part of it; and those of America were originally transported from Europe by the Spaniards; for this species of animals did not exist in the new world. The Spaniards carried over a great number of horses, lest them in different islands, &c. with a view to propagate that useful animal in their colonies. These have multiplied incredibly in the vast deserts of those thinly peopled countries, where they roan at large, without any restraint. M. de Salle relates, that he saw, in the year 1635, horses feeding in the meadows of North America, near the bay of St Louis, which were so ferocious that nobody durst come near them. Oexmelin says, that he has seen large troops of them in St Domingo running in the valleys; that when any person approached, they all stooped; and one of them would advance till within a certain distance, then snort with his nose, take to his heels, and the whole troop after him. Every author who takes notice of these horses of America, agree that they are smaller and less handsome than those of Europe. These relations sufficiently prove, that the horse when at full liberty, though not a fierce or dangerous animal, has no inclination to associate with mankind; that all the softness and docility of his temper proceeds entirely from the culture and polish he receives in his domestic education, which in some measure commences as soon as he is brought forth.

The motions of the horse are chiefly regulated by the bit and the spur; the bit informs him how to direct his course, and the spur quickens his pace. The mouth of the horse is endowed with an amazing sensibility: the slightest motion or pressure of the bit gives him warning, and instantly determines his course.

The horse has not only a grandeur in his general appearance, but there is the greatest symmetry and proportion in the different parts of his body. The regularity and proportion of the different parts of the head gives him an air of lightness, which is well supported by the strength and beauty of his chest. He erects his head, as if willing to exalt himself above the condition of other quadrupeds: his eyes are open and lively;

his

*Fig. 1. EQUUS CABALLUS*  
or HORSE.

*Fig. 2. EQUUS ASINUS*  
or ASS.

*Fig. 3. EQUUS ZEBRA.*

his ears are handsome, and of a proper height; his main adorns his neck, and gives him the appearance of strength and boldness.

At the age of two years, or two years and a half, the horse is in a condition to propagate; and the mare, like most other females, is ready to receive him still sooner. But the foals produced by such early embraces are generally ill made and weakly. The horse should never be admitted to the mare till he is four or four and a half; this is only meant with regard to draught-horses. Fine horses should not be admitted to the mare before they be six years old; and Spanish stallions not till seven. The mares are generally in season from the beginning of April to the end of March; but their chief ardour for the horse lasts but about 15 or 20 days, and this critical season should always be embraced. The stallion ought to be sound, well made, vigorous, and of a good breed. For fine saddle horses, foreign stallions, as Arabians, Turks, Barbs, and Andalusians, are preferable to all others. Next to these, British stallions are the best; because they originally sprang from those above mentioned, and are very little degenerated. The stallions of Italy, and especially the Neapolitans, are very good. The best stallions for draught or carriage horses, are those of Naples, Denmark, Holstein, and Freezeland. The stallions for saddle-horses should be from 14 to 15 hands high, and for draught-horses at least 15 hands. Neither ought the colour of stallions to be overlooked; as a fine black, grey, bay, sorrel, &c. Besides these external qualities, a stallion ought to have courage, tractability, spirit, agility, a sensible mouth, sure limbs &c. These precautions in the choice of a stallion are the more necessary, because he has been found by experience to communicate to his offspring almost all his good or bad qualities, whether natural or acquired.

The mare contributes less to the beauty of her offspring than the stallion; but she contributes perhaps more to their constitution and stature: for these reasons, it is necessary that the mares for breed be perfectly sound, and make good nurses. For elegant horses, the Spanish and Italian mares are best; but, for draught-horses, those of Britain and Normandy are preferable. However, when the stallions are good, the mares of any country will produce fine horses, provided they be well made and of a good breed.

Mares go with young eleven months and some days. They bring forth standing; contrary to the course of most other quadrupeds, who lie during this operation. They continue to bring forth till the age of 16 or 18 years; and both horses and mares live between 25 and 30 years. Horses cast their hair once a year, generally in the spring, but sometimes in the autumn. At this time they are weak, and require to be better fed and taken care of than at any other season.

In Persia, Arabia, and most eastern countries, they never geld their horses, as is done in Europe and China. This operation greatly diminishes their strength, courage, and spirit; but it makes them good humoured, gentle, and tractable. With regard to the time of performing this operation, the practice of different

countries is different: some geld their horses when a year old, and others at 18 months. But the best and most general practice is to delay the operation till they be two years old at least; because, when the gelding is delayed for two years or more, the animals retain more of the strength and other qualities which naturally belong to the male.

As the utility of horses surpasses that of all other domestic animals, it may be of use to subjoin some marks by which the age and other properties of horses may be distinguished.

The first teeth that appear are four, two above and two below, which are called foal-teeth, and may be easily distinguished from the others by their whiteness. The rest come out afterwards till they are twelve in number, six above and six below. When a colt is between two years and a half and three years old, he casts four of these teeth, two above and two below. These we call nippers or gatherers, and are much longer and larger than the fore teeth; with these he nips off the grass, and pulls the hay from the rack. When these are complete, the horse will be three years old, or somewhat more.

When he is about four, he casts again two above and two below, one on each side the nippers; so that now there are no fore-teeth remaining but the corner-teeth; and hence it may be concluded that he is about four years old. The tusks appear next after these, and are a little crooked. Those below come out before those on the upper jaw, and at four years old they are very small. When all the colt-teeth are cast, and the corner-teeth begin to shew themselves, then the horse comes five.

From five to five and a half the corner teeth remain hollow within, and are not quite filled up till the horse is six. At five and a half they are about a quarter of an inch high, and when he is full six near half an inch. Every thing that is to be examined at six years old, are the corner-teeth and the tusks. That part of the corner-teeth that had flesh in it first turns to a brownish spot, like the eye of a garden-bean. At seven the mark or spot becomes faint, and the tooth more even. At eight it quite disappears, though it possibly may remain in a very small degree for two or three years more, which has deceived many. The longer the corner teeth are, the older is the horse; and they are apt to grow foul and turn yellow. When the mark is gone, if you touch the tusks on the upper jaw with your finger, and find it worn away and equal with the palate, you may certainly judge that the horse is ten years old at least. Lastly, when the flanks of a horse are much sunk, the feet broken and spoiled, the pace bad, and the eye-pits very yellow, you may certainly conclude the horse is considerably advanced in years.

When the horse is without blemish, the legs and thighs are clean, the knees strait, the skin and flank thin, and the back sinew strong and well braced. The sinews and the bones should be so distinct, as to make the legs appear thin and lathy, not full and round. The pastern joints should never be large and round;

END

nor must there be any swelling near the coronet. The hocks should be lean and dry, not puffed up with wind. With regard to the hoof, the coronet should be equally thick, and the horn shining and greyish. A white horn is a sign of a bad foot, for it will wear out in a short time; and likewise when the horn is thin, it is liable to be spoiled in shoeing, and by travelling hard on stony grounds. This is best known when the shoe is taken off; for then the verge all round the sole will appear thin, and the horse will wince at the least touch of the pincers.

A strong foot has the fibres of the hoof very distinct running in a direct line from the coronet to the toe, like the grain of wood. In this case care must be taken to keep the foot moist and pliable. The greatest inconvenience attending a hard strong foot, is its being subject to rifts and fissures, which cleave the hoof quite through sometimes from the coronet down to the bottom.

A narrow heel is likewise a defect; and when it is not above two fingers in breadth the foot is bad. A high heel causes a horse to trip and stumble often; and the low one, with long yielding pasterns, is very apt to be worn quite away on a journey. Too large a foot in proportion to the rest of the body, renders a horse weak and heavy.

The head of a horse should be small, and rather lean than fleshy. The ears should be small, erect, thin, sprightly, and pointed. The forehead, or brow, should be neither too broad nor too flat, and should have a star or snip thereon. The nose should rise a little, and the nostrils should be wide that he may breathe more freely. The muzzle should be small, and the mouth neither too deep nor too shallow. The jaws should be thin, and not approach too near together at the throat, nor too high upwards towards the osset, that the horse may have sufficient room to carry his head in an easy graceful posture. The eyes should be of a middle size, bright, lively, and full of fire. The tongue should be small, that it may not be too much pressed by the bit; and it is a good sign when his mouth is full of white froth, for it shews that he will not soon be overheated.

The neck should be arched towards the middle, growing smaller by degrees from the breast and shoulders to the head. The hair of the main should be long, small, and fine; and if it be a little frizzled, so much the better. The shoulders should be pretty long, the withers thin, and enlarge gradually from thence downwards; but so as to render his breast neither too narrow nor too gross. A thick-shouldered horse soon tires, and trips and stumbles every minute; especially if he has a thick large neck at the same time. When the breast is so narrow that the fore-thighs almost touch, they are never good for much. A horse of a middle size should have the distance of five or six inches between his fore-thighs, and there should be less distance between his feet than his thighs near the shoulders when he stands upright.

The body or carcase of a horse should be of a middling size in proportion to his bulk, and the back

should sink a little below the withers; but the other parts should be straight, and no higher behind than before. He should also be home-ribbed; but the short ribs should not approach too near the haunches, and then he will have room to fetch his breath. When a horse's back is short in proportion to his bulk, and yet otherwise well limbed, he will hold out a journey though he will travel slow. When he is tall, at the same time with very long legs, he is but of little value.

The wind should never be overlooked in the choice of a horse; and it may easily be known by his flanks, if he is broken-winded, when he stands quiet in the stable; because he always pinches them in with a very slow motion, and drops them suddenly. A thick-winded horse fetches his breath often, and sometimes rattles and wheezes. This may be always discovered when he is put to brisk exercises.

The temper of a horse should always be observed; a vicious horse generally lays his ears close to his pole, shews the whites of his eyes, and looks fullen and dogged. An angry horse may be known by his frowning looks; and he generally seems to stand in a posture of defence. When he is very vicious, he pays no regard to the groom that feeds him: However, some horses that are ticklish will lay back their year ears, and yet be of a good disposition. A fearful horse is apt to start, and never leaves it off till he is old and useless. A fretful horse is very unfit for a journey; and you may discover his temper as soon as he gets out of the stable. A dull, heavy, sluggish horse may be easily known, whatever tricks are used to rouse his spirits.

With regard to the colour of a horse, the bright bay, and indeed all kinds of bays in general, are accounted a good colour. The chestnut horse is generally preferable to the sorrel, unless the former happens to be bald, or partly-coloured with white legs. Brown horses have generally black manes and tails, and their joints are of a rusty black. Those of this colour that are dappled are much handsomer than the rest. Horses of a shining black, and well-marked, without too much white, are in high esteem for their beauty. A star, or blaze, or white muzzle, or one or more feet tipped with white, are thought to be rather better than those that are quite black.

Of greys, the dappled are accounted best; though the silver grey makes a more beautiful appearance, and often prove good. The iron grey with white manes and tails are thought not to be so hardy. Greys of every kind will turn white sooner or later; but the nutmeg grey, when the dappled parts incline to bay or chestnut, are said to be good hardy horses. Roan horses have a diversity of colours mixed together; but the white is more predominant than the rest. They are all generally hardy, and fit for the road; and some are exceeding good. Those of a strawberry colour most resemble the sorrel, and they are often marked with white on the face and legs. When the bay is blended with it, he seems to be tintured with claret; and some of these prove to be very good. Dun, fallow, and cream-coloured horses have a list down their backs; and their manes and tails are black.

Dun

Don horses are seldom chosen by gentlemen, and yet they may be very useful to the country farmer. The fallow and cream-coloured are better esteemed, both for beauty and use. Those horses that are finely spotted with gay colours like leopards are a great rarity, and for that reason are only in the hands of great men.

There is some difference in horses according to the different countries where they are bred. For instance, in France, those of Bretagne are pretty strong made, and have generally black hair, or brown bay; and they have good legs and feet, with a hardy mouth, and a head short and fleshy; but in general they are pretty clumsy. The horses of Franche Comté are said to have the legs of tigers, and the belly of a hind; but they are short and thick, and of a middle size; being much more proper for drawing than riding. The horses of Gascony are not unlike those of Spain; but they are not so handsome, nor so active, and therefore they are more proper to draw carriages. The Limosin horses are very vicious, and are good for little till they are six years old. Their colour is generally bay, or a bay brown. The horses of Normandy are much like those of Bretagne; and those of Poitou have good bodies, legs, feet, and eyes; but they are far from being handsome.

The horses of Germany are much better and more handsome than those of the Low countries. They are of great use for carriages; but much more for the army, and for drawing the artillery. They have a great deal of hair, especially about the legs. They are not large, but they are well set; and yet they have tender feet. The Hungarian horses are excellent for the coach, as well as for riding; but they are large, though well proportioned, and they are of all colours, and in general very swift.

The British horses are of all kinds, they having been brought at first from different countries; but for racers no country can equal them, they having been bred from what are called barbs. The Danish horses are low, short, and square; but they have a fine head, and short hair. The horses of the Low countries are very fit for the coach, and they are best known by the name of Flanders-mares. The Polish horses are like the Danish; only they have not so fine a fore-hand: their colour is generally a bright bay, and that of the outward peel of an onion; and they are fiery and vicious. The horses of Switzerland are pretty much like those of Germany; which is no wonder, since the Germans purchase a great number of them. The horses of Piedmont are fiery, of a middle size, and of all sorts of colours; their legs are good and handsome, their eyes fine, their ears small, and their mouths good; but they do not carry their heads well.

The horses of Naples and Italy are generally ill made, and lean; and yet they are good and useful, for they are light and proper for racing, though not for a long course; they never do well in a colder climate. The Spanish horses are very well made, and handsome, as well as very active and nimble; they have good eyes, handsome legs and heads, and are easily managed;

they are also good for racing if they are well kept: however, they are not so good in northern climates as in their own country. The Turkish horses are of different shapes; but they are generally swift, though their mouths are bad. Most of them are white; tho' there are other colours; and they are large, hardy, strong, and fit for the road.

The horses of Barbary, commonly called barbs, have strong hoofs, and are more proper for racing than any others whatever: some have said they never grow old, because they preserve their vigour to the last. They are excellent stallions; and some of them are used as such in Britain: however, the Arabian horses are not quite so good as the Barbary, though some think they are both of the same kind, only those that are used to the deserts of Arabia are always in action. The horses of the gold-coast of Guinea are very few in number, and in other parts of that coast there are none at all; for many of the negroes, when they have been first brought over to our American plantations, have expressed great admiration at the sight of a horse, and even been afraid to come near one.

The horses of the Cape of Good Hope were originally brought from Persia; and they are generally small and of a chestnut colour; for those that are natives of that country are all wild, and could never yet be tamed. The horses of China are good, and more particularly those in the province Yun Nan, for they are very vigorous, though a little low. The horses of the Eluth Tartars are good and full of fire; and their size is much the same as the Polish horses: they are afraid of nothing, not even of lions and tigers; but perhaps this may be owing to use. In the country of the Mogul they are very numerous, and of all colours: they are generally of the middle size, tho' there are some as large and as handsome as those in Europe. The wild horses of Tartary differ little from the tame; but they are so swift, that they avoid the arrows of the most skilful hunters. [Plate LXXV. fig. 1.]

For the method of training and managing horses, see HORSEMANSHIP; and for their diseases and cure, see FARRIERY.

2. The ass is likewise a domestic animal, and easily distinguished from the horse at first sight; we never confound these two animals, even though they should happen to be of the same colour and stature; however, when we view the different parts of the ass, whether the external or internal, and compare them with the corresponding parts of the horse, the resemblance of these parts is so perfect, that we are surprised to find the individuals so different and so easily distinguishable by the eye. From this circumstance, some naturalists have considered the ass and the horse to be the same species of animals; and that the small differences between them are accidental, or owing to the influence of climate, culture, &c. Linnaeus's specific mark of the horse is, that the whole tail is covered with long hair; and his specific mark of the ass is, that the tail has long hair only towards the point, and a black cross over the shoulders. On the other hand, when we consider the differences in the temper, the manners and dispositions of these two animals, and, above all, the

impossibility of mixing them so as to produce a common or intermediate species capable of propagating and transmitting in the same manner as other distinct species, the notion that the horse and the ass are the same species will appear to be without any solid foundation. Besides, the ass differs materially from the horse in the thickness of the head, the length of the ears, the hardness of the skin, and in the voice, the dispositions, the manner of drinking, &c. With regard to animals, there is perhaps but one permanent and uniform specific distinction in nature: a male and female of different species may copulate, may produce a third animal resembling both, but very different from either: but here nature has put a final stop to all further procreation: the third animal, although it be seemingly furnished with every thing necessary for propagating, remains for ever barren. Now, the horse may be made to copulate with the ass; a mule, or mixture of the two, is the fruit of the unnatural embrace: but the impregnation of a mule is found by experience to be altogether impossible.

The ass, therefore, is a distinct species, and his race as ancient as that of the horse. Why then should this useful, patient, sober animal be so much despised? We are apt to compare him, on every occasion, with the horse, and from this comparison are led to very false and unfavourable conclusions. The horse is educated with great care and expence; while the poor ass, abandoned to the abuse of the meanest servants or the cruelty of children, instead of deriving benefit from instruction, loses in effect his natural good qualities by the bad treatment he suffers. He is the sport and buffet-block of every rustic, who beat and overload him without mercy or discretion. They never consider, that the ass would be the most useful, the best made, and most distinguished of all animals, if there were no horses in the world.

The ass is as humble, patient, and tranquil, as the horse is bold, ardent, and impetuous. He submits with firmness, perhaps with magnanimity, to strokes and chastisement; he is temperate both as to the quantity and quality of his food; he contents himself with the rigid and disagreeable herbage which the horse and other animals leave to him, and disdain to eat: he is more delicate with regard to his drink, never using water, unless it be perfectly pure. As his master does not take the trouble of combing him, he often rolls himself on the turf among thistles, ferns, &c. Without regarding what he is carrying, he lies down to roll as often as he can, seeming to reproach his master for neglect and want of attention.

When very young, the ass is a gay, sprightly, nimble, and gentle animal. But he soon loses these qualities, probably by the bad usage he meets with; and becomes lazy, untractable, and stubborn. When under the influence of love, he becomes perfectly furious. The affection of the female for her young is strong: Phoy assures us, that when an experiment was made to discover the strength of maternal affection in a she-ass, she run through the flames in order to come at her colt.

Although the ass be generally ill used, he discovers a great attachment to his master; he smells him at a

distance, searches the places and roads he used to frequent, and easily distinguishes him from the rest of mankind. The ass has a very fine eye, an excellent scent, and a good ear. When overloaded, he hangs his head, and sinks his ears: when too much teased or tormented, he opens his mouth and retracts his lips in a disagreeable manner, which gives him an air of ridicule and derision. If you cover his eyes, he will not move another step; if you lay him on his side, and place his head so that one eye rests on the ground, and cover the other with a cloth, he will remain in this situation without making any attempt to get up. He walks, trots, and gallops in the same manner as the horse; but all his motions are slower. Whatever be the pace he is going at, if you push him, he instantly stops.

The cry of the horse is known by the name of *neighing*; that of the ass, by *braying*, which is a long, disagreeable noise, consisting of alternate discords from sharp to grave and from grave to sharp: he seldom cries but when pressed with hunger or love: the voice of the female is clearer and more piercing than that of the male.

The ass is less subject to vermin than other animals covered with hair; he is never troubled with lice, probably owing to the hardness and driness of his skin; and it is probably for the same reason, that he is less sensible to the whip and spur than the horse.

The teeth of the ass fall out and grow at the same age and in the same manner as those of the horse; and he has nearly the same marks in his mouth.

Asses are capable of propagating when two years old. The females are in season during the months of May and June. The milk appears in the dugs ten months after impregnation; she brings forth in the twelfth month, and always one at a time. Seven days after the birth, the season of the female returns, and she is again in a condition to receive the male. The colt should be taken from her at the end of five or six months, that the growth and nourishment of the foetus may not be obstructed. The stallion or jack-ass should be the largest and strongest that can be found; he should be at least three years old, and never ought to exceed ten.

The ass, like the horse, takes three or four years in growing, and lives till he be 25 or 30: he sleeps less than the horse, and never lies down to sleep but when excessively fatigued. He is more robust, and less subject to diseases than the horse.

Travellers inform us that there are two sorts of asses in Persia; one of which is used for burdens, they being slow and heavy; and the other is kept like horses for the saddle, for they have smooth hair, carry their head well, and are much quicker in their motion; but when they ride them, they sit nearer their buttocks than when on a horse: they are dressed like horses, and are taught to amble like them; but they generally cleave their nostrils to give them more room for breathing. Dr Russell likewise tells us they have two sorts in Syria, one of which is like ours, and the other very large, with remarkable long ears; but they are both put to the same use, which is, to carry burdens.

The

The onager, or wild ass, has, by some authors, been confounded with the zebra; but very improperly, for this last is a distinct species; for the onager is not streaked like this, nor is his shape so beautiful. Wild asses are said to be very swift of course; and when they see a man, they make a bound, and immediately fly away; inasmuch, that there is no taking of them, but by traps and gins. They have much the same shape as common asses; but they are of a brighter colour, and there runs a white list from the head to the tail. Of the hide of these asses, and particularly of that part next the rump, they make that excellent leather which we call siagreen, and which is put to so many curious uses.

In America they have no asses at all, nor yet horses; but they have been carried thither long ago, at first by the Spaniards, and afterwards by other nations, where they have multiplied greatly; inasmuch, that, in some places, there are whole droves of them that run wild, and are very hard to be caught. Asses in general carry the heaviest burdens in proportion to their bulk; and, as their keeping costs little or nothing, it is a great wonder they are not put to more uses than they generally are among us.

The flesh of the common ass is never eaten in these parts of the world; though some pretend their colts are tender, and not disagreeable. [Plate LXXV. fig. 2.]

3. The zebra.—This animal has the figure and gracefulness of the horse, joined to the swiftness of the stag. He is about 7 feet long, from the point of the muzzle to the origin of the tail, and about 4 feet high. The colour of his skin is beautiful and uniform, consisting of alternate parallel rings of black and white disposed in the most regular manner, as represented in the plate, [LXXV. fig. 3.] He is generally less than the horse, and larger than the ass.

The Zebra is found no where but in the eastern and southern provinces of Africa, from Æthiopia to the Cape of Good Hope, and from the Cape of Good Hope to Congo. The Dutch have been at great pains to tame and use them for domestic purposes, but with little success. He is hard-mouthed, and kicks when any person attempts to touch or come near him. He is restless and obstinate as a mule: but perhaps the wild horse is naturally as untractable as the Zebra; for, it is probable, if he were early accustomed to obedience and a domestic life, he would become as docile as the horse.

ERANARCHA, a public officer among the ancient Greeks, whose business was to preside over and direct the alms and provisions made for the poor. Cornelius Nepos, in his life of Epaminondas, describes his office thus: when any person was reduced to poverty, taken captive, or had a daughter to marry, which he could not effect for want of money, &c. the eranarcha called an assembly of friends and neighbours, and taxed each according to his means and estate, to contribute towards his relief.

ERANTHEMUM, in botany, a genus of the diandria monogynia class. The calix is divided into five segments; the tube is filiform; and the stigma is simple. There is but one species, a native of Æthiopia.

ERASED, in heraldry. See ARRACHE.

ERECTION, in a general sense, the act of raising or elevating any thing, as the erection of a perpendicular, &c. It is also used in a figurative sense, as the erection of a bishopric, marquise, &c.

ERECTOR CLITORIS. See CLITORIS.

ERECTOR PENIS. See PENIS.

EREMIT. See HERMIT.

EREMITA, in zoology. See SCARABÆUS.

ERFURT, a large and beautiful city of Upper Saxony in Germany, capital of Thuringia, and subject to the elector of Mentz: E. long. 11° 6', N. lat. 51°.

ERGOT, in farriery, is a stub, like a piece of soft horn, about the bigness of a chestnut, placed behind and below the pastern-joint, and commonly hid under the tuft of the fetlock.

ERICA, or HEATH, in botany, a genus of the octandria monogynia class. The calix consists of four leaves, and the corolla of four segments; the filaments are inserted into the receptacle; the antheræ are bifid; and the capsule has four cells. There are thirty-eight species, five of which are natives of Britain, viz. the vulgaris, or common heath; the cinerea, or fine-leaved heath; the tetralix, or cross-leaved heath; the ciliaris, or rough-leaved heath; and the multiflora, or fir-leaved heath.

ERIDANUS, in astronomy. See Vol. I. p. 487.

ERIE, a vast lake to the westward of Pennsylvania, in North America, situated between 80° and 87° W. long. and between 41° and 42° N. lat.

ERIGERON, or SWEET FLEA-BANE, in botany, a genus of the syngenesia polygamia superflua class. The receptacle is naked; the pappus is hairy; and the radii of the corolla are linear and very narrow. There are sixteen species, two of which are natives of Britain, viz. the acre, or blue-flowered flea-bane; and the canadense, or Canada flea-bane.

ERINACEUS, or HEDGE-HOG, in zoology, a genus of quadrupeds belonging to the order of fera, the characters of which are these: they have two foreteeth in the upper-jaw, at a considerable distance from one another, and two in the under jaw, less distant; and they have two recumbent dog-teeth, one on each side. There are three species, viz. 1. The europæus, or common hedge-hog, with round ears, and crested nostrils. It is about nine inches long; the upper part of the body is totally covered with sharp prickles, and the under part is covered with hair. The hedge-hog, even when standing on his legs, has a very ugly aspect. His body is an oblong mass, convex above, terminated on the fore-part by a very sharp muzzle, and mounted on four short legs, of which nothing appears but the feet, and the tail is not discernible. His ears are broad, round, and short; and his eyes are small and protuberant. The length of his body, from the point of the muzzle to the anus, is about nine inches.

The hedge-hog has a very uncommon method of defending himself from the attacks of other animals: being possessed of little strength or agility, he does not attempt to fly from or assail his enemies; but erects his bristles, and rolls himself up like a ball, exposing no

part

part of his body that is not furnished with sharp weapons of defence; he will not unfold himself, unless thrown into water: the more he is frightened or harassed, the closer he shuts himself up, and frequently discharges his urine, which has a very foetid and loathsome smell. While in this state, molt dogs, instead of biting him, stand off and bark, not daring to seize him; or, if they attempt it once, their mouths are so pricked with his bristles, that they cannot be prevailed on to attempt it a second time. Both the male and female are covered with bristles from the head to the tail. These bristles are of great use in defending them from other animals; but must be very inconvenient when they incline to copulate. This operation they cannot perform in the manner of other quadrupeds; but do it face to face, either standing on end, or the female lying on her back. The females come in season in the spring, and bring forth their young in the beginning of summer. They commonly bring forth three or four, and sometimes five, at a time. The young ones are of a whitish colour, and only the points of the bristles appear above the skin. It is impossible to tame them: the mother and her young have frequently been confined together, and furnished with plenty of provisions: but, instead of nourishing them, she uniformly devoured them one after another. Males and females have likewise been kept in one apartment, where they lived, but never copulated. Hedge-hogs feed upon fallen fruits, some roots, and insects: they are very fond of flesh-meat, whether raw or roasted. They frequent woods, and live under the trunks of old trees, in the chinks of rocks, or under large stones. Naturalists alledge that they go into gardens, mount the trees, and come down with pears, apples, or plumbs, stuck upon their bristles. But this is a mistake: although kept in a garden, they never attempt to climb trees, or stick even fallen fruit upon their bristles, but lay hold of their food with their mouth. They never come out of their holes in the day, but go about in quest of food during the night. They eat but little, and can live very long without taking any nourishment. They do not lay up any store of provisions in harvest: such an instinct would be useless, as they sleep all the winter. See Plate LXXIV. fig. 6.

2. The inauris, or white hedge hog, has no external ears. It is a native of America.

3. The malacensis, has hanging ears, and is a native of Asia.

ERINGO, in botany. See ERYNGIUM.

ERIOCAULON, in botany, a genus of the triandria trigynia class. The common calix has an imbricated capitulum; it has three equal petals: and the stamina are above the germen. There are five species, none of them natives of Britain.

ERIOCEPHALUS, in botany, a genus of the syngenesia polygamia necessaria class. The receptacle is somewhat hairy; it has no pappus; the calix consists of six equal petals: and there are five stamules in the radius. There are two species, none of them natives of Britain.

ERIOPHORUM, in botany, a genus of the triandria monogynia class. The gluma is palaceous, and imbricated on each side; the corolla is wanting; and there is but one seed, surrounded by long down.

ERITHACUS, in ornithology. See MOTACILLA.

ERIVAN, a city of Persia, on the frontiers of Turkey, situated on the south end of a lake of the same name: E. long. 45°, N. lat. 40° 16'.

ERKELENS, a city of Westphalia, in Germany, ten miles north of Juliers: E. long. 6°, N. lat. 51°.

ERMIN, in zoology. See MUSTELA.

ERMIN, in heraldry, is always argent and sable, that is, a white field, or fur, with black spots. These spots are not of any determinate number, but may be more or less, at the pleasure of the painter, as the skins are thought not to be naturally so spotted; but serving for lining the garments of great persons, the furriers were wont, in order to add to their beauty, to sew bits of the black tails of the creatures that produced them, upon the white of their skin, to render them the more conspicuous, which alteration was introduced into armory. See Plate LXXIV. fig. 7.

ERMIN, or EARS OF CORN, an order of knights in France, instituted by Francis the last of that name, duke of Britany.

This order was so called on account that the collar of it was made up of ears of corn, lying athwart one another in saltier, bound together, both above and below, each ear being crossed twice, the whole of gold. To this collar there hung a little white beast, called an ermin, running over a bank of grass diversified with flowers.

ERMINE', or CROSS ERMINE', is one composed of four ermin spots, placed as represented in Plate LXXIV. fig. 8.

It is to be observed, that the colours in these arms are not to be expressed, because neither this cross nor these arms can be of any other colour but white and black.

ERMINITES should signify little ermines, but it is otherwise; for it expresses a white field powdered with black, only that every such spot hath a little red hair on each.

Erminites also signify a yellow field powdered with black, which the French express much better by *or semée d'ermine de sable*.

EROSION, among physicians, denotes much the same with corrosion, only in a stronger degree. See CORROSION, and CORROSIVES.

EROTIC, in general, any thing relating to the passion love.

ERRATIC, in general, something that wanders, or is not regular: hence it is the planets are called erratic stars.

ERRHINES, in pharmacy, medicines which, when snuffed up the nose, promote a discharge of mucus from that part.

ERROUR, ERROR, a mistake of our judgment, giving assent to that which is not true.

Mr Locke reduces the causes of error to these four: first

first, want of proofs; secondly, want of ability to use them; thirdly, want of will to use them; and fourthly, wrong measures of probability.

**ERUCA**, in general, denotes caterpillars of all kinds. See *NATURAL HISTORY, Of insects*.

**ERUCA**, the **WHITE ROCKET**, in botany. See *BRASSICA*.

**ERUCA MARINA**. See *APHRODITA*.

**ERUCAGO**, in botany. See *BUNIAS*.

**ERUDITION** denotes an extensive acquaintance with books, especially such as treat of the belles lettres.

**ERVU SPECIES**, in botany. See *SOPHORA*.

**ERUPTION**, in medicine, a sudden and copious excretion of humours, as pus or blood: it signifies also the same with exanthema, any breaking out, as the pustules of the plague, small-pox, measles, &c. See *MEDICINE*.

**ERVUM**, in botany, a genus of the diadelphia decandria class. The calix consists of five segments of an equal length with the corolla. There are six species, three of which are natives of Britain, viz. the solonense, or spring tare; the tetraspermum, or smooth tare; and the hirsutum, or hairy tare.

**ERINGIUM**, **ERINGO**, in botany, a genus of the pentandria digynia class. The flowers are capitated, and the receptacle is paleaceous. There are ten species, two of which are natives of Britain, viz. the maritimum, or sea-holly eringo; and the campestre, or common eringo. The root of the sea-holly is said to be aperient, diuretic, and aphrodisiac.

**ERYSIMUM**, in botany, a genus of the tetradynamia siliquosa class. The pod is four-sided, divided into two cells. There are six species, four of which are natives of Britain, viz. the officinale, or hedge-mustard; the cheiranthoides, or treacle worm-feed; the barbarea, rocket, or winter-crelles; and the alliaria, Jack-by-the-hedge, or sawce-alone. The leaves of the hedge-mustard are said to promote expectoration, and to excite urine and other excretions.

**ERYSIPELAS**, in medicine, an eruption of a fiery or acrid humour, from which no part of the body is exempted, though it chiefly attacks the face. See *MEDICINE*.

**ERYTHRINA**, in botany, a genus of the diadelphia decandria class. The calix is bilabiated; and the corolla consists of a long lanceolated vexillum. There are three species, none of them natives of Britain.

**ERYTHRINUS**, in ichthyology, a species of sparus. See *SPARUS*.

**ERYTHROIDES**, in anatomy, the first of the proper tunics or coats which cover the testicles. See *ANATOMY*, p. 170.

**ERYTHRONIUM**, **DOG'S-TOOTH VIOLET**, in botany, a genus of the hexandria monogynia class. The corolla is bell-shaped, and consists of six petals; there are two nectariferous tubercles at the base of every second petal. There is but one species, a native of Germany.

**ERYTHROPHIALMUS**, in ichthyology, a species of cyprinus. See *CYPRINUS*.

VOL. II. NO. 47.

**ERZERUM**, the capital of the province of Turcomania, or Armenia: E. long. 41°, N. lat. 40°. It is a great thoroughfare from Persia and India to Constantinople, by the way of Trebisond and the Black-sea.

**ESCHAR**, in surgery, the crust or scab occasioned by burns or caustic medicines.

**ESCHAROTICS**, in pharmacy, medicines which produce eschars. See *ESCHAR*.

**ESCHEAT**, in Scots law, is that forfeiture which is incurred upon a person's being denounced rebel. It is either single or liferent: single escheat is the forfeiture of the rebel's moveable estate; liferent escheat is the forfeiture of the rents of his heritable estate, during his life. See *SCOTS LAW*, title 12.

**ESCHIRAKITES**, in matters of religion, a sect of Mahometans, who believe that man's sovereign good consists in the contemplation of God. They avoid all manner of vice, and appear always in good humour, despising the sensual paradise of Mahomet. The most able preachers, in the royal mosques, are of this sect.

**ESCLATTE**, in heraldry, signifies a thing forcibly broken, or rather a shield that has been broken and shattered with the stroke of a battle-ax.

**ESCUAGE**, in our old customs, a kind of knight-service, called service of the shield, by which the tenant was bound to follow his lord to the wars at his own charge.

**ESCULENT**, an appellation given to such plants as may be eaten. See *BOTANY*, p. 628.

**ESCULUS**, in botany. See *QUERCUS*.

**ESCURIAL**, a palace of the king of Spain, twenty-one miles north-west of Madrid; being one of the largest and most beautiful in the world. It has eleven thousand windows, fourteen thousand doors, one thousand eight hundred pillars, seventeen cloysters or piazzas, and twenty-two courts; with every convenience and ornament that can render a place agreeable in so hot a climate, as an extensive park, groves, fountains, cascades, grottos, &c.

**ESCUTCHEON**, or **SCUTCHEON**, in heraldry, is derived from the French *escusson*, and that from the Latin *scutum*, and signifies the shield whereon coats of arms are represented.

Most nations, of the remotest antiquity, were wont to have their shields distinguished by certain marks painted on them; and to have such on their shields was a token of honour, none being permitted to have them till they had performed some honourable action.

The escutcheon, as used at present, is square, only rounded off at the bottom.

**ESDRAS**, the name of two apocryphal books, usually bound up with the scriptures. They were always excluded the Jewish canon, and are not admitted as canonical by the papists themselves.

**ESENS**, a town of Westphalia, twenty-five miles north of Embden.

**ESK**, a river which forms part of the boundary between England and Scotland; and, running from north east to south-west, falls into the Solway frith: it gives name to the country of Eskdale.

**ESKIMAUX**, sometimes called New Britain, and Terra de Labrador, is an extensive country of North America, situated between  $59^{\circ}$  and  $80^{\circ}$  W. long. and between  $50^{\circ}$  and  $64^{\circ}$  N. lat.

It is bounded by Hudson's straits, which separate it from Greenland, on the north; by the Atlantic ocean, on the east; by the river and bay of St Laurence, on the south-east; and by Hudson's bay, on the west.

**ESLINGEN**, an imperial city of Swabia in Germany, seven miles south-east of Stutgard.

**ESOX**, in ichthyology, a genus belonging to the order of abdominales. The body is elongated; the head is plainish above; the upper jaw is plain, and shorter than the under one, which is dotted; and the branchiostegic membrane has from seven to twelve rays. There are nine species.

**ESPALIERS**, in gardening, are rows of trees planted about a whole garden or plantation, or in hedges, so as to inclose quarters or separate parts of a garden; and are trained up regularly to a lattice of wood work in a close hedge, for the defence of tender plants against the injuries of wind and weather.

The trees chiefly planted for espaliers, are apples, pears, and some plumbs. See **GARDENING**.

**ESPERIE**, a city of Hungary, forty miles north of Tokay: it is remarkable for its salt mines.

**ESPINAL**, a town of Lorraine on the Moselle, thirty-five miles south-east of Nancy.

**ESPLANADE**, in fortification, the sloping of the parapet of the covered way towards the campaign.

**ESPLEES**, in law, the general products which lands yield, or the profit or commodity that is to be taken or made of a thing.

**ESPOUSALS**, in law, signify a contract or promise made between a man and a woman, to marry each other; and in cases where marriage may be consummated, espousals go before. Marriage is termed an *espousal de presenti*.

**ESQUIRE** was anciently the person that attended a knight in time of war, and carried his shield.

This title has not for a long time, had any relation to the office of the person, as to carry arms, &c. Those to whom the title of esquire is now of right due, are all noblemen's younger sons, and the eldest sons of such younger sons; the eldest sons of knights, and their eldest sons; the officers of the king's courts, and of his household; counsellors at law, justices of the peace, &c. though those latter are only esquires in reputation: besides, a justice of the peace holds this title no longer than he is in commission, in case he is not otherwise qualified to bear it: but a sheriff of a county, who is a superior officer, retains the title of esquire during life, in consequence of the trust once reposed in him: the heads of some ancient families are said to be esquires by prescription.

**ESQUIRES of the king**, are such as have that title by creation, wherein there is some formality used, as the putting about their necks a collar of SS, and bestowing on them a pair of silver-spurs, &c.

**ESSAY**, a trial or experiment for proving the quality of any thing; or an attempt to learn, whether or no any invention will succeed.

**ESSAY**, in literature, a peculiar kind of composition, the character whereof is to be free, easy, and natural; not tied to strict order or method, nor worked up and finished like a formal system.

**ESSAY-HATCH** is the miner's term for a little trench or hole, which they dig to search for shod or ore.

**ESSECK**, a town of Hungary, near the confluence of the rivers Drave and Danube, with a bridge five miles over: it lies about eighty miles north-west of Belgrade.

**ESSEN**, a town of Westphalia, about ten miles north-east of Dusseldorp.

**ESSENCE**, in metaphysics, that which constitutes the particular nature of each genus or kind, and distinguishes it from all others; being nothing but that abstract idea to which this name is affixed; so that every thing contained in it, is essential to that particular kind.

**ESSENES**, or **ESSENIANS**, in Jewish antiquity, one of the three ancient sects among that people. They allowed a future state, but denied a resurrection from the dead. Their way of life was very singular: they did not marry, but adopted the children of others, whom they bred up in the institutions of their sect: they despised riches, and had all things in common, and never changed their cloaths till they were entirely worn out. When initiated, they were strictly bound not to communicate the mysteries of their sect to others; and if any of their members were found guilty of enormous crimes, they were expelled.

Pliny tells us, that they dwelt on the west side of the lake of Asphaltites; and that they were a solitary kind of men, living without women or money, and feeding upon the fruit of the palm-tree: he adds, that they were constantly recruited by new-comers, whom the surges of ill fortune had made weary of the world; in which manner the sect was kept up for several thousands of years, without any being born among them. The reason why we find no mention made of them in the New Testament, may be their recluse and retired way of life, no less than their great simplicity and honesty, whereby they lay open to no censure or reproof.

**ESSENTIAL**, something necessarily belonging to a thing, from which it cannot be conceived distinct: thus the primary qualities of bodies, as extension, figure, number, &c. are essential or inseparable from them in all their changes and alterations.

**ESSENTIAL OIL**. See **CHEMISTRY**, p. 93.

**ESSEX**, a county of England, bounded by Suffolk, on the north; by the German sea, on the east; by the river Thames, which divides it from Kent, on the south; and by Middlesex and Hertfordshire, on the west.

**ESSOIN**, in law, an excuse for a person summoned to appear and answer to an action, on account of the sickness or other just cause of his absence.

**ESSORANT**, in heraldry, denotes a bird standing on the

the ground with its wings expanded, as if it had been wet, and were drying itself.

**ESTATE**, in law, signifies the title or interest that a person has in lands, tenements, or other effects.

**ESTATES**, in a political sense, is used either to denote the dominions of some prince, or the general classes into which the people are divided.

In Britain, the estates are the king, lords, and commons; or rather the lords and commons, who meet the king in parliament, for reforming abuses, and enacting good and wholesome laws.

**ELSETE'**, in heraldry, denotes the heads of beasts torn off by main force. See **ARACHE'** and **ERASED**.

**ESTHER**, a canonical book of the Old Testament, containing the history of a Jewish virgin, dwelling with her uncle Mordecai at Shushan, in the reign of Ahasuerus, one of the kings of Persia.

**ESTOILE'E**, or **CROSS ESTOILLE'E**, in heraldry, a star with only four long rays in form of a cross; and, accordingly, broad in the centre, and terminating in sharp points.

**ESTONIA**, a province subject to Russia, on the north of Livonia.

**ESTRAY**, in law, any beast not wild that is found within a lordship, and owned by nobody.

**ESTREMADURA**, a province of Spain, bounded by Leon, on the north; by the two Castiles, on the east; by Andalusia, on the south; and by the province of Alentejo, in Portugal, on the west.

**ESTREMADURA** is also a province of Portugal, lying north of Alentejo, and westward of Spanish Estremadura. Lisbon is its capital, as also of the kingdom.

**ESTREMOS**, a town of Alentejo, in Portugal, eighty-five miles south east of Lisbon.

**ETCHING**, a method of engraving on copper, in which the lines or strokes, instead of being cut with a tool or graver, are eaten in with aquafortis.

Etching is done with more ease and expedition than engraving: it requires fewer instruments, and represents most kind of subjects better and more agreeable to nature, as landscapes, ruins, grounds, and all small, faint, loose, remote objects, buildings, &c. See **ENGRAVING**.

The method of etching is as follows: Chuse the copperplate as directed for engraving, and furnish yourself with a piece of ground, tied up in a bit of thin silk, kept very clean, to be laid upon the plate, when both have been warmed; proper needles, to hatch with on the ground; a pencil or brush, to wipe away the bits of ground which rise after its hatching; a polisher; two or three gravers; a pair of compasses, to measure distances and draw circles; a ruler, to hatch straight lines; green wax, to make the wall round the edges of the plate, to contain the aquafortis; an oil-stone; a bottle of aquafortis; some red lead, to colour the back side of the copy; a stiff, and a hand-vice, to hold the plate over the candle. See **NEEDLE**, **GRAVER**, **POLISHER**, **COMPASS**, &c.

To make the ground, take three ounces of asphaltum, two ounces of clean rosin, half an ounce of Burgundy-pitch, three ounces of black wax, and three

ounces of virgin-wax: let all these be melted in a clean earthen pipkin over a slow fire, stirring it all the time with a small stick; if it burn to the bottom, it is spoiled. After the ingredients are well melted, and it boils up, put it into a pan of fair water; and before it be quite cold, take it out, and roll it into small lumps to be kept from dust: this ground is what others call the varnish. The next thing is to clean the plate to receive the ground: take a piece of lising, roll it up as big as an egg, tie it very tight, so as to make it a rubber; and having dropped a small quantity of sweet oil, and added a little powder of rotten stone on the plate, rub it with this ball, till it will almost shew your face. Then wipe it all off with a clean rag; and after that, make it quite dry with another clean rag and a little fine whitening.

The next thing is to lay on the varnish; to do which aright you must take a hand-vice, and fix it at the middle of one part of the plate, with a piece of paper between the teeth of the hand-vice and the plate, to prevent the marks of the teeth: then laying the plate on a chaffing-dish, with a small charcoal fire in it, till the plate be so hot, that, by spitting on the back-side, the wet will fly off: rub the plate with the ground tied up in silk, till it be covered all over; and after that daub the plate with a piece of cotton wrapped up in silk, till the ground be quite smooth, keeping the plate a little warm all the time. The varnish being thus smoothed upon the plate, it must be blacked in the following manner: take a thick tallow candle that burns clear, with a short snuff; and having driven two nails into the wall, to let it rest upon, place the plate against the wall with the varnish side downward, and take care not to touch the ground with your fingers: then taking the candle, apply the flame to the varnish as close as possible, without touching the varnish with the snuff of the candle, and guide the flame all over it, till it become perfectly black. After this is done, and the plate dry, the design is traced with a needle through the varnish, and a rim or border of wax is raised round the circumference of the plate; and then the artist has a composition of common varnish and lamp-black, made very thin, wherewith he covers the parts that are not to be bitten, by means of a hair-pencil. And he is every now and then covering or uncovering this or that part of the design, as occasion may require; the conduct of the aquafortis being the principal concern, on which the effect of the print very much depends. The operator must be attentive to the ground, that it does not fail in any part, and where it does to stop up the place with the above composition. The plate is defended from the aquafortis every where, but in the lines or hatches cut through it with the needle, through which the water eats into the copper to the depth required; remembering to keep it stirring with a feather all the while; which done, it is to be poured off again.

Single aquafortis is most commonly used; and if it be too strong, mix it with vinegar, otherwise it will make the work very hard, and sometimes break up the ground: the aquafortis having done its part, the ground

ground is taken off, and the plate washed and dried: after which nothing remains for the artist, but to examine the work with his graver, to touch it up, and heighten it where the aquafortis has missed.

And, lastly, it is to be remembered, that a fresh dip of aquafortis is never given, without first washing out the plate in fair water, and drying it at the fire.

**ETERNITY**, an attribute of God, expressing his infinite or endless duration.

According to Mr Locke, we come by the idea of eternity, by being able to repeat any part of time, as a year, as often as we will, without ever coming to an end.

**ETHER.** See **ÆTHER.**

**ETHICS.** See **MORALS.**

**ETHIOPIA**, or **ÆTHIOPIA**, a very extensive country of Africa, comprehending Abyssinia, Nubia, and Abex: it is bounded by Egypt, and the desert of Barca, on the north; by the Red sea and Indian ocean, on the east; by Anian, and the unknown parts of Africa, on the south; and by other unknown countries on the west.

**ETHMOIDAL**, in anatomy. See **ANATOMY**, p. 152.

**ETHMOIDES os**, in anatomy. See **ANAT.** p. 157.

**ETNA**, or mount **GIBELLO**, a volcano, or burning mountain of Sicily, situated fifty miles south-west of Messina, and twenty west of Catania. See **VULCANO.**

**ETYMOLOGY**, that part of grammar which considers and explains the origin and derivation of words, in order to arrive at their first and primary signification. See **GRAMMAR.**

**EVACUANTS**, in pharmacy, are properly such medicines as diminish the animal fluids, by throwing out some morbid or redundant humour, or such as thin, attenuate, and promote the motion and circulation thereof.

**EVACUATION**, in medicine, the art of diminishing, emptying, or attenuating the humours of the body. See **MEDICINE.**

**EVANGELIST**, a general name given to those who write or preach the gospel of Jesus Christ.

The word is of Greek origin, signifying one who publishes glad tidings, or is the messenger of good news.

According to Hooker, evangelists were presbyters of principal sufficiency, whom the apostles sent abroad, and used as agents in ecclesiastical affairs, wheresoever they saw need.

The term evangelist however is at present confined to the writers of the four gospels.

**EVANID**, a name given by some authors to such colours as are of no long duration, as those in the rainbow, in clouds before and after sun set, &c.

Evanid colours are also called fantastical and emphatical colours.

**EVANTES**, in antiquity, the priestesses of Bacchus, thus called, by reason, that in celebrating the orgia, they ran about as if distracted, crying, *Evan, evan, olé evan.* See **BACCHANALIA.**

**EVAPORATION**, in chemistry, the setting a liquor in a gentle heat to discharge its superfluous humidity, re-

duce it to a proper consistence, or obtain its dry remainder. See **CHEMISTRY.**

**EVATES**, a branch or division of the druids, or ancient Celtic philosophers. Strabo divides the British and Gaulish philosophers into three sects; bards, evates, and druids. He adds, that the bards were the poets and musicians; the evates, the priests and naturalists; and the druids were moralists as well as naturalists: But Marcellus and Hornius reduce them all to two sects, viz. the bards and druids.

**EUBAGES**, an order of priests, or philosophers, among the ancient Celta, or Gauls: some will have the eubages to be the same with the druids and faronidæ of Diodorus; and others, that they were the same with what Strabo calls evates.

**EUCCHARIST**, the sacrament of the Lord's supper, properly signifies giving thanks.

This sacrament was instituted by Christ himself, and the participation of it called communion.

As to the manner of celebrating the eucharist among the ancient Christians, after the customary oblations were made, the deacon brought water to the bishops and presbyters, standing round the table, to wash their hands, according to that of the psalmist, "I will wash my hands in innocency, and so will I compass thy altar, O Lord." Then the deacon cried out aloud, "Mutually embrace and kiss each other;" which being done, the whole congregation prayed for the universal peace and welfare of the church, for the tranquillity and repose of the world, for the prosperity of the age, for wholesome weather, and for all ranks and degrees of men. After this followed mutual salutations of the minister and people; and then the bishop or presbyter having sanctified the elements by a solemn benediction, he brake the bread, and delivered it to the deacon, who distributed it to the communicants; and after that the cup. Their sacramental wine was usually diluted or mixed with water. During the time of administration, they sang hymns and psalms; and, having concluded with prayer and thanksgiving, the people saluted each other with a kiss of peace, and so the assembly broke up.

**EVER-GREEN**, in gardening, a species of perennials, which continue their verdure, leaves, &c. all the year: such are hollies, phillyria's, laurustinus's, bays, pines, firs, cedars of Lebanon, &c.

**EVERLASTING PEA**, a genus of plants, otherwise called lathyrus. See **LATHYRUS.**

**EVESDROPPERS**, in law, persons who stand under the eaves, walls, or windows of a house, by day or by night, to listen after news, and carry it to others, thereby raising strife and contention in the neighbourhood.

**EVESHAM**, a borough town thirteen miles south-east of Worcester, which sends two members to parliament.

**EUGENIA**, the **SILVER TREE**, in botany, a genus of the icolandria monogynia class. The calix is above the fruit, and consists of four segments; the petals are four; and the drupa is quadrangular, and contains

ONE

one fixed. There are five species, none of them natives of Britain.

**EVIAN**, a town of Savoy, situated twenty-five miles north-east of Geneva, on the south side of the lake of Geneva.

**EVICITION**, in law, signifies a recovery of lands, or tenements by law.

**EVIDENCE**, that perception of truth which arises either from the testimony of the senses, or from an induction of reason. See **METAPHYSICS**, and **MORALS**.

**EVIDENCE**, in law, any proof, whether it be by testimony of men on oath, or by writings and records so called, because hereby the point in issue is made evident by a jury.

**EVIL**. See **MORALS**.

*King's-Evil*, in medicine. See **MEDICINE**.

**EULOGY**, in church-history, a name by which the Greeks call the *panis benedictus*, or bread over which a blessing is pronounced, and which is distributed to those who are unqualified to communicate.

**EUMENIDES**, in antiquity. See **FURIES**.

**EUNOMIANS**, in church-history, Christian heretics, in the fourth century. They were a branch of Arians, and took their name from Eunomius, bishop of Cyzicus, who was instructed by Ætius, in the points which were then controverted in the church, after having at first followed the profession of arms. Eunomius so well answered the designs of his master, and declaimed so vehemently against the divinity of the Word, that the people had recourse to the authority of the prince, and had him banished; but the Arians obtained his recall, and elected him bishop of Cyzicus. The manners and doctrines of the Eunomians were the same with those of the Arians.

**EUNUCH**, a castrated person. See **CASTRATION**.

**EUNUCHS**, in church-history, a sect of heretics in the third century, who were mad enough to castrate, not only those of their own persuasion, but even all others that they could lay hold of: they took their rise from the example of Origen, who, misunderstanding the following words of our Saviour,—“ And eunuchs who made themselves eunuchs for the kingdom of heaven,”—castrated himself.

**EVOLUTION**, in algebra. See **ALGEBRA**, p. 86.

**EVOLUTION**, in the art of war, the motion made by a body of troops, when they are obliged to change their form and disposition, in order to preserve a post, or occupy another, to attack an enemy with more advantage, or to be in a condition of defending themselves the better.

**EUONYMOIDES**, in botany. See **CELASTRUS**.

**EUONYMUS**, the **SPINDLE-TREE**, in botany, a genus of the pentandria monogynia class. The corolla consists of five petals; the capsule is five-sided, and has five coloured cells; and the seeds have calyptra. There are two species, one of which, *viz.* the *europæus*, spindle-tree, or prickwood, is a native of Britain.

**EVORA**, or **EBORA**, a city of Portugal, seventy miles south-east of Lisbon.

VOL. II. No. 47.

†

**EUPATORIOPHALACRON**, in botany. See **VIRGINESINA**.

**EUPATORIUM**, **HEMP-AGRIMONY**, in botany, a genus of the syngenesia polygamia æqualis class. The receptacle is naked; the pappus is plumose; the calix is oblong and imbricated; and the stylus is long and semi-bifid. There are twenty-one species, only one of which is a native of Britain, *viz.* the *cannabinum*, hemp-agrimony, or Dutch agrimony. The leaves are said to strengthen the stomach.

**EUPHYMISM**, in rhetoric, a figure which expresses things in themselves disagreeable and shocking, in terms implying the contrary quality.

**EUPHORBIA**, in botany, a genus of the dodecandria trigynia class. The corolla consists of four or five petals; and the calix has but one leaf. There are sixty-two species, twelve of which are natives of Britain, *viz.* the peplus, or small purple sea-spurge; the peplus, or petty spurge; the exigua, or dwarf-spurge; the segetalis, or corn-spurge; the helioscopia, sun-spurge, or wart-wort; the portlandica, or Portland spurge; the paralias, or sea-spurge; the verrusca, or rough fruited spurge; the platyphyllus, or broad-leaved spurge; the amygdaloides, or wood-spurge; the characias, or red spurge; and the hyberna, or knotty-rooted spurge. The spurges are exceedingly acrid, and are now rejected both by the Edinburgh and London dispensaries.

**EUPHORBIIUM**, in pharmacy, a gum resin brought us always in loose, smooth, and glossy gold-coloured drops or granules. It is the produce of the *euphorbium antiquorum verum*, which grows to ten or twelve feet high. Its principal use is externally in sinapisms, and plasters applied to the feet, which are intended to stimulate, but not absolutely to raise blisters: for it is observed by Avicenna, that when taken internally in large doses, it has been found to exulcerate the intestines, and bring on death itself, after the most terrible symptoms.

**EUPHRASIA**, in botany, a genus of the didynamia angiospermia class. The calix is cylindrical, and consists of four segments; and the capsule is oblong and bilocular. There are six species, two of which are natives of Britain, *viz.* the *officinalis*, or eye-bright; and the *odontites*, or red eye bright. The eye-bright was formerly celebrated as an ophthalmic, but is now totally disregarded.

**EUPHRATES**, the finest river in Turkey in Asia, has two sources, northward of the city of Erzerum, in 40° N. lat. After passing through Armenia, it divides Syria from Diarbec or Assyria, runs through Eyraca or Chaldea; and uniting with the Tygris, it passes by the city of Bassora, fifty miles below which it falls into the gulf of Persia.

**EUREUX**, a city of Normandy in France, twenty-five miles south of Rouen.

**EURIPUS**, a strait between the island of Negropont, and the continent of Greece, remarkable for its irregular tides.

The term *euripus* is sometimes used, in a more general

2

5 O

general

general sense, for any straits where the water is much agitated.

**EUROPE**, the East of the four grand divisions of the earth, is situated between  $36^{\circ}$  and  $72^{\circ}$  N. lat.; and between  $10^{\circ}$  degrees W. long. and  $65^{\circ}$  E. long. being about 5000 miles long from north to south, and 2500 miles broad from east to west. It is bounded by the frozen ocean on the north, by Asia on the east, by the Mediterranean, which separates it from Africa, on the south, and by the Atlantic ocean on the west.

Europe is commonly subdivided into three grand divisions, north, middle, and south. The north or upper division comprehends Russia, or Muscovy, Sweden, Denmark, and Norway, and the islands of Britain, Iceland, Greenland, and those of the Baltic. The middle division contains Poland, Germany, and the hereditary dominions of the house of Austria, the Low Countries, or Netherlands, and France. The southern division comprehends Turkey in Europe, the ancient Greece chiefly, Switzerland, Italy, Spain and Portugal, and the islands of Sicily, Sardinia, Corsica, Majorca, Minorca, Ivica, and those of the Archipelago.

**EURYTHMY**, in architecture, painting, and sculpture, is a certain majesty, elegance, and easiness, appearing in the composition of divers members, or parts of a body, painting, or sculpture, and resulting from the fine proportion of it.

**EUSTACE**, or **EUSTATIA**, one of the Caribbee islands, four miles west of St Christopher's, and subject to the Dutch.

**EUSTYLE**, in architecture, a sort of building in which the pillars are placed at the most convenient distance one from another, the intercolumniations being just two diameters and a quarter of the column, except those in the middle of the face, before and behind, which are three diameters distant.

**EUTYCHIANS**, in church-history, heretics in the Vth century, who embraced the errors of the monk Eutyches, maintaining that there was only one nature in Jesus Christ.

**EUXINE**, the same with the Black Sea. See **BLACK SEA**.

**EWAGE**, a toll paid for the passage of water, and otherwise called aquage.

**EWE**, the English name of a female sheep. See **OVIS**.

**EWRY**, in the British customs, an office in the king's household, which has the care of the table-linen, of laying the cloth, and serving up water in silver ewers after dinner.

**EXACERBATION**. See **PARONYSM**.

**EXACUM**, in botany, a genus of the tetrandria monogynia class. The calix consists of four leaves, and the corolla of four segments, with a roundish tube; the capsule is bifurcated, and has two cells containing many seeds. There are two species, none of them natives of Britain.

**EXAREISIS**, in surgery, the operation of extracting or taking away something that is hurtful to the human body.

**EXAGGERATION**, in rhetoric, a kind of hyperbole,

whereby things are augmented or amplified, by saying more than the truth, either as to good or bad.

**EXAGGERATION**, in painting, a method by which the artist, in representing things, changes them too much, or makes them too strong, either in respect of the design or the colouring.

**EXALTATION**, in chemistry, signifies an operation by which a substance has its properties changed, and raised to a higher degree of dignity and virtue.

**EXAMINERS**, in chancery, two officers of that court, who examine, upon oath, witnesses produced in causes depending there, by either the complainant or defendant, where the witnesses live in London, or near it. Sometimes parties themselves, by particular order, are examined. In the country, above twenty miles from London, on the parties joining in commission, witnesses are examined by commissioners, being usually counsellors or attorneys not concerned in the cause.

**EXANTHEMA** among physicians, denotes any kind of efflorescence or eruption, as the measles, purple spots in the plague, or malignant fevers, &c.

**EXARCH**, in antiquity, an officer sent by the emperors of the east into Italy, in quality of viceroy, or rather prefect, to defend that part of Italy which was yet under their obedience, and particularly the city of Ravenna, against the Lombards. The exarch resided at Ravenna, which place, with Rome, was all that was left to the emperors of their Italian dominions. The first exarch was under Justin the younger, in the year 567, after Belisarius and Narces had driven the barbarians out of Italy. The last was Eutychius, defeated by Adolphus king of the Lombards in 752.

**EXCELLENCY**, a title anciently given to kings and emperors, but now to ambassadors, and other persons who are not qualified for that of *highness*, and yet are to be elevated above the other inferior dignities.

**EXCENTRIC**, in geometry, a term applied to circles and spheres which have not the same centre, and consequently are not parallel; in opposition to concentric, where they are parallel, having one common centre.

**EXCENTRICITY**, in astronomy, is the distance of the centre of the orbit of a planet from the centre of the sun; that is, the distance between the centre of the ellipse and the focus thereof. See **ASTRONOMY**.

**EXCEPTION**, in law, denotes a stop or stay to an action.

**EXCERPTA**, in matters of literature. See **EXTRACT**.

**EXCESS**, in arithmetic and geometry, is the difference between any two unequal numbers or quantities, or that which is left after the lesser is taken from or out of the greater. See **ARITHMETIC**.

**EXCHANGE**, in a general sense, a contract or agreement, whereby one thing is given or exchanged for another.

**EXCHANGE**, in commerce, is the receiving or paying of money in one country for the like sum in another, by means of bills of exchange.

The security which merchants commonly take from one another when they circulate their business, is a bill

bill of exchange, or a note of hand: these are looked upon as payment.

The punctuality of acquitting those obligations is essential to commerce; and no sooner is a merchant's accepted bill protested, than he is considered as a bankrupt. For this reason, the laws of most nations have given very extraordinary privileges to bills of exchange. The security of trade is essential to every society; and were the claims of merchants to linger under the formalities of courts of law when liquidated by bills of exchange, faith, confidence, and punctuality would quickly disappear, and the great engine of commerce would be totally destroyed.

A regular bill of exchange is a mercantile contract, in which four persons are concerned, *viz.* 1. The drawer, who receives the value: 2. His debtor in a distant place, upon whom the bill is drawn, and who must accept and pay it: 3. The person who gives value for the bill, to whose order it is to be paid: and, 4. The person to whom it is ordered to be paid, creditor to the third.

By this operation, reciprocal debts, due in two distant parts, are paid by a sort of transfer, or permutation of debtors and creditors.

(A) in London is creditor to (B) in Paris, value 100*l.* (C) again in London is debtor to (D) in Paris for a like sum. By the operation of the bill of exchange, the London creditor is paid by the London debtor, and the Paris creditor is paid by the Paris debtor; consequently, the two debts are paid, and no money is sent from London to Paris, nor from Paris to London.

In this example, (A) is the drawer, (B) is the acceptor, (C) is the purchaser of the bill, and (D) receives the money. Two persons here receive the money, (A) and (D), and two pay the money, (B) and (C); which is just what must be done when two debtors and two creditors clear accounts.

This is the plain principle of a bill of exchange. From which it appears, that reciprocal and equal debts only can be acquitted by them.

When it therefore happens that the reciprocal debts of London and Paris (to use the same example) are not equal, there arises a balance on one side. Suppose London to owe Paris a balance, value 100*l.* How can this be paid? Answer, It may either be done with or without the intervention of a bill.

With a bill, if an exchange<sup>r</sup>, finding a demand for a bill upon Paris for the value of 100*l.* when Paris owes no more to London, sends 100*l.* to his correspondent at Paris in coin, at the expence (suppose) of 1*l.* and then, having become creditor on Paris, he can give a bill for the value of 100*l.* upon his being repaid his expence, and paid for his risk and trouble.

Or it may be paid without a bill, if the London debtor sends the coin himself to his Paris creditor, without employing an exchange<sup>r</sup>.

This last example shews of what little use bills are in the payment of balances. As far as the debts are equal, nothing can be more useful than bills of exchange; but the more they are useful in this easy way of business, the less profit there is to any person to make a trade of ex-

change, when he is not himself concerned either as debtor or creditor.

When merchants have occasion to draw and remit bills for the liquidation of their own debts, active and passive, in distant parts, they meet upon change; where, to pursue the former example, the creditors upon Paris, when they want money for bills, look out for those who are debtors to it. The debtors to Paris again, when they want bills for money, seek for those who are creditors upon it.

This market is constantly attended by brokers, who relieve the merchant of the trouble of searching for those he wants. To the broker every one communicates his wants, so far as he finds it prudent; and by going about among all the merchants, the broker discovers the side upon which the greater demand lies, for money, or for bills.

He who is the demander in any bargain, has constantly the disadvantage in dealing with him of whom he demands. This is no where so much the case as in exchange, and renders secrecy very essential to individuals among the merchants. If the London merchants want to pay their debts to Paris, when there is a balance against London, it is their interest to conceal their debts, and especially the necessity they may be under to pay them; from the fear that those who are creditors upon Paris would demand too high a price for the exchange over and above par.

On the other hand those who are creditors upon Paris, when Paris owes a balance to London, are as careful in concealing what is owing to them by Paris, from the fear that those who are debtors to Paris would avail themselves of the competition among the Paris creditors, in order to obtain bills for their money, below the value of them, when at par. A creditor upon Paris, who is greatly pressed for money at London, will willingly abate something of his debt, in order to get one who will give him money for it.

From the operation carried on among merchants upon change, we may discover the consequence of their separate and jarring interests. They are constantly interested in the state of the balance. Those who are creditors on Paris, fear the balance due to London; those who are debtors to Paris, dread a balance due to Paris. The interest of the first is to dissemble what they fear; that of the last, to exaggerate what they wish. The brokers are those who determine the course of the day: and the most intelligent merchants are those who dispatch their business before the fact is known.

Now, how is trade in general interested in the question, Who shall outwit, and who shall be outwitted, in this complicated operation of exchange among merchants?

The interest of trade and of the nation is principally concerned in the proper method of paying and receiving the balances. It is also concerned in preserving a just equality of profit and loss among all the merchants, relative to the real state of the balance. Unequal competition among men engaged in the same pursuit, constantly draws along with it bad consequences to the general undertaking; and secrecy in trade will be found, upon examination, to be much more useful to merchants in their private

private capacity, than to the trade they are carrying on.

Merchants endeavour to simplify their business as much as possible; and commit to brokers many operations which require no peculiar talents to execute. This of exchange is of such a nature, that it is hardly possible for a merchant to carry on the business of his bills, without their assistance, upon many occasions. When merchants come upon change, they are so full of fears and jealousies, that they will not open themselves to one another, lest they should discover what they want to conceal. The broker is a confidential man, in some degree, between parties, and brings them together.

Besides the merchants who circulate among themselves their reciprocal debts and credits arising from their importation and exportation of goods, there is another set of merchants who deal in exchange; which is the importation and exportation of money and bills.

Were there never any balance on the trade of nations, exchangers and brokers would find little employment: reciprocal and equal debts would easily be transacted openly between the parties themselves. No man feigns and dissembles, except when he thinks he has an interest in so doing.

But when balances come to be paid, exchange becomes intricate; and merchants are so much employed in particular branches of business, that they are obliged to leave the liquidation of their debts to a particular set of men, who make it turn out to the best advantage to themselves.

Whenever a balance is to be paid, that payment costs, as we have seen, an additional expence to those of the place who owe it, over and above the value of the debt.

If, therefore, this expence be a loss to the trading man, he must either be repaid this loss by those whom he serves, that is, by the nation; or the trade he carries on will become less profitable.

Every one will agree, that the expence of high exchange upon paying a balance, is a loss to a people, no way to be compensated by the advantages they reap from enriching the few individuals among them who gain by contriving methods to pay it off: and if an argument is necessary to prove this proposition, it may be drawn from this principle, to wit, whatever renders the profit upon trade precarious or uncertain, is a loss to trade in general: this loss is the consequence of high exchange; and although a profit does result from it upon one branch of trade, the exchange-business, yet that cannot compensate the loss upon every other.

We may, therefore, here repeat what we have said above, that the more difficulty is found in paying a balance, the greater is the loss to the nation.

#### *The course of EXCHANGE.*

The course of exchange is the current price betwixt two places, which is always fluctuating and unsettled being sometimes above and sometimes below par, according to the circumstances of trade.

When the course of exchange rises above par, the country where it rises may conclude for certain, that the balance of trade runs against them. The truth of this will appear, if we suppose Britain to import from any foreign place goods to the value of 100,000*l.* at par, and export only to the value of 80,000*l.*; in this case, bills on the said foreign place will be scarce in Britain, and consequently will rise in value; and after the 80,000*l.* is paid, bills must be procured from other places at a high rate to pay the remainder, so that perhaps 120,000*l.* may be paid for bills to discharge a debt of 100,000*l.*

Though the course of exchange be in a perpetual flux, and rises or falls according to the circumstances of trade, yet the exchanges of London, Holland, Hamburgh, and Venice, in a great measure regulate those of all other places in Europe.

#### *I. Exchange with Holland.*

#### MONEY-TABLE.

	Par in Sterling.	s.	d.
8 Pennings, or 2 duytes,	1 groat or penny	=	0 0.54
2 Groats, or 16 pennings,	1 stiver	=	0 1.09
6 Stivers, or 12 pence,	1 schilling	=	0 6.56
20 Schillings,	1 pound Flemish	=	10 11 18
20 Stivers, or 40 pence,	1 guilder or florin	=	1 9.86
6 Guilders, or florins,	1 pound Flemish	=	10 11.18
2½ Guilders, or florins,	1 rixdollar	=	4 6.66

In Holland there are two sorts of money, bank and current. The bank is reckoned good security; demands on the bank are readily answered; and hence bank-money is generally rated from 3 to 6 *per cent.* better than the current. The difference between the bank and current money is called the *agio*.

Bills on Holland are always drawn in bank-money; and if accounts be sent over from Holland to Britain in current money, the British merchant pays these ac-

counts by bills, and in this case has the benefit of the *agio*.

#### PROB. I. *To reduce bank money to current money.*

RULE. As 100 to 100+*agio*, so the given guilders to the answer.

EXAMPLE. What will 2210 guilders in bank money amount to in Holland currency, the *agio* being  $3\frac{1}{4}$  *per cent.*?

*Guild.*

In Amsterdam, Rotterdam, Middleburgh, &c. books and accounts are kept by some in guilders, stivers, and pennings, and by others in pounds, shillings, and pence, Flemish.

VOL. II. No. 47.

( 521 )

E X C

Britain gives 1 l. Sterling for an uncertain number of shillings and pence Flemish. The par is 1 l. Sterling for 36.59 s. Flemish; that is, 1 l. 16 s. 7.03 d. Flemish.

When the Flemish rate rises above par, Britain gains and Holland loses by the exchange, and *vice versa*.

Sterling money is changed into Flemish, by saying,

As 1 l. Sterling to the given rate,

So is the given Sterling to the Flemish sought.

Or, the Flemish money may be call up by practice.

Dutch money, whether pounds, shillings, pence Flemish, or guilders, stivers, pennings, may be changed into Sterling, by saying,

As the given rate to 1 l. Sterling,

So the given Dutch to the Sterling sought.

EXAMPLE. 1. A merchant in Britain draws on Amsterdam for 782 l. Sterling: How many pounds Flemish, and how many guilders will that amount to, exchange at 34 s. 8 d. per pound Sterling?

L. s. d.			Decimally.		
As 1 :	34 8 ::	782	As 1 :	34 8 ::	782
	12			782	
	416			693	
	782			27733

	3328			210)27109.8	
	2912			L. 1355 9 4 Flem.	
12)325312					
	d.				
210)27109 4					
L. 1355 9 4 Flem.					

By practice.

L. s. d.	
782	
10 s. = $\frac{1}{2}$	391
4 s. = $\frac{1}{4}$	156 8
8 d. = $\frac{1}{5}$	26 1 4
	1355 9 4 Fl.

Or thus:

L. s. d.	
782	
14 s. = $\frac{7}{5}$	547 8
8 d. = $\frac{1}{5}$	26 1 4
	1355 9 4 Fl.

Multiply the Flemish pounds and shillings by 6, and the product will be guilders and stivers; and if there be any pence, multiply them by 8 for pennings; or, divide the Flemish pence by 40, and the quot will be guilders, and the half of the remainder, if there be any, will be stivers, and 1 penny odd will be half a stiver, or 8 pennings, as follows.

Holland exchanges with other nations as follows, viz.  
 with

	<i>Flem d:</i>
Hamburgh, on the dollar,	= 66 $\frac{2}{3}$
France, on the crown,	= 54
Spain, on the ducat,	= 109 $\frac{4}{3}$
Portugal on the crusade,	= 50
Venice, on the ducat,	= 93
Genoa, on the pezzo,	= 100
Leghorn, on the piaſtre,	= 100
Florence, on the crown,	= 120
Naples, on the ducat,	= 74 $\frac{1}{3}$
Rome, on the crown,	= 136
Milan, on the ducat,	= 102
Bologna, on the dollar,	= 94 $\frac{4}{3}$

Exchange between Britain and Antwerp, as alſo the  
 Auſtrian Netherlands, is negociated the ſame way as with  
 Holland, only the par is ſomewhat different, as will be  
 deſcribed in article 2d, following.

( 522 )

# E X C

II. Exchange with Hamburgh.

## MONEY-TABLE.

	<i>Par in Sterling.</i>	<i>s. d.</i>
12 Pennings	1 ſchilling-lub	= 0 1 $\frac{1}{2}$
16 Schilling-lubs	1 mark	= 1 6
2 Marks	1 dollar	= 3 0
3 Marks	1 rixdollar	= 4 6
6 $\frac{1}{2}$ Marks	1 ducat	= 9 4 $\frac{1}{2}$

Books and accounts are kept at the bank, and by moſt  
 people in the city, in marks, ſchilling-lubs, and pennings;  
 but ſome keep them in pounds, ſhillings, and groots  
 Flemiſh.

The agio at Hamburgh runs between 20 and 40 *per cent*.  
 All bills are paid in bank-money.

Hamburgh exchanges with Britain by giving an uncer-  
 tain number of ſhillings and groots Flemiſh for the  
 pound Sterling. The groot or penny Flemiſh here, as  
 alſo at Antwerp, is worth  $\frac{1}{16}$  of a penny Sterling; and  
 ſo ſomething better than in Holland, where it is only  
 $\frac{1}{160}$  d. Sterling.

	<i>Flemiſh.</i>
6 Pennings	1 groot or penny
6 Schilling lubs	1 ſchilling
1 Schilling-lub	2 pence or groots
1 Mark	32 pence or groots
7 $\frac{1}{2}$ Marks	1 pound.

The par with Hamburgh, and alſo with Antwerp, is  
 35 s. 6  $\frac{1}{2}$  d. Flemiſh for 1 l. Sterling.

EXAMPLES. 1. How many marks muſt be received at  
 Hamburgh for 300 l. Sterling, exchange at 35 s. 3 d.  
 Flemiſh *per l.* Sterling?

	67816,
	271264

*d. L. s. d.*  
160)28143640(175897½ = 732 18 1½

If Sterling money be given, it may be reduced or changed into pezzos of Genoa, by reverting the former operation.

Exchange money is reduced to lire money, by being multiplied by 5½, as follows:

<i>Pez. foldi.</i>	<i>Decimally.</i>
3390 16	3390.8
5½	5.75
16954 0	169550
½ = 1695 8	237356
¼ = 847 14	169540

Lires 19497 2      Lires 19497.100

And lire money is reduced to exchange money by dividing it by 5½.

### *Soldi of Genoa.*

In Milan, 1 crown = 80  
In Naples, 1 ducat = 86  
In Leghorn, 1 piaſtre = 20  
In Sicily, 1 crown = 127½

VIII. *Exchange with Leghorn.*

MONEY-TABLE.

12 Denari } make { 1 soldi s. d.  
20 Soldi } { 1 piaſtre = 4 6 Ster.

Books and accounts are kept in piaſtres, ſoldi, and denari. The piaſtre here conſiſts of 6 lire, and the lire contains 20 ſoldi, and the ſoldi 12 denari, and conſequently exchange money is 6 times better than lire money. The courſe of exchange is from 47 d. to 58 d. Sterling *per* piaſtre.

EXAMPLE. What is the Sterling value of 731 piaſtres, at 55½ d. each.

s.	d.	731 piaſtres, at 55½ d.
4 or	48 = ⅘	146 4
	7 = ⅙	18 5 6
	1½ = ¼	4 11 4½

L. 169 0 10½ *Anſ.*

Sterling money is reduced to money of Leghorn, by reverſing the former operation; and exchange money is reduced to lire money by multiplying by 6, and lire money to exchange money by dividing by 6.

100 piaſtres of Leghorn are  
In Naples = 134 ducats. | In Geneva = 185½ crowns.

*Soldi of Leghorn.*

In Sicily, 1 crown = 133½

In Sardinia, 1 dollar = 95½

The above are the chief places in Europe with which Britain exchanges directly; the exchanges with other places are generally made by bills on Hamburg, Holland, or Venice. We ſhall here however ſubjoin the par of exchange betwixt Britain and moſt of the other places in Europe, with which we have any commercial inter-  
course.

	Par in Sterling.	L. s. d.
Rome	1 crown	= 6 1½
Naples,	1 ducat	= 3 4½
Florence,	1 crown	= 5 4½
Milan,	1 ducat	= 4 7

Dantzic,	13½ florins	= 1 0 0
Stockholm,	34½ dollars	= 1 0 0
Ruffia,	1 rubble	= 4 5
Turkey,	1 aſper	= 4 6

The following places, *viz.* Switzerland, Norem-  
burgh, Leipſic, Drefden, Oſnaburgh, Brunſwic, Co-  
logn, Liege, Straſburgh, Cracow, Denmark, Norway,  
Riga, Revil, Narva, exci. ge with Britain, when di-  
rect exchange is made, upon the rixdollar, the par being  
4s. 6d. Sterling.

IX. *Exchange with America and the Weſt Indies.*

In North America and the Weſt Indies, accounts, as  
in Britain, are kept in pounds, ſhillings, and pence. In  
North America they have few coins circulating among  
them, and on that account have been obliged to ſubſtitute  
a paper-currency for a medium of their commerce; which  
having no intrinsic value, is ſubjected to many diſadvan-  
tages, and generally ſuffers a great diſcount. In the  
Weſt Indies coins are more frequent, owing to their  
commercial intercourſe with the Spaniſh ſettlements.

Exchange betwixt Britain and America, or the Weſt  
Indies, may be computed as in the following examples:

1. The neat proceeds of a cargo from Britain to Bo-  
ſton amount to 845 l. 17s. 6d. currency: How much is  
that in ſterling money, exchange at 80 *per cent.*?

If 180 : 100	
18 : 10	L. s. d.
9 : 5 :: 845 17 6	
	5
9)4229 7 6	

L. 469 18 7½ *Anſ.*

2. Boſton remits to Britain a bill of 469 l. 18 s. 7½ d.  
Sterling: How much currency was paid for the bill at  
Boſton, exchange at 80 *per cent.*?

If 100 : 180	L. s. d.
5 : 9 :: 469 18 7½	
	9
5)4229 7 6	
845 17 6 currency.	<i>Anſ.</i>

3. How much Sterling money will 1730 l. Jamaica  
currency amount to, exchange at 40 *per cent.*?

If 140 : 100	
14 : 10	L.
7 : 5 :: 1780	
	5
7)8900	
	s. d.
1271 8 6½	Ster. <i>Anſ.</i>

Bills of exchange from America, the rate being high,  
is an expenſive way of remitting money to Britain; and  
therefore merchants in Britain generally chuſe to have  
the debts due to them remitted home in ſugar, rum, or  
other produce.

X. *Exchange with Ireland,*

At Dublin, and all over Ireland, books and accounts  
are kept in pounds, ſhillings, and pence, as in Britain;  
and they exchange on the 100 l. Sterling.

The

The par of one shilling Sterling is one shilling and one penny Irish: and so the par of 100 l. Sterling is 108 l. 6 s. 8 d. Irish. The course of exchange runs from 6 to 15 per cent.

EXAMP. 1. London remits to Dublin 586 l. 10 s. Sterling: How much Irish money will that amount to, exchange at  $9\frac{1}{4}$  per cent.?

	L.
If 100 : 109 $\frac{1}{4}$ :: 586.5	
8	877
800 : 877	41055
	41055

9 $\frac{1}{4}$	56.450625 add
	642.950625

2. How much Sterling will 625 l. Irish amount to, exchange at  $10\frac{1}{4}$  per cent.?

If 110 $\frac{1}{4}$ : 100 :: 625	
8	800
883	800 883)500000
	(566 5 0 $\frac{1}{4}$ Ster. Ans.

#### XI. Exchange betwixt London and other places in Britain.

The several towns in Britain exchange with London for a small premium in favour of London; such as, 1, 1 $\frac{1}{4}$ , &c. per cent. The premium is more or less according to the demand for bills.

EXAMP. Edinburgh draws on London for 860 l. exchange at  $1\frac{1}{4}$  per cent.: How much money must be paid at Edinburgh for the bill?

L.	860
per cent.	
1 = $\frac{1}{100}$	8 12
$\frac{1}{4}$ = $\frac{1}{400}$	2 3
$\frac{1}{8}$ = $\frac{1}{800}$	1 6
	11 16 6 premium.
	871 16 6 paid for the bill.

To avoid paying the premium, it is an usual practice to take the bill payable at London a certain number of days after date; and in this way of doing, 73 days is equivalent to 1 per cent.

#### XII. Arbitration of Exchanges.

The course of exchange betwixt nation and nation naturally rises or falls according as the circumstances and balance of trade happen to vary. Now to draw upon and remit to foreign places, in this fluctuating state of exchange, in the way that will turn out most profitable, is the design of arbitration. Which is either simple or compound.

##### I. Simple Arbitration.

In simple arbitration the rates or prices of exchange from one place to other two are given; whereby is found the correspondent price between the said two places, called the *arbitrated price*, or *par of arbitration*: and hence is derived a method of drawing and remitting to the best advantage.

EXAMP. 1. If exchange from London to Amsterdam be 33 s. 9 d. per l. Sterling; and if exchange from London to Paris be 32 d. per crown; what must be the rate of exchange from Amsterdam to Paris, in order to be on a par with the other two?

Ster.	Flem.	Ster.
s.	s.	d. d.
If 20 : 33 9 :: 32		
12	12	
240	405	
	32	
	810	
	1215	

240)12560(54 d. Flem. per crown. Ans.

2. If exchange from Paris to London be 32 d. Sterling per crown; and if exchange from Paris to Amsterdam be 54 d. Flemish per crown; what must be the rate of exchange between London and Amsterdam, in order to be on a par with the other two?

Ster.	Flem.	Ster.
d.	d.	d.
If 32 : 54 :: 240		
	240	
	216	
	108	

—12) s. d.  
32)12960(405 (33 9 Flem. per l. Ster. Ans.

From these operations it appears, that if any sum of money be remitted, at the rates of exchange mentioned, from any one of the three places to the second, and from the second to the third, and again from the third to the first, the sum so remitted will come home entire, without increase or diminution.

From

From the par of arbitration thus found, and the course of exchange given, is deduced a method of drawing and remitting to advantage, as in the following example.

3. If exchange from London to Paris be 32 d. Sterling *per* crown, and to Amsterdam 405 d. Flemish *per* l. Sterling; and if, by advice from Holland or France, the course of exchange between Paris and Amsterdam is fallen to 52 d. Flemish *per* crown; what may be gained *per cent.* by drawing on Paris, and remitting to Amsterdam?

The par of arbitration between Paris and Amsterdam in this case, by Ex. 1. is 54 d. Flemish *per* crown. Work as under.

$$\begin{array}{rcl}
 d. St. Cr. & L. St. & Cr. \\
 \text{If } 52 : 1 :: 100 : 750 \text{ debit at Paris} \\
 Cr. d. Fl. & Cr. & d. Fl. \\
 \text{If } 1 : 52 :: 750 : 39000 \text{ credit at Amsterdam.} \\
 d. Fl. L. St. & d. Fl. & L. s. d. Ster. \\
 \text{If } 405 : 1 :: 39000 : 96 \text{ } 5 \text{ } 11 \frac{1}{2} \text{ to be remitted.} \\
 & & 100 \\
 \hline
 & & 3 \text{ } 14 \text{ } 0 \frac{3}{4}
 \end{array}$$

But if the course of exchange between Paris and Amsterdam, instead of falling below, rise above the par of arbitration, suppose to 56 d. Flemish *per* crown; in this case, if you propose to gain by the negotiation, you must draw on Amsterdam, and remit to Paris. The computation follows.

$$\begin{array}{rcl}
 L. St. d. Fl. & L. St. & d. Fl. \\
 \text{If } 1 : 405 :: 100 : 40500 \text{ debit at Amsterdam.} \\
 d. Fl. Cr. & d. F. & Cr. \\
 \text{If } 56 : 1 :: 40500 : 723 \frac{1}{4} \text{ credit at Paris.} \\
 Cr. d. St. & Cr. & L. s. d. Ster. \\
 \text{If } 1 : 32 :: 723 \frac{1}{4} : 96 \text{ } 8 \text{ } 6 \frac{7}{8} \text{ to be remitted.} \\
 & & 100 \\
 \hline
 & & 3 \text{ } 11 \text{ } 5 \frac{1}{2} \text{ gained } per \text{ cent.}
 \end{array}$$

In negotiations of this sort, a fund for remittance is afforded out of the sum you receive for the draught; and your credit at the one foreign place pays your debit at the other.

## II. Compound Arbitration.

In compound arbitration the rate or price of exchange between three, four, or more places, is given, in order to find how much a remittance passing through them all will amount to at the last place; or to find the arbitrated price, or par of arbitration, between the first place and the last. And this may be done by the following

**RULES.** I. Distinguish the given rates or prices into antecedents and consequents; place the antecedents in one column, and the consequents in another on the right, fronting one another by way of equation.

II. The first antecedent, and the last consequent to which an antecedent is required, must always be of the same kind.

III. The second antecedent must be of the same kind

with the first consequent, and the third antecedent of the same kind with the second consequent, &c.

IV. If to any of the numbers a fraction be annexed, both the antecedent and its consequent must be multiplied into the denominator.

V. To facilitate the operation, terms that happen to be equal or the same in both columns, may be dropped or rejected, and other terms may be abridged.

VI. Multiply the antecedents continually for a divisor, and the consequents continually for a dividend, and the quot will be the answer or antecedent required.

**EXAMP. 1.** If London remit 1000 l. Sterling to Spain, by way of Holland, at 35 s. Flemish *per* l. Sterling; thence to France, at 58 d. Flemish *per* crown; thence to Venice, at 100 crowns *per* 60 ducats; and thence to Spain, at 360 mervadies *per* ducat; how many pialtres, of 272 mervadies, will the 1000 l. Sterling amount to in Spain?

Antecedents.	Consequents.	Abridged.
1 l. Sterling =	35 s. or 420 d. Fl.	1=210
58 d. Flemish =	1 crown France	29= 1
100 crowns France=	60 ducats Venice	1= 30
1 ducat Venice=	360 mervadies Spain	1= 45
272 mervadies =	1 pialtre	17= 1
How many pialtres=	1000 l. Sterling	= 10

In order to abridge the terms, divide 58 and 420 by 2, and you have the new antecedent 29, and the new consequent 210; reject two ciphers in 100 and 1000; divide 272 and 360 by 8, and you have 34 and 45; divide 34 and 60 by 2, and you have 17 and 30; and the whole will stand abridged as above.

Then,  $29 \times 17 = 493$  divisor; and,  $210 \times 30 \times 45 \times 10 = 2835000$  dividend; and,  $493 \mid 2835000 (5750 \frac{1}{2}$  pialtres. *Ans.*

Or, the consequents may be connected with the sign of multiplication, and placed over a line by way of numerator; and the antecedents, connected in the same manner, may be placed under the line, by way of denominator; and then abridged, as follows:

$$\begin{array}{r}
 \frac{420 \times 60 \times 360 \times 100}{58 \times 100 \times 272} = \frac{210 \times 60 = 360 \times 10}{29 \times 1 \times 272} \\
 = \frac{210 \times 60 \times 45 \times 100}{29 \times 34} = \frac{210 \times 30 \times 45 \times 10}{29 \times 17} \\
 = \frac{2835000}{493}
 \end{array}$$

And,  $493 \mid 2835000 (5750 \frac{1}{2}$  pialtres. *Ans.*

The placing the terms by way of antecedent and consequent, and working as the rules direct, save so many statings of the rule of three, and greatly shortens the operation. The proportions at large for the above question would stand as under.

$$\begin{array}{rcl}
 L. St. d. Fl. & L. St. & d. Fl. \\
 \text{If } 1 : 420 :: & 1000 & : 420000 \\
 d. Fl. Cr. & d. Fl. & Cr. \\
 \text{If } 58 : 1 :: & 420000 & : 7241 \frac{1}{2}
 \end{array}$$

Cr.

Gr.	Duc.	Gr.	Duc.
If 100	: 60	:: 7241 $\frac{1}{2}$	: 4344 $\frac{1}{2}$
Duc.	Mer.	Duc.	Mer.
If 1	: 360	:: 4344 $\frac{1}{2}$	: 1564137 $\frac{1}{2}$
Mer.	Piaſt.	Mer.	Piaſt.
If 2 $\frac{1}{2}$	: 1	:: 1564137 $\frac{1}{2}$	: 5750 $\frac{1}{2}$

If we ſuppoſe the courſe of direct exchange to Spain to be 42 $\frac{1}{2}$  d. Sterling *per* piaſtre, the 1000l. remitted would only amount to 5647 $\frac{1}{2}$  piaſtres; and, conſequent-ly, 103 piaſtres are gained by the negotiation; that is, about 2 *per cent*.

2. A banker in Amſterdam remits to London 400 l. Flemiſh; firſt to France at 56 d. Flemiſh *per* crown; from France to Venice at 100 crowns *per* 60 ducats; from Venice to Hamburgh at 100 d. Flemiſh *per* ducat; from Hamburgh to Liſbon at 50 d. Flemiſh *per* cruſade of 400 rees; and, laſtly, from Liſbon to London at 64 d. Sterling *per* milree: How much Sterling money will the remittance amount to? and how much will be gained or ſaved, ſuppoſing the direct exchange from Holland to London at 36 s. 10 d. Flemiſh *per* l. Sterling?

*Antecedents. Conſequents.*

56 d. Flem. = 1 crown

100 crowns = 60 ducats.

1 ducat = 100 d. Flem.

50 d. Flem. = 400 rees.

1000 rees = 64 d. Sterling.

How many d. Ster = 400 l. or 96000 d. Flemiſh?

This, in the fractional form, will ſtand as follows.

$$\frac{60 \times 100 \times 400 \times 64 \times 96000}{50 \times 100 \times 50 \times 1000} = \frac{368640}{7}, \text{ and}$$

$$7) 368640 (52662\frac{6}{7} \text{ d. Ster.} = 219 \text{ l. } 8 \text{ s. } 6\frac{6}{7} \text{ d. St. Anf.}$$

To find how much the exchange from Amſterdam di-rectly to London, at 36 s. 10 d. Flemiſh *per* l. Sterling, will amount to, ſay,

s. d.	d. Fl.	L. St.	d. Fl.	L.	s. d. St.
36	10	If 442	: 1	:: 96000	: 217 3 10 $\frac{1}{2}$
12					219 8 6 $\frac{1}{2}$
442		Gained or ſaved,	2	4	8 $\frac{1}{2}$

In the above example, the par of arbitration, or the arbitrated price, between London and Amſterdam, *viz.* the number of Flemiſh pence given for 1 l. Sterling, may be found thus:

Make 64 d. Sterling, the price of the milree, the firſt antecedent; then all the former conſequents will be- come antecedents, and all the antecedents will become conſequents. Place 240, the pence in 1 l. Sterling, as the laſt conſequent, and then proceed as taught above, *viz.*

VOL. II. No 48.

†

64 d. Ster. = 1000 rees.

400 rees = 50 d. Flem.

100 d. Flem. = 1 ducat.

60 ducats = 100 crowns.

1 crown = 56 d. Flem.

How many d. Flem. = 240 d. Ster.?

$$\frac{1000 \times 50 \times 100 \times 56 \times 240}{64 \times 400 \times 100 \times 60} = \frac{975}{2}, \text{ and}$$

2) 975 (437 $\frac{1}{2}$  d. = 36 s. 5 $\frac{1}{2}$  d. Flem. *per* l. Ster. Anf.

Or the arbitrated price may be found from the answer to the queſtion, by ſaying,

d. Ster. d. Flem. d St.

If 368640 : 96000 :: 240

$$\begin{array}{r} 7 \quad \quad 7 \\ \hline 672000 \\ 240 \\ \hline 2688 \\ 1344 \end{array}$$

d. s. d. Flem.

368640)161280000(437 $\frac{1}{2}$  = 36 5 $\frac{1}{2}$  as before.

The work may be proved by the arbitrated price thus: As 1 l. Sterling to 36 s. 5 $\frac{1}{2}$  d. Flemiſh, ſo 219 l. 8 s. 6 $\frac{6}{7}$  d. Sterling to 400 l. Flemiſh.

The arbitrated price compared with the direct courſe ſhows whether the direct or circular remittance will be moſt advantageous, and how much. Thus the banker at Amſterdam will think it better exchange to receive 1 l. Sterling for 36 s. 5 $\frac{1}{2}$  d. Flemiſh, than for 36 s. 10 d. Flemiſh.

EXCHANGE ſignifies alſo a place in moſt conſiderable tra- ding cities, wherein the merchants, negociants, agents, bankers, brokers, interpreters, and other perſons concerned in commerce, meet on certain days, and at certain times thereof, to confer and treat toge- ther of matters relating to exchanges, remittances, pay- ments, adventures, aſſurances, freightments, and other mercantile negotiations, both by ſea and land.

EXCHEQUER, in the Britiſh jurisprudence, an ancient court of record, in which all cauſes concerning the re- venues and rights of the crown are heard and determi- ned, and where the crown-revenues are received.

It took this name from the cloth that covered the ta- ble of the court, which was partly-coloured, or che- quered.

This court is ſaid to have been created by William the conqueror, its model being taken from a like court eſtabliſhed in Normandy long before that time. An- ciently its authority was ſo great, that it was held in the king's palace, and the acts thereof were not to be examined or controlled in any other of the king's courts; but, at preſent, it is the laſt of the four courts at Weſtmiſter.

In the exchequer, some reckon seven courts, viz. those of pleas, accounts, receipts, exchequer-chamber, (which is an assembly of all the judges on difficult matters in law) errors in the exchequer, errors in the king's bench, and, lastly, the court of equity in the exchequer.

But the exchequer, for dispatch of business, is generally divided into two parts; one of which is chiefly conversant in the judicial hearing and deciding of all causes relating to the king's coffers, formerly termed the exchequer of accounts: the other is called the receipt of the exchequer, as being principally employed in receiving and payment of money.

Officers of the receipt may take one penny in the pound, as their fee for sums issued out; and they are obliged, without delay, to receive the money brought thither; and the money received is to be put in chests under three different locks and keys, kept by three several officers. All sheriffs, bailiffs, &c. are to account in the exchequer; and in the lower part, termed the receipt, the debtors of the king, and persons in debt to them, the king's tenants, and the officers and ministers of the court, are privileged to sue one another, or any stranger, and to be sued in the like actions as are brought in the courts of king's bench and common-pleas.

The judicial part of the exchequer, is a court both of law and equity. The court of law is held in the office of pleas, according to the course of common law, before the barons: in this court, the plaintiff ought to be a debtor or accountant to the king; and the leading process is either a writ of subpœna, or quo minus, which last goes into Wales, where no process out of our courts of law ought to run, except a *capias utlagatum*.

The court of equity is held in the exchequer-chamber before the treasurer, chancellor, and barons; but, generally, before the barons only; the lord chief baron being the chief judge to hear and determine all causes. The proceedings in this part of the exchequer, are by English bill and answer, according to the practice of the court of chancery; with this difference, that the plaintiff here must likewise set forth that he is a debtor to the king, whether he be so or not. It is in this court of equity that the clergy exhibit bills for the recovery of their tithes, &c. Here too the attorney-general exhibits bills for any matters concerning the crown; and a bill may be exhibited against the king's attorney by any person aggrieved in any cause prosecuted against him on behalf of the king, to be relieved therein: in which case, the plaintiff is to attend on the attorney-general with a copy of the bill, and procure him to give in an answer thereto; in the making of which he may call in any person interested in the cause, or any officer, or others, to instruct him, that the king be not prejudiced thereby, and his answer is to be put in without oath.

But besides the business relating to debtors, farmers, receivers, accountants, &c. all penal punishments, intrusion, and forfeitures upon popular actions, are matters likewise cognizable by this court; where there also sits a justice-baron, who administers the oaths to high-

sheriffs, bailiffs, auditors, receivers, collectors, comptrollers, surveyors and searchers of all the customs, &c.

The exchequer in Scotland, has the same privileges and jurisdiction as that of England; and all matters competent to the one, are likewise competent to the other.

*Black book of the EXCHEQUER*, a book containing a description of the court of England in 1175, and its officers, with their ranks, wages, privileges, perquisites, &c. also the revenues of the crown, both in money and cattle.

**EXCIPIENT**, in pharmacy, denotes the ingredient, which, in compound medicines, receives all the rest; as the conserve in electuaries, the syrup in boluses, &c.

**EXCISE**, a certain duty or impost charged upon liquors, as beer, ale, cyder, &c. malt, and several other commodities, within the kingdom of Great Britain, and town of Berwick upon Tweed.

The excise is one of the most considerable branches of the king's revenue. It was formerly farmed out, but is now managed for the king by commissioners in both kingdoms, who receive the whole product of the excise, and pay it into the exchequer. These commissioners are nine in number in England, and four in Scotland. The former have a salary of 1000 l. a year, the later 500 l. They are obliged by oath to take no fee or reward but from the king himself; and from them there lies an appeal to five other commissioners called commissioners of appeals.

The duty of excise was first granted to king Charles II. by act of parliament in the year 1660, during the life of that monarch. 1. It was 15 d. *per* barrel upon every barrel of beer or ale above 6 s. the barrel, and 3 d. *per* barrel for every barrel of 6 s. or under, brewed for retail; 15 d. for every hoghead of cyder or perry sold by retail; 1 d. for every gallon of strong water, aqua vitæ, &c. 2. A new excise was granted for ever by the fifth money-act of William and Mary, being for every barrel of beer or ale above 6 s. the barrel, 9 d.; and for every barrel of 6 s. or under, 3 d.; for every hoghead of cyder or perry, 1 s. *per* hoghead. In this excise, the price of the liquor is to be reckoned exclusive of the duty. 3. An excise was granted of 6 d. a bushel on malt in the reign of king William, which by subsequent statutes has been continued yearly ever since. But such malt as shall be made for exportation, and be so entered and kept separate from other malt, is exempted from the payment of this duty. 4. Another new excise upon home made liquors was granted in queen Anne's reign; being an additional excise upon every barrel of beer or ale brewed for sale above 6 s. the barrel, 5 d. exclusive of the duties; and for every barrel at 6 s. or under, 1 d.; for every hoghead of cyder or perry, 5 d.; for every gallon of strong waters or aqua vitæ, 1 d. This excise was not laid upon any such liquors imported. 5. An excise on candles was first granted in the reign of queen Anne, and continued for ever, being a duty of 4 d. a pound on wax, and a half-penny the pound on tallow candles, made in Great Britain for sale or not for sale; but makers for their own use may compound for 1 s. a head for every person in their family. An additional excise on candles was afterwards granted.

granted, being the same with the former in every respect. 6. An excise upon hides and skins tanned in Britain, first granted in queen Anne's reign, was an excise of seventeen different kinds, upon so many different kinds of hides and skins particularly named, and upon all others not named, 13 l. *per cent. ad valorem*. An additional excise was afterwards granted, being an additional duty of different kinds, upon so many different sorts of hides and skins particularly named, and on all others not named, 15 l. *per cent.* on the value. 7. An excise on home-made vellum and parchment, first granted by the same act, being 1 s. *per dozen* on vellum, and 6 d. the dozen on parchment. And afterwards an additional excise on vellum, &c. was granted, being an additional duty of 2 s. the dozen on vellum, and 1 s. the dozen on parchment. 8. An excise on hops of home growth was first granted in queen Anne's reign, being 1 d. *per pound*. 9. An excise on paper, pasteboards, milled-boards, and scale-boards, was first granted in the reign of queen Anne, being a duty of eleven different kinds on so many different sorts of paper particularly named, made in Great Britain; on pasteboards, &c. 3 s. the hundred weight, and on all sorts of paper not named, 12 l. *per cent.* on the value. An additional duty on paper, &c. was granted of eleven different kinds, &c. on pasteboard, 1 s. 6 d. the hundred weight, and on all sorts of paper not named, 6 l. *per cent.* on the value; and on painted paper for hangings, a halfpenny the yard square. 10. An excise of 1 d. *per pound* on soap made in Great Britain, was granted by the same act; to which an additional excise has been added of a halfpenny *per pound*. 11. An excise upon printed silks, calicoes, linens and stuffs made in Great Britain, and printed, painted, stained or dyed here, was first granted in queen Anne's reign, being a duty of 3 d. on silks and calicoes, and 1½ d. on linen and stuffs the yard square, excepting silk handkerchiefs, linens and stuffs dyed of one colour, and stuffs made of woollen, or the greatest part in value of woollen. And an additional excise was granted of 6 d. the yard of half-yard broad silks; 1 d. the yard square of silk handkerchiefs; 3 d. the yard square of calicoes, and 1½ d. the yard square of linens and stuffs, excepting, as before, calicoes, &c. dyed of one colour, and woollen stuffs. 12. An excise on starch was first granted for 1 d. the pound; and afterwards an additional excise of 1 d. the pound. 13. The excise on gilt and silver wire made in Great Britain, is 8 d. the ounce on gilt wire, and 6 d. the ounce on silver wire.

If any brewers do not make true entries of their liquors brewed, once a-week at the excise-office, they forfeit 10 l. but this is subject to mitigation, so as not to be less than double the duty; and the retailers of beer and ale and strong waters, neglecting to make their entries once a-month of what liquors they retail, are liable to 40 s. penalty. In case any brewer erects or alters any back, copper, cooler, &c. or keeps a private store-house, or if any maltster keeps any private vessel for steeping barley, without giving proper notice to the officers of excise, such brewer or maltster forfeit 50 l. and where they bribe a gauger, it is 10 l. The officers

of excise may go on board ships, and search for any excisable liquors, as officers of the customs do, and seize commodities forfeited, &c. and complaints made at the chief office of excise are to be heard by three or more commissioners; but two justices of the peace have the power to determine in seizures out of the limits of the excise-office in London.

**EXCLAMATION**, in rhetoric, a figure that expresses the violent and sudden breaking out, and vehemence of any passion.

**EXCOMMUNICATION**, an ecclesiastical penalty or censure, whereby such persons as are guilty of any notorious crime or offence, are separated from the communion of the church, and deprived of all spiritual advantages.

Excommunication among the Jews, according to Elias, a German rabbin, was distinguished into three kinds: 1. Niddui, which was a separation of but a few days; 2. Cherem, a separation attended with execration and malediction; and, 3. Shammatha, which was the last and greater excommunication. But Selden says, that niddui and shammatha are the same thing; and therefore that there were but two kinds of excommunication among the Jews, *viz.* the greater and the lesser. They made also another distinction in excommunication, into total or universal, by which a man was excommunicated with regard to all men; and partial, by which a man was excommunicated in one city, and with regard to certain persons, and not others.

It is observable, that not only the judges had the power of excommunicating, but that each particular person in conversation might excommunicate another, and himself likewise; and this excommunication, if well grounded, was of force: nay, if a man dreamed that he was excommunicated by himself or by another, he was considered as an excommunicated person, because this dream was supposed to be sent from God.

As to the effects of the Jewish excommunication, the lesser excluded the excommunicated person from the society of men; that is, he was not to come nearer them than four cubits, neither he, his wife, children, or domestics, according to Buxtorf. The greater absolutely sequestered the person from the conversation of others; and sometimes he was shut up in a small chamber or prison, where he lived alone. Baronius and Beza pretend, that the greater excommunication excluded men from the use of sacred things. Selden, on the contrary, affirms, that they were allowed to be present in the temple, and partake of the public worship. Buxtorf, who is of the same opinion, adds, that whereas others came into the temple at the right hand, and went out at the left, the excommunicated were obliged both to go in and out at the left.

Excommunication, among the modern Jews, is attended with the most terrible consequences. The excommunicated person is refused all human assistance: if there be a corpse in his house, or a child to be circumcised, none must help him. He is cursed by the book of the law, by the curse of Joshua against Jericho, by that of Elisha against the children, by heaven and earth,

earth, and God is besought that a whirlwind may dash him to pieces. He is pelted with stones if he appear in the streets; and if he obtains absolution, it is upon the most mortifying conditions; for he is publicly tied to a post and whipped, after which he lays himself down at the door of the synagogue, and all those who go out pass over him. This was the very case of the famous Jew Acolla.

In the ancient Christian church, the power of excommunication, as well as other acts of ecclesiastical discipline, was lodged in the hands of the clergy, who distinguished it into the greater and lesser. The lesser excommunication, simply called *aphorismus*, separation or suspension, consisted in excluding men from the participation of the eucharist, and the prayers of the faithful. But they were not expelled the church; for they had the privilege of being present at the reading of the scriptures, the sermons, and the prayers of the catechumens and penitents. This excommunication was inflicted for lesser crimes, such as neglecting to attend the service of the church, misbehaviour in it, and the like.

The greater excommunication, called *panteles aphorismus*, total separation and anathema, consisted in an absolute and entire exclusion from the church and the participation of all its rites. When any person was thus excommunicated, notice was given of it by circular letters to the most eminent churches all over the world, that they might all confirm this act of discipline, by refusing to admit the delinquent to their communion. The consequences of this latter excommunication was very terrible. The excommunicated person was avoided in civil commerce and outward conversation. No one was to receive him into his house, nor eat at the same table with him; and when dead, he was denied the solemn rites of burial. It has been a question, whether the ancient church used to add execration to her censures. Grotius thinks this was done, though very seldom, as in the case of Julian the apostate, for whose destruction the ancient Christians absolutely prayed to God. St Chrysostom was utterly against this practice, affirming that we ought not to pray against the sinner, but against his opinions or actions.

The Romish pontifical takes notice of three kinds of excommunication. 1. The minor, incurred by those who have any correspondence with an excommunicated person. 2. The major, which falls upon those who disobey the commands of the holy see, or refuse to submit to certain points of discipline; in consequence of which they are excluded from the church militant and triumphant, and delivered over to the devil and his angels. 3. Anathema, which is properly that pronounced by the pope against heretical princes and countries. In former ages, these papal fulminations were most terrible things; but at present, they are formidable to none but a few petty states of Italy.

Excommunication in the Greek church, cuts the offender off from all communion with the 318 fathers of the first council of Nice, and with the saints; consigns him over to the devil, and the traitor Judas; and commands his body to remain after death as hard as a flint

or piece of steel, unless he humbles himself and makes atonement for his sins by a sincere repentance. The form abounds with dreadful imprecations; and the Greeks assert, that if a person dies excommunicated, the devil enters into the lifeless corpse; and therefore, in order to prevent it, the relations of the deceased cut his body in pieces, and boil them in wine. It is a custom for the patriarch of Jerusalem annually to excommunicate the pope and the church of Rome; on which occasion, together with a great deal of idle ceremony, he drives a nail into the ground with a hammer, as a mark of malediction.

The form of excommunication in the church of England anciently ran thus: "By the authority of God the Father Almighty, the Son and Holy Ghost, and of Mary the blessed mother of God, we excommunicate, anathematize, and sequester from the pale of holy mother church," &c. The causes of excommunication in England are, contempt of the bishop's court, heresy, neglect of public worship and the sacraments, incontinency, adultery, simony, &c. It is published in the church; and if the offender does not submit in forty days, the civil magistrate interposes, and the excommunicated person is imprisoned till he submits and obtains absolution. Excommunication disables a person from doing any judicial act, as suing in an action at law, being a witness, &c.

Excommunication, among the Pagans, excluded the person from the sacrifices and the temples, and delivered him over to the furies, which was called *exsecrare*, and *diris devovere*. When Marcus Crassus set out on his expedition against the Parthians, Atticus, tribune of the people, not being able to prevent him, ran to the gate of the city through which the general was to pass, and setting a chaffing-dish in the middle of the way with fire in it, when Crassus drew near, he threw some perfumes into the chaffing dish, and pronounced curses against Crassus with great exclamation, and thus excommunicated him.

**EXCORIATION**, in medicine and surgery, the galling or rubbing off of the cuticle, especially of the parts between the thighs, and about the anus.

**EXCREMENT**, whatever is discharged out of the body of animals after digestion, or the fibrous parts of the aliment, mixed with the bile, saliva, and other fluids. Urine and the feces are the gross excrements that are discharged out of the bladder or belly. Other excrements are the various humours that are secreted from the blood through the various strainers in the body, and which serve for several uses, such as the saliva, sweat, bile, the pancreatic juice, lymph, the semen, nails, the hair, the horns and hoofs of animals.

**EXCRESCENCE**, in surgery, denotes every preternatural tumour which arises upon the skin, either in the form of a wart or tubercle. If they are born with a person, as they frequently are, they are called *naevi materni*, or marks from the mother; but if the tumour is large, so as to depend from the skin like a fleshy mass, it is then called a sarcoma.

**EXCRETION**, or **SECRETION**, in medicine, a separation of some fluid, mixed with the blood, by means of the

the glands. Excretions, by which we mean those that evacuate superfluous and heterogeneous humours, purify the mass of blood: the humours which are generated in the blood are excreted by the glands, and are replaced by a sufficient quantity of aliment.

**EXCRETORY**, in anatomy, a term applied to certain little ducts or vessels, destined for the reception of a fluid, secreted in certain glandules, and other viscera, for the excretion of it in the appropriated places.

**Letters of EXCULPATION**, in Scots law, a writ or summons issued by authority of the court of judicatory, at the instance of a panel, for citing witnesses to prove his defences, or his objections to any of the jury or witnesses cited against him. See tit. 33.

**EXCURSION**, in astronomy, is used in a synonymous sense with elongation. See **ELONGATION**.

**EXECRATION**, in antiquity, a kind of punishment, consisting of direful curses and marks of infamy: such was that used against Philip king of Macedon, by the Athenians. A general assembly of the people being called, they made a decree, that all the statues and images of that king, and of all his ancestors, should be demolished, and their very names razed; that all the festivals, sacred rites, priests, and whatever else had been instituted in honour of him, should be profaned; that the very places where there had been any monument or inscription to his honour, should be detestable; that nothing should be set up, or dedicated in them, which could be done in clean places: and, lastly, that the priests, as often as they prayed for the Athenian people, allies, armies, and fleets, should as many times detest and execrate Philip, his children, kingdom, land and sea forces, and the whole race and name of the Macedonians.

**EXECUTION**, in a general sense, the act of accomplishing, finishing, or achieving any thing.

**Execution of summonses or letters**, in Scots law, see **LAW**, tit. 12. Execution of testaments; see tit. 28. Execution of civil sentences and decrees; see tit. 32. Execution of criminal sentences; see tit. 33.

**EXECUTOR**, in Scots law, signifies either the person intitled to succeed to the moveable estate of one deceased, or who by law or special appointment is intrusted with the administration of it. See tit. 28.

**EXECUTRY**, in Scots law, is the moveable estate falling to the executor. Under executry, or moveables, is comprehended every thing that moves itself, or can be moved; such as corns, cattle, furniture, ready money, &c. See tit. 9. and 28.

**EXEDRÆ**, in antiquity, a general name for such buildings as were distinct from the main body of the churches, and yet within the limits of the church taken in its largest sense. Among the exedræ the chief was the baptistery. See **BAPTISTERY**.

**EXEGESIS**, a discourse by way of explanation or comment upon any subject. In the Scotch universities, there is an exercise among the students in divinity, called an exegesis, in which a question is stated by the respondent, who is then opposed by two or three other students in their turns; during which time the professor moderates, and solves the difficulties which the respondent cannot overcome.

**EXEMPLAR**, denotes much the same with model. See **MODEL**.

**EXEMPLIFICATION of letters patent**, a transcript or duplicate of them, made from the inrollment thereof, and sealed with the great seal.

**EXEMPTION**, in law, a privilege to be free from some service or appearance: thus, barons and peers of the realm are, on account of their dignity, exempted from being sworn upon inquests; and knights, clergymen, and others, from appearing at the sheriff's turn. Persons of seventy years of age, apothecaries, &c. are also by law exempted from serving on juries; and justices of the peace, attorneys, &c. from parish-offices.

**EXERCISE**, among physicians, such an agitation of the body, as produces salutary effects in the animal œconomy. See **MEDICINE**.

**Exercise**, in military affairs, is the ranging a body of soldiers in form of battle, and making them perform the several motions and military evolutions with different management of their arms, in order to make them expert therein.

**EXERCITOR**, in Scots law, he who employs a ship in trade, whether he be owner, or only freights her from the owner.

**EXERGUM**, among antiquarians, a little space around or without the figures of a medal, left for the inscription, cypher, device, date, &c.

**EXETER**, the capital city of Devonshire, situated on the river Ex, ten miles north of the British channel: W. long. 3° 40', N. lat. 50° 44'.

**EXFOLIATION**, a term used by surgeons for the scaling of a bone, or its rising and separating into thin laminæ or scales.

**EXHALATION**, a general term for all effluvia or steams raised from the surface of the earth in form of vapour.

**EXHIBIT**, in law, is where a deed, or other writing, being produced in a chancery suit, to be proved by witnesses, the examiner, or commissioner appointed for the examination of any such, certifies on the back of the deed or writing, that the same was shewn to the witness at the time of his examination, and by him sworn to.

**EXHORTATION**, in rhetoric, differs only from suasion, as being more directly addressed to the passions.

**EXIGENT**, in law, a writ which lies where the defendant in a personal action cannot be found, nor any effects of his within the county, by which he may be attached or distrained.

**EXIGENTERS**, four officers in the court of common-pleas, who make all exigents and proclamations, in all actions where process of outlawry lies. Writs of superseades, as well as the prothonotaries upon exigents, were likewise drawn up in their office.

**EXILE**. See **BANISHMENT**.

**EXISTENCE**, that whereby any thing has an actual essence, or is said to be. See **METAPHYSICS**.

**EXIT** in a theatrical sense, the action of a player in going off the stage, after he has played his part.

**EXLEGALITUS**, among lawyers, the same with an outlawed person.

**EXOCOETUS**, the **FLYING-FISH**, in ichthyology, a genus belonging to the order of abdominales. The head is scaly, and it has no teeth; it has ten radii in the branchiophage membrane; the body is whitish, and

the belly is angular: the pectoral fins are very large. When pursued by any other fish, it raises itself from the water by means of these long fins, and flies in the air to a considerable distance, till the fins dry, and then it falls down into the water. There are two species, viz. 1. The volitans, with the belly carinated on each side. It is a native of the European and American seas. 2. The evolans, with a cylindrical belly. It is a native of the German ocean.

**EXODIARY**, in the ancient Roman tragedy, was the person who, after the drama or play was ended, sung the exodium. See **EXODIUM**.

**EXODIUM**, in the ancient Greek drama, one of the four parts or divisions of tragedy, being so much of the piece as included the catastrophe and unravelling of the plot, and answering nearly to our fourth and fifth acts.

**EXODIUM**, among the Romans, consisted of certain humorous verses rehearsed by the exodiary at the end of the *Fabulæ Atellanæ*.

**EXODIUM**, in the Septuagint, signifies the end or conclusion of a feast. Particularly it is used for the eighth day of the feast of tabernacles, which, it is said, had a special view to the commemoration of the exodus, or departure out of Egypt.

**EXODUS**, a canonical book of the Old Testament; being the second of the pentateuch, or five books of Moses.

It is so called, from the Greek, [*exodos*], the going out, or departure of the children of Israel from the land of Egypt; the history of which is delivered in this book, together with the many miracles wrought on that occasion.

**EX OFFICIO**, among lawyers, signifies the power a person has, by virtue of his office, to do certain acts without being applied to.

**EXOMPHALUS**, in surgery, called also omphalocele, and hernia umbilicalis, is a preternatural tumour of the abdomen, at the navel, from a rupture, or distension of the parts which invest that cavity. See **SURGERY**.

**EXORCISM**, among ecclesiastical writers, the expelling devils from persons possessed, by means of conjurations and prayers.

Exorcism makes a considerable part of the superstition of the church of Rome, the rituals of which forbid the exorcising any person without the bishop's leave.

The ceremony is performed at the lower end of the church, towards the door. The exorcist first signs the possessed person with the sign of the cross, makes him kneel, and sprinkles him with holy water. Then follow the litanies, psalms, and prayer; after which the exorcist asks the devil his name, and adjures him by the mysteries of the Christian religion not to afflict the person any more: then, laying his right hand on the dæmoniac's head, he repeats the form of exorcism, which is this: "I exorcise thee, unclean spirit, in the name of Jesus Christ: tremble, O Satan! thou enemy of the faith, thou foe of mankind, who hast brought death into the world, who hast deprived men of life, and hast rebelled against justice; thou seducer of mankind, thou root of evil, thou source of avarice, discord, and envy."

The Romanists likewise exorcise houses and other places, supposed to be haunted by unclean spirits; and the ceremony is much the same with that for persons possessed.

**EXORCISTS**, in church history, an order of men in the ancient church, whose employment it was to exorcise or cast out devils. See the preceding article.

**EXORDIUM**, in rhetoric, is the preamble or beginning, serving to prepare the audience for the rest of the discourse.

Exordiums are of two kinds, either just and formal, or vehement and abrupt. The last are most suitable on occasions of extraordinary joy, indignation, or the like.

**EXOTIC**, an appellation denoting a thing to be the produce of foreign countries.

**EXPANSION**, among metaphysicians, denotes the idea we have of lasting distance, all whole parts exist together.

**EXPANSION**, in physiology, the swelling or increase of the bulk of bodies when heated.

**EXPECTORANTS**, in pharmacy, medicines which promote expectoration. See the next article.

**EXPECTORATION**, the act of evacuating or bringing up phlegm or other matters out of the trachea, lungs, &c. by coughing, hawking, spitting, &c.

**EXPERIENCE**, a kind of knowledge acquired by long use, without any teacher. Mr Locke says, that men receive all the materials of knowledge from experience and observation.

**EXPERIMENT**, in philosophy, is the trial of the result or effect of the applications and motions of certain natural bodies, in order to discover something of their motions and relations, whereby to ascertain some of their phenomena, or causes.

**EXPERIMENTAL PHILOSOPHY**, that philosophy which proceeds on experiments, which deduces the laws of nature, and the properties and powers of bodies, and their actions upon each other, from sensible experiments and observations. The business of experimental philosophy is to inquire into, and to investigate the reasons and causes of, the various appearances and phenomena of nature; and to make the truth or probability thereof obvious and evident to the senses, by plain, undeniable, and adequate experiments, representing the several parts of the grand machinery and agency of nature. See **MECHANICS**, **HYDROSTATICS**, **OPTICS**, and the other branches of **NATURAL PHILOSOPHY**.

**EXPIATION**, a religious act, by which satisfaction, atonement, or amends, is made for the commission of some crime, the guilt done away, and the obligation to punishment cancelled.

The method of expiation among the Jews was chiefly by sacrifice, whether for sins of ignorance, or to purify themselves from certain pollutions.

*Great day of EXPIATION*, an annual solemnity of the Jews, upon the tenth day of the month Tisri, which answers to our September. On this occasion the high-priest laid aside his breast-plate and embroidered ephod, as being a day of humiliation. He first offered a bullock and a ram for his own sins, and those of the priests;

priests; then he received from the heads of the people two goats for a sin offering, and a ram for a burnt-offering, to be offered in the name of the whole multitude. It was determined by lot which of the goats should be sacrificed, and which set at liberty. After this he perfumed the sanctuary with incense, and sprinkled it with blood: then, coming out, he sacrificed the goat upon which the lot had fallen. This done, the goat which was to be set at liberty being brought to him, he laid his hands upon its head, confessed his sins, and the sins of the people, and then sent him away into some desert place: it was called azazel, or the scape-goat.

As to the expiations among the heathens, they were of several kinds, as sacrifices, and religious washings.

**EXPIATION**, in a figurative sense, is applied by divines to the pardon procured to mens sins, by the merits of Christ's death.

**EXPIRATION**, in phyc, that part of respiration whereby the air is expelled, or driven out of the lungs.

**EXPLICIT**, in the schools, something clear, distinct, formal, and unfolded.

**EXPLOSION**, in physics, is properly applied to the going off of gun-powder and the report made thereby. Hence, it is used to express such sudden actions of bodies as generate air instantaneously.

**EXPONENT**, in algebra. See **ALGEBRA**.

**EXPONENT** is also used in arithmetic, in the same sense as index or logarithm.

**EXPORTATION**, the shipping and carrying out of the the kingdom wares and commodities for other countries. See **COMMERCE**.

**EXPOSITION**, in general, denotes the setting a thing open to public view: thus it is the Romanists say, the host is exposed, when shewn to the people.

**EXPOSITION**, in a literary sense, the explaining an author, passage, writing, or the like, and setting their meaning in an obvious and clear light.

**EXPOSITOR**, or **EXPOSITORY**, a title given to small dictionaries, serving to explain the hard words of a language.

**EXPOSTULATION**, in rhetoric, a warm address to a person, who has done another some injury, representing the wrong in the strongest terms, and demanding redress.

**EXPOSURE**, in gardening, the situation of a garden, wall, or the like, with respect to the points of the compass, as south or east.

**EXPRESS**, something that is determinate or precise, or in such formal terms as leaves no room for doubt.

**EXPRESS** also denotes a courier. See **COURIER**.

**EXPRESSED OILS**, in chemistry. See **CHEMISTRY**, p. 93.

**EXPRESSION**, in rhetoric, the elocution, diction, or choice of words in a discourse. See **COMPOSITION**.

**EXPRESSION**, in painting, a natural and lively representation of the subject, or of the several objects intended to be shewn.

The expression consists chiefly in representing the human body and all its parts, in the action suitable to

it: in exhibiting in the face the several passions proper to the figures, and observing the motions they impress on the external parts.

**EXPULSION**, in a general sense, the act of violently driving a person out of any city, society, &c.

**EXPULSION**, in medicine, the act whereby any thing is forcibly driven out of the place in which it is: thus we say, the expulsion of the fœtus in delivery.

**EXTASY**, a transport which suspends the function of the senses, by the intense contemplation of some extraordinary or supernatural object.

**EXTASY**, in medicine, a species of catalepsy, when a person perfectly remembers, after the paroxysm is over, the ideas he conceived during the time it lasted.

**EXTENSION**, in philosophy, one of the common and essential properties of body, or that by which it possesses or takes up some part of universal space, which is called the place of that body. See **METAPHYSICS**.

**EXTENSOR**, an appellation given to several muscles, from their extending or stretching the parts to which they belong. See **ANATOMY**, Part II.

*Old and new* **EXTENT**, in Scots law. The *old extent* was a valuation or estimate of the annual value of all the lands in Scotland, taken (it is thought before the reign of Alexander III.) for the purpose of proportionating the public subsidies, and ascertaining the rates of certain feudal casualties. By improvement, and the alteration in the nominal value of money, this valuation, or old extent, became, in length of time, too low a standard for computing their feudal casualties; wherefore, about the reign of Robert I. all inquests for serving heirs were ordained to take proof also of the *present value* of the lands contained in the brief. This last was called the *new extent*. See **SCOTS LAW**, title 12.—None of these extents is the rule by which the land-tax is now proportioned in Scotland. See **VALUATION**, or **VALUED RENT**.

**EXTERIOR**, or **EXTERNAL**. See **EXTERNAL**.

**EXTERMINATION**, in general, the extirpating or destroying something.

**EXTERMINATION**, in Algebra. See **ALGEBRA**, p. 104.

**EXTERNAL**, a term of relation applied to the surface or outside of a body; or that part which appears or presents itself to the eye, touch, &c. in contradistinction to internal.

**EXTERNAL** is also used to signify any thing that is without-side a man, or that is not within himself, particularly in his mind, in which sense we may say external objects, &c.

**EXTINCTION**, in general, denotes the putting out or destroying something, as a fire or flame.

**EXTINGUISHMENT**, in law, is a consolidation or union, as where one has due to him a yearly rent out of lands, and afterwards purchases the lands out of which the rent arises: in this case, both the property and the rent being united in one possessor, the rent is said to be extinguished.

**EXTIRPATION**, the same with extermination. See **EXTERMINATION**.

**EXTISPEX**, in antiquity, the person who drew pre-juges from viewing the entrails of animals offered in sacrifice.

crifice. See **SACRIFICE**, **HARUSPEX**, and **DIVINATION**.

**EXTORTION**, in law, is an illegal manner of wresting any thing from a man either by force, menace, or authority.

**EXTRACT**, in pharmacy, is a solution of the purer parts of a mixed body inspissated, by distillation or evaporation, nearly to the consistence of honey. See **CHEMISTRY**.

**EXTRACT**, in matters of literature, is something copied or collected from a book or paper.

**EXTRACTION**, in chemistry and pharmacy, the operation by which essences, tinctures, &c. are drawn from natural bodies. See **CHEMISTRY**.

**EXTRACTION**, in surgery, is the drawing any foreign matter out of the body by the hand, or by the help of instruments. See **SURGERY**.

**EXTRACTION**, in genealogy, implies the stock or family from which a person is descended.

**EXTRACTION of roots**, in algebra and arithmetic. See **ALGEBRA**, p. 86. and **ARITHMETICK**, p. 420.

**EXTRACTOR**, in midwifery, an instrument, or forceps, for extracting children by the head. See **MIDWIFERY**.

**EXTRAVAGANTES**, those decretal epistles, which were published after the clementines. See **CLEMENTINES**.

They were so called because, at first, they were not digested, or ranged, with the other papal constitutions, but seemed to be, as it were, detached from the canon law. They continued to be called by the same name when they were afterwards inserted in the body of the canon law. The first extravagantes are those of John XXII. successor of Clement V. the last collection was brought down to the year 1483, and was called the common extravagantes, notwithstanding that they were likewise incorporated with the rest of the canon law.

**EXTRAVASATION**, in contusions, fissures, depressions, fractures, and other accidents of the cranium, is when one or more of the blood-vessels, that are distributed on the dura mater, is broke or divided, whereby there is such a discharge of blood as greatly oppresses the brain, and disturbs its office; frequently bringing on violent pains, and other mischiefs; and at length death itself, unless the patient is timely relieved. See **SURGERY**, and **MEDICINE**.

**EXTREMES**, in logic, the terms expressing the two ideas whose relation we inquire after in a syllogism.

**EXTREME UNCTION**. See **UNCTION**.

**EXTRINSIC**, among metaphysicians, is taken in various senses: sometimes it signifies a thing's not belonging to the essence of another; in which sense, the efficient cause and end of a thing are said to be extrinsic. Sometimes it signifies a thing's not being contained within the capacity of another; in which sense, these

causes are called extrinsic which introduce something into a subject from without, as when a fire introduces heat. Sometimes it signifies a thing added or applied to another; in which sense accidents and adherents are said to be extrinsic to the subjects to which they adhere. Sometimes the vision is said to be extrinsic from some form which does not exist in that thing, but is adjacent to it, or by some means or other without it.

**EXULCERATION**, in surgery. See **ULCER**.

**EXUVIÆ**, among naturalists, denote the cast-off parts or coverings of animals, as the skins of serpents, caterpillars, and other insects.

**EYE**, in anatomy. See **ANATOMY**, p. 289.

**Bull's EYE**, in astronomy. See **ALDEBARAN**.

**EYE-GLASS**, in the microscope. See **MICROSCOPE** and **OPTICS**.

**EYEMOUTH**, or **AYMOUTH**, a port-town of Scotland, about six miles north of Berwick.

**EYRAC**, or **IZACA ARABIC**, a province of Asiatic Turkey, situated on the river Euphrates, being the ancient Chaldea or Babylonia.

**EYRAC**, or **IRAC ADEM**, the ancient Parthia, now the principal province of Persia, is situated almost in the centre of that kingdom, its capital city being Isfahan, the metropolis of the whole kingdom.

**EYRE**, or **EIRE**, in law, the court of itinerant justices. See **JUSTICES**.

**EYSENACH**, a city of Germany, in the circle of Upper Saxony: E. long. 10° 12', and N. lat. 51°.

**EZEKIEL**, a canonical book of the Old Testament, referring chiefly to the degenerate manners and corruptions of the Jews of those times.

It abounds with fine sentences and rich comparisons, and discovers a good deal of learning in profane matters.

Ezekiel was carried captive to Babylon with Jeconiah, and began his prophecies in the fifth year of the captivity. He was cotemporary with Jeremiah, who prophesied at the same time in Judea. He foretold many events, particularly the destruction of the temple, the fatal catastrophe of those who revolted from Babylon to Egypt, and the happy return of the Jews to their own land.

**EZRA**, a canonical book of the Old Testament, comprehending the history of the Jews from the time of Cyrus's edict for their return, to the twentieth year of Artaxerxes Longimanus. It specifies the number of Jews who returned, and Cyrus's proclamation for the rebuilding the temple, together with the laying its foundation, the obstructions it met with, and the finishing thereof in the reign of Darius.

The illustrious author of this book, was also the restorer and publisher of the canon of the Old Testament.

F A C

**FABA**, in botany. See **VICIA**.**FABAGO**, in botany. See **ZYGOPHILLUM**.**FABER**, in ichthyology. See **ZEUS**.**FABLE**, a tale, or feigned narration, designed either to instruct or divert, disguised under the allegory of an action, &c.

Fables were the first pieces of wit that made their appearance in the world, and have been still highly valued, not only in times of the greatest simplicity, but among the most polite ages of the world. Jotham's fable of the trees is the oldest that is extant, and as beautiful as any that have been made since. Nathan's fable of the poor man is next in antiquity. We find Æsop, in the most distant ages of Greece; and in the early days of the Roman commonwealth, we read of a mutiny appeased by the fable of the belly and the members. As fables had their rise in the very infancy of learning, they never flourished more than when learning was at its greatest height; witness Horace, Boileau, and Fontaine.

**FABLE**, is also used for the plot of an epic or dramatic poem; and is, according to Aristotle, the principal part, and, as it were, the soul of a poem. See **COMPOSITION**.

**FACE**, in anatomy, comprehends all that part of the head which is not covered with the common long hair. See **ANATOMY**, Part I. II. and VI.

**FACE**, in the military art, a word of command, intimating to turn about: thus, *face to the right*, is to turn upon the left heel a quarter-round to the right; and, *face to the left*, is to turn upon the right heel a quarter-round to the left.

**FACET**, or **FACETS**, among jewellers, is the name of the little faces or planes to be found in brilliant and rose diamonds.

**FACTION**, a cabal or party formed in a state, city, or company.

**FACTION**, in antiquity, a name given to the different companies of combatants in the circus. They were four, *viz.* the white, the red, the green, and the blue; to which Domitian added another of purple colour. They were so denominated from the colour of the liveries they wore, and were dedicated, according to M. Aur. Cassiodorus, to the four seasons of the year, the green being consecrated to spring, the blue to winter, the red to summer, and the white to autumn. It appears from ancient inscriptions, that each faction had its procurators and physician; and from history, that party rage ran so high among them, that in a dissension between two factions, in the time of Justinian, almost forty thousand men lost their lives in the quarrel.

**FACTITIOUS**, any thing made by art, in opposition to what is the produce of nature. Thus, factitious cinnabar is opposed to native cinnabar.

**FACTOR**, in commerce, is an agent or correspondent

VOL. II. No. 49.

†

F A C

residing beyond the seas, or in some remote part, commissioned by merchants to buy or sell goods on their account, or assist them in carrying on their trade.

A factor receives from the merchants, his constituents, in lieu of wages, a commission or factorage, according to the usage of the place where he resides, or the business he transacts, this being various in different countries, on the purchases and sales of different commodities. He ought to keep strictly to the tenor of his orders; as a deviation from them, even in the most minute particular, exposes him to make ample satisfaction for any loss that may accrue from his non-observance of them. When unlimited orders are given to factors, and they are left to sell or buy on the best conditions they can, whatever detriment occurs to their constituents, they are excused, as it is to be presumed they acted for the best, and were governed by the dictates of prudence. But a bare commission to sell is not sufficient authority for the factor to trust any person, wherefore he ought to receive the money on the delivery of the goods; and, by the general power, he may not trust beyond one, two, or three months, &c. the usual time allowed for sales, otherwise he shall be answerable out of his own estate. If a factor sells on the usual trust to a person of good credit, who afterwards becomes insolvent, he is discharged; but not if the man's credit was bad at the time of sale. If a factor gives a man time for payment of money contracted on sale of his principal's goods, and, after that time is elapsed, sell him goods of his own for ready money, and the man becomes insolvent, the factor in equity ought to indemnify his principal; but he is not compellable by the common law. A factor should always be punctual in the advices of his transactions, in sales, purchases, freights, and more especially in draughts by exchange. If he purchases goods for another at a price limited, and afterwards they rise, and he fraudulently takes them for his own account, and sends them to another part, in order to secure an advantage that seemingly offers, he will, on proof, be obliged, by the custom of merchants, to satisfy his principal for damages. If a factor, in conformity with a merchant's orders, buys with his money, or on his credit, a commodity he shall be directed to purchase; and, without giving advice of the transaction, sells it again to profit, and appropriates to himself the advantage, the merchant shall recover it from him, and besides have him amerced for his fraud. When factors have obtained a profit for their principal, they must be cautious how they dispose of it; for, if they act without commission, they are responsible: and if a merchant remits goods to his factor, and about a month after draws a bill on him, the factor, having effects in his hands, accepts the bill, then the principal breaks; and the goods are seized in the factor's hands

2

5 T

for

for the behalf of the creditors, it has been conceived the factor must answer the bill notwithstanding, and come in a creditor for so much as he was obliged, by reason of his acceptance, to pay. A factor who enters into a charter-party with a master for freight, is obliged by the contract; but if he loads aboard generally, the principal and the lading are liable for the freightment, and not the factor. If a factor, having money in his hands belonging to his principal, neglect to insure a ship and goods, according to order; if the ship miscarry, the factor, by the custom of merchants, shall make good the damage; and if he make any composition with the insurers after insurance, without orders so to do, he is answerable for the whole insurance.

As fidelity and diligence are expected from the factor, so the law requires the like from the principal: if, therefore, a merchant remits counterfeit jewels to his factor, who sells them as if true; if he receive loss or prejudice by imprisonment or other punishment, the principal shall not only make full satisfaction to the factor, but to the party who bought the jewels.

What is here said of factors, is meant of such as reside abroad to act for merchants, and may be applied to supercargoes, who go a voyage to dispose of a cargo, and afterwards return with another to their principals: but it is also the custom of the merchants of the highest credit throughout the world, to act mutually in the capacity of factors for each other. The business so executed is called commission business, and is generally desirable by all merchants, provided they have always effects in their hands, as a security for all the affairs which they transact for the account of others. And this class of traders of established reputation, have current as well as commission account, constantly between them, and draw on, remit to, and send commissions to each other only by the intercourse of letters, which, among men of honour, are as obligatory and authoritative as all the bonds and ties of law.

**FACTOR**, in arithmetick. See **ARITHMETICK**, p. 371.

**FACTORAGE**, called also commission, is the allowance given to factors by the merchant who employs them. The gain of factorage is certain, however the voyage or sale prove to the merchant: but the commissions vary; at Jamaica, Barbadoes, Virginia, and most of the western parts of the world, the commission runs at 8 per cent. generally through Italy, 2½; in France, Spain, and Portugal, &c. 2; and in Holland and other places near home, 1½ per cent.

**FACTORY** is a place where a considerable number of factors reside, to negotiate for their masters or employers. See **FACTOR**.

The most considerable factories belonging to the British are those established in the East-Indies, Portugal, Turkey, &c.

**FACTUM**, in arithmetic, the product of two quantities multiplied by each other.

**FACULÆ**, in astronomy, certain bright and shining parts, which the modern astronomers have, by means of telescopes, observed upon or about the surface of the sun: they are but very seldom seen.

**FACULTY**, in law, a privilege granted to a person, by

favour and indulgence, of doing what, by law, he ought not to do.

For granting these privileges, there is a court under the archbishop of Canterbury, called the court of the faculties, the chief officer whereof is styled master of the faculties; who has a power of granting dispensations in divers cases, as to marry without the bans being first published; to eat flesh on days prohibited; to ordain a deacon under age; for a son to succeed his father in his benefice; a clerk to hold two or more livings, &c.

**FACULTY**, in the schools, a term applied to the different members of an university, divided according to the arts and sciences taught there: thus in most universities there are four faculties, viz. 1. Of arts, which include humanity and philosophy. 2. Of theology. 3. Of physics. And 4. Of civil law.

**FACULTY of Advocates**. See **ADVOCATES**.

**FACULTY** is also used to denote the powers of the human mind, viz. understanding, will, memory, and imagination. See **METAPHYSICS**.

**FÆCES**, in chemistry, the gross matter, or sediment, that settles at the bottom after distillation, fermentation, and the like.

**FÆCES**, in medicine, the excrements voided by stool.

**FÆCULENT**, in general, is applied to things abounding with fæces, or dregs: thus the blood and other humours of the human body, are said to be fæculent, when without that purity which is necessary to health.

**FAENSA**, a city and bishop's see of Italy, situated in the pope's territories, about thirty miles east of Bologna: E. long. 12° 38', and N. lat. 44° 30'.

**FAGARA**, in botany, a genus of the tetrandria monogynia class. The calix consists of four segments, and the corolla of four petals; and the capsule has four cells, two valves, and contains one seed. There are three species, none of them natives of Britain.

**FAGGOT**, in times of popery here, was a badge worn on the sleeve of the upper garment of such persons as had recanted, or abjured what was then termed heresy; being put on after the person had carried a faggot, by way of penance, to some appointed place of solemnity. The leaving off the wear of this badge was sometimes interpreted a sign of apostacy.

**FAGGOTS**, among military men, persons hired by officers, whose companies are not full, to muster and hide the deficiencies of the company; by which means they cheat the king of so much money.

**FAGONIA**, in botany, a genus of the decandria monogynia class. The calix consists of five leaves, and the corolla of five cordated petals; the capsule has five cells with one seed in each, and ten valves. There are three species, none of them natives of Britain.

**FAGOPYRUM**. See **POLYGONUM**.

**FAGUS**, the **BEECH**, in botany, a genus of the monœcia polyandria class. The calix of the male is bell-shaped, and consists of five segments; it has no corolla, but twelve stamens: the calix of the female consists of four teeth; it has no corolla; the styli are three; and the capsule is muricated, has four cells and two seeds. There are three species, two of them natives of Britain, viz. the castanea, or chestnut-tree; and the sylatica, or beech-tree.

**FAINTING**.

**FAINTING.** See **LIPOTHYMIA**.

**FAIR**, a greater kind of market, granted to a town, by privilege, for the more speedy and commodious providing of such things as the place stands in need of. See **MARKET**.

It is incident to a fair, that persons shall be free from being arrested in it for any other debt contracted than what was contracted in the same; or, at least, promised to be paid there. These fairs are generally kept once or twice a year, and, by statute, they shall not be held longer than they ought, by the lords thereof, on pain of their being seized into the king's hands, &c. Also proclamation is to be made how long they are to continue; and no person shall sell any goods after the time of the fair is ended, on forfeiture of double the value, one fourth to the prosecutor, and the rest to the king. There is a toll usually paid in fairs, on the sale of things, and for stallage, picafe, &c. See **TOLL**.

**FAIRFIELD** a town of New England, in the province of Connecticut, about an hundred miles south-west of Boston: W. long. 72°, and N. lat. 41°.

**FAIRFORD**, a market-town about nineteen miles south-east of Gloucester.

**FAIRY**, in ancient traditions and romances, signifies a sort of deity, or imaginary genius, conversant on earth, and distinguished by a variety of fantastical actions, either good or bad.

The fairies are a peculiar species of divinities, that have but little relation to any of those of the ancient Greeks or Romans, unless perhaps to the larvæ; tho' others, with great reason, will not have them ranked among gods, but suppose them an intermediate kind of beings, neither gods, angels, men, or devils. They are of oriental extraction, and seem to have been invented by the Persians and Arabs, whose religion and history abound with relations concerning them: these have a particular country which they suppose the fairies to inhabit, called Fairy-land.

Spencer's Fairy Queen is an epic poem, under the persons and characters of fairies. In this sort of writing the poet loses sight of nature, and entertains the reader's imagination with the characters of fairies, witches, magicians, dæmons, and departed spirits. It requires an odd turn of thought, and a peculiar cast of fancy, with an imagination naturally fruitful and superstitious.

This sort of poetry raises a pleasing kind of horror in the mind of the reader, and amuses his imagination with the strangeness and novelty of the persons who are represented in it; but the judicious object to it, as not having probability enough to affect the imagination.

**FAIRY CIRCLE OR RING**, a phenomenon pretty frequent in the fields, &c. supposed by the vulgar to be traced by the fairies in their dances: there are two kinds of it, one of about seven yards in diameter, containing a round bare path, a foot broad, with green grass in the middle of it. The other is of different bigness, encompassed with a circumference of grass. Mess. Jessop and Walker, in the Philosophical Tranfact. 2-

scribe them to lightning, which is confirmed by their being most frequently produced after storms of that kind, as well as by the colour and brittleness of the grass roots, when first observed.

Lightning, like all other fires, moves round, and burns more in the extremity than in the middle: the second circle arises from the first, the grass burnt up growing very plentifully afterwards. Others maintain that these circles are made by ants, which are frequently found in great numbers therein.

**FAITH**, in divinity and philosophy, the firm belief of certain truths upon the testimony of the person who reveals them.

The grounds of a rational faith are, 1. That the things revealed be not contrary to, though they may be above natural reason. 2. That the revealer be well acquainted with the things he reveals. 3. That he be above all suspicion of deceiving us.

Where these criterions are found, no reasonable person will deny his assent: thus, we may as well doubt of our own existence, as of the truth of a revelation coming from God, who can neither be deceived himself, nor deceive others by proposing things to be believed that are contradictory to the faculties he has given us. Whatever propositions, therefore, are beyond reason, but not contrary to it, are, when revealed, the proper matter of faith.

*Confession of FAITH.* See **CONFESSION**.

**FAITHFUL**, an appellation assumed by the Mahometans. See **MAHOMETANS**.

**FAKENHAM**, a market-town of Norfolk, about sixteen miles north-west of Norwich.

**FAKIR**, in Pagan theology, a kind of Indian monks, who even outdo the mortifications and severities of the ancient Christian anachorets. See **ANACHORET**.

Some of them mangle their bodies with scourges and knives; others never lie down; and others remain all their lives in one posture.

There are also another kind of fakirs, who do not practise such severities: these flock together in companies, and go from village to village, prophesying and telling fortunes. It is said that even persons of fortune, in India, become fakirs, and that there are more than two millions of them.

**FALCADE**, in the menage, the motion of a horse when he throws himself upon his haunches two or three times, as in very quick corvets; which is done in forming a stop and half stop. See **STOP**.

**FALCATED**, something in the form of a sickle: thus, the moon is said to be falcated when she appears horned. See **MOON** and **PHASES**.

**FALCO**, in ornithology, a genus belonging to the order of accipitres, the characters of which are these: the beak is crooked, and furnished with wax at the base; the head is thick-set with feathers, and the tongue is cloven. There are thirty-two species, viz. 1. The coronatus, or crowned eagle of Edwards, with ash-coloured wax; the legs are covered with white downy feathers, interspersed with black spots; the breast is reddish; and there are black belts on the sides. It is a native of Guinea. 2. The melanæetus, or black

black eagle of Ray, has yellowish wax on the beak; the legs are half covered with feathers; and the body is ash-coloured and streaked with yellow. It is a native of Europe. 3. The leucocephalus, or white-headed eagle of Catesby, is ash-coloured, with the head and tail white; the iris of the eye is white, over which is a prominence covered with a yellow skin; the bill and the feet or wax are yellow, as are likewise the legs and feet; and the talons are black. Though it is an eagle of small size, it weighs nine pounds, is strong and full of spirit, preying on lambs, pigs, and fawns. They always make their nests near the sea, or great rivers, and usually upon old, dead pine or cypress trees, continuing to build annually on the same tree till it falls. Tho' he is so formidable to all birds; yet he suffers them to build near his royal nest without molestation; particularly the fishing hawk, herons, &c. which all build on high-trees, and in some places are so near one another that they appear like a rookery. It is a native both of Europe and America. *Pl. 76. fig. 1.* 4. The ossifragus, with yellow wax, and half-feathered legs; it is about the size of a peacock; the feathers are white at the base, iron-coloured in the middle, and black at the points; and the legs are yellow: it is a native of Europe. 5. The chrysaetos, or golden eagle, has yellow wax on the beak, and feathered legs; the body is variegated with a brown and iron colour; and the base of the tail is undulated with an ash-colour: it is a bird of Europe. 6. The fulvus, with yellow wax, feathered legs, a brown back, and a white streak on the tail; the face is bare betwixt the eyes and nostrils: it is a native of Europe and Canada. 7. The rusticolus, with a yellow wax, yellow ring round the eyes, and yellow legs; the body is ash-coloured undulated with white, and a white ring round the neck: it is a native of Sweden. 8. The barbarus, with yellow wax, and yellow legs; the body is blueish, and spotted with brown: it is a native of Barbary. 9. The cæruleus, with yellow wax, a yellow ring round the eyes, and the feet yellow underneath; the back is of a blackish blue colour; and the temples are surrounded with a white line. This is the smallest bird of the genus, and is a native of Asia. 10. The cyaneus, with white wax, yellow legs, a whitish blue body, and a white ring round the eyes and throat. It is the blue hawk of Edwards, and is a native of Europe and Africa. 11. The pygargus, with yellow wax and legs; the body is ash-coloured, with pale red spots along the belly, and white orbits. It is a bird of Europe. 12. The milvus, or kite, with yellow wax on the back, a forked tail, and iron-coloured bill, and the head of a lighter colour. It is a bird of Europe, Asia, and Africa. Bellonius relates, that, about the end of April, in less than fourteen days, incredible numbers of them are seen flying over the Black Sea into Asia. They feed upon offals, young-birds, &c. Like all the species of this genus, they fly remarkably high, and are endowed with uncommon acuteness of vision. 13. The gentilis, with yellow wax and legs; the body is ash-coloured, with brown spots; and the tail has four blackish streaks. It is a native of the Alps, and is peculiarly fond of larks. 14. The subbuteo, with yellow wax and legs; the back is brown, the nape of the neck white, and the belly is pale, with oblong brown spots. It is

called the hobby by English authors, and is a native of Europe. 15. The buteo, with yellowish wax and legs, a brown body, and a pale belly, with brown spots. He feeds upon rabbits, toads, &c. and is a bird of Europe. 16. The tinnunculus, with yellow wax and legs; the back is reddish, and spotted with black; it has brownish streaks on the breast, and a roundish tail. It inhabits old buildings, and lives upon small birds and mice. 17. The fuffator, with yellowish wax and legs; the body is of a brownish white colour; and the covers of the eyes are bony. He has a fleshy lobe between the nostrils, which, when angry or terrified, he inflates till his head becomes as large as his whole body. He is a native of Surinam. 18. The cachinnans, or laughing hawk, has yellowish legs and wax, and white eye-brows; the body is variegated with brown and white; and it has a black ring round the top of the head. It makes a laughing kind of noise when it observes any person, and is a native of America. 19. The hudsonius, has yellow wax, and yellow legs, a brown back, and white eye-brows. It is found at Hudson's bay. 20. The sparverius, has yellow wax, a brown head, a red belly, and blueish wings. It is a native of America. 21. The columbarius, or pigeon-hawk of Catesby, weighs about six ounces. The bill is black at the point, and whitish at the base; the iris of the eye is yellow; the base of the upper mandible is covered with a yellow fear or wax; all the upper part of the body, wings, and tail, are brown. The interior vanes of the quill-feathers have large red spots. The tail is marked with four regular transverse white lines; the throat, breast, and belly are white, mixed with brown; the small feathers that cover the thighs reach within half an inch of the feet, and are white, with a tincture of red, beset with long spots of brown; the legs and feet are yellow. It is a very swift and bold hawk, preying on pigeons, young turkeys, &c. and is a native of Carolina. *Pl. 76. fig. 3.* 22. The superciliosus has yellow legs and wax, and yellow eye-brows; and the body is brown, waved with white. It is a native of Surinam. 23. The vespertinus, is about the size of a pigeon; the body is of a blueish brown colour; and the bill is yellow, and brown at the point. It is a native of Ingria, and flies both in the day and in the night. 24. The lanarius, has yellowish wax, and the bill and legs, which are short, are blueish. It is a native of Europe. 25. The furcatus, or swallow-tailed hawk, weighs about 14 ounces; the bill is black; the eyes are large and black, with a red iris; the head, neck, breast, and belly are white; the upper part of the back and wings a dark purple; but more dusky towards the lower parts, with a tincture of green. The wings are long in proportion to the body, and, when extended, are four feet. The tail is dark purple mixed with green, and remarkably forked. Like swallows, they continue long on the wing, catching, as they fly, beetles, flies, and other insects. They are said to prey upon lizards and serpents, and are found in America. *Pl. 76. fig. 2.* 26. haliaetus, or fishing hawk of Catesby, weighs three pounds and a quarter; it measures, from one end of the wing to the other, five feet and a half. The bill is black, with a blue fear or wax; the iris of the eye is yellow, and the crown of the head brown, with a mixture of white feathers; from each eye, backwards, runs a brown stripe: the

*A Bell Group*

the back, wings, and tail, are of a dark brown; the throat, neck, and belly white; the legs and feet are rough and scaly, and of a pale blue colour; the talons are black, and nearly of an equal size; the feathers of the thighs are short, and adhere close to them, contrary to others of the hawk-kind, which nature seems to have designed for their more easy penetrating the water. Their manner of fishing is, after hovering a while over the water, to precipitate into it with prodigious swiftness, where they remain for some minutes, and seldom rise without a fish. The white-headed eagle, who is generally on the watch, no sooner spies him with his fish, than he flies furiously upon him: the hawk immediately mounts, and screams out; but the eagle always soars above him, and compels him to let the fish fall; the eagle instantly darts down upon the fish, and seldom fails to catch it before it reaches the water. It is remarkable, that, whenever the hawk catches a fish, he calls out, as if it were to give warning to his enemy the eagle, who always obeys the call when within hearing. The lower parts of the rivers and creeks near the sea in America, abound with those eagles and hawks, where these diverting contests are frequently seen. *Pl. 77. fig. 1. 27.* The gyrfalco, with blue wax on the beak, yellow legs, a brown body, marked with ash-coloured streaks underneath, and the sides of the tail white. It is the gyrfalco of Ray, lives upon cranes, pigeons, &c. and is a native of Europe. 28. The aviporus, with black wax, yellow legs, half naked, the head of an ash-colour, and having an ash-coloured stripe on the tail, which is white at the end. It is the honey-buzzard of Ray, and is a native of Europe; it feeds upon mice, lizards, frogs, bees, and other insects. 29. The æruginosus, with greenish wax, a greyish body; and the top of the head, nape of the neck, and legs, are yellowish. It is a native of Europe, and builds its nest in marshes. 30. The palumbarius, with black wax edged with yellow, yellow legs, a brown body, and the prime feathers of the tail are marked with pale streaks, and the eye-brows are white. It is the goose-hawk of Ray, is an inhabitant of Europe, and an enemy to domestic fowls. 31. The nisus, with green wax, yellow legs, and a white belly undulated with grey; the tail is marked with blackish belts. It is the sparrow-hawk of Ray, and a native of Europe. It is peculiarly fond of pigeons, sparrows, and larks. 32. The minutus, with brown wax, yellow legs, and the body is white underneath. It is the least hawk of Brissonius, being about the size of a thrush, and is found at Melita.

