# I. PREFACE OF THE 10TH EDITION OF THE PH. EUR.

Only a few years ago, in 2014, we had occasion to commemorate the 50th year anniversary of the European Pharmacopoeia. This year, in 2019, we have another jubilee to celebrate, with the publication of the 10th edition of this fundamental reference work for the quality of medicinal products.

The world has changed considerably since the 8 founder countries started the work on the European Pharmacopoeia in 1964. Today we live in a globalised world where goods – including medicinal products, active substances and excipients – are produced and distributed all around the planet.

The European Pharmacopoeia has kept pace with this development: it is today a European single point of reference for the quality of medicines, with a global influence. The texts published within its pages provide a public, legally binding standard in the 38 member states and the European Union (EU) which are signatories to the *Convention on the elaboration of a European Pharmacopoeia*. The European Pharmacopoeia community has continued to grow in the past 3 years, with the accession of the Republic of Moldova to the Convention in 2017 and the arrival of 3 new observer states (India and Japan in 2016 and the Republic of Uzbekistan in 2018), clearly illustrating the lasting appeal and dynamism of the European Pharmacopoeia. The remarkable fact that today 6 European countries, 22 non-European countries, the Taiwan Food and Drug Administration of the Ministry of Health and Welfare (TFDA) and the World Health Organization (WHO) are observers, illustrates that the European Pharmacopoeia serves not only the health of several hundreds of millions of European citizens, but also has a worldwide impact.

The activities of the European Pharmacopoeia are coordinated by the European Directorate for the Quality of Medicines & HealthCare (EDQM). The work is carried out by 20 groups of experts and around 40 active working parties, together consisting of more than 700 members and involving experts from Europe and beyond. Since 2016, membership has also been extended to include experts from all around the world, a measure introduced to keep pace with the reality of market globalisation and which has enriched discussions within the groups.

It is my personal conviction that everyone involved in the work of the European Pharmacopoeia can be very proud that it is possible to establish and keep updated a work containing more than 2500 texts, each of which can only be adopted with the unanimous agreement of the Ph. Eur. member states. This is outstanding proof that humans can indeed overcome potential barriers and cultural differences.

The publication of the 10th Edition of the European Pharmacopoeia is the ideal time to look back on its development from the 1st to the 10th Edition.

The 1st Edition was published as 3 bound volumes between 1968 and 1976.

The 2nd Edition, published in 1980, came in loose-leaf binder format with a new fascicle issued in the middle of each year, containing all the texts adopted by the European Pharmacopoeia Commission in the previous year. This 2nd Edition culminated with the publication of fascicle 19 in 1995.

By the 3rd Edition, the European Pharmacopoeia included approximately 1200 texts and was issued for the first time in both electronic format (CD-ROM) and as a bound A4 book. This edition was published in 1996 and had a projected publication cycle of 5 years. To ensure that it remained current, a supplement was published every subsequent year and gradually compiled into a companion volume to the "main" publication.

From the 4th Edition, published in book and CD-ROM form, the publication cycle was reduced to 3 years, complemented by 3 non-cumulative supplements (2 only the year of publication of the main Edition), a schedule which continues today. In 2003 (Supplement 4.6), the European Pharmacopoeia entered a new era with the launch of the online version, giving users a choice of 3 different formats. The CD-ROM was then replaced by a DVD version in 2009 (Supplement 6.7) which in turn was replaced by a USB version in 2010 (7th Edition), itself replaced by a downloadable version in 2017 (Supplement 9.3).

The 10th Edition of the European Pharmacopoeia contains 2792 texts. We have come a long way from the original 3 bound volumes of the 1st Edition!

I have had the honour of acting as the 18th elected Chair of the European Pharmacopoeia Commission for the last 3 years. The challenges were numerous, but thanks to the willingness to collaborate, the readiness to find compromises and the enthusiasm of everyone involved, the European Pharmacopoeia continued to progress very well. To some of the advances made in this period, I would like to draw your attention:

- Following the decision of the European Pharmacopoeia Commission (COM) to elaborate **monographs on medicinal products containing chemically defined active substances**, 7 new monographs (*Deferiprone oral solution (2987)*, *Deferiprone tablets (2986)*, *Lacosamide infusion (2991)*, *Lacosamide oral solution (2990)*, *Lacosamide tablets (2989)*, *Raltegravir chewable tablets (2939)* and *Raltegravir tablets (2938)*) were adopted and published by Supplement 9.8, all elaborated under the P4 procedure for single-source products still under patent. The first monograph on a medicinal product containing a chemically-defined active substance, *Sitagliptin tablets (2927)*, had been already published as part of the 8th Edition of the European Pharmacopoeia.
- Since the last edition, the COM has achieved an important milestone in the field of **biotherapeutic products**. The P4Bio pilot phase was successfully concluded with the adoption of the monograph for *Etanercept (2895)*, further proof that the standardisation challenges stemming from the complexity and heterogeneity of biotherapeutics can be overcome and that monograph specifications are compatible with the emergence of biosimilars.

  The adoption of the monograph for *Infliximab concentrated solution (2928)* in November 2017 together with the feedback received from stakeholders during the Pharmeuropa public consultation, demonstrated that it was also feasible to set meaningful quality requirements for a complex monoclonal antibody (mAbs) with a molecular mass of approximately 150 kDa. In pursuit of this goal, the COM will carry on setting public standards for therapeutic mAbs through the development of a set of suitable general requirements and methodologies applicable to various quality attributes common to (classes/sub-classes of) mAbs (e.g. TNF-alpha product-based standards).

- The COM continued to update its **general chapters** through a programme of revisions and new elaborations. New general chapters were adopted on:
  - *Chemical imaging (5.24)*, the first of its kind to be introduced in any pharmacopoeia worldwide. This chapter provides specific recommendations on how to assess the performance of chemical imaging systems used for qualitative and quantitative investigations.
  - *Process analytical technology (5.25)* focusing on the interfacing of analytical techniques with the manufacturing process as a means of enhancing process control and improving process understanding.
  - *Scanning electron microscopy* (*2.9.52*) concentrating on scanning electron microscopy applied to pharmaceutical materials, from research to quality control.