**FALCONER**, one who tames, manages, and looks after falcons, or other hawks. See the next article.

**FALCONRY**, the art of training all manner of hawks, but more especially the larger sort, to the exercise of hawking. See **HAWKING**.

When a falcon is taken, she must be seel'd in such a manner, that as the seeling slackens, she may see what provision lies before her; but care ought to be taken, not to seel her too hard. A falcon or hawk newly taken, should have all new furniture, as new jesses of good leather, mailed leashes with buttons at the end, and new bewets. There should also be provided a small round stick, to stroke the hawk; because the oftener

VOL. II. No 49.

†

this is done, the sooner and better will she be manned. She must also have two good bells, that she may be found when she scattereth. Her hood should be well fashioned, raised and embossed against her eyes, deep, and yet strait enough beneath, that it may fallen about her head without hurting her; and her beak and talons must be a little copied, but not so near as to make them bleed.

**FALKIRK**, a town of Scotland: W. long.  $3^{\circ} 48'$ , N. lat.  $56^{\circ} 20'$ .

**FALL**, the descent of a heavy body towards the center of the earth; it is also the name of a measure of length used in Scotland, containing six ells.

**FALLACY**, a deception, fraud, or false appearance.

The Epicureans deny that there is any such thing as a fallacy of the senses: for, according to them, all our sensations and perceptions, both of sense and phantasy, are true: whence they make sense the primary criterion of truth.

**FALLING-SICKNESS**. See **MEDICINE**.

**FALLOPIAN TUBES**. See **ANATOMY**, p. 275.

**FALLOW**, a pale red colour, like that of brick half burnt: such is that of a fallow-deer.

**FALLOW-FIELD**, or **FALLOW GROUND**, land laid up, or that has lain untill'd for a considerable time.

**FALLOWING of land**, a particular method of improving land. See **AGRICULTURE**.

**FALMOUTH**, a port-town of Cornwall, in England, situated in W. long.  $5^{\circ} 30'$ , N. lat.  $50^{\circ} 15'$ , on a fine bay of the English channel, the entrance whereof is guarded by two forts.

**FALSE**, in general, something contrary to truth, or not what it ought to be; thus we say, a false witness, false action, false weights, false claim, &c.

**FALSHOOD**, in philosophy, is the representing a thing otherwise than it is.

**Crimen falsi**, in the civil law, is fraudulent subornation or concealment with design to darken or hide the truth, and make things appear otherwise than they are. The crimen falsi is committed, 1. By words, as when a witness swears falsely. 2. By writing, as when a man antedates a contract, or the like. 3. By deed, as when he sells by false weights and measures.

**FALX**, in anatomy. See **ANATOMY**, p. 284.

**FAN**, a machine used to raise wind and cool the air by agitating it. The custom which now prevails of wearing fans, was borrowed from the East, where they are almost indispensably necessary for keeping off the sun and the flies. Fans are made of a thin skin or piece of paper, taffaty, or other light stuff, cut semicircularly, and mounted on several little sticks of wood, ivory, tortoise-shell, or the like. The paper, &c. is usually painted, and in mounting is plaited in such a manner, as that the plaits may be alternately inward and outward.

**FAN** is also an instrument used in winnowing corn.

Fans for corn pay on importation, 1 s. 3  $\frac{4}{10}$  d. and draws-back on exportation, 1 s. 1  $\frac{3}{10}$  d. India fans pay for every 100 l. gross value at the sale 26 l. 14 s. 2  $\frac{5}{10}$  d.

The draw-back on exportation is 25 l. 2 s. 11  $\frac{1}{10}$  d.

5 U

FA-

**FANATICS**, wild, enthusiastic, visionary persons, who pretend to revelation and inspiration.

**FANCY**, or **IMAGINATION**. See **IMAGINATION**.

**FANIONS**, in the military art, small flags carried along with the baggage.

**FANO**, a bishop's see and port-town of Italy, situated on the gulph of Venice, in 14° E. long. and 44° N. lat.

**FAR**, in horsemanship, an appellation given to any part of a horse's right side: thus the far foot, far shoulder, &c. is the same with the right foot, right shoulder, &c.

**FARCE**, was originally a droll or petty shew exhibited by mountebanks and their buffoons in the open streets, to gather the people together. At present it is of more dignity: it is removed from the street to the theatre, and instead of being performed by merry-andrews to amuse the rabble, is acted by comedians, and become the entertainment of a polite audience. Poets have reformed the wildness of the primitive farces, and brought them to the taste and manner of comedy. The difference between the two on our stage is, that comedy keeps to nature and probability, and therefore is confined to certain laws prescribed by ancient critics; whereas farce disallows of all laws, or rather sets them aside on occasion. Its end is purely to make merry; and it sticks at nothing which may contribute thereto, however wild and extravagant. Hence the dialogue is usually low, the persons of inferior rank, the fable or action trivial or ridiculous, and nature and truth every where heightened and exaggerated to afford the more palpable ridicule.

**FARCIN**, **FARCY**, or **FASIONS**, in farriery, a creeping ulcer, and the most loathsome, stinking, and filthy disease that a horse can be affected with.

For the cure, first bleed the horse well; then take oil of bay and euphorbium mixed together, and anoint the knots with it; or bathe the place with the stale of

an ox or cow, and the herb called lion's foot, all boiled together. Some apply tallow and horse-dung, burn the knots with a hot iron, or wash the sore with salt, vinegar, alum, verdigrease, green copperas, and gun-powder, boiled in chamber-lee. Others again anoint the sores with a salve made of a penny-worth of tar, two penny worth of white mercury, and two handfuls of pigeon's dung.

**FARDING-DEAL**, the fourth part of an acre of land. See **ACRE**.

**FARE**, most commonly signifies the money paid for a voyage, or passage by water; but, in London, it is what persons pay for being conveyed from one part of the town to another in a coach or chair.

**FAREHAM**, a market town of Hampshire, ten miles east of Southampton.

**FAREWELL CAPE**, the most southerly promontory of Greenland, in 50° W. long. and 60° N. lat.

**FARINA FOECUNDANS**, among botanists, the supposed impregnating meal or dust on the apices or anthers of flowers. See **BOTANY**, Sect. III.

**FARINGTON**, a market town of Berkshire, twenty-five miles north-west of Reading.

**FARM**, or **FERM**, signifies the chief messuage in a village; or any large messuage, whereto belongs land, meadow, pasture, wood, common, &c. and which has been used to let for term of life or years, under a certain yearly rent payable by the tenant for the same.

**FARNHAM**, a market-town in the county of Surry, ten miles west of Guilford, remarkable for its large plantations of hops.

**FARO**, a sea-port town of Portugal, in the province of Algarva: W. long. 9°, N. lat. 36° 50'.

**FARREATION**, in antiquity. See **CONFARREATION**.

**FARRIER**, one whose employment is to shoe horses, and cure them when diseased or lame.

## F A R R I E R Y.

**FARRIERY**, the art of curing the diseases of horses. The practice of this useful art has been hitherto almost entirely confined to a set of men who are totally ignorant of anatomy, and the general principles of medicine. It is not therefore surprising, that their prescriptions should be equally absurd as the reasons they give for administering them. It cannot indeed be expected that farriers, who are almost universally illiterate men, should make any real progress in their profession. They prescribe draughts, they rowel, cauterise, &c. without being able to give any other reason for their practice, but because their fathers did so before them. How can such men deduce the cause of a disease from its symptoms, or form a rational method of cure, when they are equally ignorant of the causes of diseases and the operation of medicines?

The miserable state of this useful art, especially in this country, has determined us to select, from the best authors, such a system of practice as seemed to be formed on rational principles; this, we hope, will be a sufficient apology for being so full upon this article.

### *General Directions with regard to the Management of Horses.*

It ought to be laid down as a general rule, to give horses as few medicines as possible; and by no means to comply with the ridiculous custom of some, who are frequently bleeding, purging, and giving balls, though their horses be in perfect health, and have no indication that requires such treatment.

Proper management in their feeding, exercise, and dressing, will alone cure many disorders, and prevent most;

most; for the simplicity of a horse's diet, which chiefly consists of grain and herbage, when good in kind, and dispensed with judgment, secures him from those complicated disorders, which are the general effects of intemperance in the human body.

In France, Germany, and Denmark, horses are seldom purged; there they depend much on alteratives; the use of the liver of antimony, we have from the French, which is in general a good medicine for that purpose, and may, in many cases, be substituted in the room of purging.

As hay is so material an article in a horse's diet, great care should be taken to procure the best: when it is not extraordinary, the dust should be well shook out before it is put in the rack; for such hay is very apt to breed vermin.

Beans afford the strongest nourishment of all grain, but are fittest for laborious horses; except on particular occasions. In some seasons they breed a kind of vermin called the red bugs, which is thought to be dangerous; the best method in such a case, is to procure them well dried and split.

Bran scalded is a kind of panada to a sick horse; but nothing is worse than a too frequent use of it, either dry or scalded; for it relaxes and weakens the bowels too much. The bots in young horses may be owing to too much musty bran and chaff, given with other foul feed to make them up for sale: particular care therefore should be taken that the bran be always sweet and new.

Oats, well ripened, make a more hearty and durable diet than barley, and are much better suited to the constitutions of British horses. A proper quantity of cut straw and hay mixed with them, is sometimes very useful to horses troubled with bots, indigestion, &c.

Horses who eat their litter, should particularly have cut straw and powdered chalk given them with their feed; as it is a sign of a depraved stomach, which wants correcting.

The salt-marshes are good pasture for horses who have been surfeited, and indeed for many other disorders; they purge more by dung and urine than any other pasture, and make afterwards a firmer flesh: their water is for the most part brackish, and of course, as well as the the grass, saturated with salts from the sea-water.

A summer's grass is often necessary; more particularly to horses glutted with food, and which use little exercise; but a month or two's running is proper for most: those especially who have been worked hard, and have stiff limbs, swelled legs, or wind-galls. Horses whose feet have been impaired by quitters, bad shoeing, or any other accidents, are also best repaired at grass. Those lamenesses particularly require turning out to grass, where the muscles or tendons are contracted or shrunk; for by the continual gentle exercise in the field, with the assistance of a patten shoe on the opposite foot, the shortened limb is kept on the stretch, the wasted parts are restored to their usual dimensions, and the limb again recovers its usual tone and strength.

The fields which lie near great towns, and are much dunged, are not proper pasture for horses; but on observation appear very injurious to them, if they feed thereon all the summer.

Horses may be kept abroad all the year, where they have a proper stable or shed, to shelter them from the weather, and hay at all times to come to. So treated, they are seldom sick, their limbs are always clean and dry; and, with the allowance of corn, will hunt, and do more business than horses kept constantly within doors.

If horses, when taken from grass, should grow hot and colicive, mix bran and chopt hay with their corn; and give them sometimes a feed of scalded bran for a fortnight, or longer: let their exercise and diet be moderate for some time, and increase both by degrees.

When horses are soiled in the stable, care should be taken that the herbage is young, tender, and full of sap; whether it be green barley, tares, clover, or any thing else the season produces, and that it be cut fresh once every day at least, if not oftener.

When horses lose their flesh much in soiling, they should in time be taken to a more solid diet; for it is not in soiling as in grazing; where, though a horse loses his flesh at first, yet, after the grass has purged him, he soon grows fat.

Young horses who have not done growing, must be indulged more in their feeding, than those come to their maturity; but if their exercise is so little, as to make it necessary to abridge their allowance of hay, a little fresh straw should constantly be put in their racks, to prevent their nibbling the manger, and turning cribbiters; they should also sometimes be strapped back in order to cure them of this habit.

It is obvious to every one, what care should be taken of a horse after violent exercise, that he cools not too fast, and drinks no cold water, &c. for which reason we shall wave particular directions,

Most horses fed for sale, have the interstices of their muscles so filled with fat, that their true shapes are hardly known. For which reason, a horse just come out of the dealer's hands, should at first be gently used. He ought to lose blood, and have his diet lowered, though not too much: walking exercise is most proper at first, two hours in a day; in a week or fortnight two hours at a time, twice a-day; after this usage for a month bleed him again, and give him two or three times a-week scalded bran, which will prepare him for purging physic, that may now be given safely, and repeated at the usual intervals.

When a horse comes out of a dealer's hands, his cloathing must be abated by degrees, and care taken to put him in a moderately warm stable; otherwise the sudden transition would be attended with the worst consequences.

#### *Some General Directions in regard to Bleeding, Purging, &c.*

Horses who stand much in stable, and are full fed, require bleeding now and then, especially when their eyes look heavy, dull, red, and inflamed; as also, when they feel hotter than usual, and mangle their hay.

Young horses should be bled when they are shedding their teeth, as it takes off those feverish heats they are then subject to. But the cases that chiefly require bleeding are colds, fevers of most kinds, falls, bruises, hurts of the eyes, strains, and all inflammatory disorders, &c.

It is right to bleed a horse, when he begins to grow fleshy

fleshy at grafts, or at any other time when he looks heavy: and it is generally proper to bleed before purging.

Let your horse always be bled by measure, that you may know what quantity you take away: two or three quarts is always enough at one time; when you repeat it, allow for the disorder, and the horse's constitution.

Let the blood, when cold, be carefully examined, both as to colour and consistence, whether black, florid, fizy, &c.

Purging is often necessary in gross full horses, in some disorders of the stomach, liver, &c. but should be directed with caution. Before a purge is given to any horse, it is necessary some preparation should be made for it, in order to render the operation more safe and efficacious; thus a horse that is full of flesh should first be bled, and at the same time have his diet lowered for a week, especially those that have been pampered for sale; several mashies of scalded bran should also previously be given, in order to open the bowels, and unload them of any indurated excrement; which sometimes proves an obstacle to the working of the physic, by creating great sickness and griping.

Let it be remembered, that a horse is purged with difficulty; that the physic generally lies twenty-four hours in the guts before it works; and, that the tract of bowels it has to pass through, is above thirty yards; and lying horizontally, consequently resinous and other improper drugs may, and often do, by their violent irritations, occasion excessive gripings and cold sweats, shave off the very mucus or lining of the guts, and bring on inflammations, which often terminate in mortifications, and death.

It is remarkable too, that the stomach and guts of a horse are but thin, compared to some other animals of the same bulk, and therefore must be more liable to inflammation and irritation.

Horses kept much in the stable, who have not the proper benefit of air, and exercise, in proportion to their food, should in spring have a mild purge or two, after a previous preparation by bleeding, lowering their diet, and scalded mashies.

Horses that fall off in their stomach, whether it proceeds from too full feeding, or ingendering crudities and indigested matter, should have a mild purge or two.

Horses of a hot temperament, will not bear the common aloetic purges; their physic therefore should be mild and cooling.

Purging is always found very beneficial in stubborn dry coughs: but mild mercurials joined with them, make them yet more efficacious.

Horses of a watery constitution, who are subject to swelled legs, that run a sharp briny ichor, cannot have the causes removed any way so effectually as by purging.

The first purge you give to a horse should be mild, in order to know his constitution.

It is a mistaken notion, that if a proper prepared purge does not work to expectation, the horse will be injured by it; for though it does not pass by stool, its operation may be more efficacious, as an alterative to purify the blood, and it may pass by urine, or other secretions.

Purging medicines are very successfully given in small

quantities, mixed with others; and at then as alteratives.

If mercurial physic is given, care should be taken that it be well prepared; and warmer cloathing, and greater circumspection is then required.

Purges should be given early in the morning upon an empty stomach: about three or four hours after the horse has taken it, he should have a feed of scalded bran; and a lock or two of hay may then be put into his rack. The same day give him two more mashies; but should he refuse warm meat, he may be allowed raw bran.

All his water should be milk warm, and have a handful of bran squeezed in it; but if he refuses to drink white water, give it him without bran.

Early the next morning, give him another mash; but if he refuses to eat it, give him as much warm water as he will drink: let him be properly clothed, and rode gently about. This should be done two or three times a day, unless he purges violently, once or twice will then be sufficient: at night give him a feed of oats mixed with bran.

During the working, a horse should drink plentifully; but, if he will not drink warm water, he must be indulged with cold, rather than not drink at all.

We shall here insert some general forms of purges,

**TAKE** succotrine aloes ten drams, jallap and salt of tartar each two drams, grated ginger one dram, oil of cloves thirty drops; make them into a ball with syrup of buckthorn.

Or,

**TAKE** aloes and cream of tartar each one ounce, jallap two drams, cloves powdered one dram, syrup of buckthorn a sufficient quantity.

Or,

The following, which has an established character among sportsmen.

**TAKE** aloes, from ten drams to an ounce and an half, myrrh and ginger powdered each half an ounce, saffron and oil of anniseed each half a dram.

Mr Gibbon recommends the following,

**TAKE** succotrine aloes ten drams, myrrh finely powdered half an ounce, saffron and fresh jallapin powder of each a dram, make them into a stiff ball with syrup of roses, then add a small spoonful of rectified oil of amber.

The succotrine aloes should always be preferred to the Barbadoes or plantation aloes; though the latter may be given to robust strong horses, but even then should always be prepared with the salt, or cream of tartar; which by opening its parts, prevents its adhesion to the coats of the stomach, and bowels; from whence horrid gripings, and even death itself has often ensued. This caution is well worth remarking, as many a horse hath fallen a sacrifice to the neglect of it.

Half an ounce of Castile soap, to a horse of a gross constitution, may be added to any of the above; and the proportions may be increased for strong horses.

When mercurial physic is intended, give two drams of calomel over night, mixed up with half an ounce of a diapente and a little honey, and the purging ball the next morning.

The

The following, when it can be afforded, is a very gentle and effectual purge, particularly for fine delicate horses; and if prepared with the Indian rhubarb, will not be expensive.

**Take** of the finest succotrine aloes one ounce, rhubarb powdered half an ounce or six drams, ginger grated one dram; make into a ball with syrup of roses.

The following purging drink may be given with the utmost safety; it may be quickened, or made stronger, by adding an ounce more fenna, or two drams of jalap.

**Take** fenna two ounces, infuse it in a pint of boiling water two hours, with three drams of salt of tartar; pour off, and dissolve in it four ounces of Glauber's salts, and two or three of cream of tartar.

This last physic is cooling, easy, and quick in its operation; and greatly preferable in all inflammatory cases to any other purge, as it passes into the blood, and operates also by urine.

When horses lose their appetites after purging, it is necessary to give them a warm stomach-drink, made of an infusion of chamomile flowers, anniseeds and saffron: or the cordial ball may be given for that purpose.

Should the purging continue too long, give an ounce of discordium in an English pint of Port wine, and repeat it once in twelve hours, if the purging continues. Plenty of gum arabic water should also be given; and in case of violent gripes, fat broth glysters, or tripe liquor, should be often thrown up, with an hundred drops of laudanum in each.

The arabic solution may be thus prepared.

**Take** of gum arabic and tragacanth of each four ounces, juniper-berries and caraway-seeds of each an ounce, cloves bruised half an ounce; simmer gently in a gallon of water, till the gums are dissolved: give a quart at a time in half a pail of water; but if he will not take it freely this way, give it him often in a horn.

When a purge does not work, but makes the horse swell, and refuse his food and water, which is sometimes the effect of bad drugs, or catching cold, warm diuretics are the only remedy; of which the following are recommended.

**Take** a pint of white wine, nitre one ounce; mix with it a dram of camphire, dissolved in a little rectified spirit of wine; then add two drams of oil of juniper, and the same quantity of unrectified oil of amber, and four ounces of honey, or syrup of marshmallows.

When a horse swells much with physic, do not suffer him to be rode about till he has some vent; but rather lead him gently in hand, till some evacuation is obtained.

As it is observed, that horses more willingly take sweet and palatable things, than those that are bitter and of an ill taste; care should be taken, that the latter are given in balls; and that their drinks are always contrived to be as little nauseous as possible, and sweetened either with honey or liquorice. Those that are prepared with gross powders, are by no means so agreeable to a horse, as those made by infusion; as the former often clam the mouth, irritate the membranes about the palate and throat, and

frequently occasion the cough they are intended to prevent.

Balls should be of an oval shape, and not exceed the size of a pullet's egg; when the dose is larger, it should be divided into two; and they should be dipt in oil, to make them slip down the easier.

As we have given some general forms of purges, we shall observe the same rule in regard to glysters, with some few cautions and remarks.

Let it be observed then, that, before the administering emollient clysters in costive disorders, a small-hand, well oiled, should be passed up the horse's fundament, in order to bring away any hardened dung, which otherwise would be an obstacle to the glyster's passage.

A bag and pipe of a proper form, is to be preferred to a syringe, which throws up the glyster with so much force, that it often surprises a horse, and makes him reject it as fast as it goes in; whereas the liquor, when pressed gently from the bag, gives him no surprize or uneasiness, but passes easily up into the bowels, where it will sometimes remain a long time, and be extremely useful, by cooling and relaxing them; and will sometimes incorporate so with the dung, as not easily to be distinguished from the other contents of the guts. These emollient glysters are extremely serviceable in most fevers, and greatly preferable to purging ones; which in general are too pungent, and stimulate too much, especially if aloes are a part of the composition.

Nutritive glysters are very necessary, and often save a horse from starving, when his jaws are so locked up by convulsions that nothing can be conveyed by the mouth.

They should not exceed a quart or three pints at a time, but be often repeated: nor should they be too fat; but made of sheeps heads, trotters, or any other meat-broths, milk pottage, rice-milk strained, and many other such nourishing things. For an emollient glyster, take the following.

**Take** marshmallows and chamomile flowers each a large handful, bay-berries and sweet fennel-seeds bruised each an ounce; boil in a gallon of water to three quarts, pour off into a pan, and dissolve in it half a pound of treacle, and a pint of lint-seed oil, or any common oil.

To make it more laxative, add four ounces of lenitive electuary, or the same quantity of cream of tartar, or common purging salts.

#### *Purging Glyster.*

**Take** two or three handful of marshmallows, fenna one ounce, bitter apple half an ounce, bay berries and anniseed bruised each an ounce, salt of tartar half an ounce; boil a quarter of an hour in three quarts of water; pour off, and add four ounces of syrup of buckthorn, and half a pint of oil.

This glyster will purge a horse pretty briskly; and may be given successfully, when an immediate discharge is wanting; especially in some fevers with inflamed lungs, or other disorders, which require speedy relief.

But it is necessary to caution against a solution of course aloes for this purpose, as it has been found to gripe horses violently, and excite feverish, and sometimes convulsive

convulsive symptoms; and indeed all pungent and stimulating medicines, as the stronger purgatives generally are, should be given in this form with great caution.

But the generality of emollient glysters, may be prepared with much less trouble: as two quarts of water-gruel, with a half a pound of treacle, a pint of oil, and a handful of common salt, will as effectually answer every purpose. The following is a restraining glyster.

TAKE pomegranate-bark or oak-bark two ounces, red rose-leaves fresh or dry a handful, balauftines an ounce; boil in two quarts of water, till one is near consumed; pour off and dissolve in it four ounces of diascordium; to which may be added a pint of Port wine.

This will answer in all common cases, where restraints are necessary, but should never be given in larger quantities; for the longer glysters of this kind lie in the bowels, the more efficacious they are.

#### *Of Colds.*

By taking cold, we mean that the pores and outlets of the skin (which in a natural healthy state of body are continually breathing out a fine fluid, like the steam arising from hot water, or smoke from fire) are so far shut up, that these streams, or perspirable matter, not having a free passage through them, are hindered from going off in the usual manner; the consequence of which is, their recoiling on the blood, vitiating its quality, overfilling the vessels, and affecting the head, glands or kernels of the neck and throat, the lungs, and other principal parts.

To enumerate the various causes of colds would be endless; the most usual are, riding horses till they are hot, and suffering them to stand in that condition where the air is cold and piercing; removing a horse from a hot stable to a cold one, and too suddenly changing his cloathing; hence it is, that horses often catch such severe colds, after they come out of dealers hands; and by not being carefully rubbed down, when they come in hot, off journeys.

The signs of a horse's catching cold, are a cough, heaviness and dullness, which affect him more or less in proportion to the severity of it: the eyes are sometimes moist and watery, the kernels about the ears and under the jaws swell, the nose gleets, and he rattles in his breathing; and when the cold is violent, the horse will be feverish, his flanks work, and he will both loath his hot meat and refuse his water. When these last symptoms are attended with a slimy mouth, ears, and feet cold, and a great inward soreness, there is danger of a bad fever.

But when the horse coughs strong, snorts after it, is but little off his stomach, pricks up his ears, and moves briskly in his stall, dungs and stales freely, his skin feels kindly, and his coat does not stare, he is in no danger, and there will be no occasion for medicines of any kind: but you should bleed him about two quarts, keep him warm, and give him feeds of scalded bran, with as much warm water as he will drink, in order to dilute his blood.

If the disorder should increase, the horse feel hot, and

refuse his meat, bleed him, if strong, two quarts more; and if you are not satisfied, without giving medicines, avoid, as you would poison, a farrier's drench; (which is generally composed of some hot, nauseous powders, given in a quantity of ale; which too often increases the fever, by overheating the blood, and palls the horse's stomach by its loathsomeness;) and instead of it, infuse two ounces of anniseeds, with a dram of saffron, in a pint and a half of boiling water; pour off the clear, and dissolve in it four ounces of honey; to which may be added four spoonfuls of salad oil: this drink may be given every night; or one of the following balls, provided there is no fever; in which case, it always will be more eligible to give two or three ounces of nitre or salt prunella every day in his feeds, or water, till it is removed; but should the horse be inclined to costiveness, remember that his body should be kept open by emollient glysters, or cream of tartar dissolved in his water, to the quantity of three or four ounces a-day.

#### *Pectoral Horse-ball.*

TAKE of the fresh powders of anniseed, clicampane, caraway, liquorice, turmeric, and flour of brimstone, each three ounces; juice of liquorice four ounces, dissolved in a sufficient quantity of mountain; saffron powdered half an ounce, salad oil and honey half a pound, oil of anniseed one ounce: mix together with wheat flour enough to make them into a paste.

Or, the following from Dr BRACKEN.

TAKE anniseed, caraway seed, and greater cardamoms, finely powdered, of each one ounce, flour of brimstone two ounces, turmeric in fine powder one ounce and a half, saffron two grams, Spanish juice dissolved in water two ounces, oil of anniseed half an ounce, liquorice powder one ounce and a half, wheat flower a sufficient quantity to make into a stiff paste, by beating all the ingredients well in a mortar.

These balls consist of warm opening ingredients; and, given in small quantities, about the size of a pullet's egg, will encourage a free perspiration; but in case of a fever, should be cautiously continued. They are much more efficacious, and in all cases superior to the farrier's drenches, if dissolved in a pint of warm ale.

This simple method, with good nursing and hot mashes, warm water and cloathing, especially about the head and throat, which promotes the running at the nostrils, will answer the most sudden colds; and when the horse feeds heartily, and snorts after coughing, moderate exercise every day will hasten his recovery.

To a horse loaded with flesh, a rowel may sometimes be necessary, as may also a gentle purge or two, to some, when the distemper is gone off.

#### *Of Fevers in general.*

The symptoms of a fever are great restlessness, the horse ranging from one end of his rack to the other; his flanks beat; his eyes are red and inflamed; his tongue parched and dry; his breath is hot, and smells strong; he

he loses his appetite, and nibbles his hay, but does not chew it, and is frequently snelling to the ground; the whole body is hotter than ordinary, (though not parched, as in some inflammatory disorders;) he dungs often, little at a time, usually hard, and in small bits; he sometimes stales with difficulty, and his urine is high-coloured; his flanks beat; and he seems to thirst, but drinks little at a time, and often; his pulse beats full and hard, to fifty strokes and upwards in a minute.

The first intention of cure is bleeding, to the quantity of two or three quarts, if the horse is strong and in good condition; then give him a pint of the following drink, four times a-day; or an ounce of nitre, mixed up into a ball with honey, may be given thrice a-day, instead of the drink, and washed down with three or four horns of any small liquor.

TAKE of baum, sage and chamomile flowers, each a handful, liquorice root sliced half an ounce, salt prunel or nitre three ounces; infuse in two quarts of boiling water; when cold, strain off, and squeeze into it the juice of two or three lemons, and sweeten with honey.

As the chief ingredient to be depended on in this drink is the nitre; it may perhaps be as well given in water alone; but as a horse's stomach is soon palled, and he requires palatable medicines, the other ingredients may in that respect have their use. Soleysel for this purpose advises two ounces of salt of tartar, and one of sal armoniac to be dissolved in two quarts of water, and mixed with a pail of common water, adding a handful of bran or barley-flour to qualify the unpleasant taste: this may be given every day, and is a useful medicine.

His diet should be scalded bran, given in small quantities; which, if he refuses, let him have dry bran sprinkled with water; put a handful of picked hay into the rack, which a horse will often eat, when he will touch nothing else; his water need not be much warmed, but should be given often, and in small quantities: his cloathing should be moderate; too much heat and weight on a horse being improper in a fever; which scarce ever goes off in critical sweats (as those in the human body terminate) but by strong perspiration.

If in a day or two he begins to eat his bran, and pick a little hay; this method with good nursing will answer: but if he refuses to feed, more blood should be taken away, and the drinks continued; to which may be added two or three drams of saffron, avoiding at this time all hotter medicines: the following glyster should be given, which may be repeated every day, especially if his dung is knotty or dry.

TAKE two handfuls of marshmallows, and one of chamomile flowers; fennel seed an ounce; boil in three quarts of water to two; strain off, and add four ounces of treacle, and a pint of linseed oil, or any common oil.

Two quarts of water-gruel, fat broth, or pot-liquor, with the treacle and oil, will answer this purpose; to which may be added a handful of salt. These sort of glysters are properer than those with purging ingredients.

The following opening drink is very effectual in these

fevers, and may be given every other day, when the glysters should be omitted; but the nitre balls or drink may be continued, except on those days these are taken.

TAKE of cream of tartar and Glauber's salts, each four ounces; dissolve in barley water, or any other liquor: an ounce or two of lenitive electuary may be added, or a dram or two of powder of jallap, to quicken the operation in some horses.

Four ounces of Glauber's salts, or cream of tartar, with the same quantity of lenitive electuary, may be given for the same purpose, if the former should not open the body sufficiently.

In four or five days the horse generally begins to pick his hay, and has a seeming relish to food; though his flanks will heave pretty much for a fortnight: yet the temper of his body and return of appetite shew, that nothing more is requisite to complete his recovery, than walking him abroad in the air, and allowing plenty of clean litter to rest him in the stable.

This method of treating a fever is simple, according to the laws of nature; and is confirmed by long experience, to be infinitely preferable to the hot method.

The intention here is to lessen the quantity of blood; promote the secretion of urine and perspiration, and cool and dilute the fluids in general.

There is another sort of fever that horses are subject to, of a more complicate and irregular nature than the former; which if not properly treated, often proves fatal.

The signs are a slow fever with languishing, and great depressions; the horse is sometimes inwardly hot, and outwardly cold; at other times hot all over, but not to any extreme; his eyes look moist and languid; he has a continual moisture in his mouth, which is the reason he seldom cares to drink, and when he does it is but little at a time. He feeds but little, and leaves off as soon as he has eat a mouthful or two; he moves his jaws in a feeble, loose manner, with an unpleasant grating of his teeth; his body is commonly open; his dung soft and moist, but seldom greasy; his staling is often irregular, sometimes little, at other times profuse, seldom high-coloured, but rather pale, with little or no sediment.

When a horse's appetite declines daily, till he refuses all meat, it is a bad sign. When the fever doth not diminish, or keep at a stand, but increases, the case is then dangerous. But when it sensibly abates, and his mouth grows drier, the grating of his teeth ceases, his appetite mends, and he takes to lay down (which perhaps he has not done for a fortnight) these are promising signs. A horse in these fevers always runs at the nose, but not the kindly white discharge, as in the breaking of a cold, but of a reddish or greenish dusky colour, and of a consistence like glue, and sticks like turpentine to the hair on the inside of the nostrils: If this turns to a gleet of clear thin water, the horse's hide keeps open, and he mends in his appetite; these are certain signs of recovery.

The various and irregular symptoms that attend this slow fever, require great skill to direct the cure, and more knowledge of the symptoms of horses diseases, than the generality of gentlemen are acquainted with. The experienced

perienced farrier should therefore be consulted and attended to, in regard to the symptoms; but very seldom as to the application of the remedy, which is generally above their comprehension; though it may be readily selected, by duly attending to the observations here inculcated.

First then, a moderate quantity of blood, not exceeding three pints, may be taken away, and repeated in proportion to his strength, fullness, inward soreness, cough, or any tendency to inflammation. After this, the fever-drink, (p. 457. col. 1. parag. 3.) may be given, with the addition of an ounce of snake-root, and three drams of saffron and camphor dissolved first in a little spirit of wine; the quantity of the nitre may be lessened, and these increased, as the symptoms indicate.

The diet should be regular; no oats given, but scalded, or raw bran sprinkled; the best flavoured hay should be given by handfuls, and often by hand, as the horse sometimes cannot lift up his head to the rack.

As drinking is so absolutely necessary to dilute the blood, if the horse refuses to drink freely of warm water or gruel, he must be indulged with having the chill only taken off, by standing in the stable; nor will any inconvenience ensue, but oftener an advantage; for the nauseous warmth of water, forced on horses for a time, palsies their stomachs, and takes away their appetites, which the cold water generally restores.

Should the fever after this treatment increase, the horse feed little, stale often, his urine being thin and pale, and his dung sometimes loose, and at other times hard: should the moisture in his mouth continue, his skin being sometimes dry, and at others moist, with his coat looking starting, and surfeited: upon these irregular symptoms, which denote great danger, give the following balls, or drink; for in these cases there is no time to be lost.

**TAKE** of contrayerva-root, myrrh, and snake-root powdered, each two drams, saffron one dram, mithridate or Venice treacle half an ounce; make into a ball with honey, which should be given twice or thrice a-day, with two or three horns of an infusion of snake-root, sweetened with honey; to a pint and a half of which may be added half a pint of treacle water or vinegar, which latter is a medicine of excellent use in all kinds of inflammatory and putrid disorders, either external or internal.

Should these balls not prove successful, add to each a dram of camphor, and where it can be afforded, to a horse of value, the same quantity of castor. Or the following drink may be substituted in their stead for some days.

**TAKE** of contrayerva and snake-root of each two ounces, liquorice-root sliced one ounce, saffron two drams; infuse in two quarts of boiling water clove covered for two hours; strain off, and add half a pint of distilled vinegar, four ounces of spirit of wine, wherein half an ounce of camphor is dissolved, and two ounces of mithridate or Venice treacle; give a pint of this drink every four, six, or eight hours.

Should the horse be costive, recourse must be had to glysters, or the opening drink: should he purge, take care not to suppress it, if moderate; but if, by continuance, the horse grows feeble, add diascordium to his

drinks, instead of the mithridate; if it increases, give more potent remedies.

Let it be remembered, that camphor is a very powerful and effectual medicine in these kinds of putrid fevers; being both active and attenuating, and particularly calculated to promote the secretions of urine and perspiration.

Regard should also be had to his staling; which, if in too great quantities, so as manifestly to depress his spirits, should be controuled by proper restringents, or by preparing his drinks with lime-water. If, on the contrary, it happens that he is too remiss this way, and stales so little as to occasion a fullness, and swelling of the body and legs, recourse may be had to the following drink:

**TAKE** of salt prunella, or nitre, one ounce; juniper-berries, and Venice turpentine, of each half an ounce; make into a ball with oil of amber.

Give him two or three of these balls, at proper intervals, with a decoction of marsh-mallows, sweetened with honey.

But if, notwithstanding the method we have laid down, a greenish or reddish gleet is discharged from his nostrils, with a frequent sneezing; if he continues to lose his flesh, and becomes hide-bound; if he altogether forsakes his meat, and daily grows weaker; if he swells about the joints, and his eyes look fixed and dead; if the kernels under his jaws swell, and feel loose; if his tail is raised and quivers; if his breath smells strong, and a purging ensues with a discharge of fetid dark-coloured matter, his case may then be looked on as desperate, and all future attempts to save him will be fruitless.

The signs of a horse's recovery are known by his hide keeping open, and his skin feeling kindly; his ears and feet will be of a moderate warmth, and his eyes brisk and lively; his nose grows clean and dry; his appetite mends, he lays down well, and both stales and dungs regularly.

Be careful not to overfeed him on his recovery; let his diet be light, feeds small, and increased by degrees as he gets strength; for by overfeeding, horses have frequent relapses, or great surfeits, which are always difficult of cure.

If this fever should be brought to intermit, or prove of the intermitting kind, immediately after the fit is over, give an ounce of Jesuit's bark, and repeat it every six hours, till the horse has taken four or six ounces; should eruptions or swellings appear, they ought to be encouraged, for they are good symptoms at the decline of a fever, denote a termination of the distemper, and that no further medicines are wanted.

The true reasons perhaps why so many horses miscarry in fevers, are, that their masters, or doctors, will not wait with patience, and let nature have fair play: that they generally neglect bleeding sufficiently at first; and are constantly forcing down sugar lops, or other food in a horn, as if a horse must be starved in a few days, if he did not eat: then they ply him twice or thrice a-day with hot medicines and spirituous drinks, which (excepting a very few cases) must be extremely pernicious to a horse, whose diet is naturally simple, and whose stomach and blood, unaccustomed to such heating medicines, must be greatly injured, and without doubt are often inflamed by such treatment.

Dilute

Dilute the blood with plenty of water, or white drink; let his diet be warm bran mashes, and his hay sprinkled. Should the fever rise, which will be known by the symptoms above described, give him an ounce of nitre thrice a-day in his water, or made up in a ball with honey. Let his body be kept cool and open, with the opening drink, given twice or thrice a-week; or an ounce of salt of tartar may be given every day, dissolved in his water, for that purpose, omitting then the nitre. After a week's treatment in this manner, the cordial ball may be given once or twice a-day, with an infusion of liquorice-root sweetened with honey; to which may be added, when the phlegm is tough, or cough dry and husky, a quarter of a pint of linseed or fallad oil, and the same quantity of oxymel squills.

The following cooling purge is very proper to give at the decline of the distemper, and may be repeated three or four times.

TAKE two ounces of senna; anniseed and fennel bruised, each half an ounce; salt of tartar three drams; let them infuse two hours in a pint of boiling water; strain off, and dissolve in it three ounces of Glauber's salt, and two of cream of tartar; give for a dose in the morning.

This purge generally works before night very gently; and in fevers, and all inflammatory disorders, is infinitely preferable to any other physic.

Before we close this chapter on fevers, it may be no improper hint to the curious, to take notice that a horse's pulse should more particularly be attended to than is customary, as a proper estimate may thereby be made both of the degree and violence of the fever present, by observing the rapidity of the blood's motion, and the force that the heart and arteries labour with to propel it round. The highest calculation that has been made of the quickness of the pulse in a healthy horse, is, that it beats about forty strokes in a minute; so that in proportion to the increase above this number, the fever is rising, and if farther increased to above fifty, the fever is very high.

How often the pulse beats in a minute may easily be discovered by measuring the time with a stop-watch, or minute sand-glass, while your hand is laid on the horse's near side, or your fingers on any artery; those which run up on each side the neck, are generally to be seen beating as well as felt a little above the chest; and one within side each leg may be traced with the finger.

A due attention to the pulse is so important an article, in order to form a proper judgment in fevers, that it would appear amazing it has so much been neglected, if one did not recollect, that the generality of farriers are so egregiously ignorant, that they have no manner of conception of the blood's circulation, nor in general have they ability enough to distinguish the difference between an artery and a vein.—With such pretty guardians do we intrust the healths and lives of the most valuable of animals!

#### *Of a PLEURISY, and INFLAMMATION of the LUNGS, &c.*

THESE disorders have scarce been mentioned by any writer in farriery before Mr Gibson; who, by frequent-

ly examining the carcases of dead horses, has found them subject to the different kinds of inflammations here described.

In order to distinguish these disorders from others, we shall describe the symptoms in Mr Gibson's own words.

"A pleurisy then, which is an inflammation of the pleura; and a peripneumony, which is an inflammation of the lungs; have symptoms very much alike; with this difference only, that in a pleurisy a horse shews great uneasiness, and shifts about from place to place; the fever, which at first is moderate, rises suddenly very high; in the beginning he often strives to lie down, but starts up again immediately, and frequently turns his head towards the affected side, which has caused many to mistake a pleuritic disorder for the gripes, this sign being common to both, though with this difference: in the gripes a horse frequently lies down and rolls, and when they are violent he will also have convulsive twitches, his eyes being turned up, and his limbs stretched out as if he were dying; his ears and feet are sometimes occasionally hot, and sometimes as cold as ice; he falls into profuse sweats, and then into cold damps; strives often to stale and dung, but with great pain and difficulty; which symptoms generally continue, till he has some relief: but in a pleurisy, a horse's ears and feet are always burning hot, his mouth parched and dry, his pulse hard and quick: even sometimes when he is nigh dying, his fever is continued and increasing; and though in the beginning he makes many motions to lie down, yet afterwards he reins back as far as his collar will permit, and makes not the least offer to change his posture, but stands panting with short stops, and a disposition to cough, till he has relief, or drops down.

In an inflammation of the lungs, several of the symptoms are the same; only in the beginning he is less active, and never offers to lie down during the whole time of his sickness; his fever is strong, breathing difficult, and attended with a short cough: and whereas in a pleurisy a horse's mouth is generally parched and dry; in an inflammation of the lungs, when a horse's mouth is open, a ropy slime will run out in abundance; he gleans also at the nose a reddish or yellowish water, which sticks like glue to the inside of his nostrils.

In a pleurisy, a horse heaves and works violently at his flanks, with great restlessness, and for the most part his belly is tucked up; but in an inflammation of the lungs, he always shews fullness, and the working of his flanks is regular, except after drinking and shifting his posture; and his ears and feet are for the most part cold, and often in damp sweats.

The cure of both these disorders is the same. In the beginning a strong horse may lose three quarts of blood, the next day two quarts more; and if symptoms do not abate, the bleedings must be repeated, a quart at a time; for it is speedy, large, and quick-repeated bleedings that are in these cases chiefly to be depended on. But if a horse has had any previous weakness, or is old, you must bleed him in less quantities, and oftener. Mr Gibson recommends rowels on each side the breast, and one on the belly; and a blistering ointment to be rubbed all over his brisket upon the foremost ribs.

The diet and medicines should be both cooling, attenuating, relaxing, and diluting; and the horse should have warm mashes, and plenty of water or gruel. The following balls may be given thrice a-day.

**Take** of spermaceti and nitre, of each one ounce; oil of anniseed, thirty drops; honey enough to make a ball.

A pint of barley-water, in which figs and liquorice-root have been boiled, should be given after each ball; to which the juice of lemons may be added; and if the lungs are greatly oppressed with a dry short cough, two or three horns full of the decoction may be given three or four times a-day, with four spoonfuls of honey and linseed oil. A strong decoction of the rattle-snake-root is also much recommended in pleuritic disorders, and may be given to the quantity of two quarts a-day, sweetened with honey. It remarkably attenuates the blood, and disperses the inflammation, and in some parts is deemed a specific for this complaint.

An emollient glyster should be injected once a day, to which may be added two ounces of nitre or cream of tartar.

In two or three days he will probably run at the nose, and begin to feed; but should he not, and continue hot and short-breathed, you must bleed him again, and give the following glyster.

**Take** fenna and marshmallows, of each two ounces; fennel and bay-berries, each one ounce; boil in five pints of clear water, to two quarts; pour off the clear, and add four ounces of purging salts, two or three of syrup of buckthorn, and half a pint of linseed, or any common oil.

If by these means he grows cooler, and his pain moderates, repeat the glyster the next day, unless it worked too much; then intermit a day; and when he comes to eat scalded bran and picked hay, leave off the balls, and continue only the decoction, with now and then a glyster.

But let it be observed, that a horse seldom gets the better of these disorders, unless he has relief in a few days; for if the inflammation is not checked in that time, it usually terminates in a gangrene, or collection of matter, which, for want of expectoration, soon suffocates him.

But as pleuritic disorders are apt to leave a taint on the lungs, great care should be taken of the horse's exercise and feeding, which should be light and open for two or three weeks.

There is also an external pleurisy, or inflammation of the muscles between the ribs, which, when not properly treated, proves the foundation of that disorder called the *chest-founder*; for if the inflammation is not dispersed in time, and the viscid blood and juices so attenuated by internal medicines, that a free circulation is obtained; such a stiffness and inactivity will remain on these parts, as will not easily be removed, and which is generally known by the name of chest-founder.

The signs of this inflammation, or external pleurisy, are a stiffness of the body, shoulders, and fore-legs; attended sometimes with a short dry cough, and a shrinking when handled in those parts.

Bleeding, soft pectorals, attenuants, and gentle purges

are the internal remedies; and externally, the parts affected may be bathed with equal parts of spirit of sal armoniac, and ointment of marshmallows, or oil of chamomile.

These outward inflammations frequently fall into the inside of the fore-leg, and sometimes near the shoulder; forming abscesses, which terminate the disorder.

The membrane which separates the lungs, and more particularly the diaphragm or midriff, is often also inflamed; which is scarce to be distinguished from the pleurisy, only in this, that when the midriff is greatly inflamed, the horse will sometimes be jaw-set, and his mouth so much closed that nothing can be got in; but the method of cure is the same.

### *Of a COUGH, and ASTHMA.*

THE consequence often of the preceding disorders injudiciously treated, are settled habitual coughs; which frequently degenerate into asthmas, and broken-wind.

Nothing has more perplexed practitioners than the cure of settled coughs; the cause of which, perhaps, has been their want of attention to the different symptoms which distinguish one cough from another; for without strict observance thereof, it is impossible to find out the true method of cure.

Thus, if a horse's cough is of long standing, attended with loss of appetite, wasting of flesh, and weakness, it denotes a consumption; and that the lungs are full of knotty, hard substances, called tubercles, which have often been discovered on dissection.

The following signs denote when the cough proceeds from phlegm, and slimy matter, that stop up the vessels of the lungs.

The horse's flanks have a sudden quick motion; he breathes thick, but not with his nostrils open, like a horse in a fever, or that is broken-winded; his cough is sometimes dry and husky, sometimes moist, before which he wheezes, rattles in the throat, and sometimes throws out of his nose and mouth great gobs of white phlegm, especially after drinking, or when he begins or ends his exercise, which discharge commonly gives great relief. Some such horses wheeze and rattle to such a degree, and are so thick-winded, that they can scarce move on, till they have been out some time in the air; though then they will perform beyond expectation.

The above asthmatic case proves often very obstinate; but, if it happens to a young horse, and the cough is not of long standing, it is greatly relieved, if not totally cured, by the following method.

If the horse is full of flesh, bleed him plentifully; if low in flesh, more sparingly; which may occasionally be repeated, on very great oppressions and difficulty of breathing, in proportionate quantities.

As mercurial medicines are found remarkably useful in these cases, give a mercurial ball (with two drams of calomel) over night, and a common purge next morning: or the following, which is recommended by Mr Gibbon.

**Take** gum-galbanum, ammoniacum, and assa foetida,  
of

of each two drams, fine aloes one ounce, saffron one dram, oil of anniseeds two drams, oil of amber one dram; with honey enough to form into a ball.

They may be repeated at proper intervals, with the usual cautions. In the intermediate days, and for some time after, one of the following balls may be given every morning.

**Take** cinnabar of antimony, finely levigated, six ounces; gum ammoniacum, galbanum, and assa fetida, of each two ounces; garlick four ounces; saffron half an ounce: make into a paste for balls, with a proper quantity of honey.

**Take** of the pectoral or cordial ball one pound, balsam of Peru half an ounce, balsam of sulphur annisated one ounce, flowers of Benjamin half an ounce, honey as much as is sufficient to form them into a paste; give the size of a pigeon's egg every morning.

Exercise in a free open air is very serviceable, and the diet should be moderate.

The following are the symptoms of a dry cough, or asthma.

The horse afflicted with this cough eats heartily, hunts and goes through his business with alacrity, appears well coated, and has all the signs of perfect health; yet he coughs at particular times almost incessantly, without throwing up any thing, except that the violence of the cough will cause a little clear water to distill from his nose. Though this cough is not periodical, yet some of these horses cough most in a morning, after drinking.

This may properly be styled a nervous asthma in a horse; as probably it chiefly affects the nerves in the membranous parts of the lungs and midriff; and is a case very doubtful at least, if not incurable; but when the horse is young, the following method may be successful.

Take away first a moderate quantity of blood; then give him two drams of calomel, mixed up with an ounce of diapente, for two nights; and the next morning a purging ball. Keep him well clothed and littered, and feed him with scalded bran and warm water.

Once in eight or ten days this purge may be repeated, with one mercurial ball only, given over-night.

The following balls may then be taken, one every day, about the size of a pullet's egg, the horse fasting two hours afterwards; and should be continued two months, or longer, to be of real service.

**Take** native cinnabar, or cinnabar of antimony, half a pound; gum guaiacum four ounces; myrrh, and gum armoniac, of each two ounces; Venice soap half a pound: the cinnabar must be finely levigated, as before observed, and the whole mixed up with honey, or oxymel squills.

The following also will be found a useful remedy in obstinate dry coughs.

**Take** gum ammoniacum, squills, and Venice soap, of each four ounces, balsam of sulphur with anniseeds one ounce; beat up into a mass, and give as the former.

Before we close this section, it may be necessary to observe here, that some young horses are subject to coughs

on cutting their teeth; their eyes also are affected from the same cause. In these cases, always bleed; and if the cough is obstinate, repeat it, and give warm mashes; which, in general, are alone sufficient to remove this complaint.

#### *Of a Broken Wind.*

This disorder hitherto seems to have been little understood; but Mr Gibbon is inclined to think, that the source of it is frequently owing to injudicious or hasty feeding young horses for sale; by which means the growth of the lungs, and all the contents within the chest, are so increased, and in a few years so preternaturally enlarged, that the cavity of the chest is not capacious enough for them to expand themselves in, and perform their functions.

A narrow contracted chest with large lungs may sometimes naturally be the cause of this disorder: and it has been observed, that horses rising eight years old are as liable to this distemper, as, at a certain period of life, men fall into althmas, consumptions, and other chronic diseases.

The reason why this disorder becomes more apparent at this age, may be, that a horse comes to his full strength and maturity at this time: at six he commonly finishes his growth in height; after that time he lets down his belly, and spreads, and all his parts are grown to their full extent; so that the pressure on the lungs and midriff is now more increased.

But how little weight soever these reasons may have, repeated dissections have given ocular proofs of a preternatural largeness, not only of the lungs of broken-winded horses, but of their heart and its bag, and of the membrane which divides the chest; as well as of a remarkable thinness in the diaphragm, or midriff.

This disproportion has been observed to be so great, that the heart and lungs have been almost of twice their natural size, perfectly sound, and without any ulceration whatever; or any defect in the wind-pipe, or its glands.

Hence it appears, that this enormous size of the lungs, and the space they occupy, by hindering the free action of the midriff, is the chief cause of this disorder; and as the substance of the lungs was found more fleshy than usual, they of course must lose a great deal of their spring and tone.

Whoever considers a broken-wind in this light, must own that it may be reckoned among the incurable distempers of horses; and that all the boasted pretensions to cure are vain and frivolous, since the utmost skill can amount to no more than now and then palliating the symptoms, and mitigating their violence.

We shall therefore only lay down such methods as may probably prevent this disorder, when pursued in time. But if they should not succeed, we shall offer some remedies and rules to mitigate its force, and to make a horse as useful as possible under this malady.

It is usual, before a broken wind appears, for a horse to have a dry obstinate cough, without any visible sickness or loss of appetite; but, on the contrary, a disposition to foul feeding, eating the litter, and drinking much water.

In order then to prevent, as much as possible, this disorder, bleed him, and give him the mercurial physic above prescribed, which should be repeated two or three times.

The following balls are then to be taken for some time, which have been found extremely efficacious in removing obstinate coughs.

**TAK**E aurum mosaicum, finely powdered, eight ounces; myrrh and elicanpane, powdered, each four ounces; anniseeds and bay-berries, each an ounce; saffron, half an ounce; make into balls with oxymel squills.

The aurum mosaicum is made of equal parts of quicksilver, tin, sal armoniac, and sulphur. We give this medicine as strongly recommended by Mr Gibson; but how far the aurum mosaicum may contribute to its efficacy, may perhaps justly be disputed: as a substitute in its room, therefore, for this purpose, we recommend the same quantity of powdered squills, or gum ammoniacum, or equal parts of each.

Broken-winded horses should eat sparingly of hay, which as well as their corn may be wetted with chamber lye or fair water; as this will make them less craving after water.

The volatile salts in the urine may make it preferable to water, and may be the reason why garlick is found so efficacious in these cases; two or three cloves given at a time in a feed, or three ounces of garlick bruised, and boiled in a quart of milk and water, and given every other morning for a fortnight, having been found very serviceable; for by warming and stimulating the solids, and dissolving the tenacious juices, which choke up the vessels of the lungs, these complaints are greatly relieved.

Careful feeding, and moderate exercise has greatly relieved broken-winded horses.

Horses sent to graze in order to be cured of an obstinate cough, have often returned completely broken-winded, where the pasture has been rich and succulent, so that they have had their bellies constantly full. As the ill consequence therefore is obvious, where you have not the convenience of turning out your horse for a constancy, you may soil him for a month or two with young green barley, tares, or any other young herbage.

To pursue thick-winded horses, Barbadoes and common tar have often been given with success, to the quantity of two spoonfuls mixed with the yolk of an egg, dissolved in warm ale, and given fasting two or three times a week, especially those days you hunt or travel.

But in order to make all these sorts of horses of any real service to you, the grand point is to have a particular regard to their diet, observing a just œconomy both in that and their exercise; giving but a moderate quantity of hay, corn, or water, at a time, and moistening the former, to prevent their requiring too much of the latter, and never exercising them but with moderation, as has before been observed. The following alterative ball may be given once a fortnight or three weeks; and as it operates very gently, and requires no confinement but those days it is given (when warm meat and water are necessary), it may be continued for two or three months.

**TAK**E succotrine aloes six drams; myrrh, galbanum, and ammoniacum, of each two drams; bay-berries half an ounce: make into a ball with a spoonful of

oil of amber, and a sufficient quantity of syrup of buckthorn.

#### *Of a CONSUMPTION.*

**WHEN** a consumption proceeds from a defect in a horse's lungs, or any principal bowel; the eyes look dull; the ears and feet are mostly hot; he coughs sharply by fits; sneezes much, and frequently groans with it; his flanks have a quick motion; he gleans often at the nose, and sometimes throws out a yellowish curdled matter; and he has little appetite to hay, but will eat corn, after which he generally grows hot.

As to the cure, one of the principal things is bleeding in small quantities (a pint, or pint and half, from some horses is sufficient) which should be repeated as often as the breath is more than ordinarily oppressed. Pectorals may be given to palliate present symptoms; but as dissections have discovered both the glands of the lungs and mesentery to be swelled, and often indurated, the whole stress lies on mercurial purges, and the following ponderous alteratives, given immediately.

**TAK**E native cinnabar, or cinnabar of antimony, one pound, powdered very fine, and add the same quantity of gum guaiacum and nitre; give the horse an ounce of this powder twice a-day, wetting his feeds.

The spring graze is often extremely serviceable, but the salt marshes are to be preferred, and to be more depended on than medicines; for great alterations are thereby made in the blood and juices, and no small benefit arises from open air and proper exercise.

#### *Of an APOPLEXY or STAGGERS, CONVULSIVE DISORDERS, LETHARGY, EPILEPSY, and PALSY.*

**FARRIERS** generally include all distempers of the head under two denominations, *viz. staggers* and *convulsions*; wherein they always suppose the head primarily affected. But in treating these disorders, we will distinguish between those that are peculiar to the head, as having their source originally thence; and those that are only concomitants of some other disease.

In an apoplexy a horse drops down suddenly, without other sense or motion than a working at his flanks.

The previous symptoms are, drowziness; watery eyes, somewhat full and inflamed; a disposition to reel, feebleness, a bad appetite; the head almost constantly hanging, or resting on the manger; sometimes with little or no fever, and scarce any alteration in the dung or urine: the horse is sometimes disposed to rear up, and apt to fall back when handled about the head; which is often the case with young horses, to which it does not prove suddenly mortal; but with proper help they may sometimes recover. If the apoplexy proceeds from wounds, or blows on the head, or matter on the brain; besides the above symptoms, the horse will be frantick by fits, especially after his feeds, so as to start and fly at every thing. These cases seldom admit of a perfect recovery; and when horses fall down suddenly, and work violently at their flanks, without any ability to rise after a plentiful bleeding, they seldom recover.

All

All that can be done is to empty the vessels as speedily as possible, by striking the veins in several parts at once, bleeding to four or five quarts, and to raise up the horse's head and shoulders, supporting them with plenty of straw. If he survives the fit, cut several rowels; give him night and morning glysters prepared with a strong decoction of senna and salt, or the purging glyster mentioned in the directions; blow once a-day up his nostrils a dram of powder of asarabacca, which will promote a great discharge; afterwards two or three aloetic purges should be given; and to secure him from a relapse, by attenuating and thinning his blood, give him an ounce of equal parts of antimony and crocus metallorum for a month; or, which is preferable, the same quantity of cinnabar of antimony and gum guaiacum.

If the fit proceeds only from fulness of blood, high feeding, and want of sufficient exercise, or a sily blood (which is often the case with young horses, who though they reel, stagger, and sometimes suddenly fall down, yet are easily cured by the above method), an opening diet with scalded bran and barley will be necessary for some time; and the bleeding may be repeated in small quantities.

As to the other disorders of the head, such as lethargy or sleeping evil, epilepsy or falling-sickness, vertigo, frenzy, and madness, convulsions, and paralytical disorders, as they are most of them to be treated as the apoplexy and epilepsy, by bleeding and evacuations with the alteratives there directed, we shall wave treating of them separately, but mention some particular rules to distinguish them, according to the plan we laid down, and then offer some general remedies for the several purposes.

In an epilepsy, or falling sickness, the horse reels and staggers, his eyes are fixed in his head, he has no sense of what he is doing, he stales and dungs insensibly, he runs round and falls suddenly; sometimes he is immovable, with his legs stretched out as if he was dead, except only a quick motion of his heart and lungs, which causes a violent working of his flanks; sometimes he has involuntary motions, and shaking of his limbs, so strong, that he has not only beat and spurned his litter, but the pavement with it; and with these alternate symptoms a horse continued more than three hours, and then he has as surprisingly recovered; at the going off of the fit, he generally foams at the mouth, the foam being white and dry, like what comes from a healthful horse when he champs on the bit.

But in all kinds of gripes, whether they proceed from disorders in the guts, or retention of urine, a horse is often up and down, rolls and tumbles about; and when he goes to lie down, generally makes several motions with great seeming carefulness, which shews he has a sense of his pain; and if he lays stretched out for any time, it is generally but for a short space.

Epilepsies and convulsions may arise from blows on the head, too violent exercise, and hard straining; and from a fulness of blood, or impoverished blood, and surfeits; which are some of the causes that denote the original disorder.

In lethargic disorders, the horse generally rests his head with his mouth in the manger, and his pole often reclined

to one side; he will shew an inclination to eat, but generally falls asleep with his food in his mouth, and he frequently swallows it whole, without chewing: emollient glysters are extremely necessary in this case, with the nervous balls recommended for the staggers and convulsions; strong purges are not requisite, nor must you bleed in too large quantities, unless the horse be young and lusty. In old horses, rowels and large evacuations are improper; but volatiles of all kinds are of use, when they can be afforded: the alterative purge (p. 554. col. 2. par. 2. from the bottom) may be given, and repeated on his amendment.

This distemper is to be cured by these means, if the horse is not old and past his vigour. It is a good sign if he has a tolerable appetite, and drinks freely without flabbering, and if he lies down, and rises up carefully, though it be but seldom.

But if a lethargic horse does not lie down; if he is altogether stupid and careless, and takes no notice of any thing that comes near him; if he dungs and stales seldom, and even while he sleeps and dozes, it is a bad sign: if he runs at the nose thick white matter, it may relieve him; but if a viscid gleet, that sticks to his nostrils like glue, turn to a profuse running of ropy, reddish and greenish matter, it is an infallible sign of a great decay of nature, and that it will prove deadly.

Young horses from four to six years, are very subject to convulsions, from bots in the spring; and the large coach breed, more than the saddle. They are seized without any previous notice; and if bots and worms are discovered in their dung, the cause seems to be out of doubt; more especially if they have lately come out of a dealer's hands.

When this convulsion proceeds from a distemperature of the midriff, or any of the principal bowels, it is to be distinguished from bots and vermin by previous symptoms; the horse falls off his stomach, and grows gradually weak, feeble, and dispirited in his work, and turns short-breathed with the least exercise.

The lively description of that universal cramp or convulsion, called by some the stag-evil, which seizes all the muscles of the body at once, and locks up the jaws, so that it is impossible almost to force them open, we shall give in Mr Gibson's own words, who says: As soon as the horse is seized, his head is raised with his nose towards the rack, his ears pricked up, and his tail cocked, looking with eagerness as an hungry horse when hay is put down to him, or like a high-spirited horse when he is put upon his mettle; insomuch, that those who are strangers to such things, when they see a horse stand in this manner, will scarce believe any thing of consequence ails him; but they are soon convinced, when they see other symptoms come on apace, and that his neck grows stiff, cramped, and almost immovable; and if a horse in this condition lives a few days, several knots will arise on the tendinous parts thereof, and all the muscles both before and behind will be so much pulled and cramped, and so stretched, that he looks as if he was nailed to the pavement, with his legs stiff, wide, and straddling; his skin is drawn so tight on all parts of the body, that it is almost impossible to move it; and if trial be made to make him walk,

walk, he is ready to fall at every step, unless he be carefully supported; his eyes are so fixed with the inaction of the muscles, as give him a deadness in his looks; he snorts and sneezes often, pants continually with shortness of breath; and this symptom increases continually till he drops down dead; which generally happens in a few days, unless some sudden and very effectual turn can be given to the distemper.

In all these cases the horse should first be bled plentifully, unless he is low in flesh, old, or lately come off any hard continued duty, then you must be more sparing of his blood; afterwards give the following ball.

**Take** assa fœtida half an ounce, Russia castor powdered two drams, valerian root powdered one ounce; make into a ball with honey and oil of amber.

This ball may be given twice a-day at first; and then once, washed down with a decoction of mistletoe or valerian sweetened with liquorice or honey: an ounce of assa fœtida may be tied up in a piece of strong coarse linen rag, and put behind his grinders to champ on.

The laxative purges and emollient glysters should be given immediately to keep the body open; but when the former balls have been taken a week or ten days, the following may be given once a-day with the valerian decoction.

**Take** cinnabar of antimony six drams, assa fœtida half an ounce, aristolochia myrrh and bay-berries of each two drams; make into a ball with treacle and oil of amber.

This is the most effectual method of treating these disorders; but when they are suspected to arise from bots, and worms, which is generally the case, mercurial medicines most lead the way, thus:

**Take** mercurius dulcis and philonium of each half an ounce; make into a ball with conserve of roses, and give the horse immediately; half the quantity may be repeated in four or five days.

The following infusion should then be given, to the quantity of three or four horns, three or four times a-day, till the symptoms abate; when the above nervous balls may be continued till they are removed.

**Take** penny-royal and rue of each two large handfuls, chamomile flowers one handful, assa fœtida and castor of each half an ounce, saffron and liquorice-root sliced of each two drams; infuse in two quarts of boiling water; pour off from the ingredients as wanted.

If the castor is omitted, add an ounce of assa fœtida.

The following ointment may be rubbed into the cheeks, temples, neck, shoulders, spines of the back and loins, and where-ever there is the greatest contractions and stiffness.

**Take** nerve and marshmallow ointment of each four ounces, oil of amber two ounces, with a sufficient quantity of camphorate spirit of wine; make a liniment.

When the jaws are so locked up that medicines cannot be given by the mouth, it is more eligible to give them by way of glyster; for forcing open the jaws by violence often puts a horse into such agonies, that the symptoms are thereby increased.

In this case also he must be supported by nourishing glysters, made of milk-pottage, broths, &c. which must be given to the quantity of three or four quarts a-day; glysters of this kind will be retained, and absorbed into the blood; and there have been instances of horses thus supported for three weeks together, who must otherwise have perished.

Mr Gibson mentions some extraordinary instances of success in cases of this sort by these methods, and repeated frictions, which are extremely serviceable in all convulsive disorders, and often prevent their being jaw-set; they should be applied with unwearied diligence every two or three hours, where ever any stiffness or contractions in the muscles appear; for a horse in this condition never lies down till they are in some measure removed.

The use of rowels in these cases is generally unsuccessful, the skin being so tense and tight, that they seldom digest kindly, and sometimes mortify; so that if they are applied, they should be put under the jaws, and in the breast.

The red-hot iron so frequently run through the forehead and mane, near the occipital bone, for this purpose, has often been found to have destroyed the cervical ligament.

In paralytic disorders, where the use of a limb or limbs is taken away, the internals above recommended should be given, in order to warm, invigorate, and attenuate the blood; and the following stimulating embrocation should be rubbed into the parts affected.

**Take** oil of turpentine four ounces, nerve ointment and oil of bays of each two ounces, camphor rubbed fine one ounce, rectified oil of amber three ounces, tincture of cantharides one ounce.

With this liniment the parts affected should be well bathed for a considerable time, to make it penetrate; and when the hind parts chiefly are lame, the back and loins should be well rubbed with the same. To the nervous medicines above recommended, may be added snake-root, contrayerva, mustard-seed, horse-raddish root steeped in strong beer, or wine where it can be afforded. Take the following for an example, which may be given to the quantity of three pints a-day alone, or two horns full may be taken after the nervous balls.

**Take** snake-root, contrayerva, and valerian, of each half an ounce; mustard-seed and horse-raddish root scraped, of each two ounces; long pepper two drams; infuse in three pints of strong wine.

When the horse is recovering from any of the above disorders, the following alterative purge may be repeated two or three times, as it operates very gently.

**Take** succotrine aloes one ounce, myrrh half an ounce, assa fœtida and gum ammoniacum of each two drams, saffron one dram; make into a ball with any syrup.

Where a retention of dung is the cause of this disorder, the great gut should first be raked thoroughly with a small hand, after which plenty of emollient oily glysters should be thrown up, and the opening drink given, till the bowels are thoroughly emptied of their imprisoned dung. Their diet should for some days be opening, and consist

consist chiefly of scalded brán, with flower of brimstone, scalded barley, &c.

*Of the STRANGLES, and VIVES.*

THE strangles is a distemper to which colts and young horses are very subject; and begins with a swelling between the jaw-bones, which sometimes extends to the muscles of the tongue; and is attended with so great heat, pain, and inflammation, that sometimes, till matter is formed, the horse swallows with the utmost difficulty.

The symptoms are extraordinary heat and feverishness, with a painful cough, and a great inclination to drink without being able; some horses losing their appetite entirely, others eating but little, by reason of the pain which chewing and swallowing occasions: when the swelling begins on the inside of the jaw-bones, it is much longer in coming to matter than when more to the middle; when it arises among the glands, and divides into several tumours, the cure is generally tedious, as it breaks in different places; and when it forms upwards on the windpipe and gullet, there is sometimes danger of suffocation, unless the swelling soon breaks. But the most dangerous kind is, when, besides the above symptoms, the horse runs at the nose; this is by some called the *bastard strangles*.

As this disorder seems to be critical, the most approved method is to assist nature in bringing the swellings to maturity, by keeping them constantly moist with ointment of marshmallows, and covering the head and neck with a warm hood. But as all swellings in glandular parts suppurate slowly, the following poultice may be applied hot twice a-day.

**TAKE** leaves of marshmallows ten handfuls, white-lily root half a pound, linseed and fenugreek-seed bruised of each four ounces; boil them in two-quarts of water till the whole is pulpy, and add four ounces of ointment of marshmallows, and a sufficient quantity of hogs-lard, to prevent its growing stiff and dry.

In five or six days, by these means, the matter is generally formed, and makes its way through the skin; and if the discharge is made freely and with ease, the opening need not be enlarged; but should be dressed with the following ointment spread on raw, still continuing the poultice over it to promote the digestion, and prevent any remaining hardness.

**TAKE** rosin and Burgundy pitch of each a pound and a half, honey and common turpentine each eight ounces, yellow wax four ounces, hogs-lard one pound, verdigrease finely powdered one ounce; melt the ingredients together, but do not put in the verdigrease, till removed from the fire; and it should be stirred in by degrees, till the whole is grown stiff and cool.

If the fever and inflammation run high, and the swelling be so situated as to endanger suffocation, a moderate quantity of blood must be taken away, and the remainder diluted with plenty of water-gruel, or warm water, mashes, &c.

The running at the nose which often attends the stran-

gles is dangerous, especially if it continues after they have ripened and broke, as the horse will be greatly weakened thereby. To prevent this waste and decay, give him every day for some time an ounce of Jesuit's bark; or a strong decoction of guaiacum shavings, which hath been found extremely beneficial in restraining these glandular discharges when too liberal, and in drying up ulcers of all kinds in horses.

If a hardness remains after the sores are healed up, they may be anointed with the mercurial ointment; and when the horse has recovered his strength, purging will be necessary.

The vives or ives differ from the strangles only in this; that the swellings of the kernels, under the ears of the horse, (which are the parts at first chiefly affected), seldom gather, or come to matter, but by degrees perspire off and disperse by warm cloathing, anointing with the marshmallow ointment, and a moderate bleeding or two. But should the inflammation continue notwithstanding these means, a suppuration must be promoted by the methods above recommended in the strangles.

When these swellings appear in an old or full-aged horse, they are signs of great malignity, and often of an inward decay, as well as forerunners of the glanders.

The mercurial ointment above-mentioned, may be prepared thus:

**TAKE** of crude mercury or quicksilver one ounce, Venice turpentine half an ounce; rub together in a mortar till the globules of the quicksilver are no longer visible; then add two ounces of hogs-lard.

*Of the Diseases of the EYES.*

In order to make the disorders of the eyes well understood, we shall consider them as arising from different causes; external injuries affecting the globe of the eye; and from internal causes affecting the humours within the globe. We shall consider also the eye as naturally weak from a bad conformation, which possibly may often be hereditary.

In all recent disorders of the eye from external injuries, such as blows, bites, &c. attended with a swelling of the lid, and a running from the eye, you must first sponge the part often with cold spring-water and vinegar; and if much swelled, bleed immediately, and apply over it a poultice made of the pulps of roasted or boiled apples, cleared from their seeds and husks; or of conserve of roses and vinegar, with a little bole, and the white of an egg. When the swelling is abated, either of the following washes will complete the cure.

**TAKE** white vitriol half an ounce, sugar of lead two drams; dissolve in a pint of spring-water; to which may occasionally be added, when the rheum is very great, and inflammation removed, half an ounce of tutty, or compound powder cerufs.

Let the eye and eyelid be bathed three or four times a-day with a clean sponge dipped in this wash; or it may be applied with a feather, leaving a few drops on the eye. When the veins under the eye have been turgid, opening them with a lancet has often been found successful.

Mr

Mr Gibson, from his own experience, recommends the following, with which alone he has succeeded in most common cases.

TAKE two drams of rose-buds, infuse them in half a pint of boiling water; when cold, pour off the infusion, and add to it twenty grains of sugar of lead.

This is to be used as the former; but the quantity of sugar of lead may occasionally be increased.

Sometimes from the violence of the inflammation, succeeding blows, and external injuries, the coats of the eye shall lose their transparency, thicken, and turn white, or pearl-colour; in the latter case, the horse has some glimmering of light; in the former, he is blind while the eye continues in this state.

If the horse be fleshy and of a gross constitution, bleeding may be repeated, and a rowel will be necessary: let his diet be scalded bran or barley; avoiding for some days oats, beans, or any thing hard to chew.

The cooling opening drink, (p. 547. col. 1. par. 1.) should be given every other day, which will answer better than stoic purges.

If the eye-lids continue swelled and moist, and the under side of the eye inflamed, an ounce of honey may be added to four ounces of the above waters; or the part may be well bathed with an ounce of honey of roses, and half a dram of sugar of lead, dissolved in three ounces of spring-water: to which may be added, when the eye is very watery, a spoonful or two of red wine, which will help to thicken the matter and dry it up.

If a film or thick slough should remain, it may be taken off, by blowing into the eye equal parts of white vitriol and sugar-candy finely powdered.

Glass finely powdered, mixed up with honey and a little fresh butter, is much recommended by Dr Bracken for this purpose; as also the following ointment.

TAKE ointment of tutty one ounce, honey of roses two drams, white vitriol burnt one scruple; this, with a feather, may be smeared over the eye twice a-day.

Let it be remembered, that it has long been observed in practice, that the eye in its first state of inflammation is so very tender, that the eye-waters prepared with tutty and other powders aggravate the disorder; consequently, during this state, the tinctures of vegetables and solutions of salts are greatly preferable.

Wounds of the eye may be dressed with honey of roses alone, or with a little sugar of lead mixed with it, adding thereto, after a few days, an eighth part of tincture of myrrh; all the preceding directions in regard to inflammation being attended to, especially bleeding, rowels, and gentle cooling physic.

When the humours of the eye are thickened, and the disorder is within the globe, sharp external applications are not only useless, but extremely detrimental, by the irritation they occasion, and consequently should be avoided.

In all cases of this sort, whether moon-eyes, which are only cataracts forming, or in confirmed ones attended with a weeping; general evacuations, with internal alteratives, can only take place.

These generally make their appearance, when a horse is turned five, coming six; at which time one eye becomes clouded, the eye-lids being swelled, and very often shut up; and a thin water generally runs from the diseased eye down the cheek, so sharp as sometimes to excoriate the skin; the veins of the temple, under the eye, and along the nose, are turgid and full: though sometimes it happens that the eye runs but little.

This disorder comes and goes till the cataract is ripe; then all pain and running disappears, and the horse becomes totally blind, which is generally in about two years. During this time some horses have more frequent returns than others; which continue in some a week or more, in others three or four; returning once in two or three months, and they are seldom so long as five without a relapse.

There is another kind of moon-blindness, which is also the forerunner of cataracts, where no humour or weeping attends. The eye is never shut up or closed here, but will now and then look thick and troubled, at which time the horse sees nothing distinctly: when the eyes appear sunk and perishing, the cataracts are longer coming to maturity; and it is not unusual in this case for one eye to escape.

These cases generally end in blindness of one, if not of both eyes; the most promising signs of recovery are when the attacks come more seldom, and their continuance grows shorter, and that they leave the cornea clear and transparent, and the globe plump and full.

The attempts to cure cataracts have hitherto been only palliative and mitigating the symptoms; yet early care has sometimes been successful. To this end the horse should be rowel'd and bled at proper intervals; except where the eyes appear sunk and perishing, where it is often pernicious. During the violence of the symptoms, observe the cooling treatment above recommended, giving him two ounces of nitre every day mixed into a ball with honey, and bathe the parts above the eye with verjuice, or vinegar, wherein rose-leaves are infused; to four ounces of which, half a dram of sugar of lead may be added. The swelling on the lid may afterwards be bathed with a sponge dipt in equal parts of lime and Hungary water, mixed together: the cooling physic, (p. 545 col. 1. par. 4.) should be given every fourth day, till the eye becomes clear, and recovers its usual brightness. The following also is very proper physic for this purpose.

TAKE lenitive electuary and cream of tartar of each four ounces, Glauber's salts three ounces, syrup of buckthorn two ounces.

When the weeping is by these means removed, the alterative powders (See the section, *Of ALTERATIVE MEDICINES*) should be given every day, till two or three pounds are taken, and after an interval of three months, the same course should be repeated. This method has often been attended with good success, where the eyes have been full, and noway perished; in that case, bathe or foment them with the following, twice a-day.

TAKE crude sal armoniac two drams, dissolve in a pint of lime-water, and add to it four ounces of brandy, or Hungary water.

This will act as a stimulus, and may help to thin and rarify

rarify the gummy juices, and bring new supplies of nourishment to the perishing eyes.

This course not succeeding, in order more powerfully to open the vessels of the chryalline humour, (which in these cases is always found opaque, and, when the cataract is confirmed, entirely loses its transparency,) and hinder as much as possible the forming of obstructions, mercurials are chiefly to be depended on: thus give every other day, for three or four mornings, two drams of calomel, mixed up with conserve of roses; and then purge off with the common ball.

During this course, particular care should be taken of the horse: after repeating this, the alterative powders before-mentioned should be given for some weeks or months, if you expect any benefit from them; or they may be beat up into a ball with live millepedes, and an ounce and a half given every day: if these should not succeed, and the horse is a valuable one, the turbith course recommended in the section on alteratives, seems to be the most promising method left. But to horses that are not so, an ounce of antimony, ground into an impalpable powder, may be given every day in one of his feeds for three months or longer; or a strong decoction of guaiacum shavings may be given for some time, to which crude antimony may be given in the following manner.

**TAKES** guaiacum shavings one pound, crude antimony tied in a rag the same quantity; boil in two gallons of forge-water to one, and give a quart a-day, either alone, or mixed with his water.

The haws is a swelling and sponginess that grows in the inner corner of the eye, so large sometimes as to cover a part of the eye. The operation here is easily performed by cutting part of it away; but the farriers are apt to cut away too much; the wound may be dressed with honey of roses; and if a fungus or spongy flesh arises, it should be sprinkled with burnt alum, or touched with blue vitriol.

#### *Of the GLANDERS.*

THE cause and seat of the glanders has till lately been so imperfectly handled, and so little understood by the writers of this distemper, that it is no wonder it should be ranked among the incurables: but a new light having been thrown on this whole affair by the study of M. La Fosse, the king of France's farrier, who has been at the pains to trace out, and discover, by dissections, the source and cause of this disorder; we hope the method he has proposed, with some further experiments and improvements, will soon bring to a certainty of cure (in most cases at least) a distemper so dangerous to our horses, and that hitherto has eluded the force of art.

M de la Fosse has distinguished seven different kinds of glanders, four of which are incurable.

The first proceeds from ulcerated lungs, the purulent matter of which comes up the trachea, and is discharged through the nostrils, like a whitish liquor, sometimes appearing in lumps and grumes: in this disorder, though the matter is discharged from the nostrils, yet the malady is solely in the lungs.

The second is a wasting humour, which usually seizes horses at the decline of a disease, caused by too hard labour; this defluxion also proceeds from the lungs.

The third is a malignant discharge, which attends the strangles sometimes, and falls upon the lungs, which run off by the nostrils.

The fourth is, when an acrimonious humour in the farcy seizes these parts, where it soon makes terrible havoc.

The fifth kind we shall describe by and by, as arising from taking cold.

The sixth kind is a discharge from the strangles, which sometimes vents itself at the nostrils.

These are the various disorders which have been observed sometimes to throw matter out from the nostrils; let us now describe the real glanders.

The matter, then, discharged from the nostrils of a glandered horse, is either white, yellow, or greenish, sometimes streaked, or tinged with blood: when the disease is of long standing, and the bones are fouled, the matter turns blackish, and becomes very fetid; and is always attended with a swelling of the kernels or glands under the jaws; in every other respect the horse is generally healthy and sound, till the distemper has been of some continuance.

It is always a bad sign, when the matter sticks to the inside of the nostrils, like glue or stiff paste; when the inside of the nose is raw, and looks of a livid or lead-colour; when the matter becomes bloody, and stinks, and when it looks of an ash-colour. But when only a limpid fluid is first discharged, and afterwards a whitish matter, the gland under the jaw not increasing, and the disorder of no long continuance, we may expect a speedy cure; for in this case, which arises from taking cold, after a horse has been overheated, the pituitary membrane is but slightly inflamed, the lymph in the small vessels condensed, and the glands overloaded, but not yet ulcerated.

From these symptoms, and some observations made both by Bracken and Gibson, it is plain they were not absolute strangers to the seat of this disorder, though they neglected pushing their inquiries to the fountain-head, and consequently were at a loss to know how to apply the remedy to the parts affected.

But our author, after examining by dissection the carcasses of glandered horses, and making a strict scrutiny into the state of the viscera, assisted for that purpose by ingenious and expert anatomists, for ten years together, ascertains this disease to be altogether local; and that the true seat of it is in the pituitary membrane which lines the partition along the inside of the nose, the maxillary sinuses or cavities of the cheek-bones on each side the nose, and the frontal sinuses or cavities above the orbits of the eyes; that the viscera, as liver, lungs, &c. of glandered horses are in general exceeding sound; and consequently that the seat of this disorder is not in those parts, as has been asserted by most authors; nor indeed is it probable it should: for how could such horses preserve their appetite, their good appearance, sleek and shining coats? in a word, all the signs of health for many years together (which many glandered horses are known to enjoy) with such distempered bowels.

But on nicely examining the heads of such horses, he found the cavities above-mentioned more or less filled with a viscous slimy matter, the membrane which lines both them and the nostrils inflamed, thickened, and corroded

with sordid ulcers, which in some cases had eat into the bones.

He observes, that when glandered horses discharge matter from both nostrils, both sides of the membrane and cavities were affected; but when they ran at one nostril only, that side only was found distempered.

It is a curious remark of our author, that the sublingual glands, or the kernels situated under the jaw-bone, which are always swelled in this distemper, do not discharge their lymph into the mouth, as in man, but into the nostrils; and that he constantly found their obstruction agreed with the discharge; if one gland only was affected, then the horse discharged from one nostril only; but if both were, then the discharge was from both.

The seat of this disorder thus discovered, our author with great ingenuity has paved the way for cure, by trepanning these cavities, and taking out a piece of bone, by which means the parts affected may be washed with a proper injection, and in fine the ulcers deterged, healed, and dried up.

But as from the observations since made by this gentleman, there are different species of the glanders, so the cure of the milder kinds may first be attempted by injections and fumigations: thus after taking cold, should a horse for fifteen or twenty days discharge a limpid fluid or whitish matter from one or both nostrils, the glands under the jaw rather growing harder than diminishing, we may expect it will degenerate into a true glanders. To prevent which, after first bleeding, and treating him as we have directed for a cold, let an emollient injection, prepared with a decoction of linseed, marshmallows, elder, chamomile flowers, and honey of roses, or such like, be thrown up as far as possible with a strong syringe, and repeated three times a-day: should the running not lessen or be removed in a fortnight by the use of this injection, a restraining one may now be prepared with tincture of roses, lime-water, &c. and the nostrils fumigated with the powders of frankincense, mastic, amber, and cinnabar, burnt on an iron heated for that purpose; the fume of which may easily be conveyed through a tube into the nostrils.

This method has been found successful when used in time; but the methods of cure depend on the stubbornness of the disorder; and when inveterate, recourse must be had to the operation above described.

*Of the CHOLIC or GRIPEs, and Pains in the Bowels, from sudden accidents.*

There seems to be no distemper so little understood by the common farrier, as the cholic or gripes in horses, one general remedy or method serving them in all cases; but as this disorder may be produced by very different causes, the method of cure must also vary, otherwise the intended remedy, injudiciously applied, will not only aggravate the complaint, but make it fatal. We shall divide this disorder into three different species: the stultent or windy, the bilious or inflammatory, and the dry gripes; each of which we shall distinguish by their different symptoms, and then point out the proper remedies.

The stultent or windy cholic is thus known. The horse is often lying down, and as suddenly rising again

with a spring; he strikes his belly with his hinder feet, stamps with his fore-feet, and refuses his meat; when the gripes are violent, he will have convulsive twitches, his eyes be turned up, and his limbs stretched out as if dying, his ears and feet being alternately very hot and cold; he falls into profuse sweats, and then into cold damps; strives often to stale, and turns his head frequently to his flanks; he then falls down, rolls about, and often turns on his back; this last symptom proceeds from a stoppage of urine, that almost always attends this sort of cholic, which may be increased by a load of dung pressing on the neck of the bladder.

These are the general symptoms of cholic and gripes from wind, drinking cold water when hot, and when the perspirable matter is retained, or thrown on the bowels by catching cold; in all which cases they are violently distended. Cribbing horses are more particularly subject to this complaint, by reason they are constantly sucking in great quantities of air.

The first intention is to empty the strait gut with a small hand dipt in oil, which frequently makes way for the confined wind to discharge itself; and by easing the neck of the bladder, the suppression of urine is taken off, and the horse stales and gets ease.

The following ball and glyster seldom fail of giving relief in these cases.

**TAK**e Strasburgh or Venice turpentine, and juniper-berries pounded, of each half an ounce; salt-prunella, or salt-petre, an ounce; oil of juniper, one dram; salt of tartar, two drams; make into a ball with any syrup; it may be given whole, and washed down with a decoction of juniper-berries, or a horn or two of ale.

If the horse does not break wind, or stale plentifully, he will find no relief; therefore in an hour or two give him another ball, and add to it a dram of salt of amber; which may be repeated a third time, if found necessary. During the fit the horse may be walked and trotted gently, but should by no means be harassed beyond his ability, or dragged about till he is jaded.

The following glyster may be given, between the balls, or alone, and repeated occasionally.

**TAK**e chamomile flowers two handfuls; anise, coriander, and fennel seeds, of each an ounce; long pepper half an ounce; boil in three quarts of water to two; and add Daffy's elixir, or gin, half a pint; oil of amber half an ounce, and oil of chamomile eight ounces.

The signs of a horse's recovery, are his lying quiet, without starting, or tumbling, and his gathering up his legs, and ceasing to lash out; and if he continues an hour in this quiet posture, you may conclude all danger over.

The next species of cholic we shall describe, is the bilious or inflammatory; which besides most of the preceding symptoms, is attended with a fever, great heat, panting, and dryness of the mouth; the horse also generally throws out a little loose dung, with a hot scalding water, which when it appears blackish, or of a redish colour, and foetid smell, denotes an approaching mortification.

In this case the horse should immediately be bled to the quantity of three quarts; and it should be repeated, if the symptoms do not abate in a few hours. The emollient

kent glyster, with two ounces of nitre dissolved in it, should be thrown up twice a-day, to cool the inflamed bowels; plenty of gum-arabic water should be taken, and a pint of the following drink given every two or three hours, till several loose stools are procured; and then it should be given only night and morning till the disorder is removed.

TAKE fenna three ounces, salt of tartar half an ounce; infuse in a quart of boiling water an hour or two; then strain off, and add two ounces of lenitive electuary, and four of Glauber's salts.

If this disorder is not removed by these means, but the inflammation and fever increase, attended with a discharge of the flesh coloured water above described, the event will most probably be fatal: and the chief thing to be depended on now, must be a strong decoction of Jesuits bark, given to the quantity of a pint every three hours, with a gill of red port-wine.

A quart of the same may be used for a glyster, with two ounces of Venice turpentine, dissolved with the yolks of two eggs, an ounce of diascordium, and a pint of red wine, and given twice a-day: if the horse recovers, give two or three mild rhubarb purges.

The last we shall describe is the dry gripes, or the cholick, which arises often from costiveness; it is discovered by the horse's frequent and fruitless motion to dung, the blackness and hardness of the dung, the frequent and quick motion of his tail, the high colour of his urine, and his great restlessness and uneasiness.

In this case the strait gut should be examined and emptied with a small hand oiled properly for that purpose; the emollient oily glyster, (p. 545. col. 2. par 7.) should be thrown up twice a day; and the above purging drink given, till the bowels are unloaded, and the symptoms removed.

The diet for a horse in the gripes, should be scalded bran, warm water-gruel, or white water, made by dissolving four ounces of gum-arabic in a quart of water, and mixing it with his other water.

From this history and division of gripes and cholicks, with their different treatment, it appears how absolutely necessary it is they should be well understood, in order to be managed skilfully: it is plain too, that violent hot medicines should in every species of this disorder be guarded against, and given with great caution and discretion, even in the first kind of flatulent cholick, where indeed they can only be wanted; yet too often, when prepared by the farriers with oil of turpentine, geneva, pepper, and brine, &c. they even increase that disorder, by stimulating the neck of the bladder, too forcibly heating the blood, and inflaming the bowels, till a mortification is brought on them. These are, in general, the constant appearances of horses that die of this disorder, whose bowels being examined for that purpose, have been found inflamed, full of red and livid spots, sometimes quite black, criped with extreme heat, and rotten.

#### *Of the LAX and SCOURING, with other Disorders of the STOMACH and BOWELS.*

IT is sometimes a nice matter to form a proper judgment when to controul or encourage a looseness, but these

general rules may be a direction: If a healthy full horse, on taking cold, or upon hard riding, overfeeding, eating unwholesome food, or with a slight fever, should have a moderate purging, by no means think of stopping it; but rather encourage it with an open diet, and plenty of warm gruel: but if it continues long, with gripings, the mucus of the bowels coming away, and the horse losing his appetite and flesh, it is then high time to give him proper medicines; if he voids great quantities of slime and greasy matter, give him the following drench, and repeat it every other day for three times.

TAKE lenitive electuary and cream of tartar of each four ounces, yellow rosin finely powdered one ounce, and four ounces of sweet oil; mix with a pint of water gruel.

The following alterative ball alone has been found successful for this purpose, when given twice a-week. with scalded bran and warm gruel.

TAKE succotrine aloes half an ounce, diapente one ounce; make into a ball with the juice of Spanish liquorice dissolved in water, and a spoonful of oil of amber.

To this may be added two drams of myrrh, and a dram of saffron, and (where it can be afforded) half an ounce of rhubarb.

When the purging is attended with a fever, rhubarb should first be given to the quantity of half an ounce, with an ounce and half of lenitive electuary; at night after the working, give half an ounce or more of diascordium in a pint of red wine mulled with cinnamon, and repeat it every day, and the rhubarb ball once in two or three.

But if the distemper increases, the horse's flanks and belly look full and distended, and he appears griped and in pain, let this glyster be given, and the quantity of diascordium increased an ounce in his night-drink.

TAKE chamomile flowers one handful, red roses half a handful, pomegranate and balaustines of each an ounce; boil in two quarts of water to one; strain off, and dissolve in it two or three ounces of diascordium, and one of mithridate; to which may be added a pint of port wine: repeat it once a-day.

If the flux continues violent, give an ounce of rock-alum, with an ounce and a half of bole, twice a-day; or, dissolve double this quantity with two ounce of diascordium, and the cordial ball, in two quarts of harts-horn drink; to which may be added a pint of port; and give the horse, three or four times a-day, a pint of this drink. For this purpose also a strong decoction of oak-bark may be given, with either of the above remedies, and to the same quantity; even by itself, it will be found on trial no inconsiderable remedy.

When the discharge is attended with an acrid mucus or slime, the griping and pains are very severe, the common lining of the bowels being washed away; in this case the following glyster should frequently be injected warm.

TAKE of tripe liquor or thin starch two quarts, oil of olives half a pint, the yolk of six eggs well broke, and two or three ounces of coarse sugar.

Some horses having naturally weak stomachs and bowels,

bowels, throw out their aliment undigested; their dung is habitually soft, and of a pale colour; they feed poorly, and get no flesh: to remedy this complaint, give the following purge two or three times; and then the infusion to the quantity of a pint every morning.

**Take** succotrine aloes six drams, rhubarb powdered three drams, myrrh and saffron each a dram; make into a ball with syrup of ginger.

**Infusion.**—**Take** zedoary, gentian, winters-bark, and orange-peel, of each two ounces; pomegranate-bark and balaustine, of each an ounce; chamomile flowers and centaury, each a handful; cinnamon and cloves, each an ounce: infuse in a gallon of port or strong beer.

The bloody flux is a distemper horses are not very subject to; however, as it sometimes does occur, whenever blood is discharged, attended with gripings, and great pain in the bowels, if the flux is not speedily restrained, the horse probably may be soon lost: we recommend therefore the following glyster and drink for that purpose.

**Take** oak-bark four ounces, tormentil-root two ounces, burnt hartshorn three ounces; boil in three quarts of forge-water to two; strain off, and add two ounces of diascordium, four ounces of starch, and half a dram of opium.

A glyster may also be prepared with the same quantity of fat broth, starch and opium, in order to plaister over the coats of the bowels, and abate their violent irritations. Also,

**Take** soft chalk two ounces, mithridate or diascordium one ounce, powder of Indian-root half a dram, liquid laudanum fifty or sixty drops; dissolve in a pint of hartshorn drink, and add to it four ounces of cinnamon-water or red wine: give it twice a day.

Gum arabic dissolved in hartshorn drink, or in common water, should be the horse's usual drink.

When horses are apt to be colicive, from whatever cause it arises, gentle openers should be given; such as cream of tartar, Glauber's salts, and lenitive electuary; four ounces of any two of these dissolved in warm ale, whey, or water, given every other morning for two or three times, will answer this purpose; especially if assisted by an oily emollient glyster, prepared with a handful of salt. Scalded bran or barely, with an ounce of senugreek and linseed, occasionally given, will prevent this complaint: but where it is constitutional, and proceeds from the power and force of digestion in the stomach and guts, as sometimes happens, and the horse is otherwise in perfect health, no inconvenience will arise from it; and it is observed that such horses are able to endure great fatigue and labour.

#### Of Worms and Bots.

**Authors** have described three different sorts of worms that affect horses, viz. *Bots*, which young horses are often troubled with in the spring; the *Rotundi*, or those resembling earth worms; and the *Ascarides*, or those about the size of the largest sewing needle, with flat heads.

The bots which breed in the stomachs of horses, and are sometimes the cause of convulsions, appear to be very large maggots, composed of circular rings, with little sharp prickly feet along the sides of their bellies (like the feet of hog-lice), which by their sharpness (like the points of the finest needles) seem to be of use to fasten them to the part where they breed and draw their nourishment, and to prevent their being loosened from such adhesion before they come to maturity. The eggs from whence these bots are produced, are dispersed into clusters all round the lower orifice of the stomach, and are laid under the inner coat or thin membrane of the stomach; so that when the animals come to form and life, they burst through this inner coat with their breech and tail straight outwards, and their trunks so fixed into the muscular or fleshy coat of the stomach, that it sometimes requires a good pull to disengage them; from the blood of this last coat they draw their nourishment, which they suck like so many leeches, every one ulcerating and purging up the part where it fixes like a honey-comb; and they often make such quick havock, as to destroy the horse.

The symptoms of worms are various. The bots that many horses are troubled with in the beginning of the summer, are always seen sticking on the strait gut, and are often thrust out with the dung, with a yellowish coloured matter like melted sulphur; they are noways dangerous there, but are apt to make a horse restless and uneasy, and rub his breech against the posts. The season of their coming is usually in the months of May and June, after which they are seldom to be seen, and rarely continue in any one horse above a fortnight or three weeks. Those that take their lodgment in the stomach, are extremely dangerous by causing convulsions; and are seldom discovered by any previous signs before they come to life, when they throw a horse into violent agonies. The other kinds are more troublesome than dangerous; but are known by the following signs: The horse looks lean and jaded, his hair stares as if he was surfeited, and nothing he eats makes him thrive; he often strikes his hind-feet against his belly, is sometimes griped, but without the violent symptoms that attend a cholic or stranguary; for he never rolls and tumbles, but only shews uneasiness, and generally lays himself down quietly on his belly for a little while, and then gets up and falls a feeding; but the surest sign is when he voids them with his dung.

For the cure of bots in the stomach, we have already taken notice that calomel should first be given in large quantities, and repeated at proper intervals, (see p. 554. col. 1.) *Æthiops mineral*, or some of the under-mentioned forms, may be given afterwards.

But bots in the strait gut may be cured by giving the horse a spoonful of safin, cut very small, once or twice a-day in his oats or bran, moistened; and three or four cloves of garlick may be added to advantage. Give also an aloeic purge between whiles; the following stands recommended.

**Take** fine succotrine aloes, ten drams; fresh jallap, one dram; aristochia, or birthwort, and myrrh powdered,

powdered, of each two drams; oil of favin and amber, of each one dram; syrup of buckthorn enough to form into a ball.

But as the source of worms in general proceeds from a vitiated appetite and a weak digestion, recourse must first be had to mercurials, and afterwards to such things as are proper to strengthen the stomach, promote digestion, and, by destroying the supposed ova, prevent the regeneration of these animals. Thus, two drams of calomel may be given with half an ounce of diapente, and mixed up with conserve of wormwood, over night; and the next morning the above purge: these may be repeated six or eight days. Or the following mercurial purge may be given, which will be less troublesome, and no less efficacious.

**TAKE** crude quicksilver two drams, Venice turpentine half an ounce; rub the quicksilver till no glistening appears; then add an ounce of aloes, a dram of grated ginger, thirty drops of oil of favin, and a sufficient quantity of syrup of buckthorn to make a ball.

One of these balls may be given every six days, with the usual precautions in regard to mercurial physic; and these powders intermediately.

**TAKE** powdered tin and Æthiops mineral of each half an ounce: give every night in a mash, or among his corn.

The various preparations of antimony and mercury must be given several weeks together, in order to get entire riddance of these vermin. The Æthiops mineral may be given to the quantity of half an ounce a-day; the mercurius alkalifatus to two drams a-day, incorporated with a bit of cordial ball. The cinnabar powders, as directed in the farcy, are no less effectual: and when worms are bred from high feeding, or unwholesome food; rue, garlick, tanfy, favin, box, and many other simples, may be given successfully; being for that purpose mixed with their food; as also cut tobacco, from half an ounce to an ounce a-day.

#### *Of the YELLOWS, or JAUNDICE.*

HORSES are frequently subject to this distemper; which is known by a dusky yellowness of the eyes; the inside of the mouth and lips, the tongue and bars of the roof of the mouth, looking also yellow. The horse is dull, and refuses all manner of food; the fever is slow, yet both that and the yellowness increase together. The dung is often hard and dry, of a pale yellow, or light pale green. His urine is commonly of a dark dirty brown colour; and when it has settled some time on the pavement, it looks red like blood. He stales with some pain and difficulty; and if the distemper is not checked soon, grows delirious and frantic. The off-side of the belly is sometimes hard and distended; and in old horses, when the liver has been long diseased, the cure is not practicable, and ends fatally with a wasting diarrhœa: but when the distemper is recent, and in young horses, there is no fear of a recovery, if the following directions are observed.

First of all bleed plentifully; and give the laxative glyster (p. 547. col. 1. par. 2. from the bottom) as horses  
Vol. II. No. 50.

2

are apt to be very costive in this distemper; and the next day give him this purge.

**TAKE** of Indian rhubarb powdered one ounce and a half, saffron two drams, succotrine aloes six drams, syrup of buckthorn a sufficient quantity.

If the rhubarb should be found too expensive, omit it, and add the same quantity of cream of tartar, and half an ounce of Castile soap, with four drams more of aloes. This may be repeated two or three times, giving intermediately the following balls and drink.

**TAKE** of Æthiops mineral half an ounce, millepedes the same quantity, Castile soap one ounce; make into a ball, and give one every day, and wash it down with a pint of this decoction.

**TAKE** madder-root and turmeric of each four ounces, burdock-root sliced half a pound, Monk's rhubarb four ounces, liquorice sliced two ounces; boil in a gallon of forge-water to three quarts; strain off; and sweeten with honey.

Balls of Castile soap and turmeric may be given also for this purpose, to the quantity of three or four ounces a day, and will in most recent cases succeed.

By these means the distemper generally abates in a week, which may be discovered by an alteration in the horse's eyes and mouth; but the medicines must be continued till the yellowness is intirely removed. Should the distemper prove obstinate, and not submit to this treatment, you must try more potent remedies, *viz.* mercurial physic, repeated two or three times at proper intervals; and then the following balls.

**TAKE** salt of tartar two ounces, cinnabar of antimony four ounces, live millepedes and filings of steel of each three ounces, saffron half an ounce, Castile or Venice soap half a pound: make into balls, the size of a pullet's egg, with honey; and give one, night and morning, with a pint of the above drink.

It will be proper, on his recovery, to give two or three mild purges; and if a fat full horse, to put in a rowel.

#### *Of the Disorders of the KIDNEYS and BLADDER.*

THE signs of the kidneys being hurt or affected are, a weakness of the back and loins, difficulty of staling, faintness, loss of appetite, and deadness in the eyes; the urine is thick, foul, and sometimes bloody, especially after a violent strain. A horse diseased in his kidneys can seldom back, that is, move strait backwards without pain, which is visible as often as he is put to the trial: the same thing is observable indeed in horses, whose backs have been wrung and wrenched; but with this difference, that in the latter there is seldom any defect or alteration in the urine, except that it is higher coloured.

Bleeding is the prime remedy, and that plentifully, in order to prevent inflammation; and the more so, if a fever attends a difficulty in staling, for then we may suspect the kidneys already inflamed. A rowel in the belly has been found useful; and the following balls may be given twice or thrice a-day, with a pint of marshmallow-decoction, in which half an ounce of gum arabic is dissolved, with an ounce of honey.

**TAKE** lucatellus-balsam one ounce, spermaceti six drams,

†

6 B

drams,

drams, sal prunella half an ounce; mix into a ball with honey: if the urine is bloody, add half an ounce of japan earth.

Should the fever continue, bleed largely, give emollient glysters, and the cooling opening drink, (p. 547. col. 1. par. 3.) till it abates.

If the urine passes with difficulty and pain, notwithstanding these means, give this ball, and repeat it twice or thrice a-day till the horse stales freely and without pain, his urine become of a right consistence, and free from any purulent settlement.

**TAKE** balsam of copivi or Strasburgh turpentine, and Venice soap, of each one ounce, nitre six drams, myrrh powdered two drams; make into a ball with honey, and wash it down with the marshmallow decoction.

As a suppression of urine arises sometimes from an inflammation of the kidney; so at others, from a paralytic disorder, disabling them in their office of separating the urine from the blood: in this latter case, the bladder is usually empty, so that a horse will make no motion to stale; and if he continues a few days in this condition, his body will swell to a great degree, breaking out in blotches all over, and death will soon close the scene.

If it arises from inflammation, bleed largely, and treat the horse as above recommended; but if not, give stimulating glysters, and strong diuretics, such as the following balls, once in four hours: for if a horse stales not in thirty hours, his danger must be great.

**TAKE** juniper-berries powdered one ounce, sal prunella six drams, ætherial oil of turpentine half an ounce, camphor one dram, oil of juniper two drams; make into a ball with honey, and give after it three or four horns of the marshmallow decoction and honey.

Or,

**TAKE** squills powdered two or three drams, nitre half an ounce or six drams; make into a ball with honey.

If the complaint is not removed by these means, rub the horse's reins well with two parts of oil of turpentine, and one of oil of amber; and apply a poultice of garlick, horse radish, mustard-seed, camphor, and green soap, spread on thick cloth, over them. Give the horse also two drams of calomel over night, and a moderate purge the next morning. These perhaps are the chief and best remedies that can be given in this generally fatal disorder.

When the strangury in a horse does not arise from wind, or dung pressing on the neck of the bladder (as was observed in the Section on Cholicks) the cause is from inflammation, or too long a retention of the urine. Such horses make frequent motions to stale, stand wide and straddling, are full, and have their flanks distended. In this case bleed largely; give the following drink, and repeat it every two hours, for two or three times, till the horse is relieved.

**TAKE** Venice turpentine, broke with the yolk of an egg, one ounce, nitre or sal prunella six drams, half a pint of sweet oil, and a pint of white wine.

If this drink should not have the desired effect, the diu-

retic ball above mentioned may be given in the same manner, omitting the myrrh.

Give the horse plenty of the marshmallow decoction, in a quart of which dissolve an ounce of nitre and gum arabic, and two of honey.

Horses subject to a *diabetes*, or profuse staling, if old, or of a weak constitution, are seldom cured; they soon lose their flesh and appetite, grow feeble, their coat staring, and they die rotten. Of a young horse there are more hopes; but he must not be indulged with too much water, or moist food. Give him the following:

**TAKE** jesuit's bark four ounces, bistort and tormentil-root of each two ounces; boil in two gallons of lime-water to the consumption of half, and give a pint three times a-day.

As this disorder generally proceeds from too violent exercise, over-training, &c. repeated bleedings in small quantities are absolutely necessary, till the mouths of the vessels close up.

#### Of MOLTEN-GREASE.

By molten-grease is meant a fat or oily discharge with the dung, and arises from a colliquation, or melting down of the fat of a horse's body by violent exercise in very hot weather. It is always attended with a fever, heat, restlessness, starting and tremblings, great inward sickness, shortness of breath, and sometimes with the symptoms of a pleurisy. His dung will be extremely greasy, and he will fall into a scouring; his blood will have a thick skin or fat over it when cold, of a white or yellow hue, but chiefly the latter; the congealed part or sediment is commonly a mixture of size and grease, which makes it so extremely slippery, that it will not adhere to the fingers, and the small portion of serum feels also slippery and clammy. The horse soon loses his flesh and fat, which probably is dissolved and absorbed into blood; and those that survive this shock, commonly grow hide-bound for a time, their legs swelling both before and behind, and continue in this state till the blood and juices are rectified; and if this is not done effectually, the farcy, or some obdurate surfeit, generally follows, very difficult to remove.

In the first place bleed plentifully, and repeat it for two or three days successively in smaller quantities; two or three rowels should also be immediately put in, and the cooling emollient glysters (p. 547. col. 1. par. 2. from the bottom) daily thrown up to abate the fever, and drain off the greasy matter from the intestines. By the mouth give plenty of warm water or gruel, with cream of tartar or nitre, to dilute and attenuate the blood, which in this case is greatly disposed to run into grumes, and endanger a total stagnation.

When the fever is quite gone off, and the horse has recovered his appetite, gentle aloetic purges should be given once a-week, for a month or six weeks, in order to bring down the swelled legs. To this end give the following, which, repeated for some time, will entirely remove this disorder.

**TAKE** of succotrine aloes six drams, of gum guaiacum powdered

powdered half an ounce, of diaphoretic antimony and powder of myrrh of each two drams; make into a ball with syrup of buckthorn.

These will seldom take a horse from his business above two or three days in a week; neither will he lose his flesh or appetite with them, but on the contrary mend in both; which cannot be obtained by any other method of purging, and gives this greatly the preference in many cases.

#### *Of SURFEITS, MANGE, and HIDE-BOUND.*

SURFEITS arise from various causes; but are commonly the effects of some diseases not attended to, or that have been ill cured.

A horse is said to be surfeited, when his coat stares, and looks rusty and dirty, though proper means has not been wanting to keep him clean. The skin is full of scales and dander, that lies thick and mealy among the hair, and is constantly supplied with a fresh succession of the same, for want of due transpiration. Some horses have hurdles of various sizes like peas or tares; some have dry fixed scabs all over their limbs and bodies; others a moisture, attended with heat and inflammation; the humours being so sharp, and violently itching, that the horses rub so incessantly, as to make themselves raw. Some have no eruptions at all, but an unwholesome look, and are dull, sluggish and lazy; some appear only lean and hide-bound: others have flying pains and lameness, resembling a rheumatism; so that in the surfeits of horses, we have almost all the different species of the scurvy and other chronical distempers.

The following method is usually attended with success in the dry species. First take away about three or four pounds of blood, and then give the following mild purge, which will work as an alterative, and should be repeated once a week, or ten days, for some time.

**TAKE** succotrine aloes six drams or one ounce, gum guaiacum half an ounce, diaphoretic antimony and powder of myrrh of each two drams; make into a ball with syrup of buckthorn.

In the intermediate days, an ounce of the following powder should be given, morning and evening, in his feeds.

**TAKE** native cinnabar, or cinnabar of antimony, finely powdered, half a pound; crude antimony, in fine powder, four ounces; gum guaiacum, also in powder, four ounces: make into sixteen doses for eight days.

This medicine must be repeated till the horse coats well, and all the symptoms of surfeit disappear.

The wet surfeit, which is no more than a moist running scurvy, appears on different parts of the body of a horse, attended sometimes with great heat and inflammation; the neck oftentimes swells so in one night's time, that great quantities of a hot briny humour issues forth, which, if not allayed, will be apt to collect on the poll or withers, and produce the poll-evil or fistula. This disease also frequently attacks the limbs, where it proves obstinate and hard to cure: and in some horses shews itself spring and fall.

In this case bleed plentifully, avoid externally all repellents, and give cooling physic twice a week; as, four ounces of lenitive electuary, with the same quantity of cream of tartar; or the latter, with four ounces of Glauber's salts, quicked, if thought proper, with two or three drams of powder of jallap, dissolved in water-gruel, and given in a morning fasting.

After three or four of these purges two ounces of nitre made into a ball with honey may be given every morning for a fortnight; and if attended with success, repeated for a fortnight longer.

The powders above-mentioned may be also given with the horse's corn; or a strong decoction of guaiacum shavings or logwood may be given alone to the quantity of two quarts a-day. These, and indeed all alterative medicines, must be continued for a long time, where the disorder proves obstinate.

The diet should be cool and opening, as scalded bran or barley; and if the horse is hide-bound, an ounce of fenugreek seeds should be given in his feeds for a month or longer; and, as this disorder often proceeds from worms, give the mercurial physic too, and afterwards the cinnabar powders, as above directed; but as in general, it is not an original disease, but a symptom only of many, in the cure regard must be had to the first cause: thus, as it is an attendant on surfeits, fevers, worms, &c. the removal of this complaint must be variously effected.

In a mangy horse the skin is generally tawny, thick, and full of wrinkles, especially about the mane, the loins and tail; and the little hair that remains in those parts stands almost always strait out or bristly: the ears are commonly naked and without hair, the eye and eyebrows the same; and when it affects the limbs, it gives them the same aspect; yet the skin is not raw, nor peels off, as in the hot inflamed surfeit.

Where this distemper is caught by infection, if taken in time it is very easily cured: and we would recommend a sulphur ointment as most effectual for that purpose, rubbed in every day. To purify and cleanse the blood, give antimony and sulphur for some weeks after. There are a great variety of external remedies for this purpose, such as train-oil and gun-powder, tobacco steeped in chamber-lye, &c. Solleyfell recommends the following.

**TAKE** burnt alum and borax in fine powder of each two ounces. white vitriol and verdegrease powdered of each four ounces; put them into a clean pot, with two pounds of honey, stirring till they are incorporated; when cold, add two ounces of strong aqua-fortis.

But when this disorder is contracted by low feeding, and poverty of blood, the diet must be mended, and the horse properly indulged with hay and corn. The following ointments are effectually used for this disorder, rubbed into the parts affected every day.

**TAKE** powdered brimstone, train-oil, and tar, of each equal quantities; to which may be added ginger, or white hellebore.

Or,

**TAKE** sulphur vivum half a pound, crude sal armoniac one ounce, hogs lard or oil a sufficient quantity to form into an ointment.

These

These are both very powerful remedies for this disorder, and can scarce fail of success.

*Of the FARCIN or FARCY.*

THE true farcy is properly a distemper of the blood-vessels, which generally follows the tract of the veins, and, when inveterate, thickens their coats and integuments, so that they become like so many chords. We shall not describe the different sorts of farcies, seeing they are only degrees of one and the same distemper; but proceed to paint the distemper by its symptoms, which are pretty manifest to the eye.

At first, one or more small swellings, or round buds like grapes or berries, spring out over the veins, and are often exquisitely painful to the touch; in the beginning they are hard, but soon turn into soft blisters, which when broke discharge an oily or bloody ichor, and turn into very foul and ill-disposed ulcers. In some horses it appears on the head only; in some on the external jugular; in others on the plate vein, and runs downwards on the inside of the fore arm towards the knee, and very often upwards towards the brisket: in some the farcy shews itself on the hind parts, about the pasterns, and along the large veins on the inside of the thigh, rising upwards into the groin, and towards the sheath; and sometimes the farcy makes its appearance on the flanks, and spreads by degrees towards the lower belly, where it often becomes very troublesome.

When the farcy appears on the head only, it is easily cured; especially when it is seated in the cheeks and forehead, the blood-vessels being here small: but it is more difficult when it affects the lips, the nostrils, the eyes, the kernels under the jaws, and other soft and loose parts, especially if the neck-vein becomes chorded. When it begins on the outside of the shoulder or hips, the cure is seldom difficult: but when the farcy arises on the plate-vein, and that vein swells much, and turns corded, and the glands or kernels under the arm pit are affected, it is hard to cure; but more so when the crural veins within side of the thigh are corded, and beset with buds, which affects the kernels of the groin and the cavernous body of the yard. When the farcy begins on the pasterns or lower limbs, it often becomes very uncertain, unless a timely stop is put to it; for the swelling in those dependant parts grows so excessively large in some constitutions, and the limbs so much disfigured thereby with foul sores and callous ulcerations, that such a horse is seldom fit for any thing afterwards but the meanest drudgery: but it is always a promising sign, wherever the farcy happens to be situate, if it spreads no further. It is usual to affect only one side at a time; but when it passes over to the other, it shews great malignancy: when it arises on the spines, it is then for the most part dangerous, and is always more so to horses that are fat and full of blood, than to those that are in a more moderate case. When the farcy is epidemical, as sometimes happens, it rises on several parts of the body at once, forms nasty foul ulcers, and makes a profuse running of greenish bloody matter from both nostrils; and soon ends in a miserable rot.

When the farcy makes its first appearance on the head,

it rises on the cheeks and temples, and looks like a net-work, or small creeping twigs full of berries. Sometimes it inflames the eye, and sometimes little blisters or buds run along the side of the nose. It arises often on the outside of the shoulder, running along the small veins with heat and inflammation; and sometimes a few small buds appear near the withers, and on the outside of the hip. In all these appearances, the disease being superficial, and affecting only the smaller vessels, is easily conquered by the following method, when taken in time; for the simplest farcy, if neglected, may degenerate into the worst sort.

This distemper, then, being of an inflammatory nature, and in a particular manner affecting the blood vessels, must necessarily require large bleeding, particularly where the horse happens to be fat and full of blood. This always checks the beginning of a farcy, but is of small service afterwards; and if a horse is low in flesh, the loss of too much blood sometimes proves injurious. After bleeding, let the horse have four ounces of cream of tartar and lenitive electuary; which may be given every other day for a week, to cool the blood, and open the body; and then give nitre three ounces a-day for three weeks or a month, and anoint the buds and swellings with the following ointment twice a day.

TAKE ointment of elder four ounces, oil of turpentine two ounces, sugar of lead half an ounce, white vitriol powdered two drams; mix together in a gally-pot.

The buds sometimes by this method are dispersed, leaving only little bald spots, which the hair soon covers again. When they break and run, if the matter be thick and well digested, they will soon be well: but in order to confirm the cure, and to disperse some little lumps which often remain for some time on the skin without hair, give the liver of antimony for a month; two ounces a-day for a fortnight, and then one ounce a-day for the other fortnight: by following this method, a farcy which affects only the small vessels, may be stopped in a week or ten days, and soon after totally eradicated.

When the farcin affects the larger blood-vessels, the cure is more difficult; but let it always be attempted early: therefore on the plate, thigh, or neck veins appearing chorded, bleed immediately on the opposite side, and apply the following to the chorded vein.

TAKE oil of turpentine in a pint bottle six ounces, oil of vitriol three ounces; drop the oil of vitriol into the oil of turpentine by little at a time, otherwise the bottle will burst; when it has done smoking, drop in more oil of vitriol, and so on till all is mixed.

This mixture is one of the best universals in a beginning farcy; but where it is seated in loose fleshy parts, as flanks or belly, equal parts of the oil of vitriol and turpentine are necessary.

Rub the parts first with a woollen cloth; and then apply some of the mixture over the buds, and where-ever there is any swelling, twice a day. Give the cooling physic every other day, and then three ounces of nitre every day for some time.

When the farcy begins on the flanks, or towards the lower belly, it often takes its rise from a single puncture of

of a sharp spur. The pain and smarting is one sure sign to distinguish the farcy from common accidents; the flaring of the hair, which stands up like a tuft all round the buds or blisters, and the matter that issues from the buds, which is always purulent and of a clammy greasy consistence, are other certain signs. After bathing with the mixture above mentioned till the ulcers are smooth and healing, should the swelling not subside, to prevent the spreading of the buds, and to disperse them, bathe with either of these mixtures as far as the centre of the belly; and at the same time give a course of antimonials, as will presently be prescribed.

**TAKE** spirits of wine four ounces, oil of vitriol and turpentine, of each two ounces, white-wine vinegar, or verjuice, six ounces.

Or the following:

**TAKE** spirits of wine rectified four ounces, camphor half an ounce, vinegar or verjuice six ounces, white vitriol, dissolved in four ounces of spring water, one ounce; mix together.

In the lower limbs the farcy lies sometimes concealed for a great while, and makes so slow a progress, that it is often mistaken for grease, or for a blow or kick, and goes by the general appellation of a humour settled there. In order to distinguish the one from the other, we shall observe that a kick, or bruise, is generally attended with a sudden swelling, or a contused wound, which for the most part digests easily: the grease is also a smooth swelling that breaks out above the bending of the pastern backwards; but the farcy begins on the pastern joint usually with one bud, and runs upwards like a knotty crab-tree.

Very simple means have sometimes stopped it, before it has begun to spread; a poultice with bran and verjuice bound round the part, and renewed once a-day, will often alone succeed; and if proud flesh should arise, touch it with oil of vitriol, or aqua fortis, an hour before you apply the poultice; for when the distemper is local, as we suppose it here, it is to be conquered by outward applications.

When the distemper grows inveterate, and resists the above method, and the vessels continue chorded, Gibson recommends the following mixture.

**TAKE** linseed oil half a pint; oil of turpentine and salt-petre, of each three ounces; tincture of euphorbium and hellebore, of each two drams; the soldiers ointment two ounces; or oil of bays, or oil of origanum, half an ounce; double aqua fortis half an ounce: after the ebullition is over, add two ounces of Barbadoes tar.

Rub this into the chorded veins, and where-ever there is a swelling, once in two or three days; but if the orifices are choked up with proud flesh, or the skin so much thickened over the ulcers as to confine the matter, in either case it is necessary to make an open passage with a small hot iron, and destroy the proud flesh, after which it may be kept down by touching with oil of vitriol, aqua fortis, or butter of antimony. A salve may also be prepared with quicksilver and aqua fortis, rubbing any quantity of the former with enough of the latter, to the consistence of a liniment; smear the ulcers with this whenever

ver they appear foul, and you will find it preferable to most other curing medicines.

Our farriers, after opening the buds, put in usually a small quantity of corrosive sublimate or arsenic, which they call coring out the farcy; this may answer where the buds are few, and not situated near large blood-vessels, joints, or tendons: others use Roman vitriol, or sublimate and vitriol, in equal quantities: but let it be remembered, that many a horse has been poisoned by these medicines ignorantly used, and in too large quantities.

The following balls are proper in every state of the farcy; and when the distemper has been in its infancy, before the skin was much defaced, has often cured it in a week or two, by giving them only once or twice a-day: but in an old farcy they should be given for two or three months together.

**TAKE** of native cinnabar, or cinnabar of antimony, eight ounces; long birthwort and gum guaiacum powdered, of each four ounces: make into a paste with honey, and form into balls of the size of a large walnut, and roll them into liquorice powder.

The tediousness of this course has encouraged the giving of mercurials; and indeed where they are directed with skill, they must be attended with success: the stronger preparations, as the red and white precipitates, and turbith, being combined with sharp saline parts, may be hazardous and injurious; but the latter given in small quantities have been found very successful in such kind of inveterate disorders. Mr Gibson says, he has given it to a dram at a doze, where the limbs have been greatly swelled; that in forty-eight hours the sores were all dried up, and the limbs reduced; but that it made the horse so violently sick for several days, and scoured him to such a degree, that it could not be repeated.

One would have thought that the success attending this medicine so suddenly, might have encouraged Gibson to have made further trials in smaller quantities; which had he done, it is more than probable he would not have been disappointed: for the grand secret in giving mercurials as alteratives, is the introducing them into the blood, without operating on the stomach and bowels; and to do this effectually, they must be given in small quantities, and so bridled as to controul their force on the first passages; taken in this manner, they will mix gradually with the blood and juices, and operate both effectually and safely.

Dr Bracken recommends the knots and chords to be rubbed with the mercurial ointment before they break, in order to disperse them; and after breaking, to dress the sores with equal parts of Venice turpentine and quicksilver: if by these means the mouth should become sore, treat as above.—This method seems to be effectual with proper care.

The following is also recommended by the same gentleman:

**TAKE** butter of antimony and bezzar mineral, of each one ounce; beat up with half a pound of cordial ball, and give the bigness of a walnut, or three quarters of an ounce, every day for two or three weeks, falling two or three hours after it.

We shall here take notice of what is called the water-farcy, which has no resemblance to a true farcy, either in its cause, symptoms, or effects, but has only obtained this name through custom and ignorance.

This water farcy then is of two kinds; one the product of a feverish disposition, terminating on the skin, as often happens in epidemical colds; the other is dropical, where the water is not confined to the belly and limbs, but shews itself in several parts of the body by soft swellings yielding to the pressure of the finger. This last kind usually proceeds from foul feeding, or from the latter grass and fog, that often comes up in great plenty with continued cold rains, and breeds a sluggish viscid blood. In the former case, we have seen the limbs and whole body enormously swelled, and very hard, the belly and sheath greatly distended; which were as surprisingly reduced in four and twenty hours, by slight scarifications within side the leg and thigh, with a sharp penknife, and three or four strokes on the skin of the belly on each side the sheath; from these scarifications there was a constant and surprising large dripping of water, which soon relieved the horse; when a few purges completed his recovery.

In the other species of dropsy the curative intentions are to discharge the water, recover the crasis or strength of the blood, and brace up the relaxed fibres throughout the whole body. To this end, purge once a-week or ten days; and give intermediately either of the following.

**TAKE** black hellebore fresh gathered, two pounds; wash, bruise, and boil in six quarts of water, to four; and then strain out the liquor, and put two quarts of white-wine on the remaining hellebore, and let it infuse warm forty-eight hours; then strain off, mix both together, and give the horse a pint night and morning.

**TAKE** nitre two ounces, squills powdered three drams or half an ounce, camphor one dram, honey enough to form into a ball, to be given once a-day alone, or washed down with a horn or two of the above drink.

Before we close this section, it is proper to lay down the symptoms of an incurable farcy, that the owners of such horses may save themselves unnecessary expense and trouble in their endeavours to obtain a cure.

When a farcy, by improper applications, or by neglect, has spread and increased, or after long continuance resisted the medicines above recommended; if fresh buds are continually sprouting forth, while the old ones remain foul and ill conditioned; if they rise on the spines of the back and loins; if the horse grows hide bound, and runs at the nose; if abscesses are formed in the fleshy parts between the interstices of the large muscles; if his eyes look dead and lifeless; if he forsakes his food, and scours often, and his excrements appear thin and of a blackish colour; if the plate or thigh vein continues large and chorded after firing, and other proper applications: these symptoms denote the distemper to have penetrated internally, and that it will degenerate into an incurable consumption: it is most probable also, that the whole mass of fluids are tainted, and become irremediable by art.

#### OF ALTERATIVE MEDICINES.

By alteratives, or altering medicines, are to be understood such as, having no immediate sensible operation, gradually gain upon the constitution, by changing the humours or juices from a state of distemperature to health. This intention in some cases may perhaps be effected by correcting the acrimony of the juices, and accelerating the blood's motion; and in others by attenuating, or breaking its particles, and dividing those cohesions which obstruct the capillaries or finer vessels; and so promote the due secretions of the various fluids. It is certain, that many have but an indifferent opinion of a medicine that does not operate externally, and gratify their senses with a quantity of imaged humours ejected from the body: but let such people remember, that there are good humours as well as bad, which are thrown off together; that no evacuating medicine has a power of selecting, or separating the bad from the good; and consequently that they are thrown out only in a proportionate quantity. These few hints may be sufficient to convince the judicious reader of the great advantages arising from alteratives, and the preference due to them in most cases over purgatives; unless it could be proved, as already mentioned, that the latter could cull out and separate from the blood the bad humours solely, leaving the good behind; but this selective power has long been justly exploded as ridiculous and uncertain, since it is plain, that all kinds of purging medicines differ only in degree of strength, and operate no otherwise upon different humours than as they stimulate more or less.

We shall therefore take this opportunity of recommending some alterative medicines, which are not so generally known as they ought to be; and that too on the surest grounds, a proper experience of their good effects in repeated trials. The first then is nitre or purified saltpetre, which has long been in great esteem, and perhaps is more to be depended on in all inflammatory fevers than any other medicine whatever: but besides this extensive power of allaying inflammatory disorders, it is now offered as a remedy, taken in proper quantities, as an alterative for surfeits, molten-grease, hide-bound, grease-heels, &c. And as it has been known to succeed even in the cure of the farcy, what other distempers in horses, arising from vitiated fluids, may it not be tried on, with a strong probability of success? This great advantage will arise from the use of this medicine over most others, that, as its operation is chiefly by urine, it requires no confinement or cloathing; but the horse may be worked moderately throughout the whole course. This medicine has been found equally efficacious (by many trials made in one of our hospitals) in correcting the acrimony of the juices, and disposing the most obstinate and inveterate sores to heal up, and hence probably it came recommended as an alterative to our horses.

The quantity of nitre given at a time should be from two to three ounces a-day; let it be finely powdered, and then mix with it by little at a time as much honey as will

will form it into a ball; give it every morning fasting for a month; or it may be given at first for a fortnight only, intermitting a fortnight, and then repeat it. If it be observed that the horse shews an uneasiness at the stomach after taking it, a horn or two of any liquor should be given after it, or it may be dissolved at first in his water, or mixed with his corn; though the ball, where it agrees, is the easiest method of giving.

When horses take drinks with great reluctance, powders must be given in their feeds; thus crude antimony, or liver of antimony finely powdered, may be given to the quantity of half an ounce, night and morning; but in all surfeits, gum guaiacum mixed with antimony is found more efficacious. Thus,

Take of crude antimony finely powdered, or, where it can be afforded, cinnabar of antimony, and gum guaiacum, of each a pound: mix together with an oily pistle to prevent the gum's caking: divide the whole into thirty-two dozes, viz. an ounce each doze; let one be given every day in the evening feed.

Or,

Take of cinnabar of antimony, gum guaiacum, and Castile or Venice soap, of each half a pound, salt of tartar four ounces; beat them up into a mass, and give an ounce every day. To these may be added very advantageously, an ounce and an half of camphor.

Æthiops mineral given to the quantity of half an ounce a-day, is a very good sweetener and corrector of the blood and juices; but it has been observed, after having been taken a week or ten days, to make some horses flabby, and unable to chew their hay and oats; and the same symptoms have arose, where only two drams of crude mercury has been given, and continued about the same space of time.

*Diet Drinks.*—1. A decoction of logwood, prepared like that of guaiacum, is also successfully given in surfeits.

2. Lime-water, prepared with shavings of sassaparilla and liquorice, is a good diet-drink, to sweeten and correct a horse's blood; and may be given with the nitre balls for that purpose.

3. Tar-water also, as has before been hinted, may in many cases be well worth trial: but let it be remembered, that all medicines of this kind should be continued a considerable time in obstinate cases.

#### Of ROWELLING.

THERE seems to be no remedy so much made use of, and so little understood by farriers in general, as rowels; for which reason we shall endeavour to set the whole affair in a clearer light, than hitherto it has appeared in.

We shall begin then by describing rowelling, which is an artificial vent made between the skin and flesh, in order to unload and empty the vessels in general, and thereby relieve particular parts, when too much oppressed by a fulness or redundancy.

The general and absurd reasoning of farriers on the effects and use of rowelling, in some measure makes this section the more necessary, as it is too notorious how

impertinently they talk on this subject: for in short, with them, a rowel is to draw off all the bad and corrupt humours from the blood by a sort of magic.

It is necessary to observe, that the matter generally discharged by a rowel, is nothing more than an ouzing from the extremities of the vessels divided in the making of it; in fact then, it is blood, which loses its colour, by being shed out of the vessels, the warmth of the part, and its confinement.

If this is granted, it will evidently appear, that the good effects ensuing this operation, must be owing to a gradual depletion or emptying of the vessels in general; by which means the surcharge or load on a particular part, is taken off and removed, and impurities or bad juices (generally called humours) run off with the good in proportion to their quantity in the blood.

Thus, to lean hide-bound horses, and those of a dry hot constitution, the discharge, by depriving the constitution of so much blood and fluids, is daily exhausting the strength of the animal; and may be productive of bad consequences, by defrauding the constitution of a necessary fluid.

But in disorders from fulness, attended with acrimony, or sharpness of the juices, and with desfluxions on the eyes, lungs, or any part of consequence; the gradual discharge, brought on by these means, will contribute to lessen the fulness on the parts affected, and give the vessels an opportunity of recovering their tone, while evacuating and alterative medicines are doing their office.

It may be necessary, however, to observe, that there is a wonderful communication between the vessels of the cellular membrane under the skin, which remarkably appears, by inflating those of sheep, calves, &c. by the butchers; hence probably it is that some disorders of this integument, are so apparently relieved by issues, or rowels, without our having any recourse to that general depletion of the vessels, we have just observed, to account for it; and hence also may be deduced their utility, sometimes in draining off any extravasated fluids, which may lodge between the interstices of the muscles, after violent strains of the shoulder; also in discharging such vitious or sharp fluids as are thrown on the membranes, and occasion those flying pains and lamenesses, which we find are often removed by this local remedy.

#### Of STRAINS in VARIOUS PARTS.

IT is necessary to observe, that in all strains, the muscular or tendinous fibres are overstretched; and sometimes ruptured, or broke. To form therefore a true idea of these disorders, let us first consider every muscle and tendon as composed of springy elastic fibres, which have a proper power of their own to contract and extend themselves; or, to make their action more familiar, let us compare them to a piece of catgut, that we may the better judge with what propriety oily medicines are directed for their cure. Thus then, if by a violent extension of this catgut, you had so overstretched it as to destroy its springiness or elasticity, and was inclined to recover its lost tone; would you for that purpose think of soaking it in oil? And is not the method of treating strains, or over-stretched

stretched muscles and tendons, full as preposterous, when you bathe or soak them in oily medicines, at a time that they want restringents to brace them up? Yet custom has so established this practice, and fallacious experience seemingly so confirmed it, that it would be a difficult task to convince the illiterate and prejudiced of the absurdity, who, by attributing effects to wrong causes, are led into this error, and the oils usurp the reputation that is due only to rest and quiet: they seem, however, to be aware of the ill consequences, by their adding the hot oils, as spike, turpentine, and origanum; which, though they in some measure guard against the too suppling quality of the other oils, yet the treatment is still too relaxing to be of real service.

And indeed, in all *violent* strains of either tendons or muscles, whatever opinion we may entertain of bathing and anointing with favourite nostrums, which often succeed in slight cases, where perhaps bandage alone would have done; yet it is the latter, with proper resting the relaxed fibres, till they have thoroughly recovered their tone, that are the chief things to be depended on; and frequently some months are necessary for effecting the cure.

All violent strains of the ligaments, which connect the bones together, especially those of the thigh, require time, and turning out to graze, to a perfect recovery. External applications can avail but little here, the parts affected lying too deep, and so surrounded with muscles that medicine cannot penetrate to them. The sooner, in these cases, a horse is turned out to graze, the better; as the gentle motion in the field will prevent the ligaments and joint oil from thickening, and of course the joint itself from growing stiff.

When a horse's shoulder is overstrained, he does not put out that leg as the other; but to prevent pain, sets the sound foot hardly on the ground to save the other; even though he be turned short on the lame side, which motion tries him the most of any. When trotted in hand, instead of putting his leg forward in a right line, he forms a circle with the lame leg; and when he stands in the stable, that leg is advanced before the other.

In order to cure this lameness, first bleed him, and let the whole shoulder be well bathed three times a day with hot verjuice or vinegar, in which may be dissolved a piece of soap; but if the lameness continues without swelling, or inflammation, after resting two or three days, let the muscles be well rubbed for a considerable time, to make them penetrate, with good opodeldoch, or either of the following mixtures:

TAKE camphorated spirit of wine, two ounces; oil of turpentine, one ounce; this proportion will prevent the hair coming off.

Or,

TAKE the best vinegar, half a pint; spirit of vitriol, and camphorated spirit of wine, of each two ounces.

When the shoulder is very much swelled, it should be fomented with woollen cloths (large enough to cover the whole) wrung out of hot verjuice and spirit of wine; or a fomentation prepared with a strong decoction of wormwood, bay-leaves, and rosemary, to a quart of which may be added half a pint of spirit of wine.

A towel in the point of the shoulder in this case often

does great service; especially if the strain has been very violent, and the swelling very large: but as to boring up the shoulder with a hot iron, and afterwards inflating it, is both a cruel and absurd treatment; and the pegging up the sound foot, or setting on a patten-shoe, to bring the lame shoulder on a stretch, is a most preposterous practice, and directly calculated to render a horse incurably lame; for it can only be necessary in cases the very opposite to this, where the muscles have been long contracted, and we want to stretch them out.

Where poultices can be applied, they are at first undoubtedly very effectual, after bathing with hot vinegar or verjuice, and are to be preferred greatly to cold charges, which, by drying so soon on the part, keep it stiff and uneasy: let them be prepared with oat-meal, rye-flour, or bran boiled up in vinegar, strong beer or red-wine lees, with lard enough to prevent their growing stiff; and when by these means the inflammation and swelling is brought down, bathe the part twice a-day with either of the above mixtures, opodeldoch, or camphorated spirit of wine; and roll the part three or four inches, both above and below, with a strong linen roller, of about two fingers width; which contributes not a little to the recovery, by bracing up the relaxed tendon; and perhaps is more to be depended on than the applications themselves.

In strains of the *coffin joint*, that have not been discovered in time, there will grow such a stiffness in the joint, that the horse will only touch the ground with his toe; and the joint cannot be played with the hand; the only method here is repeated blistering, and then firing superficially.

Strains of the *back sinews* are very common, and are easily discovered by the swelling, which extends sometimes from the back-side of the knee down to the heel, but for the most part the horse sets that leg before the other. The tendon should be well bathed three or four times a-day with hot vinegar; and if much swelled, apply the poultices above recommended; and when the swelling is down, bathe with the mixtures above, or with camphorated spirit of wine and oil of amber, in which is dissolved as much camphor as the spirits will take up, and roll up the tendon with a proper bandage, or laced stocking; which last, properly fitted to the limb, might be wore to great advantage, not only in these sort of injuries, but in most others, where there is a disposition to the grease, or other swellings of the limbs, from weak and relaxed fibres. Carriers shavings wetted with vinegar have been found useful for this purpose; as has also tar and spirit of wine: but where the tendons have suffered by repeated injuries of this kind, the case will demand blistering, firing, and proper rest.

Strains of the *knees* and *pasterns* arise frequently from kicks or blows; if they are much swelled, apply first the poultices; and when the swelling is abated, bathe with the above, or the following.

TAKE vinegar, one pint; camphorated spirits of wine, four ounces; white vitriol, dissolved in a little water, two drams.

Or,

TAKE the white of three or four eggs, beat them into a froth with a spoon; to which add an ounce of rock

rock allum, finely powdered; spirit of turpentine, and wine, of each half an ounce; mix them well together.

As great weakness remains in the pasterns after violent strains, the best method is to turn the horse out to graze till he is perfectly recovered; when this cannot be complied with, the general way is to blister and fire.

When a horse is lame in the *stifle*, he generally treads on his toe, and cannot set the heel to the ground. Treat him at first with the vinegar and cooling retringents; but if a large swelling, with puffiness, ensues, foment it well with the discutient fomentation till it disperses; and then bathe the part with any of the above medicines.

A lameness in the *wheel-bone* and hip, is discovered by the horse's dragging his leg after him, and dropping backward on his heel when he trots. If the muscles of the hip are only injured, this kind of lameness is cured easily; but when the ligaments of the joint are affected, the cure is often very difficult, tedious, and uncertain. In either case, at first bathe the parts well with the cooling medicines, four or five times a-day; in the muscular strain, this method alone may succeed; but in the ligamentous, it is rest and time only can restore the injured parts to their proper tone.

Strains in the *hock* are to be treated by soaking the parts with coolers and repellers; but when the ligaments are hurt, and they are attended with great weakness and pain, use the fomentation. If a hardness should remain on the outside, it may be removed by repeated blistering; if within, it may be out of the power of any external applications to remove; however, the joint should be fired gently with small razes or lines pretty close together, and then covered with a mercurial plaster. To the discutient fomentation above mentioned may be added crude sal armoniac, with a handful of wood-ashes boiled in it.

The blistering ointment for the above purposes may be found in the Section of Bone-spavin; but the sublimate should be omitted.

The *firing*, used for the strengthening relaxed sinews or tendons, should act only on the skin, which, by contracting and hardening it all round the sinews, compresses them more firmly like a bandage. The bow-men of old submitted to this operation, in order to give strength to the muscles and tendons of their arms. A proper degree of skill is very requisite to perform it effectually on a horse; for a due medium should be observed, and the instrument neither so slightly applied, as to scarify the skin only superficially, nor so deep as to wound or cauterize the sinew or its sheath. The lines should be drawn pretty close together, on each side of the joint or sinew, following the course of the hair; no cross lines should be made, as they but disfigure the horse afterwards, without any real use. The firing instrument, or knife, ought to be a little rounded on the edge, gradually thickening to the back, that it may retain the heat for some time, but should not be applied till the flaming redness is partly gone off. The cauterized parts may be bathed with spirit of wine at first, and anointed afterwards with bees-wax and oil, which alone is sufficient to complete the cure.

### OF TUMOURS and IMPOSTHUMES.

TUMOURS, or swellings, arise either from external injuries, or internal causes.

Swellings, caused by external accidents, as blows and bruises, should at first be treated with retringents; thus, let the part be bathed frequently with hot vinegar or verjuice, and, where it will admit of bandage, let a flannel wetted with the same be rolled on: if by this method the swelling does not subside, apply, especially on the legs, a poultice with red-wine lees, strong-beer grounds, and oatmeal, or with vinegar, oil, and oatmeal; either of these may be continued twice a-day, after bathing, till the swelling abates: when, in order to disperse it entirely, the vinegar should be changed for camphorated spirit of wine, to four ounces of which may be added one of spirit of sal armoniac; or it may be bathed with a mixture of two ounces of crude sal armoniac boiled in a quart of chamber-lye, twice a day, and rags dipped in the same may be rolled on.

Fomentation made by boiling worm-wood, bay-leaves, and rosemary, and adding a proper quantity of spirits, are often of great service to thin the juices, and fit them for transpiration; especially if the injury has affected the joints.

But in bruises, where the extravasated blood will not by these means be dispersed, the shortest way is to open the skin, and let out the grumes.

Critical tumours, or swellings, which terminate fevers, should by no means be dispersed; except when they fall on the pastern or coffin joint, so as to endanger them: in this case the discutient fomentation, (p. 568. col. 1. bottom) should be applied three or four times a-day, and a cloth or flannel frequently wrung out of the same should be bound on, in order to keep the joint continually breathing.

But if the swelling fixes under the jaws, behind the ears, on the poll, withers, or in the groins and sheath, &c. it should be encouraged and forwarded by ripening poultices where-ever they can be applied; oatmeal boiled soft in milk, to which a proper quantity of oil and lard is added, may answer this purpose; or the poultice recommended in the Section of Strangles: these must be applied twice a-day, till the matter is perceived to fluctuate under the fingers, when it ought to be let out; for which purpose, let the tumour be opened with a knife or strong lancet, the whole length of the swelling, if it can be done safely; for nothing contributes so much to a kind healing, as the matter's having a free discharge, and the openings being big enough to dress to the bottom.

Pledgets of tow, spread with black or yellow basilicon (or the wound ointment) and dipped in the same, melted down with a fifth part of oil of turpentine, should be applied to the bottom of the sore, and filled up lightly with the same, without cramming; it may be thus dressed once or twice a-day, if the discharge is great, till a proper digestion is procured, when it should be changed for pledgets spread with the red precipitate ointment, applied in the same manner.

Should the sore not digest kindly, but run a thin water and look pale, foment, as often as you dress, with the above fomentation; and apply over your dressing the strong-beer poultice, and continue this method till the matter grows thick, and the sore florid.

The following ointments will generally answer your expectations in all common cases, and may be prepared without, as well as with, the verdegrease.

**Take** Venice turpentine and bees-wax of each a pound, oil of olives one pound and a half, yellow rosin twelve ounces; when melted together, two or three ounces of verdegrease, finely powdered, may be stirred in, and kept so till cold, to prevent its subsiding.

**Take** of yellow basilicon, or the above ointment, without verdegrease, four ounces; red precipitate, finely powdered, half an ounce: mix them together cold with a knife or spatula.

This last, applied early, will prevent a fungus, or proud flesh, from shooting out; for if you dress too long with the above digestive, the fungus will rise fast, and give some trouble to suppress it; when it will be necessary to wash the sore as often as you dress, with a solution of blue vitriol in water, or to sprinkle it with burnt alum and precipitate. If these should not be powerful enough, touch with a caustic, or wash with the sublimate water, made by dissolving half an ounce of corrosive sublimate in a pint of lime-water.

But this trouble may in a great measure be prevented, if the sore is on a part where bandages can be applied with compresses of linen cloth: for even when these excrescences regerminate, as it were under the knife, and spring up in spite of the caustics above mentioned, they are to be subdued by moderate compression made on the sprouting fibres, by these means.

Authors on farriery have given in general very proper receipts to answer every intention of this kind by medicines; but as they have not laid down sufficient rules for their application in those cases where they are most wanted, the following general directions will not be unacceptable; as the difficulty in healing some kinds of sores arises frequently from the unskilful manner of dressing them.

It may be necessary then to observe here, once for all, that the cures of most sores are affected by the simplest methods, and that it is often of much more consequence to know how to dress a sore, than what to dress it with; and in this consists indeed the chief art of this branch of surgery; for the most eminent in that profession have long since discovered, that variety of ointments and salves are unnecessary in the cure of most wounds and sores, and they have accordingly discarded the greatest part, formerly in repute for that purpose; repeated observations having taught them, that after the digestion, nature is generally disposed to heal up the wound fast enough herself, and that the surgeon's chief care is to prevent a luxuriancy, commonly called proud flesh; which all ointments, wherein lard or oil enters, are but too prone to encourage, as they keep the fibres too lax and supple; and which dry lint alone, early applied, as easily prevents, by its absorbing quality, and light compression on the sprouting fibres.

Thus, if a hollow wound or sore is crammed with tents, or the dressings are applied too hard, the tender shoots of flesh from the bottom are prevented pushing up; and the sides of the sore in time from this distension may grow horny, and turn fistulous; nor has the matter by this method a free discharge.

On the other hand, if sores of any depth are dressed superficially, the external parts being more disposed to heal and come together than the internal, they will fall into contact, or heal too soon; and the sore, not filling up properly from the bottom, will break out afresh.

Hence we may justly conceive how little stress is to be laid on famous ointments, or family salves, unskilfully applied; for unless this due medium is observed, or obtained in the dressing, no hollow sore can heal up properly.

As soon then as a good digestion is procured (which is known by the thickness and whiteness of the matter discharged, and the florid red colour at the bottom of the sore) let the dressings be changed for the precipitate medicine; or the sore may be filled up with dry lint alone, or dipped in lime-water with a little honey and tincture of myrrh, or brandy, about a fifth part of the latter to one of the former; a pledget of lint dipped in this mixture should also be applied to the bottom of the sore, which should be filled up with others to the surface or edges, but not crammed in too hard, as before observed, nor yet applied too loosely.

By this method, the sore would incarn, or heal up properly, and soft spongy flesh would be prevented, or suppressed in time; whereas when ointments or salves are too long continued, a fungus, or proud flesh, is thereby so encouraged in its growth, that it requires some time to destroy and eat it down again: a proper compress of cloth, and a linen roller, is absolutely necessary both for this purpose, and to secure on the dressings, where ever they can conveniently be applied.

#### *Of Wounds in General.*

In all fresh wounds made by cutting instruments, there is nothing more required than bringing the lips of the wound into contact by suture or bandage, provided the part will allow of it; for on wounds of the hips, or other prominent parts, and across some of the large muscles, the stitches are apt to burst on the horse's lying down and rising up in the stall; in such cases the lips should not be brought close together: one stitch is sufficient for a wound two inches long; but in large wounds, they should be at an inch or more distance; and if the wound is deep in the muscles, care should be taken to pass the needles proportionably deep, otherwise the wound will not unite properly from the bottom.

Should the wound bleed much from an artery divided, the first step should be to secure it, by passing a crooked needle underneath, and tying it up with a waxed thread: if the artery cannot be got at this way, apply a button of lint or tow to the mouth of the bleeding vessel, dipped in a strong solution of blue vitriol, styptic water, oil of vitriol, or hot oil of turpentine, powdered vitriol, or colcothar, &c. and remember always to apply it close to the mouth of the bleeding vessels,

vessels, and take care that it is kept there by proper compress and bandage, till an eschar is formed; otherwise it will elude your expectations, and frequently alarm you with fresh bleedings.

In a memoir presented to the Royal Academy of Sciences by M. La Fosse, he gives an account of the success he had met with in stopping the bleedings of very considerable arteries in horses, by the application of the powder of puff balls, the arteries cicatrizing by this means only, without any succeeding hæmorrhage. This Lycoperdon, or puff-ball, was made use of for this purpose in human subjects, about 160 years ago, by Felix Wurtz, a famous old surgeon in Germany; but he does not seem to have a thought of trussing to it in such considerable arteries as M. La Fosse mentions, viz. those of the leg and thigh, the bleedings from which divided vessels he stopt in a few minutes by the use of this powder only. The agaric of the oak may also be used for this purpose, where it can be retained by a proper bandage.

These applications, as indeed all styptics, seem to act by constringing the extremity of the vessel, or choaking it up, till a grume of blood is formed internally, which plugs up the orifice; and has been found to adhere to it so, as to constitute one body with the vessel.

We avoid setting down any famous receipts for fresh wounds, whether ointments, or Fryar's balsams, being well assured, that in a healthy sound constitution, nature furnishes the best balsam, and performs herself the cure, which is so often attributed to the medicine; when it is otherwise, and the blood is deprived of its balsamic state, as will appear from the aspect of the wound, and its manner of healing, it must be rectified by proper internal medicines, before a good foundation for healing can be laid by any external applications whatever.

The lips of the wound when being brought together by the needle or bandage, it needs only to be covered with rags dipped in brandy, or a pledget of tow spread with the wound ointment, (see p. 570. col. 1. par. 3.) the directions in the preceding sections being observed, and the wounded part kept as much as possible from motion.

Punctured wounds from thorns, or any other accidents, should be treated in the same manner; applying the beer, or bread and milk poultice over the dressing, till some signs of digestion appear; and fomenting the part well every day. This method is also very successfully used to those swellings, which often arise on the neck from bleeding, the sores being sprinkled with precipitate, and burnt alum powdered, to fetch out the core, or fungus, which choaks up the orifice. The usual method is to introduce a piece of vitriol, or sublimate, which often brings on a plentiful discharge, fetches out the core, and makes a cure; but it is often with the loss of the vein, and it sometimes leaves a large swelling and imposthumation.

In gun-shot wounds, when the ball has not penetrated too deep, it should be extracted, if it can be fetched away without disturbance, together with any extraneous bodies that might pass in with it; the wound should be dressed with the old digestive of Venice or common turpentine, divided with the yolks of eggs, to which may be added some honey and tincture of myrrh. The entrance of these wounds frequently requires to be enlarged, and

a depending orifice should always be procured if possible; and if the wound should not digest kindly, apply the beer poultice, and foment with the discutient fomentation, p. 569. col. 2. par. 3.

In scalds, or burns from gun-powder, or any other cause, when the skin remains entire, bathe the part well, and keep it soaked with rags dipped in spirit of wine camphorated: salt bound thick on the part has been found very effectual for this purpose: and indeed all saline and spirituous applications excel others, while the skin is yet unbroke; but when the skin is separated, anoint the part, and keep it constantly supple with linseed or sallad oil, and a plaister spread with bees-wax and oil; if the skin is so scorched, that sloughs must be digested out, dress with the wound ointment and oil of turpentine, and finish the cure with any drying ointment. Should the horse be feverish from the pain, bleed him, give cooling glysters, and treat him as we have directed in simple fevers.

### *Of Ulcers in General.*

WE shall not here enter into a description of each particular species of ulcers, but only lay down some directions for their general treatment; by which means we shall avoid the usual proximity of authors on this subject, and yet give so general an idea of the nature of ulcers, as we hope will be sufficiently instructive both of the application and of the proper remedy to each.

It may be necessary to observe, that we may often in vain pursue the best methods of cure by external applications, unless we have recourse to proper internal remedies; for as all ulcers, difficult to heal, proceed from a particular indisposition of the blood and juices, before the former can be brought into any order, the latter must be corrected by alteratives and sweetening medicines.

The first intention in the cure of ulcers is bringing them to digest, or discharge a thick matter; which will, in general, be effected by the green ointment, or that with precipitate; but should the sore not digest kindly by these means, but discharge a gleety thin matter, and look pale, you must then have recourse to warmer dressings, such as balsam, or oil of turpentine, melted down with your common digestive, and the strong beer poultice over them; it is proper also in these kind of sores where the circulation is languid, and the natural heat abated, to warm the part, and quicken the motion of the blood, by fomenting it well at the time of dressing; which method will thicken the matter, and rouse the native heat of the part, and then the former dressings may be re applied.

If the lips of the ulcer grow hard or callous, they must be pared down with a knife, and afterwards rubbed with the caustic.

Where soft fungous flesh begins to rise, it should carefully be suppressed in time, otherwise the cure will go on but slowly; if it has already sprouted above the surface, pare it down with a knife, and rub the remainder with a bit of caustic; and, to prevent its rising again, sprinkle the sore with equal parts of burnt alum, and red precipitate; or wash with the sublimate water, and dress with dry lint even to the surface, and then roll over a compress of linen as tight as can be borne; for a proper degree of pressure,

pressure, with mild applications, will always oblige these spongy excrescences to subside, but without bandage the strongest will not so well succeed.

All sinuses, or cavities, should be laid open as soon as discovered, after bandages have been ineffectually tried; but where the cavity penetrates deep into the muscles, and a counter opening is impracticable or hazardous; where, by a continuance, the integuments of the muscles are constantly dripping and melting down; in these cases injections may be used, and will frequently be attended with success. A decoction of colcothar boiled in forge-water; or solution of lapis medicamentosus in lime water, with a fifth part of honey and tincture of myrrh, may be first tried, injected, three or four ounces twice a day; or some resin melted down with oil of turpentine, may be used for this purpose: if these should not succeed, the following, which is of a sharp and caustic nature, is recommended on Mr Gibson's experience.

TAKE of Roman vitriol half an ounce; dissolve in a pint of water: then decant and pour off gently into a large quart-bottle: add half a pint of camphorated spirit of wine, the same quantity of the best vinegar, and two ounces of *Egyptiacum*.

This mixture is also very successfully applied to ulcerated greasy heels, which it will both cleanse and dry up.

These sinuses, or cavities, frequently degenerate into *fistule*, that is, grow pipey, having the inside thickened, and lined, as it were, with a horny callous substance. In order to their cure, they must be laid open, and the hard substance all cut away; where this is impracticable, scarify them well, and trust to the precipitate medicine made strong, rubbing now and then with caustic, butter of antimony, or equal parts of quicksilver and aquafortis.

When a rotten or foul bone is an attendant on an ulcer, the flesh is generally loose and flabby, the discharge oily, thin, and stinking, and the bone discovered to be carious, by its feeling rough to the probe passed through the flesh for that purpose. In order to a cure, the bone must be laid bare, that the rotten part of it be removed; for which purpose, destroy the loose flesh, and dress with dry lint; or the drossils may be pressed out of tincture of myrrh or euphorbium: the throwing off the scale is generally a work of nature, which is effected in more or less time, and in proportion to the depth the bone is affected; though burning the foul bone is thought by some to hasten its separation.

Where the cure does not properly succeed, mercurial physic should be given, and repeated at proper intervals: and to correct and mend the blood and juices, the antimonial and alterative powders, with a decoction of guaiacum and lime-waters, are proper for that purpose.

#### Of a BONE-SPAVIN.

WITHOUT entering at all into the cause of this disorder, which is a bony excrescence, or hard swelling, growing on the inside of the hock of a horse's leg, we shall content ourselves with describing the different kinds thereof, by their symptoms; and then enter on their cure.

A spavin, that begins on the lower part of the hock,

is not so dangerous as that which puts out higher, between the two round processes of the leg bone; and a spavin near the edge is not so bad as that which is more inward toward the middle, as it does not so much affect the bending of the hock.

A spavin, that comes by a kick or blow, is at first no true spavin, but a bruise on the bone, or membrane which covers it; therefore not of that consequence, as when it proceeds from a natural cause: and those that put out on colts, and young horses, are not so bad as those that happen to horses in their full strength and maturity; but in very old horses they are generally incurable.

The usual method of treating this disorder is by blisters and firing, without any regard to the situation, or cause whence it proceeds. Thus, if a fulness on the fore-part of the hock comes upon hard riding, or any other violence, which threatens a spavin; in that case, such coolers and repellers are proper, as are recommended in strains and bruises. Those happening to colts and young horses are generally superficial, and require only the milder applications; for it is better to wear them down by degrees, than to remove them at once by severe means.

Various are the prescriptions for the blistering ointment; but the following, on proper experience, stands well recommended by Mr Gibson.

TAKE nerve and marsh mallow ointment, of each two ounces; quicksilver, one ounce, thoroughly broke with an ounce of Venice turpentine: Spanish flies powdered, a dram and a half; sublimate, one dram; oil of origanum, two drams.

The hair is to be cut as close as possible, and then the ointment applied pretty thick over the part; this should be done in the morning, and the horse kept tied up all day without any litter till night; when he may be untied, in order to lie down; and a pitch or any sticking plaister may be laid over it, and bound on with a broad tape or bandage to keep all close.

After the blister has done running, and the scabs begin to dry and peel off, it may be applied a second time, in the same manner as before; this second application generally taking greater effect than the first, and in colts and young horses makes a perfect cure.

When the spavin has been of long standing, it will require to be renewed, perhaps, five or six times; but after the second application, a greater distance of time must be allowed, otherwise it might leave a scar, or cause a baldness; to prevent which, once a fortnight or three weeks is often enough; and it may in this manner be continued six or seven times, without the least blemish, and will generally be attended with success.

But the spavins that put out on older, or full-aged horses, are apt to be more obstinate, as being seated more inward; and when they run among the sinuosities of the joint, they are for the most part incurable, as they then lie out of the reach of applications, and are arrived to a degree of impenetrable hardness.

The usual method in these cases is to fire directly, or to use the strongest kind of caustic blisters; and sometimes to fire and lay the blister immediately over the part; but this way seldom succeeds farther than putting a stop

to the growth of the spavin, and is apt to leave both a blemish and stiffness behind; besides the great risk run (by applications of these fiery and caustic medicines to the nervous and tendinous parts about the joints) of exciting violent pain and anguish, and destroying the limb.

The best and safest way therefore, is to make trial of the blistering ointment above, and to continue it according to the directions there laid down, for some months, if found necessary; the horses in the intervals working moderately: the hardness will thus be dissolved by degrees, and wear away insensibly.

Where the spavin lies deep, and runs so far into the hollow of the joint, that no application can reach it, neither firing nor medicines can avail, for the reasons above-mentioned; though bold ignorant fellows have sometimes succeeded in cases of this sort (by men of judgment deemed incurable) by the application of caustic ointments with sublimate, which act very forcibly, enter deep, and make a large discharge, and by that means destroy a great part of the substance, and dissolve away the remainder: Tho', whoever is at all acquainted with the nature of these medicines, must know how dangerous in general their operation is on these occasions; and that a proper prepared cautery made like a fleam, under the direction of a skilful hand, may be applied with less danger of injuring either tendons or ligaments. After the substance of the swelling has been properly penetrated by the instrument, it must be kept running by the precipitate medicine, or mild blistering ointment. Where the spavin lies not deep in the joint, and the blistering method will not succeed, the swelling may be safely fired with a thin iron forced pretty deep into the substance, and then should be dressed, as is above directed.

#### Of a CURB and RING-BONE.

As a spavin rises among the bones on the fore-part of the hock, so a curb takes its origin from the junctures of the same bones, and rises on the hind-part, forming a pretty large tumour over the back part of the hind-leg, attended with stiffness, and sometimes with pain and lameness.

A curb proceeds from the same causes that produce spavins; viz. hard riding, strains, blows, or kicks. The cure at first is generally easy enough effected by blistering, repeated two or three times, or oftener. If it does not submit to this treatment, but grows excessively hard, the quickest and surest way is to fire with a thin iron, making a line down the middle from top to bottom, and drawing several lines in a penniform manner pretty deep; and then to apply a mild blistering plaister or ointment over it.—This method will entirely remove it.

There is another swelling taken notice of on the outside of the hock, which is called a *jardon*. This commonly proceeds from blows and kicks of other horses; but frequently happens to menaged horses, by setting them on their haunches: it is seldom attended with much lameness, unless it has been neglected, or some little process of the bone be broke. It should first be treated with the coolers and repellers in (p. 574 and 575.); but if any swelling continues hard, and insensible, the best way is to blister or fire; but the mild blisters alone generally succeed.

The *ring-bone* is a hard swelling on the lower part of the pastern, which generally reaches half-way round the fore-part thereof, and from its resemblance to a ring has its denomination. It often arises from strains, &c. and when behind, from putting young horses too early upon their haunches; for in that attitude a horse throws his whole weight as much, if not more, upon his pasterns, than on his hocks.

When it appears distinctly round the pastern, and does not run downwards toward the coronet, so as to affect the coffin-joint, it is easily cured; but if it takes its origin from some strain or defect in the joint originally, or if a callosity is found under the round ligament that covers that joint, the cure is generally dubious, and sometimes impracticable; as it is apt to turn to a quittor, and in the end to form an ulcer upon the hoof.

The ring-bones that appear on colts and young horses, will often insensibly wear off of themselves, without the help of any application; but when the substance remains, there needs no other remedy besides blistering, unless when by long continuance it is grown to an oblongate hardness, and then it may require both blistering and firing.

To fire a ring-bone successfully, let the operation be performed with a thinner instrument than the common one, and let the lines or razes be made not above a quarter of an inch distant, crossing them obliquely, somewhat like a chain: apply a mild blister over all, and, when quite dried up, the rupture-plaister; and then turn the horse to graze for some time.

#### Of SPLENTS.

THESE are hard excrescences that grow on the shank-bone, and are of various shapes and sizes. Some horses are more subject to splents than others; but young horses are most liable to these infirmities, which often wear off and disappear of themselves. Few horses put out splents after they are seven or eight years old, unless they meet with blows or accidents.

A splent that arises in the middle of the shank-bone is no ways dangerous; but those that arise on the back part of this bone, when they grow large and press against the back sinew, always cause lameness or stiffness, by rubbing against it: the others, except they are situated near the joints, seldom occasion lameness.

As to the cure of splents, the best way is not to meddle with them, unless they are so large as to disfigure a horse, or are so situated as to endanger his going lame.

Splents in their infancy, and on their first appearance, should be well bathed with vinegar, or old verjuice; which, by strengthening the fibres, often put a stop to their growth: for the membrane covering the bone, and not the bone itself, is here thickened: and in some constitutions purging, and afterwards diuretic drinks, will be a great means to remove the humidity and moisture about the limbs, which is what often gives rise to such excrescences.

Various are the remedies prescribed for this disorder; the usual way is to rub the splent with a round stick or the handle of a hammer, till it is almost raw, and then touch it with oil of origanum. Others lay on a pitch-plaister,

plaster, with a little sublimate, or arsenic, to destroy the substance: some use oil of vitriol; some tincture of cantharides: all which methods have at times succeeded; only they are apt to leave a scar with the loss of hair. Those applications that are of a more caustic nature, often do more hurt than good, especially when the splent is grown very hard, as they produce a rottenness, which keeps running several months before the ulcer can be healed, and then leaves an ugly scar.

Mild blisters often repeated, as recommended in the section upon the *Bone-Spavin*, should first be tried as the most eligible method, and will generally succeed, even beyond expectation: but if they fail, and the splent be near the knee or joints, you must fire and blister in the same manner as for the bone-spavin.

Splents on the back part of the shank-bone are difficult to cure, by reason of the back sinews covering them: the best way is to bore the splent in several places with an iron not very hot; and then to fire in the common way, not making the lines too deep, but very close together.

#### *Of the POLL-EVIL.*

THE poll-evil is an abscess near the poll of a horse, formed in the sinuses between the poll-bone, and the uppermost vertebrae of the neck.

If it proceeds from blows, bruises, or any external violence, at first bathe the swelling often with hot vinegar; and if the hair be fretted off with an ouzing through the skin, make use of two parts of vinegar, and one of spirit of wine; but if there be an itching, with heat and inflammation, the safest way is to bleed, and apply poultices with bread, milk, and elder-flowers: this method, with the assistance of physick, will frequently disperse the swelling, and prevent this evil.

But when the tumour is critical, and has all the signs of matter, the best method then is to forward it by applying the ripening poultices already taken notice of, till it comes to maturity, and bursts of itself; or if opened with a knife, great care should be taken to avoid the tendinous ligament that runs along the neck under the mane: when matter is on both sides, the opening must be made on each side, and the ligament remain undivided.

If the matter flows in great quantities, resembles melted glue, and is of an oily consistence, it will require a second incision, especially if any cavities are discovered by the finger or probe; these should be opened by the knife, the orifices made depending, and the wound dressed with the common digestive of turpentine, honey, and tincture of myrrh, and, after digestion, with the precipitate ointment; or wash the sore with the following, made hot, and fill up the cavity with tow soaked in it.

TAKE vinegar or spirit of wine half a pint, white vitriol dissolved in spring-water half an ounce, tincture of myrrh four ounces.

This may be made sharper by adding more vitriol; but if the flesh is very luxuriant, it should first be pared down with a knife before the application; with this wash alone Mr Gibson has cured this disorder without any other formality of dressing, washing with it twice a-day, and

laying over the part a quantity of tow soaked in vinegar and the white of eggs beat together.

But the most compendious method of cure, is found by observation to be by *scalding*, as the farriers term it; and is thus prosecuted when the sore is foul, of a bad disposition, and attended with a profusion of matter.

TAKE corrosive sublimate, verdegrease in fine powder, and Roman vitriol, of each two drams; green copperas half an ounce, honey or *Ægyptiacum* two ounces, oil of turpentine and train oil of each eight ounces, rectified spirit of wine four ounces; mix together in a bottle.

The manner of scalding is first to clean the abscess well with a piece of sponge dipped in vinegar; then put a sufficient quantity of the mixture into a ladle with a spout, and when it is made scalding hot, pour it into the abscess, and close the lips together with one or more stitches. This is to remain in several days; and if good matter appears, and not in an over great quantity, it will do well without any other dressing, but bathing with spirit of wine; if the matter flows in great abundance, and of a thin consistence, it must be scalded again, and repeated till the matter lessens and thickens.

#### *Of a FISTULA, and BRUISES on the WITHERS; WARBLER on the Back, and SIT-FASTS.*

BRUISES on the withers frequently imposthume, and for want of care turn fistulous. They arise often from pinches of the saddle, and should be treated with repellents: for this purpose bathe the tumour well with hot vinegar three or four times a day; if that does not succeed alone, an ounce of oil of vitriol may be put to a quart of vinegar, or half an ounce of white vitriol dissolved in a little water, and added to the same quantity. These are generally very effectual repellents for this purpose in horses, and will frequently prevent imposthumation: when the swelling is attended with heat, smarting, and little hot watery pimples, the following mixture will then be more proper to bathe with.

TAKE two ounces of crude sal ammoniac, boiled in a quart of lime-water; where that cannot be had, a handful of pearl or wood-ashes may be boiled in common water: pour off the decoction when settled, and mix with it half a pint of spirit of wine: anoint the part afterwards with linseed oil, or elder ointment, to soften and smooth the skin.

But when the swellings are critical, the consequence of a fever settled on this part, you must avoid the repelling method, and assist in bringing the swelling to matter, by means of suppurating poultices: experienced farriers advise, never to open these tumours till they break off themselves; for if they are opened before they are ripe, the whole sore will be spongy, and discharge a bloody ichor, which soon degenerates into a fordid ulcer. But take care to enlarge the openings and pare away the lips, that your dressings may be applied easily; and avoid the ligament which runs along the neck to the withers: if a gathering forms on the opposite side, open it in the same manner, but take care they incline downwards, for the sake of depending orifices, and letting the matter flow off.

off easily. For the method of dressing, we must refer to the preceding Section; and if the bones should be found foul, they must be dressed with tincture of myrrh till they scale off: if the fungus is very troublesome, and the discharge oily, yellow and viscid, pledgets soaked in the following, made hot, have been found very effectual, bathing the swelling round with spirit of wine and vinegar.

TAKE half an ounce of blue vitriol dissolved in a pint of water; oil of turpentine, and rectified spirit of wine, of each four ounces; white-wine vinegar, six ounces; oil of vitriol and Ægyptiacum, of each two ounces.

When the cavities are truly fistulous, the callosities must be cut out, where it can be done, with a knife; and the remainder destroyed by corrosives, *viz.* precipitate, burnt alum, and white vitriol, as we have already observed in the Section on Ulcers.

*Warbles* are small hard tumours under the saddle-part of the horse's back, occasioned by the heat of the saddle in travelling, or its uneasy situation. A hot greasy disclout at first frequently applied, will sometimes remove them. Camphorated spirits of wine are also very effectual for this purpose to disperse them, to which a little spirit of sal armoniac may be added. The repellers above-mentioned are successfully applied in these cases; and if you are obliged to work the horse, take care your saddle is nicely chambered.

A *sit-fast* proceeds generally from a warble, and is the horse's hide turned horny, which, if it cannot be dissolved and softened by rubbing with the mercurial ointment, must be cut out, and treated then as a fresh wound.

#### Of WIND-GALLS, BLOOD and BOG SPAVINS.

A WIND-GALL is a flatulent swelling, which yields to the pressure of the finger, and recovers its shape on the removal thereof: the tumour is visible to the eye, and often seated on both sides of the back sinew, above the fetlocks, on the fore-legs, but most frequently on the hind-legs; though they are met with in various parts of the body, where-ever membranes can be so separated, that a quantity of air and serosities may be included within their duplicatures.

When they appear near the joints and tendons, they are generally caused by strains, or bruises on the sinews, or the sheath that covers them; which, by being over-stretched, have some of their fibres ruptured; whence probably may ouze out that fluid which is commonly found with the included air: though where these swellings shew themselves in the interstices of large muscles, which appear blown up like bladders, air alone is the chief fluid; and these may safely be opened, and treated as a common wound.

On the first appearance of wind-galls, their cure should be attempted by restreints and bandage; for which purpose, let the swelling be bathed twice a-day with vinegar, or verjuice alone; or let the part be fomented with a decoction of oak-bark, pomegranate, and alum boiled in verjuice, binding over it, with a roller, a woollen cloth soaked in the same. Some, for this purpose, use

red-wine lees, others carriers swavings wetted with the same, or vinegar, bracing the part up with a firm bandage.

If this method, after a proper trial, should not be found to succeed, authors have advised the swelling to be pierced with an awl, or opened with a knife: but mild blistering has in general the preference given to these methods; the including fluids being thereby drawn off, the impacted air dispersed, and the tumour gradually diminished.

A *blood-spavin* is a swelling and dilatation of the vein that runs along the inside of the hock, forming a little soft swelling in the hollow part, and is often attended with a weakness and lameness of the hock.

The cure should be first attempted with the restreints and bandage above recommended, which will contribute greatly to strengthen all weaknesses of the joints, and frequently will remove this disorder, if early applied: but if by these means the vein is not reduced to its usual dimensions, the skin should be opened, and the vein tied with a crooked needle and wax-thread passed underneath it, both above and below the swelling, and the turgid part suffered to digest away with the ligatures: for this purpose, the wound may be daily dressed with turpentine, honey, and spirit of wine, incorporated together.

A *bog-spavin* is an encysted tumour on the inside the hough; or, according to Dr Bracken, a collection of brownish gelatinous matter, contained in a bag, or cyst, which he thinks to be the lubricating matter of the joint altered, the common membrane that incloses it forming the cyst. This case he has taken the pains to illustrate in a young colt of his own, where he says, When the spavin was pressed hard on the inside the hough, there was a small tumour on the outside, which convinced him the fluid was within-side the joint: he accordingly cut into it, discharged a large quantity of this gelatinous matter, dressed the sore with dossils dipped in oil of turpentine, putting into it, once in three or four days, a powder made of calcined vitriol, alum, and bole: by this method of dressing, the bag sloughed off, and came away, and the cure was successfully compleated without any visible scar.

This disorder, according to the above description, will scarcely submit to any other method, except firing, when the cyst ought to be penetrated to make it effectual; but in all obstinate cases that have resisted the above methods, both the cure of this and of the swellings called wind-galls should be attempted in this manner. If, through the pain attending the operation or dressings, the joint should swell and inflame, foment it twice a-day, and apply a poultice over the dressings till it is reduced.

#### Of MALLENDERS and SALLENDERS.

MALLENDERS are cracks in the bend of the horse's knee, that discharge a sharp indigested matter: they are often the occasion of lameness, stiffness, and the horse's tumbling.

SALLENDERS are the same distemper, situate on the bending of the hough, and occasion a lameness behind.

They are both cured by washing the parts with a lather of soap warmed, or old chamber-lye; and then apply o-

ver the cracks a strong mercurial ointment spread on tow, with which they should be dressed, night and morning, till all the scabs fall off: if this should not succeed, anoint them night and morning with a little of the following, and apply the above ointment over it.

TAKE hogs lard, two ounces; sublimate mercury, two drams.

Or,

TAKE hogs lard, two ounces; oil of vitriol, two drams.

Take the next from Gibson, which is to be depended on:

ÆTHIOPS mineral, half an ounce; white vitriol, one dram; soft green soap, six ounces.

Anoint with this often; but first clip away the hair, and clear the scabs. On their drying up, it may be proper to give a gentle purge or two; or the nitre balls may be taken advantageously, for a fortnight or three weeks.

#### OF LAMPAS, BARBS, and WOLVES TEETH.

THE *lampas* is an excrescence in the roof of the horse's mouth, which is sometimes so luxuriant, that it grows above the teeth, and hinders his feeding. The cure is in lightly cauterising the flesh with a hot iron, taking care that it does not penetrate too deep, so as to scale off the thin bone that lies under the upper bars; the part may be anointed with burnt alum and honey, which is proper for most sores in the mouth.

This operation is by some thought to be entirely unnecessary; it being a general observation with them, that all young horses have their mouths more or less full of what are called lampas; and that sometimes they rise higher than the fore-teeth; but they further observe, in proportion as a horse grows older, the roof flattens of itself, and the teeth then appear to rise. We are obliged to the ingenious M. La Fosse for this remark, and hope it will be the means of abolishing this cruel and unnecessary operation.

*Barbs* are small excrescences under the tongue, which may be discovered by drawing it aside, and are cured by cutting close off, and washing with brandy or salt and water.

A horse is said to have *wolves-teeth*, when the teeth grow in such a manner, that their points prick, or wound either the tongue, or gums, in eating. Old horses are most liable to this infirmity, and whose upper overshoot the under teeth in a great degree.

To remedy this evil, you may either chop off the superfluous parts of the teeth with a chizel and mallet, or file them down, which is the better way, till you have sufficiently wasted them.

#### Of the GREASE.

IN order to treat this disorder with some propriety; we shall consider it as arising from two different causes; a fault or relaxation in the vessels, or a bad disposition in the blood and juices. We must here observe, that the blood and juices (or humours, for there are always some in the best state of blood) are brought to the extremest parts by the arteries, and returned by the veins;

in which latter, the blood is to rise in perpendicular columns, to return the circulating fluids from the extremities: hence swellings in the legs of horses may easily be accounted for, from a partial stagnation of the blood and juices in the finer vessels, where the circulation is most languid; and especially when there is want of due exercise, and a proper muscular compression on the vessels, to push forward the returning blood, and propel the inert and half stagnating fluids through their vessels; in short, the blood in such cases cannot so readily ascend as descend, or a greater quantity is brought by the arteries than can be returned by the veins.

The grease then, considered in this light, must be treated as a local complaint, where the parts affected are alone concerned, the blood and juices being yet untainted, and in good condition; or as a disorder where they are both complicated: but when it is an attendant on some other distemper, as the farcy, yellows, dropfy, &c. such diseases must first be cured before the grease can be removed. In the former case, moderate exercise, proper dressing, cleanliness, and external application, will answer the purpose; in the latter, internals must be called in to our assistance, with proper evacuations.

When a horse's heels are first observed to swell in the stable, and subside or go down on exercise; let care be taken to wash them very clean every time he comes in, with soap-suds, chamber-lye, or vinegar and water, which, with proper rubbing, will frequently prevent, or remove this complaint: or let them be well bathed twice a-day with old verjuice, or the following mixture, which will brace up the relaxed vessels; and if rags dipped in the same are rolled on, with a proper bandage, for a few days, it is most likely the swellings will soon be removed by this method only, as the bandage will support the vessels, till they have recovered their tone. To answer this end also, a laced stocking made of strong canvas or coarse cloth, neatly fitted to the part, would be found extremely serviceable, and might easily be contrived by an ingenious mechanic.

TAKE rectified spirit of wine, four ounces; dissolve in it half an ounce of camphor; to which add wine-vinegar, or old verjuice, six ounces; white vitriol, dissolved in a gill of water, one ounce; mix together, and shake the phial when used.

But if cracks or scratches are observed, which ouze and run, let the hair be clipped away, as well to prevent a lodgment (which becomes stinking and offensive by its stay) as to give room for washing out dirt or gravel, which, if suffered to remain there, would greatly aggravate the disorder.

When this is the case, or the heels are full of hard scabs, it is necessary to begin the cure with poultices, made either of boiled turnips and lard, with a handful of linseed powdered; or oatmeal and rye flour, with a little common turpentine and hogs lard, boiled up with strong-beer grounds or red-wine lees. The digressive ointment being applied to the sores for two or three days, with either of these poultices over it, will, by softening them, promote a discharge, unload the vessels, and take down the swelling; when they may be dried up with the following:

TAKE

TAKE white vitriol and burnt alum, of each two ounces; Ægyptiacum, one ounce; lime-water, a quart or three pints: wash the sores with a sponge dipped in this, three times a-day, and apply the common white ointment spread on tow; to an ounce of which may be added two drams of sugar of lead.

This method is generally very successful, when the distemper is only local, and requires no internal medicines; but if the horse be full and gross, his legs greatly gorged, so that the hair stands up, and is what some term pen-feathered, and has a large stinking discharge from deep foul sores, you may expect to meet with great trouble, as these disorders are very obstinate to remove, being often occasioned by a poor dropical state of blood, or a general bad disposition in the blood and juices.

The cure in this case, if the horse is full and fleshy, must be begun by bleeding, rowels, and repeated purging; after which, diuretic medicines are frequently given with success. Thus,

TAKE four ounces of yellow rosin, one of sal prunellæ; grind them together with an oiled pestle, add a dram of oil of amber, and give a quart of forge-water every morning, fasting two hours before and after taking, and ride moderately.

As this drink is found very disagreeable to some horses, I would recommend the nitre-balls in its stead, given to the quantity of two ounces a-day, for a month or six weeks, mixed up with honey, or in his feeds: take the following also for that purpose.

Yellow rosin, four ounces; salt of tartar, and sal prunellæ, of each two ounces; Venice soap, half a pound; oil of juniper, half an ounce; make into balls of two ounce weight, and give one every morning.

The legs, in this case, should be bathed or fomented, in order to breathe out the stagnant juices, or to thin them, so that they may be able to circulate freely in the common current. For this purpose, foment twice a day with the discutient fomentation, p. 569. col. 2. par. 3. in which a handful or two of wood-ashes has been boiled; apply then the above poultices, or the following, till the swelling has subsided, when the sores may be dressed with the green ointment till they are properly digested, and then dried up with the water and ointment above recommended.

TAKE honey, one pound; turpentine, six ounces; incorporate with a spoon; and add of the meal of fenugreek and linseed, each four ounces; boil in three quarts of red-wine lees to the consistence of a poultice; to which add, when taken from the fire, two ounces of camphor in powder; spread it on thick cloths, and apply warm to the legs, securing it on with a strong roller.

If the sores are very foul, dress them with two parts of the wound-ointment, and one of Ægyptiacum, and apply the following, spread on thick cloths, and rolled on.

TAKE of black soap, one pound; honey, half a pound; burnt alum, four ounces; verdigrise powdered, two ounces; wheat flour, a sufficient quantity.

If the diuretic balls should not succeed, they must be

Vol. II. No. 50.

2

changed for the antimonial and mercurial alteratives, already mentioned; but turning a horse out in a field, where he has a hovel or shed to run to at pleasure, would greatly contribute to quicken the cure, and indeed would in general effect it alone; but if this cannot be complied with, let him be turned out in the day-time.

If the horse is not turned out, a large and convenient stall is absolutely necessary, with good dressing and care.

The last thing we shall recommend, is a method to oblige a horse to lie down in the stable. This undoubtedly is of the utmost consequence, as it will not a little contribute to the removal and cure of this disorder; for by only changing the position of his legs, a freer circulation would be obtained, and the swelling taken down: whereas in general it is greatly aggravated by the obstinacy of the horse, who refuses to lie down at all (probably from the pain it gives him to bend his legs for that purpose) by which means the stiffness and swelling increases, till the over-gorged and distended vessels are obliged to give way, and by bursting, discharge the fluids, which should circulate through them.

#### OF SCRATCHES, CROWN-SCABS, RAT-TAILS, and CAPELLETS.

SCRATCHES in the heels have so much affinity with the grease, and are so often concomitants of that distemper, that the method of treating them may be selected chiefly from the preceding section; which at first should be by the linseed and turnip poultice, with a little common turpentine to soften them, and relax the vessels; the green ointment may then be applied for a few days to promote a discharge, when they may be dried up with the ointments and washes recommended in the above section. It is best afterwards to keep the heels supple, and softened with currier's dubbing, which is made of oil and tallow. This will keep the hide from cracking, and be as good a preservative as it is to leather; and by using it often before exercise, will prevent the scratches, if care is taken to wash the heels with warm water, when the horse comes in. When they prove obstinate, and the sores are deep, use the following; but if any cavities or hollow places are formed, they should first be laid open; for no foundation can be laid for healing, till you can dress to the bottom.

TAKE Venice turpentine, four ounces; quicksilver, one ounce; incorporate well together by rubbing some time, and then add honey and sheeps suet, of each two ounces.

Anoint with this once or twice a day; and if the horse is full or fleshy, you must bleed and purge; and if the blood is in a bad state, the alteratives must be given to rectify it.

The *crown-scab* is an humour that breaks out round the coronet, which is very sharp and itching, and attended with a scurfulness: sharp waters prepared with vitriol are generally used for the cure; but the safest way is first to mix marshmallow and yellow basilicon, or the wound ointment, equal parts, and to spread them on tow, and lay all round the coronet. A doze or two of physic may be very proper, with the diuretic medicines, (par. 4. 5. 6. of the preced. col. and the alteratives above recommended

6 F

commended, in rebellious cases. *Vid.* the Section on ALTERATIVES.

*Rat-tails* are excrescences, which creep from the pastern to the middle of the hanks, and are so called from the resemblance they bear to the tail of a rat. Some are moist, others dry; the former may be treated with the drying ointment and washes, p. 577. col. 1. par. 1. the latter with the mercurial ointment, p. 555. col. 2. par. 6. If the hardness does not submit to the last medicine, it should be pared off with a knife, and dressed with turpentine, tar and honey, to which verdigrease or white vitriol may occasionally be added; but before the use of the knife, you may apply this ointment.

TAKE black soap, four ounces; quick-lime, two ounces; vinegar enough to make an ointment.

There are particular swellings which horses are subject to, of a wenny nature, which grow on the heel of the hock, and on the point of the elbow, and are called by the French and Italians capellets: they arise often from bruises and other accidents; and when this is the case, should be treated with vinegar and other repellers; but when they grow gradually on both heels, or elbows, we may then suspect the blood and juices in fault that some of the vessels are broke, and juices extravasated; in this case, the suppuration should be promoted, by rubbing the part with marshmallow ointment, and when matter is formed, the skin should be opened with a lancet, in some dependent part towards one side, to avoid a scar: the dressings may be turpentine, honey, and tincture of myrrh. The relaxed skin may be bathed with equal parts of spirit of wine and vinegar, to which an eighth part of oil of vitriol may be added. The contents of these tumours are various, sometimes watery, at others suety, or like thick paste; which, if care be not taken to digest out properly with the cyst, will frequently collect again; was it not for the disfigurement, the shortest method would be to extirpate them with a knife, which, if artfully executed, and the skin properly preserved, would leave very little deformity.

#### *Of the Diseases of the FEET.*

##### *Of NARROW HEELS, and BINDING of the HOOF, &c.*

THOUGH narrow heels in general arise from a natural defect, yet they are often rendered incurable by bad shoeing; for some farriers hollow the quarters so deep and thin, that they may be pinched in with the fingers, and think by that method to widen them out by a strong broad webbed shoe; but this turns them narrow above, wires their heels, and dries, or rots the frog. The best way in all such cases is not to hollow the foot in shoeing, and to pare nothing out but what is rotten or foul; if the foot be hard and dry, or inclined to be rotten, bathe it often with chamber-lye, or boil two pounds of linseed bruised in two quarts of the same, to the consistence of a poultice, then add six ounces of soft green soap, and anoint the foot with it every day, rubbing a little of it upon the sole.

Or,

TAKE bees-wax two ounces; fresh butter or lard, six

ounce; tar, one ounce; as much linseed, or neats-foot oil, as will make it the consistence of a smooth ointment.

The hoofs, if too dry, may be anointed with the above, or with lard only; some for this purpose use tar, tallow, and honey, but most greasy and unctuous applications will answer this intention; the feet also, if too dry, may be stuffed with bran and lard heated or worked up together in the hand, which is very proper also to apply every night, when your horse is travelling in hot weather on roads that are dry and hard; cow-dung likewise is a proper stuffing for the feet, but vinegar should cautiously be mixed with it; for though it is a known cooler, it is a remarkable restrigent, which in this case would be extremely prejudicial; instead of which, a print of fresh butter may be first applied to the sole, and the cow-dung laid over it.

There is another disorder the hoofs are subject to, which is their being too soft and moist; this may be constitutional, or proceed from going much in wet and marshy grounds, standing constantly on wet litter, or any infirmity that may bring too great a moisture into the feet. In this case the horse's hoofs may be bathed every day with warm vinegar, verjuice, copperas-water, and such like restrigents; to which may be added galls, alum, &c. remembering to let the horse stand constantly dry.

We say a horse is *hoof-bound*, when the hoof is so tight round the instep, that it turns the foot somewhat into the shape of a bell. This is caused sometimes by shoeing as above, to widen the heel, and sometimes by cutting the toes down too much, which gives that shape to the foot, and causes the horse to go lame.

To remedy this disorder, Mr Gibson recommends the following method: let the foot be drawn down from the coronet almost to the toe with a drawing knife, making seven or eight lines or razes through the hoof, almost to the quick; afterwards keep it charged with pitch rosin, till the lines are wore out in shoeing, which will require several months.

##### *Of SAND CRACKS and QUITTORS.*

WHAT is called a sand-crack, is a little cleft on the outside of the hoof: if it runs in a strait line downwards, and penetrates through the bony part of the hoof, it often proves troublesome to cure; but if it passes through the ligament that unites the hoof with the coronet, it is then apt to breed a quittor, or false quarter, which is dangerous.

When the crack only penetrates through the hoof, without touching the ligament, unless the hoof be hollow, it may easily be cured, by rasping only the edges smooth, and applying thick pledgets of basilicon, and binding them down with a piece of soft lilt; if some precipitate be added to it, this medicine will be improved thereby; and in general answers the end, without any other application. But if you perceive any hollownets under the hoof, and that the cleft has a tendency to penetrate through the gristle or ligament, the best method, in that case, is to fire out of hand with irons that are not made

made too hot, first rasping very thin and wide from both sides of the clift: the horse must not carry any weight for some time, but be turned out to grafs, or wintered in a good farm yard.

A quitor is an ulcer formed between the hair and hoof, usually the inside quarter of a horse's foot; it arises often from treads and bruises, sometimes from gravel, which, by working its way upwards, lodges about the coronet: if it is only superficial, it may be cured with cleansing dressings, bathing the coronet every day with spirit of wine, and dressing the sore with the precipitate medicine.

But if the matter forms itself a lodgment under the hoof, there is no way then to come at the ulcer, but by taking off part of the hoof; and if this be done artfully and well, the cure may be effected without danger.

When the matter happens to be lodged near the quarter, the farrier is sometimes obliged to take off the quarter of the hoof, and the cure is then, for the most part, but palliative; for when the quarter grows up, it leaves a pretty large seam, which weakens the foot; this is what is called a false quarter, and a horse with this defect seldom gets quite sound.

If the matter, by its confinement, has rotted the coffin-bone, which is of so soft and spongy a nature, that it soon becomes so, you must enlarge the opening, cut away the rotten flesh, and apply the actual cautery, or hot iron pointed pyramidically, and dress the bone with doffils of lint, dipped in tincture of myrrh, and the wound with the green or precipitate ointment. When the sore is not enlarged by the knife, which is the best, and less painful method, pieces of sublimate are generally applied, which bring out with them cores, or lumps of flesh; blue vitriol powdered, and mixed with a few drops of the oil, is used also for this purpose, and is said to act as effectually, and with less pain and danger; during the operation of these medicines, the foot should be kept in some soft poultice, and care should be taken, during the whole dressing, to prevent proud flesh rising, which otherwise will not only retard the cure, but prevent a firm and sound healing.

#### *Of Wounds in the FEET, from NAILS, GRAVEL, &c.*

ACCIDENTS of this sort are very common, and sometimes for want of early care, prove of bad consequence; for the parts, being naturally tender, are very susceptible of inflammation; and when matter is once formed, if a free discharge is not procured, the bone, which is spongy, soon becomes affected, and the whole foot is then in danger.

When any extraneous bodies, such as nails, stubs, thorns, &c. have passed into the horse's foot, you should endeavour to get them out as soon as possible; and after washing the part with oil of turpentine, dress the hole with lint dipped in the same, melted down with a little tar; the foot may be stopped up with bran and hogs-lard heated together, or put it into the turnip, or any soft poultice; this method is generally successful, when the nail, &c. is entirely removed; but if any piece, or particle, should remain behind, which may be suspected by the degree of pain, and discharge of matter; after par-

ing away the sole as thin as possible, introduce a bit of sponge tent, in order to enlarge the hole, that it may be drawn out by a small pair of forceps, or brought away by digestion: if this method should not succeed, but the lameness continues, with a discharge of a thin bloody, or stinking matter, you must no longer delay opening the wound with a drawing-knife to the bottom, and then dress as above directed, or with the turpentine digestive, divided with the yolk of an egg, and a little tincture of myrrh; afterwards with the precipitate medicine.

If the lameness proceeds from pricking in shoeing, the foot should be pared thin on the wound side, and after dressing with the tar and turpentine, let it be stopped with the poultices above mentioned, or with two ounces of common turpentine, melted down with four of lard; should this method not succeed, follow the above directions.

If the nail penetrates to the joint of the foot, where matter may be formed, and by its long continuance putrify, so as to erode the cartilages of the joint, the case is incurable.

If the nail has passed up to the nut-bone, it is incurable, because this little bone cannot exfoliate, and because the cartilaginous part of it is destroyed, as soon as injured.

If the nail has not passed to the tendon, the horse will do well, without a necessity for drawing the sole; but if the tendon is wounded, the sole must be carefully drawn, because a sinovia and gleet is discharged.

When gravel is the cause, it for the most part follows the nail-holes, and if it gets to the quick cannot return, unless it is scraped out; for the make of the hoof, which is spiral like an ear of corn, favours its ascent, so that the gravel continues working upwards towards the coronet, and forms what the farriers call a quitor-bone.

The nature of this disorder points out the method of cure, which is to be as expeditious and careful as possible, in getting out the gravel; if it is found difficult to effect this, let the sole or hoof be pared thin, and, if necessary, the wound enlarged to the bottom, and then dressed up as usual. Should the coffin-bone be affected, you must follow the directions laid down in the preceding section, remembering always to bathe the hoof with vinegar, or repellers, in order to allay the heat and inflammation, which often happen on such occasions; and should the pain and anguish affect the legs, treat them in the same manner, or charge the leg and pastern with a mixture of wine-lees and vinegar.

*Figs* are spongy swellings on the bottom of horses feet, generally on the sides of the frush. These, or any other kind of excrescences, such as warts, corns, grapes, &c. are best removed by the knife; and if any part of them be left behind, or should shoot up afresh, touch them with the caustic, or oil of vitriol, and dress with *Ægyptiacum*; to which may be added, when they are very rebellious, a small quantity of sublimate; when the roots are quite destroyed, you may incarn with the precipitate medicines, and dry up the sore with the following wash.

TAKE of white vitriol, alum, and galls in powder, of each two ounces; dissolve them by boiling a little in two quarts of lime water, and keep in a bottle for use, which should be shook when used.

*Of the RUNNING THRUSH, CANKER, and  
Loss of Hoof.*

THE *thrush* or *frush* is an imposthume that sometimes gathers in the frog; or a scabby and ulcerous disposition, which sometimes causes it to fall off: when the discharge is natural, the feet should be kept clean, but no drying washes made use of, it being thought as unsafe to repel some of these discharges, as to cure some sweaty feet.

When an imposthume, or gathering appears, the safest way is to pare out the hard part of the frog, or whatever appears rotten; and wash the bottom of the foot two or three times a-day with old chamber-lye; this is the safest and best way of treating them. But when a horse has been neglected, and there is a strong flux to the part, it is apt to degenerate into a canker; to prevent which, use the following wash.

Take spirit of wine and vinegar of each two ounces, tincture of myrrh and aloes one ounce, *Egyptiscum* half an ounce; mix together.

Bathe the thrush with this, where-ever there appears a more than ordinary moisture, and lay over the ulcer a little tow dipped in the same. The purges and diuretics recommended in the greafe, should be given at this time, to prevent the inconveniencies that the drying up these discharges frequently occasion.

A *canker* in the foot proceeds, for the most part, from thrushes, when they prove rotten and putrid, though many other causes may produce this disorder. The method used by farriers for the cure is generally with hot oils, such as vitriol, aqua-fortis, and batter of antimony, which are very proper to keep down the rising flesh, and should be used daily, till the fungus is suppressed, when once in two days will be sufficient, strewing fine precipitate powder over the new-grown flesh, till the sole begins to grow.

There is one great error committed often in this cure, that is, in not having sufficient regard to the hoof; for it should not only be cut off, where-ever it presses on the tender parts, but should be kept soft with linseed oil; and as often as it is dressed, bathe the hoof all round the coronet with chamber-lye. Purging is very proper to complete the cure.

The *loss of the hoof* may be occasioned by whatever accident may bring an imposthumation in the feet, whereby the whole hoof becomes loosened, and falls off from the bone. If the coffin-bone remains uninjured, a new hoof may be procured by the following method.

The old hoof should by no means be pulled off, unless some accident happens that requires its removal; for it serves as a defence to the new one, and makes it grow more smooth and even; and indeed nature will generally do this office at her own proper time.—On the removal of the hoof, a boot of leather, with a strong sole, should be laced about the pattern, bolstering and stopping the foot with soft flax, that the tread may be easy: dress the sore with the wound ointment, to which should be added the fine powders of myrrh, mastic, and olibanum. If this medicine should not be sufficient to prevent a fungus, burnt alum or precipitate may be added to

it, and the luxuriant flesh may be daily washed with the sublimate water.

*Of RUPTURES, ANTICOR, COLT-EVIL or GONORRHOEA, and Diseases of the MOUTH.*

IN regard to ruptures, though they are generally divided into particular classes, we shall only observe, that by violent efforts of the horse, or other accidents, the guts or caul may be forced between the muscles of the belly at the navel, and through the rings of the muscles into the scrotum or cod. The swellings are generally about the size of a man's fist, sometimes much larger, descending to the very hock; they are frequently soft, and yield to the pressure of the hand, when they will return into the cavity of the belly with a rumbling noise; and, in most, the vacuity may be felt through which they passed.

On their first appearance, endeavours should be made to return them by the hand; but if the swelling should be hard and painful, in order to relieve the stricture, and relax the parts, through which the gut or caul has passed, let a large quantity of blood be immediately taken away, and the part fomented twice or thrice a-day, applying over it a poultice made with oatmeal, oil and vinegar, which should be continued till the swelling grows soft and easier, or the gut is returned. In the mean time it would be proper to throw up emollient oily glysters twice a-day, and to let the horse's chief diet be boiled barley, scalded malt, or bran.

Should the swelling afterwards return, we apprehend the restraining applications, usually recommended on these occasions, will avail little without a suspensory bandage; so that an ingenious mechanic in that art is chiefly to be relied on for any future assistance; though it has been observed, that with moderate feeding, and gentle exercise, some horses have continued to be very useful under this complaint.

The *anticor* is a disorder not very common among our horses, or those in northern climates; but is particularly taken notice of by the French, Spanish, and Italian writers; who describe it a malignant swelling in the breast, which extends sometimes to the very sheath under the belly; it is attended with a fever, great depressions, and weakness, and a total loss of appetite.

The cure should first be attempted by large and repeated bleedings, to abate the inflammation; emollient glysters should be injected twice or thrice a-day, with an ounce of sal prunella in each, and the cooling drink in the Section on Fevers should be given inwardly; the swelling should be bathed with the marshmallow ointment, and a ripening poultice, with onions boiled in it, should be daily applied over it. If by this method, continued four or five days, the inflammation in the throat and gullet is removed, our attention should more particularly turn to encourage the swelling at the breast, and bring it, if possible, to matter: to which end, continue the poultice, and give two ounces of Venice treacle dissolved in a pint of beer every night; when the swelling is grown soft, it must be opened with the knife, and dressed with serpentaine digestive, the danger now being over.

But

But should it be found impracticable to bring the swelling to matter, and it increases upwards, so as to endanger suffocation; authors have advised to pierce the tumour with a hot pointed cautery in five or six places, to dress with the above digestive; and in order to stimulate and promote a greater discharge, to add to it a small quantity of Spanish flies and euphorbium in powder; fomenting at the same time, and bathing the circumjacent parts with ointment of marshmallows. M. Guerinieri, as well as Soleyfell, have advised opening the skin, when the tumour cannot be brought to matter, in order to introduce a piece of black hellebore-root steeped in vinegar, and to confine it there for twenty-four hours; this also is intended as a stimulant, and is said to answer the intention, by occasioning sometimes a swelling as big as a man's head.

Besides the disorders of the mouth, which we have already animadverted on, there are frequently observed on the inside the lips and palate, little swellings or bladders called *giggs*: slitting them open with a knife, or lancet, and washing them afterwards with salt and vinegar, is in general their cure; but when they degenerate into what are called cankers, which are known by little white specks, that spread and occasion irregular ulcers, the best method then is to touch them daily with a small flat cautery, moderately heated, till the spreading is stopped, and to rub the sores three or four times a-day with *Ægyptiacum*, and tincture of myrrh, sharpened with oil, or spirit of vitriol; when by this dressing the sloughs are separated, they may be washed frequently with a sponge dipped in copperas, or sublimate water, if they continue to spread; or a tincture made by dissolving half an ounce of burnt alum, and two ounces of honey, in a pint of tincture of roses. Either of these will dry them up, and are very useful in most disorders of the mouth.

A relaxation and swelling of the palate sometimes happens to horses on catching cold. To remedy this disorder,

blow pepper on the part, or anoint it with the same mixed up with honey. The tincture above-mentioned may be used for this purpose, to which may be added half an ounce of spirit of sal-armoniac.

The colt-evil is supposed to arise from stoned colts having full liberty with mares, before they are able to cover them; whence frequently ensues an excoriation or fretting on the glands, and a swelling on the sheath; this last disorder frequently proceeds too from dirt, or filth lodging there, and is often removed by washing the part clean with butter and beer: but when the yard itself is swelled, foment it twice a day with marshmallows boiled in milk, to which may be added a little spirit of wine; anoint the excoriation with the white ointment, or wash it with a sponge dipped in lime, to a pint of which may be added two drams of sugar of lead: the yard should be suspended up to the belly; and if the swelling should increase with the inflammation, bleed, and give the cooling physic; anoint with ointment of elder, and apply the bread and milk poultice.

If a simple gonorrhœa or seminal gleet is observed to drip from the yard, (which is often the case in high-fed young horses, where a relaxation of the glands and seminal vessels has been brought on by frequent emissions) let the horse be plunged every day into a river or pond; give him two or three rhubarb purges, at proper distances; and intermediately the following balls.

Take of balsam of copivi, or Venice turpentine, oil-banum, and mastich powdered, of each two drams; bole armoniac half an ounce: mix up into a ball with honey, and give it night and morning, till the discharge lessens, and then every night, till it goes off.

Balls prepared with rhubarb and turpentine may also be given for this purpose; two drams of the former, with half an ounce of the latter.

## F A S

**FASCES**, in Roman antiquity, axes bound up together with rods or staves, and carried before the Roman magistrates as a badge of their authority and office.

**FASCETS**, in the art of making glass, are the irons thrust into the mouths of bottles, in order to convey them into the annealing tower.

**FASCIA**, in architecture, signifies any flat member having a considerable breadth and but a small projecture, as the band of an architrave, larmier, &c.

**FASCIA LATA**, in anatomy. See *ANATOMY*, p. 206.

**FASCIÆ**, in astronomy, certain parts on Jupiter's body resembling belts or swaths. They are more lucid than the rest of that planet, and are terminated by parallel lines, sometimes broader and sometimes narrower.

**FASCIALIS**, in anatomy. See *SARTORIUS*.

**FASCINATION**, a kind of witchcraft or enchantment supposed to operate by the influence either of the eye or tongue.

**FASCINES**, in fortification, faggots of small wood, of about a foot diameter and six feet long, bound in the

VOL. II. No. 49.

middle and at both ends. They are used in raising batteries, making chandeliers, in filling up the moat to facilitate the passage to the wall, in binding the ramparts where the earth is bad, and in making parapets of trenches to screen the men.

**FASHION-PIECES**, in the sea-language, are two compassing pieces of timber, into which is fixed one on each side the transom. See *TRANSOM*.

**FAST**, or **FASTING**, in general, denotes the abstinence from food; but is more particularly used for such abstinence on a religious account.

**FASTERMANS**, among our Saxon ancestors, were pledges or bondsmen, who were answerable for each other's good behaviour.

**FASTI**, in Roman antiquity, the calendar wherein were expressed the several days of the year, with their feasts, games, and other ceremonies.

**FAT**, in anatomy, an oleaginous or butyraceous matter, secreted from the blood, and filling up the cavity of the adipose cells. Fat, properly and distinctly so called,

†

6 G

ed,

ed, is not secreted from glandules, but from the little arteries of the adipose membrane. Authors distinguish it into two kinds, which they express by the words *sebum* or *adip.*, and *pinguedo*. According to this distinction, there is no such thing as sebum or hard fat in the human body, its fat being all of that sort expressed by *pinguedo*, or soft and oily. That this oleaginous matter has a circulatory motion, or an egress into the veins, is very evident from the sudden consumption of it in many diseases, and from its vast diminution by exercise or labour.

**FAT**, in the sea-language, signifies the same with broad. Thus a ship is said to have a fat quarter, if the trussing in or tuck of her quarter be deep.

**FAT** is used also for several utensils; as, 1. A great wooden vessel, used for the measuring of malt, and containing a quarter or eight bushels. 2. A large brewing vessel, used by brewers to run their wort in. 3. A leaden pan or vessel for the making of salt at Droitwich.

**FAT** likewise denotes an uncertain measure of capacity. Thus a fat of ising glass contains from  $3\frac{1}{4}$  hundred weight to 4 hundred weight; a fat of unbound books, half a maund or four bales; of wire, from 20 to 25 hundred weight; and of yarn, from 220 to 221 bundles.

**FATE**, denotes an inevitable necessity depending upon a superior cause. It is also used to express a certain unavoidable designation of things, by which all agents, both necessary and involuntary, are swayed and directed to their ends.

**FATES**, in mythology. See **PARCÆ**.

**FATHOM**, a long measure containing six feet, used chiefly at sea for measuring the length of cables and cordage.

**FATUUS IGNIS**, in physiology, a meteor otherwise called Will-with-a-wisp. See **WILL**.

**FAVIFORM**, in general, something resembling a honey-comb. Surgeons give this appellation to certain ulcers, which emit a sanies through little holes, especially in the head.

**FAVISSÆ**, in antiquity, were, according to Festus and Gellius, cisterns to keep water in: but the favissæ in the Capitol at Rome were dry cisterns or subterraneous cellars, where they laid up the old statues, broken vessels, and other things used in the temple. These were much the same with what, in some of the modern churches, are called the archives and treasury.

**FAUNALIA**, in Roman antiquity, three annual festivals in honour of the god Faunus; the first of which was observed on the ides of February, the second on the 16th of the calends of March, and the third on the nones of December. The principal sacrifices on this occasion were lambs and kids. Faunus was a deity of the Romans only, being wholly unknown to the Greeks.

**FAUNS**, a kind of rural deities, among the ancient Romans, represented with horns on their heads, sharp-pointed ears, and the rest of their bodies like goats.

**FAWN**, among sportsmen, a buck or doe of the first year; or the young one of the buck's breed in its first year.

**FE**, or **St Fe**, the capital of New Mexico: W. long.  $100^{\circ}$ , N. lat.  $36^{\circ}$ .

**St Fe de bogota**, the capital of the kingdom of New Granada: W. long.  $73^{\circ}$ , N. lat.  $4^{\circ}$ . It is an archbishoprick and the seat of the governor of the province, &c.

**St Fe** is also a town of Spain, in the province of Granada, situated on the river Xcnil: W. long.  $3^{\circ} 45'$ , N. lat.  $37^{\circ} 20'$ .

**St Fe** is also the capital of a province of the same name, in Terra Firma in South America, situated on the river of St Martha, 200 miles south of Carthagena: W. long.  $77^{\circ}$ , N. lat.  $7^{\circ} 25'$ .

**FEALTY**, in law, an oath taken on the admittance of any tenant, to be true to the lord of whom he holds his land.

**FEAST**, or **FESTIVAL**, in a religious sense, is a day of feasting and thanksgiving.

Among the ancients, feasts were instituted upon various accounts, but especially in memory of some favourable interposition of Providence. Thus, the Jews had their feast of passover, pentecost, and tabernacles; the Greeks their *cerealia*, *panathenæa*, &c. and the Romans their *saturnalia*, *ambarvalia*, &c. See **PASSOVER**, **CEREALIA**, &c.

**FEATHER**, in physiology, a general name for the covering of birds; it being common to all the animals of this class to have their whole body, or at least the greatest part of it, covered with feathers or plumage.

**FEBRIFUGE**, in medicine, an appellation given to such medicines as mitigate, or remove a fever.

**FEBRIS**, **FEVER**, in medicine. See **FEVER**.

**FEBRUARY**, in chronology, the second month of the year, reckoning from January, first added to the calendar of Romulus by Numa Pompilius.

February derives its name from *Februa*, a feast held by the Romans in this month, in behalf of the manes of the deceased; at which ceremony sacrifices were performed, and the last offices were paid to the shades of the deceased.

February, in a common year, consists only of twenty-eight days; but in the bissextile year, it has twenty-nine, on account of the intercalary day, added that year.

**FECEIALES**, or **FOECIALES**, a college of priests instituted at Rome by Numa, consisting of twenty persons, selected out of the best families. Their business was to be arbitrators of all matters relating to war and peace, and to be the guardians of the public faith.

**FEF**, in Scots law, signifies a complete feudal property. See **SCOTS LAW**, title 10. Hence, where the bare liferent of any feudal subject is meant to be conveyed to A, and the absolute property to B; that meaning is expressed thus, to A in liferent, and to B in fee.

**FEELERS**, in natural history, a name used by some for the horns of insects.

**FEELING**, one of the five external senses, by which we obtain the ideas of solid, hard, soft, rough, hot, cold, wet, dry, and other tangible qualities.

**FEINT**, in fencing, a shew of making a thrust at one part

*Fig. 1.* FELIS LEO  
or  
LION

*Fig. 2.* FELIS TIGRIS  
or  
TIGER

part, in order to deceive the enemy, that you may really strike him in another.

A simple feint is a mere motion of the wrist, without stirring the foot.

**FELAPTON**, in logic, one of the six first modes of the third figure of syllogisms; whereof the first proposition is an universal negative, the second an universal affirmative, and the third a particular negative.

**FELIN**, a town of Livonia, about an hundred miles north-east of Riga.

**FELIS**, the **CAT**, a genus of quadrupeds belonging to the order of *feræ*, the characters of which are these: The fore teeth are equal; the molars or grinders have three points; the tongue is furnished with rough sharp prickles, and pointing backwards; and the claws are sheathed, and retractile. This genus comprehends seven genera, *viz.*

1. The **LEO**, or **LION**. The largest lions are from eight to nine feet in length, and from four to eight feet high: those of a smaller size are generally about  $5\frac{1}{2}$  feet long, and about  $3\frac{1}{2}$  high. His head is very thick, and his face is beset on all sides with long bushy yellowish hair; this shaggy hair extends from the top of the head to below the shoulders, and hangs down to his knees: the belly and breast are likewise covered with long hair. The rest of the body is covered with very short hair, excepting a bush at the point of the tail. The ears are roundish, short, and almost entirely concealed under the hair of his front. The shagginess of the fore-part of his body makes the hinder part have a naked appearance. The tail is long and very strong; the legs are thick and fleshy; and the feet are short; the length of the claws is about an inch and a quarter, are of a whitish colour, very crooked, and can be extended or retracted into the membranous sheath at pleasure: Their points are seldom blunted, as they are never extended but when he seizes his prey.

The female, or *lionness*, has no mane, or long hair about her head or shoulders; in her we see distinctly the whole face, head, ears, neck, shoulders, breast, &c. all these parts being in some measure concealed under the long hair of the male, give the female a very different appearance: besides, she is considerably less than the male. The hair of both male and female is of a yellowish colour, and whitish on the sides and belly.

In warm countries, quadrupeds in general are larger and stronger than in the cold or temperate climates. They are likewise more fierce and hardy; all their natural qualities seem to correspond with the ardour of the climate. The lions nourished under the scorching sun of Africa or the Indies, are the most strong, fierce, and terrible. Those of mount Atlas, whose top is sometimes covered with snow, are neither so strong or so ferocious as those of Biledulgerid or Zaara, whose plains are covered with burning sand. It is in these hot and barren deserts, that the lion is the dread of travellers, and the scourge of the neighbouring provinces. But it is a happy circumstance that the species is not very numerous: they even appear to diminish daily. The Romans, says Mr Shaw, brought

many more lions out of Lybia for their public shows, than are now to be found in that country. It is likewise remarked, that the lions in Turkey, Persia, and the Indies are less numerous than formerly. As this formidable and courageous animal makes a prey of most other animals, and is himself a prey to none, this diminution in the number of the species can be owing to nothing but an increase in the number of mankind: for it must be acknowledged, that the strength of this king of animals is not a match for the dexterity and address of a Negro or Hottentot, who will often dare to attack him face to face, and with very slight weapons.

The ingenuity of mankind augments with their number; that of other animals continues always the same. All the noxious animals, as the lion, are reduced to a small number, not only because mankind are become more numerous, but likewise because they have become more ingenious, and have invented weapons which nothing can resist. This superiority in the numbers and industry of mankind, at the same time that it has broke the vigour of the lion, seems likewise to have enervated his courage. This quality, though natural, is exalted or lowered according to the good or bad success with which any animal has been accustomed to employ his force. In the vast deserts of Zaara; in those which seem to separate two very different races of men, the Negroes and Moors, between Senegal and the boundaries of Mauritania; in those uninhabited regions above the country of the Hottentots; and, in general, in all the meridional parts of Africa and Asia, where mankind have disdained to dwell, lions are still as numerous, and as ferocious as ever. Accustomed to measure their strength by that of all other animals which they encounter, the habit of conquering renders them haughty and intrepid. Having never experienced the strength of man, or the power of his arms, instead of discovering any signs of fear, they disdain and set him at defiance. Wounds irritate, but do not terrify them: they are not even disconcerted at the sight of numbers. A single lion of the Desert has been known to attack a whole caravan; and if, after a violent and obstinate engagement, he found himself weakened, he retreats fighting, always keeping his face to the enemy. On the other hand, the lions which live near the villages or huts of the Indians or Africans, being acquainted with man and the force of his arms, are so dastardly as to fly and leave their prey at the sight of women or children.

This softening in the temper and disposition of the lion, shows that he is capable of culture, and susceptible, at least to a certain degree, of the impressions that he receives: accordingly, history informs us of lions yoked in triumphal chariots, trained to war, or the chase; and that, faithful to their masters, they never employed their strength or courage but against their enemies. It is, however, certain, that a lion taken young and brought up among domestic animals, will easily be accustomed to live and sport with them; that he is mild and caressing to his master, especially when he is young; and that, if his natural ferocity sometimes breaks out, it

is rarely turned against those who have been kind to him. But, as his passions are impetuous and vehement, it is not to be expected that the impressions of education will at all times be sufficient to balance them: for this reason it is dangerous to let him suffer hunger long, or to vex him by ill-timed teazings: bad treatment not only irritates him, but he remembers it long, and meditates revenge. On the other hand, he is exceedingly grateful, and seldom forgets benefits received. He has been often observed to disdain weak or insignificant enemies, to despise their insults, and to pardon their offensive liberties. When led into captivity, he will discover symptoms of uneasiness, without anger or peevishness: on the contrary, his natural temper softens, he obeys his master, caresses the hand that gives him food, and sometimes gives life to such animals as are thrown to him alive for prey; by this act of generosity he seems to consider himself as for ever bound to protect them; he lives peaceably with them, allows them a part, and sometimes the whole of his food, and will rather submit to the pangs of hunger than fill his stomach with the fruit of his beneficence. We may likewise observe, that the lion is not a cruel animal; he kills rather from necessity than choice, never destroying more than he eats, and whenever his appetite is satisfied he is mild and peaceable.

The aspect of the lion does not detract from the noble and generous qualities of his mind. His figure is respectable; his looks are determined; his gait is stately; and his voice is tremendous. In a word, the body of the lion appears to be the best model of strength joined to agility. The force of his muscles is expressed by his prodigious leaps and bounds, often 20 feet at once; by the brisk motion of his tail, a single sweep of which is sufficient to throw a man to the ground; by the ease with which he moves the skin of his face, and particularly of his forehead; and, lastly, by the faculty of erecting and agitating the hair of his mane when irritated.

Lions are very ardent in their amours: when the female is in season, she is often followed by eight or ten males, who roar incessantly, and enter into furious engagements, till one of them completely overcomes the rest, takes peaceable possession of the female, and carries her off to some secret recess. The lioness brings forth her young in the spring, and produces but once every year.

All the passions of the lion, the soft passion of love not excepted, are excessive; the love of offspring is extreme: the lioness is naturally weaker, less bold, and more gentle than the lion; but she becomes perfectly rapacious and terrible when she has young. Then she exhibits more courage than the male; she knows no danger; she attacks indifferently men and all other animals, kills them, and carries them to her young ones, whom she thus early instructs to suck their blood and tear their flesh. She generally brings forth in the most secret and inaccessible places; and, when afraid of a discovery, she endeavours to conceal the traces of her feet, by returning frequently on her steps, or rather by effacing them with her tail; and, when the danger is great, she carries off her young and conceals them somewhere else. But, when an actual attempt is made to deprive her of her young, she becomes

perfectly furious, and defends them till she be torn to pieces.

The lion seldom goes abroad in the middle of the day; he goes round in the evening and night, in quest of prey. He is afraid of fire, never approaches the artificial fires made by the shepherds for the protection of their flocks; he does not trace other animals by the scent, but is obliged to trust to his eyes. Many historians have even misrepresented him as incapable of finding out his prey; but that he is obliged to the jackal, an animal of exquisite scent, in order to provide for him, and that this animal either accompanies or goes before him for this purpose. The jackal is a native of Arabia, Lybia, &c. and, like the lion, lives upon prey; perhaps sometimes he follows the lion, but it is with a view to pick up what he leaves behind, not to provide for him; for, being a small and feeble animal, he ought rather to fly than to serve the lion.

The lion, when hungry, will attack any animal that presents itself: but he is so very formidable, that all endeavour to avoid his rencontre; this circumstance often obliges him to conceal himself, and lie in wait till some animal chances to pass. He lies squat on his belly in a thicket; from which he springs with such force and velocity, that he often seizes them at the first bound. He endures hunger longer than thirst; he seldom passes water without drinking, which he does by lapping like a dog. For his ordinary subsistence, he requires about 15 pounds of raw flesh each day.

The roaring of the lion is so strong and loud, that it resembles the rumbling of distant thunder. His roaring is his ordinary voice: but when he is irritated, his cry is shorter, repeated more suddenly, and is still more terrible than the roaring: besides he beats his sides with his tail, stamps with his feet, erects and agitates the hair of his head and mane, moves the skin of his face, shows his angry teeth, and lolls out his tongue.

The gait of the lion is stately, grave, and slow, though always in an oblique direction. His movements are not equal or measured, but consist of leaps and bounds; which prevents him from stopping suddenly, and makes him often over-leap his mark. When he leaps upon his prey, he makes a bound of 12 or 15 feet, falls above it, seizes it with his fore-feet, tears the flesh with his claws, and then devours it with his teeth.

The lion, however terrible, is hunted by large dogs, well supported by men on horseback: they dislodge him, and oblige him to retire. But it is necessary that both the dogs and horses be trained before-hand; for almost every animal frets and flies as soon as he feels the very smell of a lion. His skin, although hard and firm, does not resist either a ball or a javelin: however, he is seldom killed by a single stroke; and is more frequently taken by address than force. They put a live animal above a deep pit covered with light substances, and thus decoy him into the snare.

2. The TIGER The size of this animal, according to some authors, is larger, and, according to others, somewhat less than the lion. M. de la Landemagon assures us, that he has seen a tiger in the East-Indies 15 feet long, including undoubtedly the length of the

*Fig. 1.* FELIS PARDUS or  
PANTHER

*Fig. 2.* FELIS LEOPARDUS or  
LEOPARD

the tail, which, supposing it to be four feet, makes the body of the tiger about 10 feet in length. The skeleton preserved in the cabinet of the French king, indicates that the animal was about 7 feet long from the point of the muzzle to the origin of the tail; but then it must be considered that he was caught young, and lived all his days in confinement. The head of the tiger is large and roundish; and the ears are short, and at a great distance from each other. The form of the body has a great resemblance to that of the panther. The skin is of a darkish yellow colour, striped with long black streaks; the hair is short, excepting on the sides of the head, where it is about four inches long. The point of the tail is black, and the rest of it is interspersed with black rings. His legs and claws resemble those of the lion, only the legs are much shorter in proportion to the size of the animal.

The tiger is more ferocious, cruel, and savage than the lion. Although gorged with carnage, his thirst for blood is not appeased; he seizes and tears in pieces a new prey with equal fury and rapacity, the very moment after devouring a former one; he lays waste the country he inhabits; he neither dreads the aspect nor the weapons of men; puts to death whole troops of domestic animals; and attacks young elephants, rhinoceros's, and sometimes even braves the lion himself. The tiger seems to have no other instinct but a constant thirst after blood, a blind fury which knows no bounds or distinction, and which often stimulates him to devour his own young, and to tear the mother in pieces for endeavouring to defend them. He lies in wait at the banks of rivers, &c. where the heat of the climate obliges the other animals to repair for drink. Here he seizes his prey, or rather multiplies his massacres: for he no sooner kills one animal, than he flies with equal fury upon the next, with no other view but to plunge in his head into their bodies and drink their blood. However, when he kills a large animal, as a horse or a buffalo, he sometimes does not tear out the entrails on the spot; but, to prevent any interruption, he drags them off to the wood, which he executes with incredible swiftness. This is a sufficient specimen of the strength of this rapacious animal.

Neither force, restraint, or violence can tame the tiger. He is equally irritated with good as with bad treatment: he tears the hand which nourishes him with equal fury as that which administers blows: he roars, and is enraged at the sight of every living creature. Almost every natural historian agrees in this horrible character. When viewing the beautiful tiger which is at present exhibiting in the city of Edinburgh, we at first suspected that his character was not so bad or ferocious as represented by historians: he allowed the keeper not only to come near him, but to stroke his head and take his paw in his hand. However, this appeared to be only a forced complaisance; he was chained so close to the floor, that he had only just room to stand: he snarled and roared when his master troubled him more than he inclined; and, upon throwing him a piece of flesh, his eyes instantly sparkled with rage; he put himself in a posture of defence, set up the most horrible roarings, and made several bounds to get at the keeper as well as the spectators.

It is happy for other animals, that the species of the tiger is not numerous, and that they are confined to the warm climates. They are found in Malabar, Siam, Bengal, the interior parts of Africa, and, in general, in all the regions that are inhabited by the elephant and rhinoceros.

The tiger has always been a more rare animal than the lion, and yet brings forth an equal number of young, namely, four or five at a litter. The female is furious at all times; but, when her young are attempted to be taken from her, her rage is redoubled: she braves every danger; she pursues the ravishers, who are obliged, when hard pressed, to drop one of the young in order to retard her motion; she flups, takes it up, and carries it into some secret part of the forest; but she instantly returns and pursues the hunters into their villages or boats.

The tiger moves the skin of his face, grinds his teeth, and roars, like the lion; but the sound of his voice is different.

3. The PANTHER.—It is about the size of a large dog, and has a great resemblance to a domestic cat. The tongue is rough and remarkably red; the teeth are strong and sharp; the skin is exceedingly beautiful, being of a yellow colour, variegated with roundish black spots, and the hair is short.

The panther has a cruel and ferocious aspect; his motions are brisk and lively; his cry resembles that of an enraged dog, but more strong and rough. He is not so perfectly ungovernable as the tiger: but, notwithstanding all attempts to render him obedient and tractable, he may rather be said to be subdued than tamed; for he never entirely loses his natural ferocity. Accordingly, when kept with a view to hunting bucks, goats, or other animals, great care is necessary in training him, and still greater in conducting him. When leading out to the field, they put him in a cage and carry him on a cart. When the game is sprung, they open the door of the cage; he instantly springs towards the animal, often seizes him in a few bounds, throws him to the ground, and strangles him. But, if he happens to miss his aim, he becomes mad with rage, and sometimes falls upon his master, who, in order to prevent accidents of this kind, generally carries along with him pieces of flesh, or perhaps a lamb or a kid, which he throws to him in order to appease his fury.

The panther is no where to be found but in Africa, and the regions of the Indies.

4. The ONCA or ONCE, is less than the panther; the tail is longer; the hair is likewise longer, and of a whitish grey colour. The once is easily tamed; and is employed in hunting in several parts of Asia, where dogs are very scarce. He has not the delicate scent of a dog; does not trace other animals by the smell; neither can he run them down in a fair chase; but lies in wait for their approach, and then darts upon them unawares. He leaps so nimbly, that he easily clears a ditch or a wall several feet high: besides, he often climbs trees, waits till some animal passes, and instantly leaps down upon them. This method of catching their prey, is practised by the panther and leopard, as well as the once.

5. The LEOPARD differs from the panther and the once in the beauty of his colour, which is a lively yellow, with smaller spots than those of the two latter, and

disposed in groups. He is larger than the once, and is than the panther. The manners and disposition of the leopard are nearly the same with those of the panther. He is never tamed or employed in hunting. The panther, once, and leopard, are inhabitants of Africa and the warmer regions of Asia. In general, these animals delight in thick forests, and frequent the banks of rivers, and the neighbourhood of solitary villages, where they lie in wait to surprise domestic animals and the wild beasts that come in quest of water. They seldom attack men, even when provoked. With regard to their skins, they are all valuable, and make excellent furs.

6. The **LYNX** is about 2½ feet long and 15 inches high. He has a great resemblance to the cat; but his ears are longer, and his tail is much shorter; his hair is streaked with yellow, white, and black colours. The lynx is an inhabitant of Muscovy, Poland, Canada, &c. his eyes are brilliant, his aspect is soft, and his air is gay and sprightly; like the cat, he covers his urine with earth; he howls something like the wolf, and is heard at a considerable distance; he does not run like the dog or wolf, but walks and leaps like a cat; he pursues his prey even to the tops of trees; neither wild-cats nor squirrels can escape him; he lies in wait for stags, goats, hares, &c. and darts suddenly upon them; he seizes them by the throat and sucks their blood, then opens the head and eats the brain; after this, he frequently leaves them and goes in quest of fresh prey; the colour of his skin changes according to the season or the climate; the winter furs are more beautiful than those of summer.

7. The **CAT**, is a well-known domestic animal, and therefore requires no particular description. The wild-cat, the cat of Angora, &c. differ only in the length of their hair, and some small varieties arising from climate and their manner of living.

Of all domestic animals, the character of the cat is the most equivocal and suspicious. He is kept, not for any amiable qualities, but purely with a view to banish rats, mice, and other noxious animals from our houses, granaries, &c. Although cats, when young, are playful and gay, they possess at the same time an innate malice and perverse disposition, which increases as they grow up, and which education learns them to conceal, but never to subdue. Constantly bent upon theft and rapine, though in a domestic state, they are full of cunning and dissimulation; they conceal all their designs; seize every opportunity of doing mischief, and then fly from punishment. They easily take on the habits of society, but never its manners: for they have only the appearance of friendship and attachment. This dissimilarity of character is betrayed by the obliquity of their movements, and the ambiguity of their looks. In a word, the cat is totally destitute of friendship; he thinks and acts for himself alone. He loves ease, searches for the softest and warmest places to repose himself. The cat is likewise extremely amorous; and, which is very singular, the female is more ardent than the male; she not only invites, but searches after and calls upon him to satisfy the fury of her desires; and, if the male disdains or flies from her, she pursues, bites, and in a manner compels him. This heat of passion in females lasts but nine or ten days, and hap-

pens twice in the year, namely in the spring and autumn; however, in some it happens thrice or four times in the year. The female goes with young 55 or 56 days, and generally produces four or five at a litter. As the male has an inclination to destroy the young, the female takes care to conceal them from him; and, when she is apprehensive of a discovery, she takes them up in her mouth one by one, and hides them in holes or inaccessible places. When she has nursed a few weeks, she brings them mice, small birds, &c. in order to learn them to eat flesh. But, it is worth notice, that these careful and tender mothers sometimes become unnaturally cruel, and devour their own offspring.

The cat is incapable of restraint, and consequently of being educated to any extent. However, we are told, that the Greeks in the island of Cyprus trained this animal to catch and devour serpents, with which that island was greatly infested. This however was not the effect of obedience, but of a general taste for slaughter; for he delights in watching, attacking, and destroying all kinds of weak animals indifferently. He has no delicacy of scent, like the dog; he hunts only by the eye: neither does he properly pursue; he only lies in wait, and attacks animals by surprise: and after he has caught them, he sports with and torments them a long time, and at last kills them (when his belly is full) purely to gratify his sanguinary appetite.

The eye of the cat differs greatly from that of most other animals. The pupil is capable of a great degree of contraction and dilatation; it is narrow and contracted like a line during the day, round and wide in the dark; it is from this conformation of the eye that the cat sees best in the night, which gives him a great advantage in discovering and seizing his prey.

Although cats live in our houses, they can hardly be called domestic animals; they may rather be said to enjoy full liberty; for they never act but according to their own inclination. Besides, the greatest part of them are half wild; they do not know their masters, and frequent only the barns, out-houses, &c. unless when pressed with hunger.

Cats have a natural antipathy at water, cold, and bad smells. They love to bask in the sun, and lie in warm places. They likewise have an affection for certain aromatic smells; they are transported with the root of the valerian.

Cats take about eighteen months before they come to their full growth; but they are capable of propagation in twelve months, and retain this faculty all their life, which generally extends to nine or ten years. They eat slowly, and are peculiarly fond of fishes. They drink frequently; their sleep is light; and they often assume the appearance of sleeping, when in reality they are meditating mischief. They walk softly, and without making any noise. As their hair is always dry, it easily gives out an electrical fire, which becomes visible when rubbed across in the dark. Their eyes likewise sparkle in the dark like diamonds.

The wild, or savage cat, couples with the domestic one, and is consequently the same species. It is not unusual for domestic cats, both male and female, when stimulated by love, to repair to the woods in quest of these

vage cats. The only difference between them is, that the savage cat is stronger, larger, and more ferocious. The cat is a native of almost every country in the world; and all the varieties in their appearance may be reasonably enough attributed to the climates which produce them. See figures of the principal species of the *FELIS*, on Plate LXXVIII, LXXIX, and LXXX.

**FELKIRK**, a town of Austria, in Germany, thirty-five miles south-east of Constance.

**FELLOWSHIP**, or **COMPANY**, in arithmetic. See **ARITHMETIC**. p. 386.

**FELO DE SE**, in law, a person that lays deliberately violent hands on himself, and is the occasion of his untimely death, whether by hanging, drowning, stabbing, shooting, or any other way.

**FELON**, in law, a person guilty of felony. See **FELONY**.

**FELONY**, in law, a capital crime, next in degree to petit treason, and committed with an evil intention; such are murder, theft, suicide, sodomy, rape, &c.

**FELT**, in commerce, a sort of stuff deriving all its consistence merely from being fulled, or wrought with lees and size, without either spinning or weaving.

Felt is made either of wool alone, or of wool and hair. Those of French make,  $3\frac{1}{2}$  yards long, and  $1\frac{1}{2}$  broad, for cloaks, pay each 2*l.* 14*s.* 1*7* $\frac{1}{2}$ *d.* on importation; and draw back 1*l.* 12*s.* 3*d.* on exporting them again.

**FELTRI**, a town of Italy, subject to Venice, thirty-five miles north of Padua.

**FELUCCA**, in sea-affairs, a little vessel with six oars, frequent in the Mediterranean, which has this peculiarity, that its helm may be applied either in the head or stern, as occasion requires.

**FEMALE**, a term peculiar to animals, signifying that sex which conceives and generates its young within itself.

**FEMININE**, in grammar, one of the genders of nouns. The feminine gender serves to intimate that the noun belongs to the female. In Latin, the femine gender is most commonly distinguished by the article *hec*, as it is in the Greek by  $\eta$ . In the French, the article *la* commonly denotes this gender; but we have no such distinction by articles in the English language.

**FEMUR**, or **FEMORIS**, in anatomy. See **ANATOMY**, p. 182.

**FEN**, a place overflowed with water, or abounding with bogs.

**FENCE**, in country-affairs, a hedge, wall, ditch, bank, or other inclosure, made around gardens, woods, corn-fields, &c.

The chief reason why wood-lands and plantations so seldom prosper, is in a great measure owing to the neglect of fencing them round to keep out the cattle. This neglect prevails much in the northern parts of this island, though the use of fences is certainly more necessary there than in the south, as the lands require more shelter and warmth. There are several ways of fencing lands, but the usual is that of hedging it with either white or black thorn, crab, holly, alder, or furze, &c.

**FENCE MONTH**, the month wherein deer begin to fawn, during which it is unlawful to hunt in the forest.

It commences fifteen days before mid-summer, and ends fifteen days after it. This month, by ancient foresters is called defence-month.

**FENCING**, the art of making a proper use of the sword, as well for attacking an enemy, as for defending one's self.

**FENNEL**, in botany. See **ANETHUM**.

**FEOD**, the same with fee. See **FEU**.

**FEODAL**, and **FEODATORY**. See **FEUDAL**, and **FEUDATORY**.

**FEOFFMENT**, in law, is a gift or grant of any manors, messuages, lands, or tencements, to another in fee; that is, to him and his heirs for ever, by delivery of seisin, and possession of the estate granted.

**FERÆ**, in zoology, an order of quadrupeds, the distinguishing characters of which are, that all the animals belonging to it have six fore teeth in each jaw, and the canine, or dog-teeth, considerably long.

Under this order are comprehended the following genera, viz. the phoca, canis, felis, viverra, mustela, ursus, didelphis, talpa, forex, and erinaceus. See **CANIS**, **FELIS**, &c.

**FERALIA**, in antiquity, a festival observed among the Romans on February 21st, or, according to Ovid, on the 17th of that month, in honour of the manes of their deceased friends and relations. During the ceremony, which consisted in making presents at their graves, marriages were forbidden, and the temples of the divinities shut up; because they fancied that, during this festival, the ghosts suffered no pains in hell, but were permitted to wander about their graves, and feast upon the meats prepared for them.

**FER DE FOURCHETTE**, in heraldry, a cross having at each end a forked iron, like that formerly used by soldiers to rest their musquets on. It differs from the cross fourché, the ends of which turn forked, whereas this has that sort of fork fixed upon the square end. See Plate LXXX. fig. 4.

**FER DE MOULIN**, *milrinde*, *inke de moulin*, in heraldry, is a bearing supposed to represent the iron-ink or ink of a mill, which sustains the moving mill-stone.

**FERDEN**, or **VERDEN**, a city of Germany, subject to Hanover; it is situated in lower Saxony, on the river Aller, twenty six miles south east of Bremen: E. lon. 9°, and N. lat. 53° 24'.

**FERENTARII**, in Roman antiquity, were auxiliary troops, lightly armed; their weapons being a sword, bow, arrows, and a sling.

**FERETINO**, a city and bishop's see of Italy, about fifty miles east of Rome: E. long. 14° 5', and N. lat. 41° 45'.

**FERIÆ**, in Roman antiquity, holidays, or days upon which they abstained from work.

The Romans had two kinds of feriæ: 1. The public, common to all the people in general. 2. The private, which were only kept by some private families.

The public feriæ were fourfold: 1. Stativæ feriæ, holidays which always fell out upon the same day of the

the month, and were marked in the calendar; of these the chief were the *agonalia*, *carmentalia*, and *lupercalia*. 2. *Conceptivæ feriæ*, holidays appointed every year upon certain or uncertain days by the magistrates or the pontiff; such were the *latinæ*, *paganalia*, *compitalia*, &c. See *PAGANALIA*, &c. 3. *Imperativæ feriæ*, holidays commanded or appointed by the authority of the consuls or prætors; of this kind we may reckon the *lectisternium*. See *LECTISTERNIUM*. 4. *Nundinæ*, the days for fairs. See *NUNDINÆ*.

**FERIÆ LATINÆ** were instituted by Tarquinius Superbus, who having overcome the Tuscans, made a league with the Latins, and proposed to them to build a temple in common to Jupiter Latialis, in which both nations might meet, and offer sacrifice for their common safety. At this festival a white bull was sacrificed; and each town, both of the Latins and Romans, provided a certain quantity of meat, wine, and fruits. At first the solemnity continued but one day; after the expulsion of the kings, the senate added a third, a fourth, and so on to ten days.

**FERIA**, in the Romish breviary, is applied to the several days of the week; thus Monday is the *feria secunda*, Tuesday the *feria tertia*; though these days are not working days, but holidays. The occasion of this was, that the first Christians were used to keep the easter-week holy, calling Sunday the *prima feria*, &c. whence the term *feria* was given to the days of every week. But besides these, they have extraordinary *feriæ*, viz. the three last days of passion-week, the two following easter-day, and the second *feriæ* of rogation.

**FERMANACH**, a county of Ireland, in the province of Ulster, the chief town of which is Inniskilling.

**FERMENT**, any body which, being applied to another, produces fermentation.

Ferments are either matters already in the act of fermentation, or that soon run into this act. Of the first kind are the flowers of wine, yeast, fermenting beer, or fermenting wine, &c. and of the second are the new expressed vegetable juices of summer-fruit.

Among distillers, ferments are all those bodies which, when added to the liquor, only correct some fault therein, and, by removing some obstacle to fermentation, forward it by secondary means; as also such as, being added in time of fermentation, make the liquor yield a larger proportion of spirit, and give it a finer flavour.

**FERMENTATION**, may be defined a sensible internal motion of the constituent particles of a moist, fluid, mixt or compound body; by the continuance of which motion, these particles are gradually removed from their former situation or combination, and again, after some visible separation is made, joined together in a different order and arrangement. See *CHEMISTRY*.

P. 94.

**FERMO**, a port-town of Italy, situated on the gulf of Venice, about thirty miles south of Ancona. It is an archbishop's see.

**FERN**, *fliv*, in botany. See *FILIX*, *OSMUNDA*, *ACROSTICUM*, &c.

**FERNANDO**, or **FERNANDES**, an island in the Pacific ocean: W. long. 83°, S. lat. 33°.

**FERRARA**, a city and archbishop's see of Italy: E. long. 12° 6', N. lat. 44° 50'.

**FERRE**, or *le FERRE*, a city of Picardy, in France, forty miles south-east of Amiens: E. long. 3° 26', N. lat. 49° 45'.

**FERRET**, in zoology. See *MUSTELA*.

**FERRETS**, among glass-makers, the iron with which the workmen try the melted metal, to see if it be fit to work.

It is also used for those irons which make the rings at the mouth of bottles.

**FERRETTO**, in glass-making, a substance which serves to colour glass.

This is made by a simple calcination of copper, but it serves for several colours: there are two ways of making it, the first is this. Take thin plates of copper, and lay them on a layer of powdered brimstone, in the bottom of a crucible; over these lay more brimstone, and over that another lay of the plates, and so on alternately till the pot is full. Cover the pot, lute it well, place it in a wind furnace, and make a strong fire about it for two hours. When it is taken out and cooled, the copper will be found so calcined, that it may be crumbled to pieces between the fingers, like a friable earth. It will be of a reddish, and, in some parts, of a blackish colour. This must be powdered and sifted fine for use.

**FERRO**, W. long. 19°, N. lat. 28°, the most westerly of the Canary islands, near the African coast, where the first meridian was lately fixed in most maps; but now, the geographers of almost every kingdom make their respective capitals the first meridian, as we do London.

**FERRÓ**, some little islands situated in the northern ocean, 200 miles north-west of the Orcades, and as many south-east of Iceland: W. long. 7°, N. lat. 63°.

**FERROL**, a sea-port-town of Spain, in the principality of Galicia, situated on a bay of the Atlantic ocean, twenty miles north-east of the Groyne, and fifty miles north of Compostella, a good harbour, where the Spanish squadrons frequently secured themselves in the late war: W. long. 8° 40', N. lat. 43° 30'.

**FERRUGINOUS**, any thing partaking of iron, or which contains particles of that metal.

**FERRUGO**, *RUST*. See *RUST*.

**FERRUM**, *IRON*. See *IRON*.

**FERRY**, a liberty by prescription, or the king's grant, to have a boat for passage, on a firth or river, for carrying passengers, horses, &c. over the same for a reasonable toll.

**FERTILITY**, that quality which denominates a thing fruitful or prolific.

**FERULA**, in botany, a genus of the pentandria digynia class. The fruit is oval, compressed, and has three furrows on each side. There are nine species, none of them natives of Britain.

FESSE

**FESSE**, in heraldry, one of the nine honourable ordinaries, consisting of a line drawn directly across the shield, from side to side, and containing the third part of it, between the honour-point and the nœmbril.

It represents a broad girdle or belt of honour, which knights at arms were anciently girded with. See Plate LXXX. fig. 5.

**FESSE POINT**, is the exact centre of the escutcheon. See **POINT**.

**FESSE-WAYS**, or *in fesse*, denotes any thing borne after the manner of a fesse; that is, in a rank across the middle of the shield.

*Party per fesse*, implies a parting across the middle of the shield, from side to side, through the fesse point.

**FESTI DIES**, in Roman antiquity, certain days in the year, devoted to the honour of the gods.

Numa, when he distributed the year into twelve months, divided the same into the dies festi, dies profesti, and dies intercasti.

The festi were again divided into days of sacrifices, banquets, games, and ferizæ. See **SACRIFICE**, **EPULÆ**, **LUDI**, and **FERIÆ**.

The profesti were those days allowed to men for the administration of their affairs, whether of a public or private nature: these were divided into fasti, comitiales, comperendini, stati, and præliares. See **FASTI**, **COMITIALES**, &c.

The intercasti were days common both to gods and men, some parts of which were allotted to the service of the one, and some to that of the other.

**FESTINO**, in logic, the third mood of the second figure of the syllogism, the first proposition whereof is an universal negative, the second a particular affirmative, and the third a particular negative: as in the following example:

FES No bad man can be happy,

TI Some rich men are bad men:

NO Ergo, some rich men are not happy.

**FESTIVAL**, the same with feast. See **FEAST**.

**FESTOON**, in architecture and sculpture, &c. an ornament in form of a garland of flowers, fruits and leaves, intermixed or twisted together.

**FESTUCA**, in botany, a genus of grasses, belonging to the triandria digynia class. The calix has two valves; and the spica is oblong and cylindrical. There are sixteen species, eleven of which are natives of Britain, viz. the ovina, or sheep's fescue-grass; the rubiuscula, or hard fescue-grass; the rubra, or purple fescue-grass; the bromoides, or barren fescue-grass; the myuros, or wall fescue-grass; the pratensis, or meadow fescue-grass; the elatior, or tall fescue-grass; the decumbens, or small fescue-grass; the fluitans, or flat fescue-grass; the loliacea, or spiked fescue-grass; and the sylvatica, or wood fescue-grass.

**FETIPOUR**, a city of the hither India, twenty-five miles west of Agra: E. long. 78° 40', N. lat. 27°.

**FETLOCK**, in the menage, a tuft of hair growing behind the pastern joint of many horses; for those of a low size have scarce any such tuft.

**FEUD**, the same with fee. See **FEE**.

**FEUDAL**, or **FEODAL**, denotes any thing belonging to a fee. See **FEE**.

**FEUDATORY**, or **FEODATORY**, a tenant who formerly held his estate by feudal service.

**FEU-DUTY**, in Scots law, is the annual rent or duty which a vassal, by the tenor of his right, becomes bound to pay to his superior. See **SCOTS LAW**, title 11.

**FEU-HOLDING**, in Scots law, is that particular tenor by which a vassal is taken bound to pay an annual rent or feu-duty to his superior. See **SCOTS LAW**, tit. 11.

**FEVER**, in medicine. See **MEDICINE**.

**FEVERFEW**, in botany. See **MATRICARIA**.

**FEVERSHAM**, a port-town of Kent, and one of the cinqueports. See **CINQUEPORT**.

It stands seven miles west of Canterbury.

**FEZ**, the capital of the empire of Fez and Morocco, in Africa: W. long 6°, N. lat. 33° 30'.

It is a large and populous city, and the usual residence of the emperor.

**FIAR**, in Scots law, the person vested in the feudal property of a subject. See **FEE**.

**FIASCONE**, a city and bishop's see of Italy, about twelve miles south of Orvieto.

**FIAT**, in law, a short order or warrant signed by a judge, for making out and allowing certain processses.

**FIBRARIÆ**, a class of fossils, naturally and essentially simple, not inflammable nor soluble in water, and composed of parallel fibres, some shorter, others longer; their external appearance being bright, and in some degree transparent: add to this, that they never give fire with steel, nor ferment with, or are soluble in acid menstrua.

**FIBRE**, in anatomy, a perfectly simple body, or at least as simple as any thing in the human structure; being fine and slender like a thread, and serving to form other parts. Hence some fibres are hard, as the bony ones; and others soft, as those destined for the formation of all the other parts.

The fibres are divided also, according to their situation, into such as are straight, oblique, transverse, annular, and spiral; being found arranged in all these directions, in different parts of the body.

**FIBROSE**, something consisting of fibres, as the roots of plants. See **ROOT**.

**FIBULA**, in anatomy. See **ANATOMY**, p. 184.

**FICARIA**, in botany. See **RANUNCULUS**.

**FICEDULA**, in ornithology. See **MOTACILLA**.

**FICOIDEA**, in botany. See **ARZOO**.

**FICOIDES**, a name given to several distinct plants, as the mesembryanthemum musa, and opuntia. See **MESEMBRYANTHEMUM**.

**FICTION**. See **TABLE**.

**FICUS**, the **FIG-TREE**, in botany, a genus of the polygamia polyœcia class. The common receptacle is turbinated, fleshy, and conceals the stoscules. The calix of the male consists of three segments; it has no corolla, but has three stamina: the calix of the female consists of five segments; it has no corolla, and but one pistil, and one seed. There are seven species, all of them natives of warm climates. The fruit of the fig-tree is a soft emollient sweet, and as such enters into several compositions.

**FIDA**, a town on the slave-coast of Guinea: E. long. 3°. N. lat. 6°.

**FIDD**, in the sea-language, an iron, or wooden pin, to splice and fasten ropes together.

**FIDD-HAMMER**, one whose handle is a fidd, or made taper-wife.

**FIDDLE**. See **VIOLIN**.

**FIDEL COMMISSUM**, in Roman antiquity, an estate left in trust with one person, for the use of another. See **TRUSTEE**.

**FIDICINALES**, muscles of the fingers. See **LUMBICALES**.

**FIEF**, or **FEE**. See **FEE**.

**FIELD**, in agriculture, a piece of ground inclosed, whether for tillage or pasture.

**FIELD**, in heraldry, is the the whole surface of the shield, or the continent, so called because it containeth those achievements anciently acquired in the field of battle. It is the ground on which the colours, bearings, metals, furs, charges, &c. are represented. Among the modern heralds, field is less frequently used in blazoning than shield or escutcheon. See the article **SHIELD**, &c.

**FIELD BOOK**, in surveying, that wherein the angles, stations, distances, &c. are set down.

**FIELD-COLOURS**, in war. are small flags of about a foot and half square, which are carried along with the quarter-master general, for marking out the ground for the squadrons and battalions.

**FIELD-FARE**, in ornithology. See **TURDUS**.

**FIELD-OFFICERS**, in the art of war. See **OFFICER**.

**FIELD-PIECES**, small cannons, from three to twelve pounders, carried along with an army in the field.

**FIELD-STAFF**, a weapon carried by the gunners, about the length of a halbert, with a spear at the end; having on each side ears screwed on, like the cock of a match-lock, where the gunners screw in lighted matches, when they are upon command; and then the field-staffs are said to be armed.

**FIELD-WORKS**, in fortification, are those thrown up by an army in besieging a fortress, or by the besieged to defend the place. Such are the fortifications of camps, highways, &c.

*Elysian* **FIELDS**. See **ELYSIAN**.

**FIERI FACIAS**, in law, a writ that lies where a person has recovered judgment for debt or damages in the king's courts against one, by which the sheriff is commanded to levy the debt and damages on the defendant's goods and chattels.

**FIFE**, in music, is a sort of wind-instrument, being a small pipe. See **PIPE**.

**FIFE**, in geography, a county of Scotland bounded by the Frith of Tay on the north; by the German sea on the east; by the Frith of Forth on the south; and by Montecith and Stirling on the west.

**FIVE-RAILS**, in a ship, are those that are placed on banisters, on each side of the top of the poop, and so along with hances or falls.

They reach down to the quarter-deck. and to the stair of the gang-way.

**FIFTH**, in music, one of the harmonical intervals or concords. See **MUSIC**.

**FIG**, or fig-tree. See **FIGUS**.

**FIGWORT**, a plant called by the botanists *scrophularia*. See **SCROPHULARIA**.

**FIGURAL**, **FIGURATE**, or **FIGURATIVE**, a term applied to whatever is expressed by obscure resemblances. The word is chiefly applied to the types and mysteries of the Mosaic law; as also to any expression which is not taken in its primary and literal sense.

**FIGURE**, in physics, expresses the surface or terminating extremities of any body.

**FIGURES**, in arithmetic, are certain characters whereby we denote any number which may be expressed by any combination of the nine digits, &c. See **ARITHMETIC**.

**FIGURE**, among divines, is used for the mysteries represented under certain types.

**FIGURE**, in dancing, denotes the several steps which the dancer makes in order and cadence, considered as they mark certain figures on the floor.

**FIGURE**, in painting and designing, denotes the lines and colours which form the representation of any animal, but more particularly of a human personage.

**FIGURE**, in composition. See **ALLEGORY**, **APOSTROPHE**, **HYPERBOLE**, **PERSONIFICATION**, &c.

**FIGURED**, in general, something marked with figures.

The term figured is chiefly applied to stuffs, whereon the figures of flowers, and the like, are either wrought or stamped.

**FILAMENT**, in physiology and anatomy. See **FIBRE**.

**FILAMENT**, among botanists, is particularly used for the stamina. See **BOTANY**, Sect. II.

**FILBERT**, or **FILBERD**, the fruit of the corylus, or hazel. See **CORYLUS**.

**FILE**, among mechanics, a tool used in metal, &c. in order to smooth, polish, or cut.

This instrument is of iron, or forged steel, cut in little furrows, with chissels and a mallet, this and that way, and of this or that depth, according to the grain or touch required. After cutting the file, it must be tempered with a composition of chimney soot, very hard and dry, diluted, and wrought up with urine, vinegar, and salt; the whole being reduced to the consistence of mustard. Tempering the files consists in rubbing them over with this composition, and covering them in loam; after which they are put in a charcoal fire, and taken out by that time they have acquired a cherry colour, which is known by a small rod of the same steel put in along with them. Being taken out of the fire, they are thrown into cold spring-water; and when cold, they are cleaned with charcoal and a rag; and being clean and dry, are kept from rust by laying them up in wheat bran. Iron files require more heating than steel ones. Files are of different forms, sizes, cuts, and degrees of fineness, according to the different uses and occasions for which they are made.

**FILE**, in the art of war, a row of soldiers, standing one behind another, which is the depth of the battalion or

or Squadron. The files of a battalion of foot are generally three deep; as are sometimes those of a Squadron of horse. The files must be straight, and parallel one to another.

**FILIGRANE**, or **FILIGREE-WORK**, any piece of gold or silver-work that is curiously done with grains or drops on the filaments or threads.

**FILIPENDULA**, in botany. See **SPURFA**.

**FILIX**, in botany, an order of the cryptogamia class of plants. See **BOTANY**, p. 636.

**FILLET**, in anatomy. See **FROENUM**.

**FILLET**, or **FILLET**, in architecture, a little square member, ornament, or moulding, used in divers places, and upon divers occasions, but generally as a crowning over a greater moulding.

**FILLET**, in heraldry, a kind of orle or bordure, containing only a third or fourth part of the breadth of the common bordure. It is supposed to be withdrawn inwards, and is of a different colour from the field. It runs quite round, near the edge, as a lace over a cloak.

**FILLET**, in the menage, the loins of an horse, which begin at the place where the hinder part of the saddle rests.

**FILLER HORSE**, one yoked immediately to a cart.

**FILLY**, a term among horse-dealers, to denote the female or mare-colt.

**FILM**, a thin skin or pellicle. In plants, it is used for that thin, woody skin, which separates the seeds in the pods, and keeps them apart.

**FILTER**, or **FILTRE**, in chemistry, a strainer commonly made of bibulous or filtering paper in the form of a funnel, through which any fluid is passed, in order to separate the gross particles from it, and render it limpid.

**FIMBRIÆ**, denotes appendages disposed by way of fringe round the border of any thing.

**FIMBRIATED**, in heraldry an ordinary with a narrow bordure or hem of another tincture.

**FIN**, in natural history, a well-known part of fishes, consisting of a membrane supported by rays, or little bony or cartilaginous ossicles.

**FINAL**, in general, whatever terminates or concludes a thing.

**FINAL LETTERS**, among Hebrew grammarians, five letters so called, because they have a different figure at the end of words from what they have in any other situation.

**FINAL**, in geography, a port town of Italy, subject to Genoa, and situated on the Mediterranean, about thirty-seven miles south-west of that city.

**FINANCES**, in the French polity, signify the revenues of the king and state.

**FINCH-KIND**, in ornithology, an appellation given to a genus of birds, known among authors by the name of *fringilla*. See **FRINGILLA**.

**FINE**, in law, has divers significations, it being sometimes taken for a sum of money advanced and paid for the income of lands. It is likewise used in another

sense, where a sum is paid as an amends, or by way of punishment for an offence committed.

**FINERS of gold and silver**, are those who separate these metals from coarser ores. See **REFINERS**.

**FINERY**, in the iron works, one of the forges at which the iron is hammered and fashioned into what they call a bloom, or square bar.

**FINGERS**, in anatomy, the extreme part of the hand divided into five members. See **ANATOMY**, part I. and II.

**FINISTERRA**, the most westerly cape or promontory of Spain, in 10° 15' W. long. and 43° N. lat. This cape is likewise the most westerly part of the continent of Europe.

**FINITE**, something bounded or limited, in contradistinction to infinite. See **INFINITE**.

**FINLAND**, a province of Sweden, lying northward of the gulph of Finland, and eastward of the Bothnick gulph. It is a frontier province, bounded by Russia on the east.

**FIR-TREE**, in botany. See **PINUS**.

**FIRE**, a general name, by which men seem to understand a certain sensation or complex notion of light, heat, burning, melting, &c.

The power of fire is so great, its effects so extensive, and the manner of its acting so wonderful, that some of the wisest nations of old revered and worshipped it, as the supreme deity. Some of the chemists also, after they had discovered its surprising operations, suspected it to be an uncreated being: and indeed the most famous of them have acknowledged it as the source of all their knowledge; and hence have professed themselves philosophers by fire, nor thought they could be honoured with a nobler title. Now, amongst all the wonderful properties of fire, there is none more extraordinary than this, that though it is the principal cause of almost all the sensible effects that continually fall under our observation, yet it is itself of so infinitely a subtle nature, that it eludes the most sagacious enquiries, nor ever comes within the cognizance of our senses. Fire is generally divided into three kinds or species, *viz.* celestial, subterraneous, and culinary.

By celestial fire is principally understood that of the sun, without regard to that of the fixed stars, though this perhaps may be of the same nature.

By subterraneous fire we understand that which manifests itself in fiery eruptions of the earth, volcanoes, or burning mountains; or by any other effects it produces in mines, or the more central parts of the earth.

By culinary fire we mean that employed in all chemical operations, and the common occasions of life.

The sun's heat appears to be the actuating principle, or general instrument of all the operations in the animal, vegetable, atmospherical, marine, and mineral kingdoms.

Fire, considered in itself, seems to exist in the greatest purity and perfection in the celestial regions; at least we are insensible of any considerable smoke it yields:

yields : for the rays of light come to us from the sun, unmixed with any of that gross, feculent, or terrestrial matter, found in culinary and subterranean fires : but, allowing for this difference, the effects of the solar fire appear the same as those of culinary fire.

If we to examine the effects of subterraneous fires, we shall find them the same with those produced by culinary fire. Thus, burnt coals, cinders, and melted minerals, are thrown up by Vesuvius and other burning mountains. Warm nephritical exhalations, natural hot springs, steams, vapours, smoke, &c. are found in several parts of the globe, rising nearly in the same manner as if they were produced by the heat of a furnace. Whence it appears, that subterraneous fires are of the same nature with the culinary.

As men generally affix to the word fire, a complex idea of burning, light, heat, melting, &c. this idea should be analysed, in order to see what parts are essential, and what precarious or arbitrary.

We frequently find the effects of fire produced where no visible fire appeared. Thus the fingers are easily burnt by an iron heated below the degree of ignition, or so as to be no ways visibly red-hot or fiery : whence it follows, that the eye is no judge of fire.

So likewise the touch gives no positive notice of any degree of fire below the natural heat of the body, or any so great as to destroy the organ.

Again, the effects of fire are often produced without any manifest signs of burning, melting, &c. as in evaporations, &c. If this method of exclusion and rejection were pursued to its due length, we should perhaps find no criterion, infallible mark, or characteristic of fire in general, but that of a particular motion struggling among the minute parts of bodies, and tending to throw them off at the surface. If this should prove the case, then such a motion will be the form and essence of fire ; and which, being present, makes fire also present : and, when absent, makes fire also absent : whence to produce fire, and produce this motion in bodies, will be one and the same thing.

The great and fundamental difference in respect to the nature of fire is, whether it be originally such, formed thus by the Creator himself at the beginning of things ; or whether it be mechanically producible from other bodies, by inducing some alterations in the particles thereof. The former opinion is maintained by Homberg, Boerhaave, the younger Lemery, and s'Gravesande ; the latter is chiefly supported by the English philosophers, lord Bacon, Mr Boyle, and Sir Isaac Newton.

Bacon, in the treatise *De Forma Calicli*, deduces, from a great number of particulars, that heat in bodies is no other than motion so and so circumstanced ; so that to produce heat in a body, nothing is required but to excite a certain motion in the parts thereof.

Boyle seconds him in an express treatise of the mechanical origin of heat and cold, and maintains the same doctrine with new observations and experiments ; as a specimen of which, we shall here give the two following.

1. In the production of heat, says that able philoso-

pher, there appears nothing on the part either of the agent or patient, but motion and its natural effects. When a smith briskly hammers a piece of iron, the metal thereby becomes exceedingly hot ; yet there is nothing to make it so, except the forcible motion of the hammer impressing a vehement and variously determined agitation on the small parts of the iron, which, being a cold body before, grows, by that super-induced commotion of its small parts, hot : first, in a more loose acceptation of the word, with regard to some other bodies, compared with which it was cold before ; then sensibly hot, because this agitation surpasses that of the points of our fingers ; and in this instance oftentimes the hammer and anvil continue cold after the operation ; which shews, that the heat acquired by the iron was not communicated by either of those implements, as heat ; but produced in it by a motion, great enough strongly to agitate the parts of so small a body as the piece of iron, without being able to have the like effect upon so much greater masses of metal as the hammer and the anvil : though if the percussions were often and briskly renewed, and the hammer were small, this also might be heated : whence it is not necessary that a body itself be hot to give heat.

2. If a large nail be driven by a hammer into a plank of wood, it will receive several strokes on its head before it grows hot ; but when it is once driven to the head, a few strokes suffice to give it a considerable heat ; for while, at every blow of the hammer, the nail enters further into the wood, the motion produced is chiefly progressive, and is of the whole nail tending one way ; but when that motion ceases, the impulse given by the stroke being unable to drive the nail further on, or break it, must be spent in making a various, vehement, and intestine commotion of the parts among themselves, wherein the nature of heat consists.

Agreeable to this is the opinion of Sir Isaac Newton, who conceives that gross bodies may be converted into light, by the agitation of their particles ; and light, again, into gross bodies, by being fixed therein.

On the other hand, M. Homberg, in his *Essai du Souffre Principe*, holds, that the chemical principle, or element sulphur, which is supposed one of the simple, primary, pre-existent ingredients of all natural bodies, is real fire, and consequently that fire is coeval with bodies.

Dr s'Gravesande goes on much the same principle : fire, according to him, enters the composition of all bodies, is contained in all bodies, and may be separated or procured from all bodies, by rubbing them against each other ; and thus putting their fire in motion : but fire, he adds, is by no means generated by such motion.

Mr Lemery, the younger, agrees with these two authors in asserting this absolute and ingenerable nature of fire : but he extends it farther. Not contented to confine it as an element to bodies, he endeavours to shew, that it is equally diffused through all space, and that it is present in all places ; in the void spaces between bodies, as well as in the insensible interstices between their parts.

This

This last sentiment falls in with that of Boerhaave and the celebrated M. Musschenbroek. But notwithstanding what those able philosophers have advanced, it is evident that fire, heat, flame, &c. are only the different modifications of the particles of light, and that the particles of light themselves depend entirely on velocity for their lucific quality; since, by many experiments, we know, that the particles of bodies become lucid, or particles of light, by only producing in them a requisite degree of velocity: thus the particles in a rod of iron, being hammered very nimbly, shine and become red-hot: thus also the violent stroke of the flint against the steel, in striking fire, puts the particles of the steel, which it takes off, into such a motion as causes them to melt, and become red-hot, which makes the sparks of fire produced by each stroke: as, therefore, fire consists in the great velocity of the particles, so it may be communicated from one body in which it is, to another in which it is not, after the same manner that one body in motion will communicate motion to another that has got none.

Fire differs from heat only in this, that heat is a motion in the particles of a body, with a lesser degree of velocity; and fire, a motion with a greater degree of velocity, *viz.* such as is sufficient to make the particles shine; though we often call such a state as will burn, *fire*, though it does not actually shine; and we seldom call those lucid bodies fires, which only shine, and do not burn. These are a sort of phosphori, which, though they have no heat, yet seem to owe their lucidity to the motion of their parts.

There seems to be no other difference between fire and flame, than this; that fire consists in a glowing degree of velocity in the parts of a body, while yet subsisting together in the mass; but flame is the same degree of velocity in the particles dissipated and flying off in vapours: or, to use Sir Isaac Newton's expression, flame is nothing else but a red-hot vapour. See FLAME.

**FIRE**, in chemistry. See CHEMISTRY, p. 67. and 110. Vol. II.

**Electrical FIRE**. See ELECTRICITY.

**Walking FIRE**, in meteorology. See WILL-WITH-A WHIST.

**FIRE**, in theology. See HELL.

We read of the sacred fire in the first temple of Jerusalem, concerning which the Jews have a tradition that it came down from heaven: it was kept with the utmost care, and it was forbidden to carry any strange fire into the temple. This fire is one of the five things which the Jews confess were wanting in the second temple.

The Pagans had their sacred fires, which they kept in their temples with the most religious care, and which were never to be extinguished. Numa was the first who built a temple to Fire as a goddess, at Rome, and instituted an order of priestesses for the preservation of it. See VESTALS.

Fire was the supreme god of the Chaldeans; the magi were worshippers of fire; and the Greeks and Armenians still keep up a ceremony called the *Ilioy*

Fire, upon a perfusion that every Easter-day a miraculous fire descends from heaven into the holy sepulchre, and kindles all the lamps and candles there.

**FIRE-LOCK**. See GUN, MUSQUET, &c.

**FIRE POTS**, in the military art, small earthen pots, into which is put a charged grenade, and over that powder enough till the grenade is covered; then the pot is covered with a piece of parchment, and two pieces of match across lighted: this pot being thrown by a handle of matches where it is designed, it breaks and fires the powder, and burns all that is near it, and likewise fires the powder in the grenade, which ought to have no fuse, to the end its operations may be the quicker.

**FIRE-WORKS**. See PYROTECHNIA.

**FIRE SHIP**, in the navy, a vessel charged with artificial fire-works, which having the wind of an enemy's ship, grapples her, and sets her on fire.

**FIRE-OFFICE**, an office of insurance from fire. See ASSURANCE.

**Wild-FIRE**, a kind of artificial or factitious fire, which burns even under water, and that with greater violence than out of it. It is composed of sulphur, naphtha, pitch, gum, and bitumen; and is only extinguishable by vinegar mixed with sand and urine, or by covering it with raw hides. Its motion or tendency is said to be contrary to that of natural fire, and it always follows the direction in which it is thrown, whether it be downwards, sideways, or otherwise.

**FIRING-IRON**, in farriery, an instrument not unlike the blade of a knife; which being made red-hot, is applied to a horse's hams, or other places standing in need of it, as in preternatural swellings, farcy, knots, &c. in order to discuss them.

**FIRKIN**, an English measure of capacity, for things liquid, being the fourth part of the barrel: it contains 8 gallons of ale, soap, or herrings; and 9 gallons of beer. See MEASURE and BARREL.

**FIRLOT**, a dry measure used in Scotland. The oat-firlot contains 21½ pints of that country; the wheat-firlot contains about 2211 cubical inches; and the barley-firlot, 31 standard pints. Hence it appears that the Scotch wheat-firlot exceeds the English bushel by 33 cubical inches.

**FIRMAMENT**, in the Ptolemaic astronomy, the eighth heaven or sphere, with respect to the seven spheres of the planets which it surrounds. It is supposed to have two motions; a diurnal motion, given to it by the primum mobile, from east to west, about the poles of the ecliptic; and another opposite motion from west to east; which last it finishes, according to Tycho, in 25412 years, according to Ptolemy in 36000, and according to Copernicus in 25800, in which time the fixed stars return to the same points in which they were at the beginning. This period is commonly called the Platonic year, or the great year.

**FIRMAMENT** is also used in divers places of scripture, to denote the middle region of the air.

**FIRMAN** is a passport or permit granted by the great mogul to foreign vessels, to trade within the territories of his jurisdiction.

**FIRMNESS**, denotes the consistence of a body, or that

state wherein its sensible parts cohere in such a manner, that the motion of one part induces a motion of the rest.

**FIRST-FRUIT**s, among the Hebrews, were oblations of part of the fruit of the harvest, offered to God as an acknowledgment of his sovereign dominion.

**FIRST-FRUIT**s, in the church of England, are the profits of every spiritual benefice for the first year, according to the valuation thereof in the king's books.

**FISC**, in the civil law, the treasury of a prince. It differs from the *ærarium*, which was the treasury of the public or people: thus, when the money arising from the sale of condemned persons goods was appropriated for the use of the public, their goods were said *publicari*; but when it was destined for the support of the prince, they were called *confiscari*.

**FISCAL**, in the civil law, something relating to the pecuniary interest of the prince or people. The officers appointed for the management of the fisc, were called *procuratores fisci*, and *advocati fisci*; and among the cases enumerated in the constitutions of the empire where it was their business to plead, one is against those who have been condemned to pay a fine to the fisc on account of their litigiousness, or frivolous appeals.

**FISH**, in natural history. See **NATURAL HISTORY**.

*Breeding of FISHES* may be turned to great advantage; for besides furnishing your table, obliging your friends, and raising money, your land will be thereby greatly improved, so as to yield more this way than by any other employment whatever.

When fish are fed in large pools or ponds, either malt boiled, or fresh grains, is the best food; thus carps may be raised and fed like capons, and tenches will feed as well. The care of feeding them is best committed to a gardener or the butler, who should be always at hand. In a stew, any sort of grain boiled, especially peas, and malt coarse ground; also the grains after brewing, while fresh and sweet: but one bushel of malt not brewed, will go as far as of grains. See **FISH-POND**, *infra*.

**FISH**, in a ship, a plank or piece of timber, fastened to a ship's mast or yard, to strengthen it, which is done by nailing it on with iron spikes, and waulding or winding ropes hard about them.

**FISHES**, in heraldry, are the emblems of silence and watchfulness; and are borne either upright, imbowed, extended, endorsed respecting each other, surmounting one another, fretted, &c.

In blazoning fishes, those borne feeding, should be termed devouring; all fishes borne upright and having fins, should be blazoned hauriant; and those borne transverse the escutcheon, must be termed naiant.

**FISH-PONDS**, those made for the breeding or feeding of fish.

Fish-ponds are no small improvement of watery and boggy lands, many of which are fit for no other use. In making of a pond, its head should be at the lowest part of the ground, that the trench of the flood-gate or sluice, having a good fall, may not be too long in emptying. The best way of making the head secure,

is to drive in two or three rows of stakes above six feet long, at about four feet distance from each other, the whole length of the pond-head, whereof the first row should be rammed at least about four feet deep. If the bottom is false, the foundation may be laid with quicklime; which slacking, will make it as hard as a stone. Some lay a layer of lime, and another of earth dug out of the pond, among the piles and stakes; and when these are well covered, drive in others as they see occasion, ramming in the earth as before, till the pond-head be of the height designed.

The dam should be made sloping on each side, leaving a waste to carry off the over-abundance of water in times of floods or rains; and as to the depth of the pond, the deepest part need not exceed six feet, rising gradually in shoals towards the sides, for the fish to sun themselves, and lay their spawn. Gravelly and sandy bottoms, especially the latter, are best for breeding; and a fat soil with a white fat water, as the washings of hills, commons, streets, sinks, &c. is best for fattening all sorts of fish. For storing a pond, carp is to be preferred for its goodness, quick growth, and great increase, as breeding five or six times a-year. A pond of an acre, if it be a feeding and not breeding one, will every year feed two hundred carps of three years old, three hundred of two years old, and four hundred of a year old. Carps delight in ponds that have marl or clay bottoms, with plenty of weeds and grass, whereon they feed in hot months.

Your pond should be drained every three or four years, and your fish sorted. If it is a breeding one, the smaller ones are to be taken out, to store other ponds with; leaving a good stock of females, at least eight or nine years old, as they never breed before that age. In feeding ponds, it is best to keep them pretty near of a size.

**FISHERY**, a place where great numbers of fish are caught.

The principal fisheries for salmon, herring, mackrel, pilchards, &c. are along the coasts of Scotland, England, and Ireland; for cod, on the banks of Newfoundland; for whales, about Greenland; and for pearls, in the East and West-Indies.

**FISHERY** denotes also the commerce of fish, more particularly the catching them for sale.

Were we to enter into a very minute and particular consideration of fisheries, as at present established in this kingdom, this article would swell beyond its proper bounds; because to do justice to a subject of that concernment to the British nation, requires a very ample and distinct discussion. We shall, however, observe, that since the Divine Providence has so eminently stored the coasts of Great Britain and Ireland with the most valuable fish; and since fisheries, if successful, become permanent nurseries for breeding expert seamen: it is not only a duty we owe to the Supreme Being, not to despise the wonderful plenty he hath afforded us, by neglecting to extend this branch of commerce to the utmost; but it is a duty we owe to our country, for its natural security, which depends upon the strength of our royal navy. No nation can have a navy, where there

there is not a fund of business to breed and employ seamen, without any expence to the public; and no trade is so well calculated for training up these useful members of this society, as fisheries.

The situation of the British coasts is the most advantageous for catching fish in the world: the Scottish islands, particularly those to the north and west, lie most commodious for carrying on the fishing trade to perfection; for no country in Europe can pretend to come up to Scotland in the abundance of the finest fish, with which its various creeks, bays, rivers, lakes, and coast are replenished. King Charles I. was so sensible of the great advantage to be derived from fisheries, that he began the experiment, together with a company of merchants: but the civil wars soon occasioned that project to be set aside. King Charles II. made a like attempt; but his pressing wants made him withdraw what money he had employed that way, whereupon the merchants that joined with him did so too. Since the union, several attempts have been made to retrieve the fisheries, and a corporation settled to that effect, entitled the Royal British Fishery.

In the year 1750, the parliament of Great Britain taking the state of the fisheries into consideration, an act was passed for the encouragement of the white-herring fishery, granting a charter, whereby a corporation is created, to continue twenty one years, by the name of the Society of the Free British Fishery, to be under the direction of a governor, president, vice-president, council, &c. who are to continue in office the space of three years, with power to make bye-laws, &c. and to raise a capital of 500,000l. by way of subscription. And any number of persons, who, in any part of Great Britain, shall subscribe 10,000l. into the stock of this society, under the name of the Fishing Chamber, and carry on the said fishery on their own account of profit and loss, shall be entitled to the same bounty allowed to the society. The bounty is 30s. the tun, to be paid yearly, for fourteen years, besides 3 per cent. for the money advanced by each chamber. The act contains other proper regulations relative to the nets, marks on the herring-barrels, number of hands, and the quantity of salt that is entitled to the bounty, &c. It is then by the encouragement given by this act, that we now see a laudable emulation prevailing all over the two kingdoms, and fishing buffets fitted out from almost every port, in order to repair to the Shetland islands, where the herring-fishery is carried on with an ardor becoming so important a branch of trade. Scotland, which suffered incredibly from the neglect of this valuable and natural produce of the seas, has not been backward to join in a scheme that tends so evidently to its own advantage; for the cities of Edinburgh and Glasgow, the towns of Montrose, Dundee, Perth, Inverness, and some other boroughs, have raised the proper sum, and chambers have been erected in each of them; the gentlemen of estates adjoining to the respective places above-mentioned, liberally contributing with merchants, towards the prosecution of an undertaking so visibly tending to the good of their country in general.

*Cod-FISHERY.* There are two kinds of cod-fish, the one green or white cod, and the other dried or cured cod; though it is all the same fish differently prepared; the former being sometimes salted and barrelled, then taken out for use; and the latter, having lain some competent time in salt, dried in the sun or smoke. We shall therefore speak of each of these apart; and first of

*Green-cod FISHERY.* The chief fisheries for green cod are in the bay of Canada, on the great bank of Newfoundland, and on the isle of St Peter, and the isle of S ble, to which places vessels resort from divers parts both of Europe and America. They are from 100 to 150 tons burden, and will catch between thirty and forty thousand cod each. The most essential part of the fishery is, to have a master who knows how to cut up the cod, one who is skilled to take off the head properly, and above all a good salter, on which the preserving of them, and consequently the success of the voyage, depends. The best season is from the beginning of February to the end of April; the fish, which in the winter retire to the deepest water, coming then on the banks, and fattening extremely. What is caught from March to June keeps well; but those taken in July, August, and September, when it is warm on the banks, are apt to spoil soon. Every fisher takes but one at a time: the most expert will take from 350 to 400 in a day; but that is the most, the weight of the fish and the great coldness on the bank fatiguing very much. As soon as the cod are taken, the head is taken off; they are opened, gutted, and salted; and the salter stows them in the bottom of the hold, head to tail, in beds a fathom or two square; laying layers of salt and fish alternately, but never mixing fish caught on different days. When they have lain thus three or four days to drain off the water, they are replaced in another part of the ship, and salted again; where they remain till the vessel is loaded. Sometimes they are cut in thick pieces, and put up in barrels for the convenience of carriage.

*Dry-cod FISHERY.* The principal fishery for dry cod is, from Cape Rose to the Bay des Exports, along the coast of Placentia, in which compass there are divers commodious ports for the fish to be dried in. These, though of the same kind with the fresh cod, are much smaller, and therefore fitter to keep, as the salt penetrates more easily into them. The fishery of both is much alike; only this latter is most expensive, as it takes up more time, and employs more hands, and yet scarce half so much salt is spent in this as in the other. The bait is herrings, of which great quantities are taken on the coast of Placentia. When several vessels meet and intend to fish in the same port, he whose shallow first touches ground, becomes entitled to the quality and privileges of admiral: he has the choice of his station, and the refusal of all the wood on the coast at his arrival. As fast as the masters arrive, they unrig all their vessels, leaving nothing but the shrouds to sustain the masts, and in the mean time the mates provide a tent on shore, covered with branches of trees, and sails over them, with a scaffold of great trunks of pines, twelve, fifteen, sixteen, and often

often twenty feet high, commonly from forty to sixty feet long, and about one third as much in breadth. While the scaffold is preparing, the crew are a fishing; and as fast as they catch, they bring their fish ashore; open and salt them upon moveable benches; but the main salting is performed on the scaffold. When the fish have taken salt, they wash and hang them to drain on rails; when drained, they are laid on kinds of stages, which are small pieces of wood laid a-crofs, and covered with branches of trees, having the leaves stripped off for the passage of the air. On these stages, they are disposed, a fish thick, head against tail, with the back uppermost, and are turned carefully four times every twenty four hours. When they begin to dry, they are laid in heaps ten or twelve thick, in order to retain their warmth; and every day the heaps are enlarged, till they become double their first bulk; then two heaps are joined together, which they turn every day as before; lastly, they are salted again, beginning with those first salted; and being laid in huge piles, they remain in that situation till they are carried on board the ships, where they are laid on the branches of trees disposed for that purpose, upon the ballast, and round the ship, with mats to prevent their contracting any moisture.

There are four kinds of commodities drawn from cod, *viz.* the zounds, the tongues, the roes, and the oil extracted from the liver. The first is salted at the fishery, together with the fish, and put in barrels from 6 to 700 pound. The tongues are done in like manner, and brought in barrels from 4 to 500 pounds. The roes are also salted in barrels, and serve to cast into the sea to draw fish together, and particularly pilchards. The oil comes in barrels, from 400 to 520 pounds, and is used in dressing leather.—In Scotland, they catch a small kind of cod on the coasts of Buchan, and all along the Murra; frith on both sides; as also in the frith of Forth, Clyde, &c. which is much esteemed. They salt and dry them in the sun upon rocks, and sometimes in the chimney. They also cure skait, and other smaller fish in the same manner; but most of these are for home consumption.

*Coral-Fishery.* See *CORAL-fishery*.

*Herring-Fishery.* See *CLUPEA*.

*Pilchard-Fishery.* The chief pilchard-fisheries are along the coasts of Dalmatia on the coast of Bretagne, and along the coasts of Cornwall and Devonshire. That of Dalmatia is very plentiful: that on the coasts of Bretagne employs annually about 300 ships. The pilchards caught on our coasts, though bigger, are not so much valued as those on the coasts of France, owing principally to their not being so thoroughly cured. They naturally follow the light, which contributes much to the facility of the fishery: the season is from June to September. On the coasts of France they make use of the roes of the cod-fish as a bait, which thrown into the sea, makes them rise from the bottom, and run into the nets. On our coasts there are persons posted ashore, who, spying by the colour of the water where the shoals are, make signs to the boats to go among them to cast their nets. When taken, they are brought

on shore to a warehouse, where they are laid up in broad piles, supported with backs and sides; and as they are piled, they salt them with bay-salt, in which lying to soak for thirty or forty days, they run out a deal of blood, with dirty pickle and bitter: then they wash them clean in sea-water; and, when dry, barrel and press them hard down to squeeze out the oil, which issues out at a hole in the bottom of the cask. The Cornishmen observe of the pilchard, that it is the least fish in size, most in number, and greatest for gain, of any they take out of the sea.

*Salmon-Fishery.* The chief salmon-fisheries in Europe are in England, Scotland, and Ireland, in the rivers, and sea-coasts adjoining to the river-mouths. The most distinguished for salmon in Scotland are, the river Tweed, the Clyde, the Tay, the Dee, the Don, the Spey, the Ness, the Bewley, &c. in most of which it is very common, about the height of summer, especially if the weather happen to be very hot, to catch four or five score of salmon at a draught. The chief rivers in England for salmon are, the Tyne, the Trent, the Severn, and the Thames. The fishing usually begins about January; and in Scotland they are obliged to give over about the middle of August; because, as it is then supposed the fish come up to spawn, it would be quite depopulating the rivers to continue fishing any longer. It is performed with nets, and sometimes with a kind of locks or wears made on purpose, which in certain places have iron or wooden grates so disposed, in an angle, that being impelled by any force in a contrary direction to the course of the river, they may give way and open a little at the point of contact, and immediately shut again, closing the angle. The salmon, therefore, coming up into the rivers, are admitted into these grates, which open, and suffer them to pass through, but shut again, and prevent their return. Salmon are also caught with a spear, which they dart into him when they see him swimming near the surface of the water. It is customary likewise to catch them with a candle and lanthorn, or wisp of straw set on fire; for the fish naturally following the light, are struck with the spear, or taken in a net spread for that purpose, and lifted with a sudden jerk from the bottom. We make no mention of the method of catching salmon with a line or hook, because it is much the same with that explained under the article *Trout-Fishing*.

*Curing Salmon.* When the salmon are taken, they open them along the back, take out the guts and gills, and cut out the greatest part of the bones, endeavouring to make the inside as smooth as possible; then salt the fish in large tubs for the purpose, where they lie a considerable time soaking in brine; and about October, they are packed close up in barrels, and sent to London, or exported up the Mediterranean. They have also in Scotland, a great deal of salmon salted in the common way, which after soaking in brine a competent time, is well pressed, and then dried in smoke: this is called *kipper*, and is chiefly made for home consumption, and, if properly cured and prepared, is reckoned very delicious.

*Sturgeon-*

**Sturgeon-Fishery.** The greatest sturgeon-fishery is in the mouth of the Volga, on the Caspian sea, where the Muscovites employ a great number of hands, and catch them in a kind of inclosure formed by huge stakes representing the letter Z, repeated several times. These fisheries are open on the side next the sea, and close on the other; by which means the fish ascending in its season up the river, is embarrassed in these narrow angular retreats, and so is easily killed with a harpoon-iron. Sturgeons, when fresh, eat deliciously; and in order to make them keep, they are salted or pickled in large pieces, and put up in cags from thirty to fifty pounds. But the great object of this fishery is the roe, of which the Muscovites are extremely fond, and of which is made the caviar, or kavia, so much esteemed by the Italians. See **CAVEAR**.

**Whale-Fishery.** Whales are chiefly caught in the north sea: the largest fort are found about Greenland, or Spitzbergen. At the first discovery of this country, whales not being used to be disturbed, frequently came into the very bays, and were accordingly killed almost close to the shore, so that the blubber being cut off was immediately boiled into oil on the spot. The ships in these times took in nothing but the pure oil and the fins, and all the business was executed in the country, by which means a ship could bring home the product of many more whales than she can according to the present method of conducting this trade. The fishery also was then so plentiful, that they were obliged sometimes to send other ships to fetch off the oil they had made, the quantity being more than the fishing ships could bring away. But time and change of circumstances have shifted the situation of this trade. The ships coming in such numbers from Holland, Denmark, Hamburgh, and other northern countries, all intruders upon the English, who were the first discoverers of Greenland, the whales were disturbed, and gradually, as other fish often do, forsaking the place, were not to be killed so near the shore as before; but are now found, and have been so ever since, in the openings and space among the ice, where they have deep water, and where they go sometimes a great many leagues from the shore.

The whale fishery begins in May, and continues all June and July; but whether the ships have good or bad success, they must come away, and get clear of the ice, by the end of August; so that in the month of September at farthest, they may be expected home; but a ship that meets with a fortunate and early fishery in May, may return in June or July.

The manner of taking whales at present is as follows. As soon as the fishermen hear the whale blow, they cry out, *Fall! fall!* and every ship gets out its long boat, in each of which there are six or seven men: they row till they come pretty near the whale, then the harpooner strikes it with his harpoon. This requires great dexterity; for through the bone of his head there is no striking, but near his spout there is a soft piece of flesh, into which the iron sinks with ease. As soon as he is struck, they take care to give him rope enough, otherwise, when he goes down, as he

frequently does, he would inevitably sink the boat: this rope he draws with such violence, that, if it were not well watered, it would, by its friction against the sides of the boat, be soon set on fire. The line fastened to the harpoon is six or seven fathom long, and is called the fore-runner; it is made of the finest and softest hemp, that it may slip the easier: to this they join a heap of lines of 90 or 100 fathoms each; and when there are not enough in one long boat, they borrow from another. The man at the helm observes which way the rope goes, and steers the boat accordingly, that it may run exactly out before; for the whale runs away with the line with so much rapidity, that he would overset the boat, if it were not kept straight. When the whale is struck, the other long boats row before, and observe which way the line stands, and sometimes pull it; if they feel it stiff, it is a sign the whale still pulls in strength; but if it hangs loose, and the boat lies equally high before and behind upon the water, they pull it in gently, but take care to coil it so, that the whale may have it again easily if he recovers strength: they take care, however, not to give him too much line, because he sometimes entangles it about a rock, and pulls out the harpoon. The fat whales do not sink as soon as dead, but the lean one's do, and come up some days afterwards. As long as they see whales, they lose no time in cutting up what they have taken, but keep fishing for others: when they see no more, or have taken enough, they begin with taking off the fat and whiskers in the following manner. The whale being lashed along-side, they lay it on one side, and put two ropes, one at the head, and the other in the place of the tail, which, together with the fins, is struck off as soon as he is taken, to keep those extremities above water. On the off-side of the whale are two boats, to receive the pieces of fat, utensils, and men, that might otherwise fall into the water on that side. These precautions being taken, three or four men with irons at their feet, to prevent slipping, get on the whale, and begin to cut out pieces of about three feet thick, and eight long, which are hauled up at the capstane or windlafs. When the fat is all got off, they cut off the whiskers of the upper jaw with an ax. Before they cut, they are all lashed to keep them firm, which also facilitates the cutting, and prevents them from falling into the sea: when on board, five or six of them are bundled together, and properly stowed; and after all is got off, the carcase is turned adrift, and devoured by the bears, who are very fond of it. In proportion as the large pieces of fat are cut off, the rest of the crew are employed in slicing them smaller, and picking out all the lean. When this is prepared, they stow it under the deck, where it lies till the fat of all the whales is on board; then cutting it still smaller, they put it up in tubs in the hold, cramming them very full and close. Nothing now remains but to sail homewards, where the fat is to be boiled and melted down into train oil. See **TRAIN OIL**.

It were in vain to speak in this place of the advantages that may be derived to Great Britain from the whale-fishery. We shall only remark, that the legisla-

ture think that trade of so great importance, as to grant a very considerable bounty for the encouragement of it; for every British vessel of 200 tons or upwards, bound to the Greenland-seas on the whale-fishery, if found to be duly qualified according to the act, obtains a licence from the commissioners of the customs to proceed on such voyage: and on the ship's return, the master and mate making oath that they proceeded on such voyage and no other, and used all their endeavours to take whales, &c. and that all the whale fins, blubber, oil, &c. imported in their ship, were taken by their crew in those seas, there shall be allowed 40s. for every ton according to the admeasurement of the ship.

Besides these fisheries, there are several others both on the coasts of Great Britain and in the North Seas, which, although not much the subject of merchandize, nevertheless employ great numbers both of ships and men; as, 1. The oyster-fishing at Colchester, Faversham, the Isle of Wight, in the Swales of the Medway, and in all the creeks between Southampton and Chichester, from whence they are carried to be fed in pits about Wevenhoe and other places. See OYSTER. 2. The lobster-fishing all along the British Channel, the Frith of Edinburgh, on the coast of Northumberland, and on the coast of Norway, from whence great quantities are brought to London. And lastly, the fishing of the pot-fish, fin-fish, sea-unicorn, sea horse, and the seal, or dog-fish; all which are found in the same seas with the whales, and yield blubber in a certain degree; besides, the horn of the unicorn is as estimable as ivory, and the skins of the seals are particularly useful to trunkmakers.

**Trout FISHING.** The baits for this purpose are either natural or artificial, as earth, worms, minnows, and fishing flies, both natural and artificial. Whatever worms are used, they answer best if kept some time in an earthen pot, with moss often changed in summer. If you fish for trout with hand on the ground, the hook is to be introduced into the worm a little above the middle, coming out again a little below; then draw the worm above the arming of the hook, making your first entrance at the tail-end, that the point of the hook may come out at the head-end. When you fish with minnows, take the whitest and middle sized; and after putting the hook in at the mouth, and out at the gills, and drawing it through about three inches, slip it again into his mouth, so as the point and beard may come out at the tail. This done, tie the hook and tail together with a fine white thread, and let the body of the minnow be almost straight upon the hook.

**FISSURE of the bones,** in surgery, is when they are divided either transversely or longitudinally, not quite through, but cracked after the manner of glass, by any external force. See SURGERY.

**FISTULA,** in the ancient music, an instrument of the wind-kind, resembling our flute, or flageolet.

The principal wind-instruments of the ancients, were the tibia and fistula. But how they were constituted,

wherein they differed, or how they were played on, does not appear.

**FISTULA,** in medicine and surgery. See MEDICINE and SURGERY.

**FISTULA,** in farriery. See FARRIERY.

**FISTULAR,** or **FISTULOUS,** appellations given by surgeons to wounds and ulcers, which degenerate into fistulas.

**FIT,** in medicine. See PAROXYSM.

**FITCHEE,** in heraldry, a term applied to a cross, when the lower end of it is sharpened into a point, as in Plate LXXX. fig. 6.

**FITCHES,** in husbandry, a sort of pulse, more generally known by the name of chick-pea, or cicer. See CICER.

**FITZ,** makes part of the surname of some of the natural sons of the kings of England, as Fitz-roy; which is purely French, and signifies the king's son.

**FIVE CHURCHES,** a bishop's see of lower Hungary, 76 miles south of Buda.

**FIVES,** or **VIVES,** in farriery. See FARRIERY, p. 555.

**FIXATION,** in chemistry, the rendering any volatile substance fixed, so as not to fly off upon being exposed to a great heat; hence,

**FIXED BODIES** are those which bear a considerable degree of heat without evaporating, or losing any of their weight.

**FLACCIDITY,** among physicians, a disorder of the solids, cured by astringent and cardiac medicines, joined with exercise and good air.

**FLAG,** a general name for colours, standards, ancients, banners, ensigns, &c.

The fashion of pointed or triangular flags, as now used, Rod. Toletan assures, came from the Mahometan Arabs, or Saracens, upon their seizure of Spain, before which time all the ensigns of war were stretched or extended on cross pieces of wood, like the banners of a church. The pirates of Algiers, and throughout the coasts of Barbary, bear an hexonal flag.

**FLAG** is more particularly used at sea; for the colours, ancients, standards, &c. borne on the top of the masts of vessels, to notify the person who commands the ship, of what nation it is, and whether it be equipped for war or trade, see Plate LXXXI.

The admiral in chief carries his flag on the main top, the vice-admiral on the fore-top, and the rear-admiral on the mizzen-top.

When a council of war is to be held at sea, if it be on board the admiral, they hang a flag in the main shrouds; if in the vice-admiral, in the fore-shrouds; and if in the rear-admiral, in the mizzen shrouds.

Besides the national flag, merchant ships frequently bear lesser flags on the mizzen-mast, with the arms of the city where the master ordinarily resides; and on the fore-mast, with the arms of the place where the person who freights them lives.

**FLAG OFFICERS,** those who command the several squadrons of a fleet, such are the admirals, vice-admirals, and rear-admirals.

The

# FLAGS

Plate LXXI

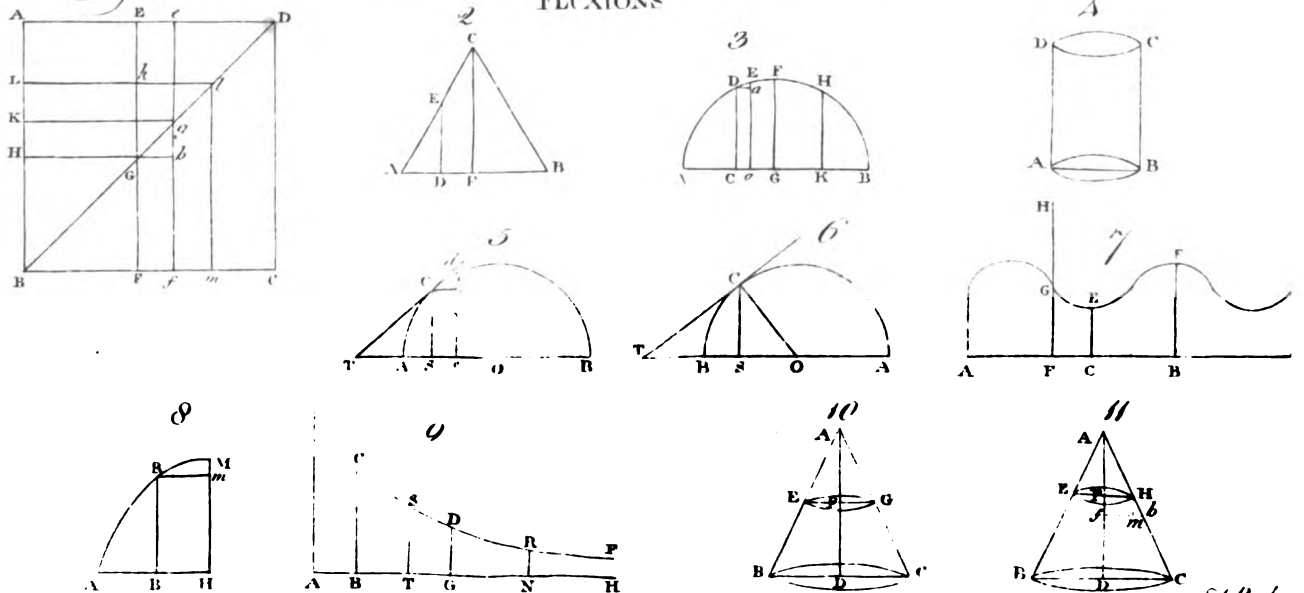

Fig. 1.

## FLUXIONS

1784.

The flag officers in our pay, are the admiral, vice-admiral, and rear-admiral of the white, red, and blue. See ADMIRAL.

**FLAG-SHIP**, a ship commanded by a general or flag-officer, who has a right to carry a flag, in contradistinction to the secondary vessels under the command thereof.

**FLAG-FLOWER**, in botany. See IRIS.

**Corn FLAG**, in botany. See GLADIOLUS.

**FLAGELLARIA**, in botany, a genus of the hexandria trigynia class. The calix consists of six segments; it has no corolla; and the berry contains but one seed. There is but one species, a native of the East-Indies.

**FLAGEOLET**, or **FLAJEOLET**, a little flute, used chiefly by the shepherds and country people. It is made of box, or other hard wood, and sometimes of ivory, and has six holes besides that at the bottom, the mouth-piece, and that behind the neck.

**FLAIL**, an instrument for threshing corn.

A flail consists of the following parts. 1. The hand-staff, or piece held in the thresher's hand. 2. The swiple, or that part which strikes out the corn. 3. The caplins, or strong double leathers, made fast to the tops of the hand-staff and swiple. 4. The middle-band, being the leather thong, or fish skin, that ties the caplins together.

**FLAMBEAU**, a kind of large taper, made of hempen wicks, by pouring melted wax on their top, and letting it run down to the bottom. This done, they lay them to dry; after which they roll them on a table, and join four of them together by means of a red-hot iron; and then pour on more wax, till the flambeau is brought to the size required.

Flambeaus are of different lengths, and made either of white or yellow wax. They serve to give light in the streets at night, or on occasion of illuminations.

**FLAMBOROUGH-HEAD**, in geography, a cape or promontory of Yorkshire, five miles east of Burlington: E. long. 25°, N. lat. 54° 15'.

**FLAME**, the small parts of an inflammable body, that are set on fire, or briskly agitated and thrown off, with a certain vibrative motion at the surface of that body into the open air: or, in Sir Isaac Newton's words, the flame of a body is only the smoke thereof heated red hot; and the smoke is only the volatile part of the body separated by the fire. See FIRE.

**FLAMEN**, in Roman antiquity, the name of an order of priests, instituted by Romulus or Numa; authors not being agreed on this head.

They were originally only three, *viz.* the flamen dialis, flamen martialis, and flamen quirinus. They were chosen by the people, and installed by the sovereign pontiff. Afterwards, their number was increased to fifteen; the three first of whom were senators, and called flamines majores; the other twelve, taken from among the people, being denominated flamines minores.

The flamen dialis, or priest of Jupiter, was a considerable person at Rome; the flamen martialis, or priest of Mars, was the second in dignity; and the flamen quirinalis, was the next to him,

**FLANDERS**, a province of the Netherlands, bounded by the German sea and the United provinces on the north; by the province of Brabant, on the east; by Hainault and Artois, on the south; and by another part of Artois and the German sea, on the west; being about sixty miles long, and fifty broad, and divided between the Austrians, the French, and the Dutch.

Flanders is a perfectly champaign country, with not a rising ground or hill in it, and watered with many fine rivers and canals. Its chief commodities are fine lace, linen, and tapestry.

**FLANEL**, or **FLANNEL**, a loose sort of woollen stuff, not crossed, and woven on a loom like bays.

**FLATS**, in music, a kind of additional notes, which, together with sharps, serve to remedy the defects of musical instruments, wherein temperament is required. See MUSIC.

**FLATULENCY**, in medicine. See MEDICINE.

**FLAW**, in the sea-language, signifies a sudden gust of wind.

**FLAX**, in botany. See LINUM.

The following particulars with regard to the manner of raising flax has been for some years past warmly commended by the Trustees for fisheries, manufactures, and improvements in Scotland.

*Of the choice of the Soil, and Preparing the Ground for FLAX.* A skilful flax-raiser always prefers a free open deep loam, and all grounds that produced the preceding year a good crop of turnip, cabbage, potatoes, barley, or broad clover; or has been formerly laid down rich, and kept for some years in pasture.

A clay soil, the second or third crop after being limed, will answer well for flax; provided, if the ground be still stiff, that it be brought to a proper mould, by tilling after harvest, to expose it to the winter frosts.

All new grounds produce a strong crop of flax, and pretty free of weeds. When a great many mole-heaps appear upon new ground, it answers the better for flax after one tilling.

Flax-seed ought never to be sown on grounds that are either too wet or dry; but on such as retain a natural moisture: and such grounds as are inclined to weeds ought to be avoided, unless prepared by a careful summer-fallow.

If the lintseed be sown early, and the flax not allowed to stand for seed, a crop of turnip may be got after the flax that very year; the second year a crop of bear or barley may be taken; and the third year, grass-seeds are sometimes sown along with the lintseed. This is the method mostly practised in and about the counties of Lincoln and Somerset, where great quantities of flax and hemp are every year raised, and where these crops have long been capital articles. There, old ploughed grounds are never sown with lintseed, unless the soil be very rich and clean. A certain worm, called in Scotland the Coup-worm, abounds in new broke up grounds, which greatly hurts every crop but flax. In small inclosures surrounded with trees or high hedges, the flax, for want of free air, is subject to fall before it be ripe, and the droppings of rain and dew

dew from the trees prevent the flax within the reach of the trees from growing to any perfection.

Of preceding crops, potatoes and hemp are the best preparation for flax. In the fens of Lincoln, upon proper ground of old tillage, they sow hemp, dunging well the first year; the second year hemp without dung; the third year flax without dung; and that same year a crop of turnip eat on the ground by sheep; the fourth year hemp with a large coat of dung, and so on for ever.

If the ground be free and open, it should be but once ploughed, and that as shallow as possible, not deeper than 2½ inches. It should be laid flat, reduced to a fine garden-mould by much harrowing, and all stones and sods should be carried off.

Except a little pigeon's dung for cold or sour ground, no other dung should be used preparatory for flax, because it produces too many weeds, and throws up the flax thin and poor upon the stalk.

Before sowing, the bulky clods should be broken, or carried off the ground; and stones, quickenings, and every other thing that may hinder the growth of the flax, should be removed.

*Of the choice of Lintseed.* The brighter in colour, and heavier the seed is, so much the better: that which when bruised appears of a light or yellowish green, and fresh in the heart, oily and not dry, and smells and tastes sweet, and not stuffy, may be depended upon.

Dutch seed of the preceding year's growth, for the most part, answers best; but it seldom succeeds if kept another year. It ripens sooner than any other foreign seed. Philadelphia seed produces fine lint and few bolls, because sown thick, and answers best in wet cold soils. Riga seed produces coarser lint, and the greatest quantity of seed. Scots seed, when well winned and kept, and changed from one kind of soil to another, sometimes answers pretty well; but should be sown thick, as many of its grains are bad, and fail. It springs well, and its flax is sooner ripe than any other; but its produce afterwards is generally inferior to that from foreign seed.

A kind has been lately imported, called memmel-seed, which looks well, is short and plump, but seldom grows above eight inches, and on that account ought not to be sown.

*Of Sowing Lintseed.* The quantity of lintseed sown, should be proportioned to the condition of the soil; for if the ground be in good heart, and the seed sown thick, the crop will be in danger of falling before it is ready for pulling. From eleven to twelve pecks Linlithgow measure of Dutch or Riga seed, is generally sufficient for one Scots acre; and about ten pecks of Philadelphia seed, which being the smallest grained, goes farthest Riga lintseed, and the next year's produce of it, is preferred in Lincolnshire.

The time for sowing lintseed is from the middle of March to the end of April, as the ground and season answers; but the earlier the seed is sown, the less the crop interferes with the corn-harvest.

Late sown lintseed may grow long, but the flax upon the stalk will be thin and poor.

After sowing, the ground ought to be harrowed till

the seed is well covered, and then (supposing the soil as before mentioned to be free and reduced to a fine mould) the ground ought to be rolled.

When a farmer sows a large quantity of lintseed, he may find it proper to sow a part earlier and part later, that in the future operations of weeding, pulling, watering, and grassing, the work may be the easier and more conveniently gone about.

It ought always to be sown on a dry bed.

*Of Weeding FLAX.* It ought to be weeded when the crop is about four inches long. If longer deferred, the weeders will so much break and crook the stalks, that they will never perhaps recover their straightness again; and when the flax grows crooked, it is more liable to be hurt in the rippling and swingling.

Quickening-grass should not be taken up; for, being strongly rooted, the pulling of it always loosens a deal of the lint.

If there is an appearance of a settled drought, it is better to defer the weeding, than by that operation to expose the tender roots of the flax to the drought.

How soon the weeds are got out, they ought to be carried off the field, instead of being laid in the furrows, where they often take root again, and at any rate obstruct the growth of the flax in the furrows.

*Of Pulling FLAX.* When the crop grows so short and branchy, as to appear more valuable for seed than flax, it ought not to be pulled before it be thoroughly ripe; but if it grows long and not branchy, the seed should be disregarded, and all the attention given to the flax. In the last case it ought to be pulled after the bloom has fallen, when the stalk begins to turn yellow, and before the leaves fall, and the bolls turn hard and sharp-pointed.

When the stalk is small, and carries few bolls, the flax is fine; but the stalk of coarse flax is gross, rank, branchy, and carries many bolls.

When flax has fallen and lies, such as lies ought to be immediately pulled, whether it has grown enough or not, as otherwise it will rot altogether.

When parts of the same field grow unequally, so that some parts are ready for pulling before other parts; only what is ready should be pulled, and the rest should be suffered to stand till ready.

The flax-raiser ought to be at pains to pull, and keep by itself, each different kind of lint which he finds in his field; what is both long and fine, by itself; what is both long and coarse, by itself; what is both short and fine, by itself; what is both short and coarse, by itself; and in like manner every other kind by itself that is of the same size and quality. If the different kinds be not thus kept separate, the flax must be much damaged in the watering, and the other succeeding operations.

What is commonly called under growth, may be neglected as useless.

Few persons that have seen flax pulled, are ignorant of the method of laying it in handfuls across other: which gives the flax sufficient air, and keeps the handfuls separate and ready for the rippler.

*Of Stacking up FLAX during the winter, and Winning the*

*the Seed.* If the flax be more valuable than the seed, it ought by no means to be stacked up; for its own natural juice abrids it greatly in the watering: where, as, if kept long unwatered, it loses that juice, and the harle adheres so much to the boon, that it requires longer time to water, and even the quality of the flax becomes thereby harsher and coarser. Besides, the flax stacked up over-year, is in great danger from vermin and other accidents; the water in spring is not so soft and warm as in harvest; and near a year is thereby lost of the use of the lint: but if the flax be so short and branchy as to appear most valuable for seed, it ought, after pulling, to be stooked and dried upon the field, as is done with corn, then stacked up for winter, rippled in spring, and after sheeling the seed should be well cleaned from bad seeds, &c.

*Of Rippling FLAX.* After pulling, if the flax is to be regarded more than the seed, it should be allowed to lie some hours upon the ground to dry a little, and so gain some firmness, to prevent the skin or harle, which is the flax, from rubbing off in the rippling; an operation which ought by no means to be neglected, as the bolls, if put into the water along with the flax, breed vermin there, and otherwise spoil the water. The bolls also prove very inconvenient in the grassing and breaking.

In Lincolnshire and Ireland, they think that rippling hurts the flax; and therefore, in place of rippling, they strike the bolls against a stone.

The handfuls for rippling should not be great, as that endangers the lint in the rippling comb.

After rippling, the flax-raiser will perceive, that he is able to assort each size and quality of the flax by itself more exactly than he could before.

*Of Watering FLAX.* A running stream wastes the lint, makes it white, and frequently carries it away. Lochs, by the great quantity and motion of the water, also waste and whiten the flax, though not so much as running streams. Both rivers and lochs water the flax quicker than canals.

But all flax ought to be watered in canals, which should be digged in clay ground if possible, as that soil retains the water best: but if a firm retentive soil cannot be got, the bottom or sides of the canal, or both the bottom and sides, may be lined with clay; or, instead of lining the sides with clay, which might fall down, a ditch may be dug without the canal, and filled with clay, which will prevent both extraneous water from entering, and the water within from running off.

A canal of forty feet long, six broad, and four deep, will generally water the growth of an acre of flax.

It ought to be filled with fresh soft water from a river or brook, if possible two or three weeks before the flax is put in, and exposed all that time to the heat of the sun. The greater way the river or brook has run, the softer, and therefore the better will the water be. Springs, or short runs from hills, are too cold, unless the water is allowed to stand long in the canal. Water from coal or iron, is very bad for flax. A little of the powder of galls thrown into a glass of water, will immediately discover if it comes from minerals of that kind, by turning it into a dark colour, more or less tinged in proportion to the quantity of vitriol it contains.

The canal ought not to be under any shade; which, besides keeping the sun from softening the water, might make part of the canal cooler than other parts, and so water the flax unequally.

The flax-raiser will observe, when the water is brought to a proper heat, that small plants will be rising quickly in it, numbers of small insects and reptiles will be generating there, and bubbles of air rising on the surface. If no such signs appear, the water must not be warm enough, or is otherwise unfit for flax.

Moss-holes, when neither too deep nor too shallow, frequently answer well for watering flax, when the water is proper, as before described.

The proper season for watering flax is, from the end of July to the end of August.

The advantage of watering flax as soon as possible, after pulling, has been already mentioned.

The flax being sorted after rippling, as before-mentioned, should next be put in beets, never larger than a man can grasp with both his hands, and tied very slack, with a band of a few stalks. Dried rushes answer exceedingly well for binding flax, as they do not rot in the water, and may be dried and kept for use again.

The beets should be put into the canals slope-ways, or half standing upon end, the root-end uppermost. Upon the crop-ends, when uppermost, there frequently breeds a deal of vermin, destructive of the flax, which is effectually prevented by putting the crop-end downmost.

The whole flax in the canal ought to be carefully covered from the sun with divots; the grassy side of which should be next the flax, to keep it clean. If it is not thus covered, the sun will discolour the flax, though quite covered with water. If the divots are not weighty enough to keep the flax entirely under water, a few stones may be laid above them. But the flax should not be pressed to the bottom.

When the flax is sufficiently watered, it feels soft to the grip, and the *harle* parts easily with the *boon* or *show*, which last is then become brittle, and looks whitish. When these signs are found, the flax should be taken out of the water, beet after beet; each gently rinsed in the water, to cleanse it of the nastiness which has gathered about it in the canal; and as the lint is then very tender, and the beet slackly tied, it must be carefully and gently handled.

Great care ought to be taken that no part is overdone; and as the coarsest waters soonest, if different kinds be mixed together, a part will be rotted, when the rest is not sufficiently watered.

When lint taken out of the canal is not found sufficiently watered, it may be laid in a heap, for twelve, eighteen, or twenty-four hours, which will have an effect like more watering; but this operation is nice, and may prove dangerous in unskilful hands.

After the flax is taken out of the canal, fresh lint should not be put a second time into it, until the former water be run off, and the canal cleaned, and supplied with fresh water.

*Of grassing FLAX.* Short heath is the best field for grassing flax, as, when wet, it softens to the heath, and is thereby prevented from being blown away by the wind. The heath also keeps it a little above the

earth, and so exposes it the more equally to the weather. When such heath is not to be got, links, or clean old lea-ground is the next best. Long grafs-grounds should be avoided, as the grafs growing thro' the lint frequently spots, tenders, or rots it; and grounds exposed to violent winds should also be avoided.

The flax, when taken out of the water, must be spread very thin upon the ground; and being then very tender, it must be gently handled. The thinner it is spread the better, as it is then the more equally exposed to the weather. But it ought never to be spread during a heavy shower, as that would wash and waste the harle too much, which is then excessively tender, but soon after becomes firm enough to bear the rains, which, with the open air and sunshine, cleans, softens, and purifies the harle to the degree wanted, and makes it blither from the boon. In short, after the flax has got a little firmness by being a few hours spread in dry weather, the more rain and sunshine it gets the better.

If there be little danger of high winds carrying off the flax, it will be much the better of being turned about once a-week. If it is not to be turned, it ought to be very thin spread. The spreading of flax and hemp requires a deal of ground, and enriches it greatly.