  Revision work targeted the widely used general chapters on:
  - *Loss on drying (2.2.32)*
  - *Osmolality (2.2.35)*
  - *Infrared absorption spectrophotometry (2.2.24)*
  - *Absorption spectrophotometry, ultraviolet and visible (2.2.25)*
- The COM further fine-tuned its **implementation strategy for the ICH Q3D Guideline on elemental impurities** and adopted the revised versions of its general monographs on *Substances for pharmaceutical use (2034)* and *Pharmaceutical preparations (2619)*, as well as revised versions of the general chapters on *Elemental Impurities (5.20)* and on *Determination of elemental impurities (2.4.20)*. Numerous individual monographs have been revised within the framework of the implementation of the ICH Q3D guideline in the Ph. Eur.
- An important milestone was also achieved in the setting of quality requirements for **live biotherapeutic products** (LBPs) – which are medicinal products that contain live micro-organisms such as bacteria or yeasts - with the adoption of quality standards for LBPs for human use. These included the general monograph *Live biotherapeutic products for human use (3053)*, and 2 general chapters, *Microbial examination of live biotherapeutic products: test for enumeration of microbial contaminants* (*2.6.36*) and *Microbiological examination of live biotherapeutic products: test for specified micro-organisms* (*2.6.38*).
- A revised general monograph on ***Products of recombinant DNA technology*** *(0784)* was also adopted by the COM. This text provides general requirements for the manufacture and control of medicinal products derived from recombinant DNA technology and also includes requirements for the active substances in these products. Several parts of the text were updated, including the Production section of the monograph which has been entirely re-structured and modernised in line with the recommendations and guidelines published by the International Council for Harmonisation (ICH), the European Medicines Agency (EMA) and the World Health Organization (WHO).
- The general monograph on ***Substances for Pharmaceutical Use*** *(2034)* was revised to clarify the requirements for the bacterial endotoxin test and align them with the policy on the same topic approved by the COM at its 149th Session in June 2014. This revision goes hand-in-hand with the revision of the chapter on *Guidelines for Using the Test for Bacterial Endotoxins* (*5.1.10.*), published in European Pharmacopoeia Supplement 8.8, which also included recommendations for establishing limits, as well as information on how to evaluate the pyrogenicity of substances. The reference to the Guideline on the Limits of Genotoxic Impurities published by the EMA has also been replaced with a reference to the new Guideline on Assessment and Control of DNA Reactive (Mutagenic) Impurities in Pharmaceuticals to Limit Potential Carcinogenic Risk (ICH M7).
- The analytical performance of chromatographic identification tests in monographs on herbal drugs and herbal drug preparations has improved since the general chapter on high-performance thin-layer chromatography of herbal drugs and herbal drug preparations (HPTLC, *2.8.25*) was introduced in Ph. Eur. The new method not only improves selectivity but also allows a more objective evaluation of the observed zones through the use of intensity markers. The equipment described ensures standardised plate preparation, and includes a system for electronic documentation of chromatograms.
- The COM has continued its efforts to critically review the number of animals required to perform scientific procedures, revising the methods used in monographs and chapters, wherever possible, to ensure that the Ph. Eur. promotes the **3Rs principles of replacing, reducing and refining the use of animals in scientific procedures**. An example of this effort is the adoption of a new chapter on the Substitution of *in vivo* methods by *in vitro* methods for the quality control of vaccines (*5.2.14*) to facilitate the transition from *in vivo* to *in vitro* methods. This chapter provides guidance on how to validate alternative *in vitro* methods in cases where a direct head-to-head comparison with an existing *in vivo* method is not possible. Following the adoption of this new chapter, the COM adopted a revised version of the general monograph on *Vaccines for human use (0153)* and on *Vaccines for veterinary use (0062)* to reduce animal testing and encourage the use of alternatives.

  In 2017, the COM endorsed the complete suppression of the test for abnormal toxicity from the Ph. Eur. As part of this exercise, the COM adopted 49 monographs revised to remove this test, 36 of which concerned vaccines for human use. The general chapter *Abnormal toxicity* (*2.6.9*) became thus obsolete and was therefore deleted from the Ph. Eur.
- The COM has also pursued its efforts to **replace the use of hazardous chemicals** whenever possible leading to the revision of a number of monographs and chapters.

This list – which is neither comprehensive nor exhaustive –illustrates the impressive dynamism of the Ph. Eur. and the willingness of the COM, together with National Pharmacopoeia Authorities and experts from member countries and beyond, to keep pace with new developments.

This period has also seen number of new working parties created or old ones reactivated to deal with emerging issues:

- A Working Party on **Pyrrolizidine Alkaloids** (PA WP) was created and tasked with the definition of a general method for testing *Pyrrolizidine alkaloids* (*2.8.26*). This decision was taken in response to a demand expressed by European regulators and following reports in some Ph. Eur. member states that herbal medicinal products, and foodstuffs, had been found to be contaminated with plants containing pyrrolizidine alkaloids.
- The Working Party on **Gene Therapy Products** has been reactivated in response to recent developments in the field. The Working Party has been tasked with the revision of general chapter *Gene transfer medicinal products for human use* (*5.14*) to take into account newly elaborated pharmacopoeial texts, such as general chapter *Raw materials of biological origin for the production of cell-based and gene therapy medicinal products* (*5.2.12*). This Working Party will also participate in the revision of transversal texts elaborated by other groups of experts

or working parties of the Ph. Eur., such as general chapter *Quantification and characterisation of residual host cell DNA* (*2.6.35*).

Furthermore, the COM initiated activities to explore new approaches for areas where existing approaches showed limitations:

- One example is the pilot phase for monographs on traditional Chinese medicine (TCM) where the possible replacement of liquid chromatographic assays by semiquantitative HPTLC is under study. The goal is to demonstrate that the same pass-fail decision for the determination of analytical markers can be obtained and that fingerprinting may lead to more meaningful characterisation of multi-component mixtures, such as herbal drugs.
- The COM also identified semiquantitative fingerprinting as a potential new approach to tackling the challenges presented by homoeopathic preparations and has reactivated important items on the work programme concerned by this issue.

Coming to the end of this preface, I would first like to thank all the members of the European Pharmacopoeia Commission for their trust and support that allowed us to make substantial progress on so many topics.

Special thanks go to the Director of the EDQM, Dr Susanne Keitel, my two vice-chairs, Prof Torbjörn Arvidsson and Dr Hilda Köszegi Szalai, the Secretary to the European Pharmacopoeia Commission, Ms Cathie Vielle, and her two deputies, Dr Emmanuelle Charton and Dr Ulrich Rose, for their excellent work and support during my time as Chair. Together, we had very open and constructive exchanges of thoughts, which have enabled us to guide the work of the European Pharmacopoeia Commission in an efficient and successful manner - and made my work a pleasure too.

Finally, I would like to express my sincere gratitude to all the chairs and experts in groups of experts and working parties, as well as the staff of the EDQM and the National Pharmacopoeia Authorities. The European Pharmacopoeia is only possible due to their omnipresent enthusiasm, hard work and collaboration.

Thanks to your dedication and efforts, the European Pharmacopoeia will continue to ensure the quality of medicines for the benefit of patients for many years to come.

Dr Tobias Gosdschan,

Chair of the European Pharmacopoeia Commission

28 February 2019

# II. INTRODUCTION

The European Pharmacopoeia is prepared under the auspices of the Council of Europe in accordance with the Convention on the Elaboration of a European Pharmacopoeia (European Treaty Series No. 50) as amended by the Protocol to the Convention (European Treaty Series No. 134), signed by the Governments of 38 member states (Austria, Belgium, Bosnia and Herzegovina, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Montenegro, Netherlands, North Macedonia, Norway, Poland, Portugal, Republic of Moldova, Romania, Serbia, Slovak Republic, Slovenia, Spain, Sweden, Switzerland, Turkey, Ukraine, United Kingdom) and the European Union. The preparation of the Pharmacopoeia is the responsibility of the European Pharmacopoeia Commission ('the Commission'), appointed in accordance with Article 5 of the above-mentioned Convention. It is composed of delegations appointed by the Contracting Parties. Each delegation consists of not more than 3 members chosen for their competence in matters within the functions of the Commission.

Observers from non-member states and international organisations are admitted to Sessions of the Commission in accordance with the Rules of Procedure. Observers are at present admitted from Albania, Algeria, Argentina, Armenia, Australia, Azerbaijan, Belarus, Brazil, Canada, China, Georgia, Guinea, India, Israel, Japan, Kazakhstan, Republic of Korea, Madagascar, Malaysia, Morocco, Russian Federation, Senegal, Singapore, South Africa, Syrian Arab Republic, Tunisia, United States of America, Uzbekistan, Taiwan Food and Drug Administration (TFDA) and the World Health Organization (WHO).

The Convention is open for signature by European countries and observer status can serve to familiarise European countries intending to become signatories with the working methods of the Commission. The Commission recognises that interactions with countries outside Europe are essential in view of the globalisation of the supply chain for pharmaceuticals. Observer status for non-European countries helps to foster these interactions by facilitating regulatory partnerships and the exchange of information and working documents as well as participation in the scientific work of the Commission. The 10th Edition of the European Pharmacopoeia contains nearly 3000 monographs and general texts. This would not have been possible without the contributions from and dedication of a network of more than 700 experts in pharmaceutical sciences from all around the world. Participation by experts and stakeholders in the European Pharmacopoeia's public standard-setting process is vital for the development of authoritative and relevant monographs.

The functions of the Commission established by Article 6 of the Convention as amended by the Protocol are:

**Article 6**

"Subject to the provisions of Article 4 of the present Convention, the functions of the Commission shall be:

(a) to determine the general principles applicable to the elaboration of the European Pharmacopoeia;

(b) to decide upon methods of analysis for that purpose;

(c) to arrange for the preparation of and to adopt monographs to be included in the European Pharmacopoeia and;

(d) to recommend the fixing of the time limits within which its decisions of a technical character relating to the European Pharmacopoeia shall be implemented within the territories of the Contracting Parties." The European Directorate for the Quality of Medicines & HealthCare (EDQM) of the Council of Europe supports the Commission in the elaboration and revision of European Pharmacopoeia texts by providing the Scientific Secretariat. In addition, it is responsible for the establishment, production, monitoring and distribution of reference standards needed when applying the monographs. The EDQM is also active in a number of other areas related to the protection of public health, for example in certifying the quality of active pharmaceutical ingredients from specific sources and in biological standardisation.

In accordance with the terms of the Convention, the Contracting Parties undertake to take the necessary measures to ensure that the monographs of the European Pharmacopoeia become the official standards applicable within their respective territories.

## PURPOSE OF THE EUROPEAN PHARMACOPOEIA

The purpose of the European Pharmacopoeia is to promote public health by the provision of recognised common standards for the quality of medicines and their components. As these standards ensure that medicines reaching the market are safe for use by patients, it is essential that they are appropriate. Their existence also facilitates the free movement of medicinal products in Europe and beyond.

European Pharmacopoeia monographs and other texts are designed to meet the needs of:

- regulatory authorities;
- those engaged in the quality control of medicinal products and their constituents;
- manufacturers of medicinal products and their individual components.

Globalisation gives rise to new challenges in terms of the quality of pharmaceutical substances and medicines. To respond to these challenges, the European Pharmacopoeia has extended its international outreach and works closely with all its stakeholders to produce quality standards appropriate for medicinal products developed in an increasingly global world.

## SEAT OF THE EUROPEAN PHARMACOPOEIA COMMISSION

The European Pharmacopoeia Commission holds its meetings in Strasbourg, the seat of the Council of Europe.

## GENERAL PRINCIPLES

General rules for interpretation of the texts of the European Pharmacopoeia are given in the General Notices. These rules are to be applied in conjunction with the information given below.

The general principles applied during elaboration of European Pharmacopoeia texts are laid down in procedures (Rules of procedure, Guide for work and Code of practice) and in Technical Guides freely available on the EDQM website. These principles are revised regularly, generally without retrospective application, so that monographs already published may not always follow the latest recommendations; however, wherever an issue with an impact on public health is identified, monographs are revised immediately.

It is recognised that general chapters are also used independently of the monographs of the Pharmacopoeia; in these circumstances users are recommended to consult the relevant technical guide, which gives extensive information on the application of many of the methods.

**General and individual monographs**. The standards of the European Pharmacopoeia take the form of general and individual monographs. General monographs provide standards that best fulfil the aims stated above and meet the needs of users. It is usually necessary to apply one or more general monographs along with any individual monograph. Where a substance or a pharmaceutical preparation is subject to the provisions of both a general monograph and an individual monograph, the two are complementary.

An individual monograph may, exceptionally, include an exemption from one or more provisions of a general monograph.

Since, for practical reasons, it is not possible to include a cross-reference to applicable or potentially applicable general monographs in each individual monograph, cross-references are not included, except where they are necessary to avoid ambiguity. A list of general monographs is included in each new edition and supplement to help users identify those required for use with an individual monograph.

**Use of animals**. In accordance with the European Convention for the Protection of Vertebrate Animals used for Experimental and Other Scientific Purposes (CETS No. 123), elaborated under the auspices of the Council of Europe, the Commission is committed to reducing the use of animals wherever possible in pharmacopoeial testing, and encourages its stakeholders to seek alternative procedures. An animal test is included in a monograph only if it has been clearly demonstrated that it is absolutely necessary to achieve satisfactory control for pharmacopoeial purposes and no alternative is available.