The skilful flax-raiser spreads his first row of flax at the end of the field opposite to the point from whence the most violent wind commonly comes, placing the root-ends foremost; he makes the root-ends of every other row overlap the crop-ends of the former row three or four inches, and binds down the last row with a rope; by which means the wind does not

easily get below the lint to blow it away: and as the crop-ends are seldom so fully watered as the root-ends, the aforesaid overlapping has an effect like giving the crop-ends more watering. Experience only can fully teach a person the signs of flax being sufficiently grafted: then it is of a clearer colour than formerly; the harle is blistered up, and easily parts with the boon, which is then become very brittle. The whole should be sufficiently grafted before any of it is lifted; for if a part be lifted sooner than the rest, that which remains is in great danger from the winds.

A dry day ought to be taken for taking up the flax; and if there is no appearance of high wind, it should be loosed from the heath or grafs, and left loose for some hours, to make it thoroughly dry.

As a great quantity of flax can scarcely be all equally watered and grafted, and as the different qualities will best appear at lifting the flax off the grafs; therefore at that time each different kind should be gathered together, and kept by itself; that is, all of the same colour, length, and quality.

The smaller the beets lint is made up in, the better for drying, and the more convenient for slacking, housing, &c. and in making up these beets, as in every other operation upon flax, it is of great consequence that the lint be laid together as it grew, the root-ends together, and the crop-ends together.

*Of keeping FLAX after it is grafted.* Nothing needs be said here, but that if the flax is to be stacked, it should be set in an airy place, upon a dry foundation, such as pob-middings, or the like, and well covered from the weather; and if housed, the floor must be dry, and the house well aired, and water-tight.

*Follows an Estimate of the Expence, Produce, and Profit of a Scots acre of FLAX,—supposing the season favourable, that no accidental losses happen, and that the farmer is neither unskilful nor negligent.*

There

There is nothing stated here as expence of the canal in which the flax is watered ; because that varies much according to the conveniencies people have for making it : and a canal once made requires for after-years only to be repaired and cleansed.

It is a certain fact, that the greater the crop is, the better is the quality of the same kind of flax.

The advantage of having both a crop of flax and a crop of turnip the same year—or of sowing grass-seeds along with the lintseed—and of reducing the ground to a fine garden mould, free of weeds, ought to be attended to.

*For Cambric and fine Lawn.* The ground must be a rich light soil, rather sandy, but cannot be too rich.

It ought to be ploughed in September, or the beginning of October, first putting a little hot rotten dung upon it.

Second ploughing in January after a hard frost ; and when you intend to sow it, plough it a third time, or rather hoe it, reducing the clods very fine ; but make no furrows : the land must be made level like a garden ; but never work the land when wet.

The seed should be sown the beginning of April, and about double the quantity that is generally sown by our farmers ; if the land be very rich, it will require rather more than double.

As soon as sown (if the weather be dry) it will be necessary to roll the ground.

The lint must be weeded very clean when about three inches high ; directly after which you must set forked sticks, of about one and half inch thick (which ought to be prepared before) every four or five feet, according to the length of the poles you are to lay upon them ; they should be well fixed in the ground, the forked part to receive the poles about six or seven inches above the lint ; each row of poles should be two, three, or four feet asunder, according to the length of the brushwood you are to lay upon them.

The poles ought to be from ten to fifteen feet long, and strong enough to support the brush across the poles ; take the longest brushwood you can get, the more branchy the better, very thick, filling up the vacancies with smaller brush, and any of the branches that rise higher than eighteen or twenty inches ought to be lopped off to make the brush lie as level as possible : any sort of brush will do except oak, as that tinges the lint.

Your lint must be pulled as soon as the seed is fully formed, which is a few days after it is out of the bloom before the lint turn yellow.

It must be pulled above the brushwood, and every handful laid upon it as soon as possible : if it is fine weather, leave it four or five hours in that manner ; then carry it to a screen near a barn, to put it under cover in case of rain ; there it must be spread four or five days, and always put in the barn at night, or when it appears to rain : the bundles must be opened in the barn, or made hollow, to prevent it from heating.

These operations must be performed until the lint is perfectly dry, and out of danger of heating ; taking care all the time to keep the roots as even as possible,

and if possible, keep it from rain or wet : if you cannot prevent it from being wet, it will be better to leave it on the grass till dry ; because when once wet, the putting it under cover before dry will make it turn black ; a thing which must be prevented at all events.

If any of the lint upon the border, or through the piece of ground, be coarser than another, it must be separated from the rest.

The utmost care must be taken to preserve the lint entire, or unbroke ; for this reason they beat off the seed with a round mell or bittle.

The most proper ground is summer fallow, or after potatoes, or lea ; if possible near a wood, to prevent the expence of carrying brush.

As soon as the seed is off, if you intend to water it that season, it must be tied in bundles about as large as you can grasp with your two hands.

The water proper for it, is a very small rivulet or soft spring free of any metallic ore, and taking care that no flood or foul water enters your pit ; which must be at least five feet deep, about nine or ten broad at the top, and seven or eight at the bottom, the length will depend on the quantity of flax you have to water. A very small stripe of water, when clear, should always be running in and off from your pit when the lint is in it.

The pit ought to be made three or four months before it be used.

You must drive poles about four inches thick, with a hook inclining downwards, in this form 7, all along the sides of the pit, about five feet asunder. The hooks must be level, or rather under the surface of the water. A long pole, the whole length of the pit, must be fixed into these hooks on each side ; and cross poles put under that, to keep the lint under water ; but, the cross poles are not used till the lint is put in. You must order it so, that all the lint should be three or four inches under water. You next bring your lint to the sides of the pit ; then put your sheaves head to head, causing each overlap the other about one third, and take as many of these as make a bundle of two or two and a half feet broad, laying the one above the other, till it is about four or four and a half feet high ; then you tie them together in the middle, and at each root-end : after this, you wrap your bundle in straw, and lay it in the water, putting the thin or broad side undermost, taking care that none of your lint touch the earth ; after it is fully pressed under water, put in your cross poles to keep it under. The bundles ought to lie in the pit a foot separate from each other. This renders it easy to take out ; for, if the bundles entangle, they will be too heavy to raise.

The time of watering depends so much upon the weather, and softness or hardness of the water, that it is impossible to fix any certain time. This must be left to the skill of the farmer. If the flax be intended for spinning yarn soft and fit for cambric, it ought to be spread upon short grass for four or five days before you put it into the water ; but if for lawns, lace, or thread, it is best to dry it outright. In either case, avoid as much as possible to let it get rain ; as much rain washes and

washes out the oil, which is necessary to preserve the strength.

The great property of this flax is to be fine and long. Thick sowing raises all plants fine and slender, and when the ground is very rich, it forces them to a great length. Pulling green prevents that coarse hardness which flax has when let stand till it be full ripe, and gives it the fine silky property. The brushwood, when the flax springs up, catches it by the middle, prevents it from lying down and rotting; infallible consequences of sowing thick upon rich ground. It likewise keeps it straight, moist, and soft at the roots; and by keeping it warm, and shaded from the sun, greatly promotes its length. The keeping it from rain, heating, taking proper care of your water, preserves the colour, and prevents these bars in cloth so much complained off by bleachers.

**FLAX-DRESSING.** *The different methods of that operation.*

For many ages it was the practice to separate the boon or core from the flax, which is the bark of the plant, by the following simple *hand-methods*. First, for breaking the boon; the stalks in small parcels were beat with a mallet; or, more dexterously, the *break* (Plate LXXXII. fig. 1. and 2.) was used thus: The flax being held in the left-hand a-crofs the three *under-teeth* or *swords* of the break (A, fig. 1. and a, fig. 2.), the *upper-teeth* (B, fig. 1. and b, fig. 2.) were with the right-hand quickly and often forced down upon the flax, which was artfully shifted and turned with the left-hand. Next, for clearing the flax of the broken boon; the workman with his left-hand held the flax over the *stock* (fig. 3. and 4.) while with his right-hand he struck or threshed the flax with the *scutcher* (fig. 5.).

These methods of breaking and scutching the flax being slow and very laborious, a *water-mill* was invented in Scotland about forty years ago, which, with some late improvements, makes great dispatch, and in skilful and careful hands gives satisfaction. It has been generally constructed to break the boon by three dented rollers, placed one above the other. The middle one of which being forced quickly round takes the other two along with it, and one end of handfuls of the flax being by the workman directed in between the upper and middle rollers, the flax is immediately drawn in by the rollers; a curved board or plate of tin behind the rollers directs the flax to return again between the middle and undermost rollers;—and thus the operation is repeated until the boon be sufficiently broke. Great weights of timber or stone at the ends of levers, press the upper and under-rollers towards the middle one.

The scutching is next carried on by the mill in the following manner: Four arms, something like the hand-scutchers before described, project from a perpendicular axle; a box around the axle incloses these projecting scutchers; and this box is divided among the workmen, each having sufficient room to stand and handle his flax, which, through slits in the upper-part and sides of the box, they hold in to the stroke of the

scutchers; which, moving round horizontally, strike the flax a-crofs or at right angles, and so thresh out or clear it of the boon.

The breaking of the flax by *rollers* is scarcely subject to any objection, but that it is dangerous to workmen not sufficiently on their guard, who sometimes allow the rollers to take hold of their fingers, and thereby their whole arm is instantly drawn in: thus many have lost their arms. To avoid this danger, a break upon the general principles of the hand-break before described, has been lately adapted to water machinery, and used in place of rollers. The horizontal stroke of the scutchers was long thought too severe, and wasteful of the flax; but very careful experiments have discovered that the waste complained of must be charged to the unskilfulness or negligence of the workmen, as in good hands the mill carries away nothing but what, if not so scutched off, must be taken off in the heckling with more loss both of time and flax. But to obviate this objection of the violence of the *horizontal scutchers*, an imitation of hand scutching has lately been applied to water. The scutchers then project from an horizontal axle, and move like the arms of a check-reel, striking the flax neither across nor perpendicularly down, but sloping in upon the parcel exactly as the flax is struck by the hand-scutcher. This sloping stroke is got by raising the scutching-stock some inches higher than the centre of the axle; and by raising or lowering the stock, over which the flax is held, or screwing it nearer to or farther from the scutchers, the workman can temper or humour the stroke almost as he pleases.

A lint-mill with horizontal scutchers upon a perpendicular axle, requires a house of two stories, the rollers or break being placed in the ground story, and the scutchers in the loft above; but a mill with vertical scutchers on an horizontal axle, requires but one ground story for all the machinery.

Another method of breaking and scutching flax, more expeditious than the old hand-methods, and more gentle than water-mills, has also been lately invented in Scotland. It is much like the break and scutcher giving the sloping stroke last described, moved by the foot. The treddle is remarkably long, and the scutchers are fixed upon the rim of a fly-wheel. The foot-break is also assisted in its motion by a fly. These foot-machines are very useful where there are no water-mills, but they are far inferior to the mills in point of expedition.—[See plans of the water-mills, and foot-machine, on the unnumbered plates betwixt the LXXXII. and LXXXIII.]

The next operation that flax undergoes after scutching, is heckling. The *heckle* (fig. 6. Plate LXXXII.) is firmly fixed to a bench before the workman, who strikes the flax upon the teeth of the heckle, and draws it thro' the teeth. To persons unacquainted with that kind of work this may seem a very simple operation; but, in fact, it requires as much practice to acquire the slight of heckling well, and without wasting the flax, as any other operation in the whole manufacture of linen. They use coarser and wider toothed heckles, or finer, according

*J. Bell & Co.*

ing to the quality of the flax; generally putting the flax thro' two heckles, a coarser one first, and next thro' a fine heckle.

**Flax for cambric and fine lawn, thread and lace**, is dressed in a manner somewhat different. It is not sketched so thoroughly as common flax; which from the sketch proceeds to the heckle, and from that to the spinner: whereas this fine flax, after a rough sketching, is scraped and cleansed with a blunt knife upon the workman's-knee covered with his leather apron; from the knife it proceeds to the spinner, who, with a brush made for the purpose, straightens and dresses each parcel just before she begins to spin it.

**TOAL-FLAX**. See **LINARIA**.

**FLEA**, in zoology. See **PULEX**.

**FLEA BANE**, in botany. See **CONYZA**.

**FLEA BITTEN**, that colour of a horse, which is white or grey, spotted all over with dark reddish spots.

**FLEAM**, in surgery and farriery, an instrument for letting a man or horse blood. A case of fleams, as it is called by farriers, comprehends six sorts of instruments; two hooked ones, called drawers, and used for cleaning wounds; a pen knife; a sharp pointed lancet, for making incisions; and two fleams, one sharp and the other broad pointed. These last are somewhat like the point of a lancet, fixed in a flat handle, only no longer than is just necessary to open the vein.

**FLECHE**, a town of France, under the meridian of London, twenty miles north-east of Angers.

**FLEECE**, the covering of wool, shorn off the bodies of sheep. See **WOOL**.

**Order of the Golden FLEECE**, an order of knighthood instituted by Philip II. duke of Burgundy. These knights at first were twenty four, besides the duke himself, who reserved the nomination of six more: but Charles V. increased them to fifty. He gave the guardianship of this order to his son Philip king of Spain, since which the Spanish monarchs are chiefs of the order. The knights had three different mantles ordained them at the grand solemnity, the collar and fleece.

**FLEET**, commonly implies a company of ships of war, belonging to any prince or state: but sometimes it denotes any number of trading ships, employed in a particular branch of commerce.

In sailing, a fleet of men of war is usually divided into three squadrons: the admiral's, the vice admiral's, and the rear-admiral's squadron, all which, being distinguished by their flags and pendants, are to put themselves, and, as near as may be, to keep themselves in their customary places, viz. The admiral, with his squadron, to sail in the van, that so he may lead the way to all the rest in the day-time, by the sight of his flag in the main top-mast head; and in the night time, by his lights or lanterns. The vice-admiral and his squadron, is to sail in the centre or middle of the fleet. The rear-admiral, and the ships of his squadron, is to bring up the rear. But sometimes other divisions are made; and those composed of the lighter ships and the best sailors, are placed as wings to the van, centre, and rear.

**FLEET** is also a noted prison in London, where persons

are committed for contempt of the king and his laws, particularly of his courts of justice: or for debt, where any person will not, or is unable to pay his creditors.

There are large rules and a warden belonging to the fleet prison, which had its name from the float or fleet of the river or ditch, on the side whereof it stands.

**FLENSBURGH**, a port town subject to Denmark, sixteen miles north of the city of Sleswick.

**FLESH**, in anatomy, a similar, fibrous part of an animal body, soft and bloody, being that whereof most of the other parts are composed, and whereby they are connected together: or more properly, it is such parts of the body where the blood-vessels are so small, as only to retain blood enough to preserve their colour red.

**FLEURY**, a town of Burgundy, in France, thirty miles north of Chalons.

**FLEXIBLE**, in physics, a term applied to bodies capable of being bent or diverted from their natural figure or direction.

**FLEXOR**, in anatomy, a name applied to several muscles, which are so called from their office, which is to bend the part to which they belong; in opposition to the extensors, which open or stretch them. See **ANATOMY**, part II.

**FLINT**, in natural history, a semipellucid stone, composed of crystal debased with earth, of one uniform substance, and free from veins; but of different degrees of colour, according to the quantity of earth it contains, and naturally surrounded with a whitish crust.

Flint is a stone of an extremely fine, compact, and firm texture, and very various, both in size and figure. It is of all the degrees of grey, from nearly quite black, to almost quite white. It breaks with a fine, even, glossy surface; and is moderately transparent, very hard, and capable of a fine polish. It readily strikes fire with steel, and makes not the least effervescence with aquafortis, and burns to a whiteness. Its uses in glass making, &c. are too well known to need a particular recital.

**FLOATAGES**, all things floating on the top of the sea or any water, a word much used in the commissions of water bailiffs.

**FLOOD**. See **DELUGE**.

**FLORENCE**, an archbishop's see and city of Italy, situated on the river Arno, in Tuscany, forty-five miles east of Leghorn: E. long. 12° 15', and N. lat. 43° 30'. Florence is one of the most elegant towns in Italy, has an university, and is six miles in circumference. The statues, paintings, and curiosities in the grand duke's palace are the admiration of travellers.

**FLORENTINE**, a town of Champaign in France, twenty-eight miles south-west of Troyes.

**FLORES**, in geography, one of the Azores islands, subject to Portugal.

**FLORID STYLE**, is that too much enriched with figures and flowers of rhetoric.

**FLORIDA**, in geography, a name first given by the Spaniards to all that part of North America which lies north of the gulph of Mexico. However, all that retains the name Florida, at present, is the peninsula between the British colony of Georgia and cape Florida,

*viz.* between  $25^{\circ}$  and  $30^{\circ}$  of N. latitude, and between  $81^{\circ}$  and  $85^{\circ}$  W. longitude.

**FLORIN**, is sometimes used for a coin, and sometimes for a money of account.

Florin, as a coin, is of different values, according to the different metals and different countries where it is struck. The gold florins are most of them of a very coarse alloy, some of them not exceeding thirteen or fourteen carrats, and none of them seventeen and a half. As to silver florins, those of Holland are worth about 1 s. 8 d. those of Genoa were worth  $8\frac{1}{4}$  Sterling.

Florin, as a money of account, is used by the Italian, Dutch, and German merchants and bankers, but admits of different divisions in different places. In Holland, it is on the footing of the coin of that name, containing 20 stivers. At Frankfort and Nuremberg it is equivalent to 3 s. Sterling, and is divided into creutzers, and pfennings. At Liege, it is equivalent to 2 s. 3 d. At Strasburg, to 1 s. 3 d. In Savoy, to 11 d. At Genoa, to  $8\frac{1}{4}$  d. And at Geneva, to  $6\frac{1}{2}$  d. See **COIN**.

**FLORIST**, a person well skilled in flowers, their kinds and cultivation.

**FLORY**, **FLOWRY**, or **FLEURY**, in heraldry, a cross that has the flowers at the end circumflex and turning down, differing from the potence, inasmuch as the latter stretches out more like that which is called patee.

The cross flory is represented in Plate LXXX. fig. 7.

**FLOS**, **FLOWER**, in botany: See **FLOWER**.

**FLOS**, in chemistry, the most subtil part of bodies separated from the more gross parts by sublimation, in a dry form. See **CHEMISTRY**.

**FLOTSON**, or **FLOTSOM**, goods that by shipwreck are lost, and floating upon the sea; which, with jetson and lagan, are generally given to the lord admiral: but this is the case only where the owners of such goods are not known. And here it is to be observed, that jetson signifies any thing that is cast out of a ship when in danger, and afterwards is beat on the shore by the water, notwithstanding which the ship perishes. Lagan is where heavy goods are thrown overboard, before the wreck of the ship, and sink to the bottom of the sea.

**FLOUNDER**, the English name of a species of pleuronectes. See **PLEURONCTES**.

**FLOUR**, the meal of wheat-corn, finely ground and sifted. See **MEAL**.

**FLOWER**, among botanists and gardeners, the most beautiful part of trees and plants, containing the organs or parts of fructification. See **BOTANY**.

**External FLOWER**. See **XERANTHEMUM**.

**Everlasting FLOWER**. See **GNAPHALIUM**.

**FLOWER FENCE**. See **POINCIANA**.

**FLOWER DE LUCE**. See **IRIS**.

**Sultan-FLOWER**. See **CYANUS**.

**Sun-FLOWER**. See **HELIANTHUS**.

**Trumpet-FLOWER**. See **BIGNONIA**.

**Wind-FLOWER**. See **ANEMONE**.

**FLOWER DE LIS**, or **FLOWER DE LUCE**, in heraldry, a bearing representing the lily, called the queen of flowers, and the true hieroglyphic of royal majesty; but of late it is become more common, being borne in some coats one, in others three, in others five, and in some semee, or spread all over the escutcheon in great numbers.

The arms of France are, three flower de lis or, in a field azure.

**FLUDDER**. See **COLYMBUS**.

**FLUID**, an appellation given to all bodies whose particles easily yield to the least partial pressure, or force impress'd.

*Laws and properties of FLUIDS*. See **HYDRAULICS** and **HYDROSTATICS**.

**FLUOR**, in physics, a fluid; or, more properly, the state of a body that was before hard or solid, but is now reduced by fusion, or fire, into a state of fluidity.

**FLUOR**, in mineralogy, implies a sort of mineral concretion, frequently found amongst ores and stones, in mines and quarries.

**FLUOR ALBUS**, or **WHITES**. See **MEDICINE**.

**FLUSHING**, or **VLISSINGEN**, a port-town of Zealand in Holland, five miles south of Middleburgh: E. long.  $3^{\circ} 25'$ , N. lat.  $51^{\circ} 30'$ . It is a town of great foreign trade, and has a good secure harbour.

**FLUTE**, an instrument of music, the simplest of all those of the wind kind. It is played on by blowing it with the mouth, and the tones or notes are changed by stopping and opening the holes disposed for that purpose along its side.

*German FLUTE*, is an instrument entirely different from the common flute. It is not, like that, put into the mouth to be played, but the end is stoppt with a tampon or plug; and the lower lip is applied to a hole about two inches and a half, or three inches, distant from the end. This instrument is usually about a foot and a half long; rather bigger at the upper end than the lower; and perforated with holes, besides that for the mouth, the lowest of which is stoppt and opened by the little finger's pressing on a brass or sometimes a silver key, like those in hautboys, bassoons, &c. Its sound is exceeding sweet and agreeable; and serves as a treble in a concert.

Coarse flutes, on importation, pay the gros, containing twelve dozen, 3 s.  $10\frac{1}{2}$  d. and on exportation draw back 3 s.  $4\frac{1}{2}$  d.

**FLUTES**, or **FLUTINGS**. See **ARCHITECTURE**.

**FLUVIALIS**, in botany. See **Najas**.

**FLUX**, in medicine, an extraordinary issue, or evacuation of some humours of the body. See **MEDICINE**.

**FLUX**, in metallurgy, whatever can cause a body otherwise not at all, or hardly, fusible by fire, to melt. See **CHEMISTRY**.

**FLUXIONS**.

# FLUXIONS.

**FLUXIONS**, a method of calculation which greatly facilitates computations in the higher parts of mathematics. Sir Isaac Newton and Mr Leibnitz contended for the honour of inventing it. It is probable they had both made progress in the same discovery, unknown to each other, before there was any publication on the subject.

In this branch of mathematics magnitudes of every kind are supposed generated by motion: a line by the motion of a point, a surface by the motion of a line, and a solid by the motion of a surface. And some part of a figure is supposed generated by an uniform motion; in consequence of which the other parts may increase uniformly or with an accelerated or retarded motion, or may decrease in any of these ways; and the computations are made by tracing the comparative velocities with which the parts flow.

Fig. 1. If the parallelogram ABCD be generated by an uniform motion of the line AB toward CD while it moves from FE towards  $\frac{1}{2}$ , while the line BF receives the increment Ff, and the figure will be increased by the parallelogram Fe; the line FE in this case undergoes no variation.

The fluxion of any magnitude at any point is the increment that it would receive in any given time, supposing it to increase uniformly from that point; and as the measures will be the same, whatever the time be, we are at liberty to suppose it less than any assigned time.

The first letters in the alphabet are used to represent invariable quantities; the letters  $x, y, z$  variable quantities; and the same letters with points over them  $\dot{x}, \dot{y}, \dot{z}$ , represent their fluxions.

Therefore if  $AB=a$ , and  $EF=x$ ; Ff, the fluxion of BF, will be  $=\dot{x}$ , and Fe, the fluxion of AF,  $=a\dot{x}$ .

If the rectangle be supposed generated by the uniform motion of FG towards CD, at the same time HG moves uniformly towards AD, the point G keeping always on the diagonal, the lines FG HG will flow uniformly; for while Bf receives the increment Ff and HB, the increment HK, FG will receive the increment  $hg$  and HG the increment  $hg$ , and they will receive equal increments in equal successive times. But the parallelogram will flow with an accelerated motion; for while F flows to f and H to K, it is increased by the gnomon KGf; but while F and H flow through the equal spaces fm KL, it is increased by the gnomon Lgm greater than KGf; consequently when fluxions of the sides of a parallelogram are uniform, the fluxion of the parallelogram increases continually.

The fluxion of the parallelogram BHGF is the two parallelograms KG and Gf; for though the parameter receives an increment of the gnomon KGf, while its sides flow to f and K, the part gG is owing to the additional velocity wherewith the parallelogram flows during that time; and therefore is no part of the measure of the fluxion, which must be computed by supposing the para-

meter to flow uniformly as it did at the beginning, without any acceleration.

Therefore if the sides of a parallelogram be  $x$  and  $y$ , their fluxions will be  $\dot{x}$   $\dot{y}$ ; and the fluxion of the parallelogram  $xy+y\dot{x}$ ; and if  $x=y$ , that is, if the figure be a square, the fluxion of  $x^2$  will be  $2x\dot{x}$ .

Fig. 2. Let the triangle ABC be described by the uniform motion of DE from A towards B, the point E moving in the line DF, so as always to touch the lines AC, CB; while D moves from A to F, DE is uniformly increased, and the increase of the triangle is uniformly accelerated. When DE is in the position FC, it is a maximum. As D moves from F to B, the line FC decreases, and the triangle increases, but with a motion uniformly retarded.

Fig. 3. If the semicircle AFB be generated by the uniform motion of CD from A towards B, while C moves from A to G, the line CD will increase, but with a retarded motion; the circumference also increases with a retarded motion, and the circular space increases with an accelerated motion, but not uniformly, the degrees of acceleration growing less as CD approaches to the position GF. When C moves from G to B, it decreases with a motion continually accelerated, the circumference increases with a motion continually accelerated, and the area increases with a motion continually retarded, and more quickly retarded as CD approaches to B.

The fluxion of a quantity which decreases is to be considered as negative.

When a quantity does not flow uniformly, its fluxion may be represented by a variable quantity, or a line of a variable length; the fluxion of such a line is called the second fluxion of the quantity whose fluxion that line is; and if it be variable, a third fluxion may be deduced from it, and higher orders from these in the same manner: the second fluxion is represented by two points, as  $\ddot{x}$ .

The increment a quantity receives by flowing for any given time, contains measures of all the different orders of fluxions; for if it increases uniformly, the whole increment is the first fluxion; and it has no second fluxion. If it increases with a motion uniformly accelerated, the part of the increment occasioned by the first motion measures the first fluxion, and the part occasioned by the acceleration measures the second fluxion. If the motion be not only accelerated, but the degree of acceleration continually increased, the two first fluxions are measured as before; and the part of the increment occasioned by the additional degree of acceleration measures the third; and so on. These measures require to be corrected, and are only mentioned here to illustrate the subject.

## DIRECT METHOD.

*Any flowing quantity being given, to find its fluxion.*

RULE I. To find the fluxion of any power of a quantity

tity, multiply the fluxion of the root by the exponent of the power, and the product by a power of the same root less by unity than the given exponent.

The fluxion of  $x^n$  is  $nx^{n-1}\dot{x}$ , of  $x^n$   $nx^{n-1}\dot{x}$ ; for the root of  $x^n$  is  $x$ , whose fluxion is  $\dot{x}$ ; which multiplied by the exponent  $n$ , and by a power of  $x$  less by unity than  $n$ , gives the above fluxion.

If  $x$  receive the increment  $\dot{x}$ , it becomes  $x+\dot{x}$ ; raise both to the power of  $n$ , and  $x^n$  becomes  $x^n+n\dot{x}x^{n-1}+\frac{n\cdot n-1}{2}\dot{x}^2x^{n-2}+\dots$ ; but all the parts of the increment, except the first term, are owing to the accelerated increase of  $x^n$ , and form measures of the higher fluxions. The first term only measures the first fluxion; the fluxion of  $x^n$  is  $\frac{1}{2}n\dot{x}x^{n-1}$ ; for put  $x=x^2+z^2$ , we have  $\dot{x}=2z\dot{z}$ , and the fluxion of  $x^2$ , which is equal to the proposed fluent, is  $\frac{1}{2}x\dot{x}$ , for which substituting the values of  $x$  and  $z$ , we have the above fluxion.

**RULE II.** To find the fluxion of the product of several variable quantities multiplied together, multiply the fluxion of each by the product of the rest of the quantities, and the sum of the products thus arising will be the fluxion sought.

Thus the fluxion of  $xy$ , is  $x\dot{y}+y\dot{x}$ ; that of  $xyz$ , is  $xy\dot{z}+xz\dot{y}+yz\dot{x}$ ; and that of  $xyzu$ , is  $xyz\dot{u}+xyuz\dot{x}+xzyu\dot{y}+yzux\dot{z}$ .

**RULE III.** To find the fluxion of a fraction.—From the fluxion of the numerator multiplied by the denominator, subtract the fluxion of the denominator multiplied by the numerator, and divide the remainder by the square of the denominator.

Thus, the fluxion of  $\frac{x}{y}$  is  $\frac{y\dot{x}-x\dot{y}}{y^2}$ ; that of  $\frac{x}{x+y}$ , is  $\frac{x\dot{y}+y\dot{x}-x\dot{x}-y\dot{y}}{(x+y)^2} = \frac{y\dot{x}-x\dot{y}}{(x+y)^2}$ .

**RULE IV.** In complex cases, let the particulars be collected from the simple rules and combined together.

The fluxion of  $\frac{x^2y^2}{z}$  is  $\frac{2x^2y\dot{y}+2y^2x\dot{x}-x^2y^2\dot{z}}{z^2}$ ; for the fluxion of  $x^2$  is  $2x\dot{x}$ , and of  $y^2$  is  $2y\dot{y}$ , by Rule I. and therefore the fluxion of  $x^2y^2$  (by Rule II)  $2x^2y\dot{y}+2y^2x\dot{x}$ ; from which, multiplied by  $z$ , (by Rule III.) and subtracting from it the fluxion of the denominator  $z$ , multiplied by the numerator, and dividing the whole by the square of the denominator, gives the above fluxion.

**RULE IV.** The second fluxion is derived from the first, in the same manner as the first from the flowing quantity.

Thus the fluxion of  $x^3$ ,  $3x^2\dot{x}$ ; its second,  $6x\dot{x}^2+3x^2\ddot{x}$  (by Rule II); and so on: but if  $x$  be invariable,  $\dot{x}=0$ , and the second fluxion of  $x^3=6x\dot{x}^2$ .

**PROB. I.** To determine maxima and minima.

When a quantity increases, its fluxion is positive; when

it decreases, it is negative; therefore when it is just betwixt increasing and decreasing, its fluxion is  $=0$ .

**RULE.** Find the fluxion, make it  $=0$ , whence an equation will result that will give an answer to the question.

**Fig. 4. EXAMP.** To determine the dimensions of a cylindric measure ABCD, open at the top, which shall contain a given quantity (of liquor, grain, &c.) under the least internal superficies possible.

Let the diameter  $AB=x$ , and the altitude  $AD=y$ ; moreover, let  $p$  (3.14159, &c.) denote the periphery of the circle whose diameter is unity, and let  $c$  be the given content of the cylinder. Then it will be  $1:p::x:(p\cdot)$  the circumference of the base; which, multiplied by the altitude  $y$ , gives  $pxy$  for the concave superficies of the cylinder. In like manner, the area of the base, by multiplying the same expression into  $\frac{1}{4}$  of the diameter  $x$ , will be found  $=\frac{px^2}{4}$ ; which drawn into the altitude  $y$ , gives

$\frac{px^2y}{4}$  for the solid content of the cylinder; which being

made  $=c$ , the concave surface  $pxy$  will be found  $=\frac{4c}{x}$

and consequently the whole surface  $=\frac{4c}{x}+\frac{px^2}{4}$ : Where-

of the fluxion, which is  $-\frac{4cx}{x^2}+\frac{pxx}{2}$  being put  $=0$ , we

shall get  $-8c+px^2=0$ ; and therefore  $x=2\sqrt{\frac{c}{p}}$ : fur-

ther, because  $px^2=8c$ , and  $pxy=4c$ , it follows, that  $x=2y$ ; whence  $y$  is also known, and from which it appears, that the diameter of the base must be just the double of the altitude.

**Fig. 7.** To find the longest and shortest ordinates of any curve, DEF, whose equation or the relation which the ordinates bear to the abscissas is known.

Make AC the abscissa  $x$ , and CE the ordinate  $=y$ ; take a value  $y$  in terms of  $x$ , and find its fluxion: which making  $=0$ , an equation will result whose roots give the value of  $x$  when  $y$  is a maximum or minimum.

To determine when it is a maximum and when a minimum, take the value of  $y$ , when  $x$  is a little more than the root of the equation so found, and it may be perceived whether it increases or decreases.

If the equation has an even number of equal roots,  $y$  will be neither a maximum nor minimum when its fluxion is  $=0$ .

**PROB. 2.** To draw a tangent to any curve.

**Fig. 5.** When the abscissa CS of a curve moves uniformly from A to B, the motion of the curve will be retarded if it be concave, and accelerated if convex towards AB; for a straight line TC is described by a uniform motion, and the fluxion of the curve at any point is the same as the fluxion of the tangent, because it would describe the tangent if it continued to move equally from that point. Now if S<sub>1</sub> or C<sub>1</sub> be the fluxion of the base, C<sub>1</sub>d will be the fluxion of the tangent, and d<sub>1</sub>e of the ordinate. And because the triangles TSC, and d<sub>1</sub>ec, are equiangular, d<sub>1</sub>e : c<sub>1</sub> :: CS : ST, wherefore

**RULE.** Find a fourth proportional to the fluxion of the

the ordinate valued in terms of the abscissa, the fluxion of the abscissa, and the ordinate, and it determines the line ST, which is called the semi-tangent, and TC joined is a tangent to the curve.

Fig. 6. **EXAMP.** To draw a right line CT, to touch a given circle BCA in a given point C.

Let CS be perpendicular to the diameter AB, and put  $AB=a$ ,  $BS=x$ , and  $SC=y$ : Then, by the property of the circle,  $y^2 (CS^2) = BS \times AS (=x \times a-x) = ax - x^2$ ; whereof the fluxion being taken, in order to determine the ratio of  $\dot{x}$  and  $\dot{y}$ , we get  $2yy\dot{y} = a\dot{x} - 2x\dot{x}$ ; consequently

$$\frac{\dot{y}}{y} = \frac{2y}{a-2x} = \frac{y}{\frac{1}{2}a-x}; \text{ which multiplied by } y, \text{ gives } \frac{y^2}{\frac{1}{2}a-x} = \frac{y^2}{ST} = \text{the subtangent ST.}$$

Whence (O being supposed the centre) we have  $OS (\frac{1}{2}a-x) : CS (y) :: CS (y) : ST$ ; which we also know from other principles.

**PROB. 3.** To determine points of contrary flexure in curves.

Fig. 7. Supposing C to move uniformly from A to B, the curve DEF will be convex towards AB when the celerity of E increases, and concave when it decreases; therefore at the point where it ceases to be convex and begins to be concave, or the opposite way, the celerity of E will be uniform, that is.  $\dot{C}\dot{C}$  will have no second fluxion. Therefore,

**RULE.** Find the second fluxion of the ordinate in terms of the abscissa, and make it  $=0$ ; and from the equation that arises you get a value of the abscissa, which determines the point of contrary flexure.

**Ex.** Let the nature of the curve ARS be defined by the equation  $ay = a^{\frac{1}{2}}x^{\frac{1}{2}} + xx$ , (the abscissa AF and the ordinate FG being, as usual, represented by  $x$  and  $y$  respectively). Then  $y$ , expressing the celerity of the point  $r$ ,

in the line FH, will be equal to  $\frac{\frac{1}{2}a^{\frac{1}{2}}x^{-\frac{1}{2}} + 2x}{a}$ : Whose

fluxion, or that of  $\frac{1}{2}a^{\frac{1}{2}}x^{-\frac{1}{2}} + 2x$  (because  $a$  and  $x$  are constant) must be equal to nothing; that is,  $-\frac{1}{4}a^{\frac{1}{2}}x^{-\frac{1}{2}} + 2x = 0$ : Whence  $a^{\frac{1}{2}}x^{-\frac{1}{2}} = 8$ ,  $a^{\frac{1}{2}} = 8x^{\frac{1}{2}}$ ,  $64x = a^2$ , and  $x = \frac{1}{8}a = AF$ ; therefore  $FG (= \frac{a^{\frac{1}{2}}x^{\frac{1}{2}} + xx}{a}) = \frac{a}{8}$ : From which the position of the point G is given.

**PROB. 4.** To find the radii of curvature.

The curvature of a circle is uniform in every point, that of every other curve continually varying; and it is measured at any point by that of a circle whose radius is of such a length as to coincide with it in curvature in that point.

All curves that have the same tangent have the same first fluxion, because the fluxion of a curve and its tangent are the same. If it moved uniformly on from the point of contact, it would describe the tangent. And the deflection from the tangent is owing to the acceleration or retardation of its motion, which is measured by its second fluxion; and consequently two curves which have not only the same tangent, but the same curvature at the

point of contact, will have both their first and second fluxions equal. It is easily proven from thence, that the radius of curvature is  $= \frac{z^2}{-xy}$ , where  $x$ ,  $y$ , and  $z$  represent the abscissa, ordinate, and curve respectively.

**EXAMP.** Let the given curve be the common parabola, whose equation is  $y = a^{\frac{1}{2}}x^{\frac{1}{2}}$ : Then will  $\dot{y} = \frac{1}{2}a^{\frac{1}{2}}x^{-\frac{1}{2}} = \frac{a^{\frac{1}{2}}}{2x^{\frac{1}{2}}}$ , and (making  $\dot{x}$  constant)  $\ddot{y} = -\frac{1}{4} \times \frac{1}{2}a^{\frac{1}{2}}x^{-\frac{3}{2}} = -\frac{a^{\frac{1}{2}}}{4x^{\frac{3}{2}}}$ : Whence  $z (\sqrt{x^2 + y^2}) = \frac{x}{2} \sqrt{\frac{4x+a}{x}}$ , and

$$\text{the radius of curvature } \left( \frac{z^2}{-xy} \right) = \frac{a+4x}{2\sqrt{a}}: \text{ Which}$$

at the vertex, where  $x=0$ , will be  $=\frac{1}{2}a$ .

### INVERSE METHOD:

*From a given fluxion to find a fluent.*

This is done by tracing back the steps of the direct method. The fluxion of  $x$  is  $\dot{x}$ ; and therefore the fluent of  $\dot{x}$  is  $x$ : but as there is no direct method of finding fluents, this branch of the art is imperfect. We can assign the fluxion of every fluent, but we cannot assign the fluent of a fluxion, unless it be such a one as may be produced by some rule in the direct method from a known fluent.

**GENERAL RULE.** Divide by the fluxion of the root, add unity to the exponent of the power, and divide by the exponent so increased.

For, dividing the fluxion  $n\dot{x}x^{n-1}$  by  $\dot{x}$  (the fluxion of the root  $x$ ) it becomes  $nx^{n-1}$ ; and, adding 1 to the exponent  $(n-1)$  we have  $nx^n$ ; which, divided by  $n$ , gives  $x^n$ , the true fluent of  $n\dot{x}x^{n-1}$ .

Hence (by the same rule) the

Fluent of  $3x^2\dot{x}$  will be  $=x^3$ ;

That of  $8x^3\dot{x} = \frac{8x^4}{4}$ ;

That of  $2x^5\dot{x} = \frac{x^6}{3}$ ;

That of  $y^{\frac{1}{2}}\dot{y} = \frac{2}{3}y^{\frac{3}{2}}$ .

Sometimes the fluent so found requires to be corrected. The fluxion of  $x$  is  $\dot{x}$ , and the fluxion of  $a+x$  is also  $\dot{x}$ , because  $a$  is invariable, and has therefore no fluxion.

Now when the fluent of  $\dot{x}$  is required, it must be determined, from the nature of the problem, whether any invariable part, as  $a$ , must be added to the variable part  $x$ .

When fluents cannot be exactly found, they can be approximated by infinite series.

**Ex.** Let it be required to approximate the fluent of

$$\frac{a^2 - x^2}{a^2 - x^2} \times \dot{x} \text{ in an infinite series,}$$

The value of  $\frac{a^2 - x^2}{c^2 - x^2}$ , expressed in a series, is  $\frac{a}{c} +$

$$\frac{a}{2c^3} - \frac{1}{2ac} \times x^2 + \frac{3x^4}{8c^5} - \frac{1}{4ac^3} - \frac{1}{8a^3c} \times x^4 + \frac{5a}{16c^7} - \frac{3}{16ac} - \frac{1}{16a^3c^3} - \frac{1}{16a^5c} \times x^6 + \text{etc.}$$

Which value being therefore multiplied by  $x^n x$ , and the fluent taken (by the common method) we get  $\frac{ax^{n+1}}{n+1 \times c} + \frac{a}{2c^3} - \frac{1}{2ac} \times \frac{x^{n+3}}{n+3} + \frac{3a}{8c^5} - \frac{1}{4ac^3} - \frac{1}{8a^3c} \times \frac{x^{n+5}}{n+5} + \frac{5a}{16c^7} - \frac{3}{16ac^5} - \frac{1}{16a^3c^3} - \frac{1}{16a^5c} \times \frac{x^{n+7}}{n+7} + \text{etc.}$

PROB. 1. To find the area of any curve.

RULE. Multiply the ordinate by the fluxion of the abscissa, and the product gives the fluxion of the figure, whose fluent is the area of the figure.

EXAMP. 1. Fig. 8. Let the curve ARMIH, whose area you will find, be the common parabola. Let  $u$  represent the area, and  $\dot{u}$  its fluxion.

In which case the relation of AB ( $x$ ) and BR ( $y$ ) being expressed by  $y^2 = ax$  (where  $a$  is the parameter) we thence get  $y = a^{\frac{1}{2}} x^{\frac{1}{2}}$ ; and therefore  $\dot{u} = RmHB (= y \dot{x}) = a^{\frac{1}{2}} x^{\frac{1}{2}} \dot{x}$ : whence  $u = \frac{2}{3} \times a^{\frac{1}{2}} x^{\frac{3}{2}} = \frac{2}{3} a^{\frac{1}{2}} x^{\frac{3}{2}} \times x = \frac{2}{3} yx$  (because  $a^{\frac{1}{2}} x^{\frac{1}{2}} = y$ )  $= \frac{2}{3} \times AB \times BR$ : hence a parabola is  $\frac{2}{3}$  of a rectangle of the same base and altitude.

EXAMP. 2. Let the proposed curve CSDR (fig. 9.) be of such a nature, that (supposing AB unity) the sum of the areas CSTBC and CDGBC answering to any two proposed abscissas AT and AG, shall be equal to the area CRNBC, whose corresponding abscissa AN is equal to AT  $\times$  AG, the product of the measures of the two former abscissas.

First, in order to determine the equation of the curve, (which must be known before the area can be found) let the ordinates GD and NR move parallel to themselves towards HF; and then having put  $GD = y$ ,  $NR = z$ ,  $AT = a$ ,  $AG = r$ , and  $AN = u$ , the fluxion of the area CDGB will be represented by  $y \dot{r}$ , and that of the area CRNB by  $z \dot{u}$ : which two expressions must, by the nature of the problem, be equal to each other; because the latter area CRNB exceeds the former CDGB by the area CSTB, which is here considered as a constant quantity: and it is evident, that two expressions, that differ only by a constant quantity, must always have equal fluxions.

Since, therefore,  $y \dot{r} = z \dot{u}$ , and  $u = ar$ , by hypothesis, it follows, that  $u = ar$ , and that the first equation (by substituting for  $u$ ) will become  $y \dot{r} = a z \dot{r}$ , or  $y = az$ , or lastly  $y \dot{r} = z \dot{u}$ , that is,  $GD \times AG = NR \times AN$ : therefore,  $GD : NR :: AN : AG$ ; whence it appears, that every ordinate of the curve is reciprocally as its corresponding abscissa.

Now, to find the area of the curve so determined, put  $AB = 1$ ,  $BC = b$ , and  $BG = x$ : then, since  $AG (1+x)$

: AB (1) :: BC ( $b$ ) : GD ( $y$ ) we have  $y = \frac{b}{1+x}$ , and

consequently  $\dot{u} (= y \dot{x}) = \frac{b \dot{x}}{1+x} = b \times \dot{x} - x \dot{x} + x^2 \dot{x} - x^3 \dot{x} + x^4 \dot{x} - \text{etc.}$  Whence, BGD C, the area itself will be  $= b \times x - \frac{x^2}{2} + \frac{x^3}{3} - \frac{x^4}{4} + \frac{x^5}{5} - \text{etc.}$  which was to be found.

Hence it appears, that as these areas have the same properties as logarithms, this series gives an easy method of computing logarithms; and the fluent may be found by means of a table of logarithms, without the trouble of an infinite series: and every fluxion whose fluent agrees with any known logarithmic expression, may be found the same way. Hence the fluents of fluxions of the following forms are deduced.

The fluent of  $\frac{x}{\sqrt{x^2 \pm a^2}} = \text{hyp. log. of } x + \sqrt{x^2 \pm a^2}$ ;

of  $\frac{x}{\sqrt{2ax + x^2}} = \text{hyp. log. of } a \times x + \sqrt{2ax + x^2}$ ;

of  $\frac{2ax}{a^2 - x^2} = \text{hyp. log. of } \frac{a+x}{a-x}$ ;

and of  $\frac{2ax}{x \sqrt{a^2 \pm x^2}} = \text{hyp. log. of } \frac{a - \sqrt{a^2 \pm x^2}}{a + \sqrt{a^2 \pm x^2}}$ .

PROB. 2. To determine the length of curves.

Fig. 5. Because Cde is a right-angled triangle,  $Cd^2 = Ce^2 + de^2$ ; wherefore the fluxions of the abscissa and ordinate being taken in the same terms and squared, their sum gives the square of the fluxion of the curve; whose root being extracted, and the fluent taken, gives the length of the curve.

EXAMP. To find the length of a circle from its tangent. Make the radius AO (fig. 5.) =  $a$ , the tangent of AC =  $t$ , and its secant =  $s$ , the curve =  $z$ , and its fluxion =  $\dot{z}$ ; because the triangles OTC, OCS, are similar, OT : OC :: OC : OS; whence OS =  $\frac{a^2}{s}$ , and SA =  $a - \frac{a^2}{s} = a - \frac{a^2}{\sqrt{a^2 + t^2}}$ ; whose

fluxion is  $\frac{a^2 t \dot{t}}{a^2 + t^2}$ ; and because the triangles OTC,

$dCe$  are similar, TC (=  $t$ ): TO (=  $\sqrt{a^2 + t^2}$ ) :: Ce =  $\left( \frac{a^2 t \dot{t}}{a^2 + t^2} \right)$ : Cd =  $\frac{a^2 \dot{t}}{a^2 + t^2} = \text{fluxion of the curve.}$

Now by converting this into an infinite series, we have the

fluxion of the curve =  $t - \frac{t^3}{3a^2} + \frac{t^5}{5a^4} - \frac{t^7}{7a^6} + \frac{t^9}{9a^8} - \text{etc.}$  and consequently  $z = t - \frac{t^3}{3a^2} + \frac{t^5}{5a^4} - \frac{t^7}{7a^6} + \frac{t^9}{9a^8} - \text{etc.} = AR$ .

Where, if (for example) sake AR be supposed an arch of 30 degrees, and AO (to render the operation more easy) be put = unity, we shall have  $t = \sqrt{3} = .5773502$  (because Ob  $\sqrt{3}$ : bR (1) :: OA (1): AT ( $t$ ) =  $\sqrt{3}$ ) Whence,

$$t^3 (= t \times t^2 = t \times \frac{1}{3}) = .1924500$$

$$t^5 (= t^3 \times t^2 = \frac{t^3}{3}) = .0641500$$

$$t^9 \left( = t^9 \times t^9 = \frac{t^{18}}{3} \right) = .0213833$$

$$t^9 \left( = t^9 \times t^9 = \frac{t^{17}}{3} \right) = .0071277$$

$$t^{11} \left( = t^9 \times t^2 = \frac{t^{11}}{3} \right) = .0023759$$

$$t^{13} \left( = t^{11} \times t^2 = \frac{t^{13}}{3} \right) = .0007919$$

$$t^{15} \left( = t^{13} \times t^2 = \frac{t^{15}}{3} \right) = .0002639$$

$\&c.$

$$\begin{aligned} \text{And therefore AR} &= .5773502 - \frac{.1934500}{3} + \\ &\frac{.0641500}{5} - \frac{.0213833}{7} \times \frac{.0091277}{9} - \frac{.0023759}{11} + \\ &\frac{.0007919}{13} - \frac{.0002639}{15} + \frac{.0000879}{17} - \frac{.0000293}{19} \\ &+ \frac{.0000097}{21} - \frac{.0000032}{23} = .5235987: \text{ for the length} \end{aligned}$$

of an arch of 30 degrees, which multiplied by 6 gives 3.141592 + for the length of the semi-periphery of the circle whose radius is unity.

Other series may be deduced from the versed line, sine and secant; and these are of use for finding fluents which cannot be expressed in finite terms. For,

the fluent of	$\left\{ \begin{array}{l} \frac{w}{\sqrt{2aw-w^2}} \\ \frac{w}{\sqrt{a^2-w^2}} \\ \frac{aw}{a^2+w^2} \\ \frac{aw}{w\sqrt{w^2-a^2}} \end{array} \right\}$	is equal to the arch whole	$\left\{ \begin{array}{l} \text{Versed-line} \\ \text{Right-line} \\ \text{Tangent} \\ \text{Secant} \end{array} \right\}$	$\left\{ \begin{array}{l} \text{is } \frac{aw}{a} \text{, and} \\ \text{Radius Unity.} \end{array} \right\}$

PROB. 3. To find the contents of a solid.

Let the surface of the generating plane be multiplied by the space it passes through in any time, the product will give a solid which is the fluxion of the solid required: the surface must therefore be computed in terms of  $x$ , which represents the line or axis on which it moves, and by its motion on which the fluxion is to be measured, and the fluent found will give the contents of the solid.

EXAMP. Let it be proposed to find the content of a cone ABC, fig. 10.

Put the given altitude (AD) of the cone  $= a$ , and the semi-diameter (BD) of its base  $= b$ , the solid  $= s$ , its fluxion  $= \dot{s}$ , and the area of a circle, whose radius is unity,  $= p$ : then the distance (AF) of the circle EFG, from the vertex A, being denoted by  $x$ ,  $\&c.$  we have, by similar triangles, as  $a : b :: x : EF (y) = \frac{bx}{a}$ . Whence in this case,  $\dot{s}$

$$(= p y^2 \dot{x}) = \frac{p b^2 x^2 \dot{x}}{a^2}; \text{ and consequently } s = \frac{p b^2 x^3}{3 a^2};$$

which, when  $x=a$  ( $=AD$ ) gives  $\frac{p b^2 a}{3}$  ( $= p \times BD^2 \times \frac{1}{3} AD$ ) for the content of the whole cone ABC: which appears from hence to be just  $\frac{1}{3}$  of a cylinder of the same base and altitude.

PROB. 4. To compute the surface of any solid body.

The fluxion of the surface of the solid is equal to the periphery of the surface, by whose motion the solid is generated, multiplied by its velocity on the edge of the solid, and the computation is made as in the foregoing.

EXAMP. Fig. 11. Let it be proposed to determine the convex superficies of a cone ABC.

Then, the semi-diameter of the base (BD, or CD) being put  $= b$ , the slanting line, or hypotenuse  $AC=c$ , and FH (parallel to DC)  $= y$ ,  $AG=x$ , the surface  $= w$ , its fluxion  $= \dot{w}$ , and  $p$  = the periphery of a circle whose diameter is unity, we shall, from the similarity of the triangles ADC and Hmb, have  $b : c :: y : \dot{z} (Hb) = \frac{\dot{w}}{b}$ : whence  $\dot{w} (2 p y \dot{z}) =$

$$\frac{2 p c y \dot{y}}{b}; \text{ and consequently } w = \frac{p c y^2}{b}.$$

This, when  $y=b$ , becomes  $= p c b = p \times DC \times AC =$  the convex superficies of the whole cone ABC: which therefore is equal to a rectangle under half the circumference of the base and the slanting line.

The method of fluxions is also applied to find the centres of gravities, and oscillation of different bodies; to determine the paths described by projectiles and bodies acted on by central forces, with the laws of centripetal force in different curves; the retardates given to motions performed in resisting media; the attractions of bodies under different forms; the direction of wind, which has the greatest effect on an engine; and to solve many other curious and useful problems.

## F L Y

FLY in zoology. See NATURAL HISTORY.

FLY, in mechanics, a cross with leaden weights at its ends; or rather a heavy wheel at right angles to the axis of a windlass, jack, or the like; by means of which the force of the power, whatever it be, is not only preserved, but equally distributed in all parts of the revolution of the machine. See MECHANICS.

FLYING, the progressive motion of a bird, or other-winged animal, in the air.

The parts of birds chiefly concerned in flying are

## F L Y

the wings, by which they are sustained or wafted along. The tail, Messrs Willughby, Ray, and many others, imagine to be principally employed in steering and turning the body in the air, as a rudder: but Borelli has put it beyond all doubt, that this is the least use of it, which is chiefly to assist the bird in its ascent and descent in the air; and to obviate the vacillations of the body and wings: for, as to turning to this or that side, it is performed by the wings and inclinations of the body, and but very little by the help of the tail. The flying

**Flying** of a bird, in effect, is quite a different thing from the rowing of a vessel. Birds do not vibrate their wings towards the tail, as oars are struck towards the stern, but waft them downwards; nor does the tail of the bird cut the air at right angles, as the rudder does the water; but is disposed horizontally, and preserves the same situation what way soever the bird turns.

In effect, as a vessel is turned about on its centre of gravity to the right, by a brisk application of the oars to the left, so a bird in beating the air with its right wing alone, towards the tail, will turn its fore part to the left. Thus pigeons changing their course to the left, would labour it with their right wing, keeping the other almost at rest. Birds of a long neck alter their course by the inclinations of their head and neck, which altering the course of gravity, the bird will proceed in a new direction.

*The manner of flying* is thus: the bird first bends his legs, and springs with a violent leap from the ground; then opens and expands the joints of his wings, so as to make a right line perpendicular to the sides of his body: thus the wings with all the feathers therein, constitute one continued lamina. Being now raised a little above the horizon, and vibrating the wings with great force and velocity perpendicularly against the subject air, that fluid resists those successions, both from its natural inactivity and elasticity, by means of which the whole body of the bird is protruded. The resistance the air makes to the withdrawing of the wings, and consequently the progress of the bird, will be so much the greater, as the waft or stroke of the fan of the wing is longer: but as the force of the wing is continually diminished by this resistance, when the two forces continue to be in equilibrio, the bird will remain suspended in the same place; for the bird only ascends so long as the arch of air the wing describes makes a resistance equal to the excess of the specific gravity of the bird above the air. If the air, therefore, be so rare as to give way with the same velocity as it is struck withal, there will be no resistance, and consequently the bird can never mount. Birds never fly upwards in a perpendicular line, but always in a parabola. In a direct ascent, the natural and artificial tendency would oppose and destroy each other, so that the progress would be very slow. In a direct descent they would aid one another, so that the fall would be too precipitate.

**FLYING FISH**, a name given by the English writers to several species of fish, which, by means of their long fins, have a method of keeping themselves out of water a long time. See **EXOCOETUS**.

**FLYING FINION**, is part of a clock, having a fly, or fan, whereby to gather air, and so bridle the rapidity of the clock's motion, when the weight descends in the striking part.

**FOAL**, or **COLT**, the young of the horse kind. The word colt, among dealers, is understood of the male kind. See **EQUUS** and **HORSEMANSHIP**.

**FOCHEN**, a town of China capital of the province of Fokein: E. long. 118°, N. lat. 26° 20'.

**FOCUS**, in geometry and conic sections, is applied to certain points in the parabola, ellipse and hyperbola, where the rays reflected from all parts of these curves concur and meet. See **CONIC SECTIONS**.

**Focus**, in optics, is the point wherein rays are collected after they have undergone reflection or refraction. See **OPTICS**.

**FOENUGREEK**, in botany. See **TRICONELLA**.

**FOETOR**, in medicine, stinking or foetid effluvia, arising from the body or any part thereof.

**FOETUS**, denotes the child while it is contained in the mother's womb, but particularly after it is formed, till which time it is more properly called embryo. See **MIDWIFERY**.

**FOG**, or **MIST**, a meteor, consisting of gross vapours, floating near the surface of the earth.

**FOIL**, among glass-grinders, a sheet of tin, with quicksilver or the like, laid on the backside of a looking-glass, to make it reflect.

**FOIL**, among jewellers, a thin leaf of metal placed under a precious stone, in order to make it look transparent, and give it an agreeable different colour, either deep or pale: thus, if you want a stone to be of a pale colour, put a foil of that colour under it; or if you would have it deep, lay a dark one under it.

**FOLIA**, among botanists, particularly signify the leaves of plants; those of flowers being expressed by the word petal. See **BOTANY**.

**FOLIACEUM EXPANSUM**, in anatomy, a term applied to the extreme part of the Fallopian tube, next the ovary, which is expanded like the mouth of a trumpet, and surrounded with a sort of fringe.

**FOLIAGE**, a cluster or assemblage of flowers, leaves, branches &c.

**FOLIAGE** is particularly used for the representations of such flowers, leaves, branches, rinds, &c. whether natural or artificial, as are used for enrichments on capitals, friezes, pediments, &c.

**FOLIO**, in merchants books, denotes a page, or rather both the right and left hand pages, these being expressed by the same figure, and corresponding to each other. See **BOOK-KEEPING**.

**FOLIO**, among printers and booksellers, the largest form of books, when each sheet is so printed, that it may be bound up in two leaves only.

**FOLKSTONE**, a market town of Kent, six miles west of Dover.

**FOMAHANT**, in astronomy, a star of the first magnitude, in the constellation aquarius.

**FOMENTATION**, in medicine, the bathing any part of the body with a convenient liquor; which is usually a decoction of herbs, water, wine, or milk; and the applying of bags stuffed with herbs and other ingredients, which is commonly called dry fomentation.

**FONDI**, a city and bishop's see of Naples, in the province of Lavoro, about thirty-five miles north-west of Capua: E. long. 14° 20', and N. lat. 41° 35'.

**FONT**, among ecclesiastical writers, a large basin, in which water is kept for the baptizing of infants, or other persons.

FON-

**FONTAINE**, a town of Hainalt, fifteen miles east of Mons.

**FONTAINEBLEAU**, a village of the isle of France, about thirty miles south-east of Paris; remarkable for an elegant royal palace.

**FONTANELLA**, in anatomy, the quadrangular aperture, between the os frontis and ossa sincipitis, in infants just born.

**FONTARABIA**, a port-town of Spain, in the province of Biscay, twenty miles west of Bayonne: W. long.  $1^{\circ} 35'$ ; and N. lat.  $43^{\circ} 20'$ .

**FONTENAYLE**, a town of Orleansois, in France, about forty-six miles west of Poitiers.

**FONTENOY**, a town of Hainalt, situated three miles south east of Tournay.

**FONTEVRAUD**, or *Order of FONTEVRAUD*, a religious order instituted about the latter end of the XIth century. By the rules of this order the nuns were to keep silence for ever, and their faces to be always covered with their veils; and the monks wore a leathern girdle, at which hung a knife and sheath.

**FONTICULUS**, or **FONTANELLA**, in surgery, an issue, seton, or small ulcer made in various parts of the body, in order to eliminate the latent corruption out of it.

**FONTINALIS**, in botany, a genus of the cryptogamia musci class. The anthera is operculated, and the calyptra is sessile. There are four species, all natives of Britain, viz. the antipyretica, or greater water-moss; the minor, or lesser water-moss; the squamosa, or scaly water-moss; and the pennata, or feathered water-moss.

**FOOD** implies whatever aliments are taken into the body, to nourish it. See **MEDICINE**.

**FOOL**, according to Mr Locke, is a person who makes false conclusions from right principles; whereas a madman, on the contrary, draws right conclusions from wrong principles.

**FOOL'S STONES**, in botany. See **ORCHIS**.

**FOOT**, a part of the body of most animals whereon they stand, walk, &c. See **NATURAL HISTORY**.

**FOOT**, in anatomy. See **ANATOMY**, part I.

**FOOT**, in the Latin and Greek poetry, a metre or measure, composed of a certain number of long and short syllables.

These feet are commonly reckoned twenty-eight, of which some are simple, as consisting of two or three syllables, and therefore called dissyllabic or trisyllabic feet; others are compound, consisting of four syllables, and are therefore called tetrasyllabic feet.

The dissyllabic feet are four in number, viz. the pyrrhichius, spondeus, iambus, and trocheus. See **PYRRHICHIVS**, &c.

The trisyllabic feet are eight in number, viz. the dactylus, anapæstus, tribrachys, molossus, amphybrachys, amphimacer, bacchius, and antibacchius. See **DACTYL**, &c.

The tetrasyllabic are in number sixteen, viz. the proclausmaticus, dispondeus, choriambus, antipastus, diiambus, dichoreus, ionicus a majore, ionicus a minore, epitritus primus, epitritus secundus, epitritus

tertius, epitritus quartus, pæon primus, pæon secundus, pæon tertius, and pæon quartus. See **PROCLEUSMATICUS**, &c.

**FOOT** is also a long measure, consisting of 12 inches.

Geometricians divide the foot into 10 digits, and the digit into 10 lines.

**FOOT square**, is the same measure both in breadth and length, containing 144 square or superficial inches.

**Cubic or Solid FOOT**, is the same measure in all the three dimensions, length, breadth, and depth or thickness, containing 1728 cubic inches.

**FOOT of a horse**, in the menage, the extremity of the leg, from the coronet to the lower part of the hoof.

**FOOT LEVEL**, among artificers, an instrument that serves as a foot-rule, a square, and a level. See **LEVEL**, **RULE**, and **SQUARE**.

**FORAMEN**, in anatomy, a name given to several apertures or perforations in divers parts of the body; as, 1. The external and internal foramina of the cranium or skull. 2. The foramina, in the upper and lower jaw. 3. Foramen lachrymale. 4. Foramen membranæ tympani. See **ANATOMY**.

**FORCALQUIER**, a town of Provence, in France, thirty miles north of Aix.

**FORCE**, in mechanics, denotes the cause of the change in the state of a body when being at rest it begins to move, or has a motion which is either not uniform or not direct. See **MECHANICS**.

**Central FORCES**. See **MECHANICS**.

**FORCE**, in law, signifies any unlawful violence offered to things or persons.

**FORCEPS**, in surgery, &c. a pair of scissors for cutting off, or dividing, the fleshy membranous parts of the body, as occasion requires. See **SURGERY**.

**FORE-CASTLE OF A SHIP**, that part where the fore-mast stands. It is divided from the rest by a bulk-head.

**FOREIGN**, some thing extraneous, or that comes from abroad.

**FOREIGNER**, the natural born subject to some foreign prince.

Foreigners, tho' made denizens, or naturalized, are disabled to bear any office in the government, to be of the privy council, or members of parliament, &c. This is by the acts of the settlement of the crown. Such persons as are not freemen of a city, or corporation, are also called foreigners, to distinguish them from the members of the same.

**FORELOCKS**, in the sea language, little flat wedges made with iron, used at the ends of bolts, to keep them from flying out of their holes.

**FORELORN-HOPE**, in the military art, signifies men detached from several regiments, or otherwise appointed, to make the first attack in day of battle; or, at a siege, to storm the counterscarpe, mount the breach, or the like.

They are so called from the great danger they are unavoidably exposed to; but the word is old, and begins to be obsolete.

**FORE-MAST** OF A SHIP, a large round piece of timber, placed in her fore-part, or fore-castle, and carrying the fore-sail and fore-top sail yards. Its length is usually  $\frac{1}{2}$  of the main-mast, and the fore-top-gallant mast is  $\frac{1}{3}$  the length of the fore-top.

**FOREMAST-MEN**, are those on board a ship that take in the top-sails, sling the yards, furl the sails, bowse, trice, and take their turn at the helm, &c.

**FOREST**, in general, a great wood, or a large extent of ground covered with trees.

**FOREST**, in law, is defined by Manwood, a certain territory of woody grounds, and fruitful pastures, privileged for wild beasts and fowls of forest, chase and warren, to rest and abide under the protection of the king, for his princely delight, bounded with unremoveable marks, and inclosures, either known by matter of record or prescription; replenished with wild beasts of venery, or chase, with great coverts of vert for the said beasts; for preservation and continuance whereof, with the vert and venison, there are certain particular laws, privileges, and officers.

Forests are of that antiquity in England, that, excepting the new forest in Hampshire erected by William the Conqueror, and Hampton Court erected by Henry VIII. it is said that there is no record or history which makes any certain mention of their erection, though they are mentioned by several writers, and in divers of our laws and statutes.

There are sixty-nine forests in England, thirteen chases, and 800 parks. The four principal forests are New Forest, Sherwood Forest, Dean Forest, and Windsor Forest.

**FOREST-TOWNS**, in geography, certain towns of Swabia, in Germany, lying along the Rhine and the confines of Switzerland, and subject to the house of Austria. Their names are Rhinefeld, Seckingen, Lausenbourg, and Waldshut.

**FORE-STAFF**, or **CROSS-STAFF**, an instrument used at sea for taking the altitude of the sun, moon or stars.

**FORESTALLER**, a person who is guilty of forestalling. See the next article.

**FORESTALLING**, in law, buying or bargaining for any corn, cattle, victuals, or merchandize, in the way as they come to fairs or markets to be sold, before they get thither, with an intent to sell the same again at a higher price.

The punishment for this offence, upon conviction at the quarter sessions, by two or more witnesses, is, for the first time, two months imprisonment and the loss of the goods, or the value; for the second offence, the offender shall be imprisoned six months, and lose double the value of the goods; for the third offence, he shall suffer imprisonment during the king's pleasure, forfeit all his goods and chattels, and stand on the pillory: but the statute does not extend to maltsters buying barley, or to badgers licensed.

**FORESTER**, a sworn officer of the forest, appointed by the king's letters-patent, to walk the forest at all hours, watch over the vert and venison; also to make attachments and true presentments of all trespasses committed within the forest.

**FORETHOUGHT FELONY**, in Scots law, signifies premeditated murder.

**FORFAR**, the capital of the county of Angus, in Scotland: W. long.  $2^{\circ} 32'$ , and N. lat.  $56^{\circ} 25'$ .

It is a parliament town, classed with Perth, Dundee, Coupar, and St Andrews, which all together send out member.

**FORFEITURE**, properly signifies the effect of transgressing some penal law, and extends to lands or goods.

**FORFICULA**, the **EAR-WIG**, in zoology, a genus of insects belonging to the order of coleoptera. The antennae are bristly; the elytra are dimidiated: the wings are covered; and the tail is forked. There are two species, viz. the auriculata, or common ear-wig, with the tops of the elytra white; and the minor, with testaceous and unspotted elytra.

**FORGE**, properly signifies a little furnace, wherein smiths and other artificers of iron or steel, &c. heat their metals red-hot, in order to soften them and render them more malleable and manageable on the anvil.

**FORGE** is also used for a large furnace, wherein iron-ore, taken out of the mine, is melted down: or it is more properly applied to another kind of furnace, wherein the iron-ore, melted down and separated in a former furnace, and then cast into sows and pigs, is heated and fused over again, and beaten afterwards with large hammers, and thus rendered more soft, pure, ductile, and fit for use.

**FORGER**, in law, one guilty of forgery. See the next article.

**FORGERY**, in a legal sense, is where a person fraudulently makes and publishes false writings to another's prejudice: or, it signifies the writ that lies against him who offends that way.

**FORISFAMILIATION**, in law, when a child, upon receiving a portion from his father, or otherwise renounces his legal title to any further share of his father's succession, he is said to be *forisfamiliated*. See SCOTS LAW, title 23.

**FORLI**, a town of Romania, in the pope's territories, fifteen miles south-west of Ravenna.

**FORM**, in physics, the essential or distinguishing modification of the matter whereof a natural body is composed, so as thereby to give it such a particular manner of existence; being that which constitutes it such a particular body, and distinguishes it from every other body.

**FORM** is also used, in a moral sense, for the manner of being or doing a thing according to rules: thus we say, a form of government, a form of argument, &c.

**FORM**, in law, the rules established and requisite to be observed in legal proceedings.

**FORM**, in carpentry, is used to denote the long seats or benches in the choirs of churches or in schools, for the priests, prebends, religious, or scholars to sit on. At schools, the word form is frequently applied to what is otherwise termed a class. See CLASS.

**FORM** also denotes the external appearance or surface of a body, or the disposition of its parts, as to the length, breadth, and thickness.

**FORM**

**FORM** is also used, among mechanics, for a sort of mould whereon any thing is fashioned or wrought: as the hatter's form, the paper-maker's form, &c.

**Printer's FORM**, an assemblage of letters, words, and lines, ranged in order, and so disposed into pages by the compositor; from which, by means of ink and a press, the printed sheets are drawn.

Every form is inclosed in an iron-chase, wherein it is firmly locked by a number of pieces of wood; some long and narrow, and others of the form of wedges. There are two forms required for every sheet, one for each side; and each form consists of more or fewer pages, according to the size of the book.

**FORMAL**, something belonging to, or constituting the form of a thing. See **FORM**.

**FORMICA**, or the **ANT**, in zoology, a genus of insects belonging to the order of hymenoptera, the characters of which are these: There is a small scale betwixt the breast and belly, and the joint is so deep that the animal appears as if it were almost cut through the body. The females, and the neuters or working ants which have no sexual characteristics, are furnished with a hidden sting; and both the males and females have wings, but the neuters have none. There are eighteen species, most of them distinguished by their colours.

These insects keep together in companies like the bees, and maintain a sort of republic. Their nest is not exactly square, but longer one way than the other; and in it there are a sort of paths, which lead to different magazines. Some of the ants are employed in making the ground firm, by mixing it with a sort of glue, for fear it should crumble, and fall down upon their heads. They may be sometimes seen to gather several twigs, which serve them for rafters, which they place over the paths, to support the covering; they lay others across them, and upon them rushes, weeds, and dried grass, which they heap up into a double declivity, which serves to turn off the water from their magazines. Some of these serve to lay up their provisions in, and in others they lay their eggs.

As for the provisions, they lay up every thing that is fit for them to eat; and you may often see one loaded with pippin, or grain of fruit, another with a dead fly, and several together with the carcase of a may-bug, or other insect. If they meet with any they cannot bring away, they eat it upon the spot, or at least so much of it, as may reduce it to a bulk small enough for them to carry. They do not run about where they please, at all adventures: for some of them are sent abroad to make discoveries; and if they bring back news they have met with a pear, or a sugar-loaf, or a pot of sweatmeats, they will run from the bottom of the garden, as high as the third story of a house, to come at it. They all follow each other in the same path, without wandering to the right or the left; but in the fields they are more at their liberty, and are allowed to run about in search of game. There is a sort of green fly, that does a great deal of mischief among the flowers, and which curl up the leaves of peach and pear trees; and these

are surrounded with a sort of glue, or honey, which the ants hunt after very greedily; for they touch neither the plant nor the flies themselves.

Next to this, their greatest passion is to lay up hoards of wheat, and other corn; and for fear the corn should sprout by the moisture of the subterraneous cells, they gnaw off the end which would produce the blade. The ants are often seen pushing along grains of wheat, or barley, much larger than themselves.

In Africa, and particularly in Guiney, the ants are exceeding troublesome, and do a great deal of mischief. They make their nests of earth in the fields, twice as high as a man; besides which they build large nests in high trees, from which places they advance in such prodigious swarms to the houses, that they frequently oblige the inhabitants to quit their beds in the night-time. They will sometimes attack a living sheep, which in a night's time they will reduce to a perfect skeleton, leaving not the least thing except the bones. It is common for them to serve domestic fowls in the same manner, and even the rats themselves cannot escape them. If you place a worm or a beetle where only one or two ants are, they will immediately depart, and bring with them above an hundred; after which they seize their prey, and march off with it in good order. These ants are of various sorts, some great, others small, some black, and others red; the sting of this last is very painful, and causes an inflammation; the white are as transparent as crystal, and have such strong teeth, that in a night's time they will eat their way through a thick wooden chest, and make it as full of holes as if it had been penetrated by hail-shot.

There are also several sorts of ants in the East Indies, whose numbers are prodigious: some of them are exceeding large, and of a ruddy colour, inclining to black; and some have wings, but others have none. They are very pernicious to the fruits of the earth, and do a great deal of mischief in houses, unless great care is taken to prevent them. It is remarkable, that if one ant meets another that is laden, it always gives way to let it pass freely.

The ant lays eggs in the manner of the common flies, and from these eggs are hatched a sort of small maggots or worms without legs: these are sharp at one end and blunt at the other; and are white, but so transparent, that the intestines are seen through the skin. These, after a short time, change into large white aureliæ, which are what are usually called ants eggs. That end which is to be the tail is the largest, and that which is the head is somewhat transparent.

The ants move these about at pleasure with their forceps. It is well known, that when a nest of these creatures is disturbed and the aureliæ scattered about, the ants are at infinite pains to get together all that are unhurt, and make a nest for them again: nay, any ants will do this, and those of one nest will often take care of the aureliæ of another.

The affection of the ant for its offspring is amazing. They carry the young worms about in their mouths, that nothing may injure them; and when the earth

earth of the nest is dry, they carry them down to a greater depth, but when wet they bring them to the surface, that they may not be injured by the damps.

The common ant builds only with small small pieces of dry earth, and there is always found a vast quantity either of eggs, worms, or aureliæ, at the bottom of the nest. The aureliæ are covered only with a thin skin; and when carefully opened, they shew the worm perfect, and in its several stages of perfection.

The forecast of ants in providing against the winter is a mistake. They are supposed not to eat in the winter, but to spend that season, like dormice and many other sorts of animals, in a state of sleep. What confirms this is, that they have been observed, as the cold draws on in the autumn, to move very heavily, and in the vintage-time they can hardly stir at all; so that the provision they make seems intended not for themselves, but for their young.

The care these creatures take of their offspring is remarkable. Whenever a hill is disturbed, all the ants are found busied in consulting the safety, not of themselves, but of the eggs or these larger bodies enclosing the maggot or young ant; they carry these down any way so as to get them out of sight, and will do this over and over as often as they are disturbed.

They carry away the eggs and vermicles together in their confusion; but as soon as the danger is over, they carefully separate them, and place each sort in parcels by themselves under shelter of different kinds, and at various depths, according to the different degrees of warmth and coverture the different states require.

In the warm season of the year, they every morning bring up the eggs, as they are usually called, to the surface, or nearly so; and from ten in the forenoon to five in the afternoon or thereabouts, all these will be found just under the surface; and if the hills be examined toward eight in the evening, they will be found to have carried them all down; and if rainy weather be coming on, it will be necessary to dig a foot deep or more, in order to find them.

These little creatures are very troublesome in gardens, and in pasture-lands; as well by feeding on the fruit, as by making up hills for their habitation. In the hotter countries, as Italy, Spain, and the West Indies; ants are the great pest of the fields. Trees may be preserved from them by encompassing the stem, for four fingers breadth, with a roll of wool, newly pulled from the sheep's belly; or by laying saw-dust all round the stump of it. Some anoint the tree with tar, which has the same effect.

The large, black, winged ants of America, to avoid the great rains which fall there at particular seasons, make to themselves large nests on trees, with a covered way for them to go up and down on the lee-side of the tree. These nests are roundish on the outside, made of light brown earth, plastered smooth. They are larger than a bushel; and in the inside are many sinous caverns or lodgings communicating with one another. See Plate LXXX. fig. 1. A, The ants

nest; B, The tubular passage, made of the same materials.

FORMICA, in medicine, a callous sort of wart.

FORMICA-LEO, the ANT-LION, or ANT-EATER, in zoology, an insect so called from its devouring great numbers of ants. It is the caterpillar or worm of a fly much resembling the libellæ or dragon-flies.

The address of this insect in catching the ant is admirable; it makes a hole of a conical or funnel shape, in the loose sand; and is sure to catch all the ants that come within the verge of this hole, by throwing up sand on them, whereby they are forcibly carried into the power of the enemy at the bottom of the hole.

FORMOSA, an island in the pacific ocean, between  $119^{\circ}$  and  $122^{\circ}$  of E. long. and between  $22^{\circ}$  and  $25^{\circ}$  N. lat. about 100 miles east of Canton in China. It is subject to the Chinese.

FORMULA, or FORMULARY, a rule or model, or certain terms prescribed or decreed by authority, for the form and manner of an act, instrument, proceeding, or the like.

FORMULA, in church-history and theology, signifies a profession of faith.

FORMULA, in medicine, imports the constitution of medicines, either simple or compound, both with respect to their prescription and consistence.

FORMULARY, a writing containing the form of an oath, declaration, attestation, abjuration, &c. to be made on certain occasions.

FORNACALIA, or FORNICALIA, in Roman antiquity, a festival instituted by Numa in honour of Fornax, the goddess of ovens; wherein certain cakes were made, and offered in sacrifice before the ovens.

FORNICATION, the act of incontinency between single persons; for when either of the parties is married, such act is adultery. See ADULTERY.

FORNIX, in anatomy. See ANATOMY, p. 285.

FORRAGE, in the military art, denotes hay, oats, barley, wheat, grass, clover, &c. brought into the camp by the troopers, for the sustenance of their horses.

It is the business of the quarter-master-general to appoint the method of forrage, and post proper guards for the security of the forragers.

FORRES, a parliament-town of Scotland in the county of Murray, about thirteen miles west of Elgin: W. long.  $3^{\circ} 20'$ , and N. lat.  $57^{\circ} 40'$ .

It is classed with Inverness, Fortrose, and Nairn.

FORT, in the military art, a small fortified place, environed on all sides with a moat, rampart, and parapet. Its use is to secure some high ground or the passage of a river, to make good an advantageous post, to defend the lines and quarters of a siege, &c.

FORTALICE, in Scots law, signified anciently a small place of strength, originally built for the defence of the country; and which on that account was formerly reckoned *inter regalia*, and did not go along with the lands upon which it was situated without a special grant from the crown. Now, fortalices are carried by a general grant of the lands; and the word is become synonymous with manor-place, messuage &c.

# FORTIFICATION.

**F**ORTIFICATION, the art of fortifying a town, or other place; or of putting them in such a posture of defence, that every one of its parts defends, and is defended by some other parts, by means of ramparts, parapets, moats, and other bulwarks; to the end, that a small number of men within, may be able to defend themselves for a considerable time against the assaults of a numerous army without; so that the enemy in attacking them, must of necessity suffer great loss.

Fortification is either ancient or modern, regular or irregular. Ancient fortification, at first, consisted of walls or defences made of trunks and other branches of trees mixed with earth, to secure them against the attacks of the enemy. This was afterwards altered to stone walls, on which were raised breast-works, behind which they made use of their darts and arrows in security. Modern fortification is that which is flanked and defended by bastions and out works, the ramparts of which are so solid, that they cannot be beat down but by the continual fire of several batteries of cannon. Regular fortification, is that built in a regular polygon, the sides and angles of which are all equal, being commonly about a musket-shot from each other. Irregular fortification, on the contrary, is that where the sides and angles are not uniform, equidistant, or equal; which is owing to the irregularity of the ground, valleys, rivers, hills, and the like.

## SECTION I. Of Regular Fortification.

THE art of regular fortification may be distinguished into two parts, viz. the elementary or theoretical, and practical.

The elementary part consists in tracing the plans and profiles of a fortification on paper, with scales and compasses; and to examine the systems proposed by different authors, in order to discover their advantages and disadvantages.

And the practical part consists in forming a project of a fortification, according to the nature of the ground and other necessary circumstances, to trace it on the ground, and to execute the project, together with all the military buildings, such as magazines, store-houses, bridges, &c.

Notwithstanding all the improvements which have been made in the art of fortifying since the invention of gunpowder, that of attacking is still superior to it: engineers have tried in vain to render the advantages of a fortification equal to those of the attack; the superiority of the besiegers fire, together with the greater number of men, obliges generally, sooner or later, the besieged to submit.

The greatest improvement made in the art of attacking

happened in the year 1697, when M. Vauban made first use of ricochet firing at the siege of Ath, whereby the besieged placed behind the parapets were as much exposed to the fire of the besiegers as if there had been none; whereas before, they had been secure as long as the parapet was not demolished: and the worst is, that there can be no remedy found to prevent this ensnaring without falling into inconveniencies almost as bad as those which we endeavour to avoid.

Although authors agree as to the general form in the present manner of fortifying, yet they mostly differ in particular constructions of the parts. As it would be both needless and superfluous to treat of all the different methods hitherto proposed, we shall content ourselves with explaining those only, which are most esteemed by the best judges, and have been mostly put in practice.

### *Construction of M. VAUBAN's Method.*

This method is divided into little, mean, and great; the little is chiefly used in the construction of citadels, the mean in that of all sorts of towns, and the great in particular cases only.

We shall give the construction of the mean, as being most useful, and refer the reader to the table hereafter, for those dimensions which are different in these several fortifications.

[Plate LXXXIII. fig. 1.] Inscribe in a circle a polygon of as many sides as the fortification is designed to have fronts; let AB be one of the sides of half an exagon, which bisect by the perpendicular CD: divide half AC of it into nine equal parts, and one of these into ten others; then these divisions will serve as a scale to construct all the parts of the fortification, and each of them is supposed to be a toise or fathom, that is six French feet; and therefore the whole side AB is supposed to be 180 toises.

As the dividing a line into so many equal parts, is troublesome and tedious; it is more convenient to have a scale of equal parts by which the works may be constructed.

If therefore, in this case, the radius is taken equal to 180 toises, and the circle described with that radius being divided into six equal parts, or the radius being carried six times round, you will have an exagon inscribed; AB being bisected by the perpendicular CD as before, set off 30 toises from C to D, and draw the indefinite lines ADG, BDF, in which take the parts AE, BH, each equal to 50 toises; from the centre E describe an arc through the point H, meeting AD in G, and from the centre H describe an arc through the point E, meeting BD in F; or which is the same, make each of the lines EG HF equal to the distance EH; then the lines joining the points A, E, F, G, H, B, will be the principal or outline of the front.

If the same construction be performed on the other sides of the polygon, you will have the principal or outline of the whole fortification.

If, with a radius of 20 toises, there be described circular arcs, from the angular points B, A, M, T, and lines are drawn from the opposite angles E, H, &c. so as to touch these arcs, their parts a b, b c, &c. together with these arcs will represent the outline of the ditch.

#### DEFINITIONS.

1. The part FEALN, is called the bastion.
2. AE, AL, the faces of the bastion.
3. EF, LN, the flanks.
4. FG, the curtain.
5. FN, the gorge of the bastion.
6. AG, BF, the lines of defence.
7. AB, the exterior side of the polygon.
8. CD, the perpendicular.
9. Any line which divides a work into two equal parts, is called the capital of that work.
10. abc, the counterscarp of the ditch.
11. A, M, the flanked angles.
12. H, E, L, the angles of the shoulder, or shoulder only.
13. G, F, N, the angles of the flank.
14. Any angle whose point turns from the place is called a salient angle, such as A, M; and any angle whose point turns towards the place, re-entering angle, such as b, F, N.
15. If there be drawn two lines parallel to the princi-

pal or outline, the one at 3 toises distance, and the other at 8 from it; then the space yx included between the principal one and that farthest distant, is called the rampart.

And the space xx, contained by the principal line, and that next to it, and which is generally stained black, is called the parapet.

16. There is a fine line drawn within four feet of the parapet, which expresses a step called banquette.

N. B. All works have a parapet of three toises thick, and a rampart of 8 to 10, besides their slopes. The rampart is elevated more or less above the level of the place, from 10 to 20 feet, according to the nature of the ground and the particular constructions of engineers.

The parapet is a part of the rampart elevated from 6 to 7½ feet above the rest, in order to cover the troops which are drawn up there from the fire of the enemy in a siege; and the banquette is two or three feet higher than the rampart, or about four feet lower than the parapet; so that when the troops stand upon it, they may just be able to fire over the parapet.

17. The body of the place, is all that which is contained within this first rampart; for which reason, it is often said to construct the body of the place; which means properly, the construction of the bastions and curtains.

18. All the works which are constructed beyond the ditch before the body of the place are called outworks.

T A B L E.

	Forts.						Little Fortif.				Mean		Great.	
Side of Polyg.	80	90	100	110	120	130	140	150	160	170	180	190	200	210
Perpendicular.	10	11	12½	14	15	16	20	21	23	25	30	31	35	37
Faces bast.	22	25	28	30	33	35	40	42	45	47	50	53	55	60
Cap. of ravel.	25	28	30	35	38	40	45	50	50	52	55	55	60	50

In the first vertical column are the numbers expressing the lengths of the exterior sides from 80 to 260.

In the second, the perpendiculars answering to these sides.

In the third, the lengths of the faces of bastions; and in the fourth, the lengths of the capitals of the ravelins.

The forts are mostly, if not always, squares; for which reason, the perpendiculars are made one eighth of the exterior sides; because if they were more, the gorges of the bastions would become too narrow.

The little fortification is chiefly designed for citadels, and are commonly pentagons; the perpendiculars are made one seventh of the exterior side; the mean is used in all kinds of fortifications from an exagon upwards to any number of sides: and the great is seldom used but in an irregular fortification, where there are some sides that cannot be made less without much expence: or in a town which lies near a great river, where the side next the river is made from 200 to 260 toises; and as that side is less exposed to be attacked than any other, the perpendicular is made shorter, which saves much expence.

The faces of the bastions are all ⅓ths of the exterior

sides, or nearly so, because the fractions are neglected.

It may be observed in general, that in all squares the perpendicular is ⅓th of the exterior side, and all pentagons ⅔th, and in all the rest upwards ⅓th.

#### 1. Construction of Orillons and retired Flanks.

Describe the front MPQRST as before, and divide the flank into three equal parts, of which suppose Sr to be one: from the opposite flanked angle M draw a line Mr, in which take the part mr 5 toises; take likewise Rn in the line of defence MR, produced, equal to 5 toises, and join nm, upon which as a base describe the equilateral triangle npm, and from the angle p, opposite to the base as centre, is described the circular flank nm.

And if Sr be bisected by the perpendicular 1, 2, and another be erected upon the face ST, at S; the intersection 2 of these two perpendiculars, will be the centre of the arc which forms the orillon.

The orillons are very useful in covering the retired flanks, which cannot be seen but directly in the front; and as these orillons are round, they cannot be so easily destroyed as they would be, if they were of any other figure.

2. Con-

2. *Construction of Ravelins or Half-moons.*

Fig. 2. Set off 50 toises, from the re-entering angle O of the counterescarp, on the capital OL of the ravelin, or on the perpendicular produced, and from the point L draw lines to the shoulders A B; whose parts LM, LN, terminated by the counterescarp, will be the faces MO, ON, the semi-gorges of the ravelin required.

This is Mr Vauban's method of constructing ravelins, according to some authors; and others will have the faces of the ravelin to terminate on those of the bastions within 3 toises of the shoulders; which seems to be the best way, for the ravelins cover the flanks much better than the others.

The ditch before the ravelin is 12 toises, its counterescarp parallel to the faces of the ravelins, and is made in a circular arc, before the salient angle; as likewise all ditches are in general.

When the ravelins are made with flanks, as in fig. 3. the faces should terminate off those of the bastions, at least 5 toises from the shoulders.

The flanks are made by setting off 10 toises from the extremities of the faces, from f to h, and from m to l, fig. 3. and from the points h, l, the flanks hk, lp, are drawn parallel to the capital LO of the ravelin.

There are sometimes redoubts made in the ravelin, such as in fig. 2. which is done by setting off 16 toises from the extremities of the faces on the semi-gorges from N to b, and from M to a; and from the points b, a, the faces are drawn parallel to those of the ravelin: the ditch before this redoubt is 6 toises, and its counterescarp parallel to the faces.

3. *Construction of Tenailles.*

A tenaille is a work made in the ditch before the curtains, the parapet of which is only 2 or 3 feet higher than the level ground of the ravelin. There are three different sorts: the first are those as in fig. 4. which are made in the direction of the lines of defence, leaving a passage of 3 toises between their extremities and the flanks of the bastions, as likewise another of 2 in the middle for a bridge of communication to the ravelin.

The second sort, are those as in fig. 5. Their faces are in the lines of defence, and 16 toises long, besides the passage of 3 toises between them and the flanks of the bastions; their flanks are found by describing arcs from one shoulder of the tenaille as centre thro' the other, on which are set off 10 toises for the flanks desired.

And the third sort, are those as in fig. 6. Their faces are 16 toises, as in the second sort, and the flanks are parallel to those of the bastions.

The use in general of tenailles, is to defend the bottom of the ditch by a grazing fire, as likewise the level ground of the ravelin, and especially the ditch before the redoubt within the ravelin, which can be defended from no where else so well as from them.

The first sort do not defend the ditch so well as the others, as being too oblique a defence; but as they are not subject to be enfiladed, M. Vauban has generally preferred them in the fortifying of places, as may be seen in the citadel of Lille, at Landau, New-Brifac, and in a great many other places.

The second sort defend the ditch much better than the

first, and add a low flank to those of the bastions; but as these flanks are liable to be enfiladed, they have not been much put in practice. This defect might however be remedied, by making them so as to be covered by the extremities of the parapets of the opposite ravelins, or by some other work.

As to the third sort, they have the same advantage as the second, and are likewise liable to the same objections; for which reason they may be used with the same precautions which have been mentioned in the second.

Tenailles are esteemed so necessary, that there is hardly any place fortified without them; and it is not without reason; for when the ditch is dry, the part behind the tenailles serves as a place of arms, from which the troops may rally, destroy the works of the enemy in the ditch, oppose their descent, and retire with safety; and the communication from the body of the place to the ravelin becomes easy and secure; which is a great advantage; for by that means the ravelin may make a much better defence, as it can be supplied with troops and necessaries at any time. And if the ditch is wet, they serve as harbours for boats, which may carry out armed men to oppose the passage over the ditch whenever they please; and the communication from the tenailles to the ravelin, becomes likewise much easier than it would be without them.

4. *Construction of Lunettes.*

Fig. 7. Lunettes are placed on both sides of the ravelin, such as B, to increase the strength of a place: they are constructed, by bisecting the faces of the ravelin with the perpendicular LN; on which is set off 30 toises from the counterescarp of the ditch, for one of its faces; the other face PN, is found by making the semi-gorge TP of 25 toises; the ditch before the lunettes is 12 toises, the parapet 3, and the rampart 8; as in the ravelin.

There is sometimes another work made to cover the salient angle of the ravelin; such as A, called *Bonnet*, whose faces are parallel to those of the ravelin, and when produced bisect those of the lunettes; the ditch before it is 10 toises.

There are likewise lunettes, such as D, in fig. 8, whose faces are drawn perpendicular to those of the ravelin, within a third part from the salient angle; and their semi-gorges are only 20 toises.

These kind of works may make a good defence, and are no very great expence; for as they are so near the ravelin, the communication with it is very easy, and one cannot well be maintained till they are all three taken.

5. *Construction of Tenaillons.*

Fig. 9. Produce the faces of the ravelin beyond the counterescarp of the ditch, at a distance MN of 30 toises, and take on the counterescarp of the great ditch 15 toises from the re-entering angle p to q, and draw Nq; then qNmp will be the tenaillon required; its ditch is 12 toises, that is, the same as that of the ravelin. Sometimes there is made a retired battery in the front of the tenaillons, as in fig. B; this battery is 10 toises from the front to which it is parallel, and 15 toises long.

There are commonly retrenchments made in the tenaillons, such as O; their parapets are parallel to the fronts

fronts MN, or rather perpendicular to the side Nq, and bisect the side qN; the ditch before this retrenchment is 3 toises, and there is a banquette before the parapet next to the ditch of about 8 feet, called *Berm*; it serves to prevent the earth of the parapet (which seldom has any revetement) from falling into the ditch.

It is to be observed, that the ravelin, before which tenaillons are constructed, must have its salient angle much greater than the former construction makes them; otherwise the salient angles of the tenaillons become too acute; for which reason we made the capital of this ravelin 45 toises, and the faces terminate within 3 toises of the shoulders.

#### 6. *Construction of Counterguards.*

Fig. 10. 11. When the counterguard is placed before the ravelin, set off 40 toises on the capital of the ravelin from the salient angle A, to the salient angle B, of the counterguard; and 10 from C to D, on the counterscarp of the ditch.

When the counterguard is before the bastion, such as in fig. 2, its salient angle F is 50 toises from the salient angle E of the bastion, and the breadth near the ditch of the ravelin is 10 toises as before.

The ditch before the counterguards is 12 toises, and its counterscarp parallel to the faces.

Counterguards are made before the ravelin in some particular occasions only, but are frequently constructed before the bastions, as covering the flanks wonderfully well. Some authors, as Blondel, and Mr Coehorn, will have them much narrower than they are here.

#### 7. *Construction of Hornworks.*

Fig. 12. Produce the capital of the ravelin beyond the salient angle A, at a distance AB of about 80 toises; draw DBE at right angles to AB; in which take BD, BE, each equal to 55 toises; and on the exterior side DE, trace a front of a polygon in the same manner as that of the body of the place, making the perpendicular BF 18 toises, and the faces 30.

The branches Da Eb of the hornwork, when produced, terminate on the faces of the bastions, within 5 toises of the shoulders. The ditch of the hornwork is 12 toises, and its counterscarp parallel to the branches; and in the front terminates at the shoulders, in the same manner as the great ditch before the bastions.

The capital of the ravelin before the front of the hornwork is 35 toises, and the faces terminate on the shoulders, or rather 2 or 3 toises beyond them: and the ditch before the ravelin is 8 toises.

There are sometimes retrenchments made within the hornwork, such as S, S: which are constructed by erecting perpendiculars to the faces of the ravelins, within 25 toises of their extremities. This retrenchment, like all others, has a parapet surmounted only with a berm of 8 feet before it; as likewise, a ditch from 3 to 5 toises broad.

Fig. 13. When a hornwork is made before the bastion, the distance DL of the front from the salient angle of the bastion is 100 toises, and the branches terminate on the faces of the adjacent ravelins within 5 toises from their extremities; all the rest is the same as before.

#### 8. *Construction of Crownworks.*

Plate LXXXIV. fig. 1. From the salient angle of

the ravelin, as a centre, describe an arc of a circle with a radius of about 120 toises, cutting the capital of the ravelin produced at C; from the point C, set off the cords CB, CF, each of them equal to 110 toises; and on each of which, as an exterior side, construct a front of a polygon of the same dimensions as in the hornwork; that is, the perpendicular should be 18 toises, the faces 30, and the branches terminate on the faces of the bastions, within 25 toises of the shoulders.

The ditch is 12 toises, the capital of the ravelin 35, and its ditch 8; that is, the same as in the hornwork.

Sometimes the crownwork is made before the bastion, as in fig. 2. the arc is described from the salient angle A of the bastion, with a radius of 120 toises, as before, and the branches terminate on the faces of the adjacent ravelins within 25 toises of their extremities; the rest of the dimensions and constructions are the same as before.

Hornworks, as well as crownworks, are never made but when a large spot of ground falls beyond the fortification, which might be advantageous to an enemy in a siege, or to cover some gate or entrance into a town;

#### 9. *Construction of Covert-ways and Glacis.*

Although we have not hitherto mentioned the covert-way, nevertheless all fortifications whatsoever have one; for they are esteemed to be one of the most essential parts of a modern fortification; and it is certain, the taking the covert-way, when it is in a good condition and well defended, is generally the most bloody action of the siege.

After having constructed the body of the place, and all the outworks which are thought necessary, lines are drawn parallel to the outmost counterscarps of the ditches, at 6 toises distant from it; and the space mnmn, included between that line and the counterscarp, will be the covert-way required.

Fig. 3. There is in every re-entering angle of the counterscarp a place of arms, m; which is found by setting off 20 toises from the re-entering angle a, on both sides from a to b, and from a to c; and from the points b, c, as centres, arcs are described with a radius of 25 toises, so as to intersect each other in d; then the lines drawn from this intersection to the points b, c, will be the faces of the places of arms.

If lines are drawn, parallel to the lines which terminate the covert way, and the places of arms, at 20 toises distant from them, the space x, x, x, between these lines and those which terminate the covert-way, will be the glacis.

At the extremities of the places of arms, are traverses made, such as v, v, which serves to inclose them; these traverses are 3 toises thick, and as long as the covert-way is broad; and a passage is cut in the glacis round them, of about 6 or 8 feet, in order to have a free communication with the rest of the covert-way.

There are also traverses of the same dimensions before every salient angle of the bastion and outworks, and are in the same direction of the faces of those works produced; and the thickness lies at the same side as the parapets.

The passages round these last traverses are likewise from 6 to 8 feet wide.

*Fig. 1.*

Fig. 1.

Profil of the Body of the Place and the Ravelin with Revetement

Profil of the Body of the Place and the Ravelin with demi-Revetement

Fig. 2.

Fig. 3.

C. Bellin sc.

In each place of arms are two sally ports *z. z.*, which are 10 or 12 feet wide, for the troops to sally out; in time of a siege they are shut up, with barriers or gates.

10. *Construction of Arrows and Detached Redoubts.*

An arrow is a work made before the salient angles of the glacis, such as *A*, fig. 3.; it is composed of a parapet of 3 toises thick, and 40 long; and the ditch before it 5 toises, terminating in a slope at both ends. The communication from the covert way into these arrows is 4 or 5 toises wide, and there is a traverse *r* at the entrance of 3 toises thick, with a passage of 6 or 8 feet round it.

A detached redoubt is a kind of work much like a ravelin, with the flanks placed beyond the glacis; such as fig. 13: they are made in order to occupy some spot of ground which might be advantageous to the besiegers; likewise to oblige the enemy to open their trenches farther off than they would do otherwise.

Their distance from the covert-way ought not to exceed 120 toises, that it may be defended by musket shot from thence.

The gorge *ab* is 40 toises, the flanks *ac*, *bf*, which are perpendicular to the gorge *ro*, and the faces *cd*, *fd* 40; the ditch before it is 6 toises, ending in slopes at both ends; the covert way 4; the branches of the covert-way are 42 toises long, or thereabouts; the faces of the places of arms *y, y*, which are perpendicular to the branches, 10; and the other, which is parallel to them, 14.

The communication from the covert-way into the redoubt, is 5 or 6 toises wide; and there is a traverse made just at the entrance; and another in the middle when it is pretty long. The parapets of this communication terminate in a slope or glacis.

If these redoubts are above 50 toises distant from the covert-way, the besiegers carry their trenches round, and enter through the gorge; by which the troops that are in them are made prisoners of war, if they do not retire betimes; to prevent this, some other outworks should be made to support them.

11. *Construction of Second Ditches, and Covert-ways.*

Fig. 4. When the ground is low, and water to be found, there is often a ditch of about 10 or 12 toises made round the glacis; and opposite to the places of arms are constructed lunettes, beyond the ditch: such as *D*, whose breadth on the counterscarp of the ditch is 10 toises, from *b* to *a*, and from *c* to *d*; and the faces *aL*, *dL*, are parallel to those of the places of arms; the ditch before them is from 8 to ten toises wide.

The second covert-way is 4 toises, the semi-gorges of the places of arms, *m*, about 15, and the faces perpendicular to the counterscarp; the second glacis is from 15 to 18 toises broad.

This second covert-way has traverses every where, in the same manner as the first.

12. *Construction of Profiles.*

Plate LXXXV. fig. 1. A profile is the representation of a vertical section of a work; it serves to shew those dimensions which cannot be represented in plans, and are necessary in the building of a fortification; they are generally constructed upon a scale of 30 feet to an

inch. It would be needless to describe all their particular dimensions, since they are marked in the schemes; we shall therefore lay down the principal rules only, given by M. Vauban, on this subject.

1. Every work ought to be at least 6 feet higher than that before it, so that it may command those before it; that is, that the garrison may fire from all the works at the same time, with great and small arms, at the besiegers in their approaches: notwithstanding this specious pretence, there are several authors, who object against it. For they say, if you can discover the enemy from all the works, they can discover, by the same reason, all the works from their batteries; so that they may destroy them without being obliged to change their situation, and thereby dismount all the guns of the place before they come near it.

But if all the works were of the same height, those within cannot be destroyed, till such time as those before them are taken; guns might be placed in the covert-way and outworks to obstruct the enemy's approach, and when they come near the place, they might be transported into the inner-works; and as the body of the place would be much lower, the expence would be considerably diminished.

But when works are low, they are easily enfiladed by the ricochet batteries, which is a kind of firing with a small quantity of powder, by giving the gun an elevation of 10 or 12 degrees: this might however be partly prevented, by making the parapets near the salient angles, for the space of 8 toises on each side, 5 or 6 feet higher than the rest of the works.

2. The covert-way should be lower than the level-ground, otherwise the body of the place must be raised very high, especially when there are several outworks; this is to be understood only when the works exceed each other in height, otherwise it need not be below the level.

3. The bases of all inward slopes of earth should be at least equal to the height, if not more.

4. The bases of all outward slopes of earth, two thirds of their heights.

5. The slopes of all walls or revetements should be one fifth of their height; but one sixth would be sufficient in our opinion: the height of a wall is estimated from the bottom of the ditch, and not from the beginning of its foundation.

6. The slopes of all parapets and traverses are one sixth of their breadth; that is, 3 feet towards the field, or the inside, where the banquettes should be, 3 feet higher than the outside.

7. When the revetement of a rampart goes quite up to the top, 4 feet of the upper-part is a vertical wall of 3 feet thick, with a square stone at the top of it, projecting 6 inches, and a circular one below, or where the slope begins, of 8 or 10 inches diameter; they go quite round the rampart, and the circular projection is called the *cordon*.

Where the straight part of the wall ends and the slope begins, the wall is always made 5 feet thick; and the counterforts or buttresses reach no higher than that place.

7. When the rampart is partly walled, and partly turf-

ed, then one fifth of the height which is turfed must be added to 5 feet, to get the thickness of the wall above.

And having the thickness of any wall above, by adding one fifth of its height from the bottom of the ditch, the sum will be the thickness of the wall at the bottom; but if a sixth part is only taken for the slope, then a sixth part must be added.

For instance, suppose a rampart of 30 feet high from the bottom of the ditch, and that 10 of which are to be turfed; then the fifth part of 10, which is 2, added to 5, gives 7 for the wall above; and as this wall is 20 feet high, the fifth of which is 4, and 3 added to the thickness 7 above, gives 11 for the thickness near the foundation.

Plate LXXXV. fig. 1. Represents, in military perspective, the profiles of the body of a place, the ravelin and covert-way; which gives a clear idea of what is meant by a profile, and from which those of all other works may be easily conceived.

## SECT. II. *Of Irregular Fortification.*

THE most essential principle in fortification, consists in making all the fronts of a place equally strong, so that the enemy may find no advantage in attacking either of the sides; this can happen no otherwise but in a regular fortification situated in a plain or even ground; but as there are but few places which are not irregular, either in their works or situations, and the nature of the ground may be such as makes it impracticable to build them regular, without too great expence; it is so much the more necessary to shew in what consists the strength or weakness of a town irregularly fortified, so that the weakest part may be made stronger by additional outworks; as likewise if such a place is to be attacked, to know which is the strongest or weakest.

### 1. *Construction of an irregular place situated in an open country.*

If the place to be fortified is an old town inclosed by a wall or rampart, as it most frequently happens, the engineer is to consider well all the different circumstances of the figure, situation, and nature of the ground, to regulate his plan accordingly, so as to avoid the disadvantages, and gain all the advantages possible; he should examine, whether by cutting off some parts of the old wall or rampart, and taking in some ground, the place cannot be reduced into a regular figure, or nearly so; for, if that can be done without increasing the expence considerably, it should by no means be omitted; old towns have often towers placed from distance to distance, as Douay, Tournay, and many other places, which are generally made use of, and mended when it may be done; if there is a rampart without bastions or towers, it must be well considered, whether bastions may not be added, or if it is not better to make only some outworks; if the ditch about this rampart is not too wide and deep, it would be advantageous to make detached bastions, otherwise ravelins and counterguards must be constructed; special care must be taken, to make all sides of the polygon as nearly equal as possible, and that the length of the lines of defence do not exceed the reach of musket-

shot; but if that cannot be done, those sides which are on the narrowest part should be made the longest.

If it should happen, that some of the sides are inaccessible or of very difficult approach, either on account of some precipice, marshy ground, or inundation, they may be made much longer than the others, which are of easy access, and the flanks need not be so large as the rest; by doing so, there will be some expences saved, which may be used in making the other sides stronger by adding more outworks.

There are few situations, but what are more advantageous in some parts than in others; it is therefore the business of an engineer to distinguish them, and to render those sides strong by art, which are not so by nature.

If the situation is low and watery, lunettes or tenailions, and such other small outworks should be constructed, because they are not of any great expence, and may make a very good defence; but if one side of the place is only low, and running water is to be had, a second ditch and covert-way with lunettes may be made, by observing, that if the first glacis is made to slope, so as to become even with the level of the water in the second ditch; or if the water can be swelled, by means of dykes or sluices, so as to overflow the best part of the first glacis, it should be done; for by so doing, these works will be able to make a very good defence, since the besiegers will find it a difficult matter to lodge themselves upon this glacis, which cannot be done but within a few toises of the first covert-way, where the besieged are ready to receive them, and to destroy their works with great advantage; whereas the enemy cannot support their workmen but from the second covert-way, which is too far off to be of any great service to them.

But if the situation is of a dry nature, without any water about it, caponiers should be made in the great ditch, from the curtains to the ravelin, and batteries raised in the entrance of the ditch before the ravelin, whose parapet must slope off into a glacis, so as to afford no cover for the enemy behind them; arrows, and detached redoubts are likewise very proper to be used in such a case, and sometimes horn or crown works, if it should be thought convenient; but these works should never be constructed, without an absolute necessity, either to occupy a spot of ground which might be advantageous to the enemy, or to cover some gate or entrance into the town, for they are of so great expence, that their defence seems not to be answerable to it.

Most of the places in Flanders are fortified with horn works, such as Ipres, Tournay, Lille, and others.

If the place to be fortified is new, and the situation will not admit of a regular construction; particular care must be taken in choosing such a spot of ground as is most advantageous, and least liable to any disadvantages, either in the building or in the maintaining of it: all hills or rising grounds should be avoided, which might command any part of the works; marshy grounds, because such situations are unwholesome; or lakes and standing waters, for the same reason, excepting a lake is, or may be made navigable: good water should be had either within the place or near it, for it is absolutely necessary for men and cattle:

cattle; the air should be wholesome, otherwif: the continual sickness that may reign in such a place might prevent people to come and live in it, and the garrison would not be in a condition to defend themselves as they ought to do; in short, all the different circumstances attending such an undertaking should be maturely considered, before a resolution is taken to fortify any place.

When a situation is pitched upon, the next thing to be considered is, the bigness of the town and the number of its outworks, which must absolutely depend upon the consequence such a place is of to a nation; if it is only to guard a pass, or entrance into a country, it need not be so large; but if it is to be a place either to promote or to protect trade, it should be large and commodious; the streets should be wide, and the buildings regular and convenient: as to what regards the fortification, its construction should depend on the nature of the situation, and the number of the works on the funds or expence a prince or a nation will be at; which however ought to be according to the benefit arising from such a place: for, as such undertakings are of very great expence, an engineer cannot be too sparing in his works; on the contrary, the greatest economy should be used, both in regard to the number of works, and to their construction. The body of the place may have \* revetements quite up to the top, or only in part, and the rest turfed; but as to the outworks, they should have half revetements, or they may be made with turf only; as being not so necessary to prevent the place from being surpris'd, and may nevertheless make a good defence.

On Plate LXXXV. fig. 2. is the plan of an octagon, one half of which is similar and equal to the other half; it being supposed, that the situation would not admit of fortification quite regular; and the exterior sides are each 180 toises, and the works are constructed according to our method; but because the sides AB, EF, are weaker than the rest, as has been proved before, we have added tenailles, redoubts in the ravelins, and lunettes, to render them nearly equal in strength with the others; and if counter-guards were made before the bastions A and B, it would effectually secure that front. Instead of lunettes, any other works may be made, as it may be thought convenient and according to the nature of the ground. If it should be judged necessary to add other outworks to the ravelins all round the place, care must be taken to add likewise more to the fronts AB, EF, in order to render the advantages and disadvantages of attacking on either side equal.

## 2. *Construction of an irregular place, situated on a hill or rock.*

In the construction of such places, care must be taken that no neighbouring hill commands any part of the works; the town should always be built on the highest part; but if it should be thought more convenient to place it lower, then the upper part must be fortified with a fort; the situation should be made level as near as possible, by removing the earth from some places to fill up others; and

if it cannot well be levelled without extraordinary expence, works must be made on the highest part, so as to command and protect the lower; the works ought to occupy all the upper part of the hill, but if it should be too extensive to be all inclosed, or so irregular as not to be fortified without great inconvenience, the parts which fall without should be fortified with some detached works, and a communication with the place must be made either above or under ground. There should be no cavity or hollow roads, within cannon-shot, round about the place, where the enemy might be able to approach under cover; if there should happen to be a spring, near the top of the hill, it should be inclosed in the fortification, or if that cannot be done, by some work or other; for there is nothing more necessary, and at the same time scarcer in such situations than water, for which reason there cannot be too much care taken in providing it; several cisterns are to be made to receive the rain-water, and to preserve it; wells should be dug likewise, though ever so deep, the water of which will serve for common use.

Places built on hills or rocks, should never be large, for their use is generally to guard passes or inlets into a country, and are seldom useful in traffic, and it is a difficult matter to provide for a large garrison in such situations, neither should any such place be built without some very material reasons; but when it is absolutely necessary, great care and precautions should be taken to render the works as perfect as the situation will admit of, and at the same time to be as frugal in the expence as possible.

## 3. *Construction of irregular fortifications, situated near rivers, lakes, or the sea.*

As the intent of building these kind of places is chiefly to facilitate and protect trade, it is of much more importance than any other kind, especially in maritime countries, where the principal strength and power depends on it; for which reason, we shall treat of it more largely than any other part.

The first thing to be considered is their situations, which ought to be such as to afford a good harbour for shipping, or a safe and easy entrance in stormy weather; but as it is hardly possible to find any, where ships may go in and lie secure with all winds, care should be taken to make them safe to enter with those winds which are most dangerous: but it is not sufficient that the harbour is safe against stormy weather, they should likewise be so against an enemy, both by land and water; for it often happens, that ships are destroyed where it was imagined they were secure, which is of too great a consequence not to be provided against; for which reason, forts or batteries must be built in the most convenient places, to prevent the enemy's ships from coming too near, so as to be able to cannonade those in the harbour, or sling shells amongst them: and if there is any danger of an enemy's approach by land, high ramparts and edifices must be built, so as to cover them.

When a river is pretty large, and it is not convenient for

\* Revetements are chiefly made to prevent a place from being surpris'd; outworks do not want to be made for, the taking them by surpris is of no great consequence, except in a siege, when other cautions are used to prevent it.

for making a harbour without great expence, the ships may ride along the shore, which, for that reason, must be made accessible for ships of burden; this may be done by advancing the quay into the river, if the water is too shallow, or by digging the river sufficiently deep for that purpose.

And to prevent any enemy from coming up the river, forts must be built on both sides, especially when there are any turnings or windings. Antwerp is such a place; for the Scheld is sufficiently deep to carry ships of great burden, which may come quite near the town-wall; and several forts are built below it on both sides, so that it would not be an easy matter for an enemy to come up the river.

When the river is but small, so that no ships of burden can come through it; it is sufficient to make it run through some of the works, where proper landing places are contrived, from whence the goods may be carried into the place; as at Sarrelouis, where a horn work is built beyond the Sarre, in the gorge of which the goods are landed.

If the breadth of the river does not exceed 200 yards, it commonly passes through the middle of the town, and proper quays are made on each side; in such a case, the fortification is so contrived as that the river passes through the curtain, in order to have a bastion on each side to defend the coming in and going out.

When M. Vauban fortified near rivers, he made always the exterior side near the water much longer than any of the others; such is Hunningen on the Rhine, and Sarrelouis on the Sarre; but for what reason he fortified these places in that manner, has not been told by any author.

But it is plain, that the sides which terminate at the river, are the weakest; because the besiegers trenches being secured by the river, they may draw most of their troops off, and act therefore with more vigour and strength on the other side: besides, as the strength of a side increases in proportion as the angle of the polygon is greater, by making the side next the river longer, the angles at its extremities become wider, and consequently the adjacent sides stronger.

There are other advantages, besides these mentioned already, which arise from the lengthening that side; for if the river is pretty deep so as not to be fordable, that side is not liable to be attacked; and by increasing its length, the capacity of the place increases much more in proportion to the expence, than if more sides were made; the centre of the place will be likewise nearer the river, which makes it more convenient for transporting the goods from the water-side to any part of the town.

Plate LXXXV. fig. 3. To illustrate this method of M. Vauban's we shall give the plan of Hunningen; this place was built for the sake of having a bridge over the Rhine, for which reason he made it only a pentagon; the side AB next to the river is 200 toises, and each of the others but 150.

About the space  $abc$ , which lies before the front AB, is a stone-wall, and the passages  $x, x$ , are shut up with sluices, to retain the water in the ditches in dry seasons, and to prevent an enemy from destroying the sluice near the point  $c$ , whereby the water would run out and leave the ditches dry; the redout  $y$  was built in the little island hard by, in order to cover that sluice; without this precaution the place might be insulted from the river-side, where the water is shallow in dry seasons.

The hornwork K beyond the Rhine was built to cover the bridge; but as this work cannot be well defended cross the river, the hornwork H was made to support the other.

Before we finish the description of this plan, we shall shew how to find the long side AB, as being useful in the following work.

After having inscribed the two sides GE, GF, in a circle, draw the diameter CD, so as to be equally distant from the line joining the points E, F, that is parallel to it; on this diameter set off 100 toises on each side of the centre, from these points draw two indefinite perpendiculars to the diameter; then if from the points E, F, as centres, two arcs are described with a radius of 150 toises, their intersections A and B, with the said perpendiculars, will determine the long side AB, as likewise the other two FB and EA. In like manner may be found the long or short side of any polygon whatsoever.

When a place near a river is to be fortified, for the safety of commerce, particular care should be taken in leaving a good space between the houses and the water-side, to have a key or landing place for goods brought by water; it should also be contrived to have proper places for ships and boats to lie secure in stormy weather, and in time of a siege; and as water-carriage is very advantageous for transporting goods from one place to another, as likewise for bringing the necessary materials, not only for building the fortification, but also the place itself, the expences will be lessened considerably, when this convenience can be had; for which reason, places should never be built any where else but near rivers, lakes, or near the sea; excepting in extraordinary cases, where it cannot be avoided.

## F O R

FORTISSIMO, in music, sometimes denoted by FFF, or *fff*, signifies to sing or play very loud or strong.

FORT-LEWIS, a fortress of Alsace, in Germany, situated on the western shore of the Rhine, subject to France: E. long  $8^{\circ}$ , and N. lat.  $48^{\circ} 46'$ .

FORTUNATE-ISLANDS, in ancient geography, certain islands, concerning the situation of which authors are not agreed, famous for the golden apples of the Hesperides. See HESPERIDES.

## F O R

The common opinion is, that they are the same with the Canary islands.

FORTUNE, a goddess worshipped with great devotion by the ancient Greeks and Romans, who believed her to preside over human affairs, and to distribute wealth and honour at her pleasure.

FORUM, in Roman antiquity, a public standing place within the city of Rome, where causes were judicially tried, and orations delivered to the people.

FORUM,

**Forum**, was also used for a place of traffic, answering to our market place: of these there were vast numbers, as the *forum piscarium*, *clitorium*, &c. These were generally called *fora vernalia*, in contradistinction to the former, which were called *fora civilia*.

**Forum**, is also used, among caluils, &c. for jurisdiction; thus they say, *In foro legis*, &c.

**FOSS**, or **Fossa**, in anatomy, a kind of cavity in a bone, with a large aperture, but no exit or perforation.

**Foss way**, one of the four principal highways of England, that anciently led through the kingdom; supposed to be made by the Romans, having a ditch upon one side thereof.

**FOSSIL**, in natural history, denotes, in general, every thing dug out of the earth, whether they be natives thereof, as metals, stones, salts, earths, and other minerals; or extraneous, repolished in the bowels of the earth by some extraordinary means. See **NATURAL HISTORY**.

**FOSSOMBRONE**, a city and bishop's see of Italy, ten miles south-east of Urbino.

**FOUMART**, in zoology. See **MUSTELA**.

**FOUNDATION**, in architecture, is that part of a building which is under ground. See **BUILDING**.

The foundation is properly so much of the masonry as reaches as high as the surface of the ground, and ought always to be proportioned to the load or weight of the building that it is to bear. Sometimes the foundation is massive, and continued under the whole building, as in the antique arches and aqueducts, and some amphitheatres; but it is more usually in spaces or intervals, either to avoid expence, or because the vacuities are at too great a distance, in which latter case they make use of insulated pillars bound together by arches.

Palladio allows a sixth part of the height of the whole building for the hollowing or under-digging; unless there be cellars under ground, in which case he would have it somewhat lower; and as to thickness, double the width of the walls is no bad rule.

**FOUNDATION of Bridges**, is laid after different manners. The first is by inclosing all round the space of ground you would build upon, by dams made with piles set deep in the ground in double rows, well strengthened and bound together with cross pieces and cords, and filling the vacant spaces between them with chalk or other earthy matter. This being done, the water must be emptied out, and the foundation dug according to the quality of the ground, driving down piles, if it be necessary, upon which the walls of the foundation must be laid. But this method is only practicable in building on such rivers, where the water is neither very rapid, nor very deep. The second is done by laying the foundation on grate work, rafts of stout oak well bound together, and made fast at the surface of the water with cables or machines, and building upon them large quarters of stone, cramped together, and joined with good mortar, or cement, and afterwards letting them descend softly by these cables and ma-

chines perpendicularly to the bottom of the water. This was the method practised in laying the foundation of Westminster Bridge, the grating being made of the bottom of a frame called by the French *Caïsson*, the sides of which were so contrived, that they might be taken off, after a pier was finished. The third is by drawing off all, or the greatest part of the water of the river into some other place.

**FOUNDER**, in a general sense, the person who lays a foundation, or endows a church, school, religious-house, or other charitable institution.

**FOUNDER** also implies an artist who casts metals, in various forms, for different uses, as guns, bells, statues, printing characters, candlesticks, buckles, &c. whence they are denominated gun-founders, bell-founders, figure-founders, letter-founders, founders of small works, &c. See **FOUNDRY**.

**FOUNDER**, in the sea language: A ship is said to founder, when by an extraordinary leak, or by a great sea breaking in upon her, she is so filled with water, that she cannot be freed of it; so that she can neither veer nor steer, but lie like a log; and not being able to swim long, will at last sink.

**FOUNDRY**, or **FOUNDRY**, the art of casting all sorts of metals into different forms. It likewise signifies the work-house or smelting-hut wherein these operations are performed.

**FOUNDRY of small-works, or casting in sand**. The sand used for casting small works, is, at first, of a pretty soft, yellowish, and clammy nature: but it being necessary to strew charcoal dust in the mould, it at length becomes of a quite black colour. This sand is worked over and over, on a board, with a roller, and a sort of knife; being placed over a trough to receive it, after it is by these means sufficiently prepared.

This done, they take a wooden board of a length and breadth proportional to the things to be cast, and putting a ledge round it, they fill it with sand, a little moistened, to make it duly cohere. Then they take either wood or metal models of what they intend to cast, and apply them so to the mould, and press them into the sand, as to leave their impression there. Along the middle of the mould is laid half a small brass cylinder, as the chief canal for the metal to run through, when melted, into the models or patterns; and from this chief canal are placed several others, which extend to each model or pattern placed in the frame. After this frame is finished, they take out the patterns, by first loosening them all round, that the sand may not give way.

Then they proceed to work the other half of the mould with the same patterns in just such another frame, only that it has pins, which, entering into holes that correspond to it in the other, make the two cavities of the pattern fall exactly on each other.

The frame thus moulded, is carried to the melter, who, after extending the chief canal of the counter-part, and adding the cross canals to the several models in both, and strewing mill-dust over them, dries them in a kind of oven for that purpose.

Both parts of the mould being dry, they are joined together by means of the pins; and to prevent their giving way, by reason of the melted metal passing through the elastic cylindrical canal, they are screwed or wedged up like a kind of a press.

While the moulds are thus preparing, the metal is fusing in a crucible of a size proportionate to the quantity of metal intended to be cast.

When the moulds are coolish, the frames are unscrewed, or unwedged, and the cast work taken out of the sand, which sand is worked over again for other castings.

**FOUNDRY of Statues.** The casting of statues depends on the due preparation of the pit, the core, the wax, the outer mould, the inferior furnace to melt off the wax, and the upper to fuse the metal. The pit is a hole dug in a dry place something deeper than the intended figure, and made according to the prominence of certain parts thereof. The inside of the pit is commonly lined with stone, or brick; or when the figure is very large, they sometimes work on the ground, and raise a proper fence to resist the impulsion of the melted metal.

The inner mould, or core, is a rude mass to which is given the intended attitude and contours. It is raised on an iron grate, strong enough to sustain it, and is strengthened within by several bars of iron. It is generally made either of potter's clay, mixed with hair, and horse-dung; or of plaster of Paris mixed with brick-dust. The use of the core is to support the wax, the shell and lessen the weight of the metal. The iron bars and the core are taken out of the brass figure through an aperture left in it for that purpose, which is soldered up afterwards. It is necessary to leave some of the iron bars of the core, that contribute to the steadiness of the projecting part, within the brass figure.

The wax is a representation of the intended statue. If it be a piece of sculpture, the wax should be all of the sculptor's own hand, who usually forms it on the core; though it may be wrought separately in cavities, moulded on a model, and afterwards arranged on the ribs of iron over the grate; filling the vacant space in the middle with liquid plaster and brick dust, whereby the inner core is proportioned as the sculptor carries on the wax.

When the wax, which is the intended thickness of the metal, is finished, they fill small waxen tubes perpendicular to it from top to bottom, to serve both as canals for the conveyance of the metal to all parts of the work; and as vent-holes, to give passage to the air, which would otherwise occasion great disorder, when the hot metal came to encompass it.

The work being brought thus far, must be covered with its shell, which is a kind of crust laid over the wax, and which being of a soft matter, easily receives the impression of every part, which is afterwards communicated to the metal upon its taking the place of the wax, between the shell and the mould. The matter of this outer mould is varied according as different layers are applied. The first is generally a composition of clay, and old white crucibles well ground and sifted, and mixed up with water, to the consistence of a

colour fit for painting: accordingly they apply it with a pencil, laying it seven or eight times over, and letting it dry between whiles. For the second impression, they add horse dung, and natural earth to the former composition. The third impression is only horse-dung and earth. Lastly, the shell is finished by laying on several more impressions of this last matter, made very thick with the hand.

The shell, thus finished, is secured by several iron girts, bound round it, at about half a foot distance from each other, and fastened at the bottom to the grate under the statue, and at top to a circle of iron where they all terminate.

If the statue be so big that it would not be easy to move the moulds with safety, they must be wrought on the spot where it is to be cast. This is performed two ways: in the first, a square hole is dug under ground, much bigger than the mould to be made therein, and its inside lined with walls of free-stone, or brick. At the bottom is made a hole of the same materials with a kind of furnace, having its aperture outwards: in this is a fire made to dry the mould, and afterwards melt the wax. Over this furnace is placed the grate, and upon this the mould, &c. formed as above. Lastly, at one of the edges of the square pit, is made another large furnace to melt the metal. In the other way, it is sufficient to work the mould above ground, but with the like precaution of a furnace and grate underneath. When finished, four walls are to be run around it, and by the side thereof a massive made for a melting-furnace. For the rest, the method is the same in both. The mould being finished, and inclosed as described, whether under ground or above it, a moderate fire is lighted in the furnace under it, and the whole covered with planks, that the wax may melt gently down, and run out at pipes contrived for that purpose, at the foot of the mould, which are afterwards exactly closed with earth, so soon as the wax is carried off. This done, the hole is filled up with bricks thrown in at random, and the fire in the furnace augmented, till such time as both the bricks and mould become red hot. After this, the fire being extinguished, and every thing cold again, they take out the bricks and fill up their place with earth moistened, and a little beaten to the top of the mould, in order to make it the more firm and steady. These preparatory measures being duly taken, there remains nothing but to melt the metal, and run it into the mould. This is the office of the furnace above described, which is commonly made in the form of an oven with three apertures, one to put in the wood, another for a vent, and a third to run the metal out at. From this last aperture, which is kept very close, while the metal is in fusion, a small tube is laid, whereby the melted metal is conveyed into a large earthen basin, over the mould, into the bottom of which all the big branches of the jets, or casts, which are to convey the metal into all the parts of the mould, are inserted.

These casts, or jets, are all terminated with a kind of plugs, which are kept close, that, upon opening the furnace, the brass, which gushes out with violence, may

may not enter any of them, till the basin be full enough of matter to run into them all at once. Upon which occasion they pull out the plugs, which are long iron rods with a head at one end, capable of filling the whole diameter of each tube. The whole of the furnace is opened with a long piece of iron fitted at the end of each pole, and the mould filled in an instant. This completes the work in relation to the casting part; the rest being the sculptor's or carver's business, who, taking the figure out of the mould and earth wherewith it is encompassed, saws off the jets with which it appears covered over, and repairs it with chisels, gravers, punchcoes, &c.

**Foundry of bells.** The metal, it is to be observed, is different for bells, from what it is for statues; there being no tin in the statue-metal: but there is a fifth, and sometimes more, in the bell-metal.

The dimensions of the core and the wax for bells, if a ring of bells especially, are not left to chance, but must be measured on a scale, or diapason, which gives the height, aperture, and thickness necessary for the several tones required. See **DIAPASON**.

It is on the wax that the several mouldings and other ornaments are formed to be represented in relief, on the outside of the bell.

The business of bell-foundry is reducible to three particulars. 1. The proportion of a bell. 2. The forming of the mould; and, 3. The melting of the metal.

The proportions of our bells differ much from those of the Chinese: in ours, the modern proportions are, to make the diameter fifteen times the thickness of the brim, and twelve times the height.

There are two kinds of preparations, *viz.* the simple and the relative: the former are those proportions only that are between the several parts of a bell, to render it sonorous; the relative proportions establish a requisite harmony between several bells.

The particulars necessary for making the mould of a bell are, 1. The earth; the most cohesive is the best: it must be well ground and sifted, to prevent any chinks. 2. Brick-stone; which must be used for the mine, mould, or core, and for the furnace. 3. Horse dung, hair, and hemp, mixed with the earth, to render the cement more binding. 4. The wax for inscriptions, coats of arms, &c. 5. The tallow equally mixed with the wax, in order to put a slight lay of it upon the outer mould, before any letters are applied to it. 6. The coals to dry the mould.

For making the mould, they have a scaffold consisting of four boards, ranged upon tressels. Upon this they carry the earth, grossly diluted, to mix it with horse-dung, beating the whole with a large spatula.

The compasses of construction is the chief instrument for making the mould, which consist of two different legs joined by a third piece. And last of all, the founders shelves, on which are the engravings of the letters, cartridges, coats of arms, &c.

They first dig a hole of a sufficient depth to contain the mould of the bell, together with the case, or cannon, under ground; and about six inches lower than

the terreplain, where the work is performed. The hole must be wide enough for a free passage between the mould and walls of the hole, or between one mould and another, when several bells are to be cast. At the centre of the hole is a stake erected, that is strongly fastened in the ground. This supports an iron peg, on which the pivot of the second branch of the compasses turns. The stake is encompassed with a solid brick-work, perfectly round, about half a foot high, and of the proposed bell's diameter. This they call a mill-stone. The parts of the mould are, the core, the model of the bell, and the shell. When the outer surface of the core is formed, they begin to raise the core, which is made of bricks that are laid in courses of equal height upon a lay of plain earth. At the laying each brick, they bring near it the branch of the compasses, on which the curve of the core is shaped, so as that there may remain between it and the curve the distance of a line, to be afterwards filled up with layers of cement. The work is continued to the top, only leaving an opening for the coals to bake the core. This work is covered with a layer of cement, made of earth and horse dung, on which they move the compasses of construction, to make it of an even smoothness every where.

The first layer being finished, they put the fire to the core, by filling it half with coals; through an opening that is kept shut, during the baking, with a cake of earth, that has been separately baked. The first fire consumes the stake, and the fire is left in the core half or sometimes a whole day: the first layer being thoroughly dry, they cover it with a second, third, and fourth; each being smoothed by the board of the compasses, and thoroughly dried before they proceed to another.

The core being completed, they take the compasses to pieces, with intent to cut off the thickness of the model, and the compasses are immediately put in their place to begin a second piece of the mould. It consists of a mixture of earth and hair, applied with the hand on the core, in several cakes that close together. This work is finished by several layers of a thinner cement of the same matter smoothed by the compasses, and thoroughly dried, before another is laid on. The first layer of the model is a mixture of wax and grease spread over the whole. After which are applied the inscriptions, coats of arms, &c. besmeared with a pencil dipped in a vessel of wax in a chafing-dish: this is done for every letter. Before the shell is begun, the compasses are taken to pieces, to cut off all the wood that fills the place of the thickness to be given to the shell.

The first layer is the same earth with the rest, sifted very fine; whilst it is tempering in water, it is mixed with cow's hair, to make it cohere. The whole being a thin cullis, is gently poured on the model, that fills exactly all the sinuosities of the figures, &c. and this is repeated till the whole is two lines thick over the model. When this layer is thoroughly dried, they cover it with a second of the same matter, but something thicker: when this second layer becomes of some consistence, they apply the compasses again, and

light

light a fire in the core, so as to melt off the wax of the inscriptions, &c.

After this, they go on with other layers of the shell, by means of the compasses. Here they add to the cow's hair a quantity of hemp, spread upon the layers, and afterwards smoothed by the board of the compasses. The thickness of the shell comes to four or five inches lower than the mill-stone before observed, and surrounds it quite close, which prevents the extravasation of the metal. The wax should be taken out before the melting of the metal.

The ear of the bell requires a separate work, which is done during the drying of the several incrustations of the cement. It has seven rings; the seventh is called the bridge, and unites the others, being a perpendicular support to strengthen the curves. It has an aperture at the top, to admit a large iron peg, bent at the bottom; and this is introduced into two holes in the beam, fastened with two strong iron keys. There are models made of the rings, with masses of beaten earth, that are dried in the fire, in order to have the hollow of them. These rings are gently pressed upon a layer of earth and cow's hair, one half of its depth; and then taken out, without breaking the mould. This operation is repeated twelve times for twelve half-moulds, that two and two united may make the hollows of the six rings: the same they do for the hollow of the bridge, and bake them all, to unite them together.

Upon the open place left for the coals to be put in, are placed the rings that constitute the ear. They first put into this open place the iron-ring to support the clapper of the bell; then they make a round cake of clay, to fill up the diameter of the thickness of the core. This cake, after baking, is clapped upon the opening, and foldered with a thin mortar spread over it, which binds the cover close to the core.

The hollow of the model is filled with an earth, sufficiently moist to fix on the place, which is strewed at several times upon the cover of the core; and they beat it gently with a pestle, to a proper height; and a workman smooths the earth at top with a wooden trowel dipped in water.

Upon this cover, to be taken off afterwards, they assemble the hollows of the rings. When every thing is in its proper place, they strengthen the outside of the hollows with mortar, in order to bind them with the bridge, and keep them steady at the bottom, by means of a cake of the same mortar, which fills up the whole aperture of the shell. This they let dry, that it may be removed without breaking. To make room for the metal, they pull off the hollows of the rings, through which the metal is to pass, before it enters into the vacuity of the mould. The shell being unloaded of its ear, they range under the mill-stone five or six pieces of wood, about two feet long, and thick enough to reach almost the lower part of the shell; between these and the mould they drive in wooden wedges with a mallet, to shake the shell of the model whereon it rests, so as to be pulled up, and got out of the pit.

When this and the wax are removed, they break

the model and the layer of earth, through which the metal must run, from the hollow of the rings, between the shell and the core. They smoke the inside of the shell, by burning straw under it, that helps to smooth the surface of the bell. Then they put the shell in the place, so as to leave the same interval between that and the core; and before the hollows of the rings or the cap are put on again, they add two vents, that are united to the rings, and to each other, by a mass of baked cement. After which they put on this mass of the cap, the rings, and the vent, over the shell, and folder it with thin cement, which is dried gradually by covering it with burning coals. Then they fill up the pit with earth, beating it strongly all the time, round the mould.

The furnace has a place for the fire, and another for the metal. The fire-place has a large chimney with a spacious ash-hole. The furnace which contains the metal, is vaulted, whose bottom is made of earth, rammed down; the rest is built with brick. It has four apertures; the first, through which the flame revivates; the second is closed with a stopple that is opened for the metal to run; the others are to separate the dross, or scoriae, of the metal by wooden rakes: through these last apertures passes the thick smoke. The ground of the furnace is built sloping, for the metal to run down.

**Foundry of great guns and mortar pieces.** The method of casting these pieces is little different from that of bells: they are run massy, without any core, being determined by the hollow of the shell; and they are afterwards bored with a steel trepan, that is worked either by horses, or a water-mill.

For the metal, parts, proportions, &c. of these pieces, see **CANNON**.

**Letter Foundry, or casting of printing letters.** The first thing requisite is to prepare good steel-punches, on the face of which is drawn the exact shape of the letter with pen and ink, if the letter be large, or with a smooth blunted point of a needle, if small; and then, with proper gravers, the cutter digs deep between the strokes, letting the marks stand on the punch; the work of hollowing being generally regulated by the depth of the counter punch. then he files the outside, till it is fit for the matrice.

They have a mould to justify the matrices by, which consists of an upper and under part, both which are alike, except the stool and spring behind, and a small roundish wire in the upper part, for making the nick in the shank of the letter. These two parts are exactly fitted into each other, being a male and female gage, to slide backwards and forwards. See **GAGE**.

Then they justify the mould, by casting about twenty samples of letters, which are set in a composing-stick, with the nicks towards the right hand; and comparing these every way with the pattern-letters, set up in the same manner, they find the exact measure of the body to be cast.

Next they prepare the matrix, which is of brass or copper, an inch and a half long, and of a proportionable thickness to the size of the letter it is to contain.

In

In this metal is sunk the face of the letter, by striking the letter-punch the depth of an *n*. After this, the sides and face of the matrice are justified, and cleared, with files, of all bunchings that have been made by sinking the punch.

Then it is brought to the furnace, which is built upright of brick with four square sides, and a stone at top, in which is a hole for the pan to stand in.

Printing letters are made of lead, hardened with iron or stub-nails. To make the iron run, they mingle an equal weight of antimony, beaten small in an iron mortar, and stub-nails together. They charge a proper number of earthen pots, that bear the fire, with the two ingredients, as full as they can hold, and melt it in an open furnace, built for that purpose.

When it bubbles, the iron is then melted, but it evaporates very much. This melted compost is ladled into an iron-pot, wherein is melted lead, that is fixed on a furnace close to the former, 3 lb of melted iron to 25 lb of lead; this they incorporate according to art.

The caster taking the pan off the stone, and having kindled a good fire, he sets the pan in again, and metal in it to melt. If it be a small-bodied letter, or a thin letter with great bodies, that he intends to cast, his metal must be very hot, and sometimes red hot, to make the letter come. Then taking a ladle, of which he has several sorts, that will hold as much as will make the letter and break, he lays it at the hole where the flame bursts out: then he ties a thin leather, cut with its narrow end against the face, to the leather groove of the matrice, by whipping a brown thread twice about the leather groove, and fastening the thread with a knot. Then he puts both pieces of the mould together, and the matrice into the matrice-check; and places the foot of the matrice on the stool of the mould, and the broad end of the leather on the wood of the upper half of the mould, but not tight up, lest it hinder the foot of the matrice from sinking close down upon the stool, in a train of work. Afterwards laying a little rosin on the upper part of the mould, and having his casting-ladle hot, he, with the boiling side, melts the rosin, and presses the broad end of the leather hard down on the wood, and so fastens it thereto. Now he comes to casting, when placing the under half of the mould in his left hand, with the hook or jag forward, he holds the ends of its wood between the lower part of the ball of his thumb and his three hinder fingers; then he lays the upper half of the mould upon the under half, so as the male gages may fall into the female; and, at the same time, the foot of the matrice places itself upon the stool, and clasping his left hand thumb strongly over the upper half, he nimbly catches hold of the bow or spring, with his right hand fingers at the top of it, and his thumb under it, and place the point of it against the middle of the notch in the backside of the matrice, pressing it forwards as well towards the mould, as downwards, by the shoulder of the notch, close upon the stool, while, at the same time, with his hinder fingers, as aforesaid, he draws the under half of the mould towards the ball of

his thumb, and thrusts, by the ball of his thumb, the upper part towards his fingers, that both the registers of the mould may press against both sides of the matrice, and his thumb and fingers press both sides of the mould close together.

Then he takes the handle of his ladle in his right hand, and with the ball of it gives two or three strokes outwards upon the surface of the melted metal, to clear it of the scum; then he takes up the ladle full, and having the mould in the left hand, turns his left side a little from the furnace, and brings the geat of his ladle to the mouth of his mould; and turns the upper part of his right hand towards him, to pour the metal into it, while, at the same instant, he puts the mould in his left hand forwards, to receive the metal with a strong shake, not only into the bodies of the mould, but, while the metal is yet hot, into the very face of the matrice, to receive its perfect form there as well as in the shank. Then he takes the upper half of the mould off, by placing his right thumb on the end of the wood next his left thumb, and his two middle fingers at the other end of the wood: he tosses the letter, break and all, out upon a sheet of walle paper, laid on a bench, a little beyond his left hand, and then is ready to cast another letter, as before, and likewise the whole number in that matrix.

Then boys, commonly employed for this purpose, separate the breaks from the shanks, and rub them on a stone, and afterwards a man cuts them all of an even height, which finishes the fount for the use of the printer. See next article.

A workman will ordinarily cast 3000 of these letters in a day. The perfection of letters thus cast, consists in their being all severally square and straight on every side; and all generally of the same height, and evenly lined, without stooping one way or other; neither too big in the foot, nor the head; well grooved, so as the two extremes of the foot contain half the body of the letter; and well ground, barbed, and scrapped, with a sensible notch, &c. See PRINTING.

**FOUNT**, or **FONT**, among printers, a set or quantity of letters, and all the appendages belonging thereto, as numeral characters, quadrates, points, &c. cast by a letter-founder, and sorted.

**FOUNTAIN**, in philosophy, a spring or source of water rising out of the earth. Among the ancients, fountains were held sacred, and even worshipped as a kind of divinities. For the phænomena, theory, and origin of fountains, see **HYDROSTATICS**.

**FOUNTAIN**, or **Artificial FOUNTAIN**, called also a *jet d'eau*, is a contrivance by which water is violently spouted upwards. See **HYDROSTATICS**.

**FOURCHE'E**, or **FOURCHY**, in heraldry, an appellation given to a cross forked at the ends. See **PLATE LXXX.** fig. 8.

**FOWEY**, a borough-town of Cornwall, which sends two members to parliament: W. long. 5°, and N. lat. 50° 26'

**FOWL**, among zoologists, denotes the larger sorts of birds, whether domestic or wild: such as geese, pheasants, partridges, turkey, ducks, &c.

**FOX**, in zoology. See **CANIS**.

**FOX-GLOVE**, in botany. See **DIGITALIS**.

**FOY**, or **ST FOY**, a town in Guienne, in France, thirty two miles east of Bordeaux; it is situated under the meridian of London, in  $44^{\circ}$ ,  $50'$ , N. lat.

**FRACTION**, in arithmetic and algebra. See **ARITHMETIC**, p. 387. and **ALGEBRA**, p. 83.

**Decimal Fractions**. See **ARITHMETIC**, p. 395.

**FRACTURE**, in surgery, a rupture of a bone, or a solution of continuity in a bone, when it is crushed or broken by some external cause. See **SURGERY**.

**FRÆNUM**, in anatomy, a term applied to some membranous ligaments of the body.

**FRÆNUM LINGUÆ**. See **ANATOMY**, p. 305.

**FRÆNUM PENIS**. See **ANATOMY**, p. 274.

**FRAGA**, a town of Arragon, in Spain, situated under the meridian of London: N. lat.  $41^{\circ}$   $16'$ :

**FRAGARIA**, the **STRAWBERRY**, in botany, a genus of the icofandria polygynia class. The calix is divided into ten segments; the petals are five; and the receptacle is an oval deciduous berry. There are three species, two of them natives of Britain, viz. the vesca, or common strawberry; and the sterilis, or barren strawberry.

**FRANCE**, a large kingdom of Europe, situated between  $5^{\circ}$  W. and  $7^{\circ}$  E. long. and between  $43^{\circ}$  and  $51^{\circ}$  N. lat. being bounded by the English channel and the Austrian Netherlands, on the north; by Germany, Switzerland, Savoy, and Piedmont, in Italy, on the east; by the Mediterranean sea, and the Pyrenean mountains, which separate it from Spain, on the south; and, by the bay of Biscay, on the west. This kingdom was formerly divided into twelve provinces; but at present it is divided into twenty-five general governments, over every one of which is an officer, called an intendant, appointed by the king, who has a power of controlling the governor, and all other officers of justice; and presides over the receivers-general of his generality.

**FRANCFORT**, a city of Germany, situated on the confines of Hesse and Franconia, on both sides of the river Maine: E. lon.  $7^{\circ}$   $30'$ , N. lat.  $50^{\circ}$   $10'$ .

**FRANCFORT on the Oder**, a city of Germany, in the circle of Upper Saxony, and marquisate of Brandenburg, situated in E. long.  $15^{\circ}$ , N. lat.  $52^{\circ}$   $22'$ .

**FRANCHE-COMTE**, the same with the county of Burgundy. See **BURGUNDY**.

**FRANCHE-COMTE**, a province of France bounded by Lorraine on the north; by Alsace and Switzerland, on the east; by La Bresse and Bugey, on the south; by the dukedom of Burgundy, on the west.

**FRANCHISE**, in a general sense, a privilege or exemption from ordinary jurisdiction; as that for a corporation to hold pleas among themselves to such a value, or the like.

**FRANCISCAN MONKS**, **FRIARS MINOR**, or **GREY FRIARS**, religious of the order of St Francis, founded by him in the year 1709.

The rule of the Franciscans, as established by St Francis himself, is briefly this: they are to live in com-

mon, to observe chastity, and to pay obedience to the pope and their superiors.

Before they can be admitted into the order, they are obliged to sell all they have, and give it to the poor: they are to perform a year's noviciate, and when admitted never to quit the order upon any account. They are to fast from the feast of All-saints, to the Nativity. This order has produced four popes, forty-two cardinals, and an infinite number of patriarchs.

**FRANCOLINI**, a town of Italy, situated on the river Po, about nine miles north-east of Ferrara.

**FRANCONIA**, a circle of the German empire, lying between Bohemia on the east, and the electorate of Mentz on the west. Its capital is Nuremberg; and from this county the Franks, who conquered and gave name to the kingdom of France, are said to have come.

**FRANGULA**, in botany. See **RHAMNUS**.

**FRANGULÆ SPECIES**, in botany. See **MAUROCEANIA**.

**FRANK LANGUAGE**, or **LINGUA FRANCA**, a kind of jargon spoken on the Mediterranean, and particularly throughout the coasts and parts of the Levant, composed of Italian, Spanish, French, vulgar Greek, and other languages.

**FRANK**, or **FRANC**, an ancient coin, either of gold or silver, struck and current in France. The value of the gold frank was somewhat more than that of the gold crown; the silver frank was a third of the gold one: this coin is long out of use, though the term is still retained as the name of a money of account; in which sense it is equivalent to the livre, or twenty sols.

**FRANKENDAL**, a city of Germany, in the palatinate of the Rhine, situated on the west side of the river Rhine, in E. long.  $8^{\circ}$   $15'$ , N. lat.  $49^{\circ}$   $30'$ .

**FRANCENIA**, **SEA-HEATH**, or **SEA-CHICKWEED**, a genus of the hexandria monogynia class. The calix is tunnel shaped, and divided into five segments; the petals are five; the stigma has six divisions; and the capsule consists of one cell, with three valves. There are three species, two of them natives of Britain, viz. the lævis, or smooth sea-heath; and the pulverulenta, or broad leaved sea-heath.

**FRANKENSTEIN**, a town of Germany, in the palatinate of the Rhine, and duchy of Zuebruggen, situated twelve miles north-west of Landau.

**FRANKER**, a town of the United Provinces in the province of West Friesland, nine miles west of Lewarden.

**FRANKS**, **FRANKIS**, or **FRANQUIS**, an appellation given by the Turks, and other nations of Asia, to all the people of the western parts of Europe, to which they give the name of *Frankistan*.

**FRANSTAT**, or **FRAUSTAT**, a town of Silesia, situated twenty-five miles north-east of Glogaw, subject to Prussia.

**FRASCATI**, or **FRESCATI**, a town of Italy, in the campania of Rome, thirteen miles east of that city; near which place is the Tusculum of Cicero, called Grotto Ferrate.

**FRATERNITY**, in the Roman-catholic countries, signifies

signifies a society for the improvement of devotion.

Of these there are several sorts; as, 1. The fraternity of the rosary, founded by St Dominic: it is divided into two branches, called the common rosary, and the perpetual rosary; the former of whom are obliged to confess and communicate every first Sunday in the month, and the latter to repeat the rosary continually. See ROSARY.

2. The fraternity of the scapulary, whom the blessed Virgin, according to the sabbatin bull of pope John XXII. has promised to deliver out of hell the first Sunday after their death. See SCAPULARY.

3. The fraternity of St Francis's girdle, are clothed with a sack of a grey colour, which they tie with a cord; and, in processions, walk bare-footed, carrying in their hands a wooden cross.

4. That of St Austin's leathern girdle, comprehends a great many devotees.

Italy, Spain, and Portugal, are the countries where one sees the greatest number of these fraternities, some of which assume the name of arch-fraternities. Pope Clement VII. instituted the arch-fraternity of charity, which distributes bread every Sunday among the poor, and gives portions to forty poor girls on the feast of St Jerom their patron. The fraternity of death, buries such dead as are abandoned by their relations, and causes masses to be celebrated for them.

**FRATRICELLI, LITTLE BROTHERS**, in church history, a sect of heretics who appeared in Italy about the year 1298, and afterwards spread all over Europe. They wore the habit of the Franciscan order, and pretended that ecclesiastics ought to have no possessions of their own.

**FRATRIAGE**, the partition among brothers or coheirs, coming to the same inheritance or succession.

**FRATRES ARVALES**. See ARVALES.

**FRATRICIDE**, the crime of murdering one's brother. See PARRICIDE.

**FRAUD**, in law, signifies deceit in grants, or conveyances of lands, &c. or in bargains and sales of goods, &c. to the damage of another person.

**FRAXINUS**, the **ASH**, in botany, a genus of trees, belonging to the polygamia diœcia class. The calix of the hermaphrodite is divided into four parts; it has no corolla; the stamina are two; and it has but one pistil: the female has one pistil, and one lanceolated seed. There are three species, only one of which, viz. the excelsior or common ash, is a native of Britain.

The wood of this tree is in great use among several artificers, as wheel-wrights, cart-wrights, carpenters, turners, &c. also for making ploughs, harrows, axle-trees, oars, balls, &c. It is said to be as lasting for building as oak, and often preferred before it: though the timber of the trunk greatly excels that of a bough.

**FRAY**, among sportsmen. A deer is said to fray its head, when it rubs it against a tree, to cause the pills of the new horns to come off.

**FREAM**, a name given by farmers to plowed lands worn out of heart, and laid fallow till it recover.

**FREDENBERG**, a town of Germany, in the circle of Westphalia, fifty miles west of Cassel.

**FREDERICA**, a town of Georgia, in North America, situated in W. long. 81° 30', N. lat. 31°, on the island of St Simons, in the mouth of the river Alatamaha.

**FREDERICKSBURG**, a castle and palace of the king of Denmark, situated in the isle of Zeland, twenty miles north-west of Copenhagen, built upon piles in the middle of a lake.

**FREDERICKSBURG**, a fort upon the gold-coast of Guinea, near cape Three-points, subject to the Danes. It lies in W. long. 2° N. lat. 5°.

**FREDERICKSHALL**, a strong town of Norway, in the province of Agerhuys, situated on the frontiers of Sweden, thirty miles north of Frederickstad.

**FREDERICKSODE**, a town of Jutland, in the province of Reypen, situated on the little belt in the Baltic sea, twenty miles west of Odensee.

**FREDERICKSTAT**, a town of Sleswick, or south Jutland, situated on the river Eyder, near the German ocean, thirty-one miles west of Sleswick.

**FREDERICKSTAT**, a town of Norway, in the principality of Agerhuys, situated on a bay of the sea, called the Schaggerrack, near the frontiers of Sweden: E. long. 11° 24', N. lat. 59°.

**FREE**, in a general sense, is used in opposition to whatever is constrained or necessitated. When applied to things endowed with understanding, it more peculiarly relates to the liberty of the will.

**FREE-HOLD**, signifies lands or tenements which a person holds in fee-simple, fee-tail, or for term of life.

**FREE-STONE**, a whitish stone, dug up in many parts of Britain, that works like alabaster, but is more hard and durable; being of excellent use in building, &c. It is a kind of the grit stone, but finer sanded, and a smoother stone; and is called free, from its being of such a constitution as to cut freely in any direction.

**FREE-THINKER**. See DEIST.

**FREEDOM**, in general, the state or quality of being free.

**FREEDOM of the will**, that power or faculty of the mind, whereby it is capable of acting or not acting, chusing or rejecting whatever it judges proper. Of this every man must be sensible, who finds in himself a power to begin or forbear, continue or end several actions, barely by a thought or preference of the mind.

**FREEZE**, or **FRIEZE**, in commerce, a coarse kind of woollen stuff, or cloth, for winter wear; so called, as being freezed or naped on each side.

**FREEZING**, in philosophy, the same with coagelation.

See CONGELATION and FROST.

Philosophers are by no means agreed as to the cause of this phenomenon. The Cartesians account for it by the recess or going out of the ethereal matter from the pores of the water. The corpuscularians, on the other hand, attribute it to the ingress of frigorific particles, as they call them; and Hobbes asserts, that these particles

ticles are nothing else but common air, which entangling itself with the particles of water, prevents their motion. Others will have a kind of nitrous salt to be the cause of congelation, by insinuating itself between the particles of water, and fixing them together, like nails. And, indeed, it seems probable that cold and freezing do arise from some substance of a saline nature floating in the air; since all salts, and particularly nitrous ones, when mixed with ice and snow, greatly increase their cold, and even bulk.

Boerhave observes, that it is extremely difficult to exhibit to the eye the precise degree of cold wherein ice begins to form; since heat and cold, once given to a body, adhere long to it before they quit it. When the air, therefore, is in such a state as keeps Fahrenheit's thermometer at 32 degrees, water will not freeze; because water being 800 times denser than air, retains the warmth considerably longer than air. If any person, therefore, is curious to know in what degree of cold water begins to freeze, let him first suspend a thermometer in a free open air on all sides; and then wetting a thin linen cloth with clear water, and hanging it likewise in the open air, it will grow stiff upon the first access of the freezing cold, and thereby shew when water is beginning to turn to ice. See THERMOMETER.

By means of freezing, wine, vinegar, and malt-liquors may be reduced to a fourth part of their quantity, without any considerable loss of their essential parts; since only the aqueous parts freeze, leaving the vinous parts concentrated or brought into less compass, and capable of being transported with less expence, and keeping for several years.