**Hydrates**. When monographs refer to a hydrate form, either well-defined or not, the corresponding degree of hydration (mono-, di-, tri-, *n*-hydrate or hydrate) is indicated in the title, the chemical formula and the chemical name. For non-hydrates, 'anhydrous' is not specified in the title unless otherwise justified. When monographs cover both non-hydrates and hydrates, nothing is added to the title or the chemical name, but '$xH_2O$' is stated in the chemical formula.

**Chiral substances**. Monographs on chiral substances that describe a particular enantiomer include a test to confirm enantiomeric purity, usually by chiral liquid chromatography. A test for racemic character using optical rotation is included only if there is information on the specific optical rotation of the enantiomers that indicates that such a test would be discriminating in terms of enantiomeric purity. If other techniques, such as chiral liquid chromatography, can serve the intended purpose, they are prescribed instead of optical rotation.

**Polymorphism**. Where a substance shows polymorphism, this is usually stated under Characters. In general, no particular crystalline form is required in monographs; in rare cases, however, a monograph may cover a specific crystalline form and describe, for example, an infrared absorption spectrophotometric identification test. In these cases, the spectrum is to be recorded using the substance in the solid state without recrystallisation and the chemical reference substance described is of the required crystalline form. In addition to these exceptional cases, depending on the function of a given substance in a pharmaceutical preparation, it may be necessary for a manufacturer to ensure that a particular crystalline form is used. The information given under Characters is intended to alert users to the need to evaluate this aspect during the development of a pharmaceutical preparation. The general monograph *Substances for pharmaceutical use (2034)* and general chapter *5.9. Polymorphism* should also be consulted.

**Impurities**. Together with the general monograph *Substances for pharmaceutical use (2034)*, general chapter *5.10. Control of impurities in substances for pharmaceutical use* describes the policy for the control of impurities in individual monographs and explains how the limits in the related substances test are to be understood.

The current general policy of the Commission for substances for pharmaceutical use is to include quantitative tests for impurities in monographs. Most of the older monographs that predate this policy have been revised to introduce quantitative methods. Where a monograph does not conform to the general policy, compliance with the general monograph *Substances for pharmaceutical use (2034)* implies that the individual monograph requirements need to be supplemented by the user, using the decision tree provided in general chapter *5.10*.

Monographs on medicinal products containing chemically defined active substances describe limits for degradation products arising during manufacture and shelf-life of the medicinal product, including those synthesis impurities that are also degradation products. To this end, quantitative tests are included in the monographs.

**Elemental impurities**. The strategy for the control of elemental impurities has been aligned to the International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use (ICH) Q3D guideline and the core principles of this guideline are reproduced in general chapter *5.20. Elemental impurities*. The requirements for the control of elemental impurities, which is strongly based on risk management, are given in the general monographs on *Pharmaceutical preparations (2619)* and on *Substances for pharmaceutical use (2034)*, while to a certain extent tests for elemental impurities have been removed from individual monographs (e.g. *2.4.8. Heavy metals*).

**Residual solvents**. The requirements for residual solvents are given in the general monograph *Substances for pharmaceutical use (2034)* and in general chapter *5.4. Residual solvents*. Thus, all active substances and excipients are subjected to relevant control of residual solvents, whether or not a test is specified in the individual monograph. The requirements are aligned with the ICH Q3C guideline.

**Bacterial endotoxins**. In June 2014, the Commission approved a new policy on bacterial endotoxins in substances for pharmaceutical use. The general monograph *Substances for pharmaceutical use (2034)* states that a substance must comply with the bacterial endotoxins test (BET) if it is labelled as 'bacterial endotoxin-free', or if it is intended for use in the manufacture of parenteral preparations or preparations for irrigation without a further appropriate procedure for the removal of bacterial endotoxins. The monograph references general chapters *2.6.14. Bacterial endotoxins* and *5.1.10. Guidelines for using the test for bacterial endotoxins*. According to the general monograph on *Parenteral preparations (0520)*, pharmaceutical preparations for parenteral administration must comply with the test for bacterial endotoxins.

Monographs for substances for pharmaceutical use elaborated after the implementation of this policy do not describe a test for bacterial endotoxins, this aspect being covered by the requirements of the general monograph on *Substances for pharmaceutical use (2034*). There is an exception to this rule: the test is maintained in new monographs when, for example, a specific sample preparation must be used or a specific method applied. In such cases, no limit is given. For all monographs for substances for pharmaceutical use published before the implementation of the policy, the test for bacterial endotoxins is retained: existing limits remain in these monographs to maintain the use of well-established limits.

**Equipment, reagents**. As an aid to users, information is made available via the Knowledge database (see below) on chromatographic columns that have been found to be satisfactory during development of monographs and general methods. Information is also given on other equipment and reagents where this is considered useful. This information is given as a guide and does not imply that other columns, equipment or reagents than those specified are not suitable.

**Homoeopathic preparations**. A monograph on methods of preparation of homoeopathic stocks and potentisation, general monographs on homoeopathic preparations, mother tinctures for homoeopathic preparations and herbal drugs for homoeopathic preparations, and individual monographs on raw materials and stocks for homoeopathic preparations are included in a separate section of the European Pharmacopoeia. It is understood that when the same substance is used in both homoeopathic and other preparations, the monograph in the main body of the European Pharmacopoeia applies.

**Herbal drugs and herbal drug preparations (including traditional Chinese medicines)**. All relevant monographs are grouped together in a separate section of the European Pharmacopoeia.

**Protected species**. Monographs, notably those on herbal drugs, may cover material obtained from protected species. Inclusion of these monographs is without prejudice to the provisions for protection of these species under national and international law.

**Patents**. The description in the European Pharmacopoeia of articles subject to patent protection does not confer or imply any right to the use of such patents by any person or persons other than the proprietors of the patents concerned.

MONOGRAPHS ON PHARMACEUTICAL PREPARATIONS

The general monograph *Pharmaceutical preparations (2619)* is intended to be a reference source of standards in the European Pharmacopoeia on active substances, excipients and dosage forms which are to be applied in the manufacture/preparation of pharmaceuticals, but not a guide on how to manufacture as there is specific guidance available covering methods of manufacture and associated controls.

Harmonisation and standardisation for pharmaceutical preparations is dealt with via the drafting of general dosage form monographs setting out elements common to all preparations covered by the monograph, and via the development of standard test methods used to test medicinal products. The inclusion of these general monographs and methods in the European Pharmacopoeia provides competent authorities and manufacturers with a common basis for the preparation and evaluation of marketing authorisation applications. In addition, after a successful pilot phase, individual monographs on medicinal products containing chemically defined active substances are now elaborated on a regular basis.

Reference standards established for the assay of active substances and excipients may be suitable for use as assay standards for preparations when the conditions stated in general chapter *5.12. Reference standards* are fulfilled.

WORK PROGRAMME

The work programme (elaboration of new monographs or general chapters or revision of existing texts) is decided by the Commission at the 3 annual sessions. In general, whenever 2 member states express a wish to elaborate a monograph, the Commission adds the item to the work programme. Changes to the work programme are published on the EDQM website and in Pharmeuropa. Information is also provided to industry associations registered with the Secretariat and to manufacturers' liaison contacts and in the EDQM Knowledge database (including reasons for the revision). Interested parties are invited to contact the Secretariat for any items where they wish to be involved in the work.

CERTIFICATION PROCEDURE

The procedure for the certification of suitability to the monographs of the Pharmacopoeia allows suppliers to demonstrate that the quality of their substance is suitably controlled by the relevant monographs (see Public Health Committee (Partial Agreement) Resolution AP-CSP (07) 1 or any subsequent revision, available from the EDQM and on its website) and is an aid to the use of monographs in marketing authorisation applications where relevant, complemented by additional tests appended to the certificate. The certification procedure also applies to herbal drugs, herbal drug preparations and any substance subject to the risk of transmissible spongiform encephalopathy (TSE). Certificates of suitability are issued by the EDQM only for substances produced under a suitable quality system. Certificates are granted with respect to published monographs. Details on how this scheme is run are available from the Secretariat and on the EDQM website. A daily updated list of the certificates granted is available online on the EDQM website, including voided or suspended certificates.

PUBLICATIONS

The official version of the European Pharmacopoeia is available in English and in French. Three additional supplements are published every year.

**Implementation**. The date on which monographs are to be implemented is fixed by a Resolution of the European Committee on Pharmaceuticals and Pharmaceutical Care (Partial Agreement) of the Council of Europe, following a recommendation by the Commission. This date is usually 1 year after adoption and about 6 months after publication. Where a monograph is to be implemented at a date earlier than the next publication date of the European Pharmacopoeia or a supplement, a Resolution of the European Committee on Pharmaceuticals and Pharmaceutical Care gives the full text to be implemented. The text is also published in Pharmeuropa for information and posted on the EDQM website as part of the Resolution.

**Pharmeuropa** is the European Pharmacopoeia Forum. Texts are published for public enquiry 4 times per year (with deadlines for comments) as an aid to the elaboration of monographs and as a vehicle for information on pharmacopoeial and related matters. It is therefore extremely important that manufacturers and users of the substances provide feedback on the draft monographs. Pharmeuropa Bio & Scientific Notes, a publication indexed by bibliographic services, includes scientific papers related to the establishment of biological reference preparations and validation of biological methods within the Biological Standardisation Programme of the EDQM, and to various aspects of pharmaceutical analysis and other subjects relevant to the Pharmacopoeia. Both of these are only available online as free publications.

**Knowledge database**. The EDQM website provides access to a database containing a variety of information related to monographs and other texts and intended to facilitate their proper use. Information is provided on:

- the status (e.g. whether the text is under elaboration or a revision is ongoing, together with a brief description, if deemed appropriate);
- typical chromatograms (or other raw data) obtained for certain chromatographic separations and brand names of chromatography columns used in monograph development;
- suppliers of reagents and equipment that may be difficult to find for some users;
- revisions of the texts on a historical basis, starting with the 5th Edition;
- harmonisation status;
- other relevant topics.

**Archives (online)**. The European Pharmacopoeia Archives contain copies of the 1st to the 9th Editions in PDF format. They are available to all European Pharmacopoeia subscribers with an up-to-date subscription and a registered EPID code.

**Website**. Information on activities and many other aspects of the European Pharmacopoeia can be found on the EDQM website (www.edqm.eu).

**HelpDesk**. Many technical and other enquiries are addressed to the EDQM by users. They should be submitted via the HelpDesk on the EDQM website. The EDQM will deal with enquiries that are related to the use of monographs and other texts of the European Pharmacopoeia. The HelpDesk has a section of Frequently Asked Questions that should be consulted by users before submission of an enquiry.

**Revision programme**. Proposals to revise a text of the European Pharmacopoeia may be submitted by a delegation, by the Chair of the Commission, by the chair of a group of

experts or a working party, by a user or by the Secretariat. Requests for revision may be submitted via the national pharmacopoeia authority of a member state or, where this is not possible, to the EDQM via the HelpDesk. Proposals must be accompanied by sufficient data to justify the need for the revision. Monographs and other texts of the European Pharmacopoeia are revised as necessary following a decision of the Commission. Draft revised texts are published in Pharmeuropa.

COMBISTATS

Certain tests in monographs, particularly biological assays, require statistical analysis of the results. The EDQM has developed a computer programme, CombiStats, which can be used for statistical analysis of results of biological dilution assays. Information on the programme, with conditions of access and use, is available on the EDQM website.

INTERNATIONAL HARMONISATION

In an increasingly globalised world, the need for global quality standards has become ever more pressing. Standards are a vital instrument for marketing authorisation, market surveillance and the free movement and trade of medicines amongst regions and countries. Amongst other harmonisation initiatives, the European Pharmacopoeia is engaged in a process of harmonisation with the Japanese Pharmacopoeia and the United States Pharmacopeia, within an informal structure referred to as the Pharmacopoeial Discussion Group (PDG).

Where harmonisation of general chapters is carried out, the aim is to arrive at interchangeable methods or requirements so that demonstration of compliance using a general chapter from one of the 3 pharmacopoeias implies that the same result would be obtained using the general chapter of either of the other pharmacopoeias. To help regulatory authorities and other users recognise the interchangeability of selected harmonised general chapters, the International Council for Harmonisation of Technical Requirements for Pharmaceuticals for Human Use (ICH) has issued topic-specific annexes with information about a limited number of these texts in order to facilitate their implementation. More information is available from the ICH website (ich.org).

Where harmonisation of monographs is carried out, the aim is to arrive at identical requirements for all attributes of a product. Information on any non-harmonised attributes and local requirements is included in the relevant European Pharmacopoeia general chapters and monographs.

# III. EUROPEAN PHARMACOPOEIA COMMISSION

## COMPOSITION OF THE COMMISSION, LIST OF EXPERTS AND OF THE SECRETARIAT (2019)

### CHAIR AND VICE-CHAIRS OF THE COMMISSION

| | | |
|---|---|---|
| Chair | Tobias | GOSDSCHAN |
| Vice-Chairs | Torbjörn | ARVIDSSON |
| | Hilda | KÖSZEGI SZALAI |

### MEMBERS OF THE COMMISSION

| | | |
|---|---|---|
| Austria | Andreas | MAYRHOFER |
| | Friedrich | LACKNER |
| | Gunilt | VEIDER |
| Belgium | Jos | HOOGMARTENS |
| | Katrien | VAN LANDUYT |
| Bosnia and Herzegovina | Alija | UZUNOVIC |
| | Ana | BORIC |
| | Tatjana | PONORAC |

# IV. CONTENTS OF THE 10th EDITION

The 10th Edition consists of new texts as well as all current texts from the 9th Edition, some of which have been revised or corrected.