**FREEZING MIXTURE.** Mr Boyle shews in his history of cold, that not only all kinds of salts, but likewise spirits, sugar, and saccharum saturni, mixed with snow, are capable of freezing most fluids; and the same effect was also produced by the mixture of oil of vitriol, or spirit of nitre with snow.

**FREIGHT, or FRAIGHT,** in navigation and commerce, the hire of a ship, or a part thereof, for the conveyance and carriage of goods from one port or place to another; or the sum agreed on between the owner and the merchant, for the hire and use of a vessel.

**FRENCH,** in general, something belonging to France: thus we say, the French language, French customs, polity, &c.

The French language is made up of Latin, Greek, Teutonic, and the language spoken by the old Gauls. It is natural, and easily pronounced, and therefore used by most nations of Europe in conversing with foreigners. There are very few compound words in French, which is acknowledged to be its disadvantage. It has also few diminutives; but as to purity, easiness, and flexibility, it yields to none.

**FRESCO,** a method of painting in relieve on walls, so as to endure the weather.

It is performed with water-colours on fresh plaster; or on a wall laid with mortar not yet dry. This sort of painting has a great advantage by its incorporating

with the mortar, and, drying along with it, becomes very durable.

The compost should be made of rubbish stones mix with well burnt flint, or lime, and water: but the saltiness of the lime must be washed out, by pouring water frequently on it. But this should not be done in moist weather.

To prevent the plaster from peeling, strike into the joints of the wall stumps of horse-nails six inches distant from each other. First plaster the walls pretty thick; then let it dry for some time, the design and colours being first ready prepared. This painting is chiefly performed on walls and vaults newly plastered with lime and sand; and the plaster is only to be put on in proportion as the painting proceeds.

Plaster the wall a second time, about the thickness of half a crown, only so much as you intend to work upon; and while it is wet, work the colours therein, which will incorporate with the plaster so as never to wash out.

The painting must be worked with a free hand, and your colours made high enough at first, as there can be no alteration made after the first painting.

In this work scarce any thing else is used but earths, which still retain their colour, defending it from the burning and salt of the lime. The colours are white, made of lime slacked some time, and white marble dust, red and yellow oker, violet red, verditer, lapis lazuli, finalt, black Spanish brown, Spanish white, &c. all which are grounded and worked up with water.

The brushes and pencils for this work must be long and soft, or else they will rake and raze the painting: the colours must be full and flowing from the brush, and the design or cartoon must be perfect in the paper-copy.

**FRESH,** in general, something that is new, pure, and good; or, that has little or no salt in it.

**FRET, or FRETTE,** in architecture, a kind of knot or ornament, consisting of two lists or small fillets variously interlaced or interwoven, and running at parallel distances equal to their breadth.

**FRET,** in heraldry, a bearing composed of six bars, crossed, and variously interlaced, as represented in plate LXXX. fig. 9.

Some call it the true lover's knot.

**FRET,** in music, signifies a kind of stop on some instruments, particularly bass-voles and lutes. Frets consist of strings tied round the neck of the instrument, at certain distances, within which such and such notes are to be found.

**FRET-WORK,** that adorned with frets. It is sometimes used to fill up and enrich flat empty spaces; but is mostly practised in roofs, which are fretted over with plaster work.

**FREYSTAT,** a town of Silesia, in Germany, E. long. 17° 55', N. lat. 50°.

**FRIABLE,** among naturalists, an appellation given to bodies that are easily crumbled to pieces: such are the free stone, pumice-stone, &c.

**FRIAR,** a term common to monks of all orders, founded

ed on this, that there is a kind of fraternity, or brotherhood, between the several religious persons of the same convent or monastery.

Friars are generally distinguished into these four principal branches, viz. 1. Minors, grey friars, or franciscans. 2. Augustines. 3. Dominicans, or black friars. 4. White friars, or carmelites. From these four the rest of the orders descend. See FRANCISCANS, AUGUSTINES, &c.

**FRIBURG**, the capital of a canton of the same name in Switzerland, situated eighteen miles south west of Bern: E. long. 6° 55', N. lat. 46° 50'.

**FRIBURGH**, a city of Swabia, in Germany, twenty-eight miles south of Strassburg.

**FRICENTO**, a town and bishop's see of Italy, forty-three miles east of the city of Naples.

**FRICTION**, in mechanics, the rubbing of the parts of engines and machines against each other, by which means a great part of their effect is destroyed. See MECHANICS.

**FRIDBURG**, an imperial city of Bavaria, in Germany: E. long. 10°, and N. lat. 48° 35'.

**FRIDBURG** is also the name of two other towns in Germany, both situated in the circle of Upper Saxony, the one nine miles south-west of Dresden, and the other thirty miles west of Leipzig.

**FRIEDBURG**, an imperial city of Germany, sixteen miles north of Francfort on the main.

**FRIESLAND**, one of the most northern provinces of the united Netherlands, bounded by the German ocean on the north, by Groningen and Overijssel on the east, by the Zuider-sea and Overijssel on the south, and by the same ocean on the west: its chief town is Lewarden.

*East-FRIESLAND*, a province of Westphalia, in Germany, being the north-west part of Germany, bordering on Groningen.

**FRIEZE**, **FREEZE**, or **FRISE**, in architecture, a large flat face, or member, separating the architrave from the cornice, being that part of the entablature between the architrave and the cornice. See ARCHITECTURE.

**FRIGAT**, among seamen, a ship of war, light built, and that is a good sailer.

A frigate has commonly two decks; whence that called a light frigate, is a frigate with only one deck.

**FRIGID**, is applied to a jejune style, that is unanimated by any ornaments, and consequently without any force or vigour.

**FRIGORIFIC**, in physiology, small particles of matter, which, according to Gassendus and others, being actually and essentially cold, and penetrating other bodies, produce in them that quality which we call cold.

**FRILL**, in falconry. When a hawk trembles, or shivers, they say she frills.

**FRINGILLA**, in ornithology, a genus belonging to the order of passerines. The bill is conical, straight, and sharp-pointed. There are no less than thirty species comprehended under this genus, distinguished principally by varieties in their colour.

1. The brown fringilla with a tawny neck, and white spots on the wings and hinder part of the back.

It is the Carolina ortolan of Catesby, and is a bird of the island of Cuba; only the hens pass into Carolina in the autumn. 2. The fringilla with black limbs, and the wings white on both sides; the three first feathers of the tail are without spots, but two of the chief are obliquely spotted. It is the chaffinch of English authors, and is a bird of Europe. 3. The fringilla, with the base of the wings underneath of a deep yellow colour. It is the brambling or mountain finch of English authors, and is a bird of Europe. 4. The brown fringilla, with a reddish breast and shoulders, and the black wings marked with a reddish spot: It is an inhabitant of Sweden. 5. The fringilla with a blackish spotted head, and a white spot behind the eyes. It is the greater chaffinch of Albin, and is found in Lapland. 6. The fringilla with the limbs, wings, and tail black, only the outermost from the middle externally white. It is a bird of Sweden. 7. The grey fringilla, spotted with black, has a space running from the bill to the sides of the neck black. It is the shom-burgher, a kin to the lark of Edwards, and is a bird of South America. 8. The black fringilla, with a reddish gloss, and a reddish belly, with a white spot on the wings, is the American black sparrow with red eyes, of Catesby. 9. The fringilla, with the quill-feathers red forwards, and the outermost without any spots; the two outermost are white in the middle, as the rest are at the point. This is the goldfinch of English authors. 10. The fringilla with a red face and tail, the belly undulated with white and black, and the back green. It is the green goldfinch of Edwards, and is a Chinese bird. 11. The fringilla with purple tail-feathers, with the hinder halves black. It is the amaduvad of Albin, and an inhabitant of the East Indies. The cock is all over purple; but the hen is ash-coloured, except the bill and tail. 12. The green fringilla with a red head, a yellow collar, and a blue breast. It is the red-headed green finch of Edwards. 13. The fringilla all over red, is the red fly-catcher of Catesby, and is a bird of America. 14. The yellow fringilla, with a black forehead and brown wings, is the American goldfinch of Catesby. 15. The fringilla with a black head, a tawny breast, and a white streak on the wings and above and below the eyes, is the Bahama finch of Catesby. 16. The fringilla with a wedge-like tail, a reddish body, a red bill, and the temples, rump and belly of a violet colour, is the red and blue Brazilian finch of Edwards. 17. The green fringilla, with the supercilia, breast and belly yellow, but the prime feathers of the wings are white on the outer edge. It is the Indian green finch of Edwards, and is found in Madera. 18. The fringilla with a whitish body and bill, and the prime feathers of the wings and tail greenish. This is the Canary bird of English authors, and is found in the Canary islands. 19. The fringilla with the prime feathers of the wings yellow in the middle, and the fore first chief tail-feathers without spots; but they are yellow at the base, and black at the points. It is the siskin of English authors, and haunts places where juniper-bushes grow. 20. The brown fringilla, with a flame coloured crest,

is the brown linnet of Kibin. 21. The brown fringilla, with a yellowish bill, is an European bird, as are also the two former. 22. The fringilla, with the prime feathers of the wings, and the chief feathers of the tail black, but white on the edges. It is the greater red-headed linnet of Ray, and is a bird of Europe. 24. The fringilla, with a brown back, and a blue belly and tail, is the blue bellied finch of Edwards, and is found in Africa. 25. The violet-coloured fringilla, with the forehead and under part of the body of a deep yellow colour; the back, neck, prime feathers of the wings, and upper part of the tail are of a bluish black colour; but the forehead, breast, belly, and under part of the neck are of a deep yellow. The bill is exceeding short, triangular, black and crooked at the point. 26. The fringilla with the chief feathers of the tail brown, and the outermost marked with a wedge-like spot; the body is variegated with grey and black, and the head is black. It is the reed sparrow of English authors, and is a bird of Europe. 27. The fringilla with the prime feathers of the wings and tail brown, the body variegated with grey and black, and a single white streak on the wings. This is the house-sparrow of English authors, and is an European bird. 28. The fringilla with the prime feathers of the wings and tail brown, the body variegated with grey and black, and a double white streak on the wings. This is the mountain sparrow of Ray, and is a bird of Europe. 29. The ferruginous fringilla, with a black head and a blue bill, is the Chinese sparrow of Edwards. 30. The black fringilla, with a white belly, is the American snow-sparrow of Catesby.

**FRINWALT**, or **FRIDLAND**, a town of Brandenburg, thirty miles north-east of Berlin, situated on the west side of the river Oder.

**FRIO**, a cape or promontory of Brasil: W. long.  $44^{\circ}$ , and S. lat.  $23^{\circ} 30'$ .

**FRISACH**, a town of Bavaria, sixty miles south-east of Salzburg: E. long.  $14^{\circ} 15'$ , and N. lat.  $47^{\circ} 20'$ .

**FRISONE**, in ornithology. See **LOXIA**.

**FRIT**, in the glass-manufacture, the matter or ingredients whereof glass is to be made, when they have been calcined or baked in a furnace; or it is the calcined matter to be run into glass. See **GLASS**.

**FRITH**, in its most usual acceptation, signifies an arm of the sea: such are the frith of Forth or of Edinburgh, the frith of Clyde, Murray frith, &c.

**FRITILLARIA**, in botany, a genus of the hexandria monogynia class. The corolla consists of six bell-shaped petals, with a hollow nectarium above the unguis of each petal; and the stamina are of an equal length with the petals. There are five species, only one of which is a native of Britain, *viz.* the meagris or common checkered daffodil.

**FRIULI**, a province of Italy, subject to Venice, and bounded by Carinthia in Germany on the north, by Carniola on the east, by the gulph of Venice on the south, and by the Bellunese and Feltrin on the west.

**FRIZING** of cloth, a term, in the woollen manufactory, applied to the forming of the nap of a cloth, or fluff, into a number of little hard burrs or promi-

nences, covering almost the whole ground thereof.

Some cloths are only frized on the back side, as black cloths; others on the right side, as coloured and mixed cloths, rascens, bays, freezes, &c.

Frizing may be performed two ways; one with the hand, that is, by means of two workmen, who conduct a kind of plank that serves for a frizing instrument.

The other way is by a mill, worked either by water, or a horse, or sometimes by men. This latter is esteemed the better way of frizing, by reason the motion being uniform and regular, the little knobs of the frizing are formed more equally and regularly.

**FROBISHER'S STRAITS**, in west Greenland, lie a little to the northward of Cape Farewell: W. long.  $48^{\circ}$ , and N. lat.  $63^{\circ}$ .

**FRODINGHAM**, a market-town of Yorkshire, thirty miles east of York.

**FRODSHAM**, a market-town of Chester, fourteen miles north east of Cheller.

**FROG**, in zoology. See **RANA**.

**FRONTEIRA**, a town of Portugal, in the province of Alentejo: W. long.  $8^{\circ} 6'$ , and N. lat.  $38^{\circ} 50'$ .

**FRONTIER**, the border, confine, or extremity of a kingdom or province, which the enemies find in front, when they would enter the same: thus we say, a frontier town, a frontier province, &c.

Frontiers were anciently called marches.

**FRONTIS** os, in anatomy. See **ANATOMY**, p. 152.

**FRONTIGNIAC**, a town of Languedoc in France, situated sixteen miles south-west of Montpellier, and remarkable for producing excellent wine.

**FROST**, in physiology, such an excessively cold state of the air as converts watery fluids into ice.

In very cold snowy weather, not only water, but urine, beer, ale, milk, vinegar, and even wine, are either wholly or in part converted into ice, though the last but slowly. As to the freezing of expressed oils, a very intense cold may deprive them of their fluidity, so as to be capable of being cut into portions of any figure; but whether they are convertible into real ice, is not yet determined. In Russia oil freezes much harder than with us, but does not even there become perfect ice. Common anniseed-water, and the like weak spirits, are said to be converted into an imperfect ice in Muscovy; and the strong spirits into a substance like that of oil. When brandy freezes, a liquid part, much stronger than common brandy, retires to the centre of the vessel.

Even solid bodies are liable to be affected by frost: timber is often apparently frozen, and rendered exceedingly difficult to saw. Marble, chalk, and other less solid terrestrial concretions, will be shattered by strong and durable frosts. Metals are contracted by frost: thus, an iron tube, twelve foot long, upon being exposed to the air in a frosty night, lost two lines of its length. On the contrary, it swells or dilates fluids near one tenth of their bulk. Mr Boyle made several experiments with metalline vessels, exceeding thick and strong; which being filled with water close stopp'd, and exposed to the cold, burst by the expansion of the frozen fluid within them. Trees are frequently

quently burnt up with frost, as with the most excessive heat; and in very strong frosts, walnut-trees, alders, and even oaks, are sometimes miserably split and cleft, so as to be seen through, and this with a terrible noise, like the explosion of fire arms.

Frost naturally proceeds from the upper parts of bodies downwards; but how deep it will reach in earth or water, is not easily known, because this depth may vary with the degree of coldness in the air, by a longer or shorter duration of the frost, the texture of the earth, the nature of the juices wherewith it is impregnated, the constitution of its more internal parts as to heat and cold, the nature of its effluvia, &c. Mr Boyle, in order to ascertain this depth, after four nights of hard frost, dug in an orchard, where the ground was level and bare, and found the frost had scarce reached three inches and a half; and in a garden nearer the house, only two inches below the surface. Nine or ten successive frosty nights froze the bare ground in the garden six inches and a half deep; and in the orchard, where a wall sheltered it from the south sun, to the depth of eight inches and a half. He also dug in an orchard, near a wall, about a week afterwards, and found the frost to have penetrated to the depth of fourteen inches. In a garden at Moscow, the frost in a hard season only penetrates to two feet: and the utmost effect that capt. James mentions the cold to have had upon the ground of Charlton island, was to freeze it to ten feet deep: whence may appear the different degrees of cold of that island and Russia. And as to the freezing of water at the above-mentioned island, the captain tells us, it does not naturally congeal above the depth of six feet, the rest being by accident. Water also, exposed to the cold air in large vessels, always freezes first at the upper surface, the ice gradually increasing and thickening downwards; for which reason frogs retire in frosty weather to the bottom of ditches; and it is said, that shoals of fish retire in winter to those depths of the sea and rivers, where they are not to be found in summer. Water, like the earth, seems not disposed to receive any very intense degree of cold at a considerable depth or distance from the air. The vast masses of ice found in the northern seas being only many flakes and fragments, which, sliding under each other, are, by the congelation of the intercepted water, cemented together.

In cold countries, the frost proves often fatal to mankind; not only producing cancers, but even death itself. Those who die of it have their hands and feet first seized till they grow past feeling it; after which the rest of their bodies is so invaded, that they are taken with a drowsiness, which if indulged, they awake no more, but die insensibly. But there is another way whereby it proves mortal, *viz.* by freezing the abdomen and viscera, which on dissection are found to be mortified and black.

**Hoar-Frost**, a cold moist vapour, that is drawn up a little way into the air, and in the night falls again on the earth, where it is congealed into icy crystals of various figures. Hoar-frost therefore is nothing but dew, turned into ice by the coldness of the air.

**FROTH**, a white, light substance, formed on the surface of fluids, by vehement agitation, consisting of little spherules, or globules.

**FROTH SPIT**, or **CUCKOW SPIT**, a name given to a white froth, or spume, very common, in the spring and first months of the summer, on the leaves of certain plants, particularly on those of the common white field lychnis or catch fly, thence called by some spatling poppy.

All writers on vegetables have taken notice of this froth, though few have understood the cause or origin of it till of late; being formed by a little leaping animal, called by some the flea grass-hopper, by applying its anus close to the leaf, and discharging thereon a small drop of a white viscous fluid, which containing some air in it, is soon elevated into a small bubble: before this is well formed, it deposite such another drop, and so on, till it is every way overwhelmed with a quantity of these bubbles, which form the white froth which we see.

**FRUCTIFEROUS**, signifies properly any thing that produces fruit.

**FRUCTIFICATION**, among botanists, in a more lax sense, includes the flower and fruit, with their several coverings. See **BOTANY**.

**FRUIT**, in general, includes whatever the earth produces for the nourishment and support of man, and other animals; as herbs, grain, hay, corn, &c.

**FRUIT**, more properly, signifies the production of a tree, or plant, for the propagation or multiplication of its kind; in which sense the word takes in all kinds of seeds with their furniture. But botanists usually understand by it that part of a plant wherein the seeds are contained.

**FRUIT** also implies an assemblage of seeds in a head; as in a ranunculus, &c. and all kinds of seeds, or grains, whether inclosed in a cover, capsule, or pod; and whether bony, fleshy, skinny, membranous, or the like. See **AGRICULTURE**, Part I.

**FRUMENTACEOUS**, a term applied by botanists to all such plants as have a conformity with wheat, in respect of their fruits, leaves, ears, or the like.

**FRUMENTARI**, a kind of soldiers, or archers, under the western empire.

The first time we read of these officers is in the time of the emperor Adrian, who made use of them to inform himself of whatever passed. They did not make any particular corps distinct from the rest of the forces, but there was a certain number of them in each legion. It is supposed, that they were at first a number of young persons disposed by Augustus throughout the provinces, particularly on all the grand roads, to acquaint the emperor, with all expedition, of every thing that happened.

Afterwards they were incorporated into the troops themselves, where they still retained their ancient name. As their principal office was the giving intelligence, they were often joined with the curiosi, with whom they agreed in this part of their office.

Their name of frumentarii is derived from their being also a sort of purveyors to the armies, cities, &c.

col.

collecting all the corn from the several provinces to furnish the common-wealth.

**FRUMENTATION**, in Roman antiquity, a largess of corn bestowed on the people. This practice of giving corn to the people was very ancient among the Romans; and frequently used to sooth the turbulent humour of the populace. At first the number of those to whom this largess was given, was indeterminate, till Augustus fixed it at two hundred thousand.

**FRUSH**, or **FROG**, among farriers, a sort of tender horn which arises in the middle of a horse's sole; and, at some distance from the toe, divides into two branches, running towards the heel in the form of a fork.

**FRY**, in zoology, signifies the spawn, or rather young, of fish.

**FUCUS**, in botany, a genus of submarine plants, belonging to the cryptogamia class.

The fucus consists of a tough matter, formed into a kind of leaves, which are flat and variously divaricated; and which have some appearance of fructification, in punctated tubercles, covering oblong vesicles, supposed by Linnaeus to be male flowers; and smooth roundish vesicles, hollow and interwoven with filaments, which appear to him to be female flowers. There are thirty-four species of fucus, or sea wrack, many of them to be found on our coasts.

**FUEL**, whatever is proper to burn or make a fire; as, wood, turfs, peats, bituminous earths, coals, &c.

**FUGALIA**, in Roman antiquity, a feast supposed by some to be the same with the refugium, held on the 24th of February, in memory of the expulsion of the kings, and the abolishing of the monarchical government. Others again distinguish the fugalia from the refugium. And others think, that the Fugalia was the same with the poplufugia, or the feast of Fugia, the goddess of joy, occasioned by the rout of an enemy, which was the reason the people abandoned themselves to riot and debauchery.

**FUGITIVE**, a person obliged to fly his country, or remove from a place where he had some abode, or establishment, on account of his crimes, debts, or other occasions.

**FUGUE**, in music, is when different parts of a musical composition follow each other; each repeating what the first had performed.

**FULCRUM**, in mechanics, the prop or support by which a lever is sustained. See **MECHANICS**.

**FULD**, a town and abbey of Germany, the abbot of which is a prince of the empire: E. long. 9° 35', N. lat. 50° 34'.

**PULICA**, the **COOT**, in ornithology, a genus of birds, of the order of grallæ. It has a convex bill, with the upper mandible forked over the lower at the edge; the lower mandible is gibbous behind the tip. The forehead is bald, and the feet have four toes a little lobated. There are four species.

1. The Fulica with a bald forehead, a black body, and lobated toes. It is the coot of Ray, and an inhabitant of Europe, and feeds upon seeds and herbs, and runs as well as swims upon the water. 2. The fulica with a bald forehead, and toes without webs.

It is the water-hen, or moor-hen of Ray, and is found in Europe. 3. The fulica with a bald forehead, a violet-coloured body, and toes without webs, is the purple water hen of Edwards, and it inhabits Asia and America. 4. The fulica with a carunculated forehead, a variegated body, spinous shoulders, and toes without webs; but the nail on the hinder toe is exceeding long. It is the spur-winged water-hen of Edwards, and is an inhabitant of South America. The nail on the hind toe is strait, and longer than a man's finger. The pollex rests upon one joint, and the wings are green.

**FULIGINOUS**, whatever proceeds from a thick, sooty smoke, such as litharge and lamp black.

**FULIGNO**, a city of Italy, in the pope's territories, ten miles north of Spoleto.

**FULIGO**, in natural history, a species of pumice-stone. See **PUMICE**.

**FULLER**, a workman employed in the woollen manufactories, to mill or scour cloths, serges, and other stuffs, in order to render them more thick, compact, and durable. See **CLOTH**.

**FULLER'S EARTH**, in natural history, a soft, greyish, brown, dense, and heavy marle: when dry, it is of a greyish ash-coloured brown, in all degrees from very pale to almost black, and it has generally something of a greenish cast: it is very hard and firm, of a compact texture, of a rough and somewhat dusty surface that adheres slightly to the tongue: it is very soft to the touch, not staining the hands, nor breaking easily between the fingers: it has a little harshness between the teeth, and melts freely in the mouth: thrown into water, it makes no ebullition, or hissing, but swells gradually in bulk, and falls into a fine soft powder. It makes no effervescence with aqua fortis.

It is of great use in scouring cloths, stuffs, &c. imbibing all the grease and oil used in preparing, dressing, &c. of the wool, for which reason it is made a contraband commodity, and is not to be exported under the penalty of 1 s. for every pound weight. See **FULLING**.

**FULLER'S WEED**, in botany. See **DIPSACUS**.

**FULLERY**, a place where cloths, &c. are fulled. See the next article.

**FULLING**, the art or act of scouring and pressing cloths, stuffs, stockings, &c. to cleanse, thicken, and render them more firm and strong, which is done by means of a water mill.

Fuller's earth is used with some proportion of soap; but soap alone would do much better, was it not dearer than fuller's earth.

Fulling of stockings, caps, &c. is performed either with the hands or feet, or a kind of wooden machine, either armed with wooden teeth, or those of horses or bullocks. The ingredients generally used on this occasion are fuller's earth, urine, white soap and green soap. But water softened with chalk is far preferable.

**FULMINATING**, something that thunders, or resembles thunder.

**FULMINATION**, in chemistry, is used in a synonymous sense with detonation.

Fulmination,

Fulmination in the depuration of the more perfect metals, is, when, upon infusing them with lead, a brighter colour succeeds a kind of sulphureous cloud, before appearing in the metals, during the fusion.

**FULMINATION**, in the Romish canon law, a sentence of a bishop, official, or other ecclesiastic appointed by the pope, by which it is decreed, that some bull sent from the pope shall be executed.

**FUMARIA**, in botany, a genus of the diadelphia hexandria class. The calix consists of two leaves; and the corolla is ringent. There are 11 species, three of them natives of Britain, *viz.* the officinalis, or fumitory; the capreolata, or ramping fumitory; and the claviculata, or climbing fumitory.

The whole plant of the officinalis is used in medicine, being accounted good in the scurvy, jaundice, and disorders of the mesentery and spleen.

**FUMIGATION**, in chemistry, a kind of calcination, when metals, or other hard bodies, are corroded, or softened, by receiving certain fumes for that purpose.

**FUMIGATION**, in medicine, the application of fumes to particular parts of the body; as those of sacitious cinnabar, to venereal ulcers.

**FUMITORY**, in botany. See **FUMARIA**.

**FUNCHAL**, the capital of the Madeira islands, subject to Portugal: W. long. 16°, N. lat. 32° 33'.

**FUNCTION**, the act of fulfilling the duties of any employment.

**FUNCTION**, being also applied to the actions of the body, is by physicians divided into vital, animal, and natural. The vital functions are those necessary to life, and without which the individual cannot subsist; as the motion of the heart, lungs, &c. The natural functions are such as it cannot subsist any considerable time without them, as the digestion of the aliment, and its conversion into blood. Under animal functions are included the senses of touching, tasting, &c. memory, judgment, and voluntary motion, without any, or all of which an animal may live, but not very comfortably.

The animal functions perform the motion of the body by the action of the muscles, and this action consists chiefly in the shortening the fleshy fibres, which is called contraction, the principal agents of which are the arteries and nerves distributed in the fleshy fibres.

In short, all parts of the body have their own functions, or actions peculiar to themselves. Life consists in the exercise of these functions, and health in the free and ready exercise of them.

**FUND**, in commerce, signifies the stocks of the great trading and monied companies. See **STOCKS**.

**FUNDAMENT**, in anatomy. See **ANUS**.

**FUNDI-BAY**, that situated between New England and New Scotland, in which there is said to be an excellent fishery.

**FUNEN**, the second island for magnitude belonging to the king of Denmark, situated at the entrance of the Baltic sea, and separated from Jutland by the strait called the lesser Belt, and from the island of Zealand by the strait called the great Belt. Its chief town is Odensee.

Vol. II. No. 53.

**FUNERAL RITES**, ceremonies accompanying the interment or burial of any person.

These rites differed among the ancients according to the different genius and religion of each country. The Egyptians, among the rest of their funeral rites, embalmed their dead.

Among the ancient Greeks it was usual sometimes, before the interment, to put a piece of money into the mouth of the deceased, which was thought to be Charon's fare for wafting the departed soul over the infernal river. This ceremony was not used in those countries which were supposed to be situated in the neighbourhood of the infernal regions, and to lead thither by a ready and direct road. The corpse was likewise furnished with a cake, composed of flour, honey, &c. which was designed to appease the fury of Cerberus, the door-keeper of hell, and to procure the ghost a safe and quiet entrance.

During the time the corpse continued in the house, there stood before the door a vessel of water, the design of which was, that those concerned about the body might purify themselves by washing; it being the opinion of the Greeks, as well as of the Jews, that pollution was contracted by touching a dead body.

The ceremonies by which they expressed their sorrow for the death of their friends, were various; but it seems to have been a constant rule to recede as much as possible in habit and behaviour from their ordinary customs. For this reason they abstained from banquets and entertainments; they dressed themselves of all ornaments; they tore, cut off, or shaved their hair, which they cast into the funeral pile, to be consumed with the body of their deceased friend. Sometimes they threw themselves on the ground, and rolled in the dust, or covered their head with ashes; they beat their breasts, and even tore their flesh with their nails, upon the loss of a person they much lamented. When persons of rank, such as public magistrates, or great generals, died, the whole city put on a face of mourning: all public meetings were intermitted; the schools, baths, shops, temples, and all places of concourse were shut up.

Interring or laying the dead in the ground, seems to have been the most ancient practice among the Greeks; though burning came afterwards to be generally used among them. It was customary to throw into the funeral pile those garments the deceased usually wore. The pile was lighted by one of the dead person's nearest relations or friends, who made prayers and vows to the winds to assist the flames, that the body might quickly be reduced to ashes; and during the time the pile was burning, the dead person's friends stood by it, pouring libations of wine, and calling upon the deceased.

When Numa reformed the religion of Rome, he ordered that the pontiffs should have the care of the funeral ceremonies; which, in most respects, were like those of the Greeks already described.

The funeral rites among the Hebrews, were solemn and magnificent: when any person was dead, his relations and friends rent their cloaths; which custom is but faintly imitated by the modern Jews, who only cut off a

bit of their garment, in token of affliction. It was usual to bend the dead person's thumb into the hand, and fasten it in that posture with a string; because the thumb then having the figure of the name of God, they thought the devil would not dare to approach it. When they came to the burying place, they made a speech to the dead in the following terms: "Blessed be God, who has formed thee, fed thee, maintained thee, and taken away thy life. O dead! he knows your numbers, and shall one day restore your life, &c." Then they spoke the elegium, or funeral oration, of the deceased; after which they said a prayer, called the righteousness of judgment; then turning the face of the deceased towards heaven, they called out, "Go in peace."

The ancient Christians testified their abhorrence of the Pagan custom of burning the dead; and always deposited the body entire in the ground: and it was usual to bestow the honour of embalming upon the martyrs at least, if not upon others. They prepared the body for burial, by washing it with water, and dressing it in a funeral attire. The exportation, or carrying forth of the body, was performed by near relations, or persons of such dignity as the circumstances of the deceased required. Psalmody, or singing of Psalms, was the great ceremony used in all funeral processions among the ancient Christians.

In the Romish church, when a person is dead, they wash the body, and put a crucifix in its hand. At its feet stands a vessel full of holy water, and a sprinkler, that they who come in may sprinkle both themselves and the deceased. In the mean time some priest stands by the corpse, and prays for the deceased till it is laid in the earth. In the funeral procession, the exorcist walks first, carrying the holy water; next the cross-bearer, afterwards the rest of the clergy, and last of all the officiating priest. They all sing the *miserere*, and some other psalms; and at the end of each psalm a *requiem*. We learn from Alet's ritual, that the faces of deceased laymen must be turned towards the altar, when they are placed in the church; and those of the clergy, towards the people. The corpse is placed in the church surrounded with lighted tapers: after the office for the dead, mass is said; then the officiating priest sprinkles the corpse thrice with holy water, and as often throws incense on it. The body being laid in the grave, the friends and relations of the deceased sprinkle the grave with holy water.

The funeral ceremonies of the Greek church, are much the same with those of the Latin. It needs only be observed, that after the funeral service, they kiss the crucifix, and salute the mouth and forehead of the deceased; after which each of the company eats a bit of bread, and drinks a glass of wine in the church, wishing the soul a good repose, and the afflicted family all consolation.

**FUNERAL GAMES**, a part of the ceremony of the ancient funerals.

It was customary for persons of quality, among the ancient Greeks and Romans, to institute games with all sorts of exercises, to render the death of their

friends more remarkable. This practice was generally received, and is frequently mentioned by ancient writers. Patroclus's funeral games, take up the greatest part of one of Homer's *Iliads*; and Agamemnon's ghost is introduced by the same poet telling the ghost of Achilles, that he had been a spectator at a great number of such solemnities.

The celebration of these games among the Greeks, mostly consisted of horse-races; the prizes were of different sorts and value, according to the quality and magnificence of the person that celebrated them. The garlands, given to victors on this occasion, were usually of parsley, which was thought to have some particular relation to the dead.

Those games, among the Romans, consisted chiefly of processions; and sometimes of mortal combats of gladiators around the funeral pile. They, as well as the Greeks, had also a custom, though very ancient, of cutting the throats of a number of captives before the pile, as victims to appease the manes of the deceased. Cæsar relates, that the Gauls had this custom,

The funeral games were abolished by the emperor Claudius.

**FUNERAL ORATION**, a discourse pronounced in praise of a person deceased, at the ceremony of his funeral.

**FUNGIBLES**, in Scots law, are such things as are estimated by number, weight, or measure; as, coin, butter, ale, &c.

**FUNGITÆ**, in natural history, a kind of fossile coral, of a conic figure, though sometimes flattened and striated longitudinally.

**FUNGUS**, in surgery, denotes any spongy excrescence. See **SURGERY**.

**FUNGUS**, in botany, See **BOTANY**, p. 636.

**FURCA**, in antiquity, a piece of timber resembling a fork, used by the Romans as an instrument of punishment.

The punishment of the furca was of three kinds: the first only ignominious, when a master, for small offences, forced his servant to carry a furca on his shoulders about the city. The second was penal, when the party was led about the circus, or other place, with the furca about his neck, and whipped all the way. The third was capital, when the malefactor, having his head fastened to the furca, was whipped to death.

**FURCHE**, in heraldry, a cross forked at the ends.

**FURIES**, in Pagan antiquity, certain goddesses whose office it was to punish the guilty after death. These were three in number; Alecto, Megæra, and Tisiphone, who were described with snakes instead of hair, and eyes like lightening, carrying iron-chains and whips in one hand, and in the other flaming torches; the latter to discover, and the former to punish the guilty; and they were supposed to be constantly hovering over such persons as had been guilty of any enormous crime.

Mythologists suppose, that Tisiphone punished the crimes which sprang from hatred or anger; Megæra, those from envy; and Alecto, those from an insatiable pursuit after riches and pleasure. They were worshipped at Casina in Arcadia, and at Carmia in Peloponnesus.

**FUS.** They had a temple at Athens, near the Arcopagus, and their priests were chosen from amongst the judges of that court. At Telphusia, a city in Arcadia, a black ewe was sacrificed to them.

**FURLING**, in the sea language, signifies the wrapping up and binding any sail close to the yard; which is done by hauling upon the clew lines, bunt-lines, &c. which wraps the sail close together, and being bound fast to the yard, the sail is furled.

**FURLONG**, a long measure, equal to one eighth of a mile, or forty poles.

It is also used, in some law-books, for the eighth part of an acre.

**FURLOUGH**, in the military language, a licence granted by an officer to a soldier, to be absent for some time from his duty.

**FURNACE**, an utensil, or vessel, proper to contain fire; or to raise and maintain a vehement fire in, whether of coal or wood. See **CHEMISTRY**. p. 110.

**FURNES**, a town of Flanders, ten miles east of Dunkirk: E. long.  $2^{\circ} 25'$ , and N. lat.  $51^{\circ} 10'$ .

**FUROR UTERINUS**, a disorder peculiar to women. See **MEDICINE**.

**FURR**, in commerce, signifies the skin of several wild beasts, dressed in alum with the hair on, and used as a part of dress by princes, magistrates, and others. The kinds most in use are, those of the ermine, sable, castor, hare, coney, &c.

**FURSTENBURGH**, a town and castle of Germany, the capital of a county of the same name, thirty miles north west of Constance: E. long.  $8^{\circ} 30'$ , and N. lat.  $47^{\circ} 50'$ .

**FURSTENFIELD**, a town of Austria and dutchy of Stiria, thirty-six miles east of Gratz: E. long.  $16^{\circ} 46'$ , N. lat.  $47^{\circ} 26'$ .

**FURTHCOMING**, in law, the name of an action competent to any person who has used arrestment in the hands of his debtor's creditor, for having the subject arrested declared his property. See **SCOTS LAW**, title 25.

**FURUNCLE**, or **BOIL**, in surgery, a small resisting tumour, with inflammation, redness, and great pain, arising in the adipose membrane, under the skin.

**FURZE**, in botany. See **ULEX**.

**FUSANUS**, in botany. See **EVONYMUS**.

**FUSAROLE**, in architecture, a moulding or ornament placed immediately under the echinus, in the Doric, Ionic, and Composite capitals.

**FUSEE**, in clock-work, is that conical part drawn by the spring, and about which the chain or string is wound; for the use of which, see **WATCH**.

**FUSEE**, or **FIRELOCK**. See **MUSQUET**.

**FUSIBILITY**, in natural philosophy, that quality of bodies which renders them fusible.

**FUSIL**, in heraldry, a bearing of a rhomboidal figure, longer than the lozenge, and having its upper and lower angles more acute and sharp than the other two in the middle. It is called in Latin *fusus*, a spindle, from its shape. See Plate LXXX. fig. 10.

**FUSILIERS**, or **FUSILERS**, in the military art, are foot-soldiers, armed with fuses, or firelocks.

**FUSION**, the melting of metals, minerals, &c. by means of fire. See **CHEMISTRY**.

**FUSTIAN**, in commerce, a kind of cotton stuff, which seems as it were whealed on one side.

Right fustians should be altogether made of cotton-yarn, both woof and warp; but a great many are made, of which the warp is flax, or even hemp.

There are fustians made of several kinds, wide, narrow, fine, coarse; with shag or nap, and without it.

**FUSTICK**, or **FUSTOCK**, a yellow wood, that grows in all the Caribbee islands, used in dyeing yellow. It pays no duty on importation.

**FUTTOCKS**, in a ship, the timbers raised over the keel, or the encompassing timbers that make her breadth.

**FUTURE**, in general, denotes whatever regards futurity, or the time to come.

## G

**GABARA**, or **GABBARA**, in antiquity, the dead bodies which the Egyptians embalmed, and kept in their houses, especially those of such of their friends as died with the reputation of great piety and holiness, or as martyrs. See **EMBALMING**, and **MUMMY**.

**GABEL**, according to the French duties or customs, a tax upon salt, which makes the second article in the king's revenue, and amounts to about one fourth part of the whole revenue of the kingdom.

**GABIN**, a town of great Poland, forty-six miles north-west of Warsaw: E. long.  $20^{\circ}$ , N. lat.  $52^{\circ} 35'$ .

**GABIONS**, in fortification, baskets made of osier-twigs,

of a cylindrical form, six feet high, and four wide; which being filled with earth, serve as a shelter from the enemies fire.

**GABLOCKS**, the artificial spurs of game-cocks.

**GAD**, among miners, a small punch of iron, with a long woollen handle, used to break up the ore.

One of the miners holds this in his hand, directing the point to a proper place, while the other drives it into the vein, by striking it with a sledge-hammer.

**GAD-FLY**. See **OESTRUS**.

**GADUS**, in ichthyology, a genus of fishes belonging to the order of jugulares. The head is smooth; there are

are seven cylindrical rays in the branchiostele membrane; the body is oblong, with deciduous scales; the whole fins are covered with the common skin of the fish; the rays of the back-fins are blunt, and those of the breast are sharp. There are seventeen species, principally distinguished by their cirri, and the number of back-fins.

**GAGE**, in the sea-language. When one ship is to windward of another, she is said to have the weather-gage of her. They likewise call the number of feet that a vessel sinks in the water, the ship's gage: this they find by driving a nail into a pike near the end, and putting it down beside the rudder till the nail catch hold under it; then as many feet as the pike is under water, is the ship's gage.

**GAGE**, among letter-founders, a piece of box, or other hard wood, variously notched; the use of which is to adjust the dimensions, slopes, &c. of the different sorts of letters. See **FOUNDERY**.

**Sliding-GAGE**, a tool used by mathematical instrument-makers, for measuring and setting off distances.

**Sea GAGE**, an instrument invented by Dr Hales and Dr Desaguliers, for finding the depth of the sea, the description whereof is this. AB (Plate LXXXVI. fig. 1. N<sup>o</sup> 1.) is the gage bottle, in which is cemented the gage-tube *Ff* in the brass cap at G. The upper end of tube F is hermetically sealed, and the open lower end *f* is immersed in mercury, marked C, on which swims a small thickness or surface of treacle. On the top of the bottle is screwed a tube of brass HG, pierced with several holes, to admit the water into the bottle AB. The body K is a weight hanging by its shank L, in a socket N, with a notch on one side at *m*, in which is fixed the catch *l* of the spring S, and passing through the hole L, in the shank of the weight K, prevents its falling out when once hung on. On the top, in the upper part of the brass tube at H, is fixed a large empty ball, or full-blown bladder I, which must not be so large, but that the weight K may be able to sink the whole under water.

The instrument, thus constructed, is used in the following manner: The weight K being hung on, the gage is let fall into deep water, and sinks to the bottom; the socket N is somewhat longer than the shank L, and therefore, after the weight K comes to the bottom, the gage will continue to descend, till the lower part of the socket strikes against the weight; this gives liberty to the catch to fly out of the hole L, and let go the weight K; when this is done, the ball or bladder I, instantly buoys up the gage to the top of the water. While the gage is under water, the water having free access to the treacle and mercury in the bottle, will by its pressure force it up into the tube *Ff*, and the height to which it has been forced by the greatest pressure, *viz.* that at the bottom, will be shewn by the mark in the tube which the treacle leaves behind it, and which is the only use of the treacle. This shews into what space the whole air in the tube *Ff* is compressed; and consequently the height or depth of the water, which by its weight produced that compression, which is the thing required.

If the gage-tube *Ff* be of glass, a scale might be drawn on it with the point of a diamond, shewing, by inspection, what height the water stands above the bottom. But the length of 10 inches is not sufficient for fathoming depths at sea, since that, when all the air in such a length of tube is compressed into half an inch, the depth of water is no more than 634 feet, which is not half a quarter of a mile.

If, to remedy this, we make use of a tube fifty inches long, which for strength may be a musket barrel, and suppose the air compressed into an hundredth part of half an inch; then by saying, as 1 : 99 :: 400 : 39600 inches, or 3300 feet; even this is but little more than half a mile, or 2640 feet. But since it is reasonable to suppose the cavities of the sea bear some proportion to the mountainous parts of the land, some of which are more than three miles above the earth's surface; therefore, to explore such great depths, the Doctor contrived a new form for his sea gage, or rather for the gage-tube in it, as follows: BCD*F* (*ibid.* N<sup>o</sup> 2.) is a hollow metalline globe communicating on the top with a long tube AB, whose capacity is a ninth part of that globe. On the lower part at D, it has also a short tube DE, to stand in the mercury and treacle. The air contained in the compound gage-tube is compressed by the water as before; but the degree of compression, or height to which the treacle has been forced, cannot there be seen through the tube; therefore, to answer that end, a slender rod of metal or wood, with a knob on the top of the tube AB, will receive the mark of the treacle, and shew it, when taken out.

If the tube AB be 50 inches long, and of such a bore that every inch in length should be a cubic inch of air, and the contents of the globe and tube together 500 cubic inches; then, when the air is compressed within an hundredth part of the whole, it is evident the treacle will not approach nearer than 5 inches of the top of the tube, which will agree to the depth of 3300 feet of water as above. Twice this depth will compress the air into half that space nearly, *viz.* 2½ inches, which correspond to 6600 which is a mile and a quarter. Again, half that space, or 1½ inch, will shew double the former depth, *viz.* 13200 feet, or 2½ miles, which is probably very nearly the greatest depth of the sea.

**GAIETA**, a strong fortified town of the kingdom of Naples in Italy, thirty-five miles north-west of the city of Naples: E. long. 14° 30', and N. lat. 41° 20'.

**GAINSBOROUGH**, a market-town of Lincolnshire, fourteen milles north-west of Lincoln; which gives the title of earl to the noble family of Noel.

**GAOPHRAGMIA**, in natural history, a genus of septariae, divided by septae or partitions of earthy matter, of which there are several species. See **SEPTARIAE**.

**GALACTITES**, in natural history, the name by which the ancients called a smooth, ash-coloured, indurated kind of clay, said to have been used with success for defluxions and ulcers of the eyes, and as an astringent.

**GALANGALS**, in the materia medica, the name of a root

root kept in the shops, but now mostly out of use in practice.

**GALANTHUS**, the *SNOW-DROP*, in botany, a genus of the hexandria monogynia class. It has three concave petals, a simple stigma, and a nectarium composed of three small petals. There is but one species, a native of Germany.

**GALATA**, a great suburb belonging to Constantinople, opposite to the seraglio, on the other side of the harbour. It is here the Greeks, Armenians, Franks, Christians, and Jews inhabit, and are allowed the exercise of their respective worship.

**GALATIA**, the ancient name of Amasia, a province of Lesser Asia.

**GALAX**, in botany, a genus of the pentandria monogynia class. The calix consists of ten leaves; and the capsule has one cell and two elastic valves. There is but one species, a native of Virginia.

**GALAXY**, in astronomy. See *ASTRONOMY*, p. 487.

**GALBANUM**, in pharmacy, a gum issuing from the stem of an umbelliferous plant, growing in Persia and many parts of Africa.

It is sometimes met with in the shops in loose granules, called drops or tears; and sometimes in large masses, formed of a number of these blended together; but in these masses some accidental foulness is often mixed with the gum. The single drops usually approach to a roundish, oblong, pear-like form. Galbanum is soft like wax, and, when fresh drawn, white; but it afterwards becomes yellowish or reddish: it is of a strong smell, of an acrid and bitterish taste; it is inflammable in the manner of a resin, and soluble in water like a gum.

It attenuates and dissolves tough phlegm, and is therefore of service in asthma and inveterate coughs.

**GALEGA**, in botany, a genus of the diadelphia decandria class. The calix consists of equal tubulated teeth; and the pod has oblique striæ, with a seed between each. There are eight species, none of them natives of Britain.

**GALENISTS**, in church-history, a branch of anabaptists, who are said to have adopted several Arian opinions concerning the divinity of our Saviour.

**GALEODOLON**, in botany. See *LEONURUS*.

**GALERITA**, in ichthyology, a species of blennius. See *BLENNIUS*.

**GALICIA**, the most north-west province of Spain, bounded by the ocean on the north-west, by the provinces of Asturias and Leon on the east, and by Portugal on the south.

**GALICIA**, or *GUADALAJARA*, a province of Mexico, bounded by new Mexico on the north, by the gulph of Mexico on the east, by Mexico Proper on the south, and by the Pacific Ocean and gulph of California on the west.

**GALILE**, or *GALILEE*, once a province of Judea, now of Turkey in Asia, was bounded by mount Lebanon on the north, by the river Jordan and the sea of Galilee on the east, by the river Chison on the south, and by the Mediterranean on the west. It was the scene of many of our Saviour's miracles.

Vol. II. No. 53.

**GALILEANS**, a sect of the Jews. Their founder was one Judas, a native of Galilee, from which place they derived their name. Their chief, esteeming it an indignity for the Jews to pay tribute to strangers, raised up his countrymen against the edict of the emperor Augustus, which had ordered a taxation or inrollment of all the subjects of the Roman empire.

They pretended that God alone should be owned as Master and Lord; and in other respects were of the opinion of the Pharisees; but, as they judged it unlawful to pray for infidel princes, they separated themselves from the rest of the Jews, and performed their sacrifices apart.

**GALL**, in the animal æconomy. See *BILE*.

**GALL BLADDER**. See *ANATOMY*, p. 269.

**GALL**, in natural history, denotes any protuberance or tumour produced by the puncture of insects on plants and trees of different kinds.

These galls are of various forms and sizes, and no less different with regard to their internal structure. Some have only one cavity, and others a number of small cells communicating with each other. Some of them are as hard as the wood of the tree they grow on, whilst others are soft and spongy; the first being termed gall-nuts, and the latter berry-galls, or apple-galls.

The general history of galls is this: an insect of the fly kind is instructed by nature to take care for the safety of her young, by lodging her eggs in a woody substance, where they will be defended from all injuries: she for this purpose wounds the leaves or tender branches of a tree; and the lacerated vessels, discharging their contents, soon form tumours about the holes thus made. The hole in each of these tumours, through which the fly has made its way, may for the most part be found; and when it is not, the maggot inhabitant or its remains are sure to be found within, on breaking the gall. However, it is to be observed, that in those galls which contain several cells, there may be insects found in some of them, though there be a hole by which the inhabitant of another cell has escaped.

Oak galls put, in a very small quantity, into a solution of vitriol in water, though but a very weak one, give it a purple or violet colour; which, as it grows stronger, becomes black; and on this property depends the art of making our writing ink, as also a great deal of those of dying and dressing leather, and other manufactures.

In medicine, galls are found to be very astringent, and good, under proper management, in diarrhæas, dysenteries, and hæmorrhages of all kinds; they have also a very eminent virtue as a febrifuge.

**GALLERY**, in architecture, a covered place in a house, much longer than broad, and usually in the wings of a building; its use being chiefly to walk in.

**GALLERY**, in fortification, a covered walk across the ditch of a town, made of strong beams, covered over head with planks, and loaded with earth: sometimes it is covered with raw hides to defend it from the artificial fires of the besieged.

**GALLERY of a mine**, is a narrow passage, or branch of

a mine carried on under ground to a work designed to be blown up.

**GALLERY**, in a ship, that beautiful frame, which is made in the form of a balcony, at the stern of a ship without board; into which there is a passage out of the admiral's or captain's cabin, and is for the ornament of the ship.

**GALLEY**, in naval affairs, a low-built vessel, using both sails and oars, and commonly carrying only a main-mast and fore mast, which may be struck or lowered at pleasure. Such vessels are much used in the Mediterranean, especially by the king of France. See **SHIP**.

**GALLI**, in antiquity, the priests of the goddess Cybele, who were eunuchs, and took their name from Gallus, a river in Phrygia.

When a youth was to be initiated into this order, the custom was to throw off his cloaths, to run crying aloud into the midst of the troop, and then drawing a sword to castrate himself; after this, he ran about the streets, carrying in his hands the marks of his mutilation, which he was to throw into a house, and in that house to put on a woman's dress.

**GALLICIAN**, any thing belonging to France: thus the term Gallician church denotes the church of France, or the assembly of the clergy of that kingdom.

**GALLICISM**, a mode of speech peculiar to the French language, and contrary to the rules of grammar in other languages.

**GALLINÆ**, in ornithology, an order of birds. See **NATURAL HISTORY**.

**GALLINACIOUS**, an appellation given to the birds of the order of the gallinæ.

**GALLINULA**, in ornithology. See **SCOLOPAX**.

**GALLION**, or **GALLEON**, in naval affairs, a sort of ships employed in the commerce of the West Indies. The Spaniards send annually two fleets; the one for Mexico, which they call the flota, and the other for Peru, which they call the gallions. See **FLOTA**.

**GALLIOT**, a small galley designed only for chase, carrying only one mast, and two or three patereroes; it can both sail and row, and has sixteen or twenty oars. All the seamen on board are soldiers, and each has a musket by him on quitting his oar.

**GALLIPAGO-ISLANDS**, are situated in the Pacific Ocean on both sides the equator, between 85° and 90° W. long. and about four hundred miles west of Peru.

**GALLIPOLI**, a port town of European Turkey, situated at the entrance of the Propontis, or Sea of Marmora, about 100 miles south-west of Constantinople: E. long. 28°, and N. lat. 40° 45'.

**GALLIPOLI** is also a port town of the kingdom of Naples, situated on the gulph of Otranto, about twenty-three miles west of that city: E. long. 19°, and N. lat. 40° 25'.

**GALLIUM**, **LADIES BEDSTRAW**, in botany, a genus of the tetrandria monogynia class. The corolla consists of one plane petal; and the seeds are two, and round. There are 23 species, 11 of them natives of Britain. *viz.* the verum, or yellow ladies-bedstraw; the mollugo, or wild madder; the montanum, or mountain ladies-bedstraw; the uliginosum, or marsh goose-

grafs; the erectum, or small mountain bastard madder; the pusillum, or least ladies-bedstraw; the palustre, or white ladies-bedstraw; the spurium, or goose-grafs with smoother seeds; the aparine, cleavers, or goose-grafs; the parietense, or least goose-grafs; and the boreale, or crosswood madder.

**GALLO**, an island on the Pacific Ocean near the coast of Peru, about 200 miles west of Popayan: W. long. 80°, and N. lat. 2° 15'.

**GALLO** is also a town of Italy, ten miles south of Ancona.

**GALLO**, or **PUNTO GALLO**, a sea-port of Ceylon, subject to the Dutch: E. long. 78°, and N. lat. 6°.

**GALLON**, a measure of capacity both for dry and liquid things, containing four quarts; but these quarts, and consequently the gallon itself, are different, according to the quality of the thing measured: for instance, the wine gallon contains 231 cubic inches, and holds eight pounds averdupois, of pure water: the beer and ale gallon contains 282 solid inches, and holds ten pounds three ounces and a quarter averdupois, of water: and the gallon for corn, meal, &c. 272½ cubic inches, and holds nine pounds thirteen ounces of pure water.

**GALLOPAVO**, in zoology. See **MELEAGRIS**.

**GALLOWAY**, a county of Scotland, which gives the title of earl to a branch of the noble family of Stuart.

It is divided into two districts; the western, called Upper Galloway, being the same with Wigtonshire; and the eastern, or stewartry of Kirkcudbright, called Lower Galloway.

**GALLOWAY** is also the capital of a county of the same name, in the province of Connaught, in Ireland: W. long. 9° 12', and N. lat. 53° 12'.

It has a good port, and is advantageously situated for foreign trade.

**GALLUS**, in ornithology. See **PHASIANUS**.

**GALLY**, in printing, a frame into which the compositor empties the lines out of his composing stick, and in which he ties up the page when it is completed.

The gally is formed of an oblong square board, with a ledge on three sides, and a groove to admit a false bottom, called a gally-slice.

**GAMBIA**, a great river of Africa, which, running from east to west falls into the Atlantic ocean, 14° N. lat. and 15° W. lon.

**GAMBOGE**, is a concreted vegetable juice, the produce of two trees, both called by the Indians caracapulli, and is partly of a gummy, and partly of a resinous nature. It is brought to us either in form of orbicular masses, or of cylindrical rolls of various sizes; and is of a dense, compact, and firm texture, and of a beautiful yellow. It is chiefly brought to us from Cambaja, in the East Indies, called also Cambodja, and Cambogia; and from thence it has obtained its names of cambadium, cambogium, and gambogium.

It is a very rough and strong purge; it operates both by vomit and stool, and both ways with much violence, almost in the instant in which it is swallowed; but yet without griping. It requires caution and judgment in administering it; but those who know how to give it properly,

properly, find it an excellent remedy in dropsies, cachexies, jaundice, althmas, catarrhs, and in the worst cutaneous eruptions.

**GAME**, in general, signifies any diversion, or sport, that is performed with regularity, and restrained to certain rules. See **GAMING**.

**GAMES**, in antiquity, were public diversions, exhibited on solemn occasions. Such, among the Greeks, were the Olympic, Pythian, Isthmian, Nemean, &c. games; and, among the Romans, the Apollinarian, Circensian, Capitoline, &c. games. See **OLYMPIC**, **PYTHIAN**, &c.

**GAMU**, in law, signifies birds or prey, taken or killed by fowling, or hunting. There are several statutes for punishing offences committed by persons not qualified by law to take or destroy the game.

**GAME-CKOCK**, a fighting cock, or one kept for sport; a barbarous practice, which is a disgrace to any civilized nation.

**GAMELIA**, in Grecian antiquity, a nuptial feast, or rather sacrifice, held in the ancient Greek families on the day before a marriage; thus called, from a custom they had of shaving themselves on this occasion, and presenting their hair to some deity to whom they had particular obligations.

**GAMELION**, in the ancient chronology, was the eighth month of the Athenian year, containing twenty-nine days, and answering to the latter part of our January and beginning of February. It was thus called, as being, in the opinion of the Athenians, the most proper season of the year for marriage.

**GAMING**, the art of playing or practising any game, particularly those of hazard, as cards, dice, tables, &c.

Mr de Moivre, in a treatise de Mensura Sortis, has computed the variety of chances in several cases that occur in gaming, the laws of which may be understood by what follows.

Suppose  $p$  the number of cases in which an event may happen, and  $q$  the number of cases wherein it may not happen, both sides have the degree of probability, which is to each other as  $p$  to  $q$ .

If two gamesters, A and B, engage on this footing, that, if the cases  $p$  happen, A shall win; but if  $q$  happen, B shall win, and the stake be  $a$ ; the chance of

A will be  $\frac{p a}{p+q}$ , and that of B  $\frac{q a}{p+q}$ ; consequently, if

they sell the expectancies, they should have that for them respectively.

If A and B play with a single die, on this condition, that, if A throw two or more aces at eight throws, he shall win; otherwise B shall win; what is the ratio of their chances? Since there is but one case wherein an ace may turn up, and five wherein it may not, let  $a=1$ , and  $b=5$ . And, again, since there are eight throws of the die, let  $n=8$ ; and you will have  $a^n + b^n - n a b^{n-1} - 1$ , to  $b^n + n a b^{n-1} - 1$ : that is, the chance of A will be to that of B, as 663991 to 10156525, or nearly as 2 to 3.

A and B are engaged at single quoits; and, after playing some time, A wants 4 of being up, and B 6;

but B is so much the better gamester, that his chance against A upon a single throw would be as 3 to 2; what is the ratio of their chances? Since A wants 4, and B 6, the game will be ended at nine throws; therefore, raise  $a+b$  to the ninth power, and it will be  $a^9 + 9 a^8 b + 36 a^7 b^2 + 84 a^6 b^3 + 126 a^5 b^4 + 126 a^4 b^5 + 84 a^3 b^6 + 36 a^2 b^7 + 6 a b^8 + b^9$ : call  $a$  3, and  $b$  2, and you will have the ratio of chances in numbers, viz. 1759077 to 194048.

A and B play at single quoits, and A is the best gamester, so that he can give B 2 in 3, what is the ratio of their chances at a single throw? Suppose the chances as  $z$  to 1, and raise  $z+1$  to its cube, which will be  $z^3 + 3z^2 + 3z + 1$ . Now since A could give B 2 out of 3, A might undertake to win three throws running; and, consequently, the chances in this case will be as  $z^3$  to  $3z^2 + 3z + 1$ . Hence  $z^3 = 3z^2 + 3z + 1$ ; or,  $2z^3 = z^3 + 3z^2 - 3z + 1$ . And, therefore,  $z^{\frac{1}{2}} =$

$z+1$ ; and, consequently,  $z = \frac{1}{\sqrt{2}-1}$ . The chances,

therefore, are  $\frac{1}{\sqrt{2}-1}$ , and 1, respectively.

Again, suppose I have two wagers depending, in the first of which I have 3 to 2 the best of the lay, and in the second 7 to 4, what is the probability I win both wagers?

1. The probability of winning the first is  $\frac{3}{5}$ , that is the number of chances I have to win, divided by the number of all the chances: the probability of winning the second is  $\frac{7}{11}$ : therefore, multiplying these two fractions together, the product will be  $\frac{21}{55}$ , which is the probability of winning both wagers. Now, this fraction being subtracted from 1, the remainder is  $\frac{34}{55}$ , which is the probability I do not win both wagers: therefore the odds against me are 34 to 21.

2. If I would know what the probability is of winning the first, and losing the second, I argue thus: the probability of winning the first is  $\frac{3}{5}$ , the probability of losing the second is  $\frac{4}{11}$ : therefore multiplying  $\frac{3}{5}$  by  $\frac{4}{11}$ , the product  $\frac{12}{55}$  will be the probability of my winning the first, and losing the second; which being subtracted from 1, there will remain  $\frac{43}{55}$ , which is the probability I do not win the first, and at the same time lose the second.

3. If I would know what the probability is of winning the second, and at the same time losing the first, I say thus: the probability of winning the second is  $\frac{7}{11}$ ; the probability of losing the first is  $\frac{2}{5}$ : therefore, multiplying these two fractions together, the product  $\frac{14}{55}$  is the probability I win the second, and also lose the first.

4. If I would know what the probability is of losing both wagers, I say, the probability of losing the first is  $\frac{2}{5}$ , and the probability of losing the second  $\frac{4}{11}$ : therefore, the probability of losing them both is  $\frac{8}{55}$ ; which being subtracted from 1, there remains  $\frac{47}{55}$ : therefore, the odds of losing both wagers is 47 to 8.

This way of reasoning is applicable to the happening or failing of any events that may fall under consideration.

deration. Thus if I would know what the probability is of missing an ace four times together with a die, this I consider as the failing of four different events. Now the probability of missing the first is  $\frac{5}{6}$ , the second is also  $\frac{5}{6}$ , the third  $\frac{5}{6}$ , and the fourth  $\frac{5}{6}$ ; therefore the probability of missing it four times together is  $\frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} = \frac{625}{1296}$ ; which being subtracted from 1, there will remain  $\frac{671}{1296}$  for the probability of throwing it once or oftener in four times: therefore the odds of throwing an ace in four times, is 671 to 625.

But if the flinging of an ace was undertaken in three times, the probability of missing it three times would be  $\frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} = \frac{125}{216}$ ; which being subtracted from 1, there will remain  $\frac{91}{108}$  for the probability of throwing it once or oftener in three times: therefore the odds against throwing it in three times are 125 to 91. Again, suppose we would know the probability of throwing an ace once in four times, and no more: since the probability of throwing it the first time is  $\frac{1}{6}$ , and of missing it the other three times is  $\frac{5}{6} \times \frac{5}{6} \times \frac{5}{6}$ , it follows that the probability of throwing it the first time, and missing it the other three successive times, is  $\frac{1}{6} \times \frac{5}{6} \times \frac{5}{6} \times \frac{5}{6} = \frac{125}{1296}$ ; but because it is possible to hit it every throw as well as the first, it follows, that the probability of throwing it once in four throws, and missing the other three, is  $\frac{4 \times 125}{1296} = \frac{500}{1296}$ ; which being subtracted from 1, there will remain  $\frac{796}{1296}$  for the probability of throwing it once, and no more, in four times. Therefore, if one undertake to throw an ace once, and no more, in four times, he has 500 to 796 the worst of the lay, or 5 to 8 very near.

Suppose two events are such, that one of them has twice as many chances to come up as the other, what is the probability that the event, which has the greater number of chances to come up, does not happen twice before the other happens once, which is the case of flinging 7 with two dice before 4 once? Since the number of chances are as 2 to 1, the probability of the first happening before the second is  $\frac{2}{3}$ , but the probability of its happening twice before it is but  $\frac{2}{3} \times \frac{2}{3}$  or  $\frac{4}{9}$ : therefore it is 5 to 4 seven does not come up twice before four once.

But, if it were demanded, what must be the proportion of the facilities of the coming up of two events, to make that which has the most chances come up twice, before the other comes up once? The answer is 12 to 5 very nearly: whence it follows, that the probability of throwing the first before the second is  $\frac{12}{17}$ , and the probability of throwing it twice is  $\frac{12}{17} \times \frac{12}{17}$ , or  $\frac{144}{289}$ ; therefore, the probability of not doing it is  $\frac{145}{289}$ : therefore the odds against it are as 145 to 144, which comes very near an equality.

Suppose there is a heap of thirteen cards of one colour, and another heap of thirteen cards of another colour, what is the probability that, taking one card at a venture out of each heap, I shall take out the two aces?

The probability of taking the ace out of the first heap is  $\frac{1}{13}$ , the probability of taking the ace out of the

second heap is  $\frac{1}{13}$ ; therefore the probability of taking out both aces is  $\frac{1}{13} \times \frac{1}{13} = \frac{1}{169}$ , which being subtracted from 1, there will remain  $\frac{168}{169}$ : therefore the odds against me are 168 to 1.

In cases where the events depend on one another, the manner of arguing is somewhat altered. Thus, suppose that out of one single heap, of thirteen cards of one colour I should undertake to take out first the ace; and, secondly, the two: though the probability of taking out the ace be  $\frac{1}{13}$ , and the probability of taking out the two be likewise  $\frac{1}{13}$ ; yet, the ace being supposed as taken out already, there will remain only twelve cards in the heap, which will make the probability of taking out the two to be  $\frac{1}{12}$ : therefore the probability of taking out the ace, and then the two, will be  $\frac{1}{13} \times \frac{1}{12}$ .

In this last question the two events have a dependence on each other, which consists in this, that one of the events being supposed as having happened, the probability of the other's happening is thereby altered. But the case is not so in the two heaps of cards.

If the events in question be  $n$  in number, and be such as have the same number  $a$  of chances by which they may happen, and likewise the same number  $b$  of chances by which they may fail, raise  $a+b$  to the power  $n$ . And if A and B play together, on condition that if either one or more of the events in question happen, A shall win, and B lose, the probability of A's winning will be  $\frac{a+b)^n - b^n}{a+b)^n}$ ; and that of B's

winning will be  $\frac{b^n}{a+b)^n}$ ; for when  $a+b$  is actually

raised to the power  $n$ , the only term in which  $a$  does not occur is the last  $b^n$ : therefore all the terms but the last are favourable to A.

Thus if  $n=3$ , raising  $a+b$  to the cube  $a^3+3a^2b+3ab^2+b^3$ , all the terms but  $b^3$  will be favourable to A; and therefore the probability of A's winning will be  $\frac{a^3+3a^2b+3ab^2}{a+b)^3}$ , or  $\frac{a+b)^3 - b^3}{a+b)^3}$ ; and the proba-

bility of B's winning will be  $\frac{b^3}{a+b)^3}$ . But if A and B

play on condition, that if either two or more of the events in question happen, A shall win; but in case one only happen, or none, B shall win; the probability of A's winning will be  $\frac{a+b)^n - nab^n - b^n}{a+b)^n}$ ; for

the only two terms in which  $aa$  does not occur, are the two last, viz.  $nab^n$  and  $b^n$ .

GAMMUT, in music, a scale whereon we learn to sound the musical notes, *ut, re, mi, fa, sol, la*, in their several orders and dispositions. See MUSIC.

GANG-WAY is the several passages or ways from one part of the ship to the other; and whatever is laid in any of those passages, is said to lie in the gang-way.

GANGEA, the capital of a territory in the province of Chirvan, in Persia: E. long. 46°, N. lat. 41°.

GANGES,

**GANGES**, a large river of the hither India, rises in the mountains which separate India from Tartary; and, running from the north west to the south east near 1500 miles through the Mogul's dominions, discharges itself by several channels into the bay of Bengal.

**GANGI**, or **COULER**, a town of Golconda, in the hither India: E. long. 79°, and N. lat. 16°.

**GANGLIO**, or **GANGLION**, in surgery, a hard tubercle, generally moveable, in the external or internal part of the carpus, upon the tendons or ligaments in that part, usually without any pain to the patient.

**GANGRENE**, a very great and dangerous degree of inflammation, wherein the parts affected begin to corrupt, and put on a state of putrefaction. See **MEDICINE** and **SURGERY**.

**GANTLET**, or **GAUNTLET**, a large kind of glove, made of iron, and the figures covered with small plates. It was formerly worn by cavaliers, when armed at all points.

**GAOL**, a prison, or place of legal confinement.

**GAOL DELIVERY**, is where a commission or patent is granted by the king in the nature of a letter, to certain persons, who are thereby appointed his justices, or to two or three of them, authorising them to deliver

his gaol, at such a place, of the prisoners contained therein; and for that end it commands them to meet at such a place, at the time they themselves shall appoint, when the sheriff of the county is commanded to bring all the prisoners in the gaol before them, &c.

**GAP**, a city and bishop's see of Dauphine, in France, eighteen miles west of Embrun: E. long. 5° 46', N. lat. 44° 32'.

**GARBE**, in heraldry, a sheaf of any kind of grain, bore in several coats of arms, and said to represent summer, as a bunch of grapes does autumn.

**GARCINIA**, in botany, a genus of the icosandria monogynia class. The flower consists of four roundish patent petals; and the fruit is a large unilocular coriaceous berry, containing eight hairy and fleshy seeds, convex on one side, and angular on the other. There are two species, none of them natives of Britain.

**GARDA**, a town of the Veronese, in Italy, subject to Venice: E. long. 11°, N. lat. 45° 25'.

**GARDANT**, or **GUARDANT**, in heraldry, denotes any beast full faced, and looking right forward. See **PLATE LXXXVII**, fig. 6. which represents a lion gardant.

**GARDELEBEN**, a town of Brandenburg, in Germany: E. long. 11° 45', N. lat. 52° 40'.

## G A R D E N I N G.

**GARDENING**, a branch of agriculture, containing the cultivation of gardens.

The simplest idea of a garden, is that of a spot embellished with a number of natural objects, trees, walks, polished parterres, flowers, streams, &c. One more complex comprehends statues and buildings, that nature and art may be mutually ornamental. A third approaching nearer perfection, is of objects assembled together, in order to produce, not only an emotion of beauty, essential to every garden, but also some other particular emotion, grandeur for example, or gaiety. The most perfect idea of a garden is an improvement upon the third, requiring the several parts to be arranged in such a manner, as to inspire all the different emotions that can be raised by gardening. In this idea of a garden, the arrangement is an important circumstance; for some emotions figure best in conjunction, and others ought always to appear in succession and never in conjunction. When the most opposite emotions, such as gloominess and gaiety, stillness and activity, follow each other in succession, the pleasure on the whole will be the greatest; but such emotions ought not to be united, because they produce an unpleasant mixture. For that reason, a ruin, affording a sort of melancholy pleasure, ought not to be seen from a flower-parterre, which is gay and cheerful: but to pass from an exhilarating object to a ruin, has a fine effect; for each of the emotions is the more sensibly felt by being contrasted with the other. Similar emotions, on the other hand, such as gaiety and sweetness, stillness

and gloominess, motion and grandeur, ought to be raised together; for their effects upon the mind are greatly heightened by their conjunction.

Kent's method of embellishing a field, is admirable; which is, to paint a field with beautiful objects, natural and artificial, disposed like colours upon a canvas. It requires indeed more genius to paint in the gardening way: in forming a landscape upon a canvas, no more is required but to adjust the figures to each other: an artist who lays out ground in Kent's manner, has an additional task; he ought to adjust his figures to the several varieties of the field.

One garden must be distinguished from a plurality; and yet it is not obvious wherein the unity of a garden consists. A notion of unity is indeed suggested from viewing a garden surrounding a palace, with views from each window, and walks leading to every corner: but there may be a garden without a house; in which case, what makes it one garden, is the unity of design, every single spot appearing part of a whole. The gardens of Versailles, properly expressed in the plural number, being no fewer than sixteen, are indeed all of them connected with the palace, but have scarce any mutual connection: they appear not like parts of one whole, but rather like small gardens in contiguity. Were these gardens at some distance from each other, they would have a better effect: their junction breeds confusion of ideas, and upon the whole gives less pleasure than would be felt in a slower succession.

Regularity is required in that part of a garden which joins the dwelling-house; for being considered as a more immediate accessory, it ought to partake the regularity of the principal object: but in proportion to the distance from the house considered as the centre, regularity ought less and less to be studied; for, in an extensive plan, it hath a fine effect to lead the mind insensibly from regularity to a bold variety. Such arrangement tends to make an impression of grandeur: and grandeur ought to be studied as much as possible, even in a more confined plan, by avoiding a multiplicity of small parts. A small garden, on the other hand, which admits not grandeur, ought to be strictly regular.

Milton, describing the garden of Eden, prefers justly the grand taste to that of regularity:

Flow'rs worthy of paradise, which not nice art  
In beds and curious knots; but Nature boon  
Pour'd forth profuse on hill, and dale, and plain;  
Both where the morning-sun first warmly smote  
The open field, and where the unpierc'd shade  
Imbrown'd the noontide bow'rs. *Paradise Lost*, b. 4.

An hill, by being covered with trees, appears both more powerful and more lofty; provided no other beauties be hid that might be seen if the hill were naked. To distribute trees in a plain requires more art: near the dwelling-house they ought to be so thin, as not to break the unity of the field; and even at the greatest distance of distinct vision, they ought never to be so crowded as to hide any beautiful object.

In the manner of planting a wood or thicket, much art may be displayed. A common centre of walks, termed *a star*, from whence are seen a number of remarkable objects, appears too artificial, and consequently too stiff and formal, to be agreeable: the crowding withal so many objects together, lessens the pleasure that would be felt in a slower succession. Abandoning therefore the star, let us try to substitute some form more natural, that will lay open all the remarkable objects in the neighbourhood. This may be done by various openings in the wood contrived to catch surrounding objects, which in walking bring successively under the eye these objects as by accident; sometimes a single object, sometimes a plurality in a line, and sometimes a rapid succession of them. In this form, the mind at intervals is roused and cheered by agreeable objects; and the scene is greatly heightened by the surprise it occasions when we stumble, as it were, upon objects of which we had no expectation.

An object terminating in a narrow opening in a wood, appears at a double distance. This suggests another rule for distributing trees in some quarter near the dwelling-house; which is, to place a number of thickets one behind another, with an opening in each directing the eye to the most distant through all the intermediate thickets; which, by making these thickets appear more distant from each other than they are in reality, will enlarge in appearance the size of the whole field. To give this plan its utmost effect, the thickets ought to be at a considerable distance from each other: and, in order that each may be seen distinctly, the opening nearest the eye ought to be wider than the second, the second wider than the third, and so one to the end.

By a judicious distribution of trees, various beauties may be produced, far exceeding what have been mentioned; which will appear as follows. A landscape so rich as to ingross the whole attention, and so limited as sweetly to be comprehended under a single view, has a much finer effect than the most extensive landscape that requires a wandering of the eye through successive scenes. This consideration suggests a capital rule in laying out a field; which is, never at any one station to admit a larger prospect than can easily be taken in at once. A field so happily situated as to command a great extent of prospect, is a delightful subject for applying this rule: let the prospect be split into proper parts by means of trees; studying at the same time to introduce all the variety possible. A plan of this kind executed with taste will produce charming effects: the beautiful prospects are multiplied: each of them is much more agreeable than the entire prospect was originally: and, to crown the whole, the scenery is greatly diversified.

As gardening is not an inventive art, but an imitation of nature, or rather nature itself ornamented, it follows necessarily, that every thing unnatural ought to be rejected with disdain. Statues of wild beasts vomiting water, a common ornament in gardens, prevails in those of Versailles. Is this ornament in a good taste? A jet d'eau, being partly artificial, may, without disgust, be tortured into a thousand shapes: but a representation of what really exists in nature, admits not any unnatural circumstance. These statues therefore of Versailles must be condemned; and yet so insensible has the artist been to just imitation, as to have displayed his vicious taste without the least colour or disguise: a lifeless statue of an animal pouring out water, may be endured without much disgust; but here the lions and wolves are put in violent action, each has seized its prey, a deer or a lamb, in act to devour; and yet, instead of extended claws and open mouth, the whole, as by a hocus-pocus trick, is converted into a different scene; the lion, forgetting his prey, pours out water plentifully; and the deer, forgetting its danger, performs the same operation.

In gardening, every lively exhibition of what is beautiful in nature has a fine effect: on the other hand, distant and faint imitations are displeasing to every one of taste. The cutting evergreens in the shape of animals, is a very ancient practice; as appears from the epistles of Pliny, who seems to be a great admirer of this puerile conceit. The propensity to imitation gave birth to this practice; and has supported it wonderfully long, considering how faint and insipid the imitation is. But the vulgar, great and small, devoid of taste, are entertained with the oddness and singularity of a resemblance, however distant, between a tree and an animal. An attempt in the gardens of Versailles, to imitate a grove of trees by a group of jets d'eau, appears, for the same reason, not less ridiculous.

In laying out a garden, every thing trivial or whimsical ought to be avoided. Is a labyrinth then to be justified? It is a mere conceit, like that of composing verses in the shape of an ax or an egg: the walks and hedges may be agreeable; but in the form of a labyrinth, they serve to no end but to puzzle: a riddle is a conceit not so mean; because

Because the solution is a proof of sagacity, which affords no aid in tracing a labyrinth.

The gardens of Versailles, executed with infinite expence by the best artists that could be found, are a lasting monument of a taste the most depraved: the faults above mentioned, instead of being avoided, are chosen as beauties, and multiplied without end. Nature, it would seem, was deemed too vulgar to be imitated in the works of a magnificent monarch; and for that reason preference was given to things unnatural, which probably were mistaken for supernatural.

A straight road is the most agreeable, because it shortens the journey. But in an embellished field, a straight walk has an air of stiffness and confinement: and at any rate is less agreeable than a winding or waving walk; for in surveying the beauties of an ornamented field, we love to roam from place to place at freedom. Winding walks have another advantage: at every step they open new views. In short, the walks in a field intended to please the eye, ought not to have any appearance of a road. This rule excludes not long straight openings terminating upon distant objects; which openings, beside variety, never fail to raise an emotion of grandeur, by extending in appearance the size of the field: an opening without a terminating object, soon closes upon the eye; but an object, at whatever distance, continues the opening, and deludes the spectator into a conviction, that the trees which confine the view are continued till they join the object: and the object also, as observed above, seems to be at a greater distance than it is in reality. Straight walks also in recesses do extremely well: they vary the scenery, and are favourable to meditation.

An avenue ought not to be directed in a straight line upon a dwelling-house: better far an oblique approach in a waving line, with single trees and other scattered objects interposed. In a direct approach, the first appearance continues the same to the end: we see a house at a distance, and we see it all along in the same spot without any variety. In an oblique approach, the interposed objects put the house seemingly in motion: it moves with the passenger, and appears to direct its course so as hospitably to intercept him. An oblique approach contributes also to variety: the house, being seen successively in different directions, takes on at every step a new figure.

A garden on a flat ought to be highly and variously ornamented, in order to occupy the mind, and prevent its regretting the insipidity of an uniform plan. Artificial mounts in this view are common: but no person has thought of an artificial walk elevated high above the plain. Such a walk is airy, and tends to elevate the mind: it extends and varies the prospect: and it makes the plain, seen from a height, appear more agreeable.

Whether should a ruin be in the Gothic or Grecian form? In the former; because it exhibits the triumph of time over strength, a melancholy but not unpleasant thought: a Grecian ruin suggests rather the triumph of barbarity over taste, a gloomy and discouraging thought.

Fountains are seldom in a good taste. Statues of animals vomiting water, which prevail every where, stand condemned. A statue of a whale spouting water upward

from its head, is in one sense natural, as whales of a certain species have that power; but it is sufficient to make this design be rejected, that its singularity would make it appear unnatural: there is another reason against it, that the figure of a whale is in itself not agreeable. In the many fountains in and about Rome, statues of fishes are frequently employed to support a large basin of water. This unnatural conceit is not accountable, unless from the connection between water and the fish that swim in it; which, by the way, shows the influence of even the slightest relations.

Hitherto a garden has been treated as a work intended solely for pleasure; or, in other words, for giving impressions of intrinsic beauty. What comes next in order is the beauty of a garden destined for use, termed *relative beauty*; see BEAUTY: and this branch shall be dispatched in a few words. In gardening, luckily, relative beauty need never stand in opposition to intrinsic beauty: all the ground that can be requisite for use, makes but a small proportion of an ornamented field; and may be put in any corner without obstructing the disposition of the capital parts. At the same time, a kitchen-garden, or an orchard, is susceptible of intrinsic beauty; and may be so artfully disposed among the other parts, as by variety and contrast to contribute to the beauty of the whole.

Gardening being in China brought to greater perfection than in any other known country, we shall take a slight view of Chinese gardens, which will be found entirely obsequious to the principles that govern any one of the fine arts. In general, it is an indispensable law there, never to deviate from nature; but in order to produce that degree of variety which is pleasing, every method is used that is consistent with nature. Nature is strictly imitated in the banks of their artificial lakes and rivers; which sometimes are bare and gravelly, sometimes covered with wood quite to the brink of the water. To flat spots adorned with flowers and shrubs are opposed others steep and rocky. We see meadows covered with cattle; rice grounds that run into lakes; groves into which enter navigable creeks and rivulets: these generally conduct to some interesting object, a magnificent building, terraces cut in a mountain, a cascade, a grotto, an artificial rock, or such like. Their artificial rivers are generally serpentine; sometimes narrow, noisy, and rapid; sometimes deep, broad, and slow: and to make the scene still more active, mills and other moving machines are often erected. In the lakes are interspersed islands; some barren, surrounded with rocks and shoals; others enriched with every thing that art and nature can furnish. Even in their cascades they avoid regularity, as forcing nature out of its course: the waters are seen bursting from the caverns and windings of the artificial rocks, here an impetuous cataract, there many lesser falls: and the stream often impeded by trees and stones, that seem brought down by the violence of the current. Straight lines are sometimes indulged, in order to take the advantage of some interesting object at a distance, by directing openings upon it.

Sensible of the influence of contrast, the Chinese artists deal in sudden transitions, and in opposing to each other, forms, colours, and shades. The eye is conducted from

from limited to extensive views, and from lakes and rivers to plains, hills, and woods: to dark and gloomy colours, are opposed the more brilliant: the different masses of light and shade are disposed in such a manner, as to render the composition distinct in its parts, and striking on the whole. In plantations, the trees are artfully mixed according to their shape and colour; those of spreading branches with the pyramidal, and the light green with the deep green. They even introduce decayed trees, some erect, and some half out of the ground. In order to heighten contrast, much bolder strokes are risked: they sometimes introduce rough rocks, dark caverns, trees ill formed and seemingly rent by tempests or blasted by lightning, a building in ruins or half consumed by fire. But to relieve the mind from the harshness of such objects, they are always succeeded by the sweetest and most beautiful scenes.

The Chinese study to give play to the imagination. They hide the termination of their lakes: the view of a cascade is frequently interrupted by trees, through which are seen obscurely the waters as they fall. The imagination once roused, is disposed to magnify every object.

Nothing is more studied in Chinese gardens than to raise wonder or surprize. In scenes calculated for that end, every thing appears like fairy-land; a torrent, for example, conveyed under ground, puzzling a stranger by its uncommon sound to guess what it may be; and, to multiply such uncommon sounds, the rocks and buildings are contrived with cavities and interstices. Sometimes one is led insensibly into a dark cavern, terminating unexpectedly in a landscape enriched with all that nature affords the most delicious. At other times, beautiful walks insensibly conduct us to a rough uncultivated field, where bushes, briars, and stones interrupt the passage: when we look about for an outlet, some rich prospect unexpectedly opens to view. Another artifice is, to obscure some capital part by trees or other interposed objects: our curiosity is raised to know what lies beyond; and after a few steps, we are greatly surprized with some scene totally different from what was expected.

These curious observations upon gardening, shall be closed with some reflections. Rough uncultivated ground, dismal to the eye, inspires peevishness and discontent: may not this be one cause of the harsh manners of savages? A field richly ornamented, containing beautiful objects of various kinds, displays, in full lustre, the goodness of the Deity, and the ample provision he has made for our happiness; which must fill every spectator with gratitude to his Maker, and with benevolence to his fellow-creatures. Other fine arts may be perverted to excite irregular, and even vicious, emotions: but gardening, which inspires the purest and most refined pleasures, cannot but promote every good affection. The gaiety and harmony of mind it produceth, inclining the spectator to communicate his satisfaction to others, and to make them happy as he himself is, tend naturally to establish in him a habit of humanity and benevolence.

HAVING thus unfolded the general principles of gardening, that have an influence upon taste or manners; we

shall now subjoin the practical part, in the form of a calendar.

## J A N U A R Y.

### FLOWER-GARDEN.

THIS is the proper time for planting roots of the ranunculus; the soil should be rich and sandy, and they should be planted at least three inches deep. By laying a quantity of earth made of old thatch or straw, about seven inches beneath the surface of the ground, and then filling it up with rich mould, a prodigious number of these flowers may be produced. A fine earth may likewise be made of tanner's bark, or the bottom of a wood pile, well mixed with about a third of natural soil, which will prove peculiarly serviceable.

As the wind and frost are very prejudicial to carnations and auriculas, they should this month be kept covered.

Anemonies should be planted in beds of fine earth; no dung must be used in planting them. The roots of these flowers may be increased by breaking the knots, about the size of a small button, asunder, and letting them lie two or three days in the sun, before you plant them. It should be remembered, that the roots of the anemony are to be taken up about the end of June or the beginning of July; after being dried in the sun, they should be preserved in a dry cool place, or kept in sand for a month, and then put in papers till the season for planting them. When these roots are first transplanted, a thin layer of willow-earth, or rotten sally-wood, being put under them, forwards their growth.

### FRUIT-GARDEN.

THE pruning of pears, vines, and plumbs, is the chief employment of this month. In pruning the pear, those buds which appear fuller than the rest should be carefully preserved; all branches that proceed from the knob, whereon the stalk of a pear grew, are to be taken away, but the knob must remain; and the extremity of the last year's pruning is to be taken off.

As the large branches of a pear-tree are useless in bearing, care should be taken to extend the branches sideways, and none but small branches suffered to grow in the middle, and not even those to grow directly perpendicular, as, by that means, they would soon become what is called *great wood*.

A pear-tree that is vigorous and luxuriant should not be pruned till after it has begun to shoot. A languishing pear-tree may be restored to its former state by pruning and removal into better ground. Another very good method of treating pear-trees not in a bearing state, is to bark the luxuriant branches all round about a quarter of an inch wide, more or less, according to their strength. Apple-trees will likewise bear this operation, which should be done in April. Trees that are too vigorous may be made to bear by cutting off the sap roots, or taking them up, and re-setting them, for they are often planted

planted too deep. Plumbs and cherries may be pruned in the same manner as pears.

The winter-pruning of the vine (which requires a first, second, third, and sometimes a fourth pruning) should be done either in October, November, December, or this month. The vigour of the vine is to be regarded; the small weak shoots that never bear any fruit must be cleared away, and the other branches are to be so proportioned as not to occasion any confusion; such as are thickest and best placed should be preserved, and the strong short branches left nine inches or more, according to the size of the vine. When they have shot twelve or fifteen inches long, which will be in the summer, you must begin to nail them up; and when they have shot two or three feet, stop or cut off the ends of the shoots; those on the side should not be broke off till the fruit is set: and a fruit bearing branch should be cut within three or four eyes of the fruit.

All suckers should be cut off as soon as they have shot seven or eight inches. The vine should be kept thinner of wood than any other tree, though it puts forth the largest shoots. All the old wood should be cut out, and its place supplied with vigorous young shoots.

All dead or cankered branches should this month be cut from the standard fruit-trees, as also such as cross each other; but in doing this you must be careful to make the wounded part as smooth as possible, and sloping, that the wet may not enter and be detained there, to the great prejudice of the trees.

#### KITCHEN-GARDEN.

THE management of hot-beds claims almost the sole attention of the kitchen-gardener this month. The place most exposed to the sun is best for making a hot-bed: when you have marked out the dimensions of the bed, drive stakes into the ground on every side, a yard above the ground, and a foot asunder; wind these round with bands made of hay or straw, and then fill them up with wet litter and new horse-dung, treading it down very hard as you fill; in doing which you must be careful to leave room for the earth and the shooting of your plants.

When you have thus laid the bed, fix your wooden frames fitted to the same, for the reception of the mould at top, and for the support of glass frames, which are to be fixed sloping.

The hot-bed should then be finished by putting in the earth; an old hot-bed, well rotted, affords excellent stuff for this purpose; but if that cannot be procured, some very rich mould well sifted will do.

Over the whole you must fix mats supported by short sticks, which must remain about a week; by which time the bed will abate of its extreme heat, and be of a proper temperature for use.

The bed should be warm, not hot; and when the heat lessens too much, by applying new dung to the sides, you may renew it.

When plants are come up in a hot bed, they should have air and the sun by degrees; and when strong enough, should be removed to a second hot-bed, of less heat than the former, or into very rich earth, where

they should be frequently watered gently, and kept from the meridian sun till well settled; and when the weather is cold, by covering the glasses a little before sun-set with litter and mats, they may easily be defended from it.

Gardeners in general make their seed-beds for cucumbers and melons in this month, for raising them before their natural season; but the better method is, to make hot-beds the latter end of October or beginning of November: about four feet square, and two feet high, is the proper size, wherein, after the heat is moderated, cucumbers and melons may be sown.

About a week after their coming up, plant them four inches apart in the same bed, after having well stirred up the earth. As the days in October are usually warm, the plants may be allowed to have air; but in January they must be kept covered up close. In this first raising of plants, a gardener may, with due care, make them as hardy as he pleases.

It is usual with some people to keep their melon seeds in milk four and twenty hours before they make use of them; others use them without that preparation: they should be set two or three in a hole, in the hot-bed, about an inch deep, and covered close up, to keep them warm. About the end of April is the time for planting melons, which should first be done in small baskets made of old willow-twigs, three inches deep, and eight or nine inches over.

Two or three plants should be planted in one basket; and when they will bear it, moved on another hot bed, covered with a sandy loam five or six inches thick, sifted fine, wherein they are to grow all the summer.

Cucumbers are propagated after the same manner as melons; but as a bad season may prevent their being successfully raised, it is highly necessary to put some seeds into the bed at three or four different times this month, that if some should fail, the others may supply their loss. In order to raise asparagus for hot-beds, make choice of a piece of ground that has been well dug and mellowed, then strike out lines seven or eight inches from each other, and plant the asparagus roots in them at six or seven inches apart when they are a twelvemonth old: let them be kept free from weeds, and remain in the nursery two years, in which time they will be fit for the hot-bed. The hot-bed for the reception of these roots should be made pretty strong, and covered with earth six inches thick, encompassed round with bands of straw. The asparagus-roots should be planted as close as they can be placed together without trimming; which being done, cover the buds of the plants two inches thick with earth; in which state let them remain five or six days before the frames and glasses are put over them; and then lay on over the whole three inches thick of fresh earth.

As soon as the buds appear, give them what air the season will permit, which will make them green, and of a good taste. The bed will last good about a month, producing daily fresh buds, if the weather be not too severe: when it begins to cool, warm horse-litter laid upon the glasses every night will contribute as much to facilitate the shoot of the buds as if new dung were applied to the roots.

It should be observed, that the time for this work is not only in this month, but from November till April; (making fresh buds every month to follow one another for a constant supply) and in April comes the natural crop.

A very moderate hot-bed made after the manner first directed, will serve to propagate early strawberries.

You may make a bed in two or three hours, with the use of hot lime and powdered dung, the dung being in the middle, and the lime underneath and at top; over which you should lay a quantity of fine rich mould.

To raise radishes in the hot-bed with success, you should have sufficient thickness of rich light mould, that they may have proper depth to root in before they reach the dung.

Radishes may be sowed all the year, but in hot-beds in the winter.

Mustard, lettuce, cresses, and other fallading, are generally raised from the seeds sown in drills or lines, in such an exposure as is required by the season of the year; in the winter-season, on moderate hot beds; in the spring, under glasses and frames; and in the summer, on natural beds of earth.

Cresses sown in the natural ground in August, resist the frosts of the winter, and help greatly to enrich the hot-bed fallads with the high taste they maintain by being exposed to the open air.

Small herbs should be drawn up by the roots from the hot beds; and, in sowing a second crop, seeds of another kind should be sown, and not the same kind in the same place.

The hotspur, charlton master, and other peas, must be sown in drills three feet asunder, that you may have room to go between them; and the lines should run from north to south.

When they have shot about six inches high, earth them about four inches on both sides of the lines, raising a little bank on the east side of them, to defend them from the blasting winds.

In February you may sow a second crop, and in March a third.

You must, in the beginning of the winter, sow twice the quantity of pease you need to do, if you stay till February or March; because the cold weather and the mice will destroy great part of them.

## F E B R U A R Y.

### FLOWER-GARDEN.

For the better management of the auricula, which is to be sown this month, prepare a box of oak or deal, four feet long, two feet wide, and six inches deep, with holes in the bottom, six inches distance from each other; in which, after laying two inches thick of cinders or sea-coals; and spreading over them some earth taken out of hollow willow-trees, till you have filled the box, sow the seeds on the top, without any covering of earth, pressing them into the mould with a flat board, in order to settle them below the edges of the box that the light seeds may not float over the brim in watering.

From the time of sowing to the beginning of April, this box must be placed where it will receive the sun; but after that time, it must be removed into a shady place; and the seeds must be continually refreshed with gentle waterings.

If the seedlings do not come up the first year, they will the second; and in July or August, after they appear above ground, will be strong enough to transplant; when you must set them in beds of light earth well sifted, at about four inches distance from each other, and place them where they may receive only the morning sun.

The April afterwards they will begin to shew themselves, when they should be transplanted into pots filled with soil made of one load of melon-earth, or dung well rotted, half a load of sea-sand, and half a load of sandy loam; or a load of melon earth, and the like of sandy loam; or one load of rotten wood, or the bottom of a wood-pile, the same quantity of loam, and half a load of melon earth, prepared as above.

These flowers must be carefully sheltered from the rains, which greatly impair their colours.

Provided the weather is mild, you may, toward the end of this month, plant out your choice carnations into the pots where they are to remain to flower; in doing which, you should not take too much of the earth from their roots; and when they are planted, it will be proper to place the pots in a warm situation (but not too near walls, or pales, which will draw them up weak); and arch them over with hoops, that in bad weather they may be covered with mats; for unless they acquire strength in the spring before the heat comes on, they will not produce large flowers.

The polyanthus seed must be sown upon a place prepared with earth taken out of decayed willows, often watered and kept shaded from the sun all April and May, till the young plants are come up.

The seedlings will be fit to transplant the July or August following into beds: the soil of which should be somewhat binding, and their exposure only to the morning sun.

You may have an annual supply of larkspurs without the trouble of sowing, by suffering the seeds of the flowers to drop, which will come up the ensuing spring: they are sown in spots, and flourish in variety of ground.

The single sort of Sweet William is raised by seeds sown in February or March; the double sorts, propagated from slips taken near the root about March or April, and planted in a loamy soil: they may also be laid down in the earth like carnation layers.

Holyhocks are raised by seeds sown in this month, removed in August or September to their proper places of vegetation, in rich earth.

The most agreeable disposition of this flower is, under some coarse wall, which they will handsomely fill, or in any other place guarded from the winds.

Pinks, and candy-tufts, are generally used in edgings in gardens, and insides of borders, where they are planted in spots, and have a very agreeable effect.

The seed is sown in lines in this month or March; or they may be propagated from slips planted very early in the spring, or in August.

Rose-

Rose-trees, of which there are various sorts, succeed best in a strong holding ground, tolerably moist; they may either be raised from layers or suckers, laid down and taken from the old roots in February or March, and transplanted immediately before the roots grow dry: should there be a necessity for keeping them out of the ground for some time, lay their roots in water five or six hours before they are planted.

The rose-tree does well in borders, or in the quarters of wilderness works, among other flowering shrubs; and some or other of them will be in flower for ten months in the year.

The laburnum tree is commonly planted among the other flowering shrubs of the wilderness, and will grow in the most open exposure, as well as under the shade of large trees: it may easily be raised from seeds sown in this month, and transplanted two years after it comes up.

The althæa may be raised from layers or seeds; there are several different colours of this flower, and they may be budded so as to have all the colours on one plant.

The pomegranate prospers most in a light soil; and being propagated by laying down the young shoots in this month or March, may be transplanted either in the spring or autumn season, when they may be put in pots, or against a south wall, where the fruit will ripen.

The pomegranate may also be raised from seed.

The syringa may be raised from seeds; but it is hardly thought worth the trouble, as it is very apt to put forth suckers; these, however, may with ease be taken off and transplanted at this time of the year, and in September.

It is a shady position which makes this shrub shoot, and the sun makes it flower; but it will grow almost any where.

The lilach is a plant which grows to a pretty large tree, bearing bunches of purple blossoms, likes plumes of feathers, in May; and is raised by laying down the young branches in this month or March, or by taking off the suckers, and planting them in a light soil, about the same time, or in September.

These trees are highly ornamental in the quarters of wilderness works, and small walks of them are very pleasant.

The Spanish broom is planted in wilderness works, and may be raised from seeds sown in light earth; also by laying down the tender branches, and cutting them at the joints, after the manner of the carnation; but the latter method is not so certain as the other, though it is far more troublesome.

The laurus tinus is greatly admired for producing its flower in the winter; and may be raised from the berries, managed as the holly; or from layers, which is the most expeditious way.

This plant is greatly hurt by frost, and succeeds best in moist shady places; it will flourish in loamy soil, without the help of any rich manure, which forwards its growth too much.

The laurus tinus, is often trained up as a headed plant, though it is best planted against a wall, or in wildernesses; and it is observable, that this plant, like all other exotics, is naturally inclined to blossom about the spring in its own

country, which is our autumn; for which reason, it should be pruned in our spring season after it has done blowing.

The phillyrea, may in general be propagated from the berries, or raised from layers, which will presently take root.

This plant, which succeeds best in a natural light soil, grows very fast; and being well supported with rails or stakes, a number of them makes a very thick and handsome hedge.

The yew-tree delights in a light barren soil, and is more plentifully produced on the coldest mountains than in the richest soils.

The berries of the yew may be laid in sand, as those of the holly, before they are sown; and there is no difficulty in propagating this plant, or removing it, if the roots are pruned from time to time, by digging about it while it stands in the nursery.

The holly will grow to a very large tree; but being a rooted plant, does not succeed well when transplanted, unless the roots have been often pruned in the nursery.

The berries of this plant, when ripe, are to be gathered; and after they have been laid to sweat some time, are to be put in sand or earth, till the autumn following, when, and likewise in this month, they may be sown in nursery beds.

They will lie in the ground for a long time before they begin to spring, and it will be four or five years before the young stocks will be fit to graft or inoculate upon.

The grafting must be done in March, and the inoculating in July; but for standard trees or hedges, they must be planted at their proper distances while very young, that they may be accustomed to the soil.

The bay tree, which is managed as the holly, is raised by berries sown in this month, on a bed of earth fresh dug, and covered with some fresh natural earth, well sifted, about two inches thick.

In about six weeks, the seeds thus sown will come up, should the weather prove moist; they should be covered with straw, or fern, for the three first winters, after which time they must be transplanted.

When these plants are discoloured by frost, cut off the top-branch in the spring, and they will shoot afresh.

The bay-tree may also be raised from layers laid down in the month of October, for cuttings, set in pots of fine earth, two or three inches deep; and from suckers taken up with as much root as may be, and planted in the shade, in a gravelly soil, being well watered to settle the earth about their roots.

The laurel is propagated in the same manner as the bay-tree, loves shade, resists the weather, and will thrive in almost every soil.

Towards the end of this month, if the season proves favourable, stir the surface of the ground of your flower-beds, and clear them from weeds, moss, and whatever filth may appear thereon, which will not only make your garden look neat, but be of peculiar service to the flowers.

#### FRUIT-GARDEN.

THE business of this month is chiefly pruning and grafting.

ing; and is more particularly the season for pruning fruit-trees.

When a tree has produced two well disposed branches with some weak ones intermixed, they should be shortened equally to the length of five or six inches; and if the position of the two branches be irregular, there must be only one left to begin the formation of your tree.

A tree will sometimes shoot five, six, or seven branches, the first year; when this happens, three or four only of the best branches are to be preserved.

A multitude of branches in the first year, is not always a sign of vigour; for they sometimes prove weak, occasioned by the infirmity of the roots: in pruning, generally a vigorous tree cannot have too many branches, if they are well disposed, nor a weak one too few.

The sap of all trees must be kept within due bounds, and a greater liberty is to be allowed to strong trees than to weak ones; for which reason strong and vigorous branches are left of a greater length than feeble ones: and it is best to prune weak sickly trees early, that the sap may not be too much wasted.

In the pruning of wall-fruit-trees, all the branches shooting directly forward are to be cut off close to the branch they spring from; and the utmost care must be taken to prevent their being too much crowded with wood, it being often necessary to take off even bearing branches, to preserve your trees in beauty and health; for it is impossible too great a number of branches should be supplied with juices as they ought; and if they are not, either the blossoms will drop off, or the fruit never ripen.

You should ever be careful to preserve a convenient space between one branch and another in all prunings; also that one branch does not cross another: a slender bearing branch may, notwithstanding, sometimes be permitted to steal behind the main body of the tree, and be no offence to the eye.

That a tree may be the better disposed to bear fruit, the branches should be carried horizontally as much as possible; for the more perpendicular the branches of a tree are led, the more they are inclined to run into great wood and barrenness.

Small weak branches, shooting from the like, should be cut away, as should all shoots put forth in autumn.

When an old tree shoots stronger branches towards the bottom than the top, and the top is sickly, it must be cut off, and a new figure formed from the lower branches; but if the top be in good health, you must cut off the lower ones, unless it be a few that are well placed.

Where old trees are in a weak condition, to preserve them, they are to be disburthened totally, leaving a few branches only shortened to five or six inches.

Having thus laid down the principal rules for pruning in general, we now come to the management of the peach and other fruit trees in particular.

When peach trees are vigorous, it is best to defer the first pruning till they are ready to blossom, when you may be at a certainty in preserving those branches which are most promising of fruit, and then to shorten them as they require.

You may soon discover the fruit-bearing branches by their swelling buds, and you should reduce them to the

length of five or six inches; the last year's shoots may be left ten or twelve inches long.

In the space of about three years, all the wood must at several prunings be taken away, but in the mean time the wall is to be furnished with other wood.

When you have reduced your tree to beauty and order, you have little to do but thinning your fruit till Midsummer, when the shoots are to be shortened and fastened to the wall, giving the fruit the advantage of the sun as much as possible.

If the peach-tree makes over-haste in its bearing, it is a sign of infirmity, and must be accordingly managed, by pruning the branches short, and plucking off all or most of the blossoms or fruit; which it is much less difficult to do than when a peach is over vigorous; for then nature is apt to make a confusion, which requires the greatest skill to know what branches are fit to be chosen, and what rejected.

The peach-tree requires a second, and sometimes a third pruning; the last of which is to be performed about the middle of May, or in June or July.

The apricot and nectarine may be pruned in the same manner as the peach; but it should be observed, that the apricot is more apt to run to wood than any other of these kind of wall-fruit trees.

The usual ways of grafting are, in the cleft—in the bark—by approach, and whip-grafting.

Grafting in the cleft, or slip-grafting, is performed on the cherry, pear, and plumb stocks, in the manner following.

When you have chosen a stock, in a smooth place cut off the head of it, sloping: then, with your knife make the top horizontally even; which being done, make a slit of near two inches deep down the middle of the stock; in which fix a cyon, sloped on each side from a bud; and closing the bark of both exactly, tie them round with bafs.

When you have thus finished your grafting, put a quantity of clay and horse-dung, tempered together, round the stock and lower part of the cyon; in doing which, be careful not to disturb the latter.

Grafting in the bark is generally performed only on apples, by cutting the head of the stock as already directed; but instead of slitting it, slit only the bark a little above an inch on the south-west side, or as long as the sloped part of the cyon; then, loosening the top of the bark with your knife, put in your cyon (being prepared with a flat slope about an inch long, ending in a point, and begun from the back-side of an eye) and closing it as above, cover it also in the same manner with clay.

When either an apple, pear, plumb, or cherry tree, wants a branch to make the tree uniform, a graft may be put into the side without cutting the head of it.

Grafting by approach, or inarching, is performed when a stock grows so near another tree, the fruit of which you would propagate, that it may be joined with a branch of that tree, by cutting the sides of the branch and stock about three inches long, and fitting them, that the passages of the sap may meet; in which posture let them be bound and clayed.

When they are well cemented, cut off the head of the stock

Stock about four inches above the binding; and in March following, having cut off the stubb that was left of the stock, and the cyon underneath, close the grafted place, that it may subsist by the stock only.

This manner of grafting agrees best with vines, pomegranates, oranges, and such like shrubs.

When the stock and cyon are of the same bigness, the operation of whip-grafting is performed, by sloping the stock and cyon about an inch, so as to make them fit, and then tying them together, and claying the place.

#### KITCHEN GARDEN.

Hot-beds for radishes and spring carrots should now be made, according to the directions given for a common hot-bed in the preceding month; which, by proper management, will do for all sorts of seeds that are annual.

To make a mushroom bed, dig a trench five or six inches deep, and lay in it either the dung of horses, mules, or asses, in ridges, which dung must be the last covering before the earth is laid on.

The bed, when it is complete, must be three or four feet high; and after covering the dung about two or three inches deep with such earth as is taken from under a turf, put some mushroom-earth all over the bed on the last covering of dung.

Should the weather be severe, you may defend the bed with straw or dry litter, eight or ten inches thick, or cover it with mats fastened on hoops.

The bed must be kept properly watered, twice or thrice a-week, and the mushrooms will come up in two months time at farthest; sometimes in a month, when they must be immediately cut.

By putting some mushroom earth on your cucumber-beds, you will greatly forward their growth.

In the natural ground potatoes love a sandy soil; and the smaller roots, or knots of them, are commonly saved to raise a crop from, being set about four or five inches deep in the ground, and five or six inches apart; and when their haulms begin to decay, which is generally about Michaelmas, you may take them out of the ground with forks as you have occasion to use them.

The Jerusalem artichoke succeeds best in a stiff soil, and affords a root as large as an ordinary turnip, being in taste somewhat like a potatoe, but rather more watery.

The several sorts of cabbages, as the red cabbage, the Dutch cabbage, the Savoy cabbage, the Russia cabbage, the Battersea cabbage, and the two sorts of the sugar-loaf cabbage, should be planted at proper distances, according to their several stature.

The Savoy cabbages are for winter use, and towards the spring put forth sprouts preferable to the cabbages themselves.

Almost any ground will serve for cabbages; but if the weather be dry, it must be well watered before planting.

The hardest cabbages may be taken up before the great frosts come on; and after they have hung up by the roots about a fortnight, lay them in a cellar, where they will keep a long time; or plant them deep in the ground

close to one another, and cover them with haulm or straw, till you have occasion to use them.

Carrots are most prosperous in a light ground, in which their roots will grow to a great bigness.

Spring-carrots are sown in July or August; those intended for a winter-crop, in February or March, in dry weather

When your carrots are come up, and have been above ground about a month, they must be houghed, leaving the space of about five inches between the plants; and after the first houghing they should be kept as clean as possible till they are full grown, when they may be taken up for present use, and kept in sand during the winter.

Parsnips thrive best in a rich soil, and, excepting that they should not stand so thick, are to be managed in the same manner as carrots.

The skirret requires a light, moist, yet a rich soil; and is propagated either by sowing seeds, or by transplanting the offsets from the roots,

As soon as the leaves begin to put forth, they should be taken out of the ground, and parted into as many slips as can be conveniently taken off with the roots, so as only the fresh springing fibres remain on them; drills about four or five inches deep must then be prepared to plant them five or six inches apart, and they must be kept well watered till their roots are fully grown.

The usual time for sowing turnips is in July or August, but some people sow them in this month, by way of providing them for the summer. They thrive best in a sandy, loamy soil, but will grow in any ground: when the plants have two or three leaves, they should be houghed at the distance prescribed for parsnips and carrots.

Onions are sown in this month, and in March, in rich garden soil; and toward the latter end of April, being come up, they are houghed, when about three inches should be left between the plants till they begin to grow fit for sallads, and then they may be drawn, or thinned where they grow too close together.

In sowing onions you must not be sparing of seeds, as it often happens many of them, being bad, have no effect.

When the leaves begin to change their colour, they should be pulled up, (in dry weather;) and after being well dried without doors, they must be spread on some floor, to dry more thoroughly for winter use.

Such onions as spire in the house, may this month be planted in lines six inches apart, and two inches distance for seeds for another year.

The leek is sown in a well-wrought ground, and is to be kept free from weeds, and houghed like the onion; the plants are transplanted in July, in rich light soil, in lines about five inches apart.

Strawberries prosper most in ground inclining to clay; and the best way of managing them, is to provide a quantity of horse-dung and coal-ashes well mixed together, and lay it upon the land to be dug or trenched in this month; then make borders three feet wide, on which the slips are to be planted from eight to eighteen inches apart, according to the sorts: the chila strawberries being largest, should be set two feet asunder.

Afterwards you may set beans for a summer crop, and plant roses, sweet brier, currants or gooseberries, at every five or six feet distance, as the plants will not begin to bear fruit to any purpose till the following year, and it will be the third year after planting before there will be a full crop; in the mean time the roses, gooseberries, &c. turn to a good account, besides being serviceable to the plants by shading them.

The strawberries should be kept clear of weeds, and, if their blooming season be dry, well watered: early in the spring you must cleanse them, and sling loose earth among them to strengthen their roots.

Of strawberries there are five sorts, the chila strawberry, the hautboy, the scarlet, the red, and the white wood-strawberry.

There are two kinds of raspberries, the red and white; the latter is the greater rarity, and thrives in such ground as agrees best with strawberries, being propagated by slips taken from the roots the latter end of this month or in March.

Raspberries should be planted in single rows, about a foot or eighteen inches asunder, and three feet between every row, leaving the heads two feet high when planted.

The Muscovy clustered raspberry, planted against a wall between the trees where there is a vacancy, will ripen very soon; and their chief culture is to keep them clean from weeds in the spring; to prune the tops of the strongest shoots of the last year, leaving them about three feet high; and to cut away all dead and weak branches.

The gooseberry is propagated either by seeds, suckers, or cuttings; the first may be sown as soon as ripe, and will come up the spring following; the suckers are taken from the roots of old trees when their leaves are fallen, and transplanted in nurseries, in open weather; and the cuttings will take root, being planted in the months of September or October.

This tree requires a strong holding soil, and may be transplanted with more safety in October than at this time of the year.

Currants are to be raised in the same manner as the gooseberry, and thrive best in the same kind of soil.

Liquorice should be planted at this season of the year; and the ground made choice of for planting it should be trenched three feet deep, and the liquorice set at a foot distance every way.

## M A R C H.

### FLOWER-GARDEN.

THE rose campion is propagated either from seeds sown this month, or from slips taken from the roots: the double-blossom kind is raised from slips only, as it does not produce any seeds; the last-mentioned thrives best in a loamy soil, and open exposure.

In this month also off-sets of the white hellebore are planted in a rich light soil.

Seeds are now sown of the fox-glove, which succeed best in the shade and a loamy soil; this flower does not blow till two months from the time of sowing.

The poppy, which is an annual, is sown in spots; as is the Venus looking-glass: the latter is proper also for edgings.

The valerian is raised from seeds, and some kinds of it are increased by parting the roots.

The primrose tree will grow in any soil, and the seed of it is sown in the natural ground towards the end of this month: it is very proper for the middle of borders in large gardens; and the seedling plants, which will not blossom till the second year, are to be sown in the nursery, and the young plants removed to proper places in the August after they come up.

Slips of the gentianella are planted in a sandy soil in this month or August.

Cardinal flowers are raised by seeds sown in hot-beds, in fine sifted earth; and the seeds being small, are to be lightly covered with mould: these flowers, which are commonly cultivated in pots, may be increased by parting their roots in April, and planting them in places well exposed to the sun.

You should now sow the seeds of the stock-gilliflowers, and transplant them in the August following, in a light natural dry soil.

The double kinds of this flower may be increased by slips or cuttings planted in May, June, or July.

Sow the seeds of the acanthus, in a sandy soil, and in the shade.

A loamy soil is requisite for raising the double rocket flower, which is propagated from slips taken from about the root.

The scarlet lynchis is propagated either from seeds, or slips taken from the root; it is also cultivated in pots, and requires a loamy soil, and open exposure.

The several sorts of double wall-flowers may be raised from slips planted in shady places, either in March, April, May, or June; but the bloody wall-flower may be more easily raised from seeds sown in this month: and a sandy soil is requisite to make them thrive.

The monk's hood, a flower of a poisonous quality, is propagated by parting the roots, which should be done in this month, and will thrive best in a loamy soil, in the most shady place in your garden.

The sun-flower, which will grow in any soil, is raised from seeds sown in large borders; and also by parting the roots, either in this month or in August.

The asters, or starworts, will thrive in any soil, and are fit companions for the tallest flowers in your garden: they are propagated from slips taken from the root; and the best method is to plant them in pots, otherwise they will grow so numerous as to become a nuisance rather than an ornament.

Seeds or layers of the passion-tree may be sown this month; and every cutting of it, being planted in fine earth, will take root about May or June.

This tree is a prodigious quick grower, and very hardy; loves moist and cool places; and, if constantly watered, and dunged about the roots, it will bear fruit resembling lemons.

The arbutus, thrives in a light, gravelly soil, and may be raised either from seeds or layers; and the fruit (which must be gathered about Christmas, and laid to dry for

a month) is to be sown in pots of light earth, and covered about a quarter of an inch with fine mould in this month; and the gentle heat of a hot bed will greatly assist the germination of the seeds, which are to be frequently sprinkled with pond-water as they come up.

The layers of the arbutus are made of the most tender shoots about September; but will not be strong enough to transplant the spring following, though they will take root in a year's time.

The apocynum, or dog's-bane, is propagated from seeds sown this month in hot-beds, or from cuttings; a light natural soil agrees best with them; they should be watered but seldom, and then gently; and they should be set in the hot-house sooner or later, as they are more or less tender.

Set the stone of the fruit of the palm-tree this month in light earth, and give them the assistance of the hot-bed: it is a green-house plant, but might be made to stand abroad, after sheltering for three or four years.

The green privet, which is a plant of a quick growth, and makes an admirable hedge, is propagated by sowing the berries in light earth, about an inch deep, watering them frequently till they come up; a hot gravelly soil is the most proper for this tree; and they are to be transplanted from the seed-bed the second year after sowing.

The mezeron, should now be sown in a loamy soil, and care should be taken to preserve it from the birds.

The berries of the juniper-tree may be sown this month in rich ground without watering, or in any light manure, and in about two months they will come up; and they are to remain in the seed-bed two years, during which time they must be kept free from weeds, and then they may be transplanted.

You may now take off the suckers of the *Spiraea fruticosa*, and plant them in a light soil.

Sow the seeds of the several kinds of firs ornamental in wilderness-works, which will flourish in any soil; in order to keep their bodies smooth and free from knots, you must break off their collateral buds while they are young and tender.

Upon the hot-bed, sow such exotic seeds as are less tender, and arrive sooner at perfection than those sown the last month; among which are the China or Indian pink, the *nasurtium Indicum*, *convolvulus*, and balsamines; and none of these must be planted in the natural ground till the middle of May: if you have no hot-bed, you may defer growing the marvel of Peru and the *nasurtium* till the next month, when they will come up in the natural ground.

Plant tube-roses in pots of fresh earth; giving them a gentle warmth, but no water till they sprout out of the ground.

The seeds of the *campanula pyramidalis* should now be sown, and slips taken off from the roots; fresh air should be given to the pots of this flower, and they should be set in some pit where the sun may come at them, by which means they will grow tall.

Mend and repair your shelves and places of shelter for auriculas, which should now be guarded on all sides but the east from the sun, and defended from rain; put canvas coverings or mats over your tulips, to prevent their

being blighted; and transplant your carnation layers for blowing, if they were not planted out in autumn.

The seeds of the humble and sensitive plants may now be sown upon the hot-beds; and the *noli me tangere* in the natural ground.

You may transplant your evergreens; graft the Spanish white jessamin upon the common English sort; and slip or set box for edgings, or in figured works.

Such exotic plants as have suffered in the green-house, should be removed to the hot-house; where, to prevent the steam of the bed from being of bad consequence, the dung should be covered with a due thickness of earth.

#### FRUIT-GARDEN.

You may make layers of the vine either in this or the next month, and they will be fit to transplant at Michaelmas; this tree is also propagated by laying down the young branches as soon as the fruit is gathered, or by making plantations of cuttings at that time.

If the weather proves open in February, that is the best time for planting vines; and the soil in which they best succeed is rocky or gravelly.

A chalky hill, lying very open to the sun, will produce better grapes than any of the rich soils prepared with horse-dung; but a tolerable good compost, to mix with the earth about the roots, may be made with the rubbish of old buildings.

In planting a vine, let the places where your vines are to stand be open and prepared before any of the plants are taken out of the nursery, when great care should be taken in their removal; they are to be planted six or seven feet every way, and the best grapes for a vineyard are the marlmore, chianti, claret grape, and Burgundy black morellon.

These vines are to be pruned the September before transplanted, according to their strength, leaving not more than four buds on the strongest; and to cleanse them from weeds is all the care they will require the first summer.

Shorten the summer-shoots about the end of September, and the strongest of them will begin to shew a little fruit the summer following.

In May or June of this second year, the small shoots and superfluous branches are to be carefully broke off, and two or three shoots only preserved on each vine, which should be supported by stakes or poles, till the September following, (for the nearer the grapes grow to the ground, provided they do not touch it, the sweeter they will be) and then they may be shortened.

The vineyard, thus planted and managed, will, in five or six years time, produce a good crop of grapes.

The fig is raised either from layers, seeds, or suckers; the layers are ordered like those of the vine; the seeds are sown in rubbish, or such like soil; and the suckers are separated from the old roots the beginning of this month, and transplanted without cutting off their tops.

The fig tree thrives in the same sort of soil as the vine, and may be planted either against walls or in standards.

The pruning of this tree is very different from that of

of other fruit-trees; for as the practice is to take away the small branches in pruning other trees, so here it is to be avoided, because the fig puts forth its fruit chiefly at the extremities of the last year's shoots; but you may cut off some of the weak smaller shoots which do not promise to bear, so as you do it close to the great wood.

The branches must not be suffered to grow too high, as they are prevented by that means from being full; the new thick branches must be shortened yearly to about a foot, and the bud at the end of the branches broken off in the spring time, which will cause the figs to shoot out more early, and instead of a single branch there will be two.

The pruning season of the fig is towards the end of this month; and it is best in the summer to let this tree have some liberty from the wall, and not suffer it to continue close tacked to it like other fruit-trees; but in the winter some of the straggling branches should be cut off, and the best and biggest branches tacked to the wall in November, that they may be more effectually settled, and sheltered from the frost in the winter by the defence of a mat, or otherwise, especially when the season is very cold.

The suckers which this tree puts forth in great abundance, must be kept down, and whatever you cut away, must be as close to the great wood or roots as you can; and a whole tree may, after an unkind winter, be cut down for the recovery of its former state of health.

The following is the method of making the horizontal shelters for fruit trees: Lay rows of tiles in the structure of the wall, at certain distances one above another, the tiles jetting forward, and hanging over the plane of the wall about an inch and a half; this is neither a difficult nor a chargeable work, if the wall be of brick, to place between every two rows of bricks these horizontal shelters of tiles: and if the wall be of stone, and the joints be any thing regular, it is not less easy.

In order to avoid the inconvenience of branches riding over the edges of the tiles, in each row, at convenient distances, must be left void places or gaps, for the wood branches to pass through; which gaps are to be left wider at the bottom than at the top of the wall; and the rows of the tiles are not to be laid exactly horizontal, but rather a little sloping, the better to shoot off the water from the fruit.

Blossoms and tender fruit are more especially preserved by these horizontal shelters, than by mats, or coverings, of any kind whatsoever; and by their assistance a good quantity of the choicest fruit may be depended on in the most difficult and unseasonable year.

#### KITCHEN GARDEN.

DIRECTIONS have, in the month of January, been given how to sow pease in drills, or lines, and to earth them when they come out of the ground; when beans may be planted three feet asunder between the rows, and the large peas four feet, being set about five inches apart in a stiff soil, without any manure, kept clean and watered about the time of their blossom.

Thyme is raised either by seeds sown in this month or April, or from slips planted at the same time.

Sage is also propagated from seeds or slips, but most commonly from the latter, taken from the roots at the end of this month, or the beginning of the next, and planted, in light earth, a foot apart.

Of marjoram there are two sorts; one of which is called winter sweet marjoram, and propagated by planting the slips about March or April in moist ground; and the other sort is sown annually on hot-beds.

Camomile and penny-royal are propagated from slips planted in this or the next month, in stiff soil and in a shady part of the garden.

Fennel is raised from seeds sown in this month in the natural ground; as is parsley, dill, &c.

Mint and balm will grow any where, and are propagated by parting their roots in any time of the spring as well as by sowing.

Mint is more generally propagated than balm, and when it is about a foot high you may cut it in branches, and dry it in the shade for winter use.

Rue is a plant which is multiplied by slips set in a light soil, and should have a place in the shade.

Tansey is a plant, which should always be kept dry in winter, and is increased by parting the roots in the spring.

Sellery is a hot herb, and raised from seed sown in this month, or April; in some well exposed place in the garden; it must be planted out about six weeks after it is come up in beds, allowing six inches distance between the plants, and they may remain to the middle of June, at which time some of the first sowing will be fit to plant in trenches for blanching, in a light rich soil.

Your trenches must be eight or ten inches wide, and of the same depth; in which the plants are to be put as soon as made, after having pruned off their tops and roots; place them at five inches distance; as they increase in growth, earth them up within four or five inches of their tops. Endive may be sown in this month, but April is the more proper time; a light soil agrees best with it, and when it has been come up about six weeks, plant it in beds as directed for sellery, and about the middle of July plant it in rows about six inches apart.

When it is well grown, tie up some of it to whiten; which work should be continued every ten or twelve days.

Purslane is sown in this month, and glasses are used to help it forward; and in April it is sown in warm places.

Sorrel is sown in rows or drills, like other fallading.

Of spinach, in March, April and May, you are to sow several parcels of ground at different times, about a fortnight from each other, as a constant supply for the table, till there is plenty of other greens.

There are two sorts of spinach, the prickly sort, and the round spinach, both of which thrive in a light rich soil; and such as is intended for winter use must be sown in August.

Chives are raised by off sets from the roots, planted at six inches distance, cutting off their branches at the time of planting; they succeed best in a light, rich ground; and the oftener they are cut, the smaller and finer they are.

Tarragon

Tarragon is raised from slips and seeds; the slips are taken from the root, and planted in this month in as warm an exposure as possible.

Artichoke seeds are sown about the beginning of this month, and planted out in April; and the middle of this month is the most proper time to slip the roots for new plantations; for they are raised by suckers as well as seeds.

When you have severed the slips, three heads are to be left growing upon every old root; and these slips are to be planted two feet apart, in lines four feet distance from each other, and well watered after planting.

Artichokes thrive best in a strong rich ground, exposed to the sun, with dung well mellowed in it: when they blossom the first year, the roots are endangered; you may therefore break off the blossoms, and about the middle of July break off the stems of the old roots that have done blowing, by which means you will furnish yourselves with fresh shoots.

The seeds of the cabbage and lettuce of all kinds may now be sown in the open ground among the crops; a light rich ground and a warm exposure agrees best with them; and that there may not be wanting a supply of them, they are to be sown every month from March to August, when the winter crops are to be put in, which should be planted out three weeks after they come up, at about five inches distance.

Such as produce large cabbages early in the spring may be permitted to stand for seed, and are to be staked up and defended from the wind; the seeds will be fit to gather as soon as they begin to shew their down, and then the plants are to be pulled up and set to dry in a green-house.

The cauliflower seed is sown in some well-exposed corner of the garden, where the young plants may be sheltered; and about the middle of April, when they are in their first leaf, they are to be planted in a nursery about five or six inches asunder, and there continue till the latter end of May, or June, when they are to be transplanted abroad for your crop, which should be done in moist or rainy weather; or if it be a dry season, holes are to be made in the ground, about three feet apart, and to be well watered before you plant the cauliflowers, which will make the plants shoot, being also frequently watered afterwards.

In the autumn following they will bear large flowers; but some of them will not flower till after Michaelmas, and such plants may be taken up with the earth round their roots, and set together in the green-house, or some such place, where they will enlarge themselves, and be fit for use in the winter.

To raise summer cauliflowers, you must sow the seed the beginning of August, upon some decayed hot bed; and as soon as they have put out their leaf, transplant them about three inches distance, upon some other bed: in the middle of September draw out every other plant, and set them six inches apart under a south wall, to stand there till spring, when they are to be planted out for flowering; or you may set them in the places where they are to blossom, covering them with glass-bells in the winter.

If the weather is open, the first week in this month

Vol. II. No 54.

The

you may sow asparagus; and the seedlings will be fit for planting out the February or March following.

The following is the method used by the best gardeners to produce a natural crop.

After measuring out the ground, allowing four feet for the breadth of each bed, and two feet for the alleys between the beds; open a trench at one end, and lay into the bottom of it horse-dung about six or eight inches thick; then go on and trench the same quantity of ground lying next to the first trench, throwing the earth of the second trench upon the dung at the bottom of the first, and thus continue working till the whole is done.

Having finished your beds, plant asparagus, taken fresh out of the nursery, in lines at eight or ten inches distance, spreading their roots, and covering their buds with earth about four inches thick; each bed takes up four rows; and when they are all planted, sow the whole with onions, and rake it level, for the alleys will not be of any use till after Michaelmas, when the onions will be off, and the shoots of the asparagus plants made that summer are to be cut down, the alleys dug up, part of the soil thrown upon the beds, to raise the earth about five or six inches above the buds of the plants, and the alleys supplied with dung, or some rich soil.

In March following the earth must be raked down; and the alleys are to be turned up every winter, and now and then enriched with dung.

When Michaelmas is past, you may cut down the haulm, and give them their winter-dressing; and you should not be later than the middle of March in raking and laying down the beds.

It is a general rule, not to cut any of the asparagus till the fourth year after planting; but where the plants are strong, a few may be taken here and there in very small quantities the third year.

The asparagus appears above ground the beginning of April, and may be cut till the beginning of June, when they have stood five years; but if they are younger, you must not cut them after the middle of May.

No buds that appear above ground should be suffered to grow in the cutting season, unless they proceed from fresh plants, to make good deficiencies; and those must be suffered to run up every year, till they have gathered strength: it is best to cut them downwards a little sloping with a knife made blunt at the point.

## A P R I L.

### FLOWER-GARDEN.

In this month, and the beginning of May, the seeds of the carnation are to be sown in a compost made of sandy loam, and well-consumed melon-earth, two loads of the former to one load of the latter; sift them well together, and let them lie in a heap for a time to mellow; then sift it a second time either to sow the carnation-seeds in, or to plant your layers or roots of them upon.

Having filled your pots with this earth, and smoothed them on the top, sprinkle on your seeds; and covering them with the same compost, press it gently with a board, and let them stand exposed to the weather.

The seed will come up in about three weeks; and in the July following the young plants will be big enough to transplant into beds, where they must be set about ten inches distant from one another, and shaded from the sun with mats for about three weeks.

You may find many varieties from the seedling plants in the second year; and whatever rarities appear, they must be laid down as soon as possible, by cutting half through a joint, and splitting the internode upwards, half way to the other joint above it; then the wounded part must be buried in the earth, and fastened down till it takes root, which, provided the earth is light, will be in about two months.

The most proper season for laying down the layers of the seedlings is in July; and when planted they must be carefully guarded, both from the intense heat in summer, and the chilling frosts in winter.

The flower stems will begin to put forth about April, when each flower must be supported by its stem being tied to a stick about four feet long; and as soon as the flower-buds appear, leave only one or two of the largest upon each flower stem, to blossom; and about ten days before the flowers open, the round poded kinds will begin to crack their husks on one side, when you should split or open the husk on the opposite side to the natural fraction with a fine needle; and three or four days before the complete opening of the flower, you must cut off the points on the top of the flower-pod, and supply the vacancies on each side of the husk with two small pieces of vellum, which may be easily slipped between the flower-leaves and the inside of the husk, by which means the flower will make an equal display of its parts, and the form of it, consequently, be entirely regular.

When the blossom begins to shew its colour, you should fix a piece of flat board upon the sticks, to shelter it from the sun's extreme heat.

The seeds of the carnation must be gathered towards the end of September, in dry weather, and be exposed for a month or two, through a glass, without opening the husks till the time of sowing the seeds comes round again.

The seeds of the columbine are sown in the nursery this month, from whence you may remove the choice plants to the garden, and next year they will yield flowers: the roots of this flower will hold good for three or four years, when you must have a supply of fresh ones.

The seed of the scarlet bean is annually sown in good ground, well exposed to the sun; and sticks should be fixed in the ground, round which they will twine, and make a very agreeable shew.

The amaranthus is an annual, sown on a hot-bed; and the seeds being sown in this or the preceding month, in the hottest part of your garden, are to be raised under glasses.

The African marygold is also an annual, raised on a hot-bed.

#### FRUIT-GARDEN.

You should now carefully weed your beds of strawberries, and take off their runners; and if the season is

dry, it will be proper to water them, for they produce but little fruit when this is neglected.

Lay the branches of the peach-tree horizontally, and keep them free from great wood, and perpendicular shoots in the middle, that the sap may be carried in such due proportion as is necessary; and it should be ever observed, that too much vigour is as pernicious as too little, with respect to the tree bearing a sufficient quantity of fruit.

When a pear or apple-tree is ungovernable, and will not bear fruit, strip off the bark of the strongest branches half an inch, or an inch, according to the bigness of the tree, and take it entirely away to the wood.

These branches will continue to bear fruit for several years; and when they die, there are always in a pear-tree a sufficient number of others to succeed them, especially in the middle of the tree; which, if ungovernable, ought to undergo the same kind of discipline.

This work, which should be practised only on low dwarfs, or wall-trees, is best done in March or April.

Cherry-trees, not in a thriving condition, should now be slit perpendicularly down with the point of a knife, just entering the bark of the stem of the tree, to prevent being hide-bound; after which operation they will thrive and prosper wonderfully, when, for want of it, they will continue almost barren for ten or fifteen years.

At this time you should look carefully to your young fruit-trees which were planted in the spring, observing to water them in dry weather; and if you observe the leaves beginning to curl up, you should water them gently all over their branches; which may also be practised to great advantage on old trees; but it must not be done in the heat of the day, lest the sun should scorch their leaves, nor too late in the evening, especially if the nights are cold.

Where you observe the fruit-trees to be greatly infested with insects, you should wash the branches with water, in which a great quantity of tobacco-stalks have been steeped; which, if carefully done, will infallibly destroy the insects, and not do any injury to the trees; or if the leaves which are curled are taken off, and some tobacco-dust thrown on the branches, it will destroy the insects, and may, in a day or two, be washed off again.

Towards the end of this month, you must look over your espaliers and walls of fruit-trees, training in the regular kindly shoots in their proper situation, and displacing all fore-right and luxuriant ones.

In the middle of this month uncover those fig-trees which were screened from the frost in the winter; but do it with caution, as the young fruit, which now begins to appear, may be greatly hurt by being exposed to the air too suddenly.

#### KITCHEN-GARDEN.

The middle of this month is the proper time to plant out melons, which are to be raised under paper; in making these ridges, if the ground is dry, the dung should be but a half a foot higher than the surface of the ground, and the earth should be laid at least a foot and a half thick upon the dung, that the plants may have depth enough to root; they will require no watering, after they are well

well rooted, and hereby a choicer sort of melons may be generally obtained; which, in the common method, frequently miscarry, or produce but little fruit.

The alleys between these beds should be afterwards raised with dung and earth to the level of the beds, that the roots may have room to extend on each side, for the roots of these plants spread as far in the ground as their branches extend on the surface.

Of kidney-beans we have two sorts; the one, which is called the Battersea-bean, bears early, and near the root, without running high; and the other, grows near six feet high.

We sow these beans, the first week in this month, about four inches apart, in drills from north to south, in a light fresh soil, covering them with earth, raised in a ridge, to keep the wet from them: the lines of the Battersea-beans should be two feet apart; and the other sort are to be sown in rows like rounceval-peas, having alleys between them two feet and a half wide; the former kind need not be staked, but the others will not bear well unless they are staked.

From the first sowing in this month, you may, once every three weeks till the middle of July, continue to sow fresh ground with kidney-beans to succeed one another; observing, that when the ground is very dry, as in June and July, and the weather hot, you must water the drills as soon as you have opened them, before you put in the seed, which will contribute to their vegetation; but after they are sown, you must avoid watering them.

Toward the end of this month, you may sow the nonpareils, and the Spanish morotto-peas, about two or three inches apart in lines, leaving a space of three or four feet for alleys, till the whole is sown; and when they grow up six inches high, earth them up, and set one row of sticks or boughs about six feet high, on each side, for them to run up, and you will have a plentiful crop.

The charlton, or mallow-hotspur, should be sown in December, for the first crop, in drills about two or three feet asunder, the lines running from north to south: a second crop of the same kind of peas should be sown in February; and in March we may put in a third crop of the same sort.

Some ground may be prepared about the beginning of April for the dwarf-peas, which seldom rise higher than half a foot, and are to be set four or five inches apart, in lines about eighteen inches distant from one another; and in order to have a constant supply of young peas, there is a sort of dwarf peas which may be sown in May or June, in edgings upon a gentle hot-bed, the first week in September, and will produce peas in the winter.

Spanish chardons may now be sown in the natural ground; you are to make holes for the seeds about five or six feet distance, and put four or five seeds in each hole: and when they are come up, leave growing only one strong plant in a hole for blanching.

Lavender and rosemary are raised from slips planted in this month, which take root almost immediately if they are shoots of the last year, but if they are older they will not grow: these plants should be set in a light sandy soil, in the warmest and driest part of the garden.

## M A Y.

## FLOWER-GARDEN.

The ficoides, which is propagated by the cuttings, being planted abroad in a natural bed of earth in this month, will be fit to put in pots in August, where it may remain in open air till the latter end of September; some kinds of this plant being annual, must be raised from seeds every year; and one sort of it will stand the winter, if we raise young plants of it about July or August, that do not blossom in three or four months.

The shrub-kinds, which have their stalks woody, will bear moderate waterings; but the others, which are more succulent, must have very little water. These plants must be exposed to the sun, which will open their blossoms, unless it be two kinds, which only flower in the night. The cuttings of these plants should not be planted before the wounded parts have been dried a day or two in the sun.

The torch-thistle is a succulent plant, raised from cuttings planted between May and the end of July, upon a little hill in the middle of the pot, for they can hardly endure water: and before they are put into the hot bed, they must stand abroad about twenty days to take root; their waterings must be seldom, and gentle: and the best compost for this plant is, the rubbish of old walls, mixed with about one third of sandy soil. The sidums, especially the tree-kind, are easily propagated from branches set in the earth in a light sandy soil, either in this or any of the summer-months, giving them a little water, and as much air and shade as possible in the summer; and in the winter no water at all.

There are several sorts of the geranium, which are raised by planting the cuttings, this month, in natural ground, where they will become proper for transplanting the August following; and from seeds sown in March on hot-beds. Those planted in the natural ground require a medium soil without dung, must be frequently watered, and housed with the orange-trees.

The anemum Plinii is raised from cuttings planted this month in the natural ground: during the summer it must stand in some place defended from the sun, and be constantly supplied with water.

Cuttings of the Arabian jessamin may this month be planted in a sandy soil, and is more injured by wet than cold. At the time the cuttings are taken from this plant, it should be pruned to within six inches of the last year's shoot, and have fresh earth put to the roots; by which means it will shoot near a foot in the ensuing summer.

Layers of the myrtle-tree should be made this month: the youngest shoots must be bent into the earth, after it is well stirred; and being often refreshed with water, will take root, and be fit to take off from the mother-plants in the spring following. In July, the cuttings of this tree are planted, stripping off the leaves, two inches from each cutting, and setting them that depth, about an inch apart, in pots of fine light earth, watering them frequently till they have taken root, which will be about the latter end of August; and this young plantation is to remain till the

the second of March before they are to be transplanted into pots. About the middle of April you may prune, and put earth about the roots of such old myrtle-trees as are in a bad state, and cut the branches off their heads within three or four inches of the stem.

The melianthus is a plant propagated with ease from slips taken about the roots any time between this month and August, planted in a sandy soil, and frequently watered.

The pyracantha is raised from cuttings, planted in May or June, in pots of fine earth, and watered frequently, keeping them from the sun till the following winter, when a warm exposure will be serviceable to them. This tree may also be raised from layers and seeds, and thrives best in a dry gravelly soil, unmixed with dung or any other rich manure.

The oleander plant has many varieties; the most common of which is the scarlet oleander, which being of a hardy nature, may be kept abroad all the winter under a south wall; but the sweet-scented oleander is more tender, and should be housed with the orange-tree. These shrubs are raised by layers in this month or the next, in a medium soil, and with moderate watering, and will take root to transplant the August following.

Orange and lemon trees may this month be removed and transplanted without danger, as well as brought out of the conservatory: upon bringing out your exotics, and other plants, brush and cleanse them from the dust they have contracted in the house, give them fresh earth on the surface of their pots, and water them well, when they are placed in the order they are to stand. When you transplant or remove orange-trees, you are to do it carefully, without injuring their bodies; let the cases for your trees be filled with a composition of two parts in sandy loam, one part rotten dung, and one part white sand; and when your orange-trees are so removed, give them frequent waterings, but without wetting either the stem or the leaves; set them in the shade for a fortnight, and let them have the sun by degrees; as, when it is too hot upon them, it turns their leaves yellow.

#### FRUIT-GARDEN.

In the beginning of this month, look carefully over your wall and espalier trees, and take off all fore-right shoots, and such as are luxuriant and ill-placed; and train such kindly branches as you would preserve regularly to the wall or espalier, which will prevent your trees from growing into confusion.

Fruit-trees may be transplanted in the summer months, from May to August, even when the trees are in blossom: the method of transplanting them is, by preparing holes for them before you begin to take them up; and the earth taken out of the holes you are to make very fine, and mix with water in large tubs to the consistence of thin batter, with which each hole is to be filled for the tree to be planted in, before the earthy parts have time to settle or fall to the bottom. A tree, thus planted in batter, has its roots immediately closed, and guarded from the air; and as the season now disposes every part of the tree for growth and shooting, it loses very little of

its vigour if you are careful of its roots, observing to wound but few of them at the taking the tree out of the ground, and not let them dry in the passage from one place to another. Though this way is of use in summer-plantations, yet in the usual winter-plantations it is pernicious, as it will then chill and rot the root of your trees.

As the cutting and wounding some roots of a tree, and among them of the capital ones, cannot be avoided, a mixture of gum has been contrived to plaister over the wounded parts of the great roots, and prevent the air and wet penetrating too much into the vessels of the roots; and if the root be very large, you may at the same time mark its corresponding limb or branch in the head, to be cut off about a fortnight afterwards in the same proportion, and then to be plaistered in the same manner as the root was done before.

In the removal of trees, care must be taken that it be sudden; for if the roots are permitted to grow the least dry, we may presently discern a failure in the top-branches, which will require time to redress; for which reason, it has been thought impossible to remove a large tree to any considerable distance.

There is one convenience in this last way of planting, which is not in the common way; and that is, that the tree may be taken up without any earth about the roots, which makes the transportation more easy; and by this method, and the assistance of prepared gums, peach trees, nectarines, pear-trees, plumb-trees, and cherry-trees, with fruit upon them, either green or ripe, may be removed, though the trees are six or seven years old; and trees of all sorts may be thus transplanted in the summer.

#### KITCHEN-GARDEN.

You may now give your melons air in the middle of the day, and look to your melon-ridges, weeding them, and carefully pruning off the water-branches, which are known by their flatness and extraordinary breadth; it is also necessary to pinch off the tops of the runners that have fruit upon them, having three or four joints above the fruit, and taking care that the fruit be well sheltered with leaves from the power of the sun, otherwise their growth will be spoiled; but when the growth is perfected, you cannot expose them too much to the sun for ripening. If the season be dry, rather float the alleys between the melon-ridges, than pour water upon the plant, or near the stems.

About the beginning of this month, sow cucumbers in the natural ground, both for salad and pickling: in sowing those for salads, put about twelve seeds in each hole; but leave only four or five when they come up; let the earth be fresh, and well worked with a spade, rather light than stiff; and a plantation of this kind will produce twice as much fruit as one of the same quantity of ground forced with dung.

To raise cucumbers for pickling, sow them in a drill, as you do pease or French beans; and put a row of bushy sticks on each side of them: the rows must be four or five feet asunder; and if sowed in the south border, where

where there is a vacancy, and nailed against the wall, they will grow straiter and finer flavoured than those on the ground.

Replant imperial and Silesia lettuce: sow some of the white and brown Dutch cos-lettuce, to be planted out for cabbaging in June: sow radishes and endive very thin, to be branched without transplanting; and you may also sow purslane and cabbage-seed; transplant cauliflower-plants; make your first drills for sellery, if your plants are large enough. Plant out cabbages and beet-chard; and you may yet sow thyme, sweet marjoram, and gilly-flowers.

You should now be very careful to destroy weeds before they shed their seeds; destroy also the nests of caterpillars and other insects which annoy your trees; prune off all crumpled leaves, for they harbour the worst of vermin; and if the weather be dry, water new planted trees, asparagus, &c.

## J U N E.

### FLOWER-GARDEN.

THE leaves of the saffron crocus appear as soon as the flower is past, and remain all winter, which in the spring should be tied together in knots to help the increase of the roots; and these will be fit to remove or transplant about Midsummer. This plant delights in chalky ground, but it will prosper also in a sandy soil; and the pistillum contains the saffron used in medicine. The roots of the several kinds of crocus may be taken out of the ground in this month, and replanted with other bulbs; they love a light soil, and may be increased by off-sets.

The cyclamen is propagated from seeds sown as soon as ripe, in a light soil, and transplanted in Midsummer when their leaves are decayed; and it is a general rule, that all bulbs may be safely transplanted, when their flowers and leaves are decayed.

The colchicum thrives best in a sandy soil, and will only bear transplanting about Midsummer, when the roots are entirely at rest. There are many sorts of aloes, the most common whereof are brought from America; but Africa produces the greatest variety, where they grow upon rocky ground; therefore the earth proper for them is to be made with one half sandy soil, and the other rubbish of old walls, mixed and sifted together; you should plant them shallow in the pots, raising the earth about them, so that the plant may, as it were, stand on a hill; and when you water them, do it without touching any part of the plant, otherwise they will be in danger of rotting; the off-sets of the aloe may be planted in the latter end of this month, and the beginning of July, when they should be suffered to stand abroad for about nine days; and they may be helped with a hot-bed as soon as they begin to take root; if the weather be fair while the aloes are abroad, their earth being dry, will require watering once a week; and from the time of their being housed till the middle of October, gentle refreshments may be given them while the sun is upon them in the morning; but from October to March, they must be kept very dry. In May they should be transplanted,

VOL. II. No. 54.

without disturbing the roots; the seeds of many kinds of aloes ripen in Britain, and may be sown in April upon hot-beds. The fritillaria is propagated by planting their branches in a natural bed of earth any time between June and August, and they will soon be fit to plant into pots; they succeed best in the same sort of earth as the aloe.

The Indian fig is raised by planting its leaves singly about two inches deep, in pots of earth composed of lime, rubbish, and sandy soil, after their wounds are dried, and letting them stand abroad till they take root, and then they may have the help of the hot-bed; you must give these plants a good deal of the sun, and the leaves should be planted during the summer-months.

### FRUIT-GARDEN.

THE inoculation of fruit-trees now demands the attention of the gardener, and the following is the most approved method of performing the operation. About Midsummer take off a vigorous shoot from any tree you would propagate; and after having made choice of a stock of about three or four years growth, in a smooth part of it make a downright slit in the bark, a little above an inch in length, and another crosswise at the top of that, to give way to the opening of the bark; then gently loosen the bark from the wood on both sides, beginning at the top; which being done, cut off your bud with a penknife, entering pretty deep into the wood, as much above as below the bud, to the length of the slit in the stock: after the bud is thus prepared, take out the woody part of it (carefully preserving the eye of the bud) then put it in between the bark and the wood of the stock at the cross slit, putting it downward by the stalk, where the leaf grew, till it exactly closes; then bind it about with coarse woolen yarn, the better to make all parts regularly close, and the bud incorporate with the stock: in three weeks time the bud will be incorporated with the stock, when you must loosen the yarn, that it may not gall the place too much: the quicker this operation is performed, the better; and you must put two buds into one stock, in inoculating nectarines and peaches. If the buds inoculated this month do not hit, you may make another attempt in the same year, and on the same stock. The proper time for inoculating is from the beginning of this month to the latter end of August; and care must be taken that the branch and shoot made choice of for inoculation, do not lie by, but that they be used as soon as cut.

You may upon one tree, bud peaches, nectarines, apricots, plumbs, and almonds.

### KITCHEN-GARDEN.

KIDNEY-BEANS, radishes, lettuces for cabbaging, and endive, may now be sown; as may also the large sort of peas, about five or six inches apart, allowing three or four feet distance between the lines, and they will in September afford a good crop.

Replant cabbage-lettuces; transplant-leeks in light rich ground, and at six inches distance from each other; and if the weather be dry, you may gather herbs for drying a-

†

7 D

gainst

gainst the winter, such as lavender, rosemary, sage, mint, sweet marjoram, thyme, &c.

Take especial care to preserve your plants from the scorching sun; stir up stiff ground; continue to destroy weeds; and give your plants gentle waterings about their extreme fibres, which should be done at the close of day.

## J U L Y.

### FLOWER-GARDEN.

THERE is little to be done in the flower-garden this month: the berries of the coffee-tree which are now ripe, may be sown, first cleaning their seeds from the pulp, in pots of fine earth, about an inch deep; and if you give them the help of a hot-bed, in less than six weeks time they will sprout.

The fruit of the ananas being ripe in this month, if you cut off the crown of the leaves which grows on the top of it, and plant it in a light sandy earth, it will, with the assistance of a hot-bed, presently take root.

Anemony seeds, now sown, must be sprinkled with water frequently and gently.

### FRUIT-GARDEN.

THE management of the vine should this month be chiefly attended to: it is to be observed, that from a vigorous shoot of a vine already once pruned, there will push again several Midsummer shoots weaker than the former, from the first, second, and third bud towards the extremity; which shoots are to be taken off, only remembering that it is proper to spare the last of such shoots so far as to leave one bud upon it, from whence, in Autumn, nature may a third time exert herself; for if those shoots were all entirely removed, the vine would push at those bearing buds which lie at the bottom of the shoots; in consequence of which, there would be either a want of fruit at those places next year, or a necessity of pruning the branch shorter than was intended, or is in the winter convenient.

There is no danger in exposing the grapes this month to the sun; for though the vines appear thin of wood and leaves, the Autumn shoots will recover that fault.

Put nets over your grapes to preserve them from the birds; and you should also guard against wasps and other insects, which now destroy the peaches, apricots, and other fruit; by placing phials of honey and ale near the trees, you may soon entrap a great number of them.

### KITCHEN-GARDEN.

You may now sow kidney-beans, and some peas, to bear in September and October; sow cucumbers upon a bed made with dry horse-litter, and covered with light earth ten inches thick; they must be covered at night in September with a common frame and glass, to keep them from frost and rain, and by this method you may have some cucumbers till Christmas.

Make a bed for mushrooms as directed in February; and be sure to cover it very thin with earth.

About the middle of this month sow royal Silisia, and brown Dutch, white goss, and other sorts of lettuces, chervil, carrots, and turnips.

Plant cabbages, and favoys; transplant endive for blanching against winter; earth up fennel in drills, and plant out a new crop to succeed the former; take up shallots, garlick; and water plentifully all herbs that are seeding.

## A U G U S T.

### FLOWER-GARDEN.

THE tulip-tree being a plant of the wood, should be among such trees as are designed for groves, where it will rise to a great height: the seeds of this tree come from Virginia, and are to be sown in pots this month, and sheltered the winter, and they will come up all in the spring following.

At two years growth the young plants may be transplanted into single pots, and must have shelter in the winter for the first nine years at least, till they have gathered strength enough to resist the severity of the frosts, when they may be planted in the natural ground, rather a sandy soil than any other.

The iris flower has many varieties, some with bulbous and some with tuberous-roots: the roots of the bulbous iris may be taken up as soon as the leaves begin to wither, and planted in August; and they may be increased by off-sets taken from their roots when their stalks are decayed: the best of the tuberous kind is the the chalcidonian iris, commonly called the toad-flag, which requires a warm and rich soil, and must be carefully ordered, or it will not thrive well.

The narcissus, or daffodil, is a flower of a hardy nature, and thrives greatly in any ground; these flowers are propagated from off-sets from their roots, planted in this month, and may be raised by seeds sown in September, which will produce great varieties: the seedling plants are to remain without removal two or three years, when they are to be taken up in June, and replanted in good ground at a proper distance.

The jonquil is of the same kind with the daffodil, and flowers much about the same time; the roots, which are bulbous, are to be taken out of the ground, and replanted like other bulbs.

The bulbous violet, or snow-drop, is reckoned amongst the daffodils, and is one of the earliest flowers in the spring.

You may now plant off-sets of the hyacinth, in beds of sandy soil; the tuberous hyacinth is a plant of an aspiring head, and very tender nature; the roots of it must be taken up in April, and replanted in pots of prepared earth; and, like other shrubs, it requires the assistance of a hot-bed: you may take up the bulbs of this plant in September, and preserve them in dry sand.

This is the proper time for parting the roots of the lily, which succeeds best in an open sandy soil: the striped

ped white lily is so great a rarity as to deserve a place in the nicest garden, and the orange-lily is a proper companion for it; the lily of the valley is easily raised from plants, and thrives best in shady ground.

The crown-imperial may be raised from seeds, but is commonly propagated from off sets that spring yearly from old roots, which are to be taken up in June when the stalks are dry, and replanted in August.

The work to be done this month, in the fruit and kitchen-garden, is the same as directed in the preceding month.

## S E P T E M B E R.

### FLOWER-GARDEN.

THE tulip is propagated in the following manner: the stems of this flower being left remaining upon the root, will perfect their seeds about July, which will be fit to gather when the seed-vessels begin to burst; and then they are to be cut close to the ground in a dry day, and laid in some dry place till September, when they are to be sown, in a soil composed of natural black earth and sand; and after their second appearance above ground, they may be taken from the pots they were sown in, and put in a bed of natural sandy soil, well sifted, where the thickness of half an inch of the same earth should be spread over them; and thus they are to continue, without any other culture than every year adding half an inch for their covering, till they begin to blow, which will be in five or six years time: in this manner tulip-seeds are every year to be sown for new varieties.

In planting tulips, all the forward blowers should be planted in a bed together; and of the late flowering tulips the tallest sorts should be placed in the middle line of the bed, with two rows of the shorter on each side.

Tulips planted in this month need no shelter till March, when, the flower buds appearing, they should be defended from blights with mats, or other covering; which covering will also serve to shelter them, when blown from the too powerful heat of the sun, and pernicious damps.

There are two classes of tulips; the præcocc tulips or early blowers, and the serotine or later blowers; and these are distinguished by their double and single flowers: they have also different denominations, from their colour and stature, as bagats, which are the tallest flowers, commonly purple and white marbled: agates, which grow shorter, and are veined with two colours; and beazarts, which have four colours, tending to yellow and red, of several sorts.

You may now take up the roots of the peony, part and plant them; they will prosper in any soil.

The seed of the mullein may now be sown, in a sandy soil, and a shady part of the garden; it is a beautiful plant, and blossoms four feet high.

Violets are increased by transplanting their runners either in this month or in February, which will of themselves take root at every joint; they thrive best in a binding soil, shady situation, and should be planted in the most rural parts of the garden.

You may now increase daisies by parting their roots; and they make very pretty edgings for flower beds.

Layers of the honeysuckle may now be put down; they thrive best in the shade, and are most easily trained up in pots.

There are seven sorts of the jessamine: the common white, the yellow, and the Persian jessamine, are propagated from layers or cuttings, and will grow in any soil; the layers are made in this month, and the cuttings may at the same time be planted, which should always be a foot long, and two joints be under ground. The jessamine should be planted against walls or trees, or mixed in hedges. There are jessamines of a more tender nature, which require to be sheltered in the conservatory in the winter, as the Spanish jessamine, the Portugal jessamine, the Indian jessamine, and the Arabian jessamine: these are propagated by grafting on the common white jessamine in March, or by inarching in May, or cuttings planted at the same time: the inarched plants are to be cut off the middle of August following, and in February you are to cut off the branches within four or five inches of the stem; and, after they have fresh earth put to their roots, they may be set near the glasses or windows of the green-house: they succeed best in a medium soil between sand and clay, without dung, and should not be watered too frequently.

The virgin's bower is raised from layers in this month, and from cuttings also: it is of a twining nature, must be supported with stakes: it may either be planted against a wall, or set in the wilderness; and it thrives best in a light soil.

The Virginia dog-wood blossoms early in the spring; and the flowers are succeeded by red berries, which hang a long time upon the tree: the seeds are sown in pots of light earth in autumn, and they are to stand the winter in the green-house, giving them the assistance of the hot-bed the following spring.

The Virginia myrtle, which bears berries, from which is drawn the green wax whereof candles are made, is propagated by sowing the berries in pots of black sandy earth, which should be kept continually moist.

The saffra-tree is a plant of Virginia, which loses its leaves in winter, and in the spring puts forth its yellow flowers in clusters, which are succeeded by blue berries, like those of the laurus tinus; these berries are sown in autumn, in a sandy soil.

You may now make layers or slips of the box tree; and the seeds may be sown as soon as ripe, or laid in sand during the winter, to be sown in the spring following; this plant thrives best in a chalky soil.

The dwarf or Dutch box, is of great use for edging of flower-beds, or making scroll-works; it will remain good, without renewing, a long time; and so great is the increase of it, that being earthed up every year, in four or five years after the planting, it may be taken up, parted, or slipped, and be made to plant four times the ground it stood upon.

### FRUIT GARDEN.

You may now gather the different sorts of fruit as they ripen; for those which are in eating this month, seldom continue long good.

Transplant

Transplant strawberries, gooseberries, raspberries, and currants, towards the end of this month, if the weather proves moist, otherwise it will be better to defer it till the beginning of the next month; and this is the best season to plant cuttings of gooseberries and currants, which will take root, and make better plants than those which are propagated by suckers.

Your fruit-trees against the wall of your forcing-frame, must now be pruned and trained close to the wall or espalier, that their buds may be preparing before the season for applying the heat; and you should also prepare for the ground where the fruit-trees are designed to be planted the next month, that it may lie to mellow and sweeten.

#### KITCHEN-GARDEN.

Sow Spanish radishes for the winter, and spinach to be cut in February; make plantations of the Dutch brown lettuce to stand the winter; sow sorrel, chervil, and small herbs for sallads, in some well-exposed place, observing to provide such mixtures for this season as are hotter to the taste, than in the former months.

You may now replant endive, and all sorts of fibrous-rooted herbs; continue to earth up fennel; raise the banks of earth about chardones for blanching; transplant asparagus-roots; make plantations of cabbages and coleworts; transplant young cauliflower plants in places where they are to flower; transplant strawberries; make beds for mushrooms; cover mushrooms sown in July every night; earth up your winter-plants; prepare composts; and, if the weather be dry, water your plants and herbs in the morning, and give your turnips the first houghing.

Such cucumbers as are now ripe, must be cut open, and the seed or pulp taken out of them, which should lie three or four days together before they are washed, and ten days in the sun before it is laid up; and it should ever be observed, that if seeds are not thoroughly dry before they are laid up, they will rot, and be good for nothing.

#### O C T O B E R.

##### FLOWER-GARDEN.

You should now plant anemones, and ranunculuses; and as soon as they appear, defend them from winds and frosts, with saw-dust, dry straw, or mats; and make an end of putting tulips into the ground: and likewise put *h. acinths*, tulips, narcissuses, &c. in glasses made for that purpose, to blow early in the house.

Continue to transplant and lay roses, and such like flowering shrubs; and to plant the cuttings of jessamines and honeysuckles in shady borders. Sow the berries of yew, holly, and other evergreens, prepared in earth or sand; and prune these kinds of plants if the season be mild.

This is a proper time to remove your ananas or pine-apples out of the bark-beds into the stove; and always keep a tub of water in the stove to water them when it is

wanted, which should stand twenty-four hours before it is used.

Set your pots of carnations, which are now blowing, into your green-house near the door; and the beginning of this month you are to house your myrtles, amomum Plinii, melianthus, and such tender greens as remain yet abroad. Tie up those plants that grow disorderly, and place the aloes, torch-thistles, euphorbiums, &c. nearest the sun; and the other plants, which are more hardy, towards the back of the house.

When you water your housed greens, let it be in the morning, when the sun shines upon them; but you are to give no more waterings to your tender succulent plants after the middle of the month.

The windows of the green-house are to be kept open day and night till about the fifteenth of this month; after that, in the day-time only.

##### FRUIT-GARDEN.

You may now plant peaches, apricots, and other fruit-trees; and as nothing is more prejudicial to them than dung, this should be done in untried earth.

Should this month be a wet one, you must raise the borders, and the trees planted high; for it is certain death to peaches and apricots, to stand where the water stagnates in the winter.

Vines should now be planted against walls seven or eight feet asunder, in a soil composed of sea coal ashes, drift sand, or the rubbish of old buildings, with an equal quantity of natural earth mixed with rotten dung.

About the middle of this month sow cyder-pressings in beds of fresh earth, to raise stocks for grafting, or even making of orchards without grafting; and from a nursery of this kind we may have as many different sorts of apples as we raise plants, although the seeds come all from the same tree.

You may now have plantations of apples, grafted upon paradise stocks, in pots; they will bear when the trees are very small, and very greatly set off an entertainment, being placed growing upon a table among dishes of fruit.

Transplant trees of all sorts, and lay up acorns and mast in sand; lay bare the roots of old unthriving forward blowing trees; stir up new-planted ground; and lay in a good stock of untried earth to be ready upon all occasions, for fruit-trees, ever-greens, and flowers.

##### KITCHEN-GARDEN.

This is the proper season to lay up roots for winter-store, such as carrots and parsnips; take the roots of turnips out of the ground, and lay them up in sand; make plantations of currants and gooseberries, from the suckers or cuttings.

The first week of this month sow cucumbers on the natural ground, to be afterwards transplanted into pots, for the convenience of sheltering from cold nights, till a hot-bed is prepared for them. This is better than to begin after the usual method in December or January.

Make plantations of lettuce, for winter-use: transplant cabbages

cabbages and cauliflower plants. Take up those cauliflower plants which begin to flower, tie their leaves together, and bury their roots and stalks in sand, in a cellar, or some cool place. Cut artichokes with long stalks, and preserve them in the house by setting their stalks in sand. Earth up and dress such artichokes as have done blowing: and continue to earth up sallery for blanching.

Sow kidney beans in baskets under a south wall, to be afterwards forwarded by hot-beds, for early beans; and hot-spur peas, and Spanish beans, in some well exposed border, under a wall or a hedge. Sow also radishes in some warm place, to draw early in the spring; and cresses, lettuce, mustard, spinach, &c. upon a decayed hot-bed: Put likewise some roots of mint upon a gentle hot-bed for winter fallads.

## N O V E M B E R.

### FLOWER-GARDEN.

You may now cut down the stalks of such tall blowing flowers as have done blossoming, within three inches of the root. Tie up all trees and shrubs to stakes, otherwise by their being loose, and at liberty, the winds will destroy them. Lay up heaps of earth for your several sorts of flowers, and make the proper mixtures for exotics; observing, that where the ground is too stiff, it may be brought to a state of loam, by adding to it a sufficient quantity of drift or sea-sand.

Peonies, and some fibrous roots, may now be planted. If the weather be open, you may yet transplant roses, jessamines, honeysuckles, syringa, and lilac. Unnail your passion-trees from the wall, and lay them upon the ground, that in case of severe frosts they may be covered with straw.

Plant hyacinths, jonquils, narcissus's, and polyanthus's, in pots, and plunge them into hot-beds, to blossom about Christmas: lay down your auricula pots upon their sides, the plants towards the sun, to drain them from moisture, and preserve them from frosts; and shelter young seedling bulbs from the frost, but give them daily airings.

### FRUIT GARDEN.

THE business of this month being principally planting, it may be necessary to give the reader directions for bringing fruits to perfection in the winter, so as to have, by a particular management in planting, ripe fruit throughout the year.

Apricots, cherries, early peaches, nectarines, currants, gooseberries, are to be planted in the following manner, against a paling of five feet high: the stakes to support this paling must be set about four feet distance from one another; to which you are to nail whole deal-boards of twelve feet long, well-jointed to one another, and ploughed on the edges, so as to set in laths, that thereby the steam of the dung, which is to lie at the back, may not get among the plants; because wherever such steam comes, it will cause mildews.

The deals are to be an inch in thickness; for if they

are not quite so thick, the trees will be apt to be scorched upon the first application of the hot dung; and if they are thicker, the artificial heat applied to their backs, upon the time it begins to decline, will not be powerful enough to warm thoroughly, and then the dung must be oftener refreshed.

When the paling is up, you are to mark out a border on the south side of it, about four feet wide; and on the outside of the border, fasten to the ground, in a straight line, some scantlings of wood about four inches thick, to rest glass lights upon, which are to slope back to the paling, to shelter the fruit as occasion requires: between these glass-lights, there must be bars cut of whole deal, about four inches wide, for the glasses to rest upon; and the bars must always remain fixed, as in a frame for a hot-bed.

There must be a door, shaped to the profile of the frame, at each end, to be opened, either the one or the other, as the wind happens to blow, ever observing that the door be opened on that side only which is most free from the wind.

You may plant fruit-trees in a frame of this sort the same summer it is made, and the trees will take very good root before winter, and be so well stored with sap against the following spring, that they will shew no sign of their removal, but bear extremely. Besides, by this summer planting, the trees seldom or never throw away their strength in autumn-shoots, or make any attempts towards it, till September and October, when the frosts prevent their design.

The trees planted must have time allowed for the juices to digest, before you begin to force them: therefore the hot dung is not to be applied to the back of the paling before November.

About the middle of this month, or towards the end, is the time to bring ripe cherries in February: and at the same time likewise the heat may be used for apricots, so as to make the masculine apricots as large as duke cherries by February, and ripen them the beginning of April. The Anne peach will ripen about the end of April, as will also several sorts of forward plumbs.

The early nectarine thus forced will ripen with the masculine apricot: we may have green gooseberries fit for tarts in January and February; and ripe gooseberries and currants in March and April; but cherries do not bear this alteration in nature so well.

The grapes that do best for this sort of work, are, the royal muscadine, marlmore, black sweet water, and black morillon: the best sorts of the forward peaches, nectarines, cherries, and plumbs, and the Dutch raspberry, should be ever fixed on for forcing in the above manner. A row or two of strawberries may also be planted in this frame, which would ripen at the end of February, or beginning of March; and amongst the fruit you may mix here and there a monthly rose tree; and have a border planted with early tulips, hyacinths, jonquils, narcissus's, and other flowers, which by the forcing heats would make a kind of summer all the winter.

The trees planted in these frames must be close to the paling, contrary to the methods of planting against walls;

for the roots will run under the pales, and draw nourishment equally from the earth about them; but with walls it is otherwise.

The trees need not be planted at a greater distance than four or five feet; and those that have stood seven or eight years against walls, may be removed to these forcing-frames without any danger: as to pruning these trees, the same method is to be followed as recommended for other trees in February; but the season for doing it is not the same; for in the forcing frames our Spring begins in November; but in the other case it does not begin till the end of January, or beginning of February.

The trees are to be pruned and nailed to pales about a week before the forcing heat is applied, and all the glasses put up as soon as they are pruned.

The hot-dung intended to be laid at the back of the pales, should be tossed up in an heap some days before it is used, that it may yield an heap every where alike: when it is fit to be applied to the pales, lay it four feet wide at the base; and let it slope to two feet at the top, the height in all being at first within four inches of the top of the pales, and in about six weeks time it will sink to four feet, when you are to apply fresh dung. The blossoming of the tree is very much helped by covering them with the glass lights in frosty weather: but they should not be denied the rain, if the weather be tolerably mild, till the buds begin to stir; after that, the glasses to remain over them constantly, till the sun begins to have some power.

When the sun shines warm, and the wind is not too sharp, give the air at the front of your frame; and if this does not happen during a fortnight's space, then give air at the end, and put up mats or canvas to correct the winds, and cause the air to circulate in the frames.

About three changes of dung will be sufficient to bring your cherries to ripeness in February, allowing each parcel to remain a month at the back of the pales: but if April proves cold, the forcing heat is to be continued till May, for plumbs, peaches, nectarines, and apricots.

#### KITCHEN-GARDEN.

HOT BEDS for asparagus should now be made; also gentle hot-beds for the cucumbers and kidney-beans sown in October: continue to sow radishes, lettuce, cresses, spinach, &c. on a hot-bed; and if your nursery is without roots, provide them from some old plantations.

Sow pease, and beans of the hotspur and Spanish kinds, in open ground; and if the weather be fair, earth up those sown in September. Earth up sellery, and tie up endive plants for blanching: and this is the best time to cut down asparagus haulm, when it is turned yellow; it must be cut within two or three inches of the ground, and the earth of the alleys flung up upon the beds; or if the asparagus be worn, you are to give it a covering of rich dung, not quite rotten: and cover well your artichokes with long dung, to defend them from frosts, otherwise they will be destroyed in a severe winter. House, and cover with sand, carrots, parsnips, &c. and house-cabbages.

You must now trench your ground, and lay it up in

ridges to mellow; and in a frosty season wheel on dung and other manures upon such places as want to be enriched.

Plants are to be guarded against frosts, and sheltered against cold rains; and trees must be staked, to defend them against violent winds, common in this month.

#### D E C E M B E R.

##### FLOWER-GARDEN.

You should now cover the beds of choice anemones, hyacinths, and ranunculus's; pick off dead and rotten leaves from all exotic plants; lay mulch about the roots of new-planted trees and shrubs; cover the pots of seedling flowers; turn over the earth prepared for the flower garden, that the frost may make it mellow; and mix up some new heaps, that there may be a sufficient quantity ready for use eight or ten months before it is wanted.

You must not be too hasty in warming your greenhouse with artificial heats, but let in as much sun as possible, which being a natural heat, is the most agreeable to your tender plants. The chief business is to keep out frosts; to effect which, the doors and windows of your greenhouse must be well matted, and guarded from the piercing air.

But as no plant can live without air, therefore to recruit it in the house, and feed the plants therewith without pinching them, it is adviseable, that at the end of your greenhouse there should be an antichamber, through which you are to pass to the house; which chamber will have fresh air from abroad every time you go into it; and upon opening the door of it into the greenhouse, the air will there mix with the other that has been pent up, and impregnate it with new parts, by which means, it will contribute to the vegetation of plants, without coming upon them too suddenly.

##### FRUIT-GARDEN.

CONTINUE to prune vines; prune and nail wall-fruit trees, also such standards as are hardy; examine orchard trees, and take away such branches as make confusion; covering every considerable wound with a mixture of bees wax, rosin, and tar, in equal quantities, and of tallow about half the quantity of any of the others; which are to be melted together in an earthen vessel well glazed; and, with a painting brush dipped into it, the wound is to be covered: destroy snails in every part of your garden; and you may, if the weather proves mild, remove or plant most sorts of hardy trees that in the winter shed their leaves.

##### KITCHEN-GARDEN.

If the season proves mild, you may earth up those artichokes which were in the former months neglected; in doing which, if the ground is not very good, bury some rotten dung in it, which will greatly promote the growth of your artichokes in the spring following.

Towards the middle of the month, make a hot-bed for asparagus,

*Fig. 1. SEA GAGE*

*Fig. 5.*  
**GRYLLUS LAURIFOLIUS**

*Fig. 4.*  
**GRYLLUS ACUMINATUS**

*Fig. 6.*

N. 2.

N. 3.

N. 4.

N. 5.

*Fig. 3. GAUGING ROD.*

asparagus, in like manner as that made in November. Sow upon hot-beds, lettuce, radish, cresses, mustard, and other herbs which are hot, to cut for small fallads.

In open weather you may sow early peas and beans of the same kinds, and in the same manner, as directed in November and the preceding months; and as vermin now very much destroy your roots and seeds, you are to set traps to catch them.

You should, when the weather is not too severe, uncover the cauliflower plants every day, that they may enjoy

the benefit of the air, otherwise they will be very weakly; and in dry weather take up sellery, and endive to blanch.

Great care must now be taken of the mushroom-beds; they should be covered with fresh dry straw, so thick as to keep out the wet; for as, where proper care is taken, there will be a constant supply of them for the table in the most rigorous season, so, when they are neglected, the produce will be small in proportion.

## G A R

**GARGARISM**, in medicine, is sometimes taken, in a large sense, for every collution of the mouth; but, strictly speaking, it signifies a liquid medicine, appropriated to affections of the mouth, gums, fauces, larynx, and sometimes of the head, received into the mouth, and there used by way of collution, without deglutition.

**GARLAND**, a sort of chaplet made of flowers, feathers, and sometimes precious stones, worn on the head, in manner of a crown.

**GARLAND** also denotes ornaments of flowers, fruits, and leaves, intermixed; anciently much used at the gates of temples, where feasts and solemn rejoicings were held; or at any other place where marks of public joy or gaiety were required, as at triumphal arches, tournaments, &c.

**GARNET**, in natural history, a very beautiful gem, of a red colour, with an admixture of bluish.

When pure and free from blemishes, it is little inferior, in appearance, to the oriental ruby, though only of a middle degree of hardness between the sapphire and common crystal. It is found of various sizes, from that of a pin's head to an inch in diameter.

Among our lapidaries and jewellers, genuine garnets are known by different names according to their different degrees of colour. 1. The garnet, simply so called, is the finest and most valuable kind, being of a very deep blood red, with a faint admixture of blue. 2. The rock-ruby, a name very improperly given to the garnet, when it is of a very strong but not deep red, and has a fairer cast of the blue: this is a very beautiful gem. 3. The forane or serain garnet, that of a yet brighter red, approaching to the colour of native cinnabar, with a faint blue tinge. 4. The almandine, a garnet only a little paler than that called the rock-ruby.

Garnets are very properly distinguished into the oriental and occidental kinds, as being found in Europe as well as the East Indies. The oriental ones are principally brought from Calicut, Cananor, and Cambay; and the European ones are common in Italy, Hungary, and Bohemia.

Some authors have supposed the deeper-coloured garnet to be the same with the carbuncle of the ancients; from which it really differs; since, on receiving the sun's beams, it never gives so true a fire-colour as the carbuncle.

**GARONNE**, a large river of France, which taking its

## G A R

rise in the Pyrenean mountains, runs north-west by the city of Tholouse, divides the provinces of Guienne and Gascony, and, visiting the city of Bordeaux, falls into the bay of Biscay, about sixty miles below that city. It has also a communication with the Mediterranean, by means of the royal canal of Lewis XIV. The tide flows up this river twenty miles above Bordeaux.

**GARTER**, a ligature for tying up the stocking; but particularly used for the badge of a noble order of knights, hence denominated the

*Order of the GARTER*, a military order of knighthood, the most noble and ancient of any lay-order in the world, instituted by Edward III. This order consists of twenty-six knights-companions, generally princes and peers, whereof the king of England is the sovereign or chief. They are a college or corporation, having a great and little seal.

Their officers are a prelate, chancellor, register, king at arms, and usher of the black rod. They have also a dean with twelve canons, and petty canons, vergers, and twenty-six pensioners or poor knights. The prelate is the head. This office is vested in the bishop of Winchester, and has ever been so. Next to the prelate is the chancellor; which office is vested in the bishop of Salisbury, who keeps the seals, &c. The next is the register, who by his oath is to enter upon the registry, the scrutinies, elections, penalties, and other acts of the order, with all fidelity. The fourth officer is garter, and king at arms, being two distinct offices united in one person. Garter carries the rod and sceptre at the feast of St George, the protector of this order, when the sovereign is present. He notifies the elections of new knights, attends the solemnity of their installations, carries the garter to the foreign princes, &c. He is the principal officer within the college of arms, and chief of the heralds. See *KING at arms*.

All these officers, except the prelate, have fees and pensions. The college of the order is seated in the castle of Windsor, with the chapel of St George, and the charter-house, erected by the founder for that purpose. The habit and ensign of the order are, a garter, mantle, cape, george, and collar. The four first were assigned the knights-companions by the founder; and the george and collar by Henry VIII. The garter (Plate LXXXVI. fig. 2. N<sup>o</sup> 1.) challenges pre-  
eminence

nence over all the other parts of the dress, by reason that from it the noble order is denominated; that it is the first part of the habit presented to foreign princes, and absent knights, who, and all other knights-elect, are therewith first adorned; and it is of so great honour and grandeur, that by the bare investiture with this noble ensign, the knights are esteemed companions of the greatest military order in the world. It is worn on the left leg between the knee and calf, and is enamelled with this motto, *HONI SOIT QUI MAL Y PENSE*; i. e. *Shame to him that thinks evil hereof*: The meaning of which is, that king Edward having laid claim to the kingdom of France, retorted shame and defiance upon him that should dare to think amiss of the just enterprize he had undertaken, for recovering his lawful right to that crown; and that the bravery of those knights whom he had elected into this order, was such as would enable him to maintain the quarrel against those that thought ill of it.

The mantle (*ibid.* N° 2.) is the chief of these vestments made use of upon all solemn occasions. The colour of the mantle is by the statutes appointed to be blue. The length of the train of the mantle only distinguishes the sovereign from the knights-companions. To the collar of the mantle is fixed a pair of long strings, anciently wove with blue silk only, but now twisted round, and made of Venice gold and silk, of the colour of the robe, with knobs, or buttons, and tassels at the end. The left shoulder of the mantle has, from the institution, been adorned with a large garter, with the device, *HONI SOIT, &c.* within this is the cross of the order, which was ordained to be worn at all times by king Charles I. At length the star was introduced, being a sort of cross irradiated with beams of silver. (*ibid.* N° 3.)

The collar (*ibid.* N° 4.) is appointed to be composed of pieces of gold in fashion of garters, the ground enamelled blue, and the mot o gold.

The manner of electing a knight companion into this most noble order, and the ceremonies of investiture are as follow. When the sovereign designs to elect a companion of the garter, the chancellor belonging to this order draws up the letters, which, passing both under the sovereign's sign-manual and signet of the order, are sent to the person by garter principal king at arms; and are in this manner, or to the same effect: "We, with the companions of our most noble order of the garter, assembled in chapter, holden this present day at our castle at Windsor, considering the virtuous fidelity you have shewn, and the honourable exploits you have done in our service, by vindicating and maintaining our right, &c. have elected and chosen you one of the companions of our order. Therefore, we require you to make your speedy repair unto us, to receive the ensigns thereof, and be ready for your installation upon the — day of this present month, &c."

The garter, which is of blue velvet bordered with fine gold-wire, having commonly the letters of the motto of the same, is, at the time of election, buckled

upon the left leg, by two of the senior companions, who receive it from the sovereign, to whom it was presented upon a velvet cushion, by garter king at arms, with the usual reverence, whilst the chancellor reads the following admonition, enjoined by the statutes: "To the honour of God omnipotent, and in memorial of the blessed martyr St George, tie about thy leg, for thy renown, this noble garter; wear it as the symbol of the most illustrious order, never to be forgotten or laid aside; that thereby thou mayest be admonished to be courageous; and, having undertaken a just war, in which thou shalt be engaged, thou mayest stand firm, valiantly fight, and successively conquer."

The princely garter being then buckled on, and the words of its signification pronounced, the knight elect is brought before the sovereign, who puts about his neck, kneeling, a sky-coloured ribbon, (*ibid.* N° 5.) whereunto is appendant, wrought in gold within the garter, the image of St George on horseback, with his sword drawn, encountering with the dragon. In the mean time, the chancellor reads the following admonition: "Wear this ribbon about thy neck, adorned with the image of the blessed martyr and soldier of Christ, St George, by whose imitation provoked, thou mayst so overpass both prosperous and adverse adventures, that having stoutly vanquished thy enemies, both of body and soul, thou mayst not only receive the praise of this transient combat, but be crowned with the palm of eternal victory."

Then the knight elected kisses the sovereign's hand, thanks his majesty for the great honour done him, rises up, and salutes all the companions severally, who return their congratulations. N° 2. (*ibid.*) exhibits a view of a knight of the garter in the habit of this order.

Since the institution of this order, there have been eight emperors, and twenty-eight kings, besides numerous sovereign princes, enrolled as companions thereof. Its origin is somewhat differently related: the common account is, that it was erected in honour of a garter of the countess of Salisbury, which the dropped dancing with king Edward, and which that prince picked up; but our best antiquaries think it was instituted on account of the victory over the French at Cressy, where the king ordered his garter to be displayed as a signal of the battle.

**GASCOIN**, or **GASCOIGN**, denotes the hinder thigh of a horse, which begins at the stifle, and reaches to the ply or bending of the ham.

**GASCONY**, the most south-west province of France, bounded by Guienne, on the north; by Languedoc, on the east; by the Pyrenees, which separate it from Spain, on the south; and by the Bay of Biscay, on the west.

**CASSENHOVEN**, or **GUTZENHOVEN**, a town of the Aultrian Netherlands, fifteen miles east of Louvain: E long. 50°, and N. lat. 5° 55'.

**CASTEROSTEUS**, in ichthyology, a genus of fishes belonging to the order of thoraici. There are three

rays

rays in the membrane of the gills; the body is carinated; and there are some distinct prickles before the back-fin. There are eleven species, distinguished by the number of prickles on the back.

**GASTRIC**, in general, something belonging to the stomach.

**GASTROCNEMIUS**, in anatomy. See **ANATOMY**, p. 209.

**GASTROCNEMIUS** is also the name of one of the extensor-muscles of the foot.

**GASTROMANCY**, a method of divination by water, practised by the ancient Greeks.

**GASTRORAPHY**, in surgery, the operation of sewing up wounds of the abdomen. See **SURGERY**.

**GATE**, in architecture. See **ARCHITECTURE**, p. 356.

**GATTON**, a borough-town of Surry, sixteen miles south of London, which sends two members to parliament.

**GAVEREN**, or **WAVERREN**, a town of the Austrian Netherlands, situated on the east bank of the river Scheld: E. long.  $3^{\circ} 35'$ , N. lat.  $51^{\circ}$ .

**GAUGE-POINT** of a solid measure, the diameter of a circle whose area is equal to the solid content of the same measure.

**GAUGER**, a king's officer, who is appointed to examine all tuns, pipes, hogheads, and barrels of wine, beer, ale, oil, honey, &c. and give them a mark of allowance, before they are sold in any place within the extent of his office.

**GAUGING**. See **GEOMETRY**.

**GAUNT-BELLIED**, in the menage, is said of a horse whose belly shrinks up towards his flanks.

**GAWSE**, or **GAWS**, in commerce, a very slight, thin, open kind of stuff, made of silk, and sometimes of thread; there are also figured gawzes, and some with gold or silver flowers on a silk ground.

**GAZELLA**, in zoology. See **CAPRA**.

**GAZETTE**, a news-paper, or printed account of the transactions of all the countries in the known world, in a loose sheet, or half-sheet. This name is with us confined to that paper of news published by authority.

The word is derived from *gazetta*, a Venetian coin, which was the usual price of the first news-papers printed there, and which was afterwards given to the paper itself.

**GELATINOUS**, in pharmacy and medicine, any thing approaching to the glutinous consistence of a gelatina or jelly. See **JELLY**.

**GELDERLAND**, comprehending Zutphen, is a province of the United Netherlands, bounded by the Zuider-sea and Overijssel on the north, by Westphalia on the east, by Brabant on the south, and by the province of Utrecht on the west.

**GELDING**, the operation of castrating any animal.

**GELDERS**, a city of Gelderland, situated twenty-three miles south of Nimeguen: E. long.  $6^{\circ} 8'$ , and N. lat.  $51^{\circ} 35'$ .

**GELENHAUSEN**, an imperial city of Germany, governed by its own magistrates; it is situated nine miles north of Hanau: E. long.  $8^{\circ} 50'$ , and N. lat.  $50^{\circ} 15'$ .

Vol. II. No. 54.

2

**GEM**, in natural history, a common name for all precious stones; of which there are two classes, the pellucid and semi-pellucid.

The bodies composing the class of pellucid gems are bright, elegant, and beautiful fossils, naturally and essentially compound, ever found in small detached masses, extremely hard, pellucid, and of great lustre; composed of a very firm and pure matter, without any admixture of earthy substance, giving fire without steel, not fermenting with acid menstrua, and very difficultly calcinable in the fire.

The bodies composing the class of semi-pellucid gems are, stones naturally and essentially compound, not inflammable nor soluble in water, found in detached masses, and composed of crystalline matter, debased by earth: however, they are but slightly debased; and are of great beauty and brightness, of a moderate degree of transparency, and are usually found in small masses.

**GEMARA**, in Jewish antiquity, a collection of decisions and determinations on the law, written after the Misna was completed.

It was called *gemara*, or *perfection*, because it was considered as so perfect an explication of the law, that after it no further additions could be made, or any thing more desired. It is otherwise called the talmud. See **TALMUD**.

**GEMBLOURS**, a town of the Austrian Netherlands, in the province of Brabant, situated on the river Orne, ten miles north-west of Namur: E. long.  $4^{\circ} 30'$ , and N. lat.  $50^{\circ} 30'$ .

**GEMELLUS**, in anatomy. See **ANATOMY**, p. 205.

**GEMINI**, the TWINS, in astronomy, one of the twelve signs of the zodiac, the third in order, beginning with aries. See **ASTRONOMY**.

**GEMMA**, in natural history. See **GEM**.

**GEMUND**, a town of Germany, in the circle of Westphalia, and dukedom of Juliers, situated on the river Roer: E. long.  $6^{\circ} 15'$ , and N. lat.  $50^{\circ} 34'$ .

**GEMUND**, a town of Germany, in the circle of Swabia, and county of Rechlsberg, situated on the river Rems: E. long.  $9^{\circ} 40'$ , and N. lat.  $48^{\circ} 45'$ .

**GEMUND**, a town of Germany, in the circle of Franconia, situated on the river Maine: E. long.  $9^{\circ} 45'$ , and N. lat.  $50^{\circ} 8'$ .

**GENDARMES**, or **GENS D'ARMES**, in the French armies, a denomination given to a select body of horse, on account of their succeeding the ancient gendarmes, who were thus called from their being completely clothed in armour.

The king's body-guards, the light horse of the royal house, and the musqueteers, are at present reputed to belong to the gendarmerie.

The grand gendarmes are a troop composed of about 250 gentlemen, who guard the king's person. The king himself is their captain, and one of the prime peers their captain-lieutenant, who has under him two lieutenants, three ensigns, three guidons, and other officers. There are, besides these, gendarmes of the queen, the dauphin, &c.

† J F

**GENDER**,

**GENDER**, among grammarians, a division of nouns, or names, to distinguish the two sexes.

This was the original intention of gender; but, afterwards, other words which had no proper relation, either to the one sex or the other, had genders assigned them, rather out of caprice than reason; which is at length established by custom. Hence genders vary according to the languages, or even according to the words introduced from one language into another. Thus *arbor*, in Latin, is feminine; but *arbre*, in French, is masculine; and *dens*, in Latin, is masculine; but *dent*, in French, is feminine.

**GENEALOGY**, an enumeration of a series of ancestors; or a summary account of the relations and alliances of a person or family, both in the direct and collateral line.

**GENEP**, a town in the dutchy of Clevee, in Germany, situated on the Nierse and Maese, ten miles west of Clevee: E. long.  $5^{\circ} 30'$ , and N. lat.  $51^{\circ} 40'$ .

**GENERAL**, an appellation given to whatever belongs to a whole genus. See **GENUS**.

**GENERAL CHARGE**, in law. See *CHARGE to enter heir*.

**GENERAL TERMS**, among logicians, those which are made the signs of general ideas.

**GENERAL of an army**, in the art of war, he who commands in chief.

The office of a general is, to regulate the march and encampment of the army; in the day of battle to chuse out the most advantageous ground; to make the disposition of the army; to post the artillery; and where there is occasion, to send his orders by his aids de camp. At a siege, he is to cause the place to be invested; to order the approaches and attacks; to visit the works; and to send out detachments to secure his convoys.

**GENERATING LINE**, or **FIGURE**, in geometry, is that which by its motion produces any other plane or solid figure.

**GENERATION**, in physiology, the act of procreating and producing a being similar to the parent.

According to Aristotle, the male animals contain the principle, and the female the matter of generation: for though both were furnished indeed with a seminal liquor, yet the semen of the males alone was prolific. The moderns, on the other hand, as well those who contend for the system of generation from eggs, as they who adopt that of the animalcules in the male-seed, pretend that females have no such seminal liquor at all, and that what was commonly taken for it was some other animal fluid.

Harvey is of opinion, that all females are furnished with eggs, and that the embryos, or young animals, are formed in the same manner as a chick in the egg of any bird. Generation, according to this celebrated physician, is effected wholly by means of the uterus, or womb; which conceives the fœtus by a kind of contagion communicated to it by the male-seed, much in the same way as the load-stone communicates magnetism to iron. This contagion, he thinks, acts not only on the uterus, but is communicated to the whole body of the female, which is altogether prolific; tho' the uterus, he acknowledges, is the only part that is

capable of conceiving the fœtus, just as the brain is alone capable of forming ideas and notions. Agreeable to this doctrine of Harvey, Steno and other anatomists have pretended to discover certain eggs in the ovaries or testicles of women; which Mr Buffon denies to be the case, assuming, that there are no such eggs to be found in the ovaries or testicles of women.

We cannot enter into a detail of the reasonings for and against the system of generation from eggs; and shall therefore only observe, that its advocates pretend to have discovered eggs in all the females on which they made observations; that the largest of those found in women did not exceed the bigness of a pea; that they are extremely small in young girls under fourteen, but that age and commerce with men makes them grow larger; that there are more than twenty such eggs in each ovary or testicle; that they are fecundated in the ovary by the spirituous and volatile part of the male-seed; that they afterwards are detached and fall into the uterus through the Fallopian tubes; that here the fœtus is formed of the internal substance of the egg, and the placenta of the exterior part.

Leewenhock is the author of another system of generation, from animalcules in the male seed. He tells us, he discovered many thousands of these in a drop less than a grain of sand. They are found in the semen of all males whatever, but not in that of females; and are so small, that 3,000,000,000 of them are not equal to a grain of sand, whose diameter is but the hundredth part of an inch. When any of these animalcules gets into an egg, fit to receive it, and this falls into the womb through the Fallopian tubes, the humours which distil through the vessels of the womb, penetrating the coats of the egg, swell and dilate it, as the sap of the earth does seed thrown into it. The placenta begins to appear like a little cloud, upon one side of the external coat of the egg; and, at the same time the spine of the embryo-animalcule is grown so big, as to become visible; and a little afterwards, the cerebrum and cerebellum appear like two bladders; and the eyes stand next goggling out of the head; then the beating of the heart, or *punctum saliens*, is plainly to be seen; and the extremities discover themselves last of all.

These animalcules are of different figures, some like tadpoles, and others like eels. In the semen of a man, and in that of a dog, there have been discovered two different kinds of them, the one supposed to be males and the other females. Some even pretend to have seen animalcules disengage themselves from the membranes that surround them; and that they then appeared perfectly like men, with legs, arms, &c. like those of the human body!

All the advocates for the system of generation from animalcules strongly oppose that from eggs. They contend, that these animalcules cannot be looked upon as the inhabitants of the semen, since they were of greater extent than the liquor itself; not to mention, that no such animals are found in any other liquors of the body; and since females have nothing similar to these animals, they think it manifest that the prolific principle

**NEVA.** It is a republic, governed by a council of 200, and a senate of twenty five members; and is said to contain 30,000 inhabitants.

**GENEVA, or GIN,** among distillers, an ordinary malt spirit, distilled a second time, with the addition of some juniper-berries.

Originally, the berries were added to the malt in the grilling; so that the spirit thus obtained was flavoured with the berries from first, and exceeded all that could be made by any other method. At present, they leave out the berries entirely, and give their spirits a flavour by distilling them with a proper quantity of oil of turpentine; which, though it nearly resembles the flavour of juniper-berries, has none of their valuable virtues.

**GENIAL,** an epithet given by the Pagans to certain gods who were supposed to preside over generation.

The genial gods, says Festus, were earth, air, fire, and water. The twelve signs, together with the sun and moon, were sometimes also ranked in the number.

**GENICULI,** among botanists, the knots or joints in the stalks of plants; whence they are denominated geniculate plants.

**GENIOGLOSSI,** in anatomy. See **ANATOMY**, p. 304.

**GENIOHYOIDÆUS,** in anatomy. See **ANATOMY**, p. 304.

**GENIS,** a town of Savoy, situated on the river Guier, twelve miles west of Chambery.

**GENISTA, GREEN-WEED, or DYER'S WEED,** a genus of the diadelphia decandria class. The calix is bilabiated; the vexillum is oblong, and reflected. There are 14 species, two of which are natives of Britain, viz. the tinctoria, or dyer's weed; and the anglica, or needle-furze.

**GENITAL,** an appellation given to whatever belongs to the parts of generation. See **GENERATION**.

**GENITES,** among the Hebrews, those descended from Abraham, without any mixture of foreign blood.

The Greeks distinguished by the name of genites such of the Jews as were issued from parents, who, during the Babylonish captivity, had not allied with any gentile family.

**GENITIVE,** in grammar, the second case of the declension of nouns. The relation of one thing considered as belonging in some manner to another, has occasioned a peculiar termination of nouns, called the genitive case: But in the vulgar tongues, they make use of a sign to express the relation of this case. In English they prefix the particle *of*, in French *de* or *du*, &c. Though in strictness there are no cases in either of these languages; inasmuch as they do not express the different relations of things by different terminations, but by additional prepositions, which is otherwise in the Latin.

**GENIUS,** a good or evil spirit, or dæmon, whom the ancients supposed set over each person, to direct his birth, accompany him in life, and be his guard. See **DÆMON**.

The rank and office of the genii were inferior to those of the lares; for the latter were the tutelar

gods of a family, whereas the genii had the care or government only of single persons, or places.

**GENIUS,** in matters of literature, &c. a natural talent or disposition to do one thing more than another; or the aptitude a man has received from nature to perform well and easily that which others can do but indifferently and with a great deal of pains.

To know the bent of nature is the most important concern. Men come into the world with a genius determined not only to a certain art, but to certain parts of that art, in which only they are capable of success. If they quit their sphere, they fall even below mediocrity in their profession. Art and industry add much to natural endowments, but cannot supply them where they are wanting. Every thing depends on genius. A painter often pleases without observing rules, whilst another displeases though he observes them, because he has not the happiness of being born with a genius for painting.

**GENOA,** a city and archbishop's see of Italy, and capital of a republic of the same name, is built on a strand near the sea, and rises gradually to the top of a hill; the houses, which are lofty and well built, rising like the seats of a theatre, afford a fine prospect at sea. The harbour is large and deep, and the principal street, from one end to the other, resembles a double row of palaces: E. long. 9° 30', and N. lat. 44° 30'.

**GENTIANA,** in botany, a genus of the pentandria digynia class. The corolla consists of one petal; the capsule has two valves, and one cell. There are twenty-eight species, five of which are natives of Britain, viz. the pneumonanthe, or calathian violet; the amarella, or autumnal gentian; the centaurium, or lesser centaury; the campestris, or vernal dwarf gentian; and the filiformis, or marsh centaury.

The root of this plant is large, remarkably tough, and of a firm texture. It is brought to us from Germany, where it is in many places cultivated as liquorice is amongst us; and it is to be chosen fresh, tough, of a middle size, free from the small fibres, and well dried; tho' if it be scorched, it is to be rejected. This root is one of the best stomachics.

**GENTILE,** in matters of religion, a pagan, or worshipper of false gods.

**GENTILE,** in the Roman law and history, a name which sometimes expresses what the Romans otherwise called barbarians, whether they were allies of Rome or not; but this word was used in a more particular sense for all strangers and foreigners not subject to the Roman empire.

**GENTLEMAN-USHER of the black rod.** See **ROD**.

**GENTLEMEN of the chapel,** officers whose duty and attendance is in the royal chapel, being in number thirty-two, whereof twelve are priests; the other twenty, commonly called clerks of the chapel, assist in the performance of divine service. One of the first twelve is chosen for confessor of the household, whose office it is to read prayers every morning to the household servants, to visit the sick, examine and prepare communicants, and administer the sacrament.

One of twenty clerks, well versed in music, is chosen first

ARMILLARY

WORLD

South

South

first organist, who is master of the children, to instruct them in music, and whatever else is necessary for the service of the chapel; a second is likewise an organist; a third, a lutanist; and a fourth, a violist.

There are likewise three vergers, so called from the silver-rods they carry in their hands; being a serjeant, a yeoman, and groom of the vestry; the first attends the dean and sub-dean, and finds surplices and other necessities for the chapel; the second has the whole care of the chapel, keeps the pews, and seats the nobility and gentry; the groom has his attendance within the chapel-door, and looks after it.

**GENUS**, among metaphysicians and logicians, denotes a number of beings, which agree in certain general properties common to them all; so that a genus is nothing else but an abstract idea, expressed by some general name or term.

It is plain, therefore, that by a genus we do not barely signify one particular thing, nor yet a plurality of things; but a sort or kind of things, all agreeing in certain general properties.

Thus animal is said to be a genus in respect of man and brute, in regard man and brute agree in the common nature and character of animal: so a right-lined figure of four sides, is a genus in respect of a parallelogram, and a trapezium; and so likewise is substance,

in respect of substance extended which is body, and thinking substance which is mind.

**GENUS** is also used for a character or manner applicable to every thing of a certain nature or condition: in which sense it serves to make capital divisions in divers sciences, as rhetoric, anatomy, and natural history.

**GENUS**, in rhetoric. Authors distinguish the art of rhetoric, as also orations or discourses produced thereby, into three genera or kinds, demonstrative, deliberative, and judiciary.

To the demonstrative kind belong panegyrics, genethliacons, epithalamiums, funeral harangues, &c.

To the deliberative kind belong persuasions, dissuasions, commendations, &c. To the judiciary kind belong defences and accusations.

**GENUS**, in natural history, a sub-division of any class or order of natural beings, whether of the animal, vegetable, or mineral kingdoms, all agreeing in certain common characters. See **NATURAL HISTORY**.

**GEOCENTRIC**, in astronomy, is applied to a planet or its orbit, to denote it concentric with the earth, or as having the earth for its centre, or the same centre with the earth.

**GEOGRAPHICAL MILE**, the same with the sea-mile; being one minute, or the sixtieth part of a degree of a great circle on the earth's surface.

## G E O G R A P H Y.

**GEOGRAPHY**, the doctrine or knowledge of the terrestrial globe; or the science that teaches and

explains the properties of the earth, and the parts thereof which depend upon quantity.

### THE DESCRIPTION AND USE OF THE GLOBES AND ARMILLARY SPHERE.

**I**F a map of the world be accurately delineated on a spherical ball, the surface thereof will represent the surface of the earth: for the highest hills are so inconsiderable with respect to the bulk of the earth, that they take off no more from its roundness than grains of sand do from the roundness of a common globe; for the diameter of the earth is 8000 miles, in round numbers, and no known hill upon it is three miles in perpendicular height.

For the proof of the earth's being spherical, see **ASTRONOMY**, p. 440.

With regard to what we call *up* and *down*, see **ASTRONOMY**, p. 445.

To an observer placed any where in the indefinite space, where there is nothing to limit his view, all remote objects appear equally distant from him; and seem to be placed in a vast concave sphere, of which his eye is the centre. The moon is much nearer to us than the sun; some of the planets are sometimes nearer, and sometimes farther from us, than the sun; others of them never come so near us as the sun always is; the remotest planet in our system, is beyond comparison nearer to us than any

of the fixed stars are. And yet all these celestial objects appear equally distant from us. Therefore, if we imagine a large hollow sphere of glass to have as many bright studs fixed to its inside, as there are stars visible in the heaven, and these studs to be of different magnitudes, and placed at the same angular distances from each other as the stars are; the sphere will be a true representation of the starry heaven, to an eye supposed to be in its centre, and viewing it all around. And if a small globe, with a map of the earth upon it, be placed on an axis in the centre of this starry sphere, and the sphere be made to turn round on this axis, it will represent the apparent motion of the heavens round the earth.

If a great circle be so drawn upon this sphere, as to divide it into two equal parts or hemispheres, and the plane of the circle be perpendicular to the axis of the sphere, this circle will represent the *equinoctial*, which divides the heaven into two equal parts, called the *northern* and the *southern hemispheres*; and every point of that circle will be equally distant from the *poles*, or ends of the axis in the sphere. That pole which is in the middle of the

northern hemisphere, will be called the *north pole of the sphere*; and that which is in the middle of the southern hemisphere, the *south pole*.

If another great circle be drawn upon the sphere, in such a manner as to cut the equinoctial at an angle of  $23\frac{1}{2}$  degrees in two opposite points, it will represent the *ecliptic*, or circle of the sun's apparent annual motion: one half of which is on the north side of the equinoctial, and the other half on the south.

If a large stud be made to move eastward in this ecliptic, in such a manner as to go quite round it, in the time that the sphere is turned round westward 366 times upon its axis; this stud will represent the *sun*, changing his place every day a 365th part of the ecliptic; and going round westward, the same way as the stars do; but with a motion so much slower than the motion of the stars, that they will make 366 revolutions about the axis of the sphere, in the time that the sun makes only 365. During one half of these revolutions, the sun will be on the north side of the equinoctial; during the other half, on the south; and at the end of each half, in the equinoctial.

If we suppose the terrestrial globe in this machine to be about one inch in diameter, and the diameter of the starry sphere to be about five or six feet, a small insect on the globe would see only a very little portion of its surface; but it would see one half of the starry sphere; the convexity of the globe hiding the other half from its view. If the sphere be turned westward round the globe, and the insect could judge of the appearances which arise from that motion, it would see some stars rising to its view in the eastern side of the sphere, whilst others were setting on the western: but as all the stars are fixed to the sphere, the same stars would always rise in the same points of view on the east side, and set in the same points of view on the west side. With the sun it would be otherwise, because the sun is not fixed to any point of the sphere, but moves slowly along an oblique circle in it. And if the insect should look towards the south, and call that point of the globe, where the equinoctial in the sphere seems to cut it on the left side, the *east point*; and where it cuts the globe on the right side, the *west point*; the little animal would see the sun rise north of the east, and set north of the west, for  $182\frac{1}{2}$  revolutions; after which, for as many more, the sun would rise south of the east, and set south of the west. And in the whole 365 revolutions, the sun would rise only twice in the east point, and set twice in the west. All these appearances would be the same, if the starry sphere stood still (the sun only moving in the ecliptic) and the earthly globe were turned round the axis of the sphere eastward. For, as the insect would be carried round with the globe, he would be quite insensible of its motion; and the sun and stars would appear to move westward.

We may imagine as many circles described upon the earth as we please; and we may imagine the plane of any circle described upon the earth to be continued, until it marks a circle in the concave sphere of the heavens.

The *horizon* is either *sensible* or *rational*. The *sensible* horizon is that circle which a man standing upon a large plane observes to terminate his view all around, where the heaven and earth seem to meet. The plane of our

sensible horizon continued to the heaven, divides it into two hemispheres; one visible to us, the other hid by the convexity of the earth.

The plane of the *rational horizon*, is supposed parallel to the plane of the sensible; to pass through the centre of the earth, and to be continued to the heavens. And although the plane of the sensible horizon touches the earth in the place of the observer, yet *this* plane, and that of the rational horizon, will seem to coincide in the heaven, because the whole earth is but a point compared to the sphere of the heaven.

The earth being a spherical body, the horizon, or limit of our view, must change as we change our place.

The *poles of the earth*, are those two points on its surface in which its axis terminates. The one is called the *north pole*, and the other the *south pole*.

The *poles of the heaven*, are those two points in which the earth's axis produced terminates in the heaven; so that the *north pole* of the heaven is directly over the north pole of the earth; and the *south pole* of the heaven is directly over the south pole of the earth.

The *equator* is a great circle upon the earth, every part of which is equally distant from either of the poles. It divides the earth into two equal parts, called the *northern* and *southern hemispheres*. If we suppose the plane of this circle to be extended to the heaven, it will mark the *equinoctial* therein, and will divide the heaven into two equal parts, called the *northern* and *southern hemispheres* of the heaven.

The *meridian* of any place is a great circle passing through that place and the poles of the earth. We may imagine as many such meridians as we please, because any place that is ever so little to the east or west of any other place, has a different meridian from that place; for no one circle can pass through any two such places and the poles of the earth.

The *meridian* of any place is divided by the poles into two semicircles: that which passes through the place is called the *geographical*, or *upper meridian*; and that which passes through the opposite place, is called the *lower meridian*.

When the rotation of the earth brings the plane of the geographical meridian to the sun, it is *noon* or *mid-day* to that place; and when the lower meridian comes to the sun, it is *mid-night*.

All places lying under the same geographical meridian, have their noon at the same time, and consequently all the other hours. All those places are said to have the same *longitude*, because no one of them lies either eastward or westward from any of the rest.

If we imagine 24 semicircles, one of which is the geographical meridian of a given place, to meet at the poles, and to divide the equator into 24 equal parts; each of these meridians will come round to the sun in 24 hours, by the earth's equable motion round its axis in that time. And, as the equator contains 360 degrees, there will be 15 degrees contained between any two of those meridians which are nearest to one another: for 24 times 15 is 360. And as the earth's motion is eastward, the sun's apparent motion will be westward, at the rate of 15 degrees each hour. Therefore,

They whose geographical meridian is 15 degrees eastward

ward from us, have noon, and every other hour, an hour sooner than we have. They whose meridian is fifteen degrees westward from us, have noon, and every other hour, an hour later than we have: and so on in proportion, reckoning one hour for every fifteen degrees.

For the ecliptic circle, signs, and degrees, see *ASTRONOMY*, p. 435.

The *tropics* are lesser circles in the heaven, parallel to the equinoctial; one on each side of it, touching the ecliptic in the points of its greatest declination; so that each tropic is  $23\frac{1}{2}$  degrees from the equinoctial, one on the north side of it, and the other on the south. The northern tropic touches the ecliptic at the beginning of Cancer, the southern at the beginning of Capricorn; for which reason the former is called the *tropic of Cancer*, and the latter the *tropic of Capricorn*.

The *polar circles* in the heaven, are each  $23\frac{1}{2}$  degrees from the poles, all around. That which goes round the north pole, is called the *arctic circle*. The south polar circle, is called the *antarctic circle*, from its being opposite to the arctic.

The ecliptic, tropics, and polar circles, are drawn upon the terrestrial globe, as well as upon the celestial. But the ecliptic, being a great fixed circle in the heavens, cannot properly be said to belong to the terrestrial globe; and is laid down upon it only for the conveniency of solving some problems. So that, if this circle on the terrestrial globe was properly divided into the months and days of the year, it would not only suit the globe better, but would also make the problems thereon much easier.

For the earth's motion round its axis every 24 hours; its motion in the ecliptic round the sun every year; and the vicissitude of seasons; see *ASTRONOMY*, p. 452.

### *Description of the Terrestrial Globe.*

[See Plate XLIV. fig. 2.]

The equator, ecliptic, and tropics, polar circles, and meridians, are laid down upon the globe in the manner already described. The ecliptic is divided into 12 signs, and each sign into 30 degrees. Each tropic is  $23\frac{1}{2}$  degrees from the equator, and each polar circle  $23\frac{1}{2}$  degrees from its respective pole. Circles are drawn parallel to the equator, at every ten degrees distance from it on each side to the poles: these circles are called *parallels of latitude*. On large globes there are circles drawn perpendicularly through every tenth degree of the equator, intersecting each other at the poles: but on globes of or under a foot diameter, they are only drawn through every fifteenth degree of the equator; these circles are generally called *meridians*, sometimes *circles of longitude*, and at other times *hour-circles*.

The globe is hung in a brass-ring, called the *brazen meridian*; and turns upon a wire in each pole sunk half its thickness into one side of the meridian ring; by which means, that side of the ring divides the globe into two equal parts, called the *eastern and western hemispheres*; as the equator divides it into two equal parts, called the *northern and southern hemispheres*. The ring is divided

into 360 equal parts or degrees, on the side wherein the axis of the globe turns. One half of these degrees are numbered, and reckoned, from the equator to the poles, where they end at 90: their use is to shew the latitudes of places. The degrees on the other half of the meridian ring are numbered from the poles to the equator, where they end at 90: their use is to shew how to elevate either the north or south pole above the horizon, according to the latitude of any given place, as it is north or south of the equator.

The brazen meridian is let into two notches made in a broad flat ring, called the *wooden horizon*; the upper surface of which divides the globe into two equal parts, called the *upper and lower hemispheres*. One notch is in the north point of the horizon, and the other in the south. On this horizon are several concentric circles, which contain the months and days of the year, the signs and degrees answering to the sun's place for each month and day, and the 32 points of the compass.—The graduated side of the brass meridian lies towards the east side of the horizon, and should be generally kept towards the person who works problems by the globes.

There is a small *horary circle*, so fixed to the north part of the brazen meridian, that the wire in the north pole of the globe is in the centre of that circle; and on the wire is an *index*, which goes over all the 24 hours of the circle, as the globe is turned round its axis. Sometimes there are two horary circles, one between each pole of the globe and the brazen meridian.

There is a thin slip of brass, called the *quadrant of altitude*, which is divided into 90 equal parts or degrees, answering exactly to so many degrees of the equator. It is occasionally fixed to the uppermost point of the brazen meridian by a nut and screw. The divisions end at the nut, and the quadrant is turned round upon it.

### *The Description and Use of the Armillary Sphere.*

[See Plate LXXXVII. Fig. 1.]

THE exterior parts of this machine are, a compages of brass rings, which represent the principal circles of the heaven, viz. 1. The equinoctial *AA*, which is divided into 360 degrees (beginning at its intersection with the ecliptic in Aries) for shewing the sun's right ascension in degrees; and also into 24 hours, for shewing his right ascension in time. 2. The ecliptic *BB*, which is divided into 12 signs, and each sign into 30 degrees, and also into the months and days of the year; in such a manner, that the degree or point of the ecliptic in which the sun is, on any given day, stands over that day in the circle of months. 3. The tropic of Cancer *CC*, touching the ecliptic at the beginning of Cancer in *e*, and the tropic of Capricorn *DD*, touching the ecliptic at the beginning of Capricorn in *f*; each  $23\frac{1}{2}$  degrees from the equinoctial circle. 4. The arctic circle *E*, and the antarctic circle *F*, each  $23\frac{1}{2}$  degrees from its respective pole at *N* and *S*. 5. The equinoctial colure *GG*, passing through the north and south poles of the heaven at *N* and *S*, and through the equinoctial points Aries and Libra, in the ecliptic. 6. The solstitial colure *HH*, passing through the poles of the heaven,

heaven, and through the solstitial points Cancer and Capricorn, in the ecliptic. Each quarter of the former of these colures is divided into 90 degrees, from the equinoctial to the poles of the world, for shewing the declination of the sun, moon, and stars; and each quarter of the latter, from the ecliptic at *e* and *f*, to its poles *b* and *d*, for shewing the latitude of the stars.

In the north pole of the ecliptic is a nut *b*, to which is fixed one end of a quadrantal wire, and to the other end a small sun *T*, which is carried round the ecliptic *B B*, by turning the nut: and in the south pole of the ecliptic is a pin *d*, on which is another quadrantal wire, with a small moon *Z* upon it, which may be moved round by hand: but there is a particular contrivance for causing the moon to move in an orbit which crosses the ecliptic at an angle of  $5\frac{1}{2}$  degrees, in two opposite points called the *moon's nodes*; and also for shifting these points backward in the ecliptic, as the *moon's nodes* shift in the heaven.

Within these circular rings is a small terrestrial globe *J*, fixt on an axis *KK*, which extends from the north and south poles of the globe at *n* and *s*, to those of the celestial sphere at *N* and *S*. On this axis is fixt the flat celestial meridian *LL*, which may be set directly over the meridian of any place on the globe, and then turned round with the globe, so as to keep over the same meridian upon it. This flat meridian is graduated the same way as the brass meridian of a common globe, and its use is much the same. To this globe is fitted the moveable horizon *MM*, so as to turn upon two strong wires proceeding from its east and west points to the globe, and entering the globe at the opposite points of its equator, which is a moveable brass ring let into the globe in a groove all around its equator. The globe may be turned by hand within this ring, so as to place any given meridian upon it, directly under the celestial meridian *LL*. The horizon is divided into 360 degrees all around its outermost edge, within which are the points of the compass, for shewing the amplitude of the sun and moon, both in degrees and points. The celestial meridian *LL* passes through two notches in the north and south points of the horizon, as in a common globe: but here, if the globe be turned round, the horizon and meridian turn with it. At the south pole of the sphere is a circle of 24 hours, fixt to the rings, and on the axis is an index which goes round that circle, if the globe be turned round its axis.

The whole fabric is supported on a pedestal *N*, and may be elevated or depressed upon the joint *O*, to any number of degrees from 0 to 90, by means of the arc *P*, which is fixed in the strong brass arm *Q*, and slides in the upright piece *R*, in which is a screw at *r*, to fix it at any proper elevation.

In the box *T* are two wheels (as in Dr Long's sphere) and two pinions, whose axes come out at *V* and *U*; either of which may be turned by the small winch *W*. When the winch is put upon the axis *V*, and turn backward, the terrestrial globe, with its horizon and celestial meridian, keep at rest; and the whole sphere of circles turns round from east, by south, to west, carrying the sun *T*, and moon *Z*, round the same way, and causing

them to rise above and set below the horizon. But when the winch is put upon the axis *U*, and turned forward, the sphere with the sun and moon keep at rest; and the earth, with its horizon and meridian, turn round from west, by south, to east; and bring the same points of the horizon to the sun and moon, to which these bodies came when the earth kept at rest, and they were carried round it; shewing that they rise and set in the same points of the horizon, and at the same times in the hour circle, whether the motion be in the earth or in the heaven. If the earthly globe be turned, the hour-index goes round its hour-circle; but if the sphere be turned, the hour-circle goes round below the index.

And so, by this construction, the machine is equally fitted to shew either the real motion of the earth, or the apparent motion of the heaven.

To rectify the sphere for use, first slacken the screw *r* in the upright stem *R*, and taking hold of the arm *Q*, move it up or down until the given degree of latitude for any place be at the side of the stem *R*; and then the axis of the sphere will be properly elevated, so as to stand parallel to the axis of the world, if the machine be set north and south by a small compass: this done, count the latitude from the north pole, upon the celestial meridian *LL*, down towards the north notch of the horizon, and set the horizon to that latitude; then, turn the nut *b* until the sun *T* comes to the given day of the year in the ecliptic, and the sun will be at its proper place for that day: find the place of the moon's ascending node, and also the place of the moon, by an Ephemeris, and set them right accordingly: lastly, turn the winch *W*, until either the sun comes to the meridian *LL*, or until the meridian comes to the sun (according as you want the sphere or earth to move) and set the hour-index to the XII, marked noon, and the whole machine will be rectified.——Then turn the winch, and observe when the sun or moon rise and set in the horizon, and the hour-index will shew the times thereof for the given day.

As those who understand the use of the globes will be at no loss to work many other problems by this sphere, it is needless to enlarge any farther upon it.

### *Directions for using Globes.*

In using globes, keep the east side of the horizon towards you (unless your problem require the turning of it), which side you may know by the word East upon the horizon; for then you have the graduated side of the meridian towards you, the quadrant of altitude before you, and the globe divided exactly into two equal parts, by the graduated side of the meridian.

In working some problems, it will be necessary to turn the whole globe and horizon about, that you may look on the west side thereof; which turning will be apt to jog the ball so, as to shift away that degree of the globe which was before set to the horizon or meridian: to avoid which inconvenience, you may thrust in the feather-end of a quill between the ball of the globe and the brazen meridian; which, without hurting the ball, will keep it

it from turning in the meridian, whilst you turn the west side of the horizon towards you.

PROB. I. *To find the latitude and longitude of any given place upon the globe*—Turn the globe on its axis, until the given place comes exactly under that graduated side of the brazen meridian, on which the degrees are numbered from the equator; and observe what degree of the meridian the place then lies under; which is its latitude, north or south, as the place is north or south of the equator.

The globe remaining in this position, the degree of the equator, which is under the brazen meridian, is the longitude of the place which is east or west, as the place lies on the east or west side of the first meridian of the globe.—All the Atlantic Ocean, and America, is on the west side of the meridian of London; and the greatest part of Europe, and of Africa, together with all Asia, is on the east side of the meridian of London, which is reckoned the *first meridian* of the globe by the British geographers and astronomers.

PROB. II. *The longitude and latitude of a place being given, to find that place on the globe*.—Look for the given longitude in the equator (counting it eastward or westward from the first meridian as it is mentioned to be east or west;) and bring the point of longitude in the equator to the brazen meridian, on that side which is above the south point of the horizon: then count from the equator, on the brazen meridian, to the degree of the given latitude, towards the north or south pole, according as the latitude is north or south; and under that degree of latitude on the meridian, you will have the place required.

PROB. III. *To find the difference of longitude, or difference of latitude, between any two given places*.—Bring each of these places to the brazen meridian, and see what its latitude is: the lesser latitude subtracted from the greater, if both places are on the same side of the equator, or both latitudes added together, if they are on different sides of it, is the difference of latitude required. And the number of degrees contained between these places, reckoned on the equator, when they are brought separately under the brazen meridian, is their difference of longitude; if it be less than 180: but if more, let it be subtracted from 360, and the remainder is the difference of longitude required. Or,

Having brought one of the places to the brazen meridian, and set the hour-index to XII, turn the globe until the other place comes to the brazen meridian, and the number of hours and parts of an hour, past over by the index, will give the longitude in time; which may be easily reduced to degrees, by allowing 15 degrees for every hour, and one degree for every four minutes.

N B. When we speak of bringing any place to the brazen meridian, it is the graduated side of the meridian that is meant.

PROB. IV. *Any place being given, to find all those places that have the same longitude or latitude with it*.—Bring the given place to the brazen meridian, then all those places which lie under that side of the meridian, from pole to pole, have the same longitude with the given place. Turn the globe round its axis, and all those pla-

ces which pass under the same degree of the meridian that the given place does, have the same latitude with that place.

Since all latitudes are reckoned from the equator, and all longitudes are reckoned from the first meridian, it is evident, that the point of the equator which is cut by the first meridian, has neither latitude nor longitude.—The greatest latitude is 90 degrees, because no place is more than 90 degrees from the equator. And the greatest longitude is 180 degrees, because no place is more than 180 degrees from the first meridian.

PROB. V. *To find the antæci, periæci, and antipodes, of any given place*.—Bring the given place to the brazen meridian; and having found its latitude, keep the globe in that situation, and count the same number of degrees of latitude from the equator towards the contrary pole; and where the reckoning ends, you have the *antæci* of the given place upon the globe. Those who live at the equator have no *antæci*.

The globe remaining in the same position, set the hour-index to the upper XII on the horary circle, and turn the globe until the index comes to the lower XII; then, the place which lies under the meridian, in the same latitude with the given place, is the *periæci* required. Those who live at the poles have no *periæci*.

As the globe now stands (with the index at the lower XII) the *antipodes* of the given place will be under the same point of the brazen meridian where its *antæci* stood before. Every place upon the globe has its *antipodes*.

PROB. VI. *To find the distance between any two places on the globe*.—Lay the graduated edge of the quadrant of altitude over both the places, and count the number of degrees intercepted between them on the quadrant; then multiply these degrees by 60, and the product will give the distance in geographical miles: but to find the distance in miles, multiply the degrees by  $69\frac{1}{2}$ , and the product will be the number of miles required. Or, take the distance betwixt any two places with a pair of compasses, and apply that extent to the equator; the number of degrees, intercepted between the points of the compasses, is the distance in degrees of a great circle; which may be reduced either to geographical miles, or to English miles, as above.

PROB. VII. *A place on the globe being given, and its distance from any other place, to find all the other places upon the globe which are at the same distances from the given place*.—Bring the given place to the brazen meridian, and screw the quadrant of altitude to the meridian, directly over that place; then keeping the globe in that position, turn the quadrant quite round upon it, and the degree of the quadrant that touches the second place will pass over all the other places which are equally distant with it from the given place.

This is the same as if one foot of a pair of compasses was set in the given place, and the other foot extended to the second place, whose distance is known; for if the compasses be then turned round the first place as a centre, the moving foot will go over all those places which are at the same distance with the second from it.

PROB. VIII. *The hour of the day at any place being given, to find all those places where it is noon at that time*.

*time*—Bring the given place to the brazen meridian, and set the index to the given hour; this done, turn the globe until the index points to the upper XII, and then all the places that lie under the brazen meridian have noon at that time.

*N. B.* The upper XII always stands for noon; and when the bringing of any place to the brazen meridian is mentioned, the side of that meridian on which the degrees are reckoned from the equator is meant, unless the contrary side be mentioned.

**PROB. IX.** *The hour of the day at any place being given, to find what o'clock it then is at any other place.*—Bring the given place to the brazen meridian, and set the index to the given hour; then turn the globe, until the place where the hour is required comes to the meridian, and the index will point out the hour at that place.

**PROB. X.** *To find the sun's place in the ecliptic, and his declination, for any given day of the year.*—Look on the horizon for the given day, and right against it you have the degree of the sign in which the sun is (or his place) on that day at noon. Find the same degree of that sign in the ecliptic line upon the globe, and having brought it to the brazen meridian, observe what degree of the meridian stands over it; for that is the sun's declination, reckoned from the equator.

**PROB. XI.** *The day of the month being given, to find all those places of the earth over which the sun will pass vertically on that day.*—Find the sun's place in the ecliptic for the given day, and having brought it to the brazen meridian, observe what point of the meridian is over it; then, turning the globe round its axis, all those places which pass under that point of the meridian, are the places required; for as their latitude is equal, in degrees and parts of a degree, to the sun's declination, the sun must be directly over head to each of them at its respective noon.

**PROB. XII.** *A place being given in the torrid zone, to find those two days of the year on which the sun shall be vertical to that place.*—Bring the given place to the brazen meridian, and mark the degree of latitude that is exactly over it on the meridian; then turn the globe round its axis, and observe the two degrees of the ecliptic which pass exactly under that degree of latitude: lastly, find on the wooden horizon, the two days of the year in which the sun is in those degrees of the ecliptic, and they are the days required: for on them, and none else, the sun's declination is equal to the latitude of the given place; and consequently, he will then be vertical to it at noon.

**PROB. XIII.** *To find all those places of the north frigid zone, where the sun begins to shine constantly without setting, on any given day, from the 21st of March to the 23d of September.*—On these two days, the sun is in the equinoctial, and enlightens the globe exactly from pole to pole: therefore, as the earth turns round its axis, which terminates in the poles, every place upon it will go equally through the light and the dark, and so make equal day and night to all places of the earth. But as the sun declines from the equator, towards either pole, he will shine just as many degrees round that pole, as are equal to his declination from the equator; so that no

place within that distance of the pole will then go through any part of the dark, and consequently the sun will not set to it. Now, as the sun's declination is northward, from the 21st of March to the 23d of September, he must constantly shine round the north pole all that time; and on the day that he is in the northern tropic, he shines upon the whole north frigid zone; so that no place within the north polar circle goes through any part of the dark on that day. Therefore,

Having brought the sun's place for the given day to the brazen meridian, and found his declination (by Prob. IX.) count as many degrees on the meridian, from the north pole, as are equal to the sun's declination from the equator, and mark that degree from the pole where the reckoning ends: then, turning the globe round its axis, observe what places in the north frigid zone pass directly under that mark; for they are the places required.

The like may be done for the south frigid zone, from the 23d of September to the 21st of March, during which time the sun shines constantly on the south pole.

**PROB. XIV.** *To find the place over which the sun is vertical at any hour of a given day.*—Having found the sun's declination for the given day (by Prob. IX.) mark it with a chalk on the brazen meridian: then bring the place where you are (suppose Edinburgh) to the brazen meridian, and set the index to the given hour; which done, turn the globe on its axis, until the index points to XII at noon; and the place on the globe, which is then directly under the point of the sun's declination marked upon the meridian, has the sun that moment in the zenith, or directly over head.

**PROB. XV.** *The day and hour of a lunar eclipse being given; to find all those places of the earth to which it will be visible.*—The moon is never eclipsed but when she is full, and so directly opposite to the sun, that the earth's shadow falls upon her. Therefore, whatever place of the earth the sun is vertical to at that time, the moon must be vertical to the antipodes of that place: so that the sun will be then visible to one half of the earth, and the moon to the other.

Find the place to which the sun is vertical at the given hour (by Prob. XIV.) elevate the pole to the latitude of that place, and bring the place to the upper part of the brazen meridian, as in the former problem: then, as the sun will be visible to all those parts of the globe which are above the horizon, the moon will be visible to all those parts which are below it, at the time of her greatest obscuration.

**PROB. XVI.** *To rectify the globe for the latitude, the zenith, and the sun's place.*—Find the latitude of the place (by Prob. I.) and if the place be in the northern hemisphere, raise the north pole above the north point of the horizon, as many degrees (counted from the pole upon the brazen meridian) as are equal to the latitude of the place. If the place be in the southern hemisphere, raise the south pole above the south point of the horizon, as many degrees as are equal to the latitude. Then, turn the globe till the place comes under its latitude on the brazen meridian, and fasten the quadrant of altitude so, that the chamfered edge of its nut (which is even with the graduated edge) may be joined to the zenith,

or

or point of latitude. This done, bring the sun's place in the ecliptic for the given day (found by Prob. X.) to the graduated side of the brazen meridian, and set the hour-index to XII at noon, which is the uppermost XII on the hour-circle; and the globe will be rectified.

PROB. XVII. *To find the latitude of any place, not exceeding  $66\frac{1}{2}$  degrees, and the day of the month, being given; to find the time of sun rising and setting, and consequently the length of the day and night.*—Having rectified the globe for the latitude, and for the sun's place on the given day (as directed in the preceding problem) bring the sun's place in the ecliptic to the eastern side of the horizon, and the hour-index will shew the time of sun rising; then turn the globe on its axis, until the sun's place comes to the western side of the horizon, and the index will shew the time of sun setting.

The hour of sun setting doubled, gives the length of the day; and the hour of sun rising doubled, gives the length of the night.

PROB. XVIII. *The latitude of any place, and the day of the month being given; to find when the morning twilight begins, and the evening twilight ends, at that place.*—This problem is often limited: for, when the sun does not go 18 degrees below the horizon, the twilight continues the whole night; and for several nights together in summer, between 49 and  $66\frac{1}{2}$  degrees of latitude; and the nearer to  $66\frac{1}{2}$ , the greater is the number of these nights. But when it does begin and end, the following method will shew the time for any given day.

Rectify the globe, and bring the sun's place in the ecliptic to the eastern side of the horizon; then mark that point of the ecliptic with a chalk which is in the western side of the horizon, it being the point opposite to the sun's place: this done, lay the quadrant of altitude over the said point, and turn the globe eastward, keeping the quadrant at the chalk mark, until it be just 18 degrees high on the quadrant; and the index will point out the time when the morning twilight begins: for the sun's place will then be 18 degrees below the eastern side of the horizon. To find the time when the evening twilight ends, bring the sun's place to the western side of the horizon, and the point opposite to it, which was marked with the chalk, will be rising in the east: then, bring the quadrant over that point, and keeping it thereon, turn the globe westward, until the said point be 18 degrees above the horizon on the quadrant, and the index will shew the time when the evening twilight ends; the sun's place being then 18 degrees below the western side of the horizon.

PROB. XIX. *To find on what day of the year the sun begins to shine constantly without setting, on any given place in the north frigid zone; and how long he continues to do so.*—Rectify the globe to the latitude of the place, and turn it about until some point of the ecliptic, between aries and cancer, coincides with the north point of the horizon where the brazen meridian cuts it: then find, on the wooden horizon, what day of the year the sun is in that point of the ecliptic; for that is the day on which the sun begins to shine constantly on the given place, without setting. This done, turn the globe until some point of the ecliptic, between cancer and libra, coincides

with the north point of the horizon, where the brazen meridian cuts it; and find, on the wooden horizon, on what day the sun is in that point of the ecliptic; which is the day that the sun leaves off constantly shining on the said place, and rises and sets to it as to other places on the globe. The number of natural days, or complete revolutions of the sun about the earth, between the two days above found, is the time that the sun keeps constantly above the horizon without setting: for all that portion of the ecliptic, which lies between the two points which intersect the horizon in the very north, never sets below it: and there is just as much of the opposite part of the ecliptic that never rises; therefore, the sun will keep as long constantly below the horizon in winter, as above it in summer.

PROB. XX. *To find in what latitude the sun shines constantly without setting, for any length of time less than  $182\frac{1}{2}$  of our days and nights.*—Find a point in the ecliptic half as many degrees from the beginning of cancer (either toward aries or libra) as there are natural days in the time given; and bring that point to the north side of the brazen meridian, on which the degrees are numbered from the pole towards the equator: then, keep the globe from turning on its axis, and slide the meridian up or down, until the foresaid point of the ecliptic comes to the north point of the horizon, and then the elevation of the pole will be equal to the latitude required.

PROB. XXI. *The latitude of a place, not exceeding  $66\frac{1}{2}$  degrees, and the day of the month being given; to find the sun's amplitude, or point of the compass on which he rises or sets.*—Rectify the globe, and bring the sun's place to the eastern side of the horizon; then observe what point of the compass on the horizon stands right against the sun's place, for that is his amplitude at rising. This done, turn the globe westward, until the sun's place comes to the western side of the horizon, and it will cut the point of his amplitude at setting. Or, you may count the rising amplitude in degrees, from the east point of the horizon, to that point where the sun's place cuts it; and the setting amplitude, from the west point of the horizon, to the sun's place at setting.

PROB. XXII. *The latitude, the sun's place, and his altitude, being given; to find the hour of the day, and the sun's azimuth, or number of degrees that he is distant from the meridian.*—Rectify the globe, and bring the sun's place to the given height upon the quadrant of altitude; on the eastern side of the horizon, if the time be in the forenoon; or the western side, if it be in the afternoon: then the index will shew the hour; and the number of degrees in the horizon, intercepted between the quadrant of altitude and the south point, will be the sun's true azimuth at that time.

PROB. XXIII. *The latitude, hour of the day, and the sun's place, being given; to find the sun's altitude and azimuth.*—Rectify the globe, and turn it until the index points to the given hour; then lay the quadrant of altitude over the sun's place in the ecliptic, and the degree of the quadrant cut by the sun's place is his altitude at that time above the horizon; and the degree of the horizon cut by the quadrant is the sun's azimuth, reckoned from the south.

PROB. XXIV. *The latitude, the sun's altitude, and*

*his azimuth being given; to find his place in the ecliptic, the day of the month, and hour of the day, though they had all been lost.*—Rectify the globe for the latitude and zenith, and set the quadrant of altitude to the given azimuth in the horizon; keeping it there, turn the globe on its axis until the ecliptic cuts the quadrant in the given altitude: that point of the ecliptic which cuts the quadrant there, will be the sun's place; and the day of the month answering thereto, will be found over the like place of the sun on the wooden horizon. Keep the quadrant of altitude in that position; and, having brought the sun's place to the brazen meridian, and the hour-index to XII at noon, turn back the globe, until the sun's place cuts the quadrant of altitude again, and the index will shew the hour.

Any two points of the ecliptic, which are equidistant from the beginning of Cancer or of Capricorn, will have the same altitude and azimuth at the same hour, though the months be different; and therefore it requires some care in this problem, not to mistake both the month and the day of the month; to avoid which, observe, that from the 20th of March to the 21st of June, that part of the ecliptic which is between the beginning of Aries and beginning of Cancer is to be used: from the 21st of June to the 23d of September, between the beginning of Cancer and beginning of Libra: from the 23d of September to the 21st of December, between the beginning of Libra and the beginning of Capricorn; and from the 21st of December to the 20th of March, between the beginning of Capricorn and beginning of Aries. And as one can never be at a loss to know in what quarter of the year he takes the sun's altitude and azimuth, the above caution with regard to the quarters of the ecliptic will keep him right as to the month and day thereof.

**PROB. XXV.** *To find the length of the longest day at any given place.*—If the place be on the north side of the equator (find its latitude by Prob. I.) and elevate the north pole to that latitude; then, bring the beginning of Cancer to the brazen meridian, and set the hour-index to XII at noon. But if the given place be on the south side of the equator, elevate the south pole to its latitude, and bring the beginning of Capricorn to the brazen meridian, and the hour-index to XII. This done, turn the globe westward, until the beginning of Cancer or Capricorn (as the latitude is north or south) comes to the horizon; and the index will then point out the time of sun-setting, for it will have gone over all the afternoon hours, between mid-day and sun set; which length of time being doubled, will give the whole length of the day from sun-rising to sun-setting. For, in all latitudes, the sun rises as long before mid day, as he sets after it.

**PROB. XXVI.** *To find in what latitude the longest day is, of any given length, less than 24 hours.*—If the latitude be north, bring the beginning of Cancer to the brazen meridian, and elevate the north pole to about  $66\frac{1}{2}$  degrees; but if the latitude be south, bring the beginning of Capricorn to the meridian, and elevate the south pole to about  $66\frac{1}{2}$  degrees; because the longest day in north latitude is, when the sun is in the first point of Cancer; and in south latitude, when he is in the first point of Capricorn. Then set the hour-index to XII at

noon, and turn the globe westward, until the index points at half the number of hours given; which done, keep the globe from turning on its axis, and slide the meridian down in the notches, until the aforesaid point of the ecliptic (*viz.* Cancer or Capricorn) comes to the horizon; then, the elevation of the pole will be equal to the latitude required.

**PROB. XXVII.** *The latitude of any place, not exceeding  $66\frac{1}{2}$  degrees, being given; to find in what climate the place is.*—Find the length of the longest day at the given place, by Prob. XXV. and, whatever be the number of hours whereby it exceedeth twelve, double that number, and the sum will give the climate in which the place is.

**PROB. XXVIII.** *The latitude, and the day of the month, being given; to find the hour of the day when the sun shines.*—Set the wooden horizon truly level, and the brazen meridian due north and south by a mariner's compass: then, having rectified the globe, stick a small sewing-needle into the sun's place in the ecliptic, perpendicular to that part of the surface of the globe: this done, turn the globe on its axis, until the needle comes to the brazen meridian, and set the hour-index to XII at noon; then, turn the globe on its axis, until the needle points exactly towards the sun (which it will do when it casts no shadow on the globe), and the index will shew the hour of the day.

### *The Use of the Celestial Globe.*

HAVING done for the present with the terrestrial globe, we shall proceed to the use of the celestial; first premising, that as the equator, ecliptic, tropics, polar-circles, horizon, and brazen meridian, are exactly alike on both globes, all the former problems concerning the sun are solved the same way by both globes. The method also of rectifying the celestial globe is the same as rectifying the terrestrial.

*N. B.* The sun's place for any day of the year stands directly over that day on the horizon of the celestial globe, as it does on that of the terrestrial.

The *latitude* and *longitude* of the stars, or of all other celestial phenomena, are reckoned in a very different manner from the latitude and longitude of places on the earth: for all terrestrial latitudes are reckoned from the equator; and longitudes from the meridian of some remarkable place, as of London by the British, and of Paris by the French. But the astronomers of all nations agree in reckoning the latitudes of the moon, stars, planets, and comets, from the ecliptic; and their longitudes from the equinoctial colure, in that semi-circle of it which cuts the ecliptic at the beginning of Aries; and thence eastward, quite round, to the same semi-circle again. Consequently those stars which lie between the equinoctial and the northern half of the ecliptic, have north declination and south latitude; those which lie between the equinoctial and the southern half of the ecliptic, have south declination and north latitude; and all those which lie between the tropics and poles, have their declinations and latitudes of the same denomination.

There are six great circles on the celestial globe, which

cut the ecliptic perpendicularly, and meet in two opposite points in the polar circles; which points are each ninety degrees from the ecliptic, and are called its poles. These polar points divide those circles into 12 semicircles; which cut the ecliptic at the beginnings of the 12 signs. They resemble so many meridians on the terrestrial globe; and as all places which lie under any particular meridian-semicircle on that globe, have the same longitude, so all those points of the heaven, through which any of the above semicircles are drawn, have the same longitude.—And as the greatest latitudes on the earth are at the north and south poles of the earth, so the greatest latitudes in the heaven are at the north and south poles of the ecliptic.

For the division of the stars into constellations, &c. see *ASTRONOMY*, p. 486.

**PROB. I.** *To find the right ascension and declination of the sun, or any fixed star.*—Bring the sun's place in the ecliptic to the brazen meridian; then that degree in the equinoctial which is cut by the meridian, is the sun's *right ascension*; and that degree of the meridian which is over the sun's place, is his *declination*. Bring any fixed star to the meridian, and its right ascension will be cut by the meridian in the equinoctial; and the degree of the meridian that stands over it, is its declination.

So that the right ascension and declination, on the celestial globe, are found in the same manner as longitude and latitude on the terrestrial.

**PROB. II.** *To find the latitude and longitude of any star.*—If the given star be on the north side of the ecliptic, place the 90th degree of the quadrant of altitude on the north pole of the ecliptic, where the twelve semicircles meet, which divide the ecliptic into the 12 signs: but if the star be on the south side of the ecliptic, place the 90th degree of the quadrant on the south pole of the ecliptic: keeping the 90th degree of the quadrant on the proper pole, turn the quadrant about, until its graduated edge cuts the star: then, the number of degrees in the quadrant, between the ecliptic and the star, is its latitude; and the degree of the ecliptic, cut by the quadrant, is the star's longitude, reckoned according to the sign in which the quadrant then is.

**PROB. III.** *To represent the face of the starry firmament, as seen from any given place of the earth, at any hour of the night.*—Rectify the celestial globe for the given latitude, the zenith, and sun's place, in every respect, as taught by the XVIth problem, for the terrestrial; and turn it about, until the index points to the given hour: then, the upper hemisphere of the globe will represent the visible half of the heaven for that time: all the stars upon the globe being then in such situations, as exactly correspond to those in the heaven. And if the globe be placed duly north and south, by means of a small sea-compass, every star in the globe will point toward the like star in the heaven: by which means, the constellations and remarkable stars may be easily known. All those stars which are in the eastern side of the horizon, are then rising in the eastern side of the heaven; all in the western, are setting in the western side; and all those under the upper part of the brazen meridian, between the south point of the horizon and the north pole, are at their greatest altitude, if the latitude of the place be north:

but if the latitude be south, those stars which lie under the upper part of the meridian, between the north point of the horizon and the south pole, are at their greatest altitude.

**PROB. IV.** *The latitude of the place, and day of the month, being given; to find the time when any known star will rise, or be upon the meridian, or set.*—Having rectified the globe, turn it about until the given star comes to the eastern side of the horizon, and the index will shew the time of the star's rising; then turn the globe westward, and when the star comes to the brazen meridian, the index will shew the time of the star's coming to the meridian of your place; lastly, turn on, until the star comes to the western side of the horizon, and the index will shew the time of the star's setting.

**N. B.** In northern latitudes, those stars which are less distant from the north pole, than the quantity of its elevation above the north point of the horizon, never set; and those which are less distant from the south pole, than the number of degrees by which it is depressed below the horizon, never rise: and *vice versa* in southern latitudes.

**PROB. V.** *To find at what time of the year a given star will be upon the meridian, at a given hour of the night.*—Bring the given star to the upper semicircle of the brazen meridian, and set the index to the given hour; then turn the globe, until the index points to XII at noon, and the upper semicircle of the meridian will then cut the sun's place, answering to the day of the year sought; which day may be easily found against the like place of the sun among the signs on the wooden horizon.

**PROB. VI.** *The latitude, day of the month, and azimuth of any known star, being given; to find the hour of the night.*—Having rectified the globe for the latitude, zenith, and sun's place, lay the quadrant of altitude to the given degree of azimuth in the horizon: then turn the globe on its axis, until the star comes to the graduated edge of the quadrant; and when it does, the index will point out the hour of the night.

**PROB. VII.** *The latitude of the place, the day of the month, and altitude of any known star, being given; to find the hour of the night.*—Rectify the globe as in the former problem, guess at the hour of the night, and turn the globe until the index points at the supposed hour; then lay the graduated edge of the quadrant of altitude over the known star, and if the degree of the star's height in the quadrant upon the globe, answers exactly to the degree of the star's observed altitude in the heaven, you have guessed exactly: but if the star on the globe is higher or lower than it was observed to be in the heaven, turn the globe backwards or forwards, keeping the edge of the quadrant upon the star, until its centre comes to the observed altitude in the quadrant; and then, the index will shew the true time of the night.

**PROB. VIII.** *An easy method for finding the hour of the night by any two known stars, without knowing either their altitude or azimuth; and then, of finding both their altitude and azimuth, and thereby the true meridian.*—Tie one end of a thread to a common musket-bullet; and, having rectified the globe as above, hold the other end of the thread in your hand, and carry it slowly

slowly round betwixt your eye and the starry heaven, until you find it cuts any two known stars at once. Then guessing at the hour of the night, turn the globe until the index points to that time in the hour circle; which done, lay the graduated edge of the quadrant over any one of these two stars on the globe, which the thread cut in the heaven. If the said edge of the quadrant cuts the other star also, you have guessed the time exactly; but if it does not, turn the globe slowly backwards or forwards, until the quadrant (kept upon either star) cuts them both through their centres: and then, the index will point out the exact time of the night; the degree of the horizon, cut by the quadrant, will be the true azimuth of both these stars from the south; and the stars themselves will cut their true altitude in the quadrant. At which moment, if a common azimuth-compass be so set upon a floor or level pavement, that these stars in the heaven may have the same bearing upon it (allowing for the variation of the needle) as the quadrant of altitude has in the wooden horizon of the globe, a thread extended over the north and south points of that compass will be directly in the plane of the meridian: and if a line be drawn upon the floor or pavement, along the course of the thread, and an upright wire be placed in the southmost end of the line, the shadow of the wire will fall upon that line, when the sun is on the meridian, and shines upon the pavement.

**PROB. IX.** *To find the place of the moon, or of any planet; and thereby to shew the time of its rising, southing, and setting.*—Seek in Parker's or Weaver's ephemeris the geocentric place of the moon or planet in the ecliptic, for the given day of the month; and, according to its longitude and latitude, as shewn by the ephemeris, mark the same with a chalk upon the globe. Then, ha-

ving rectified the globe, turn it round its axis westward; and as the said mark comes to the eastern side of the horizon, to the brazen meridian, and to the western side of the horizon, the index will shew at what time the planet rises, comes to the meridian, and sets, in the same manner as it would do for a fixed star.

For an explanation of the harvest moons by a globe, see **ASTRONOMY**, p. 463.

For the description and use of a planetary globe, see **ASTRONOMY**, p. 498.

For the equation of time, see **ASTRONOMY**, p. 458.

HAVING thus explained the use of the globes, and general principles of geography, we must refer to the maps for the situation of each particular country, with regard to longitude, latitude, &c. The use of maps is obvious from their construction. The degrees of the meridian, and parallels, shew the longitudes and latitudes of places; and the scale of miles annexed, their distances. The situation of places, with regard to each other, as well as the cardinal points, appears by inspection; the top of the map being always *the north*, the bottom the *south*, the right-hand the *east*, and the left the *west*, unless the compass usually annexed shew the contrary.

The brevity, which we are necessarily obliged to observe, prevents us from taking any notice of many particulars, which are to be found in large treatises on this subject. A general account of countries, cities, rivers, mountains, &c. is given under their respective names, as they occur in the order of the alphabet. We shall therefore conclude this article with the following table, which will serve to give an idea of the general division of the habitable earth; and at the same time serve to explain the maps in Plates 87. 88. 89. 90. 91. and 92.

*The Division of the Habitable Earth, the square Miles of each Division and Subdivision, Capital Cities, with the Distance and Bearing of each from London; also the Time of each Country compared with that of England.*

THE terraqueous globe is divided into	I. EUROPE	2,749,349	} Square miles, 60 miles in length to a degree.
	II. ASIA	10,257,487	
	III. AFRICA	8,506,208	
	IV. AMERICA	9,153,762	
	Habitable earth	30,666,806	
	Seas, and unknown parts	117,843,821	
	Superficies of the whole globe	148,510,627	

Division and subdivision.	Square miles.	Capital cities.	Distance and bearing from London.	Diff. of time from London.
<b>I. EUROPE.</b>				
1. Spain	150,243	Madrid	690 S	*H.M. 0 16 W
2. Portugal	27,851	Lisbon	840 S W	0 38 W
3. France	138,837	Paris	203 E	0 9 E

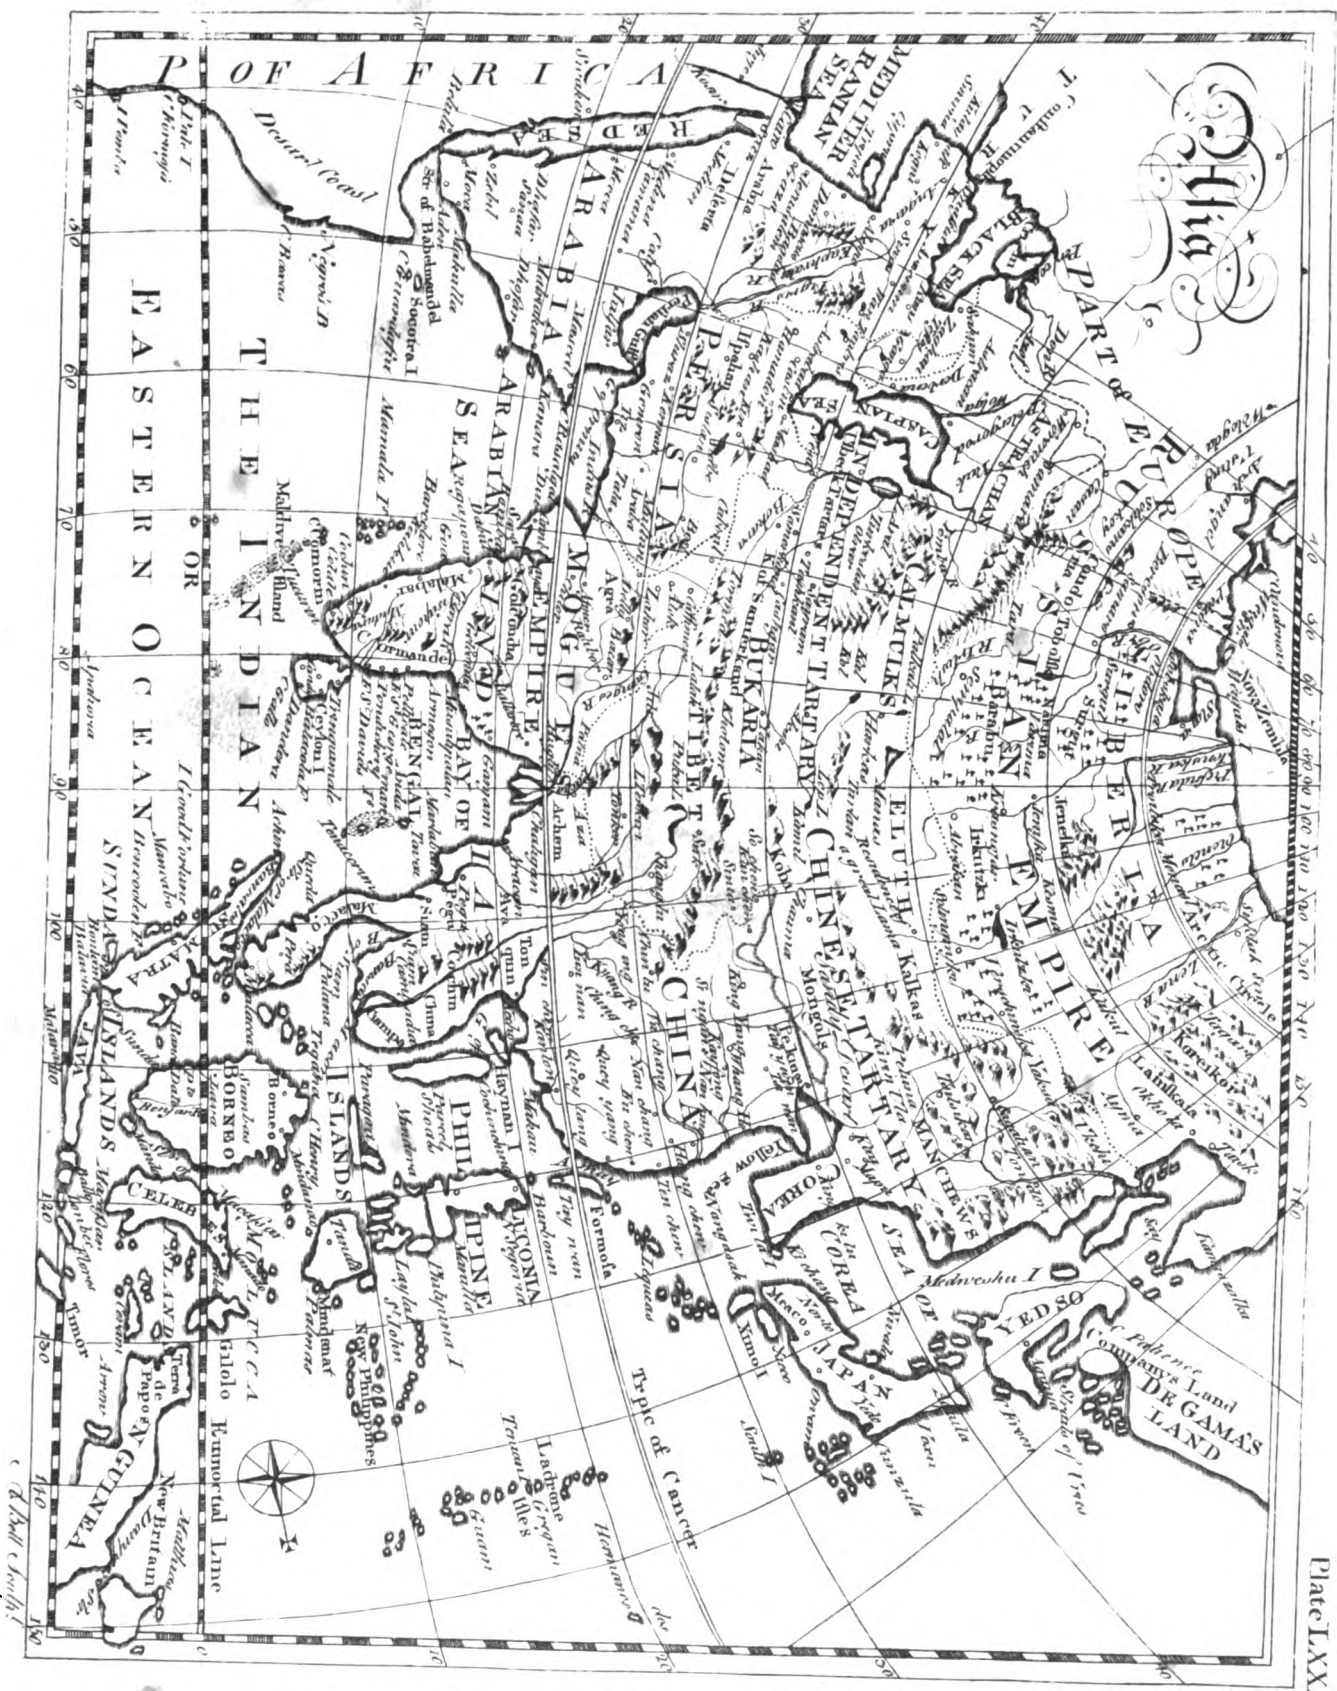

4. Italy

\* A degree of longitude being 4 minutes in time, therefore by having the longitude we have the time. A watch that is set to time at London would be 16 minutes too fast at Madrid, as it lies to the west of the meridian at London: and Vienna being 16 degrees and 20 minutes to the east of the meridian of London, consequently a watch set at London would be 1 hour and 5 minutes too slow at Vienna.

## G E O M E T R Y.

**G**EOMETRY originally signified no more than the art of measuring the earth, or any distances or dimensions within it: but at present, it denotes the science of magnitude in general; comprehending the doctrine and relations of whatever is susceptible of augmentation or diminution, considered in that light.

Hence to geometry may be referred the consideration not only of lines, surfaces, and solids; but also of time, velocity, number, weight, &c.

This science had its rise among the Egyptians, who were in a manner compelled to invent it, to remedy the confusion which generally happened in their lands, from the inundations of the river Nile, which carried away all boundaries, and effaced all the limits of their possessions. Thus this invention, which at first consisted only in measuring the lands, that every person might have what belonged to him, was called Geometry, or the art of measuring land; and it is probable that the draughts and schemes, which they were annually compelled to make, helped them to discover many excellent properties of

these figures; which speculations continued to be gradually improved, and are so to this day.

From Egypt geometry passed into Greece; where it continued to receive new improvements in the hands of Thales, Pythagoras, Archimedes, Euclid, &c. The Elements of Geometry, written by this last in fifteen books, are a most convincing proof to what perfection this science was carried among the ancients. However, it must be acknowledged, that it fell short of modern geometry; the bounds of which, what by the invention of fluxions, and the discovery of the almost infinite orders of curves, are greatly enlarged.

We may distinguish the progress of geometry into three ages; the first of which was in its meridian glory at the time when Euclid's Elements appeared; the second, beginning with Archimedes, reaches to the time of Des Cartes, who, by applying algebra to the elements of geometry, gave a new turn to this science, which has been carried to its utmost perfection by Sir Isaac Newton and Mr Leibnitz.

In treating this useful subject, we shall divide it into two parts; the first containing the general principles; and

the second, the application of these principles to the mensuration of surfaces, solids, &c.

P A R T I.

GENERAL PRINCIPLES OF GEOMETRY.

Art. 1. **A** point is that which is not made up of parts, or which is of itself indivisible.

2. A line is a length without breadth, as B—

3. The extremities of a line are points; as the extremities of the line AB, are the points A and B, fig. 1. Plate XCIII.

4. If the line AB be the nearest distance between its extremes A and B, then it is called a *strait line*, as A B; but if it be not the nearest distance, then it is called a *curve line*, as AB; fig. 1.

5. A surface is that which is considered as having only length and breadth, but no thickness, as B, fig. 2.

6. The terms or boundaries of a surface are lines.

7. A plain surface is that which lies equally between its extremes.

8. The inclination between two lines meeting one another (provided they do not make one continued line,) or the opening between them, is called an *angle*; thus the inclination of the line AB to the line CB (fig. 3.) meeting one another at B, or the opening between the two lines AB and CB, is called an angle.

9. When the lines forming the angle are right lines, then it is called a *right-lined angle*, as A, fig. 4. if one of them be right and the other curved, it is called a *mixed angle*, as B, fig 5. if both if them be curved, it is called a *curve-lined angle*, as C, fig. 6.

10. If a right line AB fall upon another DC, (fig. 7.) so as to incline neither to one side nor to the other; but make the angles ABD, ABC, on each side equal to one another; then the line AB is said to be *perpendicular* to the line DC, and the two angles are called *right-angles*.

11. An obtuse angle is that which is greater than a right one, as A, fig. 8; and an acute angle, that which is less than a right one, as B, fig. 9.

12. If a right line DC be fastened at one of its ends C, and the other end D be carried quite round, then the space comprehended is called a *circle*; the curve line described by the point D, is called the *periphery* or *circumference* of the circle; the fixed point C is called the *centre* of it. Fig. 10.

13. The describing line CD is called the *radius*, viz. any line drawn from the centre to the circumference; whence all radii of the same or equal circles are equal.

14. Any line drawn through the centre, and terminated both ways by the circumference, is called a *diameter*, as BD is a diameter of the circle BADE. And the diameter divides the circle and circumference into two equal parts, and is double the radius.

15. The circumference of every circle is supposed to be divided into 360 equal parts, called *degrees*; and each degree is divided into 60 equal parts, called *minutes*; and each minute into 60 equal parts called, *seconds*; and

Vol. II. No 55.

2

these into *thirds*, *fourths*, &c. these parts being greater or less according as the radius is.

16. Any part of the circumference is called an *arc*, or *arc*; and is called an arc of as many degrees as it contains parts of the 360, into which the circumference was divided: Thus if AD be the  $\frac{1}{4}$  of the circumference, then the arc AD is an arc of 45 degrees.

17. A line drawn from one end of an arc to the other, is called a *chord*, and is the measure of the arc; thus the right line AB is the chord of the arc ADB, fig. 11.

18. Any part of a circle cut off by a chord, is called a *segment*; thus the space comprehended between the chord AB and circumference ADB (which is cut off by the chord AB) is called a segment. Whence it is plain,

1st, That all chords divide the circle into two segments.

2dly, The less the chord is, the more unequal are the segments, and *e contra*.

3dly, When the chord is greatest, viz. when it is a diameter, then the segments are equal, viz. each a semicircle.

19. Any part of a circle (less than a semicircle) contained between two radii and an arc, is called a *sector*; thus the space contained between the two radii, AC, BC, and the arc AB, is called the sector; fig. 12.

20. The right line of any arc, is a line drawn perpendicular from one end of the arc, to a diameter drawn through the other end of the same arc; thus (fig. 13.) AD is the right line of the arc AB, it being a line drawn from A, the one end of the arc AB, perpendicular to CB, a diameter passing through B, the other end of the arc AB.

Now the lines standing on the same diameter, still increase till they come to the centre, and then becoming the radius, it is plain that the radius EC is the greatest possible line, and for that reason it is called the *whole sine*.

Since the whole-sine EC must be perpendicular to the a diameter FB (by def. 20.) therefore producing the diameter EG, the two diameters FB, EG, must cross one another at right angles, and so the circumference of the circle must be divided by them into four parts EB, BG, GF, and FE, and these four parts are equal to one another (by def. 10.) and so EB a quadrant, or fourth part of the circumference; therefore the radius EC is always the sine of the quadrant, or fourth part of the circle EB.

Sines are said to be of so many degrees, as the arc contains parts of the 360, into which the circumference is supposed to be divided; so the radius being the sine of a quadrant, or fourth part of the circumference, which contains 90 degrees (the fourth part of 360), therefore the radius must be the sine of 90 degrees.

†

7 K

21. The

21. The part of the radius comprehended between the extremity of the right line and the lower end of the arc, *viz.* DB, is called the *versed line* of the arc AB.

22. If to any point in the circumference, *viz.* B, there be drawn a diameter FCB, and from the point B, perpendicular to that diameter, there be drawn the line BH; that line is called a *tangent* to the circle in the point B; which tangent can touch the circle only in one point B, else if it touched it in more, it would go within it, and so not be a tangent but a chord, (by art. 17.)

23. The tangent of any arc AB, is a right line drawn perpendicular to a diameter through the one end of the arc B, and terminated by a line CAH, drawn from the centre through the other end A; thus BH is the tangent of the arch AB.

24. And the line which terminates the tangent, *viz.* CH, is called the *secant* of the arc AB.

25. What an arc wants of a quadrant is called the *complement* of that arc; thus AE, being what the arc AB wants of the quadrant EB, is called the complement of the arc AB.

26. And what an arc wants of a semicircle is called the *supplement* of that arc; thus since AF is what the arc AB wants of the semicircle BAF, it is the supplement of the arc AB.

27. The line, tangent, &c. of the complement of any arc, is called the *co-sine*, *co-tangent*, &c. of that arc; thus the line, tangent, &c. of the arc AE is called the *co-sine*, *co-tangent*, &c. of the arc AB.

28. The line of the supplement of an arc is the same with the line of the arc itself; for, drawing them according to the definitions, there results the self-same line.

29. A right-lined angle is measured by an arc of a circle described upon the angular point as a centre, comprehended between the two legs that form the angle; thus (fig. 14.) the angle ABD is measured by the arc AD of the circle CADE that is described upon the point B as a centre; and the angle is said to be of as many degrees as the arc is; so if the arc AD be 45 degrees, then the angle ABD is said to be an angle of 45 degrees.

Hence the angles are greater or less, according as the arc described about the angular point and terminated by the two legs contain a greater or a less number of degrees.

30. When one line falls perpendicularly on another, as AB on CD, fig. 15. then the angles are right (by the 10th def.); and describing a circle on the centre B, since the angles ABC ABD are equal, their measures must be so too, *i. e.* the arcs AC AD must be equal; but the whole CAD is a semicircle, since CD, a line passing through the centre B, is a diameter; therefore each of the parts AC AD is a quadrant, *i. e.* 90 degrees; so the measure of a right angle is always 90 degrees.

31. If one line fall any way upon another, CD, then the sum of the two angles ABC ABD is always equal to the sum of two right angles; fig. 16. For on the point B, describing the circle CAD, it is plain, that CAD is a semicircle (by the 14th); but CAD is equal to CA and AD the measure of the two angles; therefore the sum of the two angles is equal to a semicircle, that is, to two right angles, (by the last).

*Cor. 1.* From whence it is plain, that all the angles which can be made from a point in any line, towards one side of the line, are equal to two right angles.

2. And that all the angles which can be made about a point, are equal to four right ones.

32. If one line AC cross another BD in the point E, then the opposite angles are equal, *viz.* BEA to CED, and BEC equal to AED; fig. 17. For upon the point E, as a centre, describing the circle ABCD, it is plain ABC is a semicircle, as also BCD (by the 14th); therefore the arc ABC is equal to the arc BCE; and from both taking the common arc BC, there will remain AB equal to CD, *i. e.* the Angle BEA equal to the angle CED (by art. 29.). After the same manner we may prove, that the angle BEC is equal to the angle AED.

33. Lines which are equally distant from one another, are called *parallel lines*; as AB, CD, fig. 18.

34. If a line GH cross two parallels AB, CD, (fig. 19.) then the external opposite angles are equal, *viz.* GEB equal to CFH and AEG equal to HFD. For since AB and CD are parallel to one another, they may be considered as one broad line, and GH crossing it; then the vertical or opposite angles GEB CFG are equal (by art. 32.), as also AEG and HFD by the same.

35. If a line GH cross two parallels AB CD, then the alternate angles, *viz.* AEF and EFD, or CFE and FEB, are equal; that is, the angle AEF is equal to the angle EFD, and the angle CFE is equal to the angle FEB, for GEB is equal to AEF (by art. 32.), and CFH is equal to EFD (by the same); but GEB is equal to CFH (by the last); therefore AEF, is equal to EFD. The same way we may prove FEB equal to EFC.

36. If a line GH cross two parallel lines AB, CD, then the external angle GEB is equal to the internal opposite one EFD, or GEA equal to CFE. For the angle AEF is equal to the angle EFD (by the last); but AEF is equal to GEB (by art. 32.), therefore GEB is equal to EFD. The same way we may prove AEG equal to CFE.

37. If a line GH cross two parallel lines AB CD, then the sum of the two internal angles, *viz.* BEF and DFE, or AEF and CFE, are equal to two right angles; for since the angle GEB is equal to the angle EFD (by art. 36.), to both add the angle FEB, then GEB and BEF are equal to BEF and DFE; but GEB and BEF are equal to two right angles (by art. 31.) therefore BEF and DFE are also equal to two right angles. The same way we may prove that AEF and CFE are equal to two right angles.

39. A figure is any part of space bounded by lines or a line. If the bounding lines be strait, it is called a *rectilinear figure*, as A, fig. 20. if they be curved, it is called a *curvilinear figure*, as B or C, fig. 21. and fig. 22. if they be partly curve lines and partly strait, it is called a *mixt figure*, as D, fig. 23.

35. The most simple rectilinear figure is that which is bounded by three right lines, and is called a *triangle*, as A, fig. 24.

40. Triangles are divided into different kinds, both with respect to their sides and angles: with respect to their sides they are commonly divided into three kinds, *viz.*

41. A triangle having all its three sides equal to one another, is called an *equilateral triangle*, as A, fig. 25.

42. A triangle having two of its sides equal to one another, and the third side not equal to either of them, is called an *isosceles triangle*, as B, fig. 26.

43. A triangle having none of its sides equal to one another, is called a *scalene triangle*, as C, fig. 27.

44. Triangles, with respect to their angles, are divided into three different kinds, *viz.*

45. A triangle having one of its angles right, is called a *right-angled triangle*, as A, fig. 28.

46. A triangle having one of its angles obtuse, or greater than a right angle, is called an *obtuse-angled triangle*, as B, fig. 29.

47. Lastly, a triangle having all its angles acute, is called an *acute-angled triangle*, as C, fig. 30.

48. In all right-angled triangles, the sides comprehending the right angle are called the *legs*, and the side opposite to the right angle is called the *hypotenuse*. Thus in the right-angled triangle ABC, fig. 31. (the right angle being at B) the two sides AB and BC, which comprehend the right angle ABC, are the legs of the triangle; and the side AC, which is opposite to the right angle ABC, is the hypotenuse of the right-angled triangle ABC.

49. Both obtuse and acute angled triangles are in general called *oblique-angled triangles*; in all which any side is called the *base*, and the other two the *sides*.

50. The perpendicular height of any triangle is a line drawn from the vertex to the base perpendicularly; thus if the triangle ABC (fig. 32.) be proposed, and BC be made its base, then A will be the vertex, *viz.* the angle opposite to the base; and if from A you draw the line AD perpendicular to BC, then the line AD is the height of the triangle ABC standing on BC as its base.

Hence all triangles standing between the same parallels have the same height, since all the perpendiculars are equal by the nature of parallels.

51. A figure bounded by four sides is called a *quadrilateral* or *quadrangular figure*, as ABDC, fig. 33.

52. Quadrilateral figures whose opposite sides are parallel, are called *parallelograms*. Thus in the quadrilateral figure ABDC, if the side AC be parallel to the side BD which is opposite to it, and AB be parallel to CD, then the figure ABDC is called a parallelogram.

53. A parallelogram having all its sides equal and angles right, is called a *square*, as A, fig. 34.

54. That which hath only the opposite sides equal and its angles right, is called a *rectangle*, as B, fig. 35.

55. That which hath equal sides but oblique angles, is called a *rhombus*, as C, fig. 36. and is just an inclined square.

56. That which hath only the opposite sides equal and the angles oblique, is called a *rhomboides*, as D, fig. 37. and may be conceived as an inclined rectangle.

57. When none of the sides are parallel to another, then the quadrilateral figure is called a *trapezium*.

58. Every other right lined figure, that has more sides than four, is in general called a *polygon*. And figures are called by particular names according to the number of their sides, *viz.* one of five sides is called a *pentagon*, of

six a *hexagon*, of seven a *heptagon*, and so on. When the sides forming the polygon are equal to one another, the figure is called a regular figure or polygon.

59. In any triangle ABC (fig. 28.) one of its legs, as BC, being produced towards D, the external angle ACD is equal to both the internal opposite ones taken together, *viz.* to ABC and BAC. In order to prove this, through C draw CE parallel to AB; then since CE is parallel to AB, and the lines AC and BD cross them, the angle ECD is equal to ABC (by art. 36.) and the angle ACE equal to CAB (by art. 35.); therefore the angles ECD and ECA are equal to the angles ABC and CAB; but the angles ECD and ECA are together equal to the angle ACD; therefore the angle ACD is equal to both the angles ABC and CAB taken together.

*Cor.* Hence it may be proved, that if two lines AB and CD (fig. 39.) be crossed by a third line EF, and the alternate angles AEF and EFD be equal, the lines AB and CD will be parallel; for if they are not parallel, they must meet one another on one side of the line EF (suppose at G) and so form the triangle EFG, one of whose sides GE being produced to A, the exterior angle AEF must (by this article) be equal to the sum of the two angles EFG and EGF; but, by supposition, it is equal to the angle EFG alone; therefore the angle AEF must be equal to the sum of the two angles EFG and EGF, and at the same time equal to the angle EFG alone, which is absurd; so the lines AB and CD cannot meet, and therefore must be parallel.

60. In any triangle ABC, all the three angles taken together are equal to two right angles. To prove this, you must produce BC, one of its legs, to any distance, suppose to D; then by the last proposition, the external angle ACD, is equal to the sum of the two internal opposite ones CAB and ABC; to both add the angle ACB, then the sum of the angles ACD and ACB will be equal to the sum of the angles CAB and CBA and ACB. But the sum of the angles ACD and ACB, is equal to two right ones (by art. 32.); therefore the sum of the three angles CAB and CBA and ACB, is equal to two right angles; that is, the sum of the three angles of any triangle ACB is equal to two right angles.

*Cor.* 1. Hence in any triangle given, if one of its angles be known, the sum of the other two is also known: for since (by the last) the sum of all the three is equal to two right angles, or a semicircle, it is plain, that taking any one of them from a semicircle or 180 degrees, the remainder will be the sum of the other two. Thus (in the former triangle ABC) if the angle ABC be 40 degrees, by taking 40 from 180 we have 140 degrees; which is the sum of the two angles BAC, ACB: the converse of this is also plain, *viz.* the sum of any two angles of a triangle being given, the other angle is also known by taking that sum from 180 degrees.

2. In any right-angled triangle, the two acute angles must just make up a right one between them; consequently, any one of the oblique angles being given, we may find the other by subtracting the given one from 90 degrees, which is the sum of both.

61. If in any two triangles, ABC (fig. 40.) DEF (fig. 41.) two legs of the one, *viz.* AB and AC, be equal to

two legs in the other, *viz.* to DE and DF, each to each respectively, *i. e.* AB to DE, and AC to DF; and if the angles included between the equal legs be equal, *viz.* the angle BAC equal to the angle EDF; then the remaining leg of the one shall be equal to the remaining leg of the other, *viz.* BC to EF; and the angles opposite to equal legs shall be equal, *viz.* ABC equal to DEF (being opposite to the equal legs AC and DF), also ACB equal to DFE (which are opposite to the equal legs AB and DE). For if the triangle ABC be supposed to be lifted up and put upon the triangle DEF, and the point A on the point D; it is plain, since BA and DE are of equal length, the point E will fall upon the point B; and since the angles BAC EDF are equal, the line AC will fall upon the line DF; and they being of equal length, the point C will fall upon the point F; and so the line BC will exactly agree with the line EF, and the triangle ABC will in all respects be exactly equal to the triangle DEF; and the angle ABC will be equal to the angle DEF, also the angle ACB will be equal to the angle DFE.

*Cor. 1.* After the same manner it may be proved, that if in any two triangles ABC, DEF, (see the preceding figure) two angles ABC and ACB of the one, be equal to two angles DEF and EFD of the other, each to each respectively, *viz.* the angle ABC to the angle DEF, and the angle ACB equal to the angle DFE, and the sides included between these angles be also equal, *viz.* BC equal to EF, then the remaining angles and the sides opposite to the equal angles, will also be equal each to each respectively; *viz.* the angle BAC equal to the angle EDF, the side AB equal to DE, and AC equal to DF: for if the triangle ABC be supposed to be lifted up and laid upon the triangle DEF, the point B being put upon the point E, and the line BC upon the line EF, since BC and EF are of equal lengths, the point C will fall upon the point F, and since the angle ACB is equal to the angle DFE, the line CA will fall upon the line FD, and by the same way of reasoning the line BA will fall upon the line ED; and therefore the point of intersection of the two lines BA and CA, *viz.* A, will fall upon the point of intersection of the two lines ED and FD, *viz.* D, and consequently BA will be equal to DE, and AC equal to DF, and the angle BAC equal to the angle EDF.

*Cor. 2.* It follows likewise from this article, that if any triangle ABC (fig. 42.) has two of its sides AB and AC equal to one another, the angles opposite to these sides will also be equal, *viz.* the angles ABC equal to the angle ACB. For suppose the line AD, bisecting the angle BAC, or dividing it into two equal angles BAD and CAD, and meeting BC in D, then the line AD will divide the whole triangle BAC into two triangles ABD and DAC; in which BA and AD two sides of the one, are equal to CA and AD two sides of the other, each to each respectively, and the included angles BAD and DAC are by supposition equal; therefore (by this article) the angle ABC must be equal to the angle ACB.

*62. Any angle, as BAD, (fig. 43.) at the circumference of a circle BADE, is but half the angle BCD at the centre standing on the same arch BED.* To demonstrate this, draw through A and the centre C, the right

line ACE, then the angle ECD is equal to both the angles DAC and ADG (by art. 59.); but since AC and CD are equal (being two radii of the same circle) the angles subtended by them must be equal also, (by art. 62. cor. 2.) *i. e.* the angle CAD equal to the angle CDA; therefore the sum of them is double any one of them, *i. e.* DAC and ADC is double of CAD, and therefore ECD is also double of DAC: the same way it may be proved, that ECB is double of CAB; and therefore the angle BCD is double of the angle BAD, or BAD the half of BCD, which was to be proved.

*Cor. 1.* Hence an angle at the circumference is measured by half the arc it subtends; for the angle at the centre (standing on the same arc) is measured by the whole arc (by art. 29); but since the angle at the centre is double that at the circumference, it is plain the angle at the circumference must be measured by only half the arc it stands upon.

*Cor. 2.* Hence all angles, ACB, ADB, AEB, &c. (fig. 44.) at the circumference of a circle, standing on the same chord AB, are equal to one another; for by the last corollary they are all measured by the same arc, *viz.* half the arc AB which each of them subtends.

*Cor. 3.* Hence an angle in a segment greater than a semicircle is less than a right angle: thus, if ADB be a segment greater than a semicircle, (see the last figure) than the arc AB, on which it stands, must be less than a semicircle, and the half of it less than a quadrant or a right angle; but the angle ADB in the segment is measured by the half of AB, therefore it is less than a right angle.

*Cor. 4.* An angle in a semicircle is a right angle. For since ABD (fig. 45.) is a semicircle, the arc AED must also be a semicircle: but the angle ABD is measured by half the arc AED, that is, by half a semicircle or quadrant; therefore the angle ABD is a right angle.

*Cor. 5.* Hence an angle in a segment less than a semicircle, as ABD, (fig. 46.) is greater than a right angle: for since the arc ABD is less than a semicircle, the arc AED must be greater than a semicircle, and so it is half greater than a quadrant, *i. e.* than the measure of a right angle; therefore the angle ABD, which is measured by half the arc AED, is greater than a right angle.

*63. If from the centre C of the circle ABE, (fig. 47.) there be let fall the perpendicular CD on the chord AB, then that perpendicular will bisect the chord AB in the point D.* To demonstrate this, draw from the centre to the extremities of the chord the two lines CA, CB; then since the lines CA and CB are equal, the angles CAB, CBA, which they subtend must be equal also, (by art. 62. cor. 2.) but the perpendicular CD divides the triangle ACB into two right-angled triangles ACD and CDB, in which the sum of the angles ACD and CAD in the one, is equal to the sum of the angles DCB and CBD in the other, each being equal to a right angle, (by cor. 2. of art. 61.) but CAD is equal to CBD, therefore ACD is equal to BCD. So in the two triangles ACD and BCD, the two legs AC and CB in the one, are equal to the two legs BC and CD in the other, each to each respectively, and the included angles ACD and BCD are equal; therefore the remaining legs AD and BD are equal (by art. 61.) and consequently AB bisected in D.

64. If

83. If from the centre  $C$  of a circle  $ABE$ , there be drawn a perpendicular  $CD$  on the chord  $AB$ , and produced till it meet the circle in  $F$ , then the line  $CF$  bisects the arch  $AB$  in the point  $F$ ; for (see the foregoing figure) joining the points  $A$  and  $F$ ,  $F$  and  $B$  by the straight lines  $AF$ ,  $FB$ , then in the triangles  $ADF$ ,  $BDF$ ,  $AD$  is equal to  $BD$  (by art. 63.) and  $DF$  common to both; therefore  $AD$  and  $DF$ , two legs of the triangle  $ADF$ , are equal to  $BD$  and  $DF$ , two legs of the triangle  $BDF$ , and the included angles  $ADF$ ,  $BDF$  are equal, being both right; therefore (by art. 61) the remaining legs  $AF$  and  $FB$  are equal; but in the same circle equal lines are chords of equal arches, therefore the arches  $AF$  and  $FB$  are equal. So the whole arch  $AFB$  is bisected in the point  $F$  by the line  $CF$ .

*Cor. 1.* From art. 63, it follows, that any line bisecting a chord at right angles is a diameter; for since (by art. 63.) a line draw from the centre perpendicular to a chord, bisects that chord at right angles; therefore, conversely, a line bisecting a chord at right angles, must pass thro' the centre, and consequently be a diameter.

*Cor. 2.* From the two last articles it follows, that the sine of any arc is the half of the chord of twice the arc; for (see the foregoing scheme)  $AD$  is the sine of the arc  $AF$ , by the definition of a sine, and  $AF$  is half the arc  $AFB$ , and  $AD$  half the chord  $AB$  (by art. 63.); therefore the *cor.* is plain.

65. In any triangle, the half of each side is the sine of the opposite angle; for if a circle be supposed to be drawn through the three angular points  $A$ ,  $B$ , and  $D$  of the triangle  $ABD$ , fig. 48. then the angle  $DAB$  is measured by half the arch  $BKD$  (by *cor. 1.* of art. 62.) but the half of  $BD$ , viz.  $BE$ , is the sine of half the arch  $BKD$ , viz. the sine of  $BK$  (by *cor. 2.* of the last) which is the measure of the angle  $BAD$ ; therefore the half of  $BD$  is the sine of the angle  $BAD$ ; the same way it may be proved, that the half of  $AD$  is the sine of the angle  $ABD$ , and the half of  $AB$  is the sine of the angle  $ADB$ .

66. The sine, tangent, &c. of any arch is called also the sine, tangent, &c. of the angle whose measure the arc is: thus because the arc  $GD$  (fig. 49.) is the measure of the angle  $GCD$ ; and since  $GH$  is the sine,  $DE$  the tangent,  $HD$  the versed sine,  $CE$  the secant, also  $GK$  the co-sine,  $BF$  the co-tangent, and  $CF$  the co-secant, &c. of the arch  $GD$ ; then  $GH$  is called the sine,  $DE$  the tangent, &c. of the angle  $GCD$ , whose measure is the arch  $GD$ .

67. If two equal and parallel lines,  $AB$  and  $CD$  (fig. 50.) be joined by two others,  $AC$  and  $BD$ ; then these shall also be equal and parallel. To demonstrate this, join the two opposite angles  $A$  and  $D$  with the line  $AD$ ; then it is plain this line  $AD$  divides the quadrilateral,  $ACDB$ , into two triangles, viz.  $ABD$ ,  $ACD$ , in which  $AB$  a leg of the one, is equal to  $DC$  a leg of the other, by supposition, and  $AD$  is common to both triangles; and since  $AB$  is parallel to  $CD$ , the angle  $BAD$  will be equal to the angle  $ADC$ , (by art. 36.) therefore in the two triangles  $BA$  and  $AD$ ; and the angle  $BAD$  is equal to  $CD$  and  $DA$ ; and the angle  $ADC$ , that is, two legs and the included angle in the one, is equal to two legs and the included angle in the other; therefore (by art. 61)  $BD$  is equal to  $AC$ , and since the angle  $DAC$

is equal to the angle  $ADB$ , therefore the lines  $BD$   $AC$  are parallel (by *cor. art. 59.*)

*Cor. 1.* Hence it is plain, that the quadrilateral  $ABDC$  is a parallelogram, since the opposite sides are parallel.

*Cor. 2.* In any parallelogram the line joining the opposite angles (called the diagonal) as  $AD$ , divides the figure into two equal parts, since it has been proved that the triangles  $ABD$   $ACD$  are equal to one another.

*Cor. 3.* It follows also, that a triangle  $ACD$  on the same base  $CD$ , and between the same parallels with a parallelogram  $ABDC$ , is the half of that parallelogram.

*Cor. 4.* Hence it is plain, that the opposite sides of a parallelogram are equal; for it has been proved, that  $ABDC$  being a parallelogram,  $AB$  will be equal to  $CD$ , and  $AC$  equal to  $BD$ .

68. All parallelograms on the same or equal bases, and between the same parallels, are equal to one another; that is, if  $BD$  and  $GH$  (fig. 51.) be equal, and the lines  $BH$  and  $AF$  be parallel, then the parallelograms  $ABDC$ ,  $BDFE$ , and  $EFHG$ , are equal to one another. For  $AC$  is equal to  $EF$ , each being equal to  $BD$ , (by *cor. 4.* of 67.) To both add  $CE$ , then  $AE$  will be equal  $CF$ . So in the two triangles  $ABE$   $CDF$ ,  $AB$  a leg of the one, is equal to  $CD$  a leg in the other; and  $AE$  is equal to  $CF$ , and the angle  $BAE$  is equal to the angle  $DCF$  (by art. 36.); therefore the two triangles  $ABE$   $CDF$  are equal (by art. 61.); and taking the triangle  $CKE$  from both, the figure  $ABKC$  will be equal to the figure  $KDFE$ ; to both which add the little triangle  $KBD$ , then the parallelogram  $ABDC$  will be equal to the parallelogram  $BDFE$ . The same way it may be proved, that the parallelogram  $EFHG$  is equal to the parallelogram  $EFDB$ ; so the three parallelograms  $ABDC$ ,  $BDFE$ , and  $EFHG$  will be equal to one another.

*Cor.* Hence it is plain, that triangles on the same base, and between the same parallels, are equal; since they are the half of the parallelograms on the same base and between the same parallels. (by *cor. 3.* of last art.)

69. In any right-angled triangle,  $ABC$ , (fig. 52.) the square of the hypotenuse  $BC$ , viz.  $BCMH$ , is equal to the sum of the squares made on the two sides  $AB$  and  $AC$ , viz. to  $ABDE$  and  $ACGF$ . To demonstrate this, through the point  $A$  draw  $AKL$  perpendicular to the hypotenuse  $BC$ , join  $AH$ ,  $AM$ ,  $DC$ , and  $BG$ ; then it is plain that  $DB$  is equal to  $BA$  (by art. 53.), also  $BH$  is equal to  $BC$  (by the same); so in the two triangles  $DBC$   $ABH$ , the two legs  $DB$  and  $BC$  in the one are equal to the two legs  $AB$  and  $BH$  in the other; and the included angles  $DBC$  and  $ABH$  are also equal; (for  $DBA$  is equal to  $CBH$ , being both right; to each add  $ABC$ , then it is plain that  $DBC$  is equal to  $ABH$ ) therefore the triangles  $DBC$   $ABH$  are equal (by art. 61.) but the triangle  $DBC$  is half of the square  $ABDE$  (by *cor. 3.* of 67th) and the triangle  $ABH$  is half the parallelogram  $BKLI$  (by the same), therefore half the square  $ABDE$  is equal to half the parallelogram  $BKLI$ . Consequently the square  $ABDE$  is equal to the parallelogram  $BKLI$ . The same way it may be proved, that the square  $ACGF$  is equal to the parallelogram  $KCMH$ . So the sum of the squares  $ABDE$  and  $ACGF$  is equal the sum of the parallelograms  $BKLI$  and  $KCMH$ , but the sum of these parallelograms is equal to the square  $BCMH$ , therefore the

sum of the squares on  $AB$  and  $AC$  is equal to the square on  $BC$ .

*Cor. 1.* Hence in a right-angled triangle, the hypotenuse and one of the legs being given, we may easily find the other, by taking the square of the given leg from the square of the hypotenuse, and the square root of the remainder will be the leg required.

*Cor. 2.* Hence, the legs in a right-angled triangle being given, we may find the hypotenuse, by taking the sum of the squares of the given legs, and extracting the square root of that sum.

70. If upon the line  $AB$  (fig. 53.) there be drawn a semicircle  $ADB$ , whose centre is  $C$ , and on the point  $C$  there be raised a perpendicular to the line  $AB$ , viz.  $CD$ ; then it is plain the arc  $DB$  is a quadrant, or contains 90 degrees; suppose the arc  $DB$  to be divided into 9 equal arcs, each of which will contain 10 degrees, then on the point  $B$  raising  $BE$  perpendicular to the line  $AB$ , it will be a tangent to the circle in the point  $B$ , and if to every one of the divisions of the quadrant, viz.  $B 10$ ,  $B 20$ ,  $B 30$ ,  $B 40$ , &c. you draw the line, tangent, &c. (as in the scheme) we shall have the line, tangent, &c. to every ten degrees in the quadrant: and the same way we may have the line, tangent, &c. to every single degree in the quadrant, by dividing it into 90 equal parts beginning from  $B$ , and drawing the line, tangent, &c. to all the arcs beginning at the same point  $B$ . By this method they draw the lines of sines, tangents, &c. of a certain circle on the scale; for after drawing them on the circle, they take the length of them, and set them off in the lines drawn for that purpose. The same way, by supposing the radius of any number of equal parts, (suppose 1000, or 10,000, &c.) it is plain the sine, tangent, &c. of every arc must consist of some number of these equal parts; and by computing them in parts of the radius, we have tables of sines, tangents, &c. to every arc in the quadrant, called natural sines, tangents, &c. and the logarithms of these give us tables of logarithmic sines, tangents, &c. See LOGARITHMS.

71. In any triangle,  $ABC$ , (Plate XCIV. fig. 1.) if one of its sides, as  $AC$ , be bisected in  $E$ , (and consequently  $AC$  double of  $AE$ ) and through  $E$  be drawn  $ED$ , parallel to  $BC$ , and meeting  $AB$  in  $D$ , then  $BC$  will be double of  $ED$ , and  $AB$  double of  $AD$ , through  $D$  draw  $DF$ , parallel to  $AC$ , meeting  $BC$  in  $F$ : for since, by construction,  $DF$  is parallel to  $AC$ , and  $DE$  parallel to  $BC$ ; therefore, (by art. 36.) the angle  $BFD$  will be equal to the angle  $BCA$ , (and by the same article) the angle  $BCA$  will be equal to the angle  $DEA$ , consequently the angle  $BFD$  will be equal to the angle  $DEA$ ; also, (by art. 36.) the angle  $BDF$  will be equal to the angle  $DAE$ ; and since  $DF$  is parallel to  $EC$ , and  $DB$  parallel to  $FC$ , the quadrilateral  $DFCE$  will be a parallelogram; and therefore, (by art. 59. cor. 4.)  $DF$  will be equal to  $EC$ , which, by construction, is equal to  $AE$ ; so in the two triangles  $BDF$   $DAE$ , the two angles  $BFD$  and  $BDF$  in the one, are equal to the two angles  $DBA$  and  $DAE$  in the other, each to each respectively; and the included side  $DF$ , is equal to the included side  $AE$ ; therefore, (by art. 61. cor. 1.)  $AD$  will be equal to  $DB$ , and consequently  $AB$  double of  $AD$ ;

also (by the same)  $DE$  will be equal to  $BF$ ; but  $DE$  is also (by art. 67. cor. 4.) equal to  $FC$ ; therefore  $BF$  and  $FC$  together, or  $BC$ , will be double of  $DE$ .

After the same manner it may be proved, that if in the triangle  $AKG$ , (fig. 2.)  $AE$  be taken equal to a third part of  $AK$ , and through  $E$  be drawn  $ED$ , parallel to  $KG$ , and meeting  $AG$  in  $D$ ; then  $ED$  will be equal to a third part of  $GK$ , and  $AD$  equal to a third part of  $AG$ .

Likewise if in any triangle  $ABC$ , (fig. 3.) upon the side  $AB$ , be taken  $AE$ , equal to one fourth, one fifth, one sixth, &c. of  $AB$ , and through  $E$  be drawn  $ED$  parallel to  $BC$  and meeting  $AC$  in  $D$ ; then  $DE$  will be one fourth, one fifth, one sixth, &c. of  $BC$ , and  $AD$  the like part of  $AC$ ; and, in general, if in any triangle  $ABC$ , there be assumed a point  $E$  on one of its sides  $AB$ , and through that point be drawn a line  $ED$ , parallel to one of its sides  $BC$ , and meeting the other side  $AC$  in  $D$ ; then whatever part  $AE$  is of  $AB$ , the same part will  $ED$  be of  $BC$ , and  $AD$  of  $AC$ .

*Cor.* Hence it follows, that if in any triangle  $ABC$ , there be drawn  $ED$ , parallel to one of its sides  $BC$ , and meeting the other two in the points  $E$  and  $D$ , then  $AE : AB :: ED : BC :: AD : AC$ ; that is,  $AE$  is to  $AB$ , as  $ED$  is to  $BC$ , and that as  $AD$  to  $AC$ .

72. If any two triangles  $ABC$ , fig. 4.  $abc$ , fig. 5. are similar, or have all the angles of the one equal to all the angles of the other, each to each respectively; that is, the angle  $CAB$  equal to the angle  $cab$ , and the angle  $ABC$  equal to the angle  $abc$ , and the angle  $ACB$  equal to the angle  $acb$ ; then the legs opposite to the equal angles are proportioned, viz.  $AB : ab :: AC : ac ::$  and  $AB : ab :: BC : bc ::$  and  $AC : ac :: BC : bc$ . On  $AB$  of the largest triangle set off  $AE$  equal to  $ab$ , and through  $E$  draw  $ED$  parallel to  $BC$ , meeting  $AC$  in  $D$ ; then since  $DE$  and  $BC$  are parallel, and  $AB$  crossing them, the angle  $AED$  will (by art. 36.) be equal to the angle  $ABC$ , which (by supposition) is equal to the angle  $abc$ , also the angle  $DAE$  is (by supposition) equal to the angle  $cab$ ; so in the two triangles  $AED$ ,  $abc$ , the two angles  $DAE$   $AED$  of the one, are equal to two angles  $cab$   $abc$  of the other, each to each respectively, and the included side  $AE$  is (by construction) equal to the included side  $ab$ ; therefore, (by art. 61. cor. 1.)  $AD$  is equal to  $ac$ , and  $DE$  equal to  $cb$ ; but since, in the triangle  $ABC$ , there is drawn  $DE$  parallel to  $BC$  one of its sides, and meeting the two other sides in the points  $D$  and  $E$ , therefore (by cor. art. 71.)  $AB : AE :: AC : AD$ , and  $AB : AE :: BC : DE$ , and  $AC : AD :: BC : DE$ ; and in the three last proportions, instead of the lines  $AE$ ,  $DE$ , and  $AD$ , putting in their equals  $ab$ ,  $bc$ , and  $ac$ , we shall have  $AB : ab :: AC : ac$ , and  $AB : ab :: BC : bc$ , and lastly,  $AC : ac :: BC : bc$ .

73. The chord, sine, tangent, &c. of any arc in one circle, is to the chord, sine, tangent, &c. of the same arc in another, as the radius of the one is to the radius of the other, fig. 6. 6. Let  $ABD$   $abd$  be two circles,  $BD$   $bd$  two arcs of these circles, equal to one another, or consisting of the same number of degrees;  $FD$   $fd$  the tangents,  $BD$   $bd$  the chords,  $BE$   $be$  the sines, &c.

∴ of these two arcs BD bd, and CD cd the radii of the circles; then say,  $CD : cd :: FD : fd$ , and  $CD : cd :: BD : bd$ , and  $CD : cd :: BE : be$ , &c. For since the arcs BD bd are equal, the angles BCD bcd will be equal; and FD fd, being tangents to the points D and d, the angles CDF cdf will be equal, being each a right angle (art. 22.) so in the two triangles CDF cdf, the two angles FCD CDF of the one, being equal to the two angles fcd cdf of the other, each to each, the remaining angle CFD, will be equal to the remaining angle cfd, (by art. 60.) therefore the triangles CFD cfd are similar, and consequently (by art. 73)  $CD : cd :: FD : fd$ . In the same manner it may be demonstrated, that  $CD : cd :: BD : bd$ , and  $CD : cd :: BE : be$ , &c.

74. Let ABD (fig. 7.) be a quadrant of a circle described by the radius CD BD any arc of it, and BA its complement, BG or CF the sine, CG or BF the co-sine, DE the tangent, and CE the secant of that arc BD. Then since the triangles CDE CGB are similar or equiangular, it will be (by art. 72.)  $DE : EC :: GB : BC$ , i. e. the tangent of any arc, is to the secant of the same, as the sine of it is to the radius. Also since  $DE : EC :: GB : BC$ ; therefore, by inverting that proportion, we have  $EC : DE :: BC : GB$ , i. e. the secant is to the tangent, as the radius is to the sine of any arc.

Again, since the triangles CDE CGB are similar, therefore (by art. 72.) it will be  $CD : CE :: CG : CB$ , i. e. as the radius is to the secant of any arc, so is the co-sine of that arc to the radius. And by inverting the proportion we have this, viz. As the secant of any arc is to the radius, so is the radius to the co-sine of that arc.

75. In all circles the chord of 60 is always equal in length to the radius. Thus in the circle AEBD, (fig. 8.) if the arc AEB be an arc of 60 degrees, then drawing the chord AB, I say AB shall be equal to the radius CB or AC; for in the triangle ACB, the angle ACB is 60 degrees, being measured by the arc AEB; therefore the sum of the other two angles is 120 degrees, (by cor. 1. of 60.) but since AC and CB are equal to the two angles CAB, CBA will also be equal; consequently each of them half their sum 120, viz. 60 degrees; therefore all the three angles are equal to one another, consequently all the legs, therefore AB is equal to CB.

Cor. Hence the radius from which the lines on any scale are formed, is the chord of 60 on the line of chords.

### Geometrical Problems.

PROB. 1. From a point C (fig. 9.) in a given line AB to raise a perpendicular to that line.

Rule. From the point C take the equal distances CB, CA on each side of it. Then stretch the compasses to any distance greater than CB or CA, and with one foot of them in B, sweep the arc EF with the other; again, with the same opening, and one foot in A, sweep the arc GH with the other, and these two arcs will intersect one another in the point D; then join the given points C and D with the line CD, and that shall be the perpendicular required.

2. To divide a given right line AB (fig. 10.) into two equal parts; that is, to bisect it.

Rule. Take any distance with your compasses that you are sure is greater than half the given line; then setting one foot of them in B, with the other sweep the arc DFC; and with the same distance, and one foot in A, with the other sweep the arc CID; these two arcs will intersect one another in the points C D, which joined by the right line DC will bisect AB in G.

3. From a given point D, (fig. 11.) to let fall a perpendicular on a given line AB.

Rule. Set one foot of the compasses in the point D, and extend the other to any distance greater than the least distance between the given point and the line, and with that extent sweep the arc AEB, cutting the line in the two points A and B, then (by the last prob.) bisect the line AB in the point C, lastly join C and D, and that line CD is the perpendicular required.

4. (Fig. 12.) Upon the end B of a given right line BA, to raise a perpendicular.

Rule. Take any extent in your compasses, and with one foot in B fix the other in any point C without the given line; then with one point of the compasses in C, describe with the other the circle EBD, and thro' E and C draw the diameter ECD meeting the circle in D; join D and B, and the right line DB is that required; for EBD is a right angle (by cor. 4. of 63.)

5. (Fig. 13.) To draw one line parallel to another given line AB, that shall be distant from one another by any given distance D.

Rule. Extend your compasses to the given distance D; then setting one foot of them in any point of the given line (suppose A), with the other sweep the arc FCG; again, at the same extent, and one foot in any other point of the given line B, sweep the arc HDK, and draw the line CD touching them, and that will be parallel to the given line AB, and distant from it by the line D as was required.

6. (Fig. 14.) To divide a given line AB into any number of equal parts, suppose 7.

Rule. From the point A draw any line AD, making an angle with the line AB, then through the point B, draw a line BC parallel to AD; and from A, with any small opening of the compasses, set off a number of equal parts (on the line AD,) less by one than the proposed number (here 6); then from B set off the same number of the same parts (on the line BC); lastly, join 6 and 1, 2 and 5, 3 and 4, 4 and 3, 5 and 2, 6 and 1, and these lines will cut the given line as required.

7. (Fig. 15.) To quarter a given circle, or to divide it into four equal parts.

Rule. Thro' the centre C of the given circle, draw a diameter AB, then upon the point C raise a perpendicular DCE to the line AB; and these two diameters AB and DE shall quarter the circle.

8 (Fig. 16.) Thro' three given points A, B, and D, to draw a circle. (Note. The three points must not lie in the same straight line.)

Rule. Join A and B, also B and D, with the straight lines AB BD; then (by prob. 2.) bisect AB with the line

line EC, also BD with the line FC, which two lines will cut one another in some point C; that is the centre of the circle required: then fixing one point of your compasses in D, and stretching the other to A, describe the circle ABDG, which will pass thro' the three points given. The reason of this is plain from cor. 1. of art. 64.

9. (Fig. 17.) From the point A of the given line AB, to draw another line (suppose AC) that shall make with AB an angle of any number of degrees, suppose 45.

*Rule.* Let the given line AB be produced, then take off your scale the length of the chord of 60 degrees, which is equal to the radius of the circle the scale was made for (by art. 75.); and setting one foot in A, with the other sweep of the arc BC; then with your compasses take from your scale the chord of 45 degrees, and set off that distance from B to C. Lastly, join A and C, and the line AC is that required. For the angle CAB, which is measured by the arc BC, is an angle of 45 degrees, as was required.

10. An angle BAC (fig. 18.) being given, to find how many degrees it contains.

*Rule.* With your compasses take the length of your chord of 60 from your scale. Then, setting one foot of them in A, with the other sweep the arc BC, which is the arc comprehended between the two legs AB, AC produced if needful. Lastly, take with your compasses the distance BC, and applying it to your line of chords on the scale, you will find how many degrees the arc BC contains, and consequently the degrees of the angle BAC which was required.

11. Three lines  $x$ ,  $y$ , and  $z$  being given, (fig. 19 19.) to form a triangle of them; but any two of these lines taken together must always be greater than the third.

*Rule.* Make any one of them, as  $x$ , the base; then with your compasses take another of them, as  $z$ , and setting one foot in one end of the line  $x$ , as B, with the other sweep the arc DE; and taking with your compasses the length of the other  $y$ , set one foot of them in A, the other end of the line  $x$ , and with the other sweep the arc FG, which will cut the other in C; lastly, join CA and CB, and the triangle CAB is that required.

12. To make a triangle, having one of its legs of any number of equal parts (suppose 160), and one of the angles at that leg 50 degrees, and the other 44 degrees.

*Rule.* Draw an indefinite line ED, (fig. 20) then take off the line of equal parts with your compasses, 160 of them, and set them on the indefinite line, as BC; then (by prob. 9.) draw BA, making the angle ABC of 50 degrees, and (by the same) draw from C the line AC, mak-

ing the angle ACB of 44 degrees; which two lines will meet one another in A, and the triangle ABC is that required. See TRIGONOMETRY.

13. Upon a given line AB (fig. 21.) to make a square.

*Rule.* Upon the extremity A of the given line AB, raise a perpendicular AC (by prob. 4.); then take AC equal to AB, and with that extent, setting one foot of the compasses in C, sweep with the other foot the arc GH; then with the same extent, and one foot in B, with the other sweep the arc EF, which will meet the former in some point D; lastly, join C and D, D and B, and the figure ABDC will be the square required.

14. On a given line AB (fig. 22.) to draw a rhomb that shall have one of its angles equal to any number of degrees, suppose 60 degrees.

*Rule.* From the point A of the given line AB, draw the line AC, making the angle CAB of 60 degrees, (by prob. 9.) then take AC equal to AB, and with that extent, fixing one foot of the compasses in B, with the other describe the arc GH; and at the same extent, fixing one foot of the compasses in C, with the other describe the arc EF cutting the former in D; lastly, join CD and DB, and the figure ACDB is that required.

15. Given two lines  $x$  and  $z$ , of these two to make a rectangle.

*Rule.* Draw a line, as AB, (fig. 23 23.) equal in length to one of the given lines  $x$ ; and on the extremity A of that line, raise a perpendicular AC, on which take AC equal to the other line  $z$ ; then take with your compasses the length of the line AB, and at that extent, fixing one foot of them in C, with the other sweep the arc EF; and also taking with your compasses the extent of the line AC, fix one foot of them in B, and with the other sweep the arc GH, which will meet the former in D; lastly, join CD and BD, and the figure ABDC will be that required.

16. Two lines  $x$  and  $z$  being given, of these to form a rhomboides that shall have one of its angles any number of degrees, suppose 50.

*Rule.* Draw a line AB (fig. 24 24.) equal in length to one of the lines, as  $x$ ; then draw the line AC, making with the former the angle BAC equal to the proposed, suppose 50 degrees, and on that line take AC equal to the given line  $z$ , then with your compasses take the length of AB, and fixing one foot in C, sweep the arc EF; also, taking the length of AC, and setting one foot in B, with the other sweep the arc GH, which will cut the former in D; then join CD and DB, so the figure ACDB will be that required.

## P A R T II.

### THE APPLICATION OF THE FOREGOING PRINCIPLES TO THE MENSURATION OF SURFACES, SOLIDS, &c.

#### *Of the Mensuration of Lines and Angles.*

A Line, or length, to be measured, whether it be distance, height, or depth, is measured by a line less than it. With us the least measure of length is an inch

not that we measure no line less than it, but because we do not use the name of any measure below that of an inch; expressing lesser measures by the fractions of an inch: and in this treatise we use decimal fractions as the easiest. Twelve inches make a foot; three feet and an

Each make the Scots ell; six ells make a fall; forty falls make a furlong; eight furlongs make a mile: so that the Scots miles is 1184 paces, accounting every pace to be five feet. These things are according to the statutes of Scotland; notwithstanding which, the glaziers use a foot of only eight inches; and other artists for the most part use an English foot, on account of the several scales marked on the English foot-measure for their use. But the English foot is somewhat less than the Scots; so that 185 of these make 186 of those.

Lines, to the extremities and any intermediate point of which you have easy access, are measured by applying to them the common measure a number of times. But lines, to which you cannot have such access, are measured by methods taken from geometry; the chief whereof we shall here endeavour to explain. The first is by the help of the geometrical square.

“As for the English measures, the yard is three feet, or thirty-six inches. A pole is sixteen feet and a half, or five yards and a half. The chain, commonly called *Gunter's chain*, is four poles, or twenty-two yards, that is, sixty six feet. An English statute-mile is four-score chains, or 1760 yards, that is, 5280 feet.

“The chain (which is now much in use, because it is very convenient for surveying) is divided into a hundred links, each of which is  $7\frac{1}{8}$  of an inch: whence it is easy to reduce any number of those links to feet, or any number of feet to links.

“A chain that may have the same advantages in surveying in Scotland, as *Gunter's chain* has in England, ought to be in length seventy-four feet, or twenty-four Scots ells, if no regard is had to the difference of the Scots and English foot above mentioned. But, if regard is had to that difference, the Scots chain ought to consist of  $74\frac{3}{4}$  English feet, or 74 feet 4 inches and  $\frac{1}{4}$  of an inch. This chain being divided into a hundred links, each of those links is 8 inches and  $7\frac{1}{8}$  of an inch. In the following table, the most noted measures are expressed in English inches and decimals of an inch.”

# PROPOSITION I.

PROB. To describe the structure of the geometrical square.—The geometrical square is made of any solid matter, as brass or wood, or of any four plain rulers joined together at right angles, (as in Plate XCV. fig. 1.) where A is the centre, from which hangs a thread with a small weight at the end, so as to be directed always to the centre. Each of the sides BE and DE is divided into an hundred equal parts, or (if the sides be long enough to admit of it) into a thousand parts; C and F are two sights, fixed on the side AD. There is moreover an index GH, which, when there is occasion, is joined to the centre A, in such manner as that it can move round, and remain in any given situation. On this index are two sights perpendicular to the right line going from the centre of the instrument: these are K and L. The side DE of the instrument is called the upright side; E the reclining side.

# PROPOSITION II.

FIG. 2. To measure an accessible height, AB, by the help of a geometrical square, its distance being known.—Let BR be an horizontal plane, on which there stands perpendicularly any line AB: let BD, the given distance of the observer from the height, be 96 feet; let the height of the observer's eye be supposed 6 feet; and let the instrument, held by a steady hand, or rather leaning on a support, be directed towards the summit A, so that one eye (the other being shut) may see it clearly through the sights; the perpendicular or plumb line meanwhile hanging free, and touching the surface of the instrument.

strument: let now the perpendicular be supposed to cut off on the right side KN 80 equal parts. It is clear that LKN, ACK, are similar triangles; for the angles LKN, ACK are right angles, and therefore equal; moreover LN and AC are parallel, as being both perpendicular to the horizon; consequently, (by art. 60. cor. 1. part 1.) the angles KLN, KAC, are equal; wherefore, (by art. 60. cor. 2. of part 1.) the angles LNK, and AKC, are likewise equal: so that in the triangles NKL, KAC, (by art. 72. of part 1.) as NK : KL :: KC (i. e. BD) : CA; that is, as 80 to 100, so is 96 feet to CA. Therefore, by the rule of three, CA will be found to be 120 feet; and CB, which is 6 feet, being added, the whole height is 126 feet.

But if the distance of the observer from the height, as BE, be such, that, when the instrument is directed as formerly toward the summit A, the perpendicular falls on the angle P, opposite to H, the centre of the instrument, and BE or CG be given of 120 feet; CA will also be 120 feet. For in the triangles HGP, ACG, equiangular, as in the preceding case, as PG : GH :: GC : CA. But PG is equal to GH; therefore GC is likewise equal to CA: that is, CA will be 120 feet, and the whole height 126 feet as before.

Let the distance BF be 300 feet, and the perpendicular or plumb line cut off 40 equal parts from the reclining side: Now, in this case, the angles QAC, QZI, are equal, and the angles QZI, ZIS, are equal; therefore the angle ZIS is equal to the angle QAC. But the angles ZSI, QCA are equal, being right angles; therefore, in the equiangular triangles ACQ, SZI, it will be, as ZS : SI :: CQ : CA; that is, as 100 to 40, so is 300 to CA. Wherefore, by the rule of three, CA will be found to be of 102 feet. And, by adding the height of the observer, the whole BA will be 126 feet. Note, that the height is greater than the distance, when the perpendicular cuts the right side, and less if it cut the reclined side; and that the height and distance are equal, if the perpendicular fall on the opposite angle.

#### S C H O L I U M.

If the height of a tower, to be measured as above, end in a point, (as in fig. 3.) the distance of the observer opposite to it, is not CD, but is to be accounted from the perpendicular to the point A; that is, to CD must be added the half of the thickness of the tower, viz. BD: which must likewise be understood in the following propositions, when the case is similar.

#### P R O P O S I T I O N III.

FIG. 4. *From the height of a tower AB given, to find a distance on the horizontal plane BC, by the geometrical square.*—Let the instrument be so placed, as that the mark C in the opposite plane may be seen through the sights; and let it be observed how many parts are cut off by the perpendicular. Now, by what hath been already demonstrated, the triangles AEF, ABC, are similar; therefore, it will be as EF to AE, so AB (composed of the height of the tower BG, and of the height of the centre of the instrument A, above the tower BG) to the distance BC. Wherefore, if, by the rule of three, you

say, as EF to AE, so is AB to BC, it will be the distance sought.

#### P R O P O S I T I O N IV.

FIG. 5. *To measure any distance at land or sea, by the geometrical square.*—In this operation, the index is to be applied to the instrument, as was shown in the description; and, by the help of a support, the instrument is to be placed horizontally at the point A; then let it be turned till the remote point F, whose distance is to be measured, be seen through the fixed sights; and bringing the index to be parallel with the other side of the instrument, observe by the sights upon it any accessible mark B, at a sensible distance: then carrying the instrument to the point B, let the immoveable sights be directed to the first station A, and the sights of the index to the point F. If the index cut the right side of the square, as in K, in the two triangles BRK, and BAF, which are equiangular, it will be as BR to RK, so BA (the distance of the stations to be measured with a chain) to AF; and the distance AF sought will be found by the rule of three. But if the index cut the reclined side of the square in any point L, where the distance of a more remote point is sought; in the triangles BLS, BAG, the side LS shall be to SB, as BA to AG, the distance sought; which accordingly will be found by the rule of three.