Lists of the monographs and general chapters that, for the 10th Edition, are new, revised or corrected, or have had their titles or chapter numbers changed, are given below.

The version date (for example 01/2020 for a text that is new or revised for the 10th Edition), completed by 'corrected X.X' if a corrected version of the text has subsequently been published in Supplement X.X, and the reference number (4 digits for monographs and 5 digits for general chapters) are specified above the title of each monograph and general chapter. The version date, completed by 'corrected X.X' if appropriate, makes it possible to identify the successive versions of texts in different editions.

The volume in which the current version was first published is stated in the Knowledge database on the EDQM website.

As of the 10th Edition, all revised or corrected parts of a text are indicated by vertical lines in the margin and horizontal lines in the margin indicate where parts of a text have been deleted. Lines in the margin that were present in revised or corrected texts in the previous edition are deleted with each new edition.

Corrected texts are to be taken into account as soon as possible and not later than the end of the month following the month of publication of the volume. New and revised texts are to be taken into account not later than the implementation date.

A barcode is included at the start of each text, providing a link to further information on the text (e.g. the Knowledge database) for smartphones and tablets with a camera and a barcode reader app.

In addition to corrections made to individual texts, the following decisions and systematic modifications have been made to the texts of the European Pharmacopoeia for the 10th Edition.

- For texts not currently undergoing revision, the wording used in the calculation of percentage contents in the quantitative expression of acceptance criteria in tests for related substances has been modified to specify the full name of the substance (i.e. including counter-ions, hydrates etc.).
- Tests using diphosphorus pentoxide, predominantly tests for loss on drying, have been modified, where possible, to avoid the use of this substance due to its toxicity.
- The names and descriptions of the reagents used to describe stationary phases for gas chromatography have been revised.
- 'Tamper-proof' has been replaced by 'tamper-evident'.
- Reference to general chapter *2.8.23. Microscopic examination of herbal drugs* has been added when microscopic examination is carried out using a powder with a non-standard sieve size.
- The terms 'coarse' and 'coarsely' have been deleted from 'coarse powder (1400) (*2.9.12*)' and 'coarsely powdered herbal drug (1400) (*2.9.12*)'.
- Results are expressed in per cent instead of per cent *m/m* in the tests Dry residue of extracts (*2.8.16*) and Loss on drying of extracts (*2.8.17*).

*Individual copies of texts published in this edition will not be supplied.*

*Subscribers to the current version (book or electronic) of the European Pharmacopoeia have access to an online archive version of all obsolete editions and supplements of the European Pharmacopoeia in PDF format.*

*A list of new reagents published during the course of this edition is available under 'Useful information' in Pharmeuropa Online.*

## NEW TEXTS

*The following texts appear for the first time in the European Pharmacopoeia. They will be implemented on* ***1 January 2020*** *at the latest.*

### GENERAL CHAPTERS

2.6.35. Quantification and characterisation of residual host-cell DNA

2.9.49. Powder flow properties by shear cell methods

2.9.52. Scanning electron microscopy

3.3. Containers for human blood and blood components, and materials used in their manufacture; transfusion sets and materials used in their manufacture; syringes

5.25. Process analytical technology

### MONOGRAPHS

**Vaccines for veterinary use**

Infectious pancreatic necrosis vaccine (inactivated, oil-adjuvanted, injectable) for salmonids (3063)

**Herbal drugs and herbal drug preparations**

Abelmoschi corolla (2827)

Serratula coronata herb (2754)

**Monographs**

Benzydamine hydrochloride (2759)

Cocoa butter (2607)

Dronedarone hydrochloride (3039)

Octreotide (2414)

Prasugrel hydrochloride (3040)

Squalene (2805)

Tapentadol hydrochloride (3035)

Tetracaine (2909)

Topiramate (2616)

Vincamine (1800)

# REVISED TEXTS

*The following texts have been technically revised since their last publication. They will be implemented on **1 January 2020** at the latest.*

**GENERAL CHAPTERS**

2.2.25. Absorption spectrophotometry, ultraviolet and visible
2.6.8. Pyrogens
2.6.33. Residual pertussis toxin
2.7.2. Microbiological assay of antibiotics
2.7.23. Numeration of CD34/CD45+ cells in haematopoietic products
2.7.35. Immunonephelometry for vaccine component assay
2.8.25. High-performance thin-layer chromatography of herbal drugs and herbal drug preparations
2.9.1. Disintegration of tablets and capsules
2.9.20. Particulate contamination: visible particles
3.1.13. Plastic additives
3.3.1. Materials for containers for human blood and blood components
3.3.2. Materials based on plasticised poly(vinyl chloride) for containers for human blood and blood components
3.3.3. Materials based on plasticised poly(vinyl chloride) for tubing used in sets for the transfusion of blood and blood components
3.3.4. Sterile plastic containers for human blood and blood components
3.3.5. Empty sterile containers of plasticised poly(vinyl chloride) for human blood and blood components
3.3.6. Sterile containers of plasticised poly(vinyl chloride) for human blood containing anticoagulant solution
3.3.7. Sets for the transfusion of blood and blood components
3.3.8. Sterile single-use plastic syringes
4. Reagents
5.3. Statistical analysis of results of biological assays and tests
5.8. Pharmacopoeial harmonisation
5.21. Chemometric methods applied to analytical data
5.22. Names of herbal drugs used in traditional Chinese medicine
5.24. Chemical imaging

**MONOGRAPHS**

**Dosage forms**

Powders, oral (1165)

**Vaccines for human use**

Diphtheria, tetanus and pertussis (acellular, component) vaccine (adsorbed) (1931)
Diphtheria, tetanus and pertussis (acellular, component) vaccine (adsorbed, reduced antigen(s) content) (2764)
Diphtheria, tetanus, pertussis (acellular, component) and haemophilus type b conjugate vaccine (adsorbed) (1932)
Diphtheria, tetanus, pertussis (acellular, component) and hepatitis B (rDNA) vaccine (adsorbed) (1933)
Diphtheria, tetanus, pertussis (acellular, component) and poliomyelitis (inactivated) vaccine (adsorbed) (1934)
Diphtheria, tetanus, pertussis (acellular, component) and poliomyelitis (inactivated) vaccine (adsorbed, reduced antigen(s) content) (2329)
Diphtheria, tetanus, pertussis (acellular, component), hepatitis B (rDNA), poliomyelitis (inactivated) and haemophilus type b conjugate vaccine (adsorbed) (2067)
Diphtheria, tetanus, pertussis (acellular, component), poliomyelitis (inactivated) and haemophilus type b conjugate vaccine (adsorbed) (2065)
Influenza vaccine (surface antigen, inactivated, prepared in cell cultures) (2149)
Influenza vaccine (whole virion, inactivated, prepared in cell cultures) (2308)
Pertussis vaccine (acellular, component, adsorbed) (1356)
Pertussis vaccine (acellular, co-purified, adsorbed) (1595)
Poliomyelitis vaccine (oral) (0215)
Yellow fever vaccine (live) (0537)

**Vaccines for veterinary use**

Enteric redmouth disease vaccine (inactivated) for rainbow trout (1950)

**Immunosera for human use**

Botulinum antitoxin (0085)

**Herbal drugs and herbal drug preparations**

Indigo plant leaf (2727)

**Monographs**

Alfacalcidol (1286)
Aluminium magnesium silicate (1388)
Anticoagulant and preservative solutions for human blood (0209)
Apomorphine hydrochloride hemihydrate (0136)
Arachis oil, hydrogenated (1171)
Benserazide hydrochloride (1173)
Biotin (1073)
Boldine (2971)
Borage (starflower) oil, refined (2105)
Caffeine (0267)
Caffeine monohydrate (0268)
Candesartan cilexetil (2573)
Carmellose sodium (0472)
Carmellose sodium, low-substituted (1186)
Carmustine (1187)
Castor oil, hydrogenated (1497)
Castor oil, refined (2367)
Castor oil, virgin (0051)
Cellulose, microcrystalline (0316)
Cetyl palmitate (1906)
Chlorpromazine hydrochloride (0475)
Chlortalidone (0546)
Cholesterol for parenteral use (2397)
Cod-liver oil (type A) (1192)
Cod-liver oil (type B) (1193)
Copovidone (0891)
Cottonseed oil, hydrogenated (1305)
Croscarmellose sodium (0985)
Desipramine hydrochloride (0481)
Diacerein (2409)
Diethylene glycol palmitostearate (1415)
Ethylene glycol monopalmitostearate (1421)
Evening primrose oil, refined (2104)
Fenoterol hydrobromide (0901)
Fish oil, rich in omega-3 acids (1912)
Follitropin (2285)
Follitropin concentrated solution (2286)
Galactose (1215)

Galantamine hydrobromide (2366)
Gelatin (0330)
Glycerol dibehenate (1427)
Glycerol distearate (1428)
Glycerol monostearate 40-55 (0495)
Gonadotrophin, chorionic (0498)
Hard fat (0462)
Hard fat with additives (2731)
Heparin calcium (0332)
Heparin sodium (0333)
Human measles immunoglobulin (0397)
Human plasma for fractionation (0853)
Human plasma (pooled and treated for virus inactivation) (1646)
Imidacloprid for veterinary use (2924)
Infliximab concentrated solution (2928)
Irbesartan (2465)
Lauromacrogol 400 (2046)
Levodropropizine (1535)
Losartan potassium (2232)
Macrogol 15 hydroxystearate (2052)
Macrogol 30 dipolyhydroxystearate (2584)
Mesterolone (1730)
Olmesartan medoxomil (2600)
Oxytetracycline hydrochloride (0198)
Palmitic acid (1904)
Penicillamine (0566)
Phenylpropanolamine hydrochloride (0683)
Phytomenadione, racemic (3011)
Propranolol hydrochloride (0568)
Propyl gallate (1039)
Propylene glycol monopalmitostearate (1469)
Protamine sulfate (0569)
Pyridoxine hydrochloride (0245)
Safflower oil, refined (2088)
Sodium starch glycolate (type A) (0983)
Sodium starch glycolate (type B) (0984)
Sodium starch glycolate (type C) (1566)
Solutions for organ preservation (1264)
Soya-bean oil, hydrogenated (1265)
Soya-bean oil, refined (1473)
Squalane (1630)
Sucralfate (1796)
Terbutaline sulfate (0690)
Tilidine hydrochloride hemihydrate (1767)
Triglycerides, medium-chain (0868)
Urofollitropin (0958)
Urokinase (0695)
Valsartan (2423)
Vigabatrin (2305)
Vinorelbine tartrate (2107)
Wheat starch (0359)
Wheat-germ oil, refined (1379)
Wheat-germ oil, virgin (1480)

# CORRECTED TEXTS

*The following texts have been corrected for the 10th Edition and specify 'corrected 10.0' above the title. These corrections are to be taken into account as soon as possible and not later than* ***31 August 2019*** *(the end of the month following the month of publication of the 10th Edition).*

**GENERAL CHAPTERS**

1. General notices
2.2.5. Relative density
2.2.29. Liquid chromatography
2.2.31. Electrophoresis
2.4.23. Sterols in fatty oils
2.4.25. Ethylene oxide and dioxan
2.4.26. *N*,*N*-Dimethylaniline
2.4.32. Total cholesterol in oils rich in omega-3 acids
2.5.19. *O*-Acetyl in polysaccharide vaccines
2.5.37. Methyl, ethyl and isopropyl methanesulfonate in methanesulfonic acid
2.5.38. Methyl, ethyl and isopropyl methanesulfonate in active substances
2.5.39. Methanesulfonyl chloride in methanesulfonic acid
2.5.40. Methyl, ethyl and isopropyl toluenesulfonate in active substances
2.5.41. Methyl, ethyl and isopropyl benzenesulfonate in active substances
2.7.8. Assay of tetanus vaccine (adsorbed)
2.8.9. Residue on evaporation of essential oils
2.9.10. Ethanol content
2.9.11. Test for methanol and 2-propanol
3.1.14. Materials based on plasticised poly(vinyl chloride) for containers for aqueous solutions for intravenous infusion
3.2. Containers
5.1.2. Biological indicators and related microbial preparations used in the manufacture of sterile products
5.1.6. Alternative methods for control of microbiological quality
5.2.12. Raw materials of biological origin for the production of cell-based and gene therapy medicinal products
5.9. Polymorphism
5.10. Control of impurities in substances for pharmaceutical use
5.12. Reference standards
5.15. Functionality-related characteristics of excipients
5.16. Crystallinity