#### P R O P O S I T I O N V.

FIG. 6. *To measure an accessible height by means of a plain mirror.*—Let AB be the height to be measured; let the mirror be placed at C, in the horizontal plane BD, at a known distance BC; let the observer go back to D, till he see the image of the summit in the mirror, at a certain point of it, which he must diligently mark; and let DE be the height of the observer's eye. The triangles ABC and EDC are equiangular; for the angles at D and B are right angles; and ACB, ECD, are equal, being the angles of incidence and reflexion of the ray AC, as is demonstrated in optics; wherefore the remaining angles at A and E are also equal: therefore it will be, as CD to DE, so CB to BA; that is, as the distance of the observer from the point of the mirror in the right line betwixt the observer and the height, is to the height of the observer's eye, so is the distance of the tower from that point of the mirror, to the height of the tower sought; which therefore will be found by the rule of three.

Note 1. The observation will be more exact, if, at the point D, a staff be placed in the ground perpendicularly, over the top of which the observer may see a point of the glass exactly in a line, betwixt him and the tower.

Note 2. In place of a mirror may be used the surface of water contained in a vessel, which naturally becomes parallel to the horizon.

#### P R O P O S I T I O N VI.

FIG. 7. *To measure an accessible height AB by means of two staffs.*—Let there be placed perpendicularly in the ground a longer staff DE, likewise a shorter one FG, so as the observer may see A, the top of the height to be measured, over the ends DF of the two staffs; let FH and DC, parallel to the horizon, meet DE and AB in H and C; then the triangles FHD, DCA, shall be equiangular;

equiangular; for the angles at C and H are right ones; likewise the angle A is equal to the angle FDH; wherefore the remaining angles DFH, and ADC, are also equal: Wherefore, as FH, the distance of the staffs, to HD, the excess of the longer staff above the shorter; so is DC, the distance of the longer staff from the tower, to CA, the excess of the height of the tower above the longer staff. And thence CA will be found by the rule of three.

To which if the length DE be added, you will have the whole height of the tower BA.

S C H O L I U M.

FIG. 8. Many other methods may be occasionally contrived for measuring an accessible height. For example, from the given length of the shadow BD, to find out the height AB, thus: Let there be erected a staff CE perpendicularly, producing the shadow EE. The triangles ABD, CEF, are equiangular; for the angles at B and E are right; and the angles ADB and CFE are equal, each being equal to the angle of the sun's elevation above the horizon: Therefore, as EF, the shadow of the staff, to EC, the staff itself; so BD, the shadow of the tower, to BA, the height of the tower. Though the plane on which the shadow of the tower falls be not parallel to the horizon, if the staff be erected in the same plane, the rule will be the same.

P R O P O S I T I O N VII.

To measure an inaccessible height by means of two staffs.—Hitherto we have supposed the height to be accessible, or that we can come at the lower end of it; now if, because of some impediment, we cannot get to a tower, or if the point whose height is to be found out be the summit of a hill, so that the perpendicular be hid within the hill; if, for want of better instruments, such an inaccessible height is to be measured by means of two staffs, let the first observation be made with the staffs DE and FG, (as in prop. 6.); then the observer is to go off in a direct line from the height and first station, till he come to the second station; where (fig. 11.) he is to place the longer staff perpendicularly at RN, and the shorter staff at KO, so that the summit A may be seen along their tops; that is, so that the points KNA may be in the same right line. Through the point N, let there be drawn the right line NP parallel to FA: Wherefore in the triangles KNP, KAF, the angles KNP KAF are equal, also the angle AKF is common to both; consequently the remaining angle KPN is equal to the remaining angle KFA. And therefore,  $PN : FA :: KP : KF$ . But the triangles PNL, FAS are similar; therefore,  $PN : FA :: NL : SA$ . Therefore, (by the 11. 5. Encl.)  $KP : KF :: NL : SA$ . Thence, alternately, it will be, as KP (the excess of the greater distance of the short staff from the long one above its lesser distance from it) to NL, the excess of the longer staff above the shorter; so KF, the distance of the two stations of the shorter staff to SA the excess of the height sought above the height of the shorter staff. Wherefore SA will be found by the rule of three. To which let the height of the shorter staff be added, and the sum will give the whole inaccessible height BA.

Note 1. In the same manner may an inaccessible

height be found by a geometrical square, or by a plain speculum. But we shall leave the rules to be found out by the student, for his own exercise.

Note 2. That by the height of the staff we understand its height above the ground in which it is fixed.

Note 3. Hence depends the method of using other instruments invented by geometricians; for example, of the geometrical cross: And if all things be justly weighed, a like rule will serve for it as here. But we incline to touch only upon what is most material.

P R O P O S I T I O N VIII.

FIG. 9. To measure the distance AB, to one of whose extremities we have access, by the help of four staffs.—

Let there be a staff fixed at the point A; then going back at some sensible distance in the same right line, let another be fixed in C, so as that both the points A and B be covered and hid by the staff C: likewise going off in a perpendicular from the right line CB, at the point A, (the method of doing which shall be shown in the following scholium), let there be placed another staff at H; and in the right line CKG (perpendicular to the same CB, at the point B), and at the point of it K, such that the points K, H, and B may be in the same right line, let there be fixed a fourth staff. Let there be drawn, or let there be supposed to be drawn, a right line GH parallel to CA. The triangles KGH, HAH, will be equiangular; for the angles HAB KGH are right angles. Also the angles AHH, KHG are equal; wherefore, as KG (the excess of CK above AH) to GH, or to CA, the distance betwixt the first and second staff; so is AH, the distance betwixt the first and third staff, to AB the distance sought.

S C H O L I U M.

FIG. 10. To draw on a plane a right line AE perpendicular to CH, from a given point A; take the right lines AB, AD, on each side equal; and in the points B and D, let there be fixed stakes, to which let there be tied two equal ropes BE, DE, or one having a mark in the middle, and holding in your hand their extremities joined, (or the mark in the middle, if it be but one), draw out the ropes one the ground; and then, where the two ropes meet, or at the mark, when by it the rope is fully stretched, let there be placed a third stake at E; the right line AE will be perpendicular to CH in the point A (prob. 1. of part. i.). In a manner not unlike to this, may any problems that are resolved by the square and compasses, be done by ropes and a cord turned round as a radius.

P R O P O S I T I O N IX.

FIG. 12. To measure the distance AB, one of whose extremities is accessible.—From the point A, let the right line AC of a known length be made perpendicular to AB, (by the preceding scholium); likewise draw the right line CD perpendicular to CB, meeting the right line AB in D: then as DA : AC :: AC : AB. Wherefore, when DA and AC are given, AB will be found by the rule of three.

S C H O L I U M.

All the preceding operations depend on the equality of some angles of triangles, and on the similarity of the triangles arising from that equality. And on the same principles

ciples depend innumerable other operations which a geometrical will find out of himself, as is very obvious. However, some of these operations require such exactness in the work, and without it are so liable to errors, that, *ceteris paribus*, the following operations, which are performed by a trigonometrical calculation, are to be preferred; yet could we not omit those above, being most easy in practice, and most clear and evident to those who have only the first elements of geometry. But if you are provided with instruments, the following operations are more to be relied upon. We do not insist on the easiest cases to those who are skilled in plain trigonometry, which is indeed necessary to any one who would apply himself to practice. See TRIGONOMETRY.

PROPOSITION X.

FIG. 13. *To describe the construction and use of the geometrical quadrant.*—The geometrical quadrant is the fourth part of a circle divided into ninety degrees, to which two sights are adapted, with a perpendicular or plumb line hanging from the centre. The general use of it is for investigating angles in a vertical plane, comprehended under right lines going from the centre of the instrument, one of which is horizontal, and the other is directed to some visible point. This instrument is made of any solid matter as wood, copper, &c.

PROPOSITION XI.

FIG. 14. *To describe and make use of the graphometer.*—The graphometer is a semicircle made of any hard matter, of wood, for example, or brass, divided into 180 degrees; so fixed on a *fulcrum*, by means of a brass ball and socket, that it easily turns about, and retains any situation; two sights are fixed on its diameter. At the centre there is commonly a magnetical needle in a box. There is likewise a moveable ruler, which turns round the centre, and retains any situation given it. The use of it is to observe any angle, whose vertex is at the centre of the instrument in any plane, (though it is most commonly horizontal, or nearly so), and to find how many degrees it contains.

PROPOSITION XII.

FIG. 15. and 16. *To describe the manner in which angles are measured by a quadrant or graphometer.*—Let there be an angle in a vertical plane, comprehended between a line parallel to the horizon HK, and the right line RA, coming from any remarkable point of a tower or hill, or from the sun, moon, or a star. Suppose that this angle RAH is to be measured by the quadrant: let the instrument be placed in the vertical plane, so as that the centre A may be in the angular point: and let the sights be directed towards the object at R, (by the help of the ray coming from it, if it be the sun or moon, or by the help of the visual ray, if it is any thing else), the degrees and minutes in the arc BC cut off by the perpendicular, will measure the angle RAH required. For, from the make of the quadrant, BAD is a right angle; therefore BAR is likewise right, being equal to it. But, because HK is horizontal, and AC perpendicular, HAC will be a right angle; and therefore equal also to BAR. From those angles subtract the part HAB that is common to both; and there will remain the angle BAC equal to the angle RAH. But the arc BC is the measure of the

angle BAC; consequently, it is likewise the measure of the angle RAH.

Note, That the remaining arc on the quadrant DC is the measure of the angle RAZ, comprehended between the foresaid right line RA and AZ which points to the zenith.

Let it now be required to measure the angle ACB (fig. 16) in any plane, comprehended between the right lines AC and BC, drawn from two points A and B, to the place of station C. Let the graphometer be placed at C, supported by its *fulcrum* (as was shown above); and let the immoveable sights on the side of the instrument DE be directed towards the point A; and likewise (while the instrument remains immoveable) let the sights of the ruler FG (which is moveable about the centre C) be directed to the point B. It is evident, that the moveable ruler cuts off an arc DH, which is the measure of the angle ACB sought. Moreover, by the same method, the inclination of CE, or of FG, may be observed with the meridian line, which is pointed out by the magnetic needle inclosed in the box, and is moveable about the centre of the instrument, and the measure of this inclination or angle found in degrees.

PROPOSITION XIII.

FIG. 17. *To measure an accessible height by the geometrical quadrant.*—By the 12th prop. of this part, let the angle C be found by means of the quadrant. Then in the triangle ABC, right-angled at B, (BC being supposed the horizontal distance of the observer from the tower), having the angle at C, and the side BC, the required height BA will be found by the 3d case of plain trigonometry. See TRIGONOMETRY.

PROPOSITION XIV.

FIG. 18. *To measure an inaccessible height by the geometrical quadrant.*—Let the angle ACB be observed with the quadrant (by the 12th prop. of this part); then let the observer go from C to the second station D, in the right line BCD (provided BCD be a horizontal plane); and after measuring this distance CD, take the angle ADC likewise with the quadrant. Then, in the triangle ACD, there is given the angle ADC, with the angle ACD; because ACB was given before: therefore (by art. 59. of Part I.) the remaining angle CAD is given likewise. But the side CD is likewise given, being the distance of the station C and D; therefore (by the first case of oblique-angled triangles in trigonometry) the side AC will be found. Wherefore, in the right-angled triangle ABC, all the angles and the hypotenuse AC are given; consequently, by the fourth case of trigonometry, the height sought AB will be found; as also (if you please) the distance of the station C, from AB the perpendicular within the hill or inaccessible height.

PROPOSITION XV.

FIG. 19. *From the top of a given height, to measure the distance BC.*—Let the angle BAC be observed by the 12th prop. of this; wherefore in the triangle ABC, right-angled at B, there is given by observation the angle at A; whence (by the 59th art. of Part I.) there will also be given the angle BCA: moreover the side AB (being the height of the tower) is supposed to be given. Wherefore,

Abel's Invention

Wherefore, by the 3d case of trigonometry, BC, the distance sought; will be found.

PROPOSITION XVI.

FIG. 20. *To measure the distance of two places A and B, of which one is accessible, by the graphometer.*—Let there be erected at two points A and C, sufficiently distant, two visible signs; then (by the 12th prop. of this part) let the two angles BAC, BCA be taken by the graphometer. Let the distance of the stations A and C be measured with a chain. Then the third angle B being known, and the side AC being likewise known; therefore, by the first case of trigonometry, the distance required, AB, will be found.

PROPOSITION XVII.

FIG. 21. *To measure by the graphometer, the distance of two places, neither of which is accessible.*—Let two stations C and D be chosen, from each of which the places may be seen whose distance is sought: let the angles ACD, ACB, BCD, and likewise the angles BDC, BDA, CDA, be measured by the graphometer; let the distance of the stations C and D be measured by a chain, or (if it be necessary) by the preceding practice. Now, in the triangle ACD, there are given two angles ACD and ADC; therefore, the third CAD is likewise given; moreover the side CD is given; therefore, by the first case of trigonometry, the side AD will be found. After the same manner, in the triangle BCD, from all the angles and one side CD given, the side BD is found. Wherefore, in the triangle ADB, from the given sides DA and DB, and the angle ADB contained by them, the side AB (the distance sought) is found by the 4th case of trigonometry of oblique-angled triangles.

PROPOSITION XVIII.

FIG. 22. *It is required by the graphometer and quadrant, to measure an accessible height AB, placed so on a steep, that one can neither go near it in an horizontal plane, nor recede from it, as was supposed in the solution of the 14th Prop.*—Let there be chosen any situation as C, and another D; where let some mark be erected: let the angles ACD and ADC be found by the graphometer; then the third angle DAC will be known. Let the side CD, the distance of the stations, be measured with a chain, and thence (by trigon.) the side AC will be found. Again, in the triangle ACB, right angled at B, having found by the quadrant the angle ACB, the other angle CAB is known likewise: but the side AC in the triangle ADC is already known; therefore the height required AB will be found by the 4th case of right-angled triangles. If the height of the tower is wanted, the angle BCF will be found by the quadrant; which being taken from the angle ACB already known, the angle ACF will remain: but the angle FAC was known before; therefore the remaining angle AFC will be known. But the side AC was also known before; therefore, in the triangle AFC, all the angles and one of the sides AC being known, AF, the height of the tower above the hill, will be found by trigonometry.

SCHOLIUM.

It were easy to add many other methods of measuring heights and distances; but, if what is above be understood, it will be easy (especially for one that is versed in

the elements) to contrive methods for this purpose, according to the occasion: so that there is no need of adding any more of this sort. We shall subjoin here a method by which the diameter of the earth may be found out.

PROPOSITION XIX.

PLATE CXVI. FIG. 1. *To find the diameter of the earth from one observation.*—Let there be chosen a high hill AB, near the sea-shore, and let the observer on the top of it, with an exact quadrant divided into minutes and seconds by transverse divisions, and fitted with a telescope in place of the common sights, measure the angle ABE contained under the right line AB, which goes to the centre, and the right line BE drawn to the sea, a tangent to the globe at E; let there be drawn from A perpendicular to BD, the line AF meeting BE in F. Now in the right-angled triangle BAF all the angles are given, also the side AB, the height of the hill; which is to be found by some of the foregoing methods, as exactly as possible; and (by trigonometry) the sides BF and AF are found. But, by cor. 36th 3. Eucl. AF is equal to FE; therefore BE will be known. Moreover, by 36th 3. Eucl. the rectangle under BA and BD is equal to the square of BE. And thence, by 17th 6. Eucl. as AB : BE :: BE : BD. Therefore, since AB and BE are already given, BD will be found by 11th, 6. Eucl. or by the rule of three; and subtracting BA, there will remain AD the diameter of the earth sought.

SCHOLIUM.

Many other methods might be proposed for measuring the diameter of the earth. The most exact is that proposed by Mr Picart of the academy of sciences at Paris.

“According to Mr Picart, a degree of the meridian at the latitude of  $49^{\circ} 21'$ , was 57,060 French toises, each of which contains six feet of the same measure; from which it follows, that, if the earth be an exact sphere, the circumference of a great circle of it will be 123,249,600 Paris feet, and the semidiameter of the earth 19,615,800 feet: but the French mathematicians, who of late have examined Mr Picart's operations, assure us, That the degree in that latitude is 57,183 toises. They measured a degree in Lapland, in the latitude of  $66^{\circ} 20'$ , and found it of 57,438 toises. By comparing these degrees, as well as by the observations on pendulums, and the theory of gravity, it appears that the earth is an oblate spheroid; and (supposing those degrees to be accurately measured) the axis or diameter that passes through the poles will be to the diameter of the equator, as 177 to 178; or the earth will be 22 miles higher at the equator than at the poles. A degree has likewise been measured at the equator, and found to be considerably less than at the latitude of Paris; which confirms the oblate figure of the earth. But an account of this last mensuration has not been published as yet. If the earth was of an uniform density from the surface to the centre, then, according to the theory of gravity, the meridian would be an exact ellipsis, and the axis would be to the diameter of the equator as 230 to 231; and the difference of the semidiameter of the equator and semiaxis about 17 miles.”

In what follows, a figure is often to be laid down on paper, like to another figure given; and because this likeness consists in the equality of their angles, and in the sides having the same proportion to each other (by the definitions of the 6th of Eucl.) we are now to shew what methods practical geometers use for making on paper an angle equal to a given angle, and how they constitute the sides in the same proportion. For this purpose they make use of a protractor, (or, when it is wanting, a line of chords), and of a line of equal parts.

#### PROPOSITION XX.

FIG. 2. 3. 4. 5. and 6. *To describe the construction and use of the protractor, of the line of chords, and of the line of equal parts.*—The protractor is a small semicircle of brass, or such solid matter. The semicircumference is divided into 180 degrees. The use of it is, to draw angles on any plane, as on paper, or to examine the extent of angles already laid down. For this last purpose, let the small point in the centre of the protractor be placed above the angular point, and let the side AB coincide with one of the sides that contain the angle proposed; the number of degrees cut off by the other side, computing on the protractor from B, will show the quantity of the angle that is to be measured.

But if an angle is to be made of a given quantity on a given line, and at a given point of that line, let AB coincide with the given line, and let the centre A of the instrument be applied to that point. Then let there be a mark made at the given number of degrees; and a right line drawn from that mark to the given point, will constitute an angle with the given right line of the quantity required; as is manifest.

This is the most natural and easy method, either for the extent of an angle on paper, or for describing on paper an angle of a given quantity.

But when there is scarcity of instruments, or because a line of chords is more easily carried about, (being described on a ruler on which there are many other lines besides), practical geometers frequently make use of it. It is made thus: let the quadrant of a circle be divided into 90 degrees; (as in fig. 4.) The line AB is the chord of 90 degrees; the chord of every arc of the quadrant is transferred to this line AB, which is always marked with the number of degrees in the corresponding arc.

Note, that the chord of 60 degrees is equal to the radius, by corol. 15. 4th Eucl. If now a given angle EDF is to be measured by the line of chords from the centre D, with the distance DG, (the chord of 60 degrees,) describe the arch GF; and let the points G and F be marked where this arch intersects the sides of the angle. Then if the distance GF, applied on the line of chords from A to B, gives (for example) 25 degrees, this shall be the measure of the angle proposed.

When an obtuse angle is to be measured with this line, let its complement to a semicircle be measured, and thence it will be known. It were easy to transfer to the diameter of a circle the chords of all arches to the extent of a semicircle; but such are rarely found marked upon rules.

But now, if an angle of a given quantity, suppose of 50 degrees, is to be made at a given point M of the right line KL (fig. 6.) From the centre M, and the di-

stance MN, equal to the chord of 60 degrees, describe the arc QN. Take off an arc NR, whose chord is equal to that of 50 degrees on the line of chords: join the points M and R; and it is plain that MR shall contain an angle of 50 degrees with the line KL proposed.

But sometimes we cannot produce the sides, till they be of the length of a chord of 60 degrees on our scale; in which case it is fit to work by a circle of proportions (that is a sector), by which an arc may be made of a given number of degrees to any radius.

The quantities of angles are likewise determined by other lines usually marked upon rules, as the lines of sines, tangents, and secants; but, as these methods are not so easy or so proper in this place, we omit them.

To delineate figures similar or like to others given, besides the equality of the angles, the same proportion is to be preserved among the sides of the figure that is to be delineated, as is among the sides of the figures given. For which purpose, on the rules used by artists, there is a line divided into equal parts, more or less in number, and greater or lesser in quantity, according to the pleasure of the maker.

A foot is divided into inches; and an inch, by means of transverse lines, into 100 equal parts: so that with this scale, any number of inches, below twelve, with any part of an inch, can be taken by the compasses, providing such part be greater than the one hundredth part of an inch. And this exactness is very necessary in delineating the plans of houses, and in other cases.

#### PROPOSITION XXI.

FIG. 7. *To lay down on paper, by the protractor or line of chords, and line of equal parts, a right-lined figure like to one given, providing the angles and sides of the figure given be known by observation or mensuration.*

—For example, suppose that it is known that in a quadrangular figure, one side is of 235 feet, that the angle contained by it and the second side is of  $84^\circ$ , the second side of 288 feet, the angle contained by it and the third side of  $72^\circ$ , and that the third side is 294 feet. These things being given, a figure is to be drawn on paper like to this quadrangular figure. On your paper, at a proper point A, let a right line be drawn, upon which take 235 equal parts, as AB. The part representing a foot is taken greater or lesser, according as you would have your figure greater or less. In the adjoining figure, the 100th part of an inch is taken for a foot. And accordingly an inch divided into 100 parts, and annexed to the figure, is called a scale of 100 feet. Let there be made at the point B (by the preceding prop.) an angle ABC of  $85^\circ$ , and let BC be taken of 288 parts like to the former. Then let the angle BCD be made of  $72^\circ$ , and the side CD of 294 equal parts. Then let the side AD be drawn; and it will complete the figure like to the figure given. The measures of the angle A and D can be known by the protractor or line of chords, and the side AD by the line of equal parts; which will exactly answer to the corresponding angles and to the side of the primary figure.

After the very same manner, from the sides and angles given, which bound any right-lined figure, a figure like to it may be drawn, and the rest of its sides and angles be known.

C O R O L.

C O R O L L A R Y.

Hence any trigonometrical problem in right-lined triangles, may be resolved by delineating the triangle from what is given concerning it, as in this proposition. The unknown sides are examined by a line of equal parts, and the angles by a protractor or line of chords.

P R O P O S I T I O N XXII.

*The diameter of a circle being given, to find its circumference nearly.*—The periphery of any polygon inscribed in the circle is less than the circumference, and the periphery of any polygon described about a circle is greater than the circumference. Whence Archimedes first discovered that the diameter was in proportion to the circumference, as 7 to 22 nearly; which serves for common use. But the moderns have computed the proportion of the diameter to the circumference to greater exactness. Supposing the diameter 100, the periphery will be more than 314, but less than 315. The diameter is more nearly to the circumference, as 113 to 355. But Ludolphus van Cuelen exceeded the labours of all; for by immense study he found, that, supposing the diameter 100,000,000,000,000,000,000,000,000,000, the periphery will be less than

314,159,265,358,979,323,846,264,338,327,951,  
but greater than

314,159,265,358,979,323,846,264,338,327,950;  
whence it will be easy, any part of the circumference being given in degrees and minutes, to assign it in parts of the diameter.

Of Surveying and Measuring of LAND.

HITHERTO we have treated of the measuring of angles and sides, whence it is abundantly easy to lay down a field, a plane, or an entire country: for to this nothing is requisite but the protraction of triangles, and of other plain figures, after having measured their sides and angles. But as this is esteemed an important part of practical geometry, we shall subjoin here an account of it with all possible brevity; suggesting withal, that a surveyor will improve himself more by one day's practice, than by a great deal of reading.

P R O P O S I T I O N XXIII.

*To explain what surveying is, and what instruments Surveyors use.*—First, it is necessary that the surveyor view the field that is to be measured, and investigate its sides and angles, by means of an iron chain (having a particular mark at each foot of length, or at any number of feet, as may be most convenient for reducing lines or surfaces to the received measures), and the graphometer described above. Secondly, It is necessary to delineate the field *in plano*, or to form a map of it; that is, to lay down on paper a figure similar to the field; which is done by the protractor (or line of chords) and of the line of equal parts. Thirdly, It is necessary to find out the area of the field so surveyed and represented by a map. Of this last we are to treat below.

The sides and angles of small fields are surveyed by the help of a plain table; which is generally of an oblong rectangular figure, and supported by a *fulcrum*, so as to turn every way by means of a ball and socket. It has a

moveable frame, which surrounds the board, and serves to keep a clean paper put on the board close and tight to it. The sides of the frame facing the paper are divided into equal parts every way. The board hath besides a box with a magnetic needle, and moreover a large index with two sights. On the edge of the frame of the board are marked degrees and minutes, so as to supply the room of a graphometer.

P R O P O S I T I O N XXIV.

FIG. 8. *To delineate a field by the help of a plain-table, from one station whence all its angles may be seen, and their distances measured by a chain.*—Let the field that is to be laid down be ABCDE. At any convenient place F, let the plain-table be erected; cover it with clean paper, in which let some point near the middle represent the station. Then applying at this place the index with the sights, direct it so as that through the sights some mark may be seen at one of the angles, suppose A; and from the point F, representing the station, draw a faint right line along the side of the index: then, by the help of the chain, let FA the distance of the station from the forefaid angle be measured. Then taking what part you think convenient for a foot or pace from the line of equal parts, set off on the faint line the parts corresponding to the line FA that was measured; and let there be a mark made representing the angle of the field A. Keeping the table immoveable, the same is to be done with the rest of the angles; then right lines joining those marks shall include a figure like to the field, as is evident from 5. 6. Eucl.

C O R O L L A R Y.

The same thing is done in like manner by the graphometer: for having observed in each of the triangles, AFB, BFC, CFD, &c. the angle at the station F, and having measured the lines from the station to the angles of the field, let similar triangles be protracted on paper (by the 21. prop. of this) having their common vertex in the point of station. All the lines, excepting those which represent the sides of the field, are to be drawn faint or obscure.

Note 1. When a surveyor wants to lay down a field, let him place distinctly in a register all the observations of the angles, and the measures of the sides, until, at time and place convenient, he draw out the figure on paper.

Note 2. The observations made by the help of the graphometer are to be examined: for all the angles about the point F ought to be equal to four right ones. (by cor. 2. art. 30. of part I.)

P R O P O S I T I O N XXV.

FIG. 9. *To lay down a field by means of two stations, from each of which all the angles can be seen, by measuring only the distance of the stations.*—Let the instrument be placed at the station F: and having chosen a point representing it upon the paper which is laid upon the plain table, let the index be applied at this point, so as to be moveable about it. Then let it be directed successively to the several angles of the field: and when any angle is seen through the sights, draw an obscure line along the side of the index. Let the index, with the sights, be directed after the same manner to the station G: on the obscure line drawn along its side, pointing to A,

A, set off from the scale of equal parts a line corresponding to the measured distance of the stations, and this will determine the point G. Then remove the instrument to the station G, and applying the index to the line representing the distance of the stations, place the instrument so that the first station may be seen through the sights. Then the instrument remaining immovable, let the index be applied at the point representing the second station G, and be successively directed by means of its sights, to all the angles of the field, drawing (as before) obscure lines: and the intersection of the two obscure lines that were drawn to the same angle from the two stations will always represent that angle on the plan. Care must be taken that those lines be not mistaken for one another. Lines joining those intersections will form a figure on the paper like to the field.

#### SCHOLIUM.

It will not be difficult to do the same by the graphometer, if you keep a distinct account of your observations of the angles made by the line joining the stations, and the lines drawn from the stations to the respective angles of the field. And this is the most common manner of laying down whole countries. The tops of two mountains are taken for two stations, and their distance is either measured by some of the methods mentioned above, or is taken according to common repute. The sights are successively directed towards cities, churches, villages, forts, lakes, turnings of rivers, woods, &c.

Note, The distance of the stations ought to be great enough, with respect to the field that is to be measured; such ought to be chosen as are not in a line with any angle of the field. And care ought to be taken likewise that the angles, for example, FAG, FDG, &c. be neither very acute, nor very obtuse. Such angles are to be avoided as much as possible; and this admonition is found very useful in practice.

#### PROPOSITION XXVI.

FIG. 10. *To lay down any field, however irregular its figure may be, by the help of the graphometer.*—Let ABCEDHG be such a field. Let its angles (in going round it) be observed with a graphometer (by the 12. of this) and noted down; let its sides be measured with a chain; and (by what was said on the 21. of this) let a figure like to the given field be protracted on paper. If any mountain is in the circumference, the horizontal line hid under it is to be taken for a side, which may be found by two or three observations according to some of the methods described above; and its place on the map is to be distinguished by a shade, that it may be known a mountain is there.

If not only the circumference of the field is to be laid down on the plan, but also its contents, as villages, gardens, churches, public roads, we must proceed in this manner.

Let there be (for example) a church F; to be laid down in the plan. Let the angles ABF BAF be observed and protracted on paper in their proper places, the intersection of the two sides BF and AF will give the place of the church on the paper: Or, more exactly, the lines BF AF being measured, let circles be described from the centres B and A, with parts from the

scale corresponding to the distances BF and AF, and the place of the church will be at their intersection.

Note 1. While the angles observed by the graphometer are taken down, you must be careful to distinguish the external angles, as E and G, that they may be rightly protracted afterwards on paper.

Note 2. Our observations of the angles may be examined by computing if all the internal angles make twice as many right angles, four excepted, as there are sides of the figure: (for this is demonstrated by 32. 1. Eucl.) But in place of any external angle DEC, its complement to a circle is to be taken.

#### PROPOSITION XXVII.

FIG. 11. *To lay down a plain field without instruments.*—If a small field is to be measured, and a map of it to be made, and you are not provided with instruments; let it be supposed to be divided into triangles, by right-lines, as in the figure; and after measuring the three sides of any of the triangles, for example of ABC, let its sides be laid down from a convenient scale on paper, (by the 22. of this.) Again, let the other two sides BD CD of the triangle CBD be measured and protracted on the paper by the same scale as before. In the same manner proceed with the rest of the triangles of which the field is composed, and the map of the field will be perfected; for the three sides of a triangle determine the triangle; whence each triangle on the paper is similar to its correspondent triangle in the field, and is similarly situated; consequently the whole figure is like to the whole field.

#### SCHOLIUM.

If the field be small, and all its angles may be seen from one station, it may be very well laid down by the plain-table, (by the 24. of this.) If the field be larger, and have the requisite conditions, and great exactness is not expected, it likewise may be plotted by means of the plain-table, or by the graphometer, (according to the 25. of this; but in fields that are irregular and mountainous, when an exact map is required, we are to make use of the graphometer, (as in the 26. of this,) but rarely of the plain-table.

Having protracted the bounding lines, the particular parts contained within them may be laid down by the proper operations for this purpose, (delivered in the 26th proposition; and the method described in the 27th proposition may be sometimes of service;) for we may trust more to the measuring of sides, than to the observing of angles. We are not to compute four-sided and many sided figures till they are resolved into triangles: for the sides do not determine those figures.

In the laying down of cities, or the like, we may make use of any of the methods described above that may be most convenient.

The map being finished, it is transferred on clean paper, by putting the first sketch above it, and marking the angles by the point of a small needle. These points being joined by right lines, and the whole illuminated by colours proper to each part, and the figure of the mariners compasses being added to distinguish the north and south, with a scale on the margin, the map or plan will be finished and neat.

We

We have thus briefly and plainly treated of surveying, and shown by what instruments it is performed; having avoided those methods which depend on the magnetic needle, not only because its direction may vary in different places of a field (the contrary of this at least doth not appear,) but because the quantity of an angle observed by it cannot be exactly known; for an error of two or three degrees can scarcely be avoided in taking angles by it.

As for the remaining part of surveying, whereby the area of a field already laid down on paper is found in acres, roods, or any other superficial measures; this we leave to the following section, which treats of the mensuration of surfaces.

" Besides the instruments described above, a surveyor ought to be provided with an off-set staff equal in length to ten links of the chain, and divided into ten equal parts. He ought likewise to have ten arrows or small straight sticks near two feet long, shod with iron ferrils. When the chain is first opened, it ought to be examined by the off-set staff. In measuring any line, the leader of the chain is to have the ten arrows at first setting out. When the chain is stretched in the line, and the near end touches the place from which you measure, the leader sticks one of the ten arrows in the ground, at the far end of the chain. Then the leader leaving the arrow, proceeds with the chain another length; and the chain being stretched in the line, so that the near end touches the first arrow, the leader sticks down another arrow at his end of the chain. The line is preserved straight, if the arrows be always set so as to be in a right line with the place you measure from, and that to which you are going. In this manner they proceed till the leader have no more arrows. At the eleventh chain, the arrows are to be carried to him again, and he is to stick one of them into the ground, at the end of the chain. And the same is to be done at the 21. 31. 41. &c. chains, if there are so many in a right line to be measured. In this manner you can hardly commit an error in numbering the chains, unless of ten chains at once.

" The off-set staff serves for measuring readily the distances of any things proper to be represented in your plan, from the station-line while you go along. These distances ought to be entered into your field-book, with the corresponding distances from the last station, and proper remarks, that you may be enabled to plot them justly, and be in no danger of mistaking one for another when you extend your plan. The field-book may be conveniently divided into five columns. In the middle column the angles at the several stations taken by the theodolite are to be entered, with distances from the stations. The distances taken by the off-set staff, on either side of the station-line, are to be entered into columns on either side of the middle column, according to their position with respect to that line. The names and characters of the objects, with proper remarks, may be entered in columns on either side of these last.

" Because, in the place of the graphometer described by our author, surveyors now make use of the theodolite. we shall subjoin a description of Mr Sisson's latest  
Vol. II. No. 55.

" improved theodolite from Mr Gardner's practical surveying improved. See a figure of it in Plate XCVI.

" In this instrument, the three staffs, by brass ferrils at top, screw into bell-metal joints, that are moveable between brass pillars, fixed in a strong brass plate; in which, round the centre, is fixed a socket with a ball moveable in it, and upon which the four screws press, that set the limb horizontal: Next above is another such plate, through which the said screws pass, and on which, round the centre, is fixed a frustum of a cone of bell-metal, whose axis (being connected with the centre of the bell) is always perpendicular to the limb, by means of a conical brass ferril fitted to it, whereon is fixed the compass box; and on it the limb, which is a strong bell-metal ring, whereon are moveable three brass indexes; in whose plate are fixed four brass pillars, that, joining at top, hold the centre pin of the bell-metal double sextant, whose double index is fixed on the centre of the same plate: Within the double sextant is fixed the spirit-level, and over it the telescope.

" The compass box is graved with two diamonds for north and south, and with 20 degrees on both sides of each, that the needle may be set to the variation, and its error also known.

" The limb has two *fleurs de luce* against the diamonds in the box, instead of 180 each; and is curiously divided into whole degrees, and numbered to the left hand at every ten to twice 180, having three indexes distant 120, (with Nonius's divisions on each for the decimals of a degree), that are moved by a pinion fixed below one of them, without moving the limb; and in another is a screw and spring under, to fix it to any part of the limb. It has also divisions numbered, for taking the quarter girt in inches of round timber at the middle height, when standing ten feet horizontally distant from its centre; which at 20 must be doubled, and at 30 tripled; to which a shorter index is used, having Nonius's divisions for the decimals of an inch; but an abatement must be made for the bark, if not taken off.

" The double sextant is divided on one side from under its centre (when the spirit-tube and telescope are level) to above 60 degrees each way, and numbered at 10, 20, &c. and the double index (through which it is moveable) shews on the same side the degree and decimal of any altitude or depression to that extent by Nonius's divisions: On the other side are divisions numbered, for taking the upright height of timber, &c. in feet, when distant 10 feet; which at 20 must be doubled, and at 30 tripled; and also the quantities for reducing hypotenusal lines to horizontal. It is moveable by a pinion fixed in the double index.

" The telescope is a little shorter than the diameter of the limb, that a fall may not hurt it; yet it will magnify as much, and shew a distant object as perfect, as most of triple its length. In its focus are very fine cross wires, whose intersection is in the plane of the double sextant; and this was a whole circle, and turned in a lathe to a true plane, and is fixed at right angles to the limb; so that, whenever the limb is set horizontal, (which is readily done by making the spirit-tube  
" level

" level over two screws, and the like over the other two),  
 " the double sextant and telescope are moveable in a ver-  
 " tical plane; and then every angle taken on the limb  
 " (though the telescope be never so much elevated or  
 " depressed) will be an angle in the plane of the horizon.  
 " And this is absolutely necessary in plotting a horizontal  
 " plane.

" If the lands to be plotted are hilly, and not in any  
 " one plane, the lines measured cannot be truly laid down  
 " on paper, without being reduced to one plane, which  
 " must be the horizontal, because angles are taken in that  
 " plane.—

" In viewing your objects, if they have much altitude  
 " or depression, either write down the degree and decimal  
 " shewn on the double sextant, or the links shewn on the  
 " back side; which last subtracted from every chain in  
 " the station-line, leaves the length in the horizontal  
 " plane. But if the degree is taken, the following table  
 " will shew the quantity.

*A table of the links to be subtracted out of every chain  
 in hypotenusal lines of several degrees altitude, or  
 depression, for reducing them to horizontal.*

Degrees. Links.	Degrees. Links.	Degrees. Links.
4,05 — $\frac{1}{4}$	14,07 — 3	23,074 — 8
5,73 — $\frac{1}{2}$	16,26 — 4	24,495 — 9
7,02 — $\frac{3}{4}$	18,195 — 5	25,84 — 10
8,11 — 1	19,95 — 6	27,13 — 11
11,48 — 2	21,565 — 7	28,36 — 12

" Let the first station line really measure 1107 links,  
 " and the angle of altitude or depression be  $19^{\circ} 95'$ ;  
 " looking in the table you will find against  $19^{\circ} 95'$ , is 6  
 " links. Now 6 times 11 is 66; which subtracted from  
 " 1107, leaves 1041, the true length to be laid down  
 " in the plan.

" It is useful in surveying, to take the angles, which  
 " the bounding lines form, with the magnetic needle,  
 " in order to check the angles of the figure, and to plot  
 " them conveniently afterwards."

### *Of the Surfaces of Bodies.*

THE smallest superficial measure with us is a square  
 inch; 144 of which make a square foot. Wrights make  
 use of these in the measuring of deals and planks; but  
 the square foot which the glaziers use in measuring of  
 glass, consists only of 64 square inches. The other  
 measures are, first, the ell square; secondly, the fall,  
 containing 36 square ells; thirdly, the rood, containing  
 40 falls; fourthly, the acre, containing 4 roods. Slaters,  
 masons, and paviours, use the ell square and the fall; sur-  
 veyors of land use the square ell, the fall, the rood, and  
 the acre.

The superficial measures of the English are, first, the  
 square foot; secondly, the square yard, containing 9  
 square feet; for their yard contains only 3 feet; thirdly,  
 the pole, containing  $30\frac{1}{2}$  square yards; fourthly, the  
 rood, containing 40 poles; fifthly, the acre, containing

4 roods. And hence it is easy to reduce our superficial  
 measures to the English, or theirs to ours.

" In order to find the content of a field, it is most con-  
 " venient to measure the lines by the chains described a-  
 " bove, p. 693. that of 22 yards for computing the Eng-  
 " lish acres, and that of 24 Scots ells for the acres of  
 " Scotland. The chain is divided into 100 links, and the  
 " square of the chain is 10,000 square links; ten squares  
 " of the chain, or 100,000 square links, give an acre.  
 " Therefore, if the area be expressed by square links,  
 " divide by 100,000, or cut off five decimal places, and  
 " the quotient shall give the area in acres and decimals  
 " of an acre. Write the entire acres apart; but multi-  
 " ply the decimals of an acre by 4, and the product shall  
 " give the remainder of the area in roods and decimals  
 " of a rood. Let the entire roods be noted apart after  
 " the acres; then multiply the decimals of a rood by 40,  
 " and the product shall give the remainder of the area in  
 " falls or poles. Let the entire falls or poles be then  
 " writ after the roods, and multiply the decimals of a  
 " fall by 36, if the area is required in the measures of  
 " Scotland; but multiply the decimals of a pole by  $30\frac{1}{2}$ ,  
 " if the area is required in the measures of England, and  
 " the product shall give the remainder of the area in  
 " square ells in the former case, but in square yards in  
 " the latter. If, in the former case, you would reduce  
 " the decimals of the square ell to square feet, multiply  
 " them by 9.50694; but, in the latter case, the decimals  
 " of the English square yard are reduce to square feet,  
 " by multiplying them by 9.

" Suppose, for example, that the area appears to con-  
 " tain 12.65842 square links of the chain of 24 ells;  
 " and that this area is to be expressed in acres, roods,  
 " falls, &c. of the measures of Scotland. Divide the  
 " square links by 100,000, and the quotient 12.65842  
 " shows the area to contain 12 acres  $\frac{65842}{100000}$  of an acre:  
 " Multiply the decimal part by 4, and the product  
 " 2.63368 gives the remainder in roods and decimals of  
 " a rood. Those decimals of the rood being multiplied  
 " by 40, the product gives 25.3472 falls. Multiply the  
 " decimals of the fall by 36, and the product gives  
 " 12.4992 square ells. The decimals of the square ell  
 " multiplied by 9.50994 give 4.7458 square feet.  
 " Therefore the area proposed amounts to 12 acres, 2  
 " roods, 25 falls, 12 square ells, and  $47\frac{458}{10000}$  square  
 " feet.

" But if the area contains the same number of square  
 " links of Gunter's chain, and is to be expressed by  
 " English measures, the acres and roods are computed in  
 " the same manner as in the former case. The poles are  
 " computed as the falls. But the decimals of the pole,  
 " viz.  $\frac{47458}{100000}$ , are to be multiplied by  $30\frac{1}{2}$  (or 30.25),  
 " and the product gives 10.5028 square yards. The de-  
 " cimals of the square yard, multiplied by 9, give 4.5252  
 " square feet; therefore, in this case, the area is in  
 " English measure 12 acres, 2 roods, 25 poles, 10 square  
 " yards, and  $47\frac{458}{10000}$  square feet.

" The Scots acre is to the English acre, by statute,  
 " as 100,000 to 78,694. if we have regard to the diffe-  
 " rence betwixt the Scots and English foot above men-  
 " tioned. But it is customary in some parts of England  
 " to

"to have 18, 21 &c. feet to a pole, and 160 such poles  
 "to an acre; whereas, by the statute,  $16\frac{1}{2}$  feet make a  
 "pole. In such cases the acre is greater in the dupli-  
 "cate ratio of the number of feet to a pole.

"They who measure land in Scotland by an ell of 37  
 "English inches, make the acre less than the true Scots  
 "acre by  $593\frac{1}{8}$  square English feet, or by about  $\frac{1}{7}$  of  
 "the acre.

"An husband-land contains 6 acres of sock and sythe-  
 "land, that is, of land that may be tilled with a plough,  
 "and mown with a sythe; 13 acres of arable land make  
 "an oxgang or oxengate; four oxengate make a pound-  
 "land of old extent (by a decree of the Exchequer,  
 "March 11. 1585), and is called *librata terra*. A  
 "forty-shilling land of old extent contains eight oxgang,  
 "or 104 acres.

"The arpent, about Paris, contains 32400 square Pa-  
 "ris feet, and is equal to  $2\frac{1}{2}$  Scots roods, or  $1\frac{1}{3}$  Eng-  
 "lish roods

"The *astus quadratus*, according to Varro, Collu-  
 "mella, &c. was a square of 120 Roman feet. The  
 "*jugurum* was the double of this. It is to the Scots a-  
 "cre as 10,000 to 20,456, and to the English acre as  
 "10,000 to 16,097. It was divided (like the *as*) into  
 "12 *uncia*, and the *uncia* into 24 *scrupula*."—This,  
 with the three preceding paragraphs, are taken from an  
 ingenious manuscript, written by Sir Robert Stewart  
 professor of natural philosophy. The greatest part of  
 the table in p. 693. was taken from it likewise.

#### PROPOSITION XXVIII.

FIG. 12. To find out the area of a rectangular paral-  
 lelogram ABCD.—Let the side AB, for example, be  
 5 feet long, and BC (which constitutes with BA a right  
 angle at B) be 17 feet. Let 17 be multiplied by 5, and  
 the product 85 will be the number of square feet in the area  
 of the figure ABCD. But if the parallelogram proposed  
 is not rectangular as BEFC, its base BC multiplied into  
 its perpendicular height AB (not into its side BE) will  
 give its area. This is evident from art. 68. of part 1.

#### PROPOSITION XXIX.

FIG. 13. To find the area of a given triangle.—Let  
 the triangle BAC be given, whose base BC is supposed 9  
 feet long; let the perpendicular AD be drawn from the  
 angle A opposite to the base, and let us suppose AD to  
 be four feet. Let the half of the perpendicular be mul-  
 tiplied into the base, or the half of the base into the per-  
 pendicular, or take the half of the product of the whole  
 base into the perpendicular, the product gives 18 square  
 feet for the area of the given triangle.

But if only the sides are given, the perpendicular is  
 found either by protracting the triangle, or by 12th and  
 13th 2 Eucl. or by trigonometry. But how the area of  
 a triangle may be found from the given sides only,  
 shall be shewn in the 31st prop.

#### PROPOSITION XXX.

FIG. 14. To find the area of any rectilinear figure.—  
 If the figure be irregular, let it be resolved into triangles;  
 and drawing perpendiculars to the bases in each of them,  
 let the area of each triangle be found by the preceding  
 prop. and the sum of these areas will give the area of the  
 figure.

#### SCHOLIUM 1.

In measuring boards, planks, and plats, their sides are  
 to be measured by a foot-rule divided into 100 equal parts;  
 and after multiplying the sides, the decimal fractions are  
 easily reduced to lesser denominations. The mensuration  
 of these is easy, when they are rectangular parallelo-  
 grams.

#### SCHOLIUM 3.

If a field is to be measured, let it first be plotted on  
 paper, by some of the methods above described, and let  
 the figure so laid down be divided into triangles, as was  
 shown in the preceding proposition.

The base of any triangle, or the perpendicular upon  
 the base, or the distance of any two points of the field, is  
 measured by applying it to the scale according to which  
 the map is drawn.

#### SCHOLIUM 3.

But if the field given be not in a horizontal plane, but  
 uneven and mountainous, the scale gives the horizontal  
 line between any two points, but not their distance mea-  
 sured on the uneven surface of the field. And indeed it  
 would appear, that the horizontal plane is to be account-  
 ed the area of an uneven and hilly country. For if such  
 ground is laid out for building on, or for planting with  
 trees, or bearing corn, since these stand perpendicular to  
 the horizon, it is plain, that a mountainous country can-  
 not be considered as of greater extent for those uses than  
 the horizontal plane; nay, perhaps, for nourishing of  
 plants, the horizontal plane may be preferable.

If, however, the area of a figure, as it lies regularly on  
 the surface of the earth, is to be measured, this may be  
 easily done by resolving it into triangles as it lies. The  
 sum of their areas will be the area sought; which ex-  
 ceeds the area of the horizontal figure more or less, ac-  
 cording as the field is more or less uneven.

#### PROPOSITION XXXI.

FIG. 15. The sides of a triangle being given, to find the a-  
 rea, without finding the perpendicular.—Let all the sides of  
 the triangle be collected into one sum; from the half of  
 which let the sides be separately subtracted, that three  
 differences may be found betwixt the foresaid half sum  
 and each side; then let these three differences and the  
 half sum be multiplied into one another, and the square  
 root of the product will give the area of the triangle. For  
 example, let the sides be 10, 17, 21; the half of their  
 sum is 24; the three differences betwixt this half sum  
 and the three sides, are 14, 7, and 3. The first being  
 multiplied by the second, and their product by the third,  
 we have 294 for the product of the differences; which  
 multiplied by the foresaid half sum 24, gives 7056; the  
 square root of which 84 is the area of the triangle. The  
 demonstration of this, for the sake of brevity, we omit.  
 It is to be found in several treatises, particularly in Cla-  
 vius's Practical Geometry.

#### PROPOSITION XXXII.

FIG. 15. The area of the ordinate figure ABFGH  
 is equal to the product of the half circumference  
 of the polygon, multiplied into the perpendicular  
 drawn from the centre of the circumscribed circle to the  
 side of the polygon.—For the ordinate figure can be resol-  
 ved into as many equal triangles, as there are sides of the  
 figure;

figure; and since each triangle is equal to the product of half the base into the perpendicular, it is evident that the sum of all the triangles together, that is the polygon, is equal to the product of half the sum of the bases (that is the half of the circumference of the polygon) into the common perpendicular height of the triangles drawn from the centre C to one of the sides; for example, to AB.

#### PROPOSITION XXXIII.

FIG. 16. *The area of a circle is found by multiplying the half of the periphery into the radius, or the half of the radius into the periphery*—For a circle is not different from an ordinate or regular polygon of an infinite number of sides, and the common height of the triangles into which the polygon or circle may be supposed to be divided is the radius of the circle.

Were it worth while, it were easy to demonstrate accurately this proposition, by means of the inscribed and circumscribed figures, as is done in the 5th prop. of the treatise of Archimedes concerning the dimensions of the circle.

#### COROLLARY.

Hence also it appears, that the area of the sector ABCD is produced by multiplying the half of the arc into the radius, and likewise that the area of the segment of the circle ADC is found by subtracting from the area of the sector the area of the triangle ABC.

#### PROPOSITION XXXIV.

FIG. 17. *The circle is to the square of the diameter, as 11 to 14 nearly*.—For if the diameter AB be supposed to be 7, the circumference AHBK will be almost 22 (by the 22d prop. of this part), and the area of the square DC will be 49; and, by the preceding prop. the area of the circle will be  $38\frac{1}{2}$ ; therefore the square DC will be to the inscribed circle as 49 to  $38\frac{1}{2}$ , or as 98 to 77, that is, as 14 to 11. *Q. E. D.*

If greater exactness is required, you may proceed to any degree of accuracy: for the square DC is to the inscribed circle, as  $1$  to  $1 - \frac{1}{2} + \frac{1}{4} - \frac{1}{8} + \frac{1}{16} - \frac{1}{32} + \frac{1}{64}$ , &c. in infinitum.

“ This series will be of no service for computing the  
“ area of the circle accurately, without some further ar-  
“ tifice, because it converges at too slow a rate. The  
“ area of the circle will be found exactly enough for  
“ most purposes, by multiplying the square of the dia-  
“ meter by 7854, and dividing by 10,000, or cutting  
“ off four decimal places from the product; for the area  
“ of the circle is to the circumscribed square nearly as  
“ 7854 to 10,000.”

#### PROPOSITION XXXV.

FIG. 18. *To find the area of a given ellipse*—Let ABCD be an ellipse, whose greater diameter is BD, and the lesser AC, bisecting the greater perpendicularly in E. Let a mean proportional HF be found (by 13th 6. Eucl.) between AC and BD, and (by the 33d of this) find the area of the circle described on the diameter HF. This area is equal to the area of the ellipse ABCD. For because, as BD to AC, so the square of BD to the square of HF, (by 2. cor 20th 6. Eucl.): but (by the 12. Eucl.) as the square of BD to the square of HF, so is the circle of the diameter BD to the circle of the diameter HF: therefore as BD to AC, so is the circle of

the diameter BD to the circle of the diameter HF. And (by the 5th prop. of Archimedes of spheroids) as the greater diameter BD to the lesser AC, so is the circle of the diameter BD to the ellipse ABCD. Consequently (by the 11th 5. Eucl.) the circle of the diameter BD will have the same proportion to the circle of the diameter HF, and to the ellipse ABCD. Therefore, (by 9th 5. Eucl.) the area of the circle of the diameter HF will be equal to the area of the ellipse ABCD. *Q. E. D.*

#### SCHOLIUM.

From this and the two preceding propositions, a method is derived of finding the area of an ellipse. There are two ways: 1st, Say, as one is to the lesser diameter, so is the greater diameter to a fourth number, (which is found by the rule of three.) Then again say, as 14 to 11, so is the 4th number found to the area sought. But the second way is shorter. Multiply the lesser diameter into the greater, and the product by 11; then divide the whole product by 14, and the quotient will be the area sought of the ellipse. For example, Let the greater diameter be 10, and the lesser 7; by multiplying 10 by 7, the product is 70; and multiplying that by 11, it is 770; and dividing 770 by 14, the quotient will be 55, which is the area of the ellipse sought.

“ The area of the ellipse will be found more accurately,  
“ ly, by multiplying the product of the two diameters  
“ by 7854.”

We shall add no more about other plain surfaces, whether rectilinear or curvilinear, which seldom occur in practice; but shall subjoin some propositions about measuring the surfaces of solids.

#### PROPOSITION XXXVI.

*To measure the surface of any prism*.—By the 14th definition of the 11th Eucl. a prism is contained by planes, of which two opposite sides (commonly called the bases) are plain rectilinear figures; which are either regular and ordinate, and measured by prop. 32. of this; or however irregular, and then they are measured by the 39th prop. The other sides are parallelograms, which are measured by prop. 28th; and the whole superficies of the prism consists of the sum of those taken altogether.

#### PROPOSITION XXXVII.

*To measure the superficies of any pyramid*.—Since its basis is a rectilinear figure, and the rest of the planes terminating in the top of the pyramid are triangles; these measured separately, and added together, give the surface of the pyramid required.

#### PROPOSITION XXXVIII.

*To measure the superficies of any regular body*.—These bodies are called regular, which are bounded by equilateral and equiangular figures. The superficies of the tetraedron consists of four equal and equiangular triangles; the superficies of the hexaedron, or cube, of six equal squares; an octaedron, of eight equal equilateral triangles; a dodecaedron, of twelve equal and ordinate pentagons; and the superficies of an icosaedron, of twenty equal and equilateral triangles. Therefore it will be easy to measure these surfaces from what has been already shown.

In the same manner we may measure the superficies of a solid contained by any planes.

P R O -

PROPOSITION XXXIX.

FIG. 19. *To measure the superficies of a cylinder.*—Because a cylinder differs very little from a prism, whose opposite planes (or bases) are ordinate figures of an infinite number of sides, it appears that the superficies of a cylinder, without the bases, is equal to an infinite number of parallelograms; the common altitude of all which is the same with the height of the cylinder, and the bases of them all differ very little from the periphery of the circle which is the base of the cylinder. Therefore this periphery multiplied into the common height, gives the superficies of the cylinder, excluding the bases; which are to be measured separately by the help of the 33d prop.

This proposition concerning the measure of the surface of the cylinder (excluding its basis) is evident from this, that when it is conceived to be spread out, it becomes a parallelogram, whose base is the periphery of the circle of the base of the cylinder stretched into a right line, and whose height is the same with the height of the cylinder.

PROPOSITION XL.

FIG. 20. *To measure the surface of a right cone.*—The surface of a right cone is very little different from the surface of a right pyramid, having an ordinate polygon for its base of an infinite number of sides; the surface of which (excluding the base) is equal to the sum of the triangles. The sum of the bases of these triangles is equal to the periphery of the circle of the base, and the common height of the triangles is the side of the cone AB; wherefore the sum of these triangles is equal to the product of the sum of the bases (*i. e.* the periphery of the base of the cone) multiplied into the half of the common height, or it is equal to the product of the periphery of the base.

If the area of the base is likewise wanted, it is to be found separately by the 33d prop. If the surface of a cone is supposed to be spread out on a plane, it will become a sector of a circle, whose radius is the side of the cone; and the arc terminating the sector is made from the periphery of the base. Whence, by corol. 33d prop. of this, its dimension may be found.

COROLLARY.

Hence it will be easy to measure the surface of a frustum of a cone cut by a plane parallel to the base.

PROPOSITION XLI.

FIG. 21. *To measure the surface of a given sphere.*—Let there be a sphere, whose centre is A, and let the area of its convex surface be required. Archimedes demonstrates (37 prop. 1. book of the sphere and cylinder) that its surface is equal to the area of four great circles of the sphere; that is, let the area of the great circle be multiplied by 4, and the product will give the area of the sphere; or, (by the 20th 6. and 2d 12 of Eucl.) the area of the sphere given is equal to the area of a circle whose radius is the right line BC, the diameter of the sphere. Therefore having measured (by 33d prop.) the circle described with the radius BC, this will give the surface of the sphere.

PROPOSITION XLII.

FIG. 22. *To measure the surface of a segment of a sphere.*—Let there be a segment cut off by the plane

ED. Archimedes demonstrates (49, and 50. 1. De sphaera) that the surface of this segment, excluding the circular base, is equal to the area of a circle whose radius is the right line BE drawn from the vertex B of the segment to the periphery of the circle DE. Therefore, (by the 33d prop.) it is easily measured.

COROLLARY 1.

Hence that part of the surface of a sphere that lieth between two parallel planes is easily measured, by subtracting the surface of the lesser segment from the surface of the greater segment.

COROLLARY 2.

Hence likewise it follows, that the surface of a cylinder, described about a sphere (excluding the basis) is equal to the surface of the sphere, and the parts of the one to the parts of the other, intercepted between planes parallel to the basis of the cylinder.

*Of Solid Figures and their Mensuration, comprehending likewise the Principles of gauging Vessels of all Figures.*

As in the former part of this treatise we took an inch for the smallest measure in length, and an inch square for the smallest superficial measure; so now, in treating of the mensuration of solids, we take a cubical inch for the smallest solid measure. Of these 109 make a Scots pint; other liquid measures depend on this, as is generally known.

In dry measures, the firloft, by statute, contains  $19\frac{1}{2}$  pints; and on this depend the other dry measures: therefore, if the content of any solid be given in cubical inches, it will be easy to reduce the same to the common liquid or dry measures, and conversely to reduce these to solid inches. The liquid and dry measures, in use among other nations, are known from their writers.

“As to the English liquid measures, by act of parliament 1706, any round vessel, commonly called a cylinder, having an even bottom, being seven inches in diameter throughout, and six inches deep from the top of the inside to the bottom, (which vessel will be found by computation to contain  $230\frac{1}{4}\frac{2}{3}$  cubical inches), or any vessel containing 231 cubical inches, and no more, is deemed to be a lawful wine-gallon. An English pint therefore contains  $28\frac{1}{2}$  cubical inches; two pints make a quart; four quarts a gallon; 18 gallons a roundlet; three roundlets and an half, or 63 gallons, make a hoghead; the half of a hoghead is a barrel; one hoghead and a third, or 84 gallons, make a puncheon; one puncheon and a half, or two hogheads, or 126 gallons, make a pipe or butt; the third part of a pipe, or 42 gallons, make a tierce; two pipes, or three puncheons, or four hogheads, make a ton of wine. Though the English wine gallon is now fixed at 231 cubical inches, the standard kept in Guildhall being measured, before many persons of distinction, May 25th 1688, it was found to contain only 224 such inches.

“In the English beer measure, a gallon contains 282 cubical inches; consequently  $35\frac{1}{4}$  cubical inches make a pint, two pints make a quart, four quarts make a gallon,

"gallon, nine gallons a firkin, four firkins a barrel. In  
"ale, eight gallons make a firkin, and 32 gallons make  
"a barrel. By an act of the first of William and Mary,  
"34 gallons is the barrel, both for beer and ale, in all  
"places, except within the weekly bills of mortality.

"In Scotland it is known that four gills make a  
"mutchkin, two mutchkins make a chopin; a pint is  
"two chopins; a quart is two pints; and a gallon is  
"four quarts, or eight pints. The accounts of the cubi-  
"cal inches contained in the Scots pint vary considerably  
"from each other. According to our author, it contains  
"109 cubical inches. But the standard-jugs kept by the  
"dean of guild of Edinburgh (one of which has the year  
"1555, with the arms of Scotland, and the town of E-  
"dinburgh, marked upon it) having been carefully mea-  
"sured several times, and by different persons, the Scots  
"pint, according to those standards, was found to con-  
"tain about  $103\frac{4}{5}$  cubic inches. The pewterers jugs  
"(by which the vessels in common use are made) are said  
"to contain sometimes betwixt 105 and 106 cubic inches.  
"A cask that was measured by the brewers of Edinburgh,  
"before the commissioners of Excise in 1707, was found  
"to contain  $46\frac{1}{2}$  Scots pints; the same vessel contained  
"187 $\frac{1}{8}$  English ale-gallons. Supposing this mensurating  
"to be just, the Scots pint will be to the English ale-  
"gallon as 289 to 750; and if the English ale-gallon be  
"supposed to contain 282 cubical inches, the Scots pint  
"will contain 108.664 cubical inches. But it is suspect-  
"ed, on several grounds, that the experiment was not  
"made with sufficient care and exactness.

"The commissioners appointed by authority of parlia-  
"ment to settle the measures and weights, in their act of  
"February 19. 1618, relate, That having caused fill the  
"Linlithgow firlo with water, they found that it con-  
"tained  $21\frac{1}{2}$  pints of the just Stirling jug and measure.  
"They likewise ordain that this shall be the just and on-  
"ly firlo; and add, *That the wideness and breadth of*  
"*the which firlo, under and above even over within the*  
"*buirds, shall contain nineteen inches and the sixth part*  
"*of an inch, and the deepness seven inches and a third*  
"*part of an inch.* According to this act (supposing their  
"experiment and computation to have been accurate) the  
"pint contained only 99.56 cubical inches; for the con-  
"tent of such a vessel as is described in the act, is  
"2115.85, and this divided by  $21\frac{1}{2}$  gives 99.56. But,  
"by the weight of water said to fill this firlo in the same  
"act, the measure of the pint agrees nearly with the E-  
"dinburgh standard above mentioned.

"As for the English measures of corn, the Winche-  
"ster gallon contains  $272\frac{1}{4}$  cubical inches; two gallons  
"make a peck; four pecks, or eight gallons (that is 2178.  
"cubical inches) make a bushel; and a quarter is eight  
"bushels.

"Our author says, that  $19\frac{1}{2}$  Scots pints make a firlo.  
"But this does not appear to be agreeable to the statute  
"above mentioned, nor to the standard-jugs. It may be  
"conjectured that the proportion assigned by him has  
"been deduced from some experiment of how many pints,  
"according to common use, were contained in the firlo.  
"For if we suppose those pints to have been each of  
"108 664 cubical inches, according to the experiment

"made in the 1707 before the commissioners of excise.  
"described above; then  $19\frac{1}{2}$  such pints will amount to  
"2118.94, cubical inches; which agrees nearly with  
"2115.85, the measure of the firlo by statute a-  
"bove mentioned. But it is probable, that in this he  
"followed the act 1587, where it is ordained, That the  
"wheat-firlo shall contain 19 pints and two joucattes.  
"A wheat-firlo marked with the Linlithow stamps be-  
"ing measured, was found to contain about 2211 cubi-  
"cal inches. By the statute of 1618 the barley-firlo  
"was to contain 31 pints of the just Stirling-jug.

"A Paris pint is 48 cubical Paris inches, and is nearly  
"equal to an English wine-quart. The *Boisseau* con-  
"tains 644 68099 Paris cubical inches, or 780.36 Ea-  
"gliish cubical inches.

"The Roman *amphora* was a cubical Roman foot, the  
"*congius* was the eighth part of the *amphora*, the *sexta-  
"rius* was one sixth of the *congius*. They divided the  
"*sextarius* like the *as* or *libra*. Of dry measures, the  
"*medimnus* was equal to two *amphoras*, that is, about  
" $1\frac{1}{2}$  English legal bushels; and the *modius* was the  
"third part of the *amphora*."

#### PROPOSITION XLIII.

*To find the solid content of a given prism.*—By  
the 29th prop. let the area of the base of the prism be  
measured, and be multiplied by the height of the prism,  
the product will give the solid content of the prism.

#### PROPOSITION XLIV.

*To find the solid content of a given pyramid.*—The  
area of the base being found, (by the 30th prop.) let it  
be multiplied by the third part of the height of the pyra-  
mid, or the third part of the base by the height, the pro-  
duct will give the solid content, by 7th 12. Eucl.

#### COROLLARY.

If the solid content of a *frustum* of a pyramid is re-  
quired, first let the solid content of the entire pyramid be  
found; from which subtract the solid content of the part  
that is wanting, and the solid content of the broken  
pyramid will remain.

#### PROPOSITION XLV.

*To find the content of a given cylinder.*—The area  
of the base being found by prop. 33. if it be a circle,  
and by prop. 35. if it be an ellipse, (for in both cases  
it is a cylinder,) multiply it by the height of the cylinder,  
and the solid content of the cylinder will be produced.

#### COROLLARY.

FIG. 23. And in this manner may be measured the solid  
content of vessels and casks not much different from a cylin-  
der, as ABCD. If towards the middle EF it be somewhat  
groffer, the area of the circle of the base being found (by 33d  
prop.) and added to the area of the middle circle EF, and  
the half of their sum (that is, an arithmetical mean between  
the area of the base and the area of the middle circle) taken  
for the base of the vessel, and multiplied into its height,  
the solid content of the given vessel will be produced.

Note, That the length of the vessel, as well as the di-  
ameters of the base, and of the circle EF, ought to be  
taken within the staves; for it is the solid content within  
the staves that is sought.

#### PROPOSITION XLVI.

*To find the solid content of a given cone.*—Let the  
area

area of the base (found by prop. 33.) be multiplied into  $\frac{1}{3}$  of the height, the product will give the solid content of the cone; for by the 10th 12 Eucl. a cone is the third part of a cylinder that has the same base and height.

PROPOSITION XLVII.

FIG. 24. 25. To find the solid content of a frustum of a cone cut by a plane parallel to the plane of the base.—First, let the height of the entire cone be found, and thence (by the preceding prop.) its solid content; from which subtract the solid content of the cone cut off at the top, there will remain the solid content of the frustum of the cone.

How the content of the entire cone may be found, appears thus: Let ABCD be the frustum of the cone (either right or scalenous, as in the figures 2. and 3.) let the cone ECD be supposed to be completed; let AG be drawn parallel to DE, and let AH and EF be perpendicular on CD; it will be (by 2d 6. Eucl.) as CG:CA::CD:CE; but (by art. 72. of part. 1.) as CA:AH::CE:EF; consequently (by 22d 5. Eucl.) as CG:AH::CD:FF; that is, as the excess of the diameter of the lesser base is to the height of the frustum, so is the diameter of the greater base to the height of the entire cone.

COROLLARY.

FIG. 26. Some casks whose staves are remarkably bended about the middle, and flrait towards the ends, may be taken for two portions of cones, without any considerable error. Thus AB EF is a frustum of a right cone, to whose base EF, on the other side, there is another similar frustum of a cone joined, EDC F. The vertices of these cones, if they be supposed to be completed, will be found at G and H. Whence, (by the preceding prop.) the solid content of such vessels may be found.

PROPOSITION XLVIII.

FIG. 27. A cylinder circumscribed about a sphere, that is, having its base equal to a great circle of the sphere, and its height equal to the diameter of the sphere, is to the sphere as 3 to 2.

Let ABEC be the quadrant of a circle, and ABDC the circumscribed square; and likewise the triangle ADC; by the revolution of the figure about the right line AC, as axis, a hemisphere will be generated by the quadrant, a cylinder of the same base and height by the square, and a cone by the triangle. Let these three be cut any how by the plane HF, parallel to the base AB; the section in the cylinder will be a circle whose radius is FH, in the hemisphere a circle of the radius EF, and in the cone a circle of the radius GF.

By (art. 69. of part 1.)  $EAq$ , or  $HFq=EFq$  and  $FAq$  taken together, (but  $AFq=FGq$ , because  $AC=CD$ ); therefore the circle of the radius HF is equal to a circle of the radius EF together with a circle of the radius GF; and since this is true every where, all the circles together described by the respective radii HF (that is, the cylinder) are equal to all the circles described by the respective radii EF and FG (that is, to the hemisphere and the cone taken together); but, (by the 10th 12. Eucl.) the cone generated by the triangle DAC is one third part of the cylinder generated by the square BC. Whence it follows, that the hemisphere generated by the rotation of the quadrant ABEC is equal to the remaining two third

parts of the cylinder, and that the whole sphere is  $\frac{2}{3}$  of the double cylinder circumscribed about it.

This is that celebrated 39th prop. 1. book of Archimedes of the sphere and cylinder; in which he determines the proportion of the cylinder to the sphere inscribed to be that of 3 to 2.

COROLLARY.

Hence it follows, that the sphere is equal to a cone whose height is equal to the semidiameter of the sphere, having for its base a circle equal to the superficies of the sphere, or to four great circles of the sphere, or to a circle whose radius is equal to the diameter of the sphere, (by prop. 41. of this.) And indeed a sphere differs very little from the sum of an infinite number of cones that have their bases in the surface of the sphere, and their common vertex in the centre of the sphere; so that the superficies of the sphere, (of whose dimension see prop. 41. of this) multiplied into the third part of the semidiameter, gives the solid content of the sphere.

PROPOSITION XLIX.

FIG. 28. To find the solid content of a sector of the sphere.—A spherical sector ABC (as appears by the cor. of the preceding prop.) is very little different from an infinite number of cones, having their bases in the superficies of the sphere BEC, and their common vertex in the centre. Wherefore the spherical superficies BEC being found (by prop. 42. of this), and multiplied into the third part of AB the radius of the sphere, the product will give the solid content of the sector ABC.

COROLLARY.

It is evident how to find the solidity of a spherical segment less than a hemisphere, by subtracting the cone ABC from the sector already found. But if the spherical segment be greater than a hemisphere, the cone corresponding must be added to the sector, to make the segment.

PROPOSITION L.

FIG. 29. To find the solidity of the spheroid, and of its segments cut by planes perpendicular to the axis.—

In prop. 44. of this, it is shewn, that every where  $EH:EG::CF:CD$ ; but circles are as the squares described upon their rays, that is, the circle of the radius EH is to the circle of the radius EG, as  $CFq$  to  $CDq$ . And since it is so every where, all the circles described with the respective rays EH, (that is, the spheroid made by the rotation of the semi-ellipses AFB around the axis AB) will be to all the circles described by the respective radii EG, (that is, the sphere described by the rotation of the semicircle ADB on the axis AB) as  $FCq$  to  $CDq$ ; that is, as the spheroid to the sphere on the same axis, so is the square of the other axis of the generating ellipse to the square of the axis of the sphere.

And this holds, whether the spheroid be found by a revolution around the greater or lesser axis.

COROLLARY 1.

Hence it appears, that the half of the spheroid, formed by the rotation of the space AHFC around the axis AC, is double of the cone generated by the triangle AFC about the same axis; which is the 32d prop. of Archimedes of conoids and spheroids.

COROLLARY 2.

Hence, likewise, is evident the measure of segments of the

the spheroid cut by planes perpendicular to the axis. For the segment of the spheroid made by the rotation of the space ANHE, round the axis AE, is to the segment of the sphere having the same axis AC, and made by the rotation of the segment of the circle AMGE, as CF to CD.

But if the measure of this solid be wanted with less labour, by the 34th prop. of Archimedes of conoids and spheroids, it will be as BE to AC+EB; so is the cone generated by the rotation of the triangle AHE round the axis AE, to the segment of the sphere made by the rotation of the space ANHE round the same axis AE; which could easily be demonstrated by the method of indivisibles.

#### COROLLARY 3.

Hence it is easy to find the solid content of the segment of a sphere or spheroid intercepted between two parallel planes, perpendicular to the axis. This agrees as well to the oblate as to the oblong spheroid; as is obvious.

#### COROLLARY 4.

FIG. 30. If a cask is to be valued as the middle piece of an oblong spheroid, cut by the two planes DC and FG; at right angles to the axis: first, let the solid content of the half spheroid ABCD be measured by the preceding prop. from which let the solidity of the segment DEC be subtracted, and there will remain the segment ABCD; and this doubled will give the capacity of the cask required.

The following method is generally made use of for finding the solid content of such vessels. The double area of the greatest circle, that is, of that which is described by the diameter AB at the middle of the cask, is added to the area of the circle at the end, that is, of the circle DC or FG (for they are usually equal), and the third part of this sum is taken for a mean base of the cask; which therefore multiplied into the length of the cask OP, gives the content of the vessel required.

Sometimes vessels have other figures, different from those we have mentioned; the easy methods of measuring which may be learned from those who practise this art. What hath already been delivered, is sufficient for our purpose.

#### PROPOSITION LI.

FIG. 31 and 32. *To find how much is contained in a vessel that is in part empty, whose axis is parallel to the horizon.*—Let AGBH be the great circle in the middle of the cask, whose segment GBH is filled with liquor, the segment GAH being empty; the segment GBH is known, if the depth EB be known, and EH a mean proportional between the segments of the diameter AB and EB; which are found by a rod or ruler put into the vessel at the orifice. Let the basis of the cask, at a medium, be found, which suppose to be the circle CKDL; and let the segment KCL be similar to the segment GAH (which is either found by the rule of three, because as the circle AGBH is to the circle CKDL, so is the segment GAH to the segment KCL; or is found from the tables of segments made by authors); and the product of this segment multiplied by the length of the cask will give the liquid content remaining in the cask.

#### PROPOSITION LII.

*To find the solid content of a regular and ordinate*

*body.*—A tetraedron being a pyramid, the solid content is found by the 44th prop. The hexaedron, or cube, being a kind of prism, it is measured by the 43d prop. An octaedron consists of two pyramids of the same square base and of equal heights; consequently its measure is found by the 44th prop. A dodecaedron consists of twelve pyramids having equal equilateral and equiangular pentagonal bases; and to one of these being measured (by the 44th prop. of this) and multiplied by 12, the product will be equal to the solid content of the dodecaedron. The icosaedron consists of 20 equal pyramids having triangular bases; the solid content of one of which being found (by the 44th prop.) and multiplied by 20, gives the whole solid. The bases and heights of these pyramids, if you want to proceed more exactly, may be found by trigonometry. See TRIGONOMETRY.

#### PROPOSITION LIII.

*To find the solid content of a body however irregular.*—Let the given body be immersed into a vessel of water, having the figure of a parallelopipedon or prism, and let it be noted how much the water is raised upon the immersion of the body. For it is plain, that the space which the water fills, after the immersion of the body, exceeds the space filled before its immersion, by a space equal to the solid content of the body, however irregular. But when this excess is of the figure of a parallelopipedon or prism, it is easily measured by the 43d prop. of this, viz. by multiplying the area of the base, or mouth of the vessel, into the difference of the elevations of the water before and after immersion. Whence is found the solid content of the body given.

In the same way the solid content of a part of a body may be found, by immersing that part only in water.

There is no necessity to insist here on diminishing or enlarging solid bodies in a given proportion. It will be easy to deduce these things from the 11th and 12th books of Euclid.

The following rules are subjoined for the ready computation of the contents of vessels, and of any solids in the measures in use in Great Britain.

I. To find the content of a cylindric vessel in English wine gallons, the diameter of the base and altitude of the vessel being given in inches and decimals of an inch.

Square the number of inches in the diameter of the vessel; multiply this square by the number of inches in the height; then multiply the product by the decimal fraction .0034; and this last product shall give the content in wine gallons and decimals of such a gallon. To express the rule arithmetically; let D represent the number of inches and decimals of an inch in the diameter of the vessel, and H the inches and decimals of an inch in the height of the vessel; then the content in wine-gallons shall be  $DDH \times \frac{1}{294.225}$ , or  $DDH \times .0034$ . Ex. Let the diameter D = 51.2 inches, the height H = 62.3 inches, then the content shall be  $51.2 \times 51.2 \times 62.3 \times .0034 = 555.27.342$  wine-gallons. This rule follows from prop. 33. and 45. for, by the former, the area of the base of the vessel is in square inches  $DD \times .7854$ ; and by the latter, the content of the vessel in solid inches

“ inches is DDHX.7854; which divided by 231 (the  
 “ number of cubical inches in a wine-gallon) gives DDH  
 “  $\times .0034$ , the content in wine-gallons. But though  
 “ the charges in the excise are made (by statute) on the  
 “ supposition that the wine-gallon contains 231 cubical  
 “ inches; yet it is said, that in sale, 224 cubical inches,  
 “ the content of the standard measured at Guildhall (as  
 “ was mentioned above) are allowed to be a wine-gallon.

“ II. Supposing the English ale gallon to contain 282  
 “ cubical inches, the content of a cylindric vessel is com-  
 “ puted in such gallons, by multiplying the square of the  
 “ diameter of a vessel by its height as formerly, and their  
 “ product by the decimal fraction .0,027,851: that is,  
 “ the solid content in ale-gallons is DDHX.0,027,851.

“ III. Supposing the Scots pint to contain about  
 “ 103.4 cubical inches, (which is the measure given by  
 “ the standards at Edinburgh, according to experiments  
 “ mentioned above), the content of a cylindric vessel is  
 “ computed in Scots pints, by multiplying the square of  
 “ the diameter of the vessel by its height, and the prod-  
 “ uct of these by the decimal fraction .0076. Or the  
 “ content of such a vessel in Scots pints is DDHX.0076.

“ Supposing the Winchester bushel to contain 2187  
 “ cubical inches, the content of a cylindric vessel is com-  
 “ puted in those bushels by multiplying the square of the  
 “ diameter of the vessel by the height, and the product  
 “ by the decimal fraction .0,003,606. But the stan-  
 “ dard bushel having been measured by Mr Everard and  
 “ others in 1696, it was found to contain only 2145 6  
 “ solid inches; and therefore it was enacted in the act  
 “ for laying a duty upon malt, *That every round bushel,*  
 “ *with a plain and even bottom, being 18 $\frac{1}{2}$  inches dia-*  
 “ *meter throughout, and 8 inches deep, should be esteem-*  
 “ *ed a legal Winchester bushel.* According to this act  
 “ (ratified in the first year of Queen Anne) the legal  
 “ Winchester bushel contains only 2150.42 solid inches.  
 “ And the content of a cylindric vessel is computed in  
 “ such bushels, by multiplying the square of the diame-  
 “ ter by the height, and their product by the decimal  
 “ fraction .0,003,625. Or the content of the vessel in  
 “ those bushels is DDH  $\times .0,003,625$ .

“ V. Supposing the Scots wheat firloft to contain 21 $\frac{1}{2}$   
 “ Scots pints, (as is appointed by the statute 1618), and  
 “ the pint to be conform to the Edinburgh standards  
 “ above mentioned, the content of a cylindric vessel in  
 “ such firlots is computed by multiplying the square of  
 “ the diameter by the height, and their product by the  
 “ decimal fraction .00,358. This firloft, in 1426, is  
 “ appointed to contain 17 pints; in 1457, it was appoint-  
 “ ed to contain 18 pints; in 1587, it is 19 $\frac{1}{2}$  pints; in  
 “ 1628, it is 21 $\frac{1}{2}$  pints: and though this last statute ap-  
 “ pears to have been founded on wrong computations in  
 “ several respects; yet this part of the act that relates  
 “ to the number of pints in the firloft seems to be the  
 “ least exceptionable; and therefore we suppose the fir-  
 “ loft to contain 21 $\frac{1}{2}$  pints of the Edinburgh standard, or  
 “ about 2107 cubical inches; which a little exceeds the  
 “ Winchester bushel, from which it may have been ori-  
 “ ginally copied.

“ VI. Supposing the bear-firloft to contain 31 Scots  
 “ pints, (according to the statute 1618), and the pint  
 “ VOL. II. NO. 50.

“ conform to the Edinburgh standards the content of a  
 “ cylindric vessel in such firlots is found by multiplying  
 “ the square of the diameter by the height, and this  
 “ product by .000,245.

“ When the section of the vessel is not a circle, but  
 “ an ellipsis, the product of the greatest diameter by the  
 “ least, is to be substituted in those rules for the square of  
 “ the diameter.

“ VII. To compute the content of a vessel that may  
 “ be considered as a *frustum* of a cone in any of those  
 “ measures.

“ Let A represent the number of inches in the diame-  
 “ ter of the greater base, B the number of inches in the  
 “ diameter of the lesser base. Compute the square of  
 “ A, the product of A multiplied by B, and the square  
 “ of B, and collect these into a sum. Then find the  
 “ third part of this sum, and substitute it in the preceding  
 “ rules in the place of the square of the diameter; and  
 “ proceed in all other respects as before. Thus, for ex-  
 “ ample, the content in wine gallons is  $AA \times AB \times BB$   
 “  $\times \frac{1}{3} \times H \times .0034$ .

“ Or, to the square of half the sum of the diameters  
 “ A and B, add one third part of the square of half their  
 “ difference, and substitute this sum in the preceding rules  
 “ for the square of the diameter of the vessel; for the  
 “ square of  $\frac{1}{2} A \times \frac{1}{2} B$  added to  $\frac{1}{3}$  of the square of  $\frac{1}{2}$   
 “  $A - \frac{1}{2} B$ , gives  $\frac{1}{3} AA \times \frac{1}{3} AB \times \frac{1}{3} BB$ .

“ VIII. When a vessel is a *frustum* of a parabolic  
 “ conoid, measure the diameter of the section at the mid-  
 “ dle of the height of the *frustum*; and the content will be  
 “ precisely the same as of a cylinder of this diameter, of  
 “ the same height with the vessel.

“ IX. When a vessel is a *frustum* of a sphere, if you mea-  
 “ sure the diameter of the section at the middle of the  
 “ height of the *frustum*, then compute the content of a  
 “ cylinder of this diameter of the same height with the  
 “ vessel, and from this subtract  $\frac{1}{8}$  of the content of a  
 “ cylinder of the same height, on a base whose diameter  
 “ is equal to its height; the remainder will give the con-  
 “ tent of the vessel. That is, if D represent the diame-  
 “ ter of the middle section, and H the height of the  
 “ *frustum*, you are to substitute  $DD - \frac{1}{8} HH$  for the  
 “ square of the diameter of the cylindric vessel in the  
 “ first six rules.

“ X. When the vessel is a *frustum* of a spheroid, if the  
 “ bases are equal, the content is readily found by the  
 “ rule in p. 708. In other cases, let the axis of the solid  
 “ be to the conjugate axis as  $n$  to 1; let D be the dia-  
 “ meter of the middle section of the *frustum*, H the  
 “ height or length of the *frustum*; and substitute in the  
 “ first six rules  $DD - \frac{DD^2}{3n^2}$  for the square of the square  
 “ of the diameter of the vessel.

“ XI. When the vessel is an hyperbolic conoid, let  
 “ the axis of the solid be to the conjugate axis as  $n$  to  
 “ 1, D the diameter of the section at the middle of the  
 “ *frustum*, H the height or length; compute  $DD \times \frac{1}{3n^2}$   
 “  $\times HH$ , and substitute this sum for the square of the  
 “ diameter of the cylindric vessel in the first six rules.

“ XII. In general, it is usual to measure any round  
 “ vessel, by dividing it into several *frustums*, and  
 “ taking

“ taking the diameter of the section at the middle of each *frustum*; thence to compute the content of each, as if it was a cylinder of that mean diameter; and to give their sum as the content of the vessel. From the total content, computed in this manner, they subtract successively the numbers which express the circular areas that correspond to those mean diameters, each as often as there are inches in the altitude of the *frustum* to which it belongs, beginning with the uppermost; and in this manner calculate a table for the vessel, by which it readily appears how much liquor is at any time contained in it, by taking either the dry or wet inches; having regard to the inclination or drip of the vessel, when it has any

“ This method of computing the content of a *frustum* from the diameter of the section at the middle of its height, is exact in that case only when it is a portion of a parabolic conoid; but in such vessels as are in common use, the error is not considerable. When the vessel is a portion of a cone or hyperbolic conoid, the content by this method is found less than the truth; but when it is a portion of a sphere or spheroid, the content computed in this manner exceeds the truth. The difference or error is always the same, in the different parts of the same or of similar vessels, when the altitude of the *frustum* is given. And when the altitudes are different, the error is in the triplicate ratio of the altitude. If exactness be required, the error in measuring the *frustum* of a conical vessel, in this manner, is  $\frac{1}{2}$  of the content of a cone similar to the vessel, of an altitude equal to the height of the *frustum*. In a sphere, it is  $\frac{1}{2}$  of a cylinder of a diameter and height equal to the *frustum*. In the spheroid and hyperbolic conoid, it is the same as in a cone generated by the right-angled triangle, contained by the two semiaxes of the figure, revolving about that side which is the semiaxis of the *frustum*.

“ In the usual method of computing a table for a vessel, by subtracting from the whole content the number that expresses the uppermost area, as often as there are inches in the uppermost *frustum*, and afterwards the numbers for the other areas successively; it is obvious that the contents assigned by the table, when a few of the uppermost inches are dry, are stated a little too high, if the vessel stands on its lesser base, but too low when it stands on its greater base; because, when one inch is dry, for example, it is not the area at the middle of the uppermost *frustum*, but rather the area at the middle of the uppermost inch, that ought to be subtracted from the total content, in order to find the content in this case.

“ XIII. To measure round timber: Let the mean circumference be found in feet and decimals of a foot; square it; multiply this square by the decimal .079,577, and the product by the length. Ex. Let the mean circumference of a tree be 10.3 feet, and the length 24 feet. Then  $10.3 \times 10.3 \times .079,577 \times 24 = 202.615$ , is the number of cubical feet in the tree. The foundation of this rule is, that when the circumference of a circle is 1, the area is .079,577,1715, and that the

“ areas of circles are as the squares of their circumferences.

“ But the common way used by artificers for measuring round timber, differs much from this rule. They call one fourth part of the circumference the *girt*, which is by them reckoned the side of a square, whose area is equal to the area of the section of the tree; therefore they square the *girt*, and then multiply by the length of the tree. According to their method, the tree of the last example would be computed at 159.13 cubical feet only.

“ How square timber is measured, will be easily understood from the preceding propositions. Fifty solid feet of hewn timber, and forty of rough timber, make a load.

“ XIV. To find the burden of a ship, or the number of tons it will carry, the following rule is commonly given. Multiply the length of the keel taken within board, by the breadth of the ship within board, taken from the midship beam from plank to plank, and the product by the depth of the hold, taken from the plank below the keelson to the under part of the upper deck plank, and divide the product by 94, the quotient is the content of the tonnage required. This rule however cannot be accurate; nor can one rule be supposed to serve for the measuring exactly the burden of ships of all sorts. Of this the reader will find more in the Memoirs of the Royal Academy of Sciences at Paris, for the year 1721.

“ Our author having said nothing of weights, it may be of use to add briefly, that the English Troy-pound contains 12 ounces, the ounce 20 penny-weight, and the penny weight 24 grains; that the Averdupois pound contains 16 ounces, the ounce 16 drams, and that 112 pounds is usually called the hundred weight. It is commonly supposed, that 14 pounds Averdupois are equal to 17 pounds Troy. According to Mr Everard's experiments, 1 pound Averdupois is equal to 14 ounces 12 penny weight and 16 grains Troy, that is, to 7000 grains; and an Averdupois ounce is 437½ grains. The Scots Troy pound (which, by the statute 1718, was to be the same with the French) is commonly supposed equal to 15½ ounces English Troy, or 7560 grains. By a mean of standards kept by the Dean of Guild at Edinburgh, it is 7599½, or 7600 grains. They who have measured the weights which were sent from London, after the union of the kingdoms, to be the standards by which the weights in Scotland should be made, have found the English Averdupois pound (from a medium of the several weights) to weigh 7000 grains, the same as Mr Everard; according to which, the Scots, Paris, or Amsterdam-pound, will be to the pound Averdupois as 38 to 35. The Scots Troy-stone contains 16 pounds, the pound 2 marks or 16 ounces, an ounce 16 drops, a drop 26 grains. Twenty Scots ounces make a Tron pound; but because it is usual to allow one to the score, the Tron pound is commonly 21 ounces. Sir John Skene, however, makes the Tron stone to contain only 10½ pounds.”

GEORGE

**GEORGE**, or *Knights of St GEORGE*, has been the denomination of several military orders, whereof that of the garter is one of the most illustrious. See **CARTER**.

**St GEORGE-del Mina**, the capital of the Dutch settlements, on the gold-coasts of Guinea, situated seven or eight miles west of Cape-coast castle, the capital of the British settlements there: W. long. 5', and N. lat. 5°.

**Fort St GEORGE**, a town and fort on the coast of Comandel, in the Hither India: E. long. 80°, and N. lat. 13°.

The town is divided into the White and Black town. The fort, and White-town, which adjoins to it, are inhabited only by British; the whole circumference, which is not above half a mile, being surrounded by a stone wall. The outward, or Black town, called Madras, has been lately encompassed by a stone-wall and ballions and is about a mile and a half in circumference; the whole being almost environed by a river and the sea.

**St GEORGE's**, the largest of the Bermuda, or Summer-islands.

*Crofs of St GEORGE*, a red one in a field argent, which makes part of the British standard.

**GEORGIA**, in Asia, a province bounded by Circassia and Daghestan on the north, by the Caspian sea on the east, by Armenia or Turcomania on the south, and by Mingrelia on the west.

**GEORGIA**, in America, one of the British plantations, taken out of South-Carolina, from which it is separated by the river Savannah on the north, and bounded by the Atlantic ocean on the east, by the river of St John, which divides it from Spanish Florida, on the south and west.

**GEORGIC**, a poetical composition upon the subject of husbandry, containing rules therein, put into a pleasing dress, and set off with all the beauties and embellishments of poetry.

Hesiod and Virgil are the two greatest masters in this kind of poetry.

The moderns have produced nothing in this kind, except Rapin's book of Gardening, and the celebrated poem entitled Cyder by Mr Philips, who, if he had enjoyed the advantage of Virgil's language, would have been second to Virgil in a much nearer degree.

**GERANITES**, in natural history, an appellation given to such of the semipellucid gems as are marked with a spot resembling a crane's eye.

**GERANIUM**, **CRANE'S BILL**, in botany, a genus of the monodelphia decandria class. It has but one stylus; the stigmata are five; and the capsule is shaped like the bill of a crane. There are fifty-seven species, sixteen of which are natives of Britain, viz. the cicutarium, or hemlock-leaved crane's bill; the malchatum, or musked crane's bill; the maritimum, or sea crane's bill; the nodosum, or knotty crane's bill; the phœum, or spotted crane's bill; the sylvaticum, or mountain crane's bill; the pratense, or crowfoot crane's bill; the robertianum, or herb Robert; the lucidum, or shining dove's foot crane's bill; the ro-

tundifolium, or round-leaved crane's bill; the perenne, or perennial dove's-foot crane's bill; the molle, or common dove's-foot crane's bill; the pusillum, or small flowered dove's-foot crane's bill; the columbinum, or long stalked dove's foot crane's bill; the dissectum, or jagged leaved dove's-foot crane's bill; and the sanguineum, or bloody crane's bill. The leaves of the robertianum and pratense were formerly used as astringents, but are now left out both of the London and Edinburgh dispensaries.

**GERARDIA**, in botany, a genus of the didynamia angiospermia class. The calix consists of five segments; the corolla is bilabiated, the inferior lip being divided into three parts; the lobes are emarginated, the middle one being divided into two segments; and the capsule is bilocular, and opens at the base. There are five species, none of them natives of Britain.

**GERFALCON**, or **GYRFALCON**. See **FALCO**.

**GERGENTUM**, a town of Sicily, the Agrigentum of the ancients, about fifty five miles south east of Palermo: E. long. 13° 30', N. lat. 37° 20'.

**GERMAINS**, or **St GERMAINS**, a town and royal palace of France, fourteen miles north-west of Paris.

**St GERMAINS** is also a borough of Cornwall, eight miles west of Plymouth. It sends two members to parliament.

**GERM**, among gardeners. See **BUN**.

**GERMAN**, in genealogy, denotes entire or whole; thus, a brother german is one both by the father's and mother's side; and cousins german are the children of brothers or sisters.

**GERMAN**, or **GERMANIC**, also denotes any thing belonging to Germany; as the German empire, German flute, &c.

**GERMANDER**, in botany. See **TEUCRIUM**.

**GERMANY**, an extensive empire of Europe, situated between 5° and 19° E. long. and between 45° and 55° N. lat.; bounded by Denmark and the Baltic sea on the north, by Poland and Hungary on the east, by Switzerland and the Alps on the south, and by France, Holland, &c. on the west.

It is divided into ten circles, three of which lie on the north, viz. Upper and Lower Saxony, and Westphalia; three on the south, viz. Austria, Bavaria, and Swabia; three about the middle, viz. Franconia, and the Upper and Lower Rhine; the tenth, which consisted of the duchy of Burgundy and the seventeen provinces of the Netherlands, have long been detached from the empire.

There are in Germany upwards of three hundred sovereign princes and states, most of them arbitrary in their respective territories.

**GERMEN**, or **GERM**. See **BUN**.

**GERMERSHEIM**, a town of Germany, subject to France, about ten miles east of Landau: E. long. 8° 15', and N. lat. 49° 12'.

**GERMINATION**, the first sprouting of the seeds of plants. See **AGRICULTURE**, Part I.

**GERONTES**, in Grecian antiquity, a sort of magistratus of ancient Sparta, answering to the areopagites at Athens.

**GER-**

**GERTRÜDENBURG**, a fortified town of the united Netherlands, in the province of Holland, nine miles north of Breda; subject to the prince of Orange.

**GERUND**, in grammar, a verbal noun of the neuter gender, partaking of the nature of a participle, declinable only in the singular number, through all the cases except the vocative; as, nom. *amandum*, gen. *amandi*, dat. *amando*, accus. *amandum*, abl. *amando*.

**GESNERIA**, in botany, a genus of plants, of the didynamia class. The calix rests upon the germen, and consists of five segments; the corolla is bent inwards and backwards; the capsule is below the flower, and bilocular. There are three species, none of them natives of Britain.

**GESTATION**, among physicians. See **PREGNANCY**.

**GESTRICIA**, a province of Sweden, bounded by Helsingia on the north, by the Bothnic gulph on the east, by Upland on the south, and by Dalecarlia on the west.

**GESTURE**, in rhetoric, consists chiefly in the proper action of the hands and face.

**CETHYLLIS**, in botany, a genus of the decandriamono-gynia class. The calix is a spatha; the corolla consists of six segments; and the capsule has three cells. There is but one species, a native of Africa.

**GEVAUDAN**, a territory of Languedoc, adjoining to the Cevennes.

**GEUM**, in botany, a genus of the icofandriapentagynia class. The calix has eight segments; the petals are eight; and the seeds are hairy and caudated. There are five species, two of which are natives of Britain, viz. the urbanum, or common avens; and the rivale, or water avens. The root of the avens is sometimes used as a stomachic.

**GHENT**, or **GAUNT**, a city and capital of Flanders, thirty miles north west of Brussels: E. long.  $3^{\circ} 36'$ , N. lat.  $51^{\circ}$ .

It is a large fortified town, twelve miles in circumference, and defended by a citadel; and yet is a place of no great strength, by reason of the vast extent of ground it takes in.

**GIAGH**, in chronology, a cycle of twelve years; in use among the Turks and Cathayans.

Each year of the giagh bears a name of some animal: the first, that of a mouse; the second, that of a bullock; the third, of a lynx or leopard; the fourth, of a horse; the fifth, of a crocodile; the sixth, of a serpent; the seventh, of a horse; the eighth, of a sheep; the ninth, of a monkey; the tenth, of a hen; the eleventh, of a dog; and the twelfth, of a hog.

They also divide the day into twelve parts, which they call giaghs, and distinguish them by the name of some animals. Each giagh contains two of our hours, and is divided into eight kehs, as many as there are quarters in our hours.

**GIALLOLINO**, in natural history, a heavy, friable, fine, yellow ochre, called Naples yellow, and much used among painters, who esteem it a very fine colour.

**GIANT'S CAUSEWAY**, a vast collection of a black kind of marble, called basalt, in the county of Antrim, in Ireland. See **BASALT**.

**GIBBOUS**, a term in medicine, denoting any protuberance or convexity of the body, as a person haunched, or hump backed.

**GIBBOUS**, in astronomy, a term used in reference to the enlightened parts of the moon, whilst she is moving from the first quarter to the full, and from the full to the last quarter: for all that time the dark part appears horned, or falcated; and the light one hunched out, convex, or gibbous.

**GIBELINS**, **GIBELLINS**, a famous faction in Italy, opposite to another called the Guelphs.

These two factions ravaged and laid waste Italy for a long series of years, so that the history of that country, for the space of two centuries, is no more than a detail of their mutual violences and slaughters. The Gibelins stood for the emperor against the pope: but concerning their origin and the reason of their names, we have but a very obscure account. According to the generality of authors, they rose about the year 1240, upon the emperor Frederick II.'s being excommunicated by the pope Gregory IX. Other writers maintain, that the two factions arose ten years before, though still under the same pope and emperor. But the most probable opinion is that of Maimbourg, who says, that the two factions of Guelphs and Gibelins arose from a quarrel between two ancient and illustrious houses on the confines of Germany, that of the Henries of Gibeling, and that of the Guelphs of Adorf.

**GIBRALTAR**, a port-town of Andalusia, in Spain, subject to Great Britain: W. long.  $6^{\circ}$ , and N. lat.  $36^{\circ}$ .

It stands at the foot of mount Calpe, one of Hercules's pillars, about sixteen miles north of Ceuta, in Africa, from which it is divided by the Streights, to which it gives name. It is built on a rock, in a peninsula, and can only be approached on the land-side by a very narrow passage between the mountain and the sea: cross this passage the Spaniards have drawn a line, and fortified it, to prevent the garrison's having any communication with the country.

The Straits of Gibraltar are about twenty-four miles long, and fifteen broad.

**GIFT**, in Scots law. See **DONATION**.

**GIGG**, or **JIGG**, in music, denotes a brisk and lively air; or an airy kind of dance to a sprightly measure.

**GILAN**, a province of Persia, bounded by the Caspian Sea on the north. Its capital is a city of the same name: E. long.  $48^{\circ}$ , and N. lat.  $37^{\circ}$ .

**GILBERTINES**, a religious order founded in England by St Gilbert, in the reign of Henry I. The nuns followed the rule of St Benedict, and the monks that of Augustin. There were many monastries of this order in different parts of England.

**GILDING**, the art of spreading or covering a thing with gold, either in leaf or liquid.

We have this advantage over the ancients, in the manner of using and applying the gold, that the secret of painting in oil, lately discovered, furnishes us with means of gilding works, capable of enduring all the violence of time and weather, which theirs could not.

There

There are several methods of gilding in use among us, as gilding in water, gilding in oil, gilding by fire, &c.

*The method of water-gilding.* Water-gilding requires more preparation than oil gilding, and is chiefly on wooden works, and those made of stucco; and these too must be sheltered from the weather. A size is used for this way of gilding made of shreds, &c. of parchment or gloves boiled in water to the consistence of a jelly. If the thing to be gilt be of wood, it is first washed with this size, boiling hot, and then set to dry; and afterwards with white paint mixed up with the same size. Some use Spanish white for this purpose, and others plaster of Paris, well beaten and sifted. This sized paint must be laid on with a stiff brush; which is to be repeated seldomer or oftener according to the nature of the work, as ten or twelve times in flat or smooth works; but seven or eight times will be sufficient in pieces of sculpture. In the former case they are applied by drawing the brush over the work, in the latter by daubing it. When the whole is dry, they moisten it with fair water, and rub it over with several pieces of coarse linen, if it be on the flat; if not, they beat or switch it with several slips of the same linen, tied to a little stick, to make it follow and enter all the cavities and depressures thereof.

Having thus finished the white, the next thing to be done, is to colour it with yellow ochre: but if it be a piece of sculpture in relievo, they first touch it up, and prepare the several parts, which may have happened to have been disfigured, by the small iron instruments, as gouges, chisels, &c. The ochre used for this purpose must be well ground and sifted, and mixed up with the size before-mentioned. This colour is to be laid on hot; and in works of sculpture, supplies the place of gold, which sometimes cannot be carried into all the depressures and cavities of the foliages and ornaments. A lay is also applied over this yellow, which serves for the ground on which the gold is to be laid: this lay is usually composed of Armenian bole, blood-stone, black-lead, and a little fat; to which some add soap, and oil of olives; others, burnt bread, bistre, antimony, glass of tin, butter, and sugar-candy. These ingredients being all ground down together with hot size, three lays of this composition is applied upon the yellow, the one after the other has been dried; being cautious not to put any into the cavity of the work to hide the yellow.

The brush used for this purpose, must be a soft one; and when the matter is become very dry, they go over it again with a stronger brush, to rub it down, and take off the small grains that stick out, in order to facilitate the burnishing of the gold.

To be prepared for gilding, you must have three sorts of pencils; one to wet, another to touch up and amend, and a third to flatten; also a gilding cushion, for spreading the leaves of gold on when taken out of the book; a knife to cut them, and a squirrel's tail fitted with a handle; or else a piece of fine soft stuff on a slick, to take them up directly and apply them. You

Vol. II. No. 56.

2

are first to begin with wetting your pencils; by which the last lay laid on with water is moistened, that it may the better receive and retain the gold. Then you are to lay the leaves of gold on the cushion; and if whole, you must take up with the squirrel's tail, but, if in pieces, with the other instrument, or the knife wherewith they are cut, and lay and spread them gently on the parts of the work you had moistened before. If the leaves, as they frequently do, happen to crack or break in laying on, these breaches must be made up with small bits of leaf, taken up upon the repairing pencil, and the whole work is to be smoothed either with the same pencil, or another something larger; the gold being pressed into the dents, into which it could not be so easily carried by the squirrel's tail.

The work having been thus far gilded, must be set to dry, in order to be burnished and flatted. See **BURNISHING.**

The last operation is the applying the vermeil in all the little lines and cavities; and to stop and amend any little faults with shell-gold. The composition called of vermeil is made of gum gutta, vermilion, and a little of some ruddy-brown, ground together with venetian varnish and oil of turpentine. Some gilders, instead of this, make shift with fine lacca, or dragon's blood, with gum-water.

Sometimes, instead of burnishing the gold, they burnish the ground or composition laid on the last before it, and only afterwards wash the part over with the size. This method is chiefly practised for the hands, face, and other nudities in relievo: which, by this means, do not appear so very brilliant as the parts burnished, though much more so than the parts perfectly flat.

To gild a piece of work, and yet preserve white grounds, they apply a lay of Spanish white, mixed with a weak fish-glue, on all the parts of the ground, whereon the yellow or the last lay might run.

*The method of GILDING in oil.* This operation requires much less apparatus than that before-mentioned. The basis or matter whereon the gold is laid, in this method, is the remains of colours found settled to the bottom of the pots in which painters wash their pencils. This matter, which is very viscid or sticky, is first ground, and then passed through a linen-cloth, and thus laid on the matter to be gilt, after it is washed once or twice over with size; and if it be wood, with some white paint.

When this is almost dry, but yet is still unctuous enough to catch and retain the gold, the leaf-gold is laid on, either whole, if the work be large, or cut to pieces, if smaller: the leaves of gold are taken up and laid on with a piece of fine, soft, well carded cotton; or sometimes by a pallet for the purpose, or sometimes with the knife with which the leaves were cut, according to the parts of the work that are to be gilded, or the breadth of the gold that is to be laid on. As the gold is laid on, they pass over it a coarse stiff pencil brush, to make it stick and as it were incorporate with the ground; and after this they mend any cracks that

†

7 R

may

may have happened in it, either with the same pencil or one that is smaller, as has been shown before in water gilding.

This kind of gilding is chiefly used for domes and roofs of churches, courts, banquetting-houses, &c. and for figures of plates of Paris, lead, &c.

*The method of GILDING with liquid gold.* This is performed by gold reduced to a calx and amalgamated with mercury, in the proportion of about an ounce of mercury to a dram of gold. To perform this, they heat a crucible red hot, and then put the gold and mercury into it, stirring them gently about till the gold be found melted, and incorporated into a mass with the mercury. When this is done, they cast them into water, to wash and purify them; and out of that into other waters, where the amalgama, which is almost as liquid as if there were nothing but quicksilver in it, may be preserved a long time for use.

Before they proceed to lay this amalgamated gold on the metal, they first render the metal rough, by washing it over with aqua fortis, or aqua secunda; and afterwards rinse the metal in fair water, and scour it a little with fine sand, and then it is ready for the gold.

They next cover over the metal with the mixture of gold and mercury, taking it up with a slip of copper, or a brush made of brass-wire, spreading it as even as possible, to do which they wet the brush from time to time in fair water. Then they set the metal to the fire, upon a grate, or in a sort of cage, under which stands a pan of coals; and in proportion as the mercury, evaporating and flying off, discovers the places where gold is wanting, they take care to supply them by adding new parcels of amalgama.

Then the work is rubbed over with the wire brush, dipt in beer or vinegar, which leaves it in a condition to be brought to a colour which is the last part of the process, and which the gilders keep to themselves as a mighty secret.

*The method of GILDING by fire on metal.* To prepare the metal, they scratch it well, or rake it; then polish it with a polisher; and afterwards set it to the fire to blue, *i. e.* to heat, till it appear of a blue colour. When this has been done, they clap on the first lay of leaf gold, rubbing it lightly down with a polisher; and expose it thus to a gentle fire. They usually give it but three such lays, or four at the most, each lay consisting of a single leaf for common works, and of two for extraordinary ones: after each lay, it is set afresh to the fire; and after the last lay, the gold is in condition to be burnished.

*To gild paper.* Grind bole-armoniack with rain-water, and give one laying of it; when it is dry, take glair of eggs, and add to it a little sugar candy and gum-water, which lay over the former; and upon this, when it is dry enough, lay leaf-silver, or leaf-gold.

*To gild the covers of books.* Take bole armoniac, eight penny-weight; sugar-candy, two penny-weight; mix and grind them with glair of eggs: then on a bound book (while it is in the press, after it hath been smeared

ed with glair of eggs, and is dried) smear the said composition; let it dry, then rub it well and polish it; then with fair water wet the edges of the book, and suddenly lay on the gold, press it down gently with cotton, let it dry, and then polish it with a tooth.

**GILL**, a measure of capacity, containing a quarter of an English pint.

**GILLS**, in ichthyology. See BRANCHIÆ.

**GILOLO**, a large island of the pacific ocean, lying between 1° S. lat. and 2° N. lat. and between 125° and 128° E. long.

**GILOLO** is also the name of the capital of the above island, situated in 40' N. lat.

**GIN**, in mechanics, a machine for driving piles, fitted with a windlass and winches at each end, where eight or nine men heave, and round which a rope is reeved that goes over the wheel at the top: one end of this rope is seized to an iron monkey, that hooks to a beetle of different weights, according to the piles they are to drive, being from eight to thirteen hundred weight; and when hove up to a cross piece, near the wheel, it unhooks the monkey, and lets the beetle fall on the upper end of the pile, and forces the same into ground: then the monkey's own weight over-hauls the windlass, in order for its being hooked again to the beetle.

**GINGEN**, an imperial city of Germany, twenty miles E. of Ulm: E. long. 10°, and north lat. 48° 36'.

**GINGER**, the root of a species of animum, too well known to need any description: It is a very useful spice in cold flatulent colics, and in laxity and debility of the intestines.

**GINGLYMUS**, in anatomy. See ANATOMY, p. 149.

**GINSENG**, a small root brought from North America, and sometimes from China. It has a sweet taste, accompanied with a slight bitterness and warmth. The Chinese look upon it as an universal restorative in all decays.

**GIRONNE**, a large city and bishop's see of Spain, in the province of Catalonia, forty five miles north-east of Barcelona: E. long. 2° 35', and N. lat. 32°.

**GIRONNE**, or **GIRONNY**, in heraldry, a coat of arms divided into girones, or triangular figures, meeting in the centre of the shield, and alternately colour and metal. See Plate XCVII. fig. 5.

**GISBORN**, a market-town of Yorkshire, fifty miles west of York.

**GISBOROUGH**, another market town of Yorkshire, thirty-seven miles north of York.

**GISORS**, a city of Normandy in France, twenty-eight miles south-east of Rouen: E. long. 1° 25', N. lat. 50° 10'.

**GLACIS**, in building, an easy insensible slope or declivity.

The descent of the glacis is less steep than that of the talus. In girdening, a descent sometimes begins in talus, and ends in glacis.

The glacis of the corniche, is an easy imperceptible slope in the cymatium, to promote the descent and draining off the rain water.

**GLACIS**, in fortification, that mass of earth which serves

as a parapet to the covered way, sloping easily towards the champion or sield.

**GLADDON.** See **LUS.**

**GLADE**, in gardening and agriculture, an opening and light passage made through a wood, by lopping off the branches of trees along that way.

**GLADIATORS**, in antiquity, persons who fought generally in the arena at Rome, for the entertainment of the people.

The gladiators were usually slaves, and fought out of necessity; though sometimes freemen made profession thereof, like our prize fighters, for a livelihood. The Romans borrowed this cruel diversion from the *Alia*-tics; and we find that the very high-priests had their *ludi pontificales*, and *ludi sacerdotales*. As from the earliest ages of antiquity we read that it was customary to sacrifice prisoners of war to the manes of the great men that fell in the engagement; in process of time they came to sacrifice slaves at the funerals of all persons of condition; but as it would have appeared barbarous to cut their throats like beasts, they were appointed to fight with each other, and do their best to save their own lives by killing their adversary.

Hence arose the masters of arms called *lanistæ*, and men learned to fight. These *lanistæ* bought slaves to train up to this cruel trade, whom they afterwards sold to such as had occasion to exhibit shews. Junius Brutus, who expelled the kings, was the first that honoured the funeral of his father with these inhuman diversions at the sepulchre of the deceased; but afterwards they were removed to the circus and amphitheatres; and other persons, besides slaves, would hire themselves to this infamous office.

They were all first sworn that they would fight till death; and if they failed, they were put to death, either by fire, swords, clubs, whips, &c. It was usual with the people, or emperor, to grant them life when they shewed no signs of fear. Augustus decreed that it should always be granted them.

From slaves and freed men, the wanton sport spread to persons of rank, as we find in Nero's time. And Domitian exhibited combats of women in the night-time; we also read, that dwarfs encountered with one another. Constantine the Great first prohibited these combats in the East; but the practice was not entirely abolished in the West before Theodoric king of the Ostrogoths, in the year 500.

When any person desired to entertain the people with a show of gladiators, he set up bills in the public places, giving an account of the time, the number and names of the combatants, and the circumstances whereby they were to be distinguished; each having his several badge, which generally was a peacock's feather: they also gave notice what time the show would last; and sometimes gave representations of these things in painting, as is practised among us, by those who have any thing to show at fairs, &c.

Upon the day appointed for the show, in the first place the gladiators were brought out all together, and obliged to take a circuit round the arena in a very so-

lemn and pompous manner. After this they proceeded, *paria componere*, to match them by pairs, in which great care was taken to make the matches equal. The first sort of weapons they made use of were staves, or wooden files, called *rudis*; and the second were effective weapons, as swords, poinards, &c.

The first were called *arma latoria*, or *exercitoria*; the second, *decretoria*, as being given by decree or sentence of the prætor, or of him at whose expence the spectacle was exhibited.

They began to fence or skirmish with the first, which was to be the prelude to the battle; and from these, when well warmed, they advanced to the second, with which they fought naked. The first part of the engagement was called *ventilare, præludere*; and the second *dimicare ad certum, or versus armis pugnare*.

When any received a remarkable wound, either his adversary or the people used to cry out, *Habet, or, Hoc habet*. If the vanquished surrendered his arms, it was not in the victor's power to grant him life: it was the people during the time of the republic, and the prince or people during the time of the empire, that were alone empowered to grant this boon. The two signs of favour and dislike given by the people were, *premere pollicem*, and *vertere pollicem*; the former of which M. Dacier takes to be a clenching of the fingers of both hands between one another, and to holding the two thumbs upright close together, was a sign of the people's admiration of the courage shewn by both combatants; and at the same time for the conqueror to spare his antagonist's life: but the contrary motion, or bending back of the thumbs, signified the dissatisfaction of the spectators, and authorised the victor to kill the other combatant downright for a coward. The emperor saved whom he liked, if he was present at the solemnity, in the same manner.

After the engagement, several marks of favour were conferred on the victor, particularly a branch of palm-tree; and oftentimes a sum of money, perhaps gathered up among the spectators: but the most common rewards were the *pileus* and the *rudis*; the former being given only to such gladiators as were slaves, for a token of obtaining their freedom; but the *rudis* seems to have been bestowed both on slaves and freemen, with this difference, that it procured the former no more than a discharge from any further performance in public, upon which they commonly turned *lanista*: but the *rudis*, when given to such persons as, being free, had hired themselves out for these shows, restored them to a full enjoyment of their liberty. See **PILEUS**, **RUDIS**, and **LANISTA**.

**GLADIOLUS**, in botany, a genus of the triandria monogynia class. The corolla is ringent, and divided into six parts. There are ten species, none of them natives of Britain.

**GLAMA.** See **CAMELUS**.

**GLAMORGANSHIRE**, a county of South Wales, bounded by Brecknockshire on the north, and by the Bristol channel on the south. Its capital is Landaff.

**GLAND**, in anatomy. See **ANATOMY**, p. 307.

**GLANDERS**,

**GLANDERS.** See *FARRIERY*, p. 557.

**GLANS.** in anatomy. See *ANATOMY*, p. 270.

**GLARIS**, the capital of one of the cantons of Switzerland, of the same name, the inhabitants of which are both protestant and popish: it is situated thirty-five miles south-east of Zurich, in E. long.  $9^{\circ}$ , and N. lat.  $47^{\circ}$ .

**GLASGOW**, a large city of Scotland, in the shire of Lanerkshire, or Clydesdale, situated on the river Clyde, twenty miles north-west of Lanerk, and forty miles west of Edinburgh, in  $4^{\circ} 8'$ , W. long. and  $55^{\circ} 5'$ , N. lat.

This is one of the most elegant towns in Scotland.

It has an university, and a good foreign trade.

**GLASS**, a transparent, brittle, facitious body, produced by the action of fire upon a fixt salt and sand, or stone, that readily melts.

The chemists hold, that there is no body but may be vitrified, or converted into glass; being the last effect of fire, as all its force is not able to carry the change of any natural body beyond its vitrification.

When or by whom the art of making glass was first found out is uncertain: some will have it invented before the flood; but without any proof. Neri traces the antiquity of this art as far back as the time of Job: but Dr Merret will have it as ancient as either pottery, or the making of bricks: because that a kiln of bricks can scarce be burnt, or a batch of pottery be made, but some of the bricks and the ware will be at least superficially turned to glass; so that it must have been known at the building of Babel, and as long before as the making of bricks was used. It must have been known, consequently, among the Egyptians, when the Israelites were employed by them in making bricks. Of this kind, no doubt, was that fossil glass mentioned by Ferrant. Imperat. to be found under-ground in places where great fires had been. The Egyptians indeed boast, that this art was taught them by the great Hermes. Aristophanes, Aristotle, Alexander Aphrodisæus, Lucretius, and John the divine, put us out of all doubt that glass was in use in their days.

Pliny relates, that it was first discovered accidentally in Syria, at the mouth of the river Belus, by certain merchants driven thither by a storm at sea, who, being obliged to continue there, and dress their vicals, by making a fire on the ground, where there was great plenty of the herb kali; that plant burning to ashes, its salts mixed and incorporated with sand, or stones fit to vitrify, and produced glass: that this accident being known, the people of Sidon, in that neighbourhood, assayed the work, improved the hint, and brought it into use; and that this art has been improving ever since.

Venice, for many years, excelled all Europe in the fineness of its glasses; but of late the French and English have excelled in the Venetians, so that we are no longer supplied with this commodity from abroad.

*Nature and characters of GLASS.* Naturalists are divided in what class of bodies to rank glass: some making it a concrete juice; others a stone; others again rank it among semi-metals; but Dr Merret observes,

that these are all natural productions, whereas glass is a facitious compound, produced by fire, and never found in the earth, but only the sand and stone that form it: that metals are formed by nature into certain species; and that fire only produces them, by its faculty of separating heterogeneous, and uniting homogeneous bodies: whereas it produces glass, by uniting heterogeneous matter, viz. salt and sand, of both which it evidently consists; 100 lb weight of sand yielding above 150 lb of glass.

The same learned doctor gives us a precise and accurate enumeration of the several characters, or properties of glass, whereby it is distinguished from all other bodies, viz. 1. That it is an artificial concrete of salt and sand, or stones. 2. Fusible by strong fire. 3. When fused, tenacious and coherent. 4. It does not waste nor consume in the fire. 5. When melted, it cleaves to iron. 6. When it is red hot, it is ductile, and may be fashioned into any form; but not malleable; and capable of being blown into a hollowness, which no mineral is. 7. Frangible when thin, without annealing. 8. Friable, when cold. 9. Diaphanous, whether hot or cold. 10. Flexible and elastic. 11. Dissoluble by cold and moisture. 12. Only capable of being graven or cut with a diamond, or other hard stone and emery. 13. Receives any dye or colour both externally and internally. 14. Not dissoluble by aqua fortis, aqua regia, or mercury. 15. Neither acid juices nor any other matter extract either colour, taste, or any other quality from it. 16. Admits of polishing. 17. Neither loses weight nor substance by the longest and most frequent use. 18. Gives fusion to other metals, and softens them. 19. The most pliable thing in the world, and that which best retains the fashion given it. 20. Not capable of being calcined. 21. An open glass being filled with water in the summer-time, will gather drops of water on the outside, just so far as the water on the inside reaches; and a person's breath blown on it will manifestly moisten it. 22. Little glass balls filled with water, mercury, and other liquor, and thrown into the fire, as also drops of green glass being broken, will fly asunder with a great noise. 23. Neither wine, beer, nor any other liquor, will make it mussy, or change its colour, or rust it. 24. It may be cemented, as stones and metals. 25. A drinking glass, partly filled with water, and rubbed on the brim with a wet finger, yields musical notes, higher or lower as the glass is more or less full, and will make the liquor frisk and leap.

*Materials for making of GLASS.* The materials whereof glass is made, we have already mentioned to be salt and sand, or stones. The salt here used, is procured from a sort of ashes, brought from the Levant, called pulverine, or rochetta; which ashes are those of a sort of water-plant, called kali, cut down in summer, dried in the sun, and burnt in heaps, either on the ground, or on iron grates; the ashes falling into a pit, grow into a hard mass, or stone, fit for use.

To extract the salt, these ashes, or pulverine, are powdered and sifted, then put into boiling water, and there kept till one third of the water be consumed: the whole

*Fig. 1.* GLASS MAKERS at work

*Wells, 1841*

whole being stirred up, from time to time, that the ashes may incorporate with the fluid, and all its salts be extracted: then the vessel is filled up with new water, and boiled over again, till one half be consumed; what remains is a sort of lee, strongly impregnated with salt. This lee, boiled over again in fresh coppers, thickens in about twenty-four hours, and shoots its salt; which is to be ladled out, as its shoots, into earthen pans, and thence into wooden fats to drain and dry. This done, it is grossly pounded, and thus put in a sort of oven, called calcar, to dry. It may be added, that there are other plants, besides kali, which yield a salt fit for glass: such are the alga, or sea weed, the common way-thistle, bramble, hops, wormwood, woad, tobacco, fern, and the whole leguminous tribe, as pease, beans, &c.

The sand or stone, called by the artists Tarso, is the second ingredient in glass, and that which gives it the body and firmness. These stones, Agricola observes, must be such as will fuse; and of these such as are white and transparent are best; so that crystal challenges the precedence of all others.

At Venice they chiefly use a sort of pebble, found in the river Tefino, resembling white marble, and called cuogolo. Indeed Ant. Neri assures us, that all stones which will strike fire with steel, are fit to vitrify: but Dr Merret shews, that there are some exceptions from this rule. Flints are admirable; and when calcined, powdered, and searched, make a pure white crystalline metal: but the expence of preparing them makes the masters of our glass-houses sparing of their use. Where proper stones cannot be so conveniently had, sand is used; which should be white, and small, and well washed, before it be applied: such is usually found in the mouths and sides of rivers. Our glass-houses are furnished with a fine sand for crystal, from Maidstone; the same with that used for sand boxes, and in scouring; and with a coarser for green glass from Woolwich. For crystal glass, to 200 lb of tarso, pounded fine, they put 130 lb of salt of pulverine; mix them together, and put them into the calcar, a sort of reverberatory furnace, being first well heated. Here they remain baking, frying, and calcining, for five hours, during which the workman keeps mixing them with a rake, to make them incorporate: when taken out, the mixture is called frit, or bollito.

It may be further observed, that glass might be made by immediately melting the materials without thus calcining, and making them frit: but the operation would be much more tedious.

A glass much harder than any prepared in the common way may be made by means of borax, in the following manner. Take four ounces of borax, and an ounce of fine white sand, reduced to powder, and melt them together in a large close crucible set in a wind furnace, keeping a strong fire for half an hour: then take out the crucible, and, when cold, break it; and there will be found at the bottom a hard, pure glass, capable of cutting common glass almost like a diamond. This experiment duly varied, says Dr Shaw, may lead

to some considerable improvements in the art of glass, enamels, and artificial gems. It shews us an expeditious method of making glass without the use of fixed salts, which has generally been thought an essential ingredient in glass, and which is the ingredient that gives common glass its softness; and it is not yet known, whether calcined crystal, or other substances being added to this salt, instead of sand, it might not make a glass approaching to the nature of a diamond.

*Kinds of GLASS.* Of these materials we have many sorts of glass made, which may principally be distinguished according to their beauty: as the crystal blue glass, the crystal white glass, the green glass, and the bottle glass. Again these several sorts are distinguished by their several uses: as plate or coach glasses, looking glasses, optic glasses, &c. which are made of the first sort. The second sort includes crown glass, toys, phials, drinking-glasses, &c. The third sort is well known by its colour, and the second by its form.

*Balas coloured GLASS* is made thus: Put into a pot crystal frit, thrice washed in water; tinge this with manganese prepared into a clear purple: to this add alumen cativum sifted fine in small quantities, and at several times; this will make the glass grow yellowish, and a little reddish, but not blackish, and always dissipates the manganese. The last time you add manganese, give no more of the alumen cativum, unless the colour be too full. Thus will the glass be exactly of the colour of the balas-ruby.

*Red GLASS.* A blood-red glass may be made in the following manner: Put six pounds of glass of lead, and ten pounds of common glass, into a pot glazed with white glass: when the whole is boiled and refined, add, by small quantities, and at small distances of time, copper calcined to a redness, as much as, on repeated proofs, is found sufficient: then add tartar in powder by small quantities at a time, till the glass is become as red as blood; and continue adding one or other of the ingredients till the colour is quite perfect.

*Yellow GLASS.* It is a necessary remark in glass-making, that the crystal glass made with salt that has an admixture of tartar will never receive the true gold yellow, though it will all other colours: for yellow glass, therefore, a salt must be prepared from pulverine, or pot ashes alone, to make the glass.

*Furnaces for the making GLASS.* In this manufacture, there are three sorts of furnaces; one, called calcar, is for the frit; the second is for working the glass; the third serves to anneal the glass, and is called the leer. See FURNACES.

The calcar A (Plate XCVII. fig. 1.) resembles an oven ten feet long, seven broad, and two deep: the fuel, which in England is sea coal, is put into a trench on one side of the furnace; and the flame reverberating from the roof upon the frit, calcines it. The glass-furnace, or working furnace B, is round, of three yards diameter, and two high; or thus proportioned. It is divided into three parts, each of which is vaulted. The lower part C is properly called the crown,

and is made in that form. Its use is to keep a brisk fire of coal and wood, which is never put out. The mouth of it is called the *bocca*. There are several holes in the arch of this crown, through which the flame passes into the second vault, or partition, and reverberates into the pots filled with the ingredients above mentioned. Round the insides are eight or more pots placed, and piling pots on them. The number of pots is always double that of the *boccas* D, or mouths, or of the number of workmen, that each may have one pot refined to work out of, and another for metal to refine in while he works out of the other. Through the working holes the metal is taken out of the pots, and the pots are put into the furnace; and these holes are stopped with moveable covers made of lute and brick, to screen the workmens eyes from the scorching flames. On each side of the *bocca*, or mouth, is a *bocarella*, or little hole, out of which coloured glass, or finer metal, is taken from the piling pot. Above this oven, there is the third oven or leer, about five or six yards long, where the vessels, or glass, is annealed, or cooled: this part consists of a tower, besides the leer F, into which the flame ascends from the furnace. The tower has two mouths, through which the glasses are put in with a fork, and set on the floor or bottom: but they are drawn out on iron pans, called *fraches*, through the leer, to cool by degrees; so that they are quite cold by the time they reach the mouth of the leer, which enters the *sarofel*, or room where the glasses are to be stowed.

But the green glass furnace is square; and at each angle it has an arch for annealing, or cooling glasses. The metal is wrought on two opposite sides, and on the other two they have their colours, into which are made linnen holes, for the fire to come from the furnace to bake the frit, and to discharge the smoke. Fires are made in the arches to anneal the work, so that the whole process is done in one furnace.

These furnaces must not be of brick, but of hard sandy stones. In France, they build the outside of brick, and the inner part to bear the fire is made of a sort of fuller's earth, or tobacco-pipe clay, of which earth they also make their melting pots.

Mr Blancourt observes, that the worst and roughest work in this art, is the changing the pots, when they are worn out, or cracked. In this case the great working hole must be uncovered; the faulty pot must be taken out with iron hooks and forks, and a new one must be speedily put in its place, through the flames, by the hands only. For this work, the man guards himself with a garment made of skins, in the shape of a pantaloon, that covers him all but his eyes, and is made as wet as possible: the eyes are defended with a proper sort of glass.

*Instruments for making of GLASS.* The instruments made use of in this work, may be reduced to these that follow. A blowing pipe, made of iron, about two feet and a half long, with a wooden handle. An iron rod to take up the glass, after it is blown, and to cut off the former. Scissors to cut the glass when it comes off from the first hollow iron. Shears to cut and shape

great glasses, &c. an iron Ladle, with the end of the handle cased with wood, to take the metal out of the refining pot, to put it into the workmens pots. A small iron ladle, cased in the same manner, to skim the alkaline salt that swims at top. Shovels, one like a peel, to take up the great glasses; another, like a fire-shovel, to feed the furnace with coals. A hooked iron fork, to stir the matter in the pots. An iron rake for the same purpose, and to stir the frit. An iron fork, to change or pull the pots out of the furnace, &c.

*Working or blowing round GLASS.* The tools thus provided, the workman dips his blowing pipe into the melting-pot; and by turning it about, the metal sticks to the iron more firmly than turpentine. This he repeats four times, at each time rolling the end of his instrument, with the hot metal thereon, on a piece of iron G, over which is a vessel of water which helps to cool, and so to consolidate, and to dispose that matter to bind more firmly with what is to be taken next out of the melting pot. But after he has dipped a fourth time, and the workman perceives there is metal enough on the pipe, he claps his mouth immediately to the other end of it H, and blows gently through the iron tube, till the metal lengthens like a bladder about a foot. Then he rolls it on a marble stone I, a little while, to polish it, and blows a second time, by which he brings it to the shape of a globe of about eighteen or twenty inches diameter. Every time he blows into the pipe, he removes it quickly to his cheek, otherwise he would be in danger, by often blowing, of drawing the flame into his mouth; and this globe may be flattened by returning it to the fire, and brought into any form by stamp-irons, which are always ready. When the glass is thus blown, it is cut off at the collet, or neck, which is the narrow part that stuck to the iron. The method of performing this is as follows: the pipe is rested on an iron bar, close by the collet; then a drop of cold water being laid on the collet, it will crack about a quarter of an inch, which, with a slight blow, or cut of the shears K, will immediately separate the collet.

After this is done, the operator dips the iron rod into the melting-pot, by which he extracts as much metal as serves to attract the glass he has made, to which he now fixes this rod at the bottom of his work, opposite to the opening made by the breaking of the collet. In this position the glass is carried to the great *bocca*, or mouth of the oven, to be heated and scalded, by which means it is again put into such a soft state, that, by the help of an iron instrument, it can be pierced, opened, and widened without breaking. But the vessel is not finished till it is returned to the great *bocca*; where it being again heated thoroughly, and turned quickly about with a circular motion, it will open to any size, by the means of the heat and motion. And by this means we come to learn the cause why the edge of all bowls and glasses, &c. are thicker than the other parts of the same glasses; because in the turning it about in the heat, the edge thickens; and the glass being as it were doubled in that part, the circumference appears like a selvage.

If

If there remains any superfluities, they are cut off with the sheers L; for till the glass is cool, it remains in a soft, flexible state. It is therefore taken from the bocca, and carried to an earthen bench, covered with brands, which are coals extinguished, keeping it turning; because that motion prevents any settling, and preserves an evenness in the face of the glass, where, as it cools, it comes to its consistency; being first cleared from the iron rod by a slight stroke by the hand of the workman.

If the vessel conceived in the workman's mind, and whose body is already made, require a foot, or a handle, or any other member or decoration, he makes them separate; and now assays to join them with the help of hot metal, which he takes out of the pots with his iron rod: but the glass is not brought to its true hardness, till it has passed the leer, or annealing oven, described before.

*Working, or blowing, of window or table GLASS.* The method of working round glass, or vessels of any sort, is in every particular applicable to the working of window or table-glass, till the blowing iron has been dpt the fourth time. But then, instead of rounding it, the workman blows, and so manages the metal upon the iron plate, that it extends two or three feet in the form of a cylinder. This cylinder is put again to the fire, and blown a second time, and is thus repeated till it is extended to the dimensions required, the side to which the pipe is fixed diminishing gradually till it ends in a pyramidal form; so that, to bring both ends nearly to the same diameter, while the glass is thus flexible, he adds a little hot metal to the end opposite the pipe, and draws it out with a pair of iron pinchers, and immediately cuts off the same end with the help of a little cold water, as before.

The cylinder being now open at one end, is carried back to the bocca, and there, by the help of cold water, it is cut about eight or ten inches from the iron pipe or rod; and the whole length at another place, by which also it is cut off from the iron rod. Then it is heated gradually on an earthen table, by which it opens in length, while the workman, with an iron tool, alternately lowers and raises the two halves of the cylinder, which at last will open like a sheet of paper, and fall into the same flat form in which it serves for use; in which it is preserved by heating it over again, cooling it on a table of copper, and hardening it twenty-four hours in the annealing furnace, to which it is carried upon forks. In this furnace an hundred tables of glass may lie at a time, without injury to each other, by separating them into tens, with an iron shiver between, which diminishes the weight by dividing it, and keeps the tables flat and even.

This was the method formerly made use of for blowing plate-glass, looking glasses, &c.; but the workmen, by this method, could never exceed fifty inches in length, and a proportional breadth, because what were larger were always found to warp, which prevented them from reflecting the object regularly, and wanted substance to bear the necessary grinding. These imperfections have been remedied by an invention of

the Sieur Abraham Thevenot, in France, about the year 1688, of casting or running large plates of glass in the following manner.

*Casting, or running of large looking GLASS plates.* The furnace G, fig. 2. is of a very large dimension, environed with several ovens, or annealing furnaces, called carquailles, besides others for making of frit, and calcining old pieces of glass. This furnace, before it is fit to run glass, costs 3500*l*. It seldom lasts above three years, and even in that time it must be refitted every six months. It takes six months to rebuild it; and three months to refit it. The melting-pots are as big as large hogheads, and contain about 2000 weight of metal. If one of them bursts in the furnace, the loss of the matter and time amounts to 250*l*. The heat of this furnace is so intense, that a bar of iron laid at the mouth thereof becomes red hot in less than half a minute. The materials in these pots are the same as described before; and A is the man breaking the frit for that purpose. When the furnace is red-hot, these materials are put in at three different times, because that helps the fusion; and in twenty-four hours they are vitrified, refined, settled, and fit for casting. H is the bocca, or mouth of the furnace; K is the cistern that conveys the liquid glass it receives out of the melting-pots in the furnace to the casting table. These cisterns are filled in the furnace, and remain therein six hours after they are filled; and then are hooked out by the means of a large iron chain, guided by a pulley marked I, and placed upon a carriage with four wheels marked L, by two men P P. This carriage has no middle piece; so that when it has brought the cistern to the casting-table M, they slip off the bottom of the cistern, and cut rushes a torrent of flaming matter O, upon the table: this matter is confined to certain dimensions by the iron rulers N, N, N, which are moveable, retain the fluid matter, and determine the width of the glass; while a man R, with the roller Q resting on the edge of the iron rulers, reduceth it as it cools to an equal thickness, which is done in the space of a minute. This table is supported on a wooden frame, with trusses for the convenience of moving to the annealing furnace; into which, strewed with sand, the new plate is shovelled, where it will harden in about ten days. After this, the glass needs only be ground, polished, and slated for use.

*Grinding and polishing of plate-GLASS.* Glass is made transparent by fire, but it receives its lustre by the skill and labour of the grinder and polisher, the former of whom takes it rough out of the hands of the maker.

In order to grind plate glass, they lay it horizontally upon a flat stone-table, (fig. 3.) made of a very fine-grained free stone; and for its greater security they plaster it down with lime, or flucco: for otherwise the force of the workmen, or the motion of the wheel with which they grind it, would move it about.

This stone table is supported by a strong frame A, made of wood, with a ledge quite round its edges, rising about two inches higher than the glass. Upon this glass to be ground, is laid another rough glass not above half so big, and so loose as to slide upon it; but

secured

cemented to a wooden plank, to guard it from the injury it must otherwise receive from the scraping of the wheel, to which this plank is fastened; and from the weights laid upon it, to promote the grinding, or friture, of the glasses. The whole is covered with a wheel, B, made of hard light wood, about six inches in diameter; by pulling of which backwards and forwards alternately, and sometimes turning it round, the workmen who always stand opposite to each other, produce a constant attrition between the two glasses, and bring them to what degree of smoothness they please, by first pouring in water and coarse sand; after that, a finer sort of sand, as the word advanceth, till at last they must pour in the powder of smalt. As the upper or incumbent glass polishes, and grows smoother, it must be taken away, and another from time to time put in its place.

This engine is called a mill by the artists, and is used only in the largest size glasses; for in the grinding of the lesser glasses, they are content to work without a wheel, and to have only four wooden handles fastened to the four corners of the stone which loads the upper plank, by which they work it about.

When the grinder has done his part, who finds it very difficult to bring the glass to an exact plainness, it is turned over to the care of the polisher, who with the fine powder of tripoli-stone, or emery, brings it to a perfect evenness and lustre. The instrument made use of in this branch, is a board, c, c, furnished with a felt, and a small roller, which the workman moves by means of a double handle at both ends. The artist in working this roller, is assisted with a wooden hoop or spring, to the end of which it is fixed: for the spring, by constantly bringing the roller back to the same points, facilitates the action of the workman's arm.

**Painting in GLASS.** The ancient manner of painting in glass was very simple; it consisted in the mere arrangement of pieces of glass of different colours in some sort of symmetry, and constituted what is now called Mosaic. See MOSAIC.

In process of time they came to attempt more regular designs, and also to represent figures heightened with all their shades: yet they proceeded no farther than the contours of the figures in black with water-colours, and hatching the draperies after the same manner on glasses of the colour of the object they designed to paint. For the carnation, they used glass of a bright red colour; and upon this they drew the principal lineaments of the face, &c. with black.

But in time, the taste for this sort of painting improving considerably, and the art being found applicable to the adorning of churches, basilics, &c. they found out means of incorporating the colours in the glass itself, by heating them in the fire to a proper degree; having first laid on the colours. The colours used in painting or staining of glass are very different from those used in painting either in water or oil colours.

For black, Take scales of iron, one ounce; scales of copper, one ounce; jet, half an ounce; reduce them to powder, and mix them. For blue, Take powder of blue, one pound; sal nitre, half a pound; mix

them and grind them well together, For carnation, Take red chalk, eight ounces; iron scales and litharge of silver, of each two ounces; gum arabic, half an ounce; dissolve in water; grind altogether for half an hour as stiff as you can; then put it in a glass and stir it well, and let it stand to settle fourteen days. For green, Take red lead, one pound; scales of copper, one pound; and flint, five pounds; divide them into three parts; and add to them as much sal nitre; put them into a crucible, and melt them with a strong fire; and when it is cold, powder it, and grind it on a porphyry. For gold colour, Take silver an ounce; antimony, half an ounce; melt them in a crucible; then pound the mass to powder; and grind it on a copper plate; add to it yellow oker, or brick-dust calcined again, fifteen ounces; and grind them well together with water. For purple, Take minium, one pound; brown stone, one pound; white flint, five pounds; divide them into three parts, and add to them as much sal nitre as one of the parts; calcine, melt, and grind it as you did the green. For red, Take jet, four ounces; litharge of silver, two ounces; red chalk, one ounce; powder them fine, and mix them. For white, Take jet, two parts; white flint, ground on a glass very fine, one part; mix them. For yellow, take Spanish brown, ten parts; leaf silver, one part; antimony, half a part; put all into a crucible, and calcine them well.

In the windows of ancient churches, &c. there are to be seen the most beautiful and vivid colours imaginable, which far exceed any of those used by the moderns, not so much because the secret of making those colours is entirely lost, as that the moderns will not go to the charge of them, nor be at the necessary pains, by reason that this sort of painting is not now so much in esteem as formerly. Those beautiful works which were made in the glass-houses were of two kinds.

In some, the colour was diffused through the whole substance of the glass. In others, which were the more common, the colour was only on one side, scarce penetrating within the substance above one third of a line; though this was more or less according to the nature of the colour; the yellow being always found to enter the deepest. These last, though not so strong and beautiful as the former, were of more advantage to the workmen, by reason that on the same glass, though already coloured, they could shew other kind of colours where there was occasion to embroider draperies, enrich them with foliages, or represent other ornaments of gold, silver, &c.

In order to this, they made use of emery, grinding or wearing down the surface of the glass, till such time as they were got through the colour to the clear glass. This done, they applied the proper colours on the other side of the glass. By these means, the new colours were hindered from running and mixing with the former, when they exposed the glasses to the fire, as will appear hereafter.

When indeed the ornaments were to appear white, the glass was only bared of its colour with emery, without tinging the place with any colour at all; and this

this was the manner by which they wrought their lights, and heightnings, on all kinds of colour.

The first thing to be done, in order to paint or stain glass, in the modern way, is to design, and even colour the whole subject on paper. Then they chuse such pieces of glass as are clear, even, and smooth, and proper to receive the several parts, and proceed to distribute the design itself, or papers it is drawn on, into pieces suitable to those of the glass; always taking care that the glasses may join in the contours of the figures, and the folds of the draperies; that the carnations, and other finer parts, may not be impaired by the lead with which the pieces are to be joined together. The distribution being made, they mark all the glasses as well as papers, that they may be known again: which done, applying every part of the design upon the glass intended for it, they copy, or transfer, the design upon this glass with the black colour diluted in gum water, by tracing and following all the lines and strokes as they appear through the glass with the point of a pencil.

When these strokes are well dried, which will happen in about two days, the work being only in black and white, they give a slight wash over with urine, gum arabic, and a little black; and repeat it several times, according as the shades are desired to be heightened, with this precaution, never to apply a new wash till the former is sufficiently dried.

This done, the lights and risings are given by rubbing off the colour in the respective places with a wooden point, or the handle of the pencil.

As to the other colours above-mentioned, they are used with gum water, much as in painting in miniature; taking care to apply them lightly, for fear of effacing, the out-lines of the design; or even, for the greater security, to apply them on the other side; especially yellow, which is very pernicious to the other colours, by blending therewith. And here too, as in pieces of black and white, particular regard must always be had not to lay colour on colour, or lay on a new lay, till such time as the former are well dried.

It may be added, that the yellow is the only colour that penetrates through the glass, and incorporates therewith by the fire; the rest, and particularly the blue, which is very difficult to use, remaining on the surface, or at least entering very little. When the painting of all the pieces is finished, they are carried to the furnace, or oven, to anneal, or bake the colours.

The furnace here used is small, built of brick, from eighteen to thirty inches square. At six inches from the bottom is an aperture to put in the fuel, and maintain the fire. Over this aperture is a grate, made of three square bars of iron, which traverse the furnace, and divide it into two parts. Two inches above this partition, is another little aperture, through which they take out pieces to examine how the coction goes forward. On the grate is placed a square earthen pan, six or seven inches deep; and five or six inches less every way than the perimeter of the fur-

nace. On the one side hereof is a little aperture, through which to make trials, placed directly opposite that of the furnaces destined for the same end. In this pan are the pieces of glass to be placed, in the following manner. First, the bottom of the pan is covered with three strata, or layers, of quick lime pulverised; those strata being separated by two others of old broken glass, the design whereof is to secure the painted glass from the too intense heat of the fire. This done, the glasses are laid horizontally on the last or uppermost layer of lime.

The first row of glass they cover over with a layer of the same powder, an inch deep; and over this they lay another range of glasses, and thus alternately till the pan is quite full; taking care that the whole heap always end with a layer of the lime-powder.

The pan being thus prepared, they cover up the furnace with tiles, on a square table of earthen ware, closely luted all round; only leaving five little apertures, one at each corner, and another in the middle, to serve as chimneys. Things thus disposed, there remains nothing but to give the fire to the work. The fire for the first two hours must be very moderate, and must be increased in proportion as the coction advances, for the space of ten or twelve hours; in which time it is usually compleated. At last the fire, which at first was charcoal, is to be of dry wood, so that the flame covers the whole pan, and even issues out at the chimneys.

During the last hours, they make essays, from time to time, by taking out pieces laid for the purpose through the little aperture of the furnace, and pan, to see whether the yellow be perfect, and the other colours in good order. When the annealing is thought sufficient, they proceed with great haste to extinguish the fire, which otherwise would soon burn the colours, and break the glasses.

*Glass of lead.* See CHEMISTRY, p. 136.

*Glass porcelain*, the name given by many to a modern invention of imitating the china-ware with glass.

The method of making it, as given by Mr Reamur, who was the first that carried the attempt to any degree of perfection, is as follows.

The glass vessels to be converted into porcelain, are to be put into large vessels, such as the common fine earthen dishes are baked in; or into sufficiently large crucibles: the vessels are to be filled with a mixture of fine white sand, and of fine gypsum; or plaster stone, burnt into what is called plaster of Paris; and all the interstices are to be filled up with the same powder, so that the glass vessels may no where touch either one another, or the sides of the vessels they are baked in.

The vessel is to be then covered down, and luted, and the fire does the rest of the work: for this is only to be put into a common potter's furnace, and when it has stood there the usual time of baking the other vessels, it is to be taken out, and the whole contents will be found no longer glass, but converted into a white opake substance, which is a very elegant porcelain, and has almost the properties of that of china.

**GLASS** of *antimony*. See **CHEMISTRY**, p. 87.

**GLASTONBURY**, a market town of Somersetshire, five miles south of Wells.

**GLATZ**, the capital of a county of the same name in Bohemia, 100 miles east of Prague: E. long. 16° 8', N. lat. 50° 25'.

**GLAUBER'S SALT**. See **CHEMISTRY**, p. 127.

**GLAUCION**, in ornithology. See **ANAS**.

**GLAUCIUM**, in botany. See **CHELIDONIUM**.

**GLAUCOMA**, in medicine, the change of the crystalline humour of the eye into an azure-colour. See **MEDICINE**.

**GLAUCUS**, in ichthyology. See **SQUALUS**.

**GLAUX**, in botany, a genus of the pentandria monogynia class. The calix consists of one leaf; it has no corolla; the capsule has one cell, 5 valves, and 5 seeds. There is but one species, *viz.* the maritima, sea-milkwort, or glasswort, a native of Britain.

**GLAZIER**, an artificer who works in glass. See **GLASS**.

The principal part of a glazier's business consists in fitting panes and plates of glass to the sashes and window-frames of houses, pictures, &c. and in cleaning the same.

**GLAZING**, the polishing or crusting over earthen ware, by running melted lead or litharge over it.

The common ware is glazed with a composition of 50 lb. clean sand, 70 lb. lead ashes, 30 lb. wood ashes, and 12 lb. salt, all melted into a cake. With this mixture they glaze it over, and then set it in an earthen glazing pan; taking care that the vessels do not touch one another. As several colours are used for this purpose, we shall give the following receipts, from Smith's laboratory. 1. For a black, take lead-ashes, 18 parts; iron-filings, 3; copper-ashes, 3; and zaffer, 2: this, when melted, will make a brown black; and if you would have it blacker, put some more zaffer to it. 2. For blue, take lead-ashes, 1 lb. clear sand or pebble, 2 lb. salt, 2 lb. white calcined tartar, 1 lb. Venice or other glass, 16 lb. and zaffer, half a pound: mix them well together; and after melting, quench them in water, and then melt them again; which operation is to be repeated several times; and if you would have it fine and good, it will be proper to put the mixture into a glass furnace for a day or two. 3. A brown glazing may be given with a mixture of lead-glass, 12 parts, and common glass and manganese, of each one part. 4. A citron-yellow may be made of 6 parts of red-lead, 7 parts of fine red brick-dust, and 2 parts of antimony, all melted together. 5. A flesh-colour, with 12 parts of lead-ashes, and one of white glass. 6. For a green-colour, take 8 parts of litharge, 8 parts of Venice-glass, 4 parts of brass-dust, and melt them together for use; or melt together two parts yellow glass, with as much copper-dust. 7. For a gold-yellow, take of antimony, red lead, and sand, an equal quantity, and melt them into a cake. 8. For a fine purple brown, take lead-ashes, 15 parts; clear sand, 18; manganese, 1; white glass, 15 measures; and 1 of zaffer. 9. For a fine red, take antimony, 2 lb. litharge, 3 lb. rust of iron calcined, 1 lb. and grind them to a fine powder. 10. For a fine white

glazing, take 2 lb. of lead, 1 lb. of tin, and calcine them to ashes; of which take 2 parts; of calcined flint or pebble, 1 part; of salt, 1 part; and mixing them well together, melt them into a cake. At Rotterdam, they make a fine shining white glazing, by melting together 2 lb. clean tin-ashes, 10 lb. lead ashes, 2 lb. fine Venice-glass, and  $\frac{1}{2}$  lb. tartar. 11. A yellow glazing is made of 4 ounces of red lead, and 2 ounces of antimony, melted together. 12. For a fine yellow, take red lead, 3 pints; antimony and tin, of each 2 lb. then melting them into a cake, grind it fine; and repeating this several times, you will have a good yellow.

**GLEBE**, among miners, signifies a piece of earth, wherein is contained some mineral ore.

**GLEBE**, in law, the land belonging to a parish-church, besides the tithes.

**GLECHOMA**, in botany, a genus belonging to the didynamia gymnospermia class. The calix consists of five segments; and each pair of antheræ are disposed in the form of a cross. There are three species, two of which are natives of Britain, *viz.* the hederacea, or ground-ivy; and the arvensis, or upright ground-ivy. The leaves of the hederacea are corollorant, aperient, and detergent.

**GLEDITSIA**, in botany, a genus of the polygamia diœcia class. The calix of the hermaphrodite has four segments; the corolla four petals; there are six stamina, and one pistillum. The calix of the male consists of three leaves, and the corolla of three petals; and it has six stamina. The calix of the female consists of five leaves, and the corolla of five petals; it has but one pistillum; and the capsule is a legumen. There are two species, none of them natives of Britain.

**GLEET**, in medicine, the flux of a thin limpid humour from the urethra. See **MEDICINE**.

**GLIRES**, the name of Linnæus's fourth order of mammalia. See **NATURAL HISTORY**.

**GLENOIDES**, the name of two cavities, or small depressions, in the inferior part of the first vertebra of the neck.

**GLIS**, in zoology. See **SCIURUS**.

**GLISCHROMICTHES**, in natural history, the name by which Dr Hill calls the tougher and more viscid loams.

**GLISTER**, in surgery. **CLYSTER**.

**GLOBE**, in practical mathematics, an artificial spherical body, on the convex surface of which are represented the countries, seas, &c. of our earth; or the face of the heavens, the circles of the sphere, &c. See **GEOGRAPHY**.

**GLOBULARIA**, in botany, a genus of the tetrandria monogynia class. The common calix is imbricated; and the proper calix is tubular and below the fruit; the upper labium of the corollulæ is divided into two parts, and the under one into three; and the receptacle is paleaceous. There are seven species, none of them natives of Britain.

**GLOBULE**, a diminutive of globe, frequently used by physicians in speaking of the red spherical particles of the blood.

**GLOCESTER**,

**GLOCESTER**, the capital of Gloucester-shire, ninety miles west of London: W. long.  $2^{\circ} 16'$ , and N. lat.  $51^{\circ} 50'$ .

It is a bishop's see, and sends two members to parliament.

**GLOGAW**, a city of Silesia, situated on the river Oder; forty five miles north west of Breslaw: E. long  $16^{\circ} 8'$ , and N. lat  $51^{\circ} 40'$ .

*For* **GLOGAW**, a town of Silesia, fifty miles south of Breslaw.

**GLORIOSA**, **SUPERB LILY**, in botany, a genus of the hexandria monogynia class. The corolla consists of six undulated and reflected petals; and the stylus is oblique. There is but one species, a native of Malabar.

**GLOSSARY**, a sort of dictionary, explaining the obscure and antiquated terms in some old author.

**GLOSSOPETRA**, in natural history, a genus of extraneous fossils, so called from their having been supposed the tongues of serpents turned into stone, though they are really the teeth of sharks, and are daily found in the mouths of those fishes, where ever taken.

**GLOTTIS**, in anatomy. See **ANATOMY**, p. 300.

**GLOW WORM** See **CICINDELA**.

**GLUCKSTAT**, a fortified town of Germany, situated on the east side of the river Elbe, thirty miles north-west of Hamburg: E. long.  $9^{\circ}$ , and N. lat.  $54^{\circ} 20'$ .

**GLUE**, among artificers, a tenacious viscid matter, which serves as a cement to bind or connect things together.

Glues are of different kinds, according to the various uses they are designed for, as the common glue, glove-glue, and parchement glue; whereof the two last are more properly called size.

The common or strong glue is chiefly used by carpenters, joiners, cabinet makers, &c. and the best kind is that made in England, in square pieces of a ruddy brown colour; and, next to this, the Flanders glue. It is made of the skins of animals, as oxen, cows, calves, sheep, &c. and the older the creature is, the better is the glue made of its hide. Indeed, whole skins are but rarely used for this purpose, but only the shavings, parings, or scraps of them; or the feet-sinews, &c. That made of whole skins, however, is undoubtedly the best; as that made of sinews is the very worst.

*The method of making GLUE.* In making glue of parings, they first steep them two or three days in water; then washing them well out, they boil them to the consistence of a thick jelly; which they pass, while hot, through ozier-baskets, to separate the impurities from it, and then let it stand some time, to purify it further: when all the filth and ordures are settled to the bottom of the vessel, they melt and boil it a second time. They next pour it into flat frames or moulds, whence it is taken out pretty hard and solid, and cut into squares pieces or cakes. They afterwards dry it in the wind, in a sort of coarse net; and at last string it, to finish its drying.

The glue made of sinews, feet, &c. is managed after the same manner; only with this difference, that they bone and scour the feet, and do not lay them to steep.

The best glue is that which is oldest; and the surest way to try its goodness, is to lay a piece to steep three or four days, and if it swell considerably without melting, and when taken out resumes its former driness, it is excellent.

A glue that will hold against fire or water, may be made thus: mix a handful of quicklime with four ounces of linseed oil; boil them to a good thickness, then spread it on tin-plates in the shade, and it will become exceeding hard, but may be easily dissolved over a fire, as glue, and will effect the business to admiration.

*Method of preparing and using GLUE.* Set a quart of water on the fire, then put in about half a pound of good glue, and boil them gently together till the glue be entirely dissolved and of a due consistence. When glue is to be used, it must be made thoroughly hot; after which, with a brush dipped in it, besmear the faces of the joints as quick as possible; then clapping them together, slide or rub them lengthwise one upon another, two or three times, to settle them close; and so let them stand till they are dry and firm.

**GLUME**, among botanists. See **BOTANY**, p. 637.

**GLUTÆUS**, in anatomy. See **ANATOMY**, p. 204.

**GLYCINE**, in botany, a genus of the diadelphia decandria class. The calix is bilabiated: and the pod consists of two cells. There are nine species, none of them natives of Britain.

**GLYCYRRHIZA**, **LIQUORICK**, in botany, a genus of the diadelphia decandria class. The calix is bilabiated; and the pod is oval and compressed. There are three species, none of them natives of Britain.

The common liquorice is cultivated in most countries of Europe for the sake of its root. That which is cultivated in Britain is preferable to such as comes from abroad; this last being generally mouldy, which this root is very apt to become, unless kept in a dry place. The powder of liquorice usually sold is often mingled with flour, and probably too often with substances not quite so wholesome: the best sort is of a brownish yellow colour (the fine pale yellow being generally sophisticated) and of a very rich sweet taste, much more agreeable than that of the fresh root. Liquorice is almost the only sweet that quenches thirst; whence it was called by the Greeks *asipson*. Galen takes notice, that it was employed in this intention in hydroptic cases, to prevent the necessity of drinking. Mr Fuller, in his *Medicina gymnasica*, recommends this root as a very useful pectoral, and says it excellently softens acrimonious humours, at the same time that it proves gently detergent: and this account is warranted by experience.

**GLYPH**, in sculpture and architecture, denotes any canal or cavity used as an ornament.

**GRELINA**, in botany, a genus of the didynamia angiospermia class. The calix has four teeth; the corolla is bell-shaped, and divided into four segments; the antheræ are divided into two parts; and the fruit is a bicellular drupa. There is but one species, a native of the Indies.

**GRAPHILUM**, **CUDWATER**, in botany, a genus of the Syngenesia

*Syngenesia polygamia superflua* class. The receptacle is naked; the pappus is plumose; and the calix is imbricated. There are 41 species, five of them natives of Britain, *viz.* the dioicum, mountain cudweed, or cat's foot; the margaritaceum, or American cudweed; the luteo-album, or Jersey cudweed; the sylvaticum, or upright cudweed; and the uliginosum, or black-headed cudweed.

**GNAT**, in zoology. See **MUSCA**.

**GNESNA**, the capital city of great Poland, situated one hundred and ten miles west of Warsaw: E. long. 18°, and N. lat. 53°.

It is the see of an archbishop, who is always prime of Poland. See **POLAND**.

**GNIDIA**, in botany, a genus of the octandria monogynia class. The calix is funnel shaped, and consists of four segments; the petals are four, and inserted into the calix; and the berry contains but one seed. There are three species, none of them natives of Britain.

**GNOMON**, in dialling, the style, pin, or cock of a dial; which, by its shadow, shews the hour of the day. See **DIALLING**.

**GNOMON**, in astronomy, a style erected perpendicular to the horizon, in order to find the altitude of the sun.

**GNOMON of a globe**, the index of the hour-circle. See **GEOGRAPHY**.

**GNOMONICS**, the art of dialling. See **DIALLING**.

**GNOSTICS**, in church-history, Christian heretics so called, it being a name which almost all the ancient heretics affected to take, to express that new knowledge and extraordinary light to which they made pretensions; the word gnostic signifying a learned or enlightened person.

**GOA**, a city and sea-port of the hither India, situated in an island of the river Mandoua, and subject to the Portuguese: E. lon. 73° 20', and N. lat. 15° 20'.

**GOAT**, in zoology. See **CAPRA**.

**GOAT'S BEARD**, in botany. See **TRAGOPOGON**.

**GOAT'S RUE**, in botany. See **GALEGA**.

**GOAT-SUCKER**, in ornithology. See **CAPRIMULGUS**.

**GOBIUS**, in ichthyology, a genus of fishes belonging to the order of thoracici. They have two holes between the eyes, four rays in the membrane of the gills; and the belly-fins are united in an oval form. There are eight species, principally distinguished by the number of rays in their fins.

**GOD**, one of the many names of the Supreme Being. See **RELIGION**.

**GODDESS**, a heathen deity of the female sex.

The ancients had almost as many goddesses as gods; such were Juno, the goddess of air; Diana, the goddess of woods, &c. And under this character were represented the virtues, graces, and principal advantages of life; Truth, Justice, Piety, Liberty, Fortune, Victory, &c.

It was the peculiar privilege of the goddesses to be represented naked on medals; for it was supposed that the imagination must be awed and restrained by the consideration of the divine character.

**GOLCONDA**, the capital of a province of the same

name in the hither India: E. long. 77°, and N. lat. 16°.

**GOLD**. See **CHEMISTRY**, p. 78, and 129.

**GOLD-WIRE**, a cylindrical ingot of silver, superficially gilt, or covered with gold at the fire, and afterwards drawn successively through a great number of little, round holes, of a wire-drawing iron, each less than the other, till it be sometimes no bigger than a hair of the head.

It may be observed, that before the wire be reduced to this excessive fineness, it is drawn through above an hundred and forty different holes; and that each time they draw it, it is rubbed afresh over with new wax, both to facilitate its passage, and to prevent the silver's appearing through it.

**GOLD-WIRE flatted**, is the former wire flatted between two rollers of polished steel, to fit it to be spun on a stick, or to be used flat, as it is, without spinning, in certain stuffs, laces, embroideries, &c. See **STUFF**, &c.

**GOLD-THREAD**, or **SPUN-GOLD**, is a flatted gold, wrapped or laid over a thread of silk, by twisting it with a wheel and iron bobbins.

*Manner of forming GOLD-WIRE, and GOLD-THREAD, both round and flat.* First, an ingot of silver, of twenty-four pounds, is forged into a cylinder, of about an inch in diameter: then it is drawn through eight or ten holes, of a large, coarse, wire-drawing iron, both to finish the roundness, and to reduce it to about three fourths of its former diameter. This done, they file it very carefully all over, to take off any filth remaining on the forge; then they cut it in the middle; and thus make two equal ingots thereof, each about twenty six inches long, which they draw through several new holes, to take off any inequalities the file may have left, and to render it as smooth and equable as possible.

The ingot thus far prepared, they heat it in a charcoal fire; then taking some gold leaves, each about four inches square, and weighing twelve grains, they join four, eight, twelve, or sixteen of these, as the wire is intended to be more or less gilt; and when they are so joined, as only to form a single leaf, they rub the ingots reeking hot with a burnisher. These leaves being thus prepared, they apply over the whole surface of the ingot, to the number of six, over each other, burnishing or rubbing them well down with the blood-stone, to close and smoothe them. When gilt, the ingots are laid anew in a coal fire; and when raised to a certain degree of heat, they go over them a second time with the blood-stone, both to folder the gold more perfectly, and to finish the polishing. The gilding finished, it remains to draw the ingot into wire.

In order to this, they pass it through twenty holes of a moderate drawing iron, by which it is brought to the thickness of the tag of a lace: from this time the ingot loses its name, and commences gold-wire. Twenty holes more of a lesser iron leaves it small enough for the least iron; the finest holes, of which last scarce exceeding the hair of the head, finish the work.

To dispose the wire to be spun on silk, they pass it between

between two rollers of a little mill: these rollers are of nicely polished steel, and about three inches in diameter. They are set very close to each other, and turned by means of a handle fastened to one of them, which gives motion to the other. The gold wire in passing between the two, is rendered quite flat, but without losing any thing of its gilding, and is rendered so exceedingly thin and flexible, that it is easily spun on silk thread, by means of a hand wheel, and so wound on a spool or bobin.

**GOLD-LEAF, or BEATEN GOLD,** is gold beaten with a hammer into exceeding thin leaves, so that it is computed, that an ounce may be beaten into sixteen hundred leaves, each three inches square, in which state it takes up more than 159052 times its former surface.

This gold they beat on a block of black marble, about a foot square, and usually raised three feet high: they make use of three sorts of hammers, formed like mallets, of polished iron: the first, which weighs three or four pounds, serves to chase, or drive; the second, of eleven or twelve pounds, to close; and the third, which weighs fourteen or fifteen pounds, to stretch and finish. They also make use of four moulds of different sizes, *viz.* two of vellum, the smallest whereof consists of forty or fifty leaves, and the larger of two hundred; the other two, consisting each of five hundred leaves, are made of bullocks guts well scoured, and prepared. See **MOULD**.

*Method of preparing and beating GOLD.* They first melt a quantity of pure gold, and form it into an ingot: this they reduce, by forging, into a plate about the thickness of a sheet of paper; which done, they cut the plate into little pieces about an inch square, and lay them in the first or smallest mould to begin to stretch them: after they have been hammered here a while with the smallest hammer, they cut each of them into four, and put them into the second mould, to be extended further.

Upon taking them hence, they cut them again into four, and put them into the third mould; out of which they are taken, divided into four, as before, and laid in the last, or finishing mould, where they are beaten to the degree of thinness required.

The leaves thus finished, they take them out of the mould, and dispose them into little paper-books, prepared with a little red bole, for the gold to stick to; each book ordinarily contains twenty-five gold leaves. There are two sizes of these books; twenty-five leaves of the smallest only weigh five or six grains, and the same number of the largest nine or ten grains.

It must be observed, that gold is beaten more or less, according to the kind or quality of the work it is intended for; that for the gold-wire drawers to gild their ingots withal, is left much thicker than that for gilding the frames of pictures, &c. withal. See **GILDING**.

**GOLD-FINCH,** in ornithology. See **FRINGILLA**.

**GOLDSMITH,** or, as some chuse to express it, *silver-smith*, an artist who makes vessels, utensils, and ornaments, in gold and silver.

The goldsmith's work is either performed in the

mould, or beat out with the hammer or other engine. All works that have raised figures, are cast in a mould, and afterwards polished and finished: plates, or dishes, of silver or gold, are beat out from thin flat plates; and tankards, and other vessels of that kind, are formed of plates soldered together, and their mouldings are beat, not cast. The business of the goldsmiths formerly required much more labour than it does at present; for they were obliged to hammer the metal from the ingot to the thinness they wanted: but there are now invented flattening-mills, which reduce metals to the thinness that is required, at a very small expence. The goldsmith is to make his own moulds, and for that reason ought to be a good designer, and have a taste in sculpture: he also ought to know enough of metallurgy, to be able to assay mixed metals, and to mix the alloy.

**GOLDEN,** something that has a relation to gold, or consists of gold.

**GOLDEN number.** See **ASTRONOMY**, p. 492.

**GOLDEN rule.** See **ARITHMETICK**, p. 381.

**GOLDINGEN,** a city of Poland, in the duchy of Courland, sixty miles west of Mittau: E. long. 22°, N. lat. 57°.

**GOMBRON,** the greatest sea-port town in Persia, situated on the strait at the entrance of the gulph of Persia, opposite to the island of Ormus: E. long. 55° 30', N. lat. 27° 30'.

**GOMERA,** one of the Canary islands, subject to Spain, and situated west of Teneriff: W. long. 18°, N. lat. 28°.

**GOMORRO islands,** situated between 10° and 13° S. lat. on the eastern coast of Africa.

**GOMPHOSIS,** in anatomy. See **ANATOMY**, p. 148.

**GOMPHRENA,** the *purple everlasting flower*, in botany, a genus of the pentandria digynia class. The calix consists of three coloured leaves; the nectarium is cylindrical, with ten teeth; and the capsule contains one seed. There are seven species, none of them natives of Britain.

**GONDOLA,** in naval architecture, a flat kind of boat, very long and narrow, chiefly used on the canals at Venice.

**GONORRHOEA,** in medicine, an involuntary efflux of the seminal juices, and some other recrementitious matter. See **MEDICINE**.

**GOOD,** in general, whatever is apt to cause or increase pleasure, or diminish pain in us; or, which amounts to the same, whatever is able to procure or preserve to us the possession of agreeable sensations, and remove those of an opposite nature.

*Moral Good,* denotes the right conduct of the several senses and passions, or their just proportion and accommodation to their respective objects and relations. See **MORALS**.

**GOOD-HOPE,** or *Cape of GOOD-HOPE*, the most southern promontory of Africa, where the Dutch have built a good town and fort: E. long. 16° and N. lat. 34° 15'.

**GOOSE,** in ornithology. See **ANAS**.

**GOOSEBERRY,** in botany. See **PICES**

† 7 U

**GOOSE-NECK;**

**GOOSE-NECK**, in a ship, a piece of iron fixed on the one end of the tiller, to which the laniard of the whip-staff or the wheel-rope comes, for steering the ship.

**GOOSE-WING**, in the sea-language. When a ship sails before, or with a quarter wind on a fresh gale, to make the more haste, they launch out a boom, and sail on the lee side; and a sail so fitted, is called a goose-wing.

**GOR**, the capital of a province of the same name, in the East-Indies, subject to the Mogul: E. long.  $85^{\circ}$ , N. lat.  $31^{\circ} 15'$ .

**GORCUM**, a city of the United Provinces, situated in that of Holland, on the river Waal, twenty two miles east of Rotterdam: E. long.  $4^{\circ} 50'$ , N. lat.  $51^{\circ} 50'$ .

**GORDIAN KNOT**, in antiquity, a knot made in the leathers or harness of the chariot of Gordius, king of Phrygia, so very intricate, that there was no finding where it began or ended.

The inhabitants had a tradition, that the oracle had declared, that he who untied this knot, should be master of Asia. Alexander having undertaken it, was unable to accomplish it; when fearing lest his not untying it should be deemed an ill augury, and prove a check in the way of his conquests, he cut it asunder with his sword, and thus either accomplished or eluded the oracle.

**GORE**, in heraldry, one of the abatements, which, according to Guillim, denotes a coward. It is a figure consisting of two arch lines drawn one from the sinister chief, and the other from the sinister base, both meeting in an acute angle in the middle of the fess point. See Plate XCVII. fig. 4.

**GORGE**, in architecture, the narrowest part of the Tuscan and Doric capitals, lying between the astragal, above the shaft of the pillar, and the annulets.

**GORGE**, in fortification, the entrance of the platform of any work. See FORTIFICATION.

**GORGED**, in heraldry, the bearing of a crown, coronet, or the like, about the neck of a lion, a swan, &c. and in that case it is said, the lion or cygnet is gorged with a ducal coronet, &c.

Gorged is also used when the gorge or neck of a peacock, swan, or the like bird, is of a different colour or metal from the rest.

**GORGONA**, the name of two islands; one in the Pacific Ocean on the coast of Peru, W. long.  $79^{\circ}$ ; N. lat.  $3^{\circ}$ ; the other in the Mediterranean, twenty-five miles west of Leghorn.

**GORGONS**, in antiquity, a warlike female nation of Lybia, in Africa, who had frequent quarrels with another nation of the same sex, called Amazons.

**GORLITZ**, a city of Upper Saxony, in Germany, fifty miles east of Dresden: E. long.  $15^{\circ} 6'$ , N. lat.  $51^{\circ} 12'$ .

**GOSHAWK**. See FALCO.

**GOSLAR**, an imperial city of Lower Saxony, in Germany, thirty miles south of Brunswick: E. long.  $10^{\circ} 30'$ , N. lat.  $52^{\circ}$ .

**GOSPEL**, the history of the life, actions, death, resurrection, ascension and doctrine of Jesus Christ.

The word is saxon, and of the same import with the

Latin term *evangelium*, which signifies glad tidings, or good news.

This history is contained in the writings of St Matthew, St Mark, St Luke, and St John; who from thence are called evangelists. The Christian church never acknowledged any more than these four gospels as canonical; notwithstanding which, several apocryphal gospels are handed down to us, and others are entirely lost.

**GOSSYPIMUM**, in botany, a genus of the monodelphia polyandria class. The calix is double, the exterior one consisting of three leaves; the capsule has four cells; and the seeds are covered with down. There are four species, none of them natives of Britain.

**GOTHA** the capital of the duchy of Saxe Gotha, in Upper Saxony; E. long.  $10^{\circ} 36'$ , N. lat.  $51^{\circ}$ .

It is subject to the duke of Saxe Gotha, brother of her royal highness the princess dowager of Wales.

**GOTHIC**, in general, whatever has any relation to the Goths: thus, we say, Gothic customs, Gothic architecture, &c.

**GOTHLAND**, the most southern province of Sweden, being a peninsula surrounded on three sides by the Baltic Sea. It is subdivided into East and West Gothland, Smaland, Halland, Bleken, and Schonen.

**GOTHLAND**, is also an island of the Baltic, situated without the province of Gothland and Livonia.

**GOTTENBURG**, a port-town of Sweden, situated between the Sound, on the coast of the Schaggerack Sea, near the entrance of the Baltic.

**GOTTINGEN**, a city of Germany, in the circle of Lower Saxony and dukedom of Brunswick: E. long.  $9^{\circ} 45'$ , N. Lat.  $51^{\circ} 32'$ .

**GOTTORP**, a city of the dukedom of Sleswic, in Denmark, and capital of the territories of the duke of Holstein Gottorp: E. long.  $10^{\circ}$ , N. lat.  $54^{\circ} 40'$ .

**GOUDE**, a city of the United Netherlands, in the province of Holland, ten miles north-east of Rotterdam.

**GOVERNMENT**, in general, is the polity of a state, or an orderly power constituted for the public good.

Civil government was instituted for the preservation and advancement of mens civil interests, and for the better security of their lives, liberties, and properties. The use and necessity of government is such, that there never was an age or country without some sort of civil authority: but as men are seldom unanimous in the means of attaining their ends, so their difference in opinion in relation to government, has produced a variety of forms of it. To enumerate them, would be to recapitulate the history of the whole earth. But they may, in general, be reduced to one of these heads: either the civil authority is delegated to one or more, or else it is still reserved to the whole body of the people; whence arises the known distinction of government into monarchy, aristocracy, and democracy.

Mr Hooker thinks, that the first government was arbitrary, and administered by a single person; till it was found by experience, that to live by one man's will, was the cause of all mens misery: and this, he concludes, was the original of inventing laws. The Roman and most of the Grecian states were built upon

on the republican plan; but when the Goths, and other northern nations, destroyed the Roman empire, and extended their conquests into far distant countries, they established, where-ever they came, a mixed form of government. The preservation of this constitution depending upon the balance between the king, nobility, and people, the legislative power was lodged in these three states, called by different names in different countries; in the north, diets; in Spain, cortes; in France, estates; and in Britain, parliaments. The excellency of this mixed government, consists in that due poise or balance between rule and subjection, so justly observed in it, that by the necessary concurrence of the nobility and commons, in making and repealing all laws, it has the main advantage of an aristocracy, and a democracy, and yet is free from the disadvantages and evils of either of them. This mixed form of government is, however, now driven almost out of Europe, in some parts of which we can hardly find the shadow of liberty left, and in many there is no more than the name of it remaining. France, Spain, Portugal, Denmark, and part of Germany, were all, an age or two ago, limited monarchies, governed by princes, well advised by parliaments or courts, and not by the absolute will of one man. But now all their valuable rights and liberties are swallowed up by the arbitrary power of their princes: whilst we in great Britain have still happily preserved this noble and ancient Gothic constitution, which all our neighbours once enjoyed. There is such a due balance of property, power, and dominion in our constitution, that, like the ancient government of Sparta, it may be called an empire of laws, and not of men; being the most excellent plan of limited monarchy in the world.

Governments are commonly divided into two classes, arbitrary and free governments; but there are many differed sorts of each. Thus the governments of France and Spain are generally called arbitrary; tho' they differ as much from the governments of Turkey and other eastern empires, where absolute despotism prevails, as they do from the government of England, and other European nations, where liberty is said to flourish in its fullest perfection.

**GOVERNMENT** is also a post or office which gives a person the power or right to govern or rule over a place, a city, or province, either supremely or by deputation.

**GOVERNMENT** is also used for the city, country, or place to which the power of governing is extended.

**GOURD**, in botany. See **CUCURBITA**.

**GOUT**, in medicine. See **MEDICINE**.

**GRABOW**, or **GRUBOW**, a town of Lower Saxony and duchy of Mecklenburg: E. long.  $11^{\circ} 36'$ , N. lat.  $53^{\circ} 32'$ .

**GRACE**, among divines, is taken, 1st, For the free love and favour of God, which is the spring and source of all the benefits which we receive from him. 2dly, For the work of the spirit, renewing the soul after the image of God, and continually guiding and strengthening the

believer to obey his will, to resist and mortify sin, and to overcome it.

**GRACE**, in geography, a city of Provence, in France, fifteen miles south-west of Nice: E. long.  $6^{\circ} 50'$ , N. lat.  $43^{\circ} 40'$ .

**Act of GRACE**, the appellation given to the act of parliament 1696, c. 32. which allows prisoners for civil debts to be set at liberty, upon making oath, that they have not wherewithal to support themselves in prison, unless they are alimanted by the creditors upon whose diligences they were imprisoned, within ten days after intimation made for that purpose. See **SCOTS LAW**, tit. 32.

**Days of GRACE**, three days immediately following the term of payment of a bill, within which the creditor must protest it, if payment is not obtained, in order to intitle him to recourse against the drawer. See **SCOTS LAW**, tit. 21.

**GRACE** is also a title of dignity given to dukes, archbishops, and in Germany to barons and other inferior princes.

**GRACES**, in heathen mythology, three goddesses, whose names were Agla, Thalia, and Euphrosyne; that is, shining, flourishing, and gay; or, according to some authors, Pasithee, Euphrosyne, and Ægiale. Some make them the daughters of Jupiter, and Eurynome, or Eunomia, the daughter of Oceanus; but the most common opinion is, that they were the daughters of Bacchus and Venus.

They are sometimes represented dressed, but more frequently naked; to shew, perhaps, that whatever is truly graceful, is so in itself, without the aid of exterior ornaments. They presided over mutual kindness and acknowledgment; bestowed liberality, eloquence, and wisdom, together with a good grace, gaiety of disposition, and easiness of manners.

**GRACULA**, in ornithology, a genus belonging to the order of picæ. The bill is convex, cultrated, and bare at the point; the tongue is not cloven, but is fleshy and sharpish; it has three toes before, and one behind. There are eight species, principally distinguished by their colour.

**GRACULUS**, in ornithology. See **CORVUS**.

**GRADATION**, in general, the ascending step by step, or in a regular and uniform manner.

**GRADISKA**, a city of Sclavonia, situated on the river Save, twenty-five miles west of Posega: E. long.  $18^{\circ}$ , N. lat.  $45^{\circ} 33'$ .

**GRADUATE**, a person who has taken a degree in the university. See **DEGREE**.

**GRAFT**, or **GRAFF**, in gardening, a cion or shoot of a tree inserted into another, so as to make it yield fruit of the same nature with that of the tree from whence the graft was taken. See **GARDENING**.

**GRAIES**, a market-town of Essex, situated on the river Thames, sixteen miles east of London.

**GRAIN**, all sorts of corn, as wheat, barley, oats, rye, &c. See **CORN**, **WHEAT**, &c.

**GRAMMAR**.

# G R A M M A R.

**G**RAMMAR is the art of speaking or of writing any language with propriety.

Grammar considered as an *Art*, necessarily supposes the previous existence of language; and as its design is to teach any language to those who are ignorant of it, it must be adapted to the genius of that particular language of which it treats.—A just method of grammar, therefore, supposing a language introduced by custom, without attempting any alterations in it, furnishes certain observations called rules, to which the methods of speaking used in this language may be reduced; this collection of rules is what is called a grammar of any particular language. For the greater distinctness with regard to these rules, grammarians have usually divided this subject into four distinct heads, *viz.* ORTHOGRAPHY, or the art of combining letters into syllables, and syllables into words; ETYMOLOGY, or the art of deducing one

word from another, and the various modifications by which the sense of any one word can be diversified; SYNTAX, or what relates to the construction or due disposition of the words of a language into sentences or phrases; and PROSODY, or that which treats of the quantities and accents of syllables, and the art of making verses.

But grammar considered as a *Science*, views language in itself: neglecting particular modifications, or the analogy which words may bear to each other, it examines the analogy and relation between words and things; distinguishes between those particulars which are *essential* to language, and those which are only *accidental*; and thus furnishes a certain standard by which different languages may be compared, and their several excellencies or defects pointed out. This is what is called PHILOSOPHIC or UNIVERSAL GRAMMAR.

## OF UNIVERSAL GRAMMAR.

**I**T is not necessary here to inquire how language was originally invented, to trace the various changes it may have undergone, or to examine whether any one language may be considered as the original from which all others have been derived: it is sufficient for our purpose to observe, that all mankind, however diversified in other respects, agree in the common use of language; from which it appears, that language is not merely accidental and arbitrary, but founded in the nature of things, and within the reach of all mankind. It is therefore an object worthy of a philosophic inquiry to discover the foundations upon which this universal fabric has been raised.

The design of speech is to publish to others the thoughts and perceptions of our mind. The most acute feelings of man, as well as of every other animal, are expressed by simple inarticulate sounds, which, as they tend to the preservation of the individual, are universally understood. These inarticulate but significant sounds, therefore, constitute a natural and universal language, which man, as a mere sensitive being, partakes in common with the other animals. But as man is not only endowed with sensation, but with the faculty of reasoning, simple inarticulate sounds are insufficient for expressing all the various modifications of thought, or for communicating to others a chain of argumentation: it was therefore necessary to call in the aid of *articulation*; which by modifying these simple sounds, and by fixing a particular meaning to these modifications, forms the language peculiar to man, and which distinguishes him from all other animals, and enables him to communicate with facility all that diversity of ideas with which his mind is stored. These sounds, thus modified and having a determinate meaning, are called **WORDS**; and as all language is composed of significant words variously combined, a knowledge of them is necessary previous to our acquiring an adequate idea of language.

But, as it is by words that we express the various ideas which occur to the mind, it is necessary to examine how ideas themselves are suggested, before we can ascertain the various classes into which words may be distributed. With this view, therefore, let us suppose a reasonable being, devoid of every prepossession whatever, placed upon this globe. His attention would, in the first place, be directed to the various objects which he saw existing around him: these he would naturally endeavour to distinguish from one another, and give them names, by means of which the idea of them might be recalled when the objects themselves were absent. This is one copious source of words, and forms a natural class which must be common to every language; and which is distinguished by the name of **NOUNS**. And as these nouns are the names of the several substances which exist, they have likewise been called **SUBSTANTIVES**.

It would likewise be early discovered, that every one of these substances were endowed with certain qualities or attributes, to express which another class of words would be requisite. Thus, *to be weighty*, is a quality of matter; *to think*, is an attribute of man. Therefore, in every language, words have been invented to express the various qualities of the several objects which exist. These may all be comprehended under the general denomination of **ATTRIBUTIVES**.

These two classes of words must comprehend all things that exist; for whatever exists, must of necessity be either a substance, or the attribute of some substance; and hence these two classes must comprehend all those words which are significant of themselves, and may be called **WORDS SIGNIFICANT OF THEMSELVES**. If any other words occur, they can only be significant in so far as they tend to explain or connect the words of the two former classes.

But, although these words form the basis or matter of a language, in the same manner as stones form the matter

of a building; yet, as stones cannot be arranged into a regular structure without a cement to bind and connect them, so these original words stand in need of others to connect them, before they can be made to express all the variety of our ideas. Another order of words, therefore, were necessary, which, although not of themselves significant, yet, when joined with others, might acquire a meaning. These form a second general class of words that may be called **WORDS NOT OF THEMSELVES SIGNIFICANT**, and which cannot acquire any meaning but so far as they serve either to **EXPLAIN** or **CONNECT** the others.

Hence, therefore, all words which can possibly be invented, may be divided into two general classes; those that are **SIGNIFICANT OF THEMSELVES**, and those that are **NOT**. Words which are significant of themselves, are either expressive of the names of substances, and therefore called **SUBSTANTIVES**; or, of qualities, which we call **ATTRIBUTIVES**. Words which are not significant of themselves, must acquire a meaning either as defining or connecting others, which we shall arrange under the two classes of **DEFINITIVES** and **CONNECTIVES**, each of which shall be examined in their order.

## CHAPTER I. OF SUBSTANTIVES.

**SUBSTANTIVES** may be divided into two classes, *viz.* those which are primary, commonly called **NOUNS**; and those of a secondary order, which are often substituted for nouns, and are hence called **PRONOUNS**: each of which we shall consider separately.

### Section I. Of Substantives of the First Order, called **NOUNS**.

**NOUNS** are all those words by which objects or substances are denominated, and which distinguish them from one another, by names applicable to each, without marking either quantity, quality, action, or relation. And as all the objects which exist must be either in the same state that they were produced by *nature*, or changed from their original state by *art*, or *abstracted* from substances by the powers of imagination, this naturally suggests a division of nouns into **NATURAL**, as *man, vegetable, tree, &c.*; **ARTIFICIAL**, as *house, ship, watch, &c.*; or **ABSTRACT**, as *whiteness, temperance, &c.*

But the diversity of objects being so great as to render it impossible for any person to know the distinct names of every individual, therefore it has been found expedient to arrange them under certain general classes, the names of which may be more easily acquired, so that by referring any unknown object to the class to which it belongs, we in some measure supply the want of proper names. Hence, therefore, each of the above species of nouns are divided into those which denote genera, species, and individuals. Thus, in natural substances, *animal, vegetable, and fessile*, denote genera; *man, dog, tree, metal*, are species; and *Alexander, Cæsar, oak, gold*,

VOL. II. N° 57.

are individuals. In artificial substances, *edifice* is a genus; *house, tower, church*, are species; and the *Vatican, Tron-church, and Herriot's hospital*, are individuals. In *abstract* substances, *motion* is a genus; *flight, and course*, are species; the *flight of Mahomet, the course of a greyhound*, are individuals. Each of these general classes might be subdivided into many smaller; but as these lesser divisions can only relate to the particular genius of different languages, it does not fall within our plan to consider them. We therefore proceed to take notice of the accidents which accompany nouns. Of which kind may be reckoned *number* and *gender*.

As nouns are the names of substances, and as there may be many substances of the same kind, therefore nouns must be adapted to express whether there is one or more of those objects of which we speak. Nouns, therefore, in every language, admit of a certain variation to denote this circumstance, which is called *number*. Thus, in the English language, when we speak of a single place of habitation, we call it a *house*; but if of more, we call them *houses*. In the first of these cases the noun is said to be in the *singular*, and in the last case, the *plural* number: nor does the English, or any other language except the Greek, admit of any other variation but these two: and although the Greek language admits of a particular variation of the noun called the *dual* number, which is a plural limited to two objects; yet this cannot be considered as to language; and it is perhaps doubtful whether this variation ought to be considered as an elegance or a defect in that language.

But although number be a natural accident of nouns, it can only be considered as essential to those which denote genera or species, as it does not descend to individuals. Thus we say, *animal, or animals, vegetables, and fessils*; as also, *man, or men, dogs, trees, &c.* But we only say, *Xenophon, Cæsar, Rucephalus, &c.* in the singular. Nor do these admit of a plural, excepting when we consider any proper name, as a general appellation under which many others are arranged, when it is no longer the name of an individual, but that of a species, and as such admits of a plural; as the *Alexanders, the Ptolemies, the Howards, the Pelhams, the Montagues, &c.* The reason of all which will be obvious, if we consider, that every genus may be found whole and entire in each of its *species*; for *man, horse, and dog*, are each of them an entire and complete *animal*: and every species may be found whole and entire in each of its individuals; for *Socrates, Plato, and Xenophon*, are each of them completely and entirely a *man*. Hence it is, that every *genus*, though **ONE**, is multiplied into **MANY**; and every *species*, though **ONE**, is also multiplied into **MANY**, by reference to those beings which are their *subordinates*: But as *no individual has any such subordinates*, it can never in strictness be considered as **MANY**, and so is truly an **INDIVIDUAL** as well in *nature* as in *name*, and therefore cannot admit of number.

Besides number, another accident of nouns is *gender*, the nature of which may be thus explained: As nouns are the names of the various objects in nature; and as the distinctions of sex is perceptible among all those objects which are animated; and as those which are inanimate

† 7 X

cannot

cannot admit of any sex at all; therefore all the beings which can become the objects of our speculation, may be considered as either *males*, or *females*, or such as admit of *no* sex, and therefore may be said to be neuter, or of *neither* sex. Hence, therefore, grammarians have made a threefold distinction of nouns, into *masculine genders*, or those which denote *males*; *feminine*, or those which denote *females*; and *neuters*, which denote those substances that admit of no sex. But, although the origin of genders is thus so clear and obvious; yet every language that we know of, except the English, deviates from the order of nature, and often attributes sex to those substances which are totally incapable of any; nay, some languages are so particularly defective in this respect, as to class every object inanimate as well as animate under either the *masculine* or *feminine genders*, as they admit of no gender for those that are of neither sex. This is the case with the French, Italian, and Spanish. But the English, strictly following the order of nature, puts every noun which denotes a male animal, and no others, in the *masculine* gender; every name of a female animal, in the *feminine*; and every animal whose sex is not obvious, or known, as well as every inanimate object whatever, in the *neuter* gender. Nor does this rule admit of any exceptions; although poets take the liberty of personifying any objects they think proper, and endow them with whatever sex suits their purpose best; which serves admirably to distinguish between the cool language of philosophy, and the enthusiasm of poetry.

Although *Cases* are not necessary accidents of nouns; yet as they have been often considered as such, it will perhaps be deemed proper to take some notice of them:—As natural objects remain the same, although viewed from many different points of view, they are not in their own nature altered, although they may be connected with others in many different ways: their names therefore ought to remain unchanged, although their relations to other words may be varied. However, there are certain circumstances in which nouns may be considered with respect to their relation *to*, and connection *with* other words, which occur more frequently than others. Some languages, (particularly the Greek and Latin) express *some* of these circumstances, by a variation of the original noun, which variations are called *CASES*. But the English, and almost all the modern languages of Europe, have followed the order of nature, and allow the noun to remain the same, expressing its relation and connection with other words by the help of distinct words called *prepositions*.—Which of these methods is best, it is not our present purpose to inquire. See LANGUAGE.

It has been supposed the English nouns admit of one variation which answers to the genitive case of the Latins.—Thus the word *Alexander* is an English noun in its proper form, and in that case which in Latin would be called the *Nominative*. The variation which they called the *Genitive Case*, is expressed in English by adding the preposition *of* before the noun; thus, *of Alexander*. But the same meaning may be conveyed by the word *Alexander's*; for the meaning is the same if I say the house of *Alexander*, or *Alexander's* house. This, therefore, has been called a true inflection of the original noun. How-

ever, although this opinion has been adopted by all grammarians, it appears to have been adopted without sufficient examination, as will be evident from the following considerations.

There are certain circumstances in which this supposed genitive cannot be substituted instead of the other: for I may say, I speak of *Alexander*. I write of *Cæsar*, I think of *Pompey*; but I cannot say, I speak *Alexander's*, I write *Cæsar's*; or I think *Pompey's*. Hence these two are not in all cases synonymous terms; and therefore one of them must be considered as only accidentally coinciding with the other in particular circumstances.

Again, every one of these supposed genitives can with propriety assume all the various signs of the different *Cases* in the English language: for we may say simply, as in the nominative case, *Alexander's* house; but we can also say, *of Alexander's* house, *to*, *with*, *from*, *in*, *by*, or *for Alexander's* house, &c. If this then be a real genitive, it requires the sign of the genitive, as well as of the other cases, to explain it; which would be an absurdity too great to be admitted.—But it may be asked, if these are not genitives, to what class of words can they be referred?

In answer to this, it has been already observed, that the variety of substances is so great, that it is impossible for any person to know the names of every one of them; and therefore they have been arranged under the several orders of genera and species. We now further observe, that as the individuals are so exceedingly numerous, it would be impossible even to invent proper names for each, and far less would it be possible to make these names be known to every person who might accidentally see them: therefore when we want to ascertain any individual object, and distinguish it from all the other individuals of the same species, we are obliged to have recourse to particular epithets, or definitives, to ascertain that individual.—Thus, I see a particular house which I want to distinguish from other houses; this has no particular name of its own; I must therefore ascertain it in the best manner I can; and as the shortest is always the best, we most naturally denominate it from its owner or possessor if we know him, and therefore call it *Alexander's*, *James's*, or *John's* house.—Here then we see, that the words *Alexander's*, *James's*, and *John's*, do not stand as nouns, but as *articles* or *definitives* serving to ascertain and point out the individuality of the noun with which they are joined, and are much nearer allied to adjectives than to substantives. These, therefore, like other articles, do not alter the case of the noun; so that the term *Alexander's* house, is as much the proper name of a particular house, as *Alexander* or *James* are the proper names of particular men, and of consequence may be varied thro' the different cases as well as the other.—It is surprising, that this idea never occurred to grammarians; for *St Peter's* at Rome, and *St Paul's* at London, are as truly the proper names of these two noble edifices, as the *Academy* or the *Circus* are the proper names of two other structures.—We may therefore safely conclude, that the English language admits of no cases at all, and that the only essential accidents of nouns are gender and number.

## Section II. Of Substantives of the Second Order, called PRONOUNS.

All conversation passes between individuals. When these individuals are unknown to each other, how shall the one speaker address the other, when he knows not his name; or how explain himself by his own name, of which the other is wholly ignorant? This might perhaps have been at first effected by pointing; but as this method behoved to be extremely inconvenient and defective, it was necessary that a particular class of words should be invented for this purpose; and as these words always supply the place of a noun, they have been called PRONOUNS;—the nature of which may be explained as follows.

Suppose the parties conversing to be wholly unacquainted, and the subject of the conversation to be the speaker himself: here, to supply the place of pointing, the inventors of language have furnished the speaker with the pronoun *I*; *I write*, *I desire*; and as the speaker is always principal with respect to his own discourse, they have therefore called this the *pronoun* of the FIRST person.

Again, suppose the subject of the conversation to be the party addressed: here, for similar reasons, they invented the pronoun *thou*, *thou writest*, *thou walkest*; and as the party addressed is next in dignity to the speaker, or at least comes next with reference to the discourse, they therefore called this the *pronoun* of the SECOND person.

But as the subject of the conversation may be some third object different from either the speaker or the party addressed, another pronoun was necessary; and as this object might be either a *male* or a *female*, or a *neuter*, it was necessary to have one pronoun for each of the genders, *he* for the *masculine*, *she* for the *feminine*, and *it* for the *neuter*: and this, in distinction to the former, was called the *pronoun* of the THIRD person.—Hence the distribution of pronouns into *persons*.

We have already seen that nouns admit of number; pronouns, which are their substitutes, likewise admit of number. There may be many speakers of the same sentiment, as well as one who including himself speaks the same sentiment with *many*; speech may likewise be addressed to *many* at a time as well as to *one*; and the subject of the discourse may likewise be *many*; therefore the pronoun of every one of the *persons* must admit of number, to express this singularity or plurality. Hence, therefore, the pronoun of the first person *I*, has the plural *we*; that of the second person *thou*, has the plural *you*; and that of the third person *he*, *she*, or *it*, has the plural *they*, which is equally applied to all the three genders.

With regard to gender, we do not find in any language that the pronouns of the *First* or *Second* persons admit of any distinction in this respect: nor was it necessary that they should; as the speaker and party addressed are usually present with one another, this distinction is generally obvious from dress and external appearance. But this is not the case with regard to the pronoun of the *Third* person; of whose character and distinctions we often know no more than what we learn from the discourse itself; and hence it is, that in almost all languages the pronoun of the third person admits of genders, as we have already seen the English admits of the triple distinction of masculine, fe-

minine, and neuter.—The utility of which threefold distinction will be best shewn by an example. Supposing there was no such distinction, and that we should read in any history *he* caused *him* to destroy *him*, and were told that the pronoun which is here thrice repeated stood each time for something different; that is to say, for a man, for a woman, and for a city, whose names were Alexander, Thais, and Persepolis. Taking the pronoun thus divested of its genders, it does not appear which of the three was destroyed, which the destroyer, or which the cause that moved to the destruction. But there is no ambiguity when we hear the genders distinguished; and when, instead of the ambiguous sentence, *he* caused *him* to destroy *him*, we are told with the proper distinctions that *she* caused *him* to destroy *it*. Then we know with certainty, that the promoter was the *woman*, that her instrument was the *hero*, and that the subject of her cruelty was the unfortunate *city*—From this example we would be surprised how the *Italian*, *French* and *Spanish* could express themselves with precision or elegance, with no more than two variations of this person.

From the same causes as a distinction of gender is unnecessary in the pronouns of the first and second persons, we see the reason why a single pronoun to each person, an *I* for the first, and a *thou* for the second, are sufficient for all the purposes of language, as these are always supposed present and obvious. But it is not so with respect to the third person, as the various relations of different objects made it necessary to have not *one*, but *many*; such as, *he*, *she*, *it*, *this*, *that*, *other*, *some*, *all*, *any*, &c.

Although we have said that there is only one pronoun for each of the first and second persons, yet the English reader may perhaps be puzzled with finding two distinct words applied to each; *I* and *me*, for the first person; *thou* and *thee*, for the second. The learned reader will at once see that these two words *me* and *thee* are equivalent to the *accusative* case of the Latin pronoun: but, in order to make the meaning of this as plain as possible without embarrassing ourselves about unnecessary terms, we shall only observe, no effect can be produced without a cause, and no action can be performed without producing some effect. The same person may in different circumstances be either the active and efficient cause *of*, or the passive subject who suffers *by* an action: some languages have therefore formed different words to express the same object in these different circumstances. Thus in the Latin sentences, *Brutus amavit Cassium*, Brutus loved Cassius; and *Cassius amavit Brutum*, Cassius loved Brutus; the word *Brutus* in the first, and *Cassius* in the second, is the form which the noun assumes when it is used as the efficient cause; and *Brutum* and *Cassium* the forms which the same nouns assume when they are represented as the passive subjects. This last then was what was called the *accusative* case of the noun, and the first was called the *nominative*. We have already seen that the English noun admits of no cases, the active subject always preceding the verb, and the passive following it, as is plain from the above sentences, where *Brutus* and *Cassius* remain changed in both situations; and this same might be observed of all other modern languages.

yet

Yet the English and all modern languages admit of a different word to express the different state of the pronouns. Thus, we say, *I esteem* THEE, *I admire* HIM, *I love* HER: in all of which sentences *I*, the pronoun of the first person, is the *active*, and THEE of the second person, and HE and HER of the third, are the *passive* subjects, and are therefore expressed by the words THEE, HIM, and HER. But if the case be reversed, and the pronoun of the first person becomes the passive subject, and the others the active, they assume a different form; thus, THOU *esteemest*, HE *admires*, SHE *loves*—ME. Hence, therefore, it appears that we have two distinct words for each of these pronouns to express the different states in which they may be represented, exactly analogous to the nominative and accusative cases of the Romans—Whether these are to be admitted as cases of our pronouns, or whether they may not rather be considered as distinct words formed for that particular purpose, is of little consequence for us to enquire; as, in whatever light they may be considered, this variation cannot be looked upon as an essential part of language, but only as a particular refinement, invented to prevent the disagreeable repetition of the pronoun, which behaved frequently to have happened without this contrivance. This seems to be the only reason why pronouns have been endowed with this variety, and not nouns. For as nouns are in themselves greatly diversified, the sameness of sounds does not here so often occur as it would have done in the pronouns, where the same *I*, THOU, HE, SHE, or IT, answers for the name of every object which occurs in nature; but, by this diversity in the form of the words, this circumstance is in some measure obviated. And it is probably for the same reason, that the plural of each of these pronouns is so very different from the singular. Thus, from *I* of the first person is formed WE in the plural, and from ME the plural US; from THOU and THEE the plurals YE and YOU; from HE, SHE,—HIM, HER, and IT, the plurals THEY, and THEM. In all of which there is not the least resemblance between the singular and plural of any one word; and, except in HE and HIM, THEY and THEM, there is not any similarity between what may by some be thought to be the different cases of the same word.

We have seen that the same object may sometimes be the cause of an action, and sometimes the object which suffers by it. We now observe, that the same object may sometimes be, with regard to the same action, both the active cause and passive subject; as when we say, *Brutus killed himself*. In which case it is evident, that Brutus was both the cause that produced, and the object that suffered by the action; the pronoun himself being put for his name; for, were it not for the sameness of the sound, and the ambiguity which would be occasioned by it, we might surely say, *Brutus killed Brutus*. It was therefore necessary to have a particular pronoun for the passive subject, in all those cases where the same object was the agent; and on this account the word SELF has been invented, having the plural SELVES. This pronoun therefore, which serves on all occasions to represent the action as returning upon the agent that produced it, may be call-

ed the reciprocal pronoun; which has this peculiarity, that it can never stand by itself, but must always have the assistance of the pronoun in whose place it is substituted; as, MYSELF, THYSELF, HIMSELF, HERSELF, ITSELF, with their plurals. But although this seems to have been the original use of this pronoun; yet, in the English language, its use has been extended further; and, from its always having a reference to the agent of any action, it has been employed to denote that agent by way of emphasis, as performing the action without the aid or assistance of any other; as, *he himself went*. And from this circumstance it has been further extended to denote any object as performing or suffering any thing which we would not naturally have expected from its known character or nature; as in this sentence: "The most daring of mankind are sometimes startled before they venture upon the commission of any extraordinary crime; even Cæsar HIMSELF felt the utmost perturbation of mind before he dared to pass the Rubicon."

These are all that can be properly called *personal pronouns*; but there are others which are derived from them, called *possessive pronouns*, as, MY, THY, MINE, HIS, HERS, ITS, &c. the nature of which it will be necessary here to explain. We have already shewn how nouns, when they came to denote possession, were no longer to be considered as nouns, but rather as definitives or articles; so the pronouns which we here consider, being the real substitutes of *nominal* articles, ought also to be considered as a distinct class of pronominal articles; for as these never, in any case, can be substituted for a noun, they cannot be considered as pronouns. Grammarians have been led into the mistake of placing them under this head, because they are the substitutes of these words, which, altho' they assume the appearance of nouns, only perform the part of definitives. Thus we have seen, that when we say, *Alexander's house*; the word *Alexander's* can only be considered as a definitive: and, in the same manner, if Alexander was the speaker, he might say, *my house*; if the party addressed, it would be *thy house*; or if any third person, *his*, and in the same manner *hers* or *its house*. In all which cases this possessive pronoun is substituted for that word which only serves to define and ascertain the identity of the noun, and not for the noun itself, which must always be either expressed or understood. Hence the reason why one pronoun becomes the substitute of this noun and its proper definitive, whether that definitive appears in the form of a noun or pronoun: for I can say, "*Alexander's house* is more elegant than *Mary's*, or *his house* is more elegant than *hers*, although IT neither is so commodious nor agreeable to live in." In which example it is plain, that the words *his* and *hers* are strictly the substitutes only of *Alexander's* and *Mary's*, and nothing more; whereas the pronoun IT is the substitute of the whole noun with its definitive *Alexander's house*. The other class of pronouns possessive, MINE, THINE, &c. as they do not so much serve to distinguish individuals, as to ascertain the property of the thing spoken of, which may, in a certain sense, be considered as an attribute thereof, are more nearly allied to attributives, and have therefore by some been called adjectives. And

it must be acknowledged, that these two classes of words are so nearly allied to one another, that it is difficult to ascertain, in all cases, the precise boundary between them.

Besides these, there are other words which sometimes assume the province of pronouns, and are generally considered as belonging to this class, although in many cases improperly; such as, *THIS*, *THAT*, *ANY*, *SOME*, *THESE*, *THOSE*, *ALL*, and some others; which may be called *improper pronouns*. To distinguish when they may be considered as pronouns, we may observe, that when they stand by themselves, and supply the place of a noun, as when we say, *THIS is virtue*, give me *THAT*, then are they pronouns. But when they are associated to some noun, as when we say, *THIS HABIT is virtue*, or *THAT MAN defrauded me*; then, as they do not supply the place of a noun, but only serve to ascertain one, they fall rather under the species of *definitives*, or *articles*. And indeed it must be confessed, that these, as well as the possessive pronouns, are more properly adapted to define and ascertain individuals among nouns, than to supply their place; and therefore are oftener to be considered as articles than as pronouns. The best rule to distinguish when they are to be considered as the one or the other, is this. The genuine PRONOUN *always stands by itself*, assuming the power of a noun, and supplying its place. The genuine ARTICLE *never stands by itself*, but appears at all times associated to something else, requiring a noun for its support, as much as *attributives* or *adjectives*.

The three orders of pronouns already mentioned, may be called *prepositive*, because they are capable of introducing or leading a sentence, without having reference to any thing previous. But there is another order of pronouns which can never be employed but to connect sentences, and must therefore always have a reference to some sentence that precedes them; as, *WHO*; *WHICH*, *WHAT*. The nature of which may be explained as follows.

Suppose I say, *LIGHT is a body*; *LIGHT moves with great celerity*; these would apparently be two distinct sentences. But if, instead of the second *LIGHT*, I were to place the prepositive pronoun *IT*, and say, *LIGHT is a body*, *IT moves with great celerity*; the sentences would still be distinct, and two. But if I add a *connective* (as for example *AND*) saying, *LIGHT is a body*, *AND IT moves with great celerity*; I then, by connection, make the two into one. Now it is in the united powers of a *connective* and another pronoun, that we may see the force and character of the pronoun here treated of. For if, instead of the words *AND IT*, we substitute *THAT* or *WHICH*; saying, *LIGHT is a body WHICH moves with great celerity*; the sentence still retains its unity, and becomes, if possible, more compact than before. We may therefore call this pronoun the *subjunctive*; because it cannot introduce an original sentence, but only serves to *subjoin one to some other which is previous*.

The application of this *subjunctive*, like the other pronouns, is universal. It may be the substitute of all kinds of substantives, natural, artificial, or abstract; general, special, or particular: for we may say, *The man who*, *the ship which*; *Alexander who*, *virtue which*, &c. Nay,

it may even be the substitute of all the other pronouns, and is therefore of course expressive of all the three persons. Thus we say, *I who now write*; *thou who now readest*; *he who now hearst*, &c. And thus the *subjunctive* is truly a *pronoun* from its *substitution*; there being no substantive existing in whose place it may not stand. At the same time it is essentially distinguished from the other pronouns by this particular, that it is not only a *substitute*, but likewise a *connective* or.

As to the accidents of this pronoun: From its performing the part of a *connective*, it of course follows, that neither *gender* nor *number* can be considered as essential to it; because these are always expressed in the preceding parts of the sentence to which it refers; nor do we in fact find, that this pronoun, at least in modern languages, admits of any distinction to denote *number*, although the English language admits of one variation for the *gender*; as we employ *who* for the *masculine* and *feminine*, and *which* for the *neuter* gender, thus: *The man, or the woman who went to Rome*; *the tree which stands on yonder plain*, &c. It likewise admits of a variation similar to that of the accusative case; at least when applied to males or females. For when the object which it represents is the efficient cause of action, it is *who*; as, *the man who fell*, &c.; but when it is the passive subject, it then, in certain circumstances, takes the form of *whom*; as, *the man of whom I speak*; although this is not universal; as we likewise say, *the man who was beaten*. But the neuter admits of no such distinctions, as we equally say, *the tree which fell*, or *the tree of which I spoke*. But both of these admit of a variation to denote possession or qualities, which is the word *whose* for all genders. Thus, we say, *Socrates whose only study was virtue*; *Elizabeth whose reign was glorious*.

To conclude: We have seen that substantives are either *primary* or *secondary*; or, in other words, nouns or pronouns. The nouns denote substances, either *natural*, *artificial*, or *abstract*; and these either *general*, *special*, or *particular*. The pronouns, their substitutes, are either *prepositive* or *subjunctive*: the *prepositive* is distinguished into three orders, called the *first*, the *second*, and the *third* persons: the *subjunctive* includes the powers of all the three, having *superseded*, as of its own, the peculiar force of a *connective*.

## CHAPTER II. OF ATTRIBUTIVES.

As all attributives must either be expressive of the attributes of SUBSTANCES, or of other ATTRIBUTIVES, we divide this class into two kinds; calling those of the first kind, ATTRIBUTIVES of the FIRST ORDER; and those of the second kind, ATTRIBUTIVES of the SECOND ORDER.

### Section I. Attributives of the First Order.

Attributives are all those *principal* words that denote attributes considered as attributes. Such, for example,

are the words, *black, white, great, little, wise, eloquent, to write, to walk, to speak*, &c. all of which are the *attributes of substances*. Thus *black* is an attribute of *jett, white of snow*;—*wise and eloquent*, as also, *to write and speak*, are attributes of *men*.

In examining the different attributes of substances, we readily perceive that some of them have their essence in *motion*; such are, *to walk, to fly, to strike, to live, &c.* Others have it in the *privation of motion*; as, *to stop, to rest, to cease, to die, &c.* And others have it in subjects that have *nothing to do* with either *motion* or its *privation*; such are the attributes of *great and little, wise and foolish, white and black*, and, in a word, the several *quantities and qualities* of all things. This therefore furnishes a natural division of attributives of this order; and grammarians have called all those, whose essence consists in *motion* or its *privation*, **VERBS**; and all the others have been called **ADJECTIVES**; each of which we shall consider separately.

### I. OF VERBS.

**VERBS** are all those principal words which denote *attributes*, whose essence consists in *motion, or energies*, (for we chuse to make use of this last term, as it implies the exertions of the mind as well as those of the body), or their *privation*. This order of attributives differs from the other called *adjectives*; not only in the particular above-mentioned, but also because *adjectives* denote only qualities or quantities, which do not admit of any change of state; whereas the verbal attributives may be considered as in several different states, and therefore admit of several variations in the term employed to express these. It may, in the first place, be considered as a simple attribute or energy, without particularizing any circumstance relating to the state it may be in; as in the word *to write*. Or, in the second place, as these are all attributes which denote motions or energies, they may be represented as in the state of actual motion or exertion; as in the word *writing*. Or, lastly, the motion or energy may be finished, and its effect completed; as in the word *written*. Hence, therefore, every verb admits of a threefold variation in every language, in each of which languages they are distinguished by some particular names. Our grammarians have given the name of the **INFINITIVE MODE** to the original verb itself, and the other two variations of it are both distinguished by the name of **PARTICIPLES**; that variation which exhibits the verb in its state of energy being called the **PARTICIPLE PRESENT** or **ACTIVE**, and the other variation is called the **PARTICIPLE PERFECT** or **PAST**.

These variations of the verb are founded in the nature of things, and therefore must be found in every language under some form or other. As to the other supposed variations of verbs relating to person, number, time, &c. the slightest reflection on this subject will shew, that a verb, considered as a simple attributive, can admit of none of these affections, but must for ever remain the same at all times and in all situations whatever; for who does not see, that the attribute *to write* is the same whether

it is possessed by *you*, by *me*, or by any number of different persons? Nor does this attribute suffer any change, whether it is represented as having been exerted a *thousand years ago*, or at *this present moment*, or at *any other assignable period of duration*; but, like every other attribute, it must remain for ever the same. For however *substances* may vary with time, and be incessantly changing; yet *attributes* of every sort are altogether beyond its power. And we must easily perceive, that the attribute which is expressed by the word *good*, is the same now as it was at the creation, or will be while the world exists. And in the same manner, *to walk, to write, to fly*, denote attributes, which must each of them preserve their own particular nature during all the successive ages of time. Hence therefore we see, that the verbal attribute must for ever remain in that state, or modification, in which it is at first represented. Nor can it suffer any change, however different the circumstances may be in which it can be applied in language. All, therefore, that can be said of these several variations with which grammarians have usually endowed verbs, is this, That, as an attributive, it hath such an intimate connection with a substantive, as necessarily to be united with one, before it can make a principal figure in language: And as that union may be represented as taking place at different times, and under different circumstances, the inventors of some languages have contrived to express these different connections by a single word, instead of doing it by different words, as the thing in itself would naturally require; in the same manner as those who use the short-hand method of writing, make a single character express a whole word, or sentence: And as it was most natural for the contrivers of these words to derive them from the verb itself of which they are compounded, they have each of them become a *real* variation of the original *word* which expresses the verbal attribute; and, from thus being a variation of the verbal *word*, they have at last come to be considered as an *essential* variation of the *verb itself*, which has occasioned those contradictory definitions, and that confusion of ideas which we meet with among all writers on this subject. But as we here consider language as in itself, without regarding the particular forms under which it may appear, we must reject all these variations of *persons, numbers, modes, and tenses*, which the verb itself has usually been supposed to undergo; and consider them, not as essential variations of the verb itself, but as variations produced in language by the combination of the verb with other parts of speech; and therefore relating to *syntax*, and of course belonging to those grammatical disquisitions alone which treat of the peculiarities of any particular language. But as these variations have been so universally considered as essential parts of the verb itself, and as the terms which this division of the verb have introduced into grammar are so frequently to be met with, it will be necessary to explain in some measure the meaning of these several terms.

In the natural world, no attribute can possibly exist without a substance to which it belongs, nor any substance without possessing certain attributes. So necessary and intimate is the connection between these, that it is as impossible

impossible to separate them, as to create or annihilate the several substances that possess these attributes. But although we are thus circumscribed as to our bodily powers, the mind admits not of such limitation; but can with the utmost facility separate every quality from every object whatever, and consider them apart; as, *colour* without *superficies*, *superficies* without *solidity*, or *weight* without *matter*, &c. and, when thus separated, apply them to what objects, and in what manner, it pleases. In this manner the mind abstracts those attributes which denote *motions* or *energies* from their *agents* or *energizers*, in the same way as it abstracts *qualities* from their *substances*. And it is these energies thus abstracted, which form that species of words called *verbs*; in the same manner as those attributes which denote *quantities* and *qualities* abstracted from their necessary substances, form *adjectives*. Thus, the term *to walk*, denotes a particular *energy* as considered perfectly apart from every *energizer*, in the same manner as the word *good* denotes a certain *quality* without regard to any particular *substance*.

Here then we discover a most essential difference between the order of nature, and that representation of it which man makes by means of words. For in *nature*, every quality must at all times be united with some substance, nor can ever be exhibited separate from it; but in *language*, every attributive, if it be considered at all, must be separated from the object to which it naturally belongs. Hence we see the reason why, in language, every *energy* and *energizer*, not only *may* be considered separately, but *must* for ever remain separate, unless they be united by some other power than what is necessarily their own. For the attribute *to write*, can no more be united to *man* its proper energizer, than a motion could commence without a cause; and till this attribute is united to its proper energizer, it must remain in a great measure dead and inefficacious in language.—To communicate life and energy, therefore, to this inert attribute, it must be united to its proper energizer; which can only be effected by the help of an assertion of the speaker himself; which may be considered as the same with regard to language, as life is in the natural world.

It is evident that, by the assistance of an assertion, the speaker is enabled to write any energy to any particular energizer, and thus, without making any change upon the attribute itself, represent a variety of changes produced upon other bodies by its means.—Thus, if I say, *I write*, what do I more than assert that I myself am possessed of that particular attribute denoted by the verb *to write*? If I say, *You write*, or *He writes*, what do I more than assert that another person is possessed of that particular attribute or energy?—If I say, *He did write*, I only assert that the same attribute was possessed at another time, by the same person, as before. Hence therefore, by the help of this assertion of the speaker, we are enabled to join this particular attribute to many different energizers, as well as to represent these different combinations as occurring at many different times; so that the same attribute may thus be made to appear under a great many different circumstances, and exhibit a great variety of changes upon other objects, although itself remains unchanged; the several variations

which we perceive, only relating to the objects with which it is combined, or the means by which that union is effected.—In the same manner it often happens, that any object in nature, a house for example, may appear extremely different when viewed from different situations.

From the intimate connection that takes place between the energy, the energizer, the assertion, and time, these several accessories have been considered as essential parts of the verb; and therefore some grammarians have defined a verb to be *A word denoting an energy, with time, and an assertion*. But if we were thus to confound things with those which may necessarily accompany them, we could never arrive at a clear perception of any subject whatever. But not to enter into the arguments that might be produced to shew the impropriety of this definition, we shall only observe, that by the universal acknowledgment of all grammarians this cannot be just. For they unanimously agree, that the *infinitive mode* is not only a *part* of every verb, but the *most essential part*; as it forms the root from which all the other parts are derived. But as this mode neither denotes either time or an assertion, it is evident that these, even by their own acknowledgment, can be at best but accessories, and not essential parts of the verb.

From these arguments, therefore, we must conclude, that the verb itself admits of no other variations but those already taken notice of;—that before it can produce any active effect in language, like every other attribute, it must be united to some proper energizer;—that this union in language can never be effected but by means of an exertion of the vital powers of the speaker, whereby he either publishes his perception thereof, or his will that it should be;—and that this union may be represented as taking place at all the different times that can be assigned. These, therefore, are each of them necessary accompaniments of a verb, but each of them separate and distinct in their own nature, not only from this verb, but from one another; and it becomes an essential part of the syntax of every language, to consider the various ways in which these can be combined and affect one another.—Nay, so intimate has this connection been thought to be by some, that the contrivers of certain languages have arranged them under particular classes, for the sake of distinctness and precision.—The form which a verb assumed, when thus varied in all the ways that their particular language would admit of, was called the CONJUGATION of the verb; the several parts of which may be understood from the following sketch.

When the verb is considered under the compound form of which we now speak, it can admit of variations chiefly in three respects. For, first, supposing the *attribute*, the *energizer*, and the *time* when that attribute was exerted by the energizer, to be the same; a variation may be occasioned by a change being produced in the *perception* or *volition* of the speaker, (which, for brevity, we will call the *assertion*;) as in these examples: *I write*, *SCRIBO*; *I may write*, *SCRIBAM*; *do you write*, *SCRIBES*. The variations produced by this means have been called *MODES*. Secondly, Supposing the *attribute*, the *energizer*, and the *assertion*, to be the same; a change may be produced in the *time*, as in these examples: *I do*  
*write*,

*write*, SCRIBO; *I did write*, SCRIPSI; *I shall write*, SCRIBAM, &c. The variations produced from this cause have been called TENSES. And, thirdly, Supposing the attribute, the time, and the assertion, to remain unchanged, there may be a difference in the energizer; and this likewise admits of a division: for as the energizer may be only one or more persons, it must have a variation into singular and plural on these accounts; as in these examples: *I write*, SCRIBO; *thou writest*, SCRIBAS; *he writes*, SCRIBAT; and in the plural, *we write*, SCRIBAMUS; *ye write*, SCRIBATIS; *they write*, SCRIBANT. The variations produced from this cause have been called PERSON and NUMBER.—These are all the variations which have been made in the Latin or Greek languages; and therefore our grammarians, who have adopted every idea they have of grammar from these languages, mention no more: but it was not necessary that they should have stopped here, for an attribute is surely as susceptible of the distinction of sex as of person, so that they might have had a variation for Gender also; and instead of having one word SCRIBAT to answer for all the three genders, *he, she, or it wrote*, they might have had three different words.—The composers of the Hebrew language have adopted this plan, and admit of two variations on this account; and the Russian language admits of a like variation in their verb for these genders; as in this example: ON ZOMELAL, *he has done*; ONA ZOMELALA, *she has done*, &c. But as the two languages above mentioned do not admit of this distinction, therefore all the variations that our verbs are said to admit of are MODES, which include within them TENSES, which include under them PERSONS, under which head is included NUMBER; and these are all the parts into which a CONJUGATION has been divided.—As to what concerns the nature and lesser distinctions of each of these, the following general remarks may be sufficient.

With regard to MODES; as this relates solely to the perception or volition of the speaker, it necessarily follows, that there ought to be a distinct and particular mood for each diversity that there can be in his manner of perceiving or willing any thing whatever, the principal of which are the following.

If we simply declare that we perceive any object, or that such a thing is or will be, without any limitation or contingency, it forms what has been called the DECLARATIVE or INDICATIVE MODE; as, *I write*—Again, if we simply represent it to be within our power, or to depend upon our choice, it forms two other modes, which may be called the POTENTIAL, as, *I can write*; or the ELECTIVE, as, *I may write*—In the same manner, if the speaker represents himself, or any other object, as determined to perform any action, or as compelled to it, or as it is his duty to perform it; these form so many distinct modes, which may be called the DETERMINATIVE, as, *I will write*; the COMPULSIVE, as, *I must write*; and OBLIGATIVE, as, *I should write*. But although each of these represents the speaker as perceiving the agent under a different light with respect to the action; yet as all of them, except the indicative, agree in this, that however much they may represent it as the duty or inclination, &c. of the agent to perform any action

with which they are associated, yet as they are still of the nature of contingents which may never take effect, they are frequently subjoined to any other verb; therefore the Latins have comprehended all of these under one mode, which they have called the SUBJUNCTIVE. We only take notice of this circumstance here, to shew, that however naturally sentences may be distinguished into modes, according to the different situation of the speaker; yet as the whole order of the variation of words in the conjugation of a verb is merely arbitrary, those who invent them may arrange them into what order they please, and call them by what names they may think most proper. But however they may vary the names or external arrangement, this does not affect the things themselves. For by whatever name the mode may be known which comprehends the words expressive of these several meanings, the sentences formed by these will be either *potential, obligative, compulsive*, &c. as above explained.

All these modes above mentioned only relate to the different perceptions of the speaker. But as man is not only endowed with the powers of perception, but those of volition also, he must have words to express these; which forms another order of modes. As he is not only dependent himself, but has others depending upon him, he may command, intreat, beg, pray, wish, inquire.—Hence, therefore, so many different orders of modes, the IMPERATIVE, REQUISITIVE, PRÉCATIVE, OPTATIVE, INTERROGATIVE, &c. to which may be added the VOCATIVE. But although each of these display a distinct affection of the speaker, yet grammarians have allotted only one variation of their verb for all of these purposes, called the IMPERATIVE MODE; all the other volitions being expressed by this, or some other modes, by the help of particular contrivances, which are different in different languages.

With regard to that variation of the verb which relates to time, called TENSES: As an action or event may be represented as happening at any assignable period of time, it is necessary to divide that duration into certain parts, that we may be able to represent the different relations which events bear to one another with respect to this particular. The first and most obvious division of time is into *present, past, and future*. But we may go farther still in our divisions of time. For as time past and future may be infinitely extended, we may in *universal time past* assume many particular times past, and in *universal time future* many particular times future, some more, some less remote, and corresponding to each other under different relations. Even *present time*, however, in strict physical truth, it may be incapable of it, is by the power of the imagination brought to admit of these differences, and as necessarily implies some degree of extension, as every given line however minute: And hence it is not sufficient for language to denote INDEFINITELY mere *past, present, or future* times; but on many occasions to DEFINE with more precision what kind of *past, present, or future* is meant.

Tenses, therefore, or those variations of a verb which denote a difference of time only, may be all divided into PRESENT, PAST, and FUTURE; each of which may be subdivided into DEFINITE and INDEFINITE. The

*definite tenses* are those where the particular instant of time, whether present, past, or future, is pointed out. The *indefinite* are those where past, present, or future time is indicated in general, without confining it to a particular instant in either of these cases. These have been distinguished among grammarians by the name of **AORISTS**.—Thus when Milton makes Adam say,

*Millions of spiritual creatures walk the earth,  
Unseen, both when we wake and when we sleep,*

the verb **WALK** means not that they were walking at that instant only when Adam spoke, but *indefinitely* in any instant whatever. So likewise, when the same author calls hypocrisy,

— *the only evil which WALKS  
Invisible except to God alone.*

the verb **WALKS** has the like aoristical signification. *He went, he fell*, are *aorists* of the past, as they do not specify any particular instant, but refer to past time in general. So likewise in the legislative sentences, *thou shalt not kill, thou shalt not steal, &c.* the same aoristical meaning is perceived, as the prohibition does not relate to any particular time future, but is extended indefinitely to every time future.

But it is not sufficient for a language to denote time in this indefinite manner: it is necessary likewise that it should be capable of specifying any particular instant of time in an exact and definite manner. Thus, if, instead of the word **WALK** in the first sentence above quoted, we were to put **ARE WALKING**, it brings down the verb to denote a particular time, and specifies that these *spiritual creatures* are, at that very instant in which Adam speaks, walking upon the earth unseen. In like manner, in the second sentence, if the word **WALKS** were changed to **IS WALKING**, it denotes, that hypocrisy, at that particular instant in which the sentence was pronounced, was walking invisible upon the earth. And in the same manner, **WAS WALKING, OR WILL BE WALKING**, each of them denote, that these energies *were* or *will be* exerted at a particular specified time. These, therefore, form so many distinct definite tenses, under whatever technical name these may be known.

Here then we see the use of that distinction of the different states of the verb, into the *verb properly so called*, and *participles*. For as the verb itself exhibits the word as altogether *indefinite*; when this is joined to its proper energizer, it forms all these **INDEFINITE TENSES** which our language requires. Thus, *I write, I did write, I will write, I may write, I can write, &c.* each of them, although they represent the attribute as united to the energizer in some *past, present, or future* time, do not specify any particular instant, and are therefore so many aorists or indefinite tenses. Whereas in the *participle* the attribute is represented as in a state of exertion, it necessarily follows, that if it be ever united to its energizer, it must point out the particular instant when that union took effect, and of consequence form as great a variety of **DEFINITE TENSES** as the verb forms of indefinite. Thus, *I am writing*, necessarily implies that I am actually exerting this particular energy at the very instant that I declare it. So likewise if I say *I was writing*, it indicates, that at one particular instant of past duration, to which this has a reference, I was actu-

ally employed in that particular occupation. This instant is generally fixed by some collateral circumstance; as, "upon the twentieth day of August last, at 12 o'clock, *I was writing*;" or, "when the thunder broke upon the tower in my neighbourhood, *I was writing*," &c. And the same may be said of future time; as, "to-morrow at ten o'clock *I shall be writing*," &c. In all of which cases it is obvious, that a particular *new* or *instant* is pointed out, in which the attribute is represented as united to its proper energizer. We might here proceed to shew the various times that each of these different states of the verb might be made to indicate; the number of *tenses* that each mode admitted of; the several changes that might be produced by joining the *participle perfect* with any object; which cannot be here called the *energizer*, but the *subject*; for as the energy is by this participle represented as completed, if it has any connection with any person, as the attribute cannot be affected by any energizer after it is completed, it must of necessity affect the person, instead of being affected by it; and hence it is that the several variations produced by this participle perfect have been called the **PASSIVE VOICE** of the verb. But as all these particulars only relate to the construction of one particular language, it would lead us a great deal too far from the particular subject of which this article treats. We shall therefore only observe, that besides the above variations of the verb, which the Greeks and Romans have thought proper to make, the terms of which we have adopted; there are many others that they might with equal propriety have made, but which they rather chose to express by the help of other words called *adverbs*. But some other languages have gone further in this respect, and endowed their verbal word with several variations to express several other circumstances than they do. This is particularly the case with the Hebrew language, which, besides the variation for gender above mentioned, has allotted certain other variations of its verb to express several other circumstances. Thus, **PAKAD** in that language signifies *he visited*; **PAKEDA**, *she visited*, &c. **PIKED**, *he visited diligently*; **HEPKED**, *he made him visit*; and **HETHPEKED**, *he visited himself*. In this manner is every verb in that language varied; and each of these different conjugations of their verb admits of a particular variation for the passive of each—Hence, therefore, the conjugation of a verb in that language admits of a great many variations which neither the Greeks nor Romans were acquainted with: for besides the distinctions of *modes, tenses, persons*, and *number*, they have divided their verb into so many distinct divisions to answer for these distinctions above mentioned, which they have denominated **KAL, PIHEL, NIPHAL, and HITHPAHEL**, with their passives **NIPHAL, PUHAL, and HOPHAL**; each of which admits of variations through all the *modes, tenses, persons, numbers, and genders* which any of their verbs admit of.

The only use which we meant to make of these observations on the Hebrew verbs, is this: That as the authors, who have formed their idea of grammar from the forms which the several parts of speech admit of in the Greek and Latin languages, have supposed that every variation which these languages admitted of was a natural and necessary part of language; and that therefore every language which did not admit of the same number of variations,

tions with theirs in every part of speech, was in so far defective and incomplete. So, for the same reason, an author who had formed his idea of grammar upon the model of the Hebrew tongue, would as naturally suppose, that the several variations which the verb admitted of in his own favourite language, were essential and necessary; and that, of consequence, every language which did not admit of as many variations was imperfect and incomplete. But to any one who considers this matter with attention, it will appear, that there could be no end to these unnecessary discussions and groundless claims of fancied superiority: for if compound words have such an advantage over simple, the Chinese language, in which we are told almost every sentence has a particular compound character to express it, must be by far the most perfect in the world; but so far is this from being the case, that every one allows it to be the most imperfect and incomplete. The only method, therefore, which remains for us to consider this subject is, to disregard every particular form of language, and consider the words in themselves, as divested of every extraneous circumstance, and observe what variations they necessarily require, allowing every particular language to compound these with one another in what manner they shall think most proper. It is in this manner we have considered the verbal attributes, and endeavoured to disentangle them from these unnecessary fetters with which they have been loaded, and restore them to their own original freedom.

Besides the variations above-mentioned, verbs have been distinguished from one another in a different manner; the names and nature of which may be thus explained.

We have already seen, that all verbs, as they denote *energies*, necessarily have reference to certain *energizing substances*. For, how could there be such energies as *to love, to fly, to wound* &c. were there not such beings as *men, birds, swords*, &c. Farther, every energy not only requires an energizer, but is necessarily conversant about some subject. For example, if we say, *Brutus loves*, we must needs supply—*loves Cato, Cassius, or some one*. And thus it is, that every energy is necessarily situated between two substantives, an energizer which is *active*, and a subject which is *passive*. If the energizer leads the sentence, the energy has been said to follow its character, and becomes what we call a **VERB ACTIVE**: thus we say, *BRUTUS AMAT, Brutus loves*. On the contrary, if the passive subject be principal, it is said to follow the character of this too, and becomes what we call a **VERB PASSIVE**: thus we say, *PORTIA AMATUR, Portia is loved*. But in some verbs it happens, that the energy always keeps within the energizer, and never passes out to any extraneous subject. Thus, when we say, *Cæsar walketh, Cæsar sitteth*, it is impossible that the energy should pass out, because both the energizer and the passive subject are united in the same person. For what is the cause of this walking or sitting? it is the *will and vital powers* belonging to *Cæsar*: and what is the subject made so to move or sit? it is the *body and limbs* belonging also to the same *Cæsar*. This species of verbs have been by grammarians distinguished by the name of **VERBS NEUTER**, as if they were void both of *action* and *passion*, when perhaps they may be rather said

to imply both. It is in this manner, that verbs have been distinguished into the three classes of *active, passive, and neuter*. These, however, might with more propriety be divided into two classes, which might be called verbs **TRANSITIVE**, and **NOT TRANSITIVE**; the first class including all those verbs which are usually called *active*, with the *passives* belonging to them; for it is evident, that these passives are not verbs themselves, but a variation only of a verb; and the second class including those verbs commonly called *neuter*.

Some languages, as the Greek and French, have another class of verbs, which are called by the first **VERBS MIDDLE**, and by the last **RECIPROCAL VERBS**; which are employed to denote that state of any transitive verb, when the energizer himself becomes the subject; as thus, *Brutus killed himself*, &c. But as these only express a slight variation of an accompaniment of a verb, they have no claim to be considered as a distinct species.

## II. OF ADJECTIVES.

**ADJECTIVES** are all those words which denote attributes whose essence does not consist in motion or its privation: or, in other words, they are those words which denote the attributes of quantity, quality, and relation; such as, *many, few, great and little, black and white, good and bad, double, treble, quadruple*, &c.

As these attributes admit of no change of state, nor can be effected by the variations of time, or any other accident, but are in their own nature perfectly fixed and invariable, the words which express them ought to be in all situations and on all occasions the same. For as the qualities *good or bad, black or white*, admit of no change in their own nature, whether they be applied to a *man*, to a *woman*, to *many*, or to *few*; neither ought the word which expresses any one of these attributes in strictness to admit of any alteration, whether it be joined to one or other of these substantives. So that although in some languages, from the particular construction of the other parts of speech, it has been found necessary to endow their adjectives with the threefold distinction of *gender, number, and case*; yet this must only be considered as an accidental variation occasioned by particular circumstances, and not in the least essential to language, but rather a deviation from the order of nature, which would require them to be kept invariably the same in all cases. This order, the English language (which in this and almost every other case is most strictly conformable to the nature of things than any other language we are acquainted with) most strictly observes; as we say equally, *a good man, or a good woman, a good house; or good men, good houses*, &c.

It has probably been from observing, that the adjectives in some particular languages are endowed with variations conformable to the *gender, number, and case* of their substantives, that grammarians have been led into the strange absurdity of ranging them with nouns, and separating them from verbs; though with respect to verbs they are perfectly homogeneous, and with respect to nouns they are quite the contrary. Adjectives are homogeneous with respect to verbs, as both sorts denote attributes;

*attributor*; they are heterogeneous with respect to nouns, as never properly denoting substances.

Besides original adjectives, there is another class which are formed from substantives. Thus when we say, *the party of Pompey*, *the style of Cicero*, *the philosophy of Socrates*; in these cases, the party, the style, and philosophy spoken of, receive a stamp and character from the persons they respect, and actually pass into attributives, and as such assume the form of *adjectives*. And hence we say *the Pompeian party*, *the Ciceronian style*, and *the Socratic philosophy*. In like manner, for a trumpet of brass, we say, *a brazen trumpet*; for a crown of gold, *a golden crown*, &c. Even pronominal substantives admit the like mutation; as, instead of saying the book of *me*, of *thee*, or of *him*, we say, *my book*, *thy book*, *his book*, &c. Yet it must be acknowledged, that these, as they often serve rather to define a noun than to denote any quality appertaining it, they partake more of the nature of *articles* than *adjectives*; so that it is in many cases difficult to ascertain exactly to which class they are to be referred. But of this we have already taken particular notice, p. 713. col. 2. & 716. col. 2.

The nature of these variations of adjectives which have been called *degrees of comparison*, will be more properly explained under the following section.

## Section II. Of Attributives of the Second Order, called ADVERBS.

As the attributives hitherto mentioned denote the *attributes of substances*, so there is an inferior class of them which denote the *attributes only of attributes*. To explain these by examples of either kind: when we say, *Cicero and Pliny were both of them eloquent*; *Statius and Virgil both of them wrote*; in these instances, the attributes *eloquent* and *wrote*, are immediately referable to the substantives *Cicero*, *Virgil*, &c.: As, therefore, denoting the *attributes of substances*, we call them *ATTRIBUTIVES OF THE FIRST ORDER*. But when we say, *Pliny was moderately eloquent*, but *Cicero exceedingly eloquent*; *Statius wrote indifferently*, but *Virgil wrote admirably*: in these instances, the attributives *moderately*, *exceedingly*, *indifferently*, and *admirably*, are not referable to *substantives*, but to *other attributes*; that is, to the words *eloquent* and *wrote*: As, therefore, denoting *attributes of attributes*, we call them *ATTRIBUTIVES OF THE SECOND ORDER*. These have been, by grammarians, called *ADVERBS*. And indeed, if we take the word *verb* in its most comprehensive signification, as including all the words which denote the *attributes of substances*, (which was the sense in which Aristotle and many of the most ancient grammarians employed it) we shall find the name *ADVERB* to be a very just appellation, as denoting a *part of speech the natural appendage of verbs*. So great is this dependence in grammatical syntax, that an *adverb* can no more subsist without its *verb*, than a *verb* can subsist without its *substantive*.

Among the attributes of substances are reckoned quantities and qualities. Thus we say, *a white garment*, *a*

*high mountain*, &c. Now some of these quantities and qualities are capable of *intension* and *remission*. Thus we say, *a garment EXCEEDINGLY white*, *a mountain TOLERABLY or MODERATELY high*. Hence, then, one copious source of secondary attributives, or adverbs, to denote these two, that is, *intension* and *remission*; such as, *greatly*, *vastly*, *extremely*, *sufficiently*, *moderately*, *tolerably*, *indifferently*, &c.

But where there are different intensions of the same attribute, they may be compared together: thus, if the garment A be EXCEEDINGLY white, and the garment B be MODERATELY white, we may say, the garment A is MORE white than the garment B. In these instances, the adverb MORE not only denotes intension, but *relative intension*. Nay, we stop not here, as we not only denote intension merely relative, but *relative intension than which there is none greater*. Thus we not only say, the mountain A is MORE high than the mountain B, but that it is the MOST high of all mountains. Even verbs, properly so called, as they admit of *simple intensions*, so they admit also of these *comparative ones*. Thus, in the following example, *Fame he LOVETH MORE than riches*, but *virtue of all things he LOVETH MOST*; the words MORE and MOST denote the different comparative intensions of the verbal attribute *loveth*.

Hence the rise of COMPARISON of adjectives, and of its different degrees, which cannot well be more than the two species above-mentioned; one to denote *simple excess*, and one to denote *superlative*. Were we indeed to introduce more degrees than these, we ought perhaps to introduce *infinite*, which is absurd. For why stop at a limited number, when in all subjects susceptible of intension the intermediate excesses are in a manner infinite? There are infinite degrees of *more white*, between the *first simple white*, and the *superlative whiteness*; and the same may be said of *more great*, *more strong*, *more minute*, &c. The doctrine of grammarians about three such degrees of comparison, which they call the *positive*, the *comparative*, and the *superlative*, must be absurd; both because in their positive there is no comparison at all, and because their superlative is a comparative as much as their comparative itself. Examples to evince this may be met with every where; *Socrates was the MOST WISE of all the Athenians*; *Homer was the MOST SUBLIME of all poets*, &c.

The authors of language have in some instances contrived a way to retrench these comparative adverbs, by expressing their force by an inflection of the primary attributive. Thus, instead of *more fair*, they say, *FAIRER*; instead of *most fair*, *FAIREST*: and the same method of composition takes place both in the Greek and Latin languages; with this difference however between the genius of these languages and ours, that we are at liberty to form the comparison, either in the one method or the other: but in these languages, the comparison is almost never formed by the assistance of the adverb, but always by the inflection of the adjective; and hence this inflection is always considered by them as a necessary accident of the adjective. But this method of expressing the power of the adverb has reached no farther than to adjectives,

adjectives, or to their participles, which were so nearly allied to adjectives. Verbs were perhaps thought to be too much diversified, to admit of more variations without perplexity.

Some qualities admit of comparison, others admit of none: such, for example, are those which denote *that quality of bodies arising from their figure*; as, when we say, a *circular* table, a *quadrangular* court, a *conical* piece of metal, &c. The reason is, that a million of things participating the same figure, participate it *equally* if they do it at all. To say, therefore, that while A and B are both quadrangular, that A is more or less quadrangular than B, is absurd. The same holds in all attributives denoting *definite quantities* of whatever nature. For, as there can be no *comparison* without *intension* or *remission*, and as there can be no intension and remission in things *always definite*, therefore these attributives can admit of no comparison. By the same method of reasoning, we discover the cause why *no substantive is susceptible of these degrees of comparison*. A *mountain* cannot be said *MORE* to BE or TO EXIST than a *mole-hill*; nor the *lion* A cannot be *more* a *lion* than the *lion* B: but the *more* or *less* must be sought for in their quantities or qualities; a mountain is *more bulky* than a mole-hill, and the *lion* A is *more fierce* than the *lion* B; the excess being always derived from their attributes.

Of the adverbs or secondary qualities already mentioned, those denoting intension and remission may be called adverbs of QUANTITY CONTINUOUS; *once, twice, thrice*, &c. are adverbs of QUANTITY DISCRETE; *more and most, less and least*, to which may be added *equally, proportionally*, &c. are adverbs of RELATION. There are others of QUALITY; as when we say, *HONESTLY industrious, PRUDENTLY brave, they fought BRAVELY, he painted FINELY*, &c.

The adverbs hitherto mentioned, are common to *verbs of every species*; but there are some which are confined to *verbs properly so called*, that is to say, to such as denote *motions* or *energies* with their *privations*. All *motion* and *rest* imply *time* and *place* as a kind of necessary coincidence. Hence, if we would express the *place* or *time* of either, we must needs have recourse to adverbs formed for this purpose; of *PLACE*, as when we say, *he stood THERE, he went HENCE, he travelled FAR*, &c.; or of *TIME*, as when we say, *he stood THEN, he went AFTERWARD, he travelled FORMERLY*, &c. Should it be asked, Why *adverbs of time*, when verbs have *tenses*? The answer is, though *tenses* may be sufficient to denote the greater distinctions of time, yet to denote them all by *tenses* would be a perplexity without end. What a variety of forms would be necessary to denote *yesterday, to-day, to-morrow, formerly, just now, now, immediately, presently, soon, hereafter*? &c.

To these adverbs just mentioned may be added those which denote the *intensions* and *remissions peculiar to MOTION*, such as *speedily, hastily, swiftly, slowly*, &c.; as also adverbs of *place* made out of *prepositions*, such as *upward* and *downward*, from *up* and *down*. In some instances the preposition suffers no change, but be-

comes an adverb by nothing more than its application; as when we say, *he rides ABOUT, he was NEAR sailing*, &c.

There are likewise adverbs of INTERROGATION; such as, *where, whence, whither, how*, &c. of which there is this remarkable, that when they lose their *interrogative power*, they assume that of a *relative*, as to represent the *relative* or *subjunctive pronoun*; as in this doggerel translation of a line from Virgil,

*And corn doth grow WHERE Troy town stood*;

that is to say, *corn groweth in that place in which Troy stood*, the power of the relative being implied in the adverb. It is in like manner, that the *relative pronoun* becomes an *interrogative*; as in this line from Milton,

*Who first seduc'd them to that foul revolt?*

The reason of this is as follows: the *pronoun* and *adverbs* here mentioned are all, in their original character, *RELATIVES*. Even when they become interrogatives, they lose not this character, but are still relatives as much as ever: the difference is, that *without* an interrogation they have reference to a subject which is *antecedent, definite, and known*; *with* an interrogation, to a subject which is *subsequent, indefinite, and unknown*, and which it is expected the answer should express and ascertain. *Who first seduc'd them?* The question itself supposes a seducer, to which, though *unknown*, the pronoun *who* has a reference—*Th' infernal serpent*. Here, in the answer, we have the subject, which was *indefinite, ascertained*; so that we see *who*, in the *interrogation*, is as much a *relative* as if it had been said originally, without any interrogation at all, *It was the infernal serpent who first seduced them*: and thus interrogatives and relatives mutually pass into one another.

Having thus considered all those parts of speech which ARE SIGNIFICANT OF THEMSELVES, we proceed to those AUXILIARY PARTS, which are ONLY SIGNIFICANT WHEN ASSOCIATED WITH OTHERS, which we have already said are either *DEFINITIVES* or *CONNECTIVES*. Of which in their order.

### CHAPTER III.

#### Concerning DEFINITIVES commonly called ARTICLES.

THE knowledge of man is at best but limited and confined. Although we have invented words to denominate almost all the substances which exist, yet as it is impossible for any person to be acquainted with all of these, it was necessary to fall upon some contrivance in language to obviate the difficulties which would arise from this cause. With this view, we have already seen, that substances have been divided into general classes, each of which includes under it several lesser subdivisions; the names of which general classes, being but few, may be more easily retained, as *animal, edifice, motion*, &c. for by referring the several objects that we may accidentally see, and with which we are unacquainted, to the several classes to which they may belong, we are in some measure enabled to communicate our ideas without the know-

ledge

ledge of the particular names. But as this particular object must in some manner be distinguished from others of the same class to which it belongs, a particular class of words was found necessary to define and ascertain these individuals, which has given rise to this order of words of which we now treat, and which we have called *definitives*, because they serve to *define and ascertain any particular object, so as to separate it from the general class to which it does belong, and, of course, denote its individuality*. The principal of these definitives have been usually called *ARTICLES*, the nature of which may be explained as follows.

Supposing I see an object with which I am totally unacquainted, having a head and limbs, and appearing to possess the powers of self motion and sensation. If I know it not as an individual, I refer it to its proper species, and call it *a dog, a horse, a lion*, or the like; and if none of the names of any species with which I am acquainted fit it, I refer it to the genus, and call it *an animal*.

But this is not enough. The object at which we are looking, and want to distinguish, is perhaps an individual.—Of what kind? *Known or unknown?* Seen now for the first time, or seen before and now remembered? It is here we shall discover the use of the two articles *A* and *THE*; for the article *A* respects our *primary* perception, and denotes individuals as *unknown*; whereas *THE* respects our *secondary* perception, and denotes individuals as *known*. To explain this by an example, I see an object pass by which I never saw till then: What do I say? *There goes a beggar with a long beard*. The man departs, and returns a week after: What do I then say? *There goes the beggar with the long beard*. Here the article only is changed, the rest remains unaltered. Yet mark the force of this apparently minute change. The individual *once vague* is now recognised as *something known*, and that merely by the efficacy of this latter article, which tacitly insinuates a kind of *previous acquaintance*, by referring a present perception to a like perception already past. Hence therefore we see, that although the articles *A* and *THE* are both of them *definitives*, as they circumscribe the latitude of genera and species, by reducing them, for the most part, to denote individuals; yet they differ in this respect, that the article *A* leaves the individual itself *unascertained*, but the article *THE* *ascertains the individual also*, and is for that reason the more accurate definitive of the two. They differ likewise in this respect, that as the article *A* serves only to separate one particular object from the general class to which it belongs, it cannot be applied to plurals. But as the article *THE* serves to define objects, or refer to them as already known, without relation to number, or any other circumstances, it is applicable to both numbers indiscriminately, as well as nouns of every gender, without suffering any sort of change; for it is evident, that no variation of the nature of the noun can make any difference in those words which serve to define or denote a certain reference to them. So that although we find some modern languages which admit of a variation of their article, which relates to the gender of the noun with which it is associated, yet this cannot be considered

as essential to this species of words: and so far is this from being an improvement to the language, that it only serves to perplex and confuse, as it always presents a particular idea of sex, where in many cases it is not in the least necessary.

Of all the parts of speech which may be considered as essential to language, there is none in which we find so many languages defective as in this. For we know of no language, except our own, which has the particular article *A*; and the Latin language has no word of the same import with the word *THE*. The reason of which deficiency is, that as other parts of speech may be so easily converted from their original meaning, and be made to assume the character of definitives, they have made some of these perform both of these offices; and as the article *A* only separates a particular object, and is therefore so nearly allied to a *numeral*, many languages, as the *French, Italian, Spanish, and German*, have made the numeral word *ONE* supply its office, while others, as the *Greek*, have denoted this particular object by a mere negation of the other article; and as the article *THE* agrees with pronouns in this respect, that they both *denote reference*, the Latins made their pronoun, by a forced periphrasis, supply the place of this. But all of these methods of supplying the want of the genuine article are defective, as will appear more particularly by and by.

As articles are by their nature definitives, it follows of course, that they cannot be united with such words as are in their own nature *as definite as they may be*; nor with such words which, *being indefinite, cannot properly be made otherwise*; but only with those words which, *tho' indefinite, are yet capable, through the article, of becoming definite*. Hence we see the reason why it is absurd to say *THE I*, or *THE THOU*, because nothing can make these pronouns more *definite* than they are; and the same may be said of proper names. Neither can we say *THE BOTH*, because these words are *in their own nature* each of them perfectly defined. Thus, if it be said, "I have read *BOTH* poets," this plainly indicates a *definite pair*, of whom some mention has been made already. On the contrary, if it be said, "I have read *TWO* poets," this may mean *any pair* out of all that ever existed. And hence this numeral, being in this sense *indefinite*, (as indeed are all others as well as itself,) is forced to *assume the article* whenever it would become *definite*. Hence also it is, that as *TWO*, when taken alone, has reference to some *primary* and *indefinite* perception, while the article *THE* has reference to some perception *secondary* and *definite*, it is bad language to say *TWO THE MEN*, as this would be *blending of incompatibles*, that is to say, of a *defined substantive* with an *undefined attributive*. On the contrary, to say *BOTH THE MEN*, is good and allowable; because the substantive cannot possibly be less apt, by being defined, to coalesce with an attributive which is defined as well as itself. So likewise it is correct to say, *THE TWO MEN*; because here the article, being placed at the beginning, *extends its power* as well through substantive as attributive, and equally tends to *define* them both.

As some of the words above admit of no article, be-

cause they are by nature as definite as may be; so there are others which admit it not, because they are not be defined at all. Of this sort are all INTERROGATIVES. If we question about substances, we cannot say THE WHO IS THIS; but WHO IS THIS? And the same as to *qualities*, and both kinds of *quantities*: for we say, without an article, WHAT SORT OF, HOW MANY, HOW GREAT? The reason is, the article THE respects beings already known, and interrogatives respect beings about which we are ignorant; for as to what we know, interrogation is superfluous. In a word, the natural affixators with articles are ALL THOSE COMMON APPELLATIVES WHICH DENOTE THE SEVERAL GENERA AND SPECIES OF BEINGS. It is these, which, by assuming a different article, serve either to explain an individual upon its first being perceived, or else to indicate, upon its return, a recognition or repeated knowledge.

But although proper names do not admit of the article, being in their own nature definite; yet as these often fall into *homonymic*, that is, different persons often go by the same name, it is necessary to distinguish these from one another, to prevent the ambiguity that this would occasion. For this purpose we are obliged to have recourse to *adjectives* or *epithets*. For example, there were two *Grecian chiefs* who bore the name of *Ajax*; and was it not without reason that *Mnestheus* uses *epithets*, when his intention was to distinguish the one from the other: "If both *Ajaxes* cannot be spared, (says he) "at least let mighty *Telamonian Ajax* come." But as *epithets* are in their own nature perfectly indefinite, seeing the same adjective may be applied to infinite subjects, it is necessary to define these when we want to apply them to any particular object; so that it is necessary to endow these with an article, that they may have a reference to some single person only. And thus it is we say, *Trypho the grammarian*, *Appolodorus the Cyrenian*, &c. It is with reason, therefore, that the article is here also added, as it brings the adjective to an individuality as precise as the proper name. Even common appellatives, by the help of an article, come to have the force of proper names, without the assistance of any epithet whatever. Thus, in English, *city* is a name common to many places, and *speaker* a name common to many men. Yet if we prefix the article, THE CITY means our metropolis; and the THE SPEAKER, a high officer in the British parliament. And hence, by an easy transition, the article, from denoting reference, comes to denote eminence also; that is to say, from implying an ordinary pre-acquaintance, to presume a kind of general and universal notoriety. Thus, among the Greeks, THE POET meant *Homer*, and THE STAGYRITE meant *Aristotle*; not, but that there were many poets beside *Homer*, and many *stagyrites* besides *Aristotle*, but none equally illustrious.

The articles already mentioned are those strictly so called; but, besides these, there are the PRONOMIAL ARTICLES, such as *this*, *that*, *any*, *some*, *all*, *other*, *none*, &c. Of these we have already spoken in the chapter upon pronouns, where we have shewn when they may be taken as pronouns, and when as articles. Yet, in truth, if the office of an article be to define and ascer-

tain, they are much more strictly articles than any thing else, and ought to be considered as such in universal grammar. Thus, when we say, "THIS picture I approve, but THAT I dislike;" what do we perform by the help of these definitives, but bring down the common appellatives to denote individuals? So when we say, "SOME men are virtuous, but ALL men are mortal;" what is the natural effect of this ALL and SOME, but to define that *universality* and *particularity* which would remain indefinite were we to take them away? The same is evident in such sentences as these: "SOME substances have sensation, OTHERS want it; choose ANY way of acting, and SOME men will find fault, &c." For here, SOME, OTHER, and ANY, serve all of them to define different parts of a given whole; SOME, to denote a definite part; ANY, to denote an indefinite; and OTHER, to denote the remaining part, when a part has been already assumed. Even the attributive pronouns, *my*, *thy*, *his*, *her's*, &c. are, in strictness, more properly articles than any thing else, seeing each of them serve only to define and ascertain the individual object to which they are applied. As when we say, "MY house is less commodious than YOUR'S; HER form is more elegant than HIS, &c." For in these examples what do the words MY and YOUR'S do, but ascertain two individual houses; or the words HIS and HER'S, but ascertain two individual forms, which are compared with one another? In the same manner we have already seen nouns sometimes lay aside their own proper character, and become definitives, as in the words ALEXANDER'S, CÆSAR'S, POMPEY'S, &c. which may be said to form so many NOMINAL ARTICLES. But of these we have spoken so fully in the chapter of nouns, that it is unnecessary to say more of them in this place.

Before we leave this subject, we shall produce one example to shew the utility of this species of words; which, although of themselves insignificant, and seemingly of small importance; yet, when properly applied, serve to make a few general terms be sufficient for the accurate expression of a great variety of particulars, and thus makes language capable of expressing things infinite, without wandering into infinitude itself.—To explain this, let the general term be MAN, which I have occasion to employ for the denoting of some particular. Let it be required to express this particular, as unknown; I say, A man:—Known; I say, THE man:—Definite; A CERTAIN man:—Indefinite; ANY man:—Present and near; THIS man:—Present and distant; THAT man:—Like like to some other; SUCH a man:—Different from some other; ANOTHER man:—An indefinite multitude; MANY men:—A definite multitude; A THOUSAND men:—The ones of a multitude, taken throughout; EVERY man:—The same ones, taken with distinction; EACH man:—Taken in order; FIRST man, SECOND man, &c.—The whole multitude of particulars taken collectively; ALL men:—The negation of that multitude; NO man:—A number of particulars present, and at some distance; THESE men:—At a greater distance, or opposed to others; THOSE men:—A number present and near; THESE men:—A number of individuals different from another number;

*ber*; OTHER *men*:—*A great number of individuals taken collectively*; MANY *men*:—*A small number*; FEW *men*:—*A proportionally greater number*; MORE *men*:—*Smaller number*; FEWER *men*:—And so on we might go almost to infinitude. But not to dwell longer upon this article, we shall only remark, “that minute changes in PRINCIPLES, lead to mighty changes in EFFECTS; so that PRINCIPLES are well entitled to regard, however trivial they may appear.

## CHAPTER IV. OF CONNECTIVES.

CONNECTIVES, according as they connect either *sentences* or *words*, are called by the different names of CONJUNCTIONS, or PREPOSITIONS. Of these names, that of the *preposition* is taken from a mere accident, as it commonly stands in connection before the part which it connects. The *conjunction*, as is evident, has reference to its *essential* character. We shall treat of these two separately.

### Section I. Of CONJUNCTIONS.

A CONJUNCTION is a part of speech void of signification itself, but so formed as to help signification, by making two or more significant sentences to be one significant sentence. As, therefore, it is the essence of a conjunction to connect sentences; at the same time that they do this, they must either connect their meaning or not. For example, let us take these two sentences, *Rome was enslaved*,—*Cæsar was ambitious*, and connect them together by the conjunction BECAUSE; *Rome was enslaved, BECAUSE Cæsar was ambitious*. Here the meanings, as well as the sentences, appear to be connected. But if I say, *manners must be reformed, OR liberty will be lost*; here the conjunction OR, though it join the sentences, yet, as to their respective meanings, is a perfect disjunctive. And thus it appears, that though all conjunctions conjoin sentences, yet, with respect to the sense, some are CONJUNCTIVE, and others are DISJUNCTIVE.

Those conjunctions which conjoin both sentences and their meanings are either COPULATIVES or CONTINUATIVES. The principal copulative in English is AND. The continuatives are much more numerous; IF, BECAUSE, THEREFORE, WHEREFORE, HENCE, THAT, &c. The difference between these is this: The copulative does no more than barely couple sentences, and is therefore applicable to all subjects whose natures are not incompatible: Continuatives, on the contrary, by a more intimate connection, consolidate sentences into one continuous whole; and are therefore applicable only to subjects which have an essential coincidence: For example, it is no way improper to say, *Lyfippus was a statuary, AND Priscian a grammarian*; *the sun shineth, AND the sky is clear*; because these are things that may co-exist, and yet imply no absurdity. But it would be absurd to say, *Lyfippus was a statuary,*

*BECAUSE Priscian was a grammarian*; though not to say, *the sun shineth BECAUSE the sky is clear*. The reason is, with respect to the first, the co-incidence is merely accidental: with respect to the last, it is essential, and founded in nature.

As to the continuatives, they are SUPPOSITIVÉ, such as *if*; or POSITIVE, such as *because, therefore, as, &c.* Take examples of each:—*You will live happily if you live honestly*:—*You live happily BECAUSE you live honestly*:—*You live honestly, THEREFORE you live happily*. The difference between these continuatives is this: The suppositives denote connection, but do not assert actual existence; the positives imply both the one and the other.

These positives above-mentioned are either CASUAL, such as *because, since, as, &c.* or COLLECTIVE, such as *therefore, wherefore, &c.* The difference between which is this: The casuals subjoin causes to effects; “*the sun is in eclipse BECAUSE the moon intervenes*.” The collectives subjoin effects to causes; “*the moon intervenes, THEREFORE the sun is in eclipse*.” We therefore use casuals in those instances where the effect being conspicuous we seek for its cause; and collectives, in demonstrations and science, properly so called, where the cause being first known, by its help we discern effects.

All these continuatives are resolvable into copulatives: For, instead of saying, *BECAUSE it is day, it is light*; we may say, *It is day, AND it is light*. Instead of *IF it is day, it is light*; we may say, *It is at the same time necessary to be day, AND to be light*. The reason is, That the power of the copulative extends to all connections, as well to the essential as to the casual. Hence the continuative may be resolved into a copulative and something more; that is to say, into a copulative implying an essential coincidence in the subjects conjoined.

As to casual conjunctions, we may further observe, that there is no one of the four species of causes which they are not capable of denoting. For example, the MATERIAL cause; *The trumpet sounds, BECAUSE it is made of metal*. The FORMAL; *The trumpet sounds, BECAUSE it is long and hollow*. The EFFICIENT; *The trumpet sounds, BECAUSE an artist blows it*. The FINAL; *The trumpet sounds, THAT it may rouse our courage*. It is worth observing, that the three first causes are expressed by the strongest affirmation; because, if the effect actually be, that must be also. But this is not the case with respect to the last, which is only affirmed as a thing that may happen. The reason is, That however this may be the end which set the artist first to work, it may still be beyond his power to obtain, and which, like all other contingents, may either happen or not. Hence also it is connected by a particular conjunction, THAT, absolutely confined to this cause.

We now come to the DISJUNCTIVE CONJUNCTIONS; a species of words which bear this contradictory name, because, while they DISJOIN the sense, they CONJOIN the sentences.

With respect to these, we may observe, that as there is a principle of UNION diffused through all things by which THIS WHOLE is kept together and preserved from dissipation; so there is, in like manner, a principle of DI-

VERSITY diffused through all, the source of *distinction*, of *number*, and of *order*. Now, it is to express in some degree the *modifications of this diversity*, that *DISJUNCTIVE CONJUNCTIONS* seem at first to have been invented.

Of these *disjunctives*, some are *SIMPLE*, some *ADVERSATIVE*. *Simple*; as when we say, *EITHER it is day, OR it is night*:—*Adversative*; as when we say, *It is not day, BUT it is night*. The difference between these is, that the *simple* do no more than *merely* disjoin; the *adversative* disjoin with a concomitant *opposition*. Add to this, that the *adversative* are *definite*; the *simple* *indefinite*. Thus, when we say, *the number three is not an even number, BUT an odd*; we not only *disjoin* two opposite attributes, but we *definitely* affirm one, and deny the other. But when we say, *the number of the stars is EITHER even OR odd*; though we assert one attribute *to be*, and the other *not to be*, yet the alternative is notwithstanding left *indefinite*.

As to *adversative disjunctives*, it has been already said, that they imply *OPPOSITION*. Now, there can be no opposition of the *same* attribute in the *same* subject; as when we say, *Nereus was beautiful*: but the opposition must be either of the *same* attribute in different subjects, as when we say, "*Brutus was a patriot, BUT Cæsar was not*;" or of *different* attributes in the *same* subject, as when we say, "*Gorgius was a sophist, BUT not a philosopher*;" or of *different* attributes in *different* subjects, as when we say, "*Plato was a philosopher, BUT Hippias was a sophist*." The conjunctions used for all these purposes may be called *absolute* adversatives.

But there are other adversatives besides these; as when we say, "*Nereus was more beautiful THAN Achilles*;"—*Virgil was as great a poet AS Cicero was an orator*." The character of these latter is, that they go farther than the former, by marking not only *opposition*, but that *equality* or *excess* which arises from the comparison of subjects; and therefore they may be called *adversatives of comparison*.

Besides the adversatives here mentioned, there are two other species, of which the most eminent are *UNLESS* and *ALTHOUGH*: For example, "*Troy will be taken, UNLESS the Ilium be preserved*;" *Troy will be taken, ALTHOUGH Hector defend it*." The nature of these adversatives may be thus explained. As every *event* is naturally allied to its *cause*, so, by parity of reason, it is opposed to its *preventive*; and as every cause is either *adequate* or *inadequate*, (inadequate, when it endeavours, without being effectual), so in like manner is every *preventive*. Now, *adequate* preventives are expressed by such adversatives—as *UNLESS*: "*Troy will be taken, UNLESS the Palladium be preserved*;" that is, that this alone is *sufficient* to prevent it. The *inadequate* are expressed by such adversatives as *ALTHOUGH*: "*Troy will be taken, ALTHOUGH Hector defend it*;" that is, *Hector's* defence will prove *ineffectual*. These may be called adversatives *ADEQUATE* and *INADEQUATE*.

Before we leave this subject, we may observe, that the words *when* and *where*, and all others of the same nature, such as *whence*, *whether*, *when-ever*, *where-ever*, &c. may be called *ADVERBIAL CONJUNCTIONS*; because they

participate the nature both of adverbs and conjunctions; of *conjunctions*, as they *conjoin* sentences; of *adverbs*, as they denote the attributes either of *time* or *place*. And these *adverbial* conjunctions (contrary to the character of *accusatory* words, which have strictly no signification but when associated with other words) have a kind of *obscure* signification when taken alone, by denoting these attributives of time and place. And hence it is, that they appear in grammar like *zoophytes* in nature, a kind of middle beings, of amphibious character, which, by sharing the attributes of the higher and the lower, conduce to link the whole together.

## Section II. Of those Connectives, called PREPOSITIONS.

A *PREPOSITION* is a part speech devoid itself of signification, but so formed as to unite two words that are significant and that refuse to coalesce of themselves. This connective power (which relates to words only, and not to sentences) will be better understood by the following observations.

Some things naturally coalesce and unite of themselves, while others refuse to do so *without help*, and as it were by compulsion. For example, all quantities and qualities coalesce immediately with their substances: thus it is we say, *a fierce lion, a vast mountain*, &c. In like manner actions coalesce with their agents, and passions with their patients: thus it is we say, *Alexander conquers, Darius is conquered*. Nay, as every energy is a kind of medium between its agent and patient, the whole three, agent, energy, and patient, coalesce with the same facility; as when we say, *Alexander conquers Darius*. Farther than this, as the greatest part of attributives themselves may be characterised, as when we say of such attributives as *ran, beautiful, learned*, &c. "*he ran swiftly, she was very beautiful, he was moderately learned*" &c. these must readily coalesce with the attributes which they thus characterise. From all which it appears, that *those parts of speech unite of themselves in grammar whose original archetypes unite of themselves in nature*. Hence, therefore, it is, that although substances naturally coincide with their attributes, yet they absolutely refuse doing so one with another: and hence those known maxims in physics, that *body is impenetrable*, that *two bodies cannot possess the same place*, &c.

From these principles it follows, that when we form a sentence, the substance without difficulty coincides with the verb, from the natural coincidence of substance with energy; *the SUN WARMETH*: so likewise the energy with the subject on which it operates; *WARMETH the EARTH*: so likewise both substance and energy with their proper attributes; *the SPLENDID SUN GENIALLY WARMETH the FERTILE EARTH*. But suppose we are to add other substantives, as, for instance, *air*, or *heavens*; how could these coincide, or under what character be introduced? not either as the *energizer* of the verb, nor as the *subject on which it operates*; for both of these places are already filled up, the first by the word *SUN*, and the last by the substance *EARTH*: not as *attributes* to these last, or to any other thing; for attributes by nature

ture they neither *are* nor *can be made*. Here, then, we perceive the rise and use of *prepositions*: by these we connect those substantives to sentences, which, at the time, are unable to *coalesce of themselves*. Let us assume, for instance, a pair of these connectives, *THROUGH* and *WITH*, and mark their effect upon the substances here mentioned; *the splendid sun WITH his beams genially warmeth THROUGH the air the fertile curth*: the sentence, as before, remains entire and one; the substantives required are both introduced, and not a word which was there before is displaced from its proper station.

It must be here observed, that *most* if not *all* prepositions seem originally formed to denote the relations of *place*; because this is that grand *relation* which *bodies* or *natural substances* maintain at all times to one another, whether they are contiguous or remote, whether in motion or at rest: thus we have prepositions to denote the *contiguous relation of body*; as when we say, *Crius walked WITH a staff*; *the statue stood UPON a pedestal*; *the river ran OVER a precipice*; others for the *detached relation*; as when we say, *He is going TO Italy*; *the sun is risen ABOVE the hills*; *these figs came FROM Turkey*: So as to *motion* and *rest*; only with this difference, that here the preposition varies its character with the verb: thus if we say, *that lamp hangs FROM the ceiling*, the preposition *FROM* assumes the character of *quiescence*: but if we say, *that lamp is falling FROM the ceiling*, the preposition assumes a character of *motion*. So in Milton;

—To support uneasy steps

OVER the burning marle—

Again,

—He with looks of cordial love

Hung OVER her enamour'd.—

In the first of these examples, *OVER* denotes *motion*, and in the last it denotes *rest*.

But though the original use of prepositions was to denote the relations of *place*, they could not be confined to this office only; but by degrees extended themselves to subjects *incorporeal*, and came to denote relations as well *intellectual* as *local*. Thus because, in *place*, he who is *above* has commonly the advantage of him who is *below*, we transfer *OVER* and *UNDER* to *dominion* and *obedience*: of a king we say, *he ruled OVER his people*; of a common soldier, *he served UNDER such a general*: so too we say, *WITH thought*; *WITHOUT attention*; *thinking OVER a subject*; *UNDER anxiety*; *FROM fear*; *OUT of love*; *THROUGH jealousy*, &c. All which instances, with many of the like kind, shew, that the *first words* of men, like their *first ideas*, had an immediate reference to *sensible objects*; and that, in after days, when they began to discern with their *intellect*, they took these words which they found already made, and transferred them, by *metaphor*, to *intellectual conceptions*. There is indeed no method to express new ideas, but

either by *metaphor*, or by *coining new words*; both which have been practised by philosophers, according to the nature and exigence of the occasion.

In the foregoing use of prepositions, we have seen how they are employed by way of *juncta-position*; that is to say, where they are prefixed to a word without becoming a part of it: but they may be also used by way of *composition*; that is, they may be prefixed to a word so as to become a part of it: thus, to *UNDERstand*, to *FORget*, to *OVERact*, to *UNDERvalue*, to *OUTgo*, &c. are so many distinct words formed by prepositions joined intimately with some other word: in all which cases, the prepositions commonly transfuse something of their own meaning into the word with which they are compounded; and this impaired meaning in most instances, will be found referable into some of the relations of *place*, as used either in its *proper* or *metaphorical* application.

BESIDES the above parts of speech, there is another, which cannot be comprehended under any of the foregoing classes, called *INTERJECTIONS*: of this kind are the words, *AH! ALAS! FIE! &c.* *This species of words coincide with no part of speech, but are either uttered alone, or else thrown into a sentence, without altering its form either in syntax or signification.* It may be therefore objected, that as we say, that all language is divided into the several parts above enumerated, and this class cannot be comprehended in any of these divisions; of course, the analysis that we have made cannot be just, because it does not comprehend the whole. To this objection it may be answered, that the language of which we have been treating, is that which has been formed by mutual compact, for the purposes of reasoning and speculation; that besides this artificial language, man, like every other sensitive animal, is endowed with a natural language, by which he can express any strong sensation. This language does not owe its characteristical expression to the arbitrary form of articulation; but derives its whole force from the tone of voice, and modification of countenance and gesture: and of consequence these tones and gestures express the same meaning without any relation to the articulation which they may assume, and are therefore universally understood by all mankind. Now, *interjection* is the name by which we distinguish these natural expressions: these cannot be properly called words, or parts of speech; but certain adventitious sounds, or voices of nature, expressing those passions and natural emotions which spontaneously arise in the mind upon the view or narrative of interesting events. We must, therefore, still conclude, that all language properly so called is composed of *words*, all of which may be arranged into the several classes above mentioned; and as a recapitulation of the whole that we have said, we subjoin the following table, which presents at one view the several classes and subdivisions of words.

**A B L E,**

---

**GRAMMONT**, a town of the Austrian Netherlands, in the province of Flanders, situated on the river Dender: E. long.  $3^{\circ} 50'$ , and N. lat.  $50^{\circ} 55'$ .

**GRAMPOUND**, a borough-town of Cornwall, thirty-eight miles south-west of Launceston: W. long.  $5^{\circ} 25'$ , and N. lat.  $50^{\circ} 20'$ . It sends two members to parliament.

**GRAMPUS**, in ichthyology. See **DELPHINUS**.

**GRANADA**, a province of Spain, bounded by Andalusia on the north, by Murcia and the Mediterranean on the east, by the same sea on the south, and by Andalusia on the west.

**GRANADA**, the capital city of the province of Granada in Spain, situated two hundred miles south of Madrid: W. long.  $3^{\circ} 40'$ , and N. lat.  $37^{\circ} 15'$ .

**GRANADA**, a province of Terra Firma, in South America, bounded on the north by the provinces of Carthagena and St Martha, on the east by Zeneguela, by Popayan on the south, and by Darien on the west.

**GRANADA**, a city of Mexico, in North America, situated on the side of the lake Nicaragua: W. long.  $89^{\circ}$ , and N. lat.  $11^{\circ} 8'$ .

**GRANADA** is also the most southerly of the Caribbee-islands, situated one hundred and fifty miles south-west of Barbadoes: W. long.  $61^{\circ} 30'$ , and N. lat.  $12^{\circ} 15'$ .

**GRANADIER**, a soldier armed with a sword, a fire-lock, a bayonet, and a pouch full of hand grenades. They wear high caps, are generally the tallest and bravest fellows, and are always the first upon all attacks.

Every battalion of foot has generally a company of grenadiers belonging to it, or else four or five grenadiers belong to each company of the battalion; which, on occasion, are drawn out, and form a company of themselves. These always take the right of the battalion.

**GRANADILLA**. See **PASSIFLORA**.

**GRANADILLOS**, some of the Caribbee-islands, situated between the island of St Vincent and Granada; but so inconsiderable, that no nation has thought them worth possessing.

**GRANADO**, a hollow ball or shell, of iron or other metal, about two inches and a half in diameter; which, being filled with fine powder, is set on fire by means of a small fusée, fastened to the touch-hole, made of the same composition as that of a bomb: as soon as the fire enters the shell, it bursts into many pieces, much to the damage of all that stand near.

**GRANARY**, a building to lay or store corn in, especially that designed to be kept a considerable time.

Sir Henry Wotton advises, to make it look towards the north, because that quarter is the coolest and most temperate. Mr Worlidge observes, that the best granaries are built of brick, with quarters of timber wrought in the inside, to which the boards may be nailed, with which the inside of the granary must be lined so close to the bricks, that there may not be any room left for vermin to shelter themselves. There may be many stories one above another, which should be near the one to the other; because the shallower the corn lies, it is the better, and more easily turned.

**GRAND JURY**, in English law, is the jury who find bills of indictment before justices of peace and goal-delivery, or of oyer and terminer, &c. against any offenders that may be tried for the fact.

**GRANDE**, a branch of the river Niger in Africa, which discharges itself into the Atlantic ocean, in  $15^{\circ}$  W. long. and  $11^{\circ}$  N. lat.

**GRANDE**, is also a river of Brasil, in the province of Del Rey, in South America, which discharges itself into the Atlantic ocean, in  $51^{\circ}$  W. long. and  $32^{\circ}$  S. lat.

**GRANDEE**, a designation given to a nobleman of Spain or Portugal.

The grantees are suffered to be covered before the king, who treats them like princes, styling them Illustrious, in his letters; and in speaking to them, or of them, they are styled Eminences.

**GRANDENTZ**, or **GRAUDENTZ**, a city of Poland, forty-two miles south of Dantzick: E. long.  $19^{\circ}$ , and N. lat.  $53^{\circ} 30'$ .

**GRANDPRE**, a town of Champaign, in France, thirty miles east of Rheims: E. long.  $4^{\circ} 56'$ , and N. lat.  $49^{\circ} 18'$ .

**GRANICUS**, a little river near the Hellespont, in the Lesser Asia, where Alexander fought the first battle with the forces of Darius.

**GRANITE**, in natural history, a distinct genus of stones, composed of separate and very large concretions rudely compacted together; of great hardness, giving fire with steel, not fermenting with acids, and slowly and imperfectly calcinable in a great fire.

Of this genus there are three species: 1. The hard white granite, with black spots, commonly called moor-stone: this is a very valuable kind, consisting of a beautiful congeries of very variously constructed and differently coloured particles, not diffused among or running in one another, but each pure and distinct, though firmly adhering to whichever of the others it comes in contact with, and forming a very firm mass: it is much used in London for the steps of public buildings, and on other occasions where great strength and hardness are required. 2. The hard red granite, variegated with black and white, and common in Egypt and Arabia. 3. The pale whitish-granite, variegated with black and yellow. This is sometimes found in strata, but more frequently in loose nodules, and is used for paving the streets.

**GRANIVOROUS**, an appellation given to animals which feed on corn or seeds. These are principally of the bird-kind.

**GRANT**, in law, a conveyance in writing of such things as cannot pass or be conveyed by word only; such are rents, reversions, services, &c.

**GRANTHAM**, a borough-town of Lincolnshire, twenty-two miles south of Lincoln. It sends two members to parliament.

**GRANVILLE**, a port town of Normandy, from whence the noble family of Carteret take the title of earl.

**GRANULATED**, something that has undergone granulation. See the next article.

**GRANULATION**, according to Cramer, is the reducing

cing metals to small particles, in order to promote their fusion and mixture with other bodies.

**GRAPE**, the fruit of the vine. See **VINE**.

**GRAPHOMETER**, a mathematical instrument, otherwise called a semi-circle, the use of which is to observe any angle whose vertex is at the centre of the instrument in any plane (though it is most commonly horizontal, or nearly so), and to find how many degrees it contains. See **GEOMETRY**, p. 696. and Plate XCV. fig. 14.

**GRAPNELS**, a sort of anchors with four flooks, serving for boats to ride by.

There is also a kind called fire and chain grapnels, made with four barbed claws instead of flooks, and used to catch hold of the enemy's rigging, or any other part, in order for boarding them.

**GRASS**, in botany, &c. a name given to several distinct plants; as, the agrostis, or couch grass; the briza, or quaking grass, &c. Under the term grass are also comprehended all manner of herbaceous plants serving for the food of cattle, as clover, ryegrass, &c.

**GRASSHOPPER**, in zoology. See **GRYLLUS**.

**GRATIOLA**, in botany, a genus of the diandria monogynia class. The corolla is irregular; the capsule has two cells; and the calix consists of seven leaves. There are four species, none of them natives of Britain.

**GRATZ**, a city of Germany, and capital of the duchy of Stiria, sixty-five miles south of Vienna: E. long.  $15^{\circ} 55'$ , and N. lat.  $47^{\circ} 20'$ .

**GRAVE**, in music, is applied to a sound, which is of a low or deep tone.

**GRAVE**, in geography, a strong city of the Netherlands, in the province of Dutch Brabant, eight miles south of Nimeguen: E. long.  $5^{\circ} 45'$ , N. lat.  $51^{\circ} 50'$ .

**GRAVEL**, in natural history and gardening, a congeries of pebbles, which, mixed with a stiff loam, makes lasting and elegant gravel walks; an ornament peculiar to our gardens, and which gives them the advantage over those of other nations.

**GRAVEL**, in medicine. See **MEDICINE**.

**GRAVESEND**, a port-town of Kent, situated on the southern shore of the river Thames, twenty miles east of London.

**GRAVINA**, a city and bishop's see of the kingdom of Naples, twenty-seven miles south-west of Barri: E. long.  $17^{\circ}$ , and N. lat.  $41^{\circ}$ .

**GRAVITATION**. See **MECHANICS**.

**GRAVITY**. See **MECHANICS**.

*Specific GRAVITY*. See **HYDROSTATICS**.

**GRAY**, in geography, a city of Franche Compté in France, twenty-two miles north-west of Belançon: E. long.  $5^{\circ} 22'$ , N. lat.  $47^{\circ} 30'$ .

**GREASE**, a swelling and gourdiness of the legs of a horse. See **FARRIER**.

**GREECE**, the present Rumelia, and the ancient Hellas, is situated between  $20^{\circ}$  and  $26^{\circ}$  E. long. and between  $36^{\circ}$  and  $44^{\circ}$  N. lat.

It reaches from the Adriatic sea eastward to the Archipelago, and is generally a healthy and fruitful country.

**GREEK**, or **GRECIAN**, any thing belonging to ancient Greece.

The Greek language, as preserved in the writings of the celebrated authors of antiquity, as Homer, Hesiod, Demosthenes, Aristotle, Plato, Xenophon, &c. has a great variety of terms and expressions, suitable to the genius and occasions of a polite and learned people, who had a taste for arts and sciences.

**GREEK BIBLE**. See **BIBLE**.

**GREEK CHURCH**. See **CHURCH**.

**GREEK MONKS AND NUNS**, of whatever order, consider St Basil as their founder and common father, and esteem it the highest crime to deviate in the least from his constitutions. There are several beautiful convents with churches, in which the monks perform divine service day and night. Some of the monks are cenobites, or live together, wear the same habit, eat at the same table, and pursue the same exercises and employments.

**GREEN**, one of the original colours, exhibited by the rays of light. See **OPTICS**.

**GREEN**, among painters. See **BOTANY**, p. 634.

Gamboge will give five or six sorts of green with verdigrease. But the yellow, which some prefer before all others, is made of French berries; which is either deeper or fainter, according as the liquor is more or less stained by them. In like manner, a yellow, drawn from the roots of the barberry or mulberry, will answer the same purpose, being mixed with transparent verdigrease. As to verdigrease itself, it produces a fine bluish green, flows readily in the pencil, and may even serve as an ink to write with; but is subject to decay. Mountain-green is used for a grass colour. Verditer is a light green, seldom used but to colour landscapes that seem afar off. Sap-green is dark and dirty, and therefore never used but to shadow over greens in the darkest places. Copper-green is an excellent transparent and shining grass-green, if thickened in the sun shine, or over a gentle fire. It is the most used of any green in washing of prints or maps.

**GREEN CLOTH**, a board, or court of justice, held in the compting-house of the king's household, composed of the lord steward, and officers under him, who sit daily. To this court is committed the charge and oversight of the king's household in matters of justice and government, with a power to correct all offenders, and to maintain the peace of the verge, or jurisdiction of the court royal; which is every way about two hundred yards from the last gate of the palace where his majesty resides.

It takes its name, *board of green cloth*, from a green cloth spread over the board where they sit.

Without a warrant first obtained from this court, none of the king's servants can be arrested for debt.

*Clerks of the GREEN CLOTH*, are two officers of the board of green cloth, who appoint the diet of the king and his household; and keep all records, ledgers and papers relating thereto; make up bills, parcels and debentures for salaries, and provisions and necessaries for the officers of the pantry, buttery, cellar, &c.

They

They also wait upon foreign princes when entertained by his majesty.

**GREEN FINCH**, in ornithology, the English name of the greenish fringilla, with the wings and tail variegated with yellow. See **FRINGILLA**.

**GREEN-HOUSE**, or conservatory, a house in a garden contrived for sheltering and preserving the most tender and curious exotic plants, which, in our climate, will not bear to be exposed to the open air during the winter season. These are generally large and beautiful structures, equally ornamental and useful.

**GREENLAND**, or *W. Greenland*, extends from the meridian of London to 50° W. long. and from 60° to 80° N. lat.

The Danes have some colonies here, and pretend to the property of the whole. However, the Dutch make very free with the fishery on this coast, notwithstanding the representations and even menaces of the Danes on that head.

**GREENWICH**, a town of Kent, situated on the southern shore of the Thames, five miles east of London; remarkable for its royal and magnificent hospital, erected for decayed or disabled seamen who have served their country, and for its palace and most delightful park.

On the top of a steep hill in the park, stands the royal observatory, built by Charles II. and furnished with all manner of instruments for astronomical observations, and a deep dry well for observing the stars by day.

**GREGARIOUS**, among zoologists, a term applied to such animals as do not live solitary, but in herds, flocks, or coveys.

**GREGORIAN CALENDAR**, that which shews the new and full moon, with the time of Easter, and the moveable feasts depending thereon, by means of epacts, disposed through the several months of the Gregorian year. See **ASTRONOMY**, p. 490.

**GREGORIAN YEAR**. See **ASTRONOMY**, p. 490.

**GRENOBLE**, a city of France, capital of Dauphiny, forty-five miles south-east of Lyons, and thirty-six miles south-west of Chambery: E. long. 5° 28', and N. lat. 45° 12'.

**GRENOCK**, or **GREENOCK**, a port-town of Scotland, near the mouth of the river Clyde; being the principal station for the herring-fishery.

**GREWIA**, in botany, a genus of the gynandria polyandria class. The calix consists of five leaves; the petals are five; at the base of each petal there is a nectariferous scale; and the berry has four cells. There are two species, none of them natives of Britain.

**GREY**, or **GRAY**, a mixed colour partaking of the two extremes, black and white.

**GRIFFON**, in heraldry, an imaginary animal, feigned by the ancients to be half eagle and half lion; by this form they intended to give an idea of strength and swiftness joined together, with an extraordinary vigilance in guarding the things intrusted to its care. Thus the heathen naturalists persuaded the ignorant, that gold mines were guarded by these creatures with incredible watchfulness and resolution.

**GRIMPERG**, a city of Germany, in the circle of the

Lower Rhine, and earldom of Tiers: E. long. 6° 35', N. lat. 49° 40'.

**GRIMSBY**, a borough and port-town of Lincolnshire, situated at the mouth of the Humber: E. long. 4° N. lat. 53° 34'. It sends two members to parliament.

**GRINDING**, the reducing hard substances to fine powders.

*Method of GRINDING optic glasses.* Mr Huygens directs, in general, to make the breadth of the concave tool, plate, dish, or form, in which an object-glass must be ground, almost three times the breadth of the glass. Though in another place he speaks of grinding a glass whose focal distance was 200 feet, and breadth 8½ inches, in a plate only fifteen inches broad. But for eye-glasses, and others of lesser spheres, the tools must be broader in proportion to the breadth of these glasses, to afford room enough for the motion of the hand in polishing. Mr Huygens made his tools of copper, or of cast brass, which, for fear they should change their figure by bending, can hardly be cast too thick: however, he found by experience, that a tool fourteen inches broad, and half an inch thick, was strong enough for the forming glasses to a sphere of thirty-six feet diameter; when the tool was strongly cemented upon a cylindrical stone an inch thick, with hard cement made of pitch and ashes.

In order to make moulds for casting such tools as are pretty much concave, he directs, that wooden patterns should be turned in a lathe, a little thicker and broader than the tools themselves; but for tools that belong to spheres above twenty or thirty feet diameter, he says it is sufficient to make use of flat boards turned circular to the breadth and thickness required. When the plates are cast, they must be turned in a lathe exactly to the concavity required; and for this purpose it is requisite to make a couple of brass gages in the manner following, according to the directions of Mr Molyneux.

Take a wooden pole, a little longer than the radius of the spherical surface of the glass to be formed; and through the ends of it strike two small steel points, at a distance from each other equal to the radius of the sphere intended; and by one of the points hang up the pole against a wall, so that this upper point may have a circular motion in a hole or socket made of brass or iron, fixed firmly to the wall. Then take two equal plates of brass or copper, well hammered and smoothed, whose length is somewhat more than the breadth of the tool of cast brass, whose thickness may be about a tenth or a twelfth of an inch, and whose breadth may be two or three inches. Then having fastened these plates flat against the wall in a horizontal position, with the moveable point in the pole, strike a true arch upon each of them. Then file away the brass on one side exactly to the arch struck, so as to make one of the brass edges convex, and the other concave; and to make the arches correspond more exactly, fix one of the plates flat upon a table, and grind the other against it with emery. These are the gages to be made use of in turning the brass tools exactly to the sphere required.

**GRINDSTEAD**, or *East GRINDSTEAD*, a borough-town of Suffex, twenty-four miles directly south of London, which sends two members to parliament.

**GRIPSWALD**, a town of Germany, in the circle of Upper Saxony, and province of Swedish Pomerania, situated on a bay of the Baltic sea: E. long.  $13^{\circ} 40'$ , N. lat.  $54^{\circ} 15'$ .

**GRISONS**, allies of Switzerland; their country is almost of a circular form, about sixty miles over every way, and is bounded on the north by Tyrol and part of Switzerland; on the east, by Tyrol and Trent; on the south, by Italy; and by the Swiss cantons on the west.

**GRIST**, in country-affairs, denotes corn-ground, or ready for grinding.

**GROATS**, in country-affairs, oats after the hulls are off, or great oat-meal.

**GROCERS**, anciently were such persons as engrossed all merchandize that was vendible; but now they are incorporated, and make one of the companies of the city of London, which deals in sugar, foreign fruits, spices, &c.

**GROENLAND**, or **SPITZBERGEN**, a cold miserable country without inhabitants, and with very few animals or vegetables, situated between  $10^{\circ}$  and  $30^{\circ}$  E. long. and between  $77^{\circ}$  and  $82^{\circ}$  N. lat.

**GROGRAM**, a kind of stuff, made of silk and mohair.

**GRONINGEN**, the capital of a province of the same name, which makes one of the seven united provinces: E. long.  $6^{\circ} 40'$ , N. lat.  $53^{\circ} 20'$ .

**GRONOVIA**, in botany, a genus of the pentandria monogynia class. The petals are five, inserted along with the stamina into a bell-shaped calix; and the berry is dry, contains one seed, and situate below the flower. There is but one species.

**GROOM**, a name particularly applied to several superior officers belonging to the king's household, as groom of the chamber, groom of the stole. See **STOLE**, and **WARDROBE**.

**GROOM** is more particularly used for a servant appointed to attend on horses in the stable.

**GROOVE**, among miners, is the shaft or pit sunk into the earth, sometimes in the vein, and sometimes not.

**GROOVE**, among joiners, the channel made by their plough in the edge of a moulding, style, or rail, to put their pannels in, in wainscotting.

**GROSS-BEAK**, in ornithology. See **LOXIA**.

**GROSSULARIA**. See **RIBES**.

**GROTESQUE**, or **GROTESK**, in sculpture and painting, something whimsical, extravagant, and monstrous; consisting either of things that are merely imaginary, and have no existence in nature; or of things so distorted, as to raise surprize and ridicule.

**GROTSKA**, a city of Silesia, and capital of a duchy of the same name, thirty miles south of Breslaw: E. long.  $17^{\circ}$ , N. lat.  $50^{\circ} 40'$ .

**GROTTO**, a large deep cavern or den in a mountain or rock.

Of these we find several remarkable ones in different parts of the world. The most celebrated one of our own country, is that called Oukley-hole, on the

south side of Mendip-hills. Its length is about two hundred yards, and its height various; being in some places very low, and in others eight fathoms. There is another at Puzzoli, about four leagues from Naples, called the Dog's Grotto; because a dog thrown into it is immediately killed, by a destructive vapour equally fatal to all animals within its reach. The milky grotto, *crypta lactea*, about a mile from the ancient village of Bethlehem, is said to have been thus called from the holy virgin's letting fall some drops of her milk in it; on which account the earth of this cavern has been supposed to possess the virtue of restoring women's milk.

**GROTTO** is also used for a small artificial edifice made in a garden, in imitation of a natural grotto.

The outsides of these grottos are usually adorned with rustic architecture, and their inside with shell-work, coral, &c. and also furnished with various fountains, and other ornaments.

The following is recommended as a good cement for grotto-work. Take two parts of white rosin, melt it clear, add to it four parts of bees-wax; when melted together, add some flower of the stone you design to cement, two or three parts, or so much as will give the cement the colour of the stone; to this add one part of the flower of sulphur: first incorporate all together over a gentle fire, and afterwards knead it with your hands in warm water. With this fasten the stones, shells, &c. after they are well dried, and warmed before the fire.

**GROVE**, in gardening, a small wood impervious to the rays of the sun.

Groves are not only great ornaments to gardens, but are also the greatest relief against the violent heats of the sun, affording shade to walk under in the hottest parts of the day, when the other parts of the garden are useless.

**GROUND**, in agriculture, is much the same with earth or soil. See **AGRICULTURE**, p. 50.

**GROUND-IVY**, in botany. See **GLECHOMA**.

**GROUND-PINE**, in botany. See **TEUCRIUM**.

**GROUP**, in painting and sculpture, is an assemblage of two or more figures of men, beasts, fruits, or the like, which have some apparent relation to each other.

**GROUSE**, or **GROUSE**. See **TETRAO**.

**GRUBS**, in medicine, certain unctuous pimples arising in different parts of the face, but chiefly in the ale of the nose.

**GRUBBING**, in agriculture, the digging or pulling up the stubs and roots of trees.

**GRUBENHAGEN**, a town and castle of Lower Saxony, and duchy of Brunswic, remarkable for its mines of silver, copper, iron, and lead: E. long.  $9^{\circ} 36'$ , and N. lat.  $51^{\circ} 45'$ .

**GRUME**, in medicine, denotes a concreted clot of blood, milk, or other substance. Hence grumous blood is that which approaches to the nature of grume, and by its viscosity, and stagnating in the capillary vessels, produces several disorders.

**GRUMOSE roots**, such as are knotty, and fastened to one head, like those of celandine and anemonies

**GRUS**,

**GRUS**, in ichthyology. See **ARDEA**.

**GRYLLUS**, in zoology, the name of the cricket and locust kind, which, together with the grasshoppers, make only one genus of insects, belonging to the order of hemiptera: the characters of which are these: the antennæ are setaceous and filiform; the exterior wings are membranaceous, narrow, and have much of the appearance of the wings of some of the fly kind; the thorax is compressed and angulated; and the legs are formed for leaping. There are no less than 64 species. See Plate LXXXVI. fig. 3. 4. 5.

**GRYPHITES**, in natural history, an English crow's stone, an oblong fossil shell, very narrow at the head, and becoming gradually wider to the extremity, where it ends in a circular limb; the head or beak of this is very hooked or bent inward.

**GUADALAJARA**, a city of Mexico, in North America, and the capital of Guadalajara, or New Galicia: W. long. 108°, and N. lat. 20° 45'.

**GUADALAVIAR**, a river of Spain, which rises in the province of Arragon, and runs south-east through the province of Valencia, falling into the Mediterranean a little below the city of Valencia.

**GUADALAXARA**, a city of Spain, in the province of New Castile, twenty eight miles north-west of Madrid: W. long. 2° 50', and N. lat. 40° 40'.

**GUADALUPE**, one of the largest of the Caribbee-islands, eighty miles north of Martinico, subject to France: W. long. 61°, and N. lat. 16° 30'.

**GUADIANA**, a river of Spain, which rises in the middle of New Castile, and running through Estremadura, enters Portugal; where, passing through the provinces of Alentejo and Algarva, it discharges itself into the Atlantic ocean.

**GUADILBARBAR**, a river of Africa, which rises in the mountains of Atlas, runs through the kingdom of Tunis, and falls into the Mediterranean sea near Bona.

**GUADILQUIVIR**, a river of Spain, which rises in the mountains of Segura in New Castile, runs the whole length of Andalusia, and passing by Cordova and Seville falls into the Atlantic ocean at St Lucar.

**GUADIX**, a city of Spain, in the province of Granada: W. long. 3°, and N. lat. 37° 15'.

**GUAJACUM**, in botany, a genus of the decandria-monogynia class. The calix consists of five unequal segments; the petals are five, and inserted into the calix; and the capsule is angular, and has from three to five cells. There are three species, all natives of the Indies.

The wood is very ponderous, of a close compact texture; the outer part is of a yellow colour, the heart of a deep blackish green, or variegated with black, green, pale, and brown colours: the bark is thin, smooth, externally of a dark greyish hue: both have a lightly aromatic, bitterish, pungent taste. The bark is somewhat the weakest. The resin (which exudes from incisions made in the trunk of the tree) is brought to us in irregular masses, usually friable, of a dusky greenish, and sometimes of a reddish cast, with pieces of the wood among them: its taste is more acrid and pungent than that of the wood or bark.

Their general virtues are those of a warm, stimulating medicine: they strengthen the stomach and other viscera; and remarkably promote the urinary and cuticular discharge: hence in cutaneous defecations, and other disorders proceeding from obstructions of the excretory glands, and where sluggish serous humours abound, they are eminently useful: rheumatic and other pains have often been relieved by them. The resin is the most active of these drugs; and the efficacy of the others depends upon the quantity of this part contained in them: the resin is extracted from the wood in part by watery liquors, but much more perfectly by spiritous ones; the watery extract of this wood, kept in the shops, proves not only less in quantity, but considerably weaker than one made with spirit. This last extract is of the same quality with the native resin, and differs from that brought to us only in being purer. The gum, or extracts, are given from a few grains to a scruple or half a dram; which last dose proves for the most part considerably purgative.

**GUALEOR**, a city of the Hither India, and the capital of the province of Gualeor, situated forty miles south of Agra: E. long. 79°, and N. lat. 26°.

**GUAM**, the chief of the Ladrone-islands, in the Pacific ocean: E. long. 140°, and N. lat. 14°.

**GUANIHANI**, or **St SALVADOR**, now called Cattisland, one of the Bahama islands in the Atlantic ocean, in North America: W. long. 76°, N. lat. 24°.

**GUANUCO**, a town of Peru, in South America, one hundred and eighty miles north-east of Lima: W. long. 75° 15', and S. lat. 10°.

**GUARANTY**, in matters of polity, the engagement of mediatorial or neutral states, whereby they plight their faith, that certain treaties shall be inviolably observed, or that they will make war against the aggressor.

**GUARD**, in a general sense, signifies the defence or preservation of any thing; the act of observing what passes, in order to prevent surprize; or the care, precaution, and attention, we make use of, to prevent any thing happening contrary to our intention or inclinations.

**GUARD**, in the military art, is a duty performed by a body of men, to secure an army or place from being surprized by an enemy.

*Advanced GUARD*, is a party of either horse or foot, that marches before a more considerable body, to give notice of any approaching danger.

*Artillery GUARD*, is a detachment from the army, to secure the artillery: their corps de garde is in the front, and their centres round the park. This is a forty-eight hours guard: and upon a march, they go in the front and rear of the artillery, and must be sure to leave nothing behind; if a gun or waggon break down, the captain is to leave a part of his guard to assist the gunners and matrosses in getting it up again.

*Corps de GARDE*, are soldiers entrusted with the guard of a post, under the command of one or more officers.

*Forrage-GUARD*, a detachment sent out to secure the forragers, which are posted at all places, where either the enemy's party may come to disturb the forragers, or where they may be surprized too near the enemy, so

as to be in danger of being taken. They consist both of horse and foot, and must stay at their posts till the foragers all come off the ground.

**Grand GUARD**, three or four squadrons of horse, commanded by a field officer, posted at about a mile and a half from the camp, on the right and left wings, towards the enemy, for the security of the camp.

**Main GUARD**, that from whence all the other guards are detached.

**Picquet-GUARD**, a good number of horse and foot always in readiness in case of an alarm: the horse are all the time saddled, and the riders booted. The foot draw up at the head of the battalion, at the beating of the tattoo; but afterwards return to their tents, where they hold themselves in readiness to march, upon any sudden alarm. This guard is to make resistance, in case of an attack, till the army can get ready.

**Quarter-GUARD**, a small guard, commanded by a subaltern officer, posted by each battalion, about an hundred yards before the front of the regiment.

**Rear-GUARD**, that part of the army which brings up the rear, which is generally the old grand-guards of the camp. The rear-guard of a party is six or eight horse, that march about four or five hundred paces behind the party. The advanced-guard of a party on its going out, make the rear-guard on its return.

**Standard-GUARD**, a small guard, under a corporal, out of each regiment of horse, and placed on foot, in the front of each regiment.

**Van-GUARD**, that part of the army which marches in the front.

**GUARD** is more particularly understood of a soldier detached from a company or corps, to protect, detain, or secure any person, &c.

**GUARDS**, are also troops kept to guard the king's person, called also royal-guards, life-guards, gardes du corps, &c. These are distinguished into horse, foot, grenadiers, and yeomen.

The English horse-guards are distinguished by troops, and the foot-guards by regiments.

**Yeomen of the GUARDS**. See **YEOMAN**.

**The French GUARDS** are divided into those within, and those without the palace: the first consists of the guards du corps, or body-guard, which consists of four companies of horse, the first of which companies was anciently Scotch, and still retains the name, though it now consists wholly of Frenchmen. The guards without, are the gens d'armes, light horse, musqueteers, and two other regiments, the one of which is French and the other Swiss. See **GENDARMES**.

**GUARD**, in fencing, is a posture proper to defend the body from an enemy's sword.

**GUARDIAN**, in law, a person who has the charge of any thing; but more commonly it signifies one who has the custody and education of such persons as have not sufficient discretion to take care of themselves and their own affairs, as children and idiots.

**GUBEN**, a town of Germany, in the circle of Upper Saxony: E. long. 15°, and N. lat. 51° 50'.

**GUDGEON**, in ichthyology. See **GOBIOUS**.

**GUENGA**, a great river of the Hither India, which ri-

sing in the mountains of Balagate, runs north-east, and falls into the west branch of the river Ganges in Bengal.

**GUERET**, a town of France, in the province of Lionois: E. long. 2°, and north lat. 46° 5'.

**GUERNSEY**, or **GARNSEY**, an island in the English channel, on the coast of Normandy, fifty-eight miles south of Portland, in Dorsetshire, and twenty two west of cape la Hague, in Normandy; about ten miles long and as many broad, containing ten parishes. The natives, who speak French, are still governed by the Norman laws, but are subject to England.

**GUIAQUIL**, a city and port-town of Peru, situated near the Pacific ocean: W. long. 80°, and S. lat. 3°.

**GUIARA**, a port-town on the Caracoa-coast, in Terra Firma, in South America: W. long. 66°, and N. lat. 10° 35'.

**GUIDON**, a sort of flag or standard, borne by the king's life-guards; being broad at one extreme, and almost pointed at the other, and slit or divided into two.

**GUIDON**, also denotes the officer who bears the guidon. He is the same in the horse-guards that the ensign is in the foot. The guidon of a troop of horse takes place next below a cornet.

**GUIENNE**, a province of France, bounded by the Orleannois on the north, by Gascony, from which it is separated by the river Garonne, on the south, by Languedoc on the east, and by the bay of Biscay on the west.

**GUILANDINA**, in botany, a genus of the decandria monogynia class. The calix consists of one leaf; the petals are inserted into the neck of the calix; and the capsule is angular, and contains from three to six cells. There are five species, none of them natives of Britain.

**GUILD**, a fraternity or company. As to the original of these guilds or companies, it was a law among the Saxons, that every freeman of fourteen years of age should find sureties to keep the peace, or be committed; upon which the neighbours enter into an association, and become bound for each other, either to produce him who committed any offence, or to make satisfaction to the injured party; in order to which they raised a sum among themselves, which they put into a common stock; out of which they, upon occasion, made a pecuniary compensation according to the quality of the offence committed. These guilds are now companies joined together with laws and orders made by themselves, by the licence of the prince.

**Dean of Guild**, in Scots law, a magistrate of a royal borough, who is head of the merchant-company. See **SCOTS LAW**, title 4.

**GUILDFORD**, or **GULDEFORD**, a borough-town of Surry, situated on the river Wye, thirty miles south-west of London. It sends two members to parliament.

**GUILLESTRE**, a city of France, in the province of Dauphiny: E. long. 6° 20', and N. lat. 44° 45'.

**GUINEA**, a large country of Africa, situated between 15° E. and 15° W. long. and between 4° and 10° N. lat.

**1st.** The British, Dutch, French, and other nations, have forts and factories on this coast.

**GUINEA** is also the name of a British gold coin, value 1 l. 1 s. Sterling.

**GUINEA-PIG**, in zoology. See **MUS**.

**GUIPUSCOA**, the north-east division of the province of Biscay, in Spain, situated on the confines of Navarre in France.

**GUIRA**, or **GUARA GUAINUMBI**, in ornithology, the Brazilian name of the green ispida, with a crested head and very long tail.

**GUISE**, a town of France, in the province of Picardy, situated on the river Oyse: E. long 3° 36', and N. lat. 49° 55'.

**GUITAR**, **GUITARRA**, a musical instrument of the string-kind, with five double rows of strings, of which those that are bass are in the middle, unless it be for the burden, an octave lower than the fourth.

This instrument was first used in Spain, and by the Italians.

**GULA**, or **GOLA**, in architecture, a wavy member, the contour of which resembles the letter S, which the Greeks call cymatium, and our architects an ogee. See **ARCHITECTURE**.

**GULES**, in heraldry signifies the colour red, which is expressed in engraving by perpendicular lines falling from the top of the escutcheon to the bottom. See **Plate Cl. fig. 6**.

It is the first of all colours in armory, and was formerly prohibited to be worn by any person in his coat-armour, unless he were a prince, or had a permission from him. This colour is a symbol of charity, valour, and generosity, and represents blood colour, and true scarlet.

The Romans, according to Spelman, painted the bodies of their gods, and generals that triumphed, with vermilion; and under the consuls, their soldiers were clad in red; hence called ruffati. And we are told, that the Lacedemonians wore scarlet, to prevent seeing the blood issue from their wounds. Those who bear this colour are obliged to relieve such as are in danger of being oppressed by injustice.

**GULL**. See **LARUS**.

**GULPH**, or **GULF**, in geography, a part of the sea, almost surrounded by lands, the gulph of Mexico, gulph of Venice, of Lyons, &c.

**GUM**, in pharmacy, a concreted vegetable juice, which transudes through the bark of certain trees, and hardens upon the surface.

**GUM ARABIC**. See **GUM ARABIC**.

**GUM SENECA**, is a gum extremely resembling gum arabic. It is brought to us from the country through which the river Senega runs, in loose or single drops, but these are much larger than those of the gum arabic usually are; sometimes it is of the bigness of an egg, and sometimes much larger: the surface is very rough, or wrinkled, and appears much less bright than the inner substance, where the masses are broken. It has no smell, and scarce any taste. We are not acquainted with the tree which produces it. The virtues of it are the same with the gum arabic; but it is rarely used

in medicine, unless as mixed with the gum arabic: the dyers and other artificers consume the great quantities of it that are annually imported here. The negroes dissolve it in milk, and in that state make it a principal ingredient in many of their dishes; and often feed on it thus alone.

**GUM TRAGACANTH**. See **TRAGACANTH**.

**GUM MANNA**. See **MANNA**.

Other substances known by the name of gums, are as follow.

**GUM ALOES**, a preparation of aloes, as set down in the London Dispensatory.

It is made thus: Take of succotrine aloes, four ounces; of water, a quart: boil the aloes till it is dissolved as much as may be; and set all by for a night: the resin will be precipitated to the bottom of the vessel; the liquor poured off and strained, being evaporated, will have the gum. The intention of this separation of the resin, is to procure, in the gum, a medicine less purgative, but more agreeable to the stomach, than the crude aloes.

**GUM AMMONIAC**. See **AMMONIAC**.

**GUM ELEMI**. See **ELEMI**.

**GUM GUAIACUM**. See **GUAIACUM**.

**GUM LACCA**. See **LACCA**.

**GUMS**, in anatomy, See **ANATOMY**, p. 305.

**GUN**, a fire arm, or weapon of offence, which forcibly discharges a ball, shot, or other offensive matter, thro' a cylindrical barrel, by means of gun-powder. See **GUN-POWDER**.

Gun is a general name, under which are included divers or even most species of fire-arms. They may be divided into great and small.

Great guns, called also by the general name cannons, make what we also call ordinance, or artillery; under which come the several sorts of cannons, as cannon-royal, demi-cannon, &c. Culverins, demi-culverins, sakers, minions, falcons, &c. See **CANNON**.

Small guns include musquets, musketoons, carbines, blunderbusses, fowling-pieces, &c. See **MUSQUET**, &c.

Pistols and mortars are almost the only sort of regular weapons, charged with gun-powder, that are excepted from the denomination of guns. See **PISTOL** and **MORTAR**.

The advantage of large guns, or cannons, over those of a smaller bore, is generally acknowledged. Robins observes, that this advantage arises from several circumstances, particularly in distant cannonading. The distance to which larger bullets fly with the same proportion of powder, exceeds the flight of the smaller ones, almost in proportion to their diameters; so that a thirty two pound shot, for instance, being somewhat more than six inches in diameter, and a nine pound shot but four inches; the thirty-two pound will fly near half as far again as that of nine pound, if both pieces are so elevated as to range to the farthest distance possible. Another and more important advantage of heavy bullets is, that with the same velocity they break holes in all solid bodies, in a greater proportion than their weight.

weight. Finally, large cannons, by carrying the weight of their bullet in grape or lead-shot, may annoy the enemy more effectually than could be done by ten times the number of small pieces. See GUNNERY.

The author here quoted, has proposed to change the fabric of all the pieces employed in the British navy, from the twenty four pounders downwards, so that they may have the same or less weight, but a larger bore. He thinks the thirty-two pounders in present use would be proper models for this purpose. These being of fifty-two or fifty-three hundred weight, have somewhat less than a hundred and two thirds for each pound of bullet. And that this proportion would answer in smaller pieces, in point of strength, seems clear from these considerations: 1. That the strength of iron or any other metal, is in proportion to its substance. 2. That the lesser quantity of powder fired in a space it fills, has proportionably less force than a larger quantity; so that if two pieces, a large and a small one, be made in the same proportion to their respective bullets, and fired with a proportionable quantity of powder, the larger piece will be more strained, will heat more, and recoil more than the smaller.

On this scheme our present twenty-four pounders will be eased of six or eight hundred weight of useless metal; and some pieces of a less caliber, as nine and six pounders, would be sometimes eased by fourteen hundred: hence much larger guns of the same weight might be borne. Thus, instead of six, nine, twelve, and eighteen pounders, our ships might carry twelve, eighteen, and twenty-four pounders: guns would be kept cooler and quieter, and would be of more service, in many respects, if their usual charge of powder were diminished.

**GUNELLUS**, in ichthyology. See **BLENNIVS**.

**GUNNER**, an officer appointed for the service of the cannon; or one skilled to fire the guns.

In the tower of London, and other garrisons, as well as in the field, this officer carries a field-staff, and a large powder-horn in a string over his left shoulder: he marches by the guns; and when there is any apprehension of danger, his field-staff is armed with match: his business is to lay the gun to pass, and to help to load and traverse her.

**Master-GUNNER**, a patent-officer of the ordnance, who is appointed to teach all such as learn the art of gunnery, and to certify to the master general the ability of any person recommended to be one of the king's gunners. To every scholar he administers an oath, not to serve, without leave, any other prince or state; or teach any one the art of gunnery, but such as have taken the said oath.

**GUNNERY**, is the art of charging, directing, and exploding fire-arms, as cannons, mortars, muskets, &c. to the best advantage.

To the ART of GUNNERY belongs the knowledge of the force and effects of gun-powder, (see GUN POWDER), the dimensions of cannon, &c. and the proportion of the powder and ball they carry, with the

method of *managing, charging, pointing, spunging, &c.*

A cannon is a military engine, or fire-arm, for throwing iron, lead, or stone bullets, by force of gun-powder, to a place exactly opposite to the axis of the cylinder whereof it consists.

Cannons are made cylindrical, that the motion of the ball might not be retarded in its passage; and that the powder, when on fire, might not slip between the ball and the surface of the cannon, which would hinder its effect. With regard to the names, dimensions, weight, &c. of cannons, see CANNON.

Each sort of ordnance is more or less fortified; which fortification is reckoned by the thickness of the metal at the touch-hole, at the trunnions, and at the muzzle, in proportion to the diameter of the bore.

There are three degrees used in fortifying each sort of ordnance, both cannons and culverines: First, such as are ordinarily fortified, which are called legitimate pieces; secondly, such whose fortifications are lessened, which are called bastard pieces; thirdly, double fortified pieces, or extraordinary pieces.