**MONOGRAPHS**

**General monographs**

Chemical precursors for radiopharmaceutical preparations (2902)
Immunosera for human use, animal (0084)
Immunosera for veterinary use (0030)
Live biotherapeutic products for human use (3053)
Vaccines for human use (0153)
Vaccines for veterinary use (0062)

**Dosage forms**

Ear preparations (0652)
Eye preparations (1163)
Intramammary preparations for veterinary use (0945)

Liquid preparations for cutaneous application (0927)
Nasal preparations (0676)
Parenteral preparations (0520)
Rectal preparations (1145)
Semi-solid preparations for cutaneous application (0132)
Vaginal preparations (1164)

**Vaccines for human use**

Anthrax vaccine for human use (adsorbed, prepared from culture filtrates) (2188)
Diphtheria and tetanus vaccine (adsorbed) (0444)
Diphtheria and tetanus vaccine (adsorbed, reduced antigen(s) content) (0647)
Diphtheria, tetanus and pertussis (whole cell) vaccine (adsorbed) (0445)
Diphtheria, tetanus and poliomyelitis (inactivated) vaccine (adsorbed, reduced antigen(s) content) (2328)
Diphtheria vaccine (adsorbed) (0443)
Diphtheria vaccine (adsorbed, reduced antigen content) (0646)
Influenza vaccine (live, nasal) (2772)
Influenza vaccine (split virion, inactivated) (0158)
Influenza vaccine (surface antigen, inactivated) (0869)
Influenza vaccine (surface antigen, inactivated, virosome) (2053)
Influenza vaccine (whole virion, inactivated) (0159)
Measles, mumps, rubella and varicella vaccine (live) (2442)
Pneumococcal polysaccharide vaccine (0966)
Poliomyelitis vaccine (inactivated) (0214)
Shingles (herpes zoster) vaccine (live) (2418)
Tetanus vaccine (adsorbed) (0452)
Typhoid polysaccharide vaccine (1160)
Varicella vaccine (live) (0648)

**Immunosera for human use**

Viper venom antiserum, European (0145)

**Radiopharmaceutical preparations and starting materials for radiopharmaceutical preparations**

Choline ([$^{11}$C]methyl) injection (2462)
Copper tetramibi tetrafluoroborate for radiopharmaceutical preparations (2547)
Fluorocholine ($^{18}$F) injection (2793)

**Sutures for human use**

Sutures for human use: introduction (90004)
Sutures, sterile non-absorbable (0324)

**Herbal drugs and herbal drug preparations**

Herbal drugs: introduction (90029)
Achyranthes bidentata root (2999)
Akebia stem (2472)
Aloes dry extract, standardised (0259)
Amomum fruit (2554)
Artichoke leaf (1866)
Belladonna, prepared (0222)
Capsicum soft extract, standardised (2529)
Cassia oil (1496)
Cinnamon bark oil, Ceylon (1501)
Fennel, bitter (0824)
Fennel, sweet (0825)
Gentian tincture (1870)
Ginger (1522)
Goldenseal rhizome (1831)
Juniper oil (1832)
Long pepper (2453)
Mandarin oil (2355)
Mastic (1876)
Myrrh tincture (1877)
Nutmeg oil (1552)
Opium tincture, standardised (1841)
Oregano (1880)
Pepper (2477)
Roselle (1623)
Round amomum fruit (2555)
Sage tincture (1889)
Saw palmetto extract (2579)
Saw palmetto fruit (1848)
Star anise (1153)
Stramonium, prepared (0247)
Sweet orange oil (1811)
Thyme oil, thymol type (1374)
Turmeric rhizome (2543)

**Homoeopathic preparations**

Homoeopathic preparations: introduction (90006)
Agaricus phalloides for homoeopathic preparations (2290)
Anacardium for homoeopathic preparations (2094)
Belladonna for homoeopathic preparations (2489)
Cocculus for homoeopathic preparations (2486)
Hydrastis canadensis for homoeopathic preparations (2500)
Ignatia for homoeopathic preparations (2513)
Magnesium phosphoricum for homoeopathic preparations (2505)
Nux-vomica for homoeopathic preparations (2514)
Staphysagria for homoeopathic preparations (2289)

**Monographs**

*N*-Acetyltyrosine (1384)
Alimemazine hemitartrate (2650)
Almagate (2010)
Alprazolam (1065)
Alprenolol hydrochloride (0876)
Aluminium hydroxide, hydrated, for adsorption (1664)
Aluminium stearate (1663)
Alverine citrate (2156)
Amantadine hydrochloride (0463)
Amikacin sulfate (1290)
4-Aminobenzoic acid (1687)
Amoxicillin sodium (0577)
Amphotericin B (1292)
Ampicillin sodium (0578)
Anti-T lymphocyte immunoglobulin for human use, animal (1928)
Aprotinin (0580)
Aprotinin concentrated solution (0579)
Arginine hydrochloride (0805)
Aripiprazole (2617)
Articaine hydrochloride (1688)
Atazanavir sulfate (2898)
Atropine (2056)
Atropine sulfate (0068)
Azelastine hydrochloride (1633)
Bacitracin (0465)
Bacitracin zinc (0466)
Benzalkonium chloride (0372)
Benzalkonium chloride solution (0371)
Benzyl alcohol (0256)
Benzyl benzoate (0705)
Benzylpenicillin (benzathine) tetrahydrate (0373)

Benzylpenicillin potassium (0113)
Benzylpenicillin (procaine) monohydrate (0115)
Benzylpenicillin sodium (0114)
Biperiden hydrochloride (1074)
Bismuth subsalicylate (1495)
Bleomycin sulfate (0976)
Botulinum toxin type A for injection (2113)
Botulinum toxin type B for injection (2581)
Brimonidine tartrate (2760)
Bromhexine hydrochloride (0706)
Brompheniramine maleate (0977)
Bupivacaine hydrochloride (0541)
Buserelin (1077)
Calcitonin (salmon) (0471)
Calcium folinate hydrate (0978)
Calcium glucoheptonate (1399)
Calcium levofolinate hydrate (1606)
Captopril (1079)
Carbimazole (0884)
Cefalotin sodium (0987)
Cefamandole nafate (1402)
Cefapirin sodium (1650)
Cefazolin sodium (0988)
Cefepime dihydrochloride monohydrate (2126)
Cefoperazone sodium (1404)
Cefotaxime sodium (0989)
Cefoxitin sodium (0990)
Ceftazidime pentahydrate (1405)
Ceftazidime pentahydrate with sodium carbonate for injection (2344)
Ceftriaxone sodium (0991)
Cefuroxime axetil (1300)
Cefuroxime sodium (0992)
Cetostearyl alcohol (0702)
Cetostearyl alcohol (type A), emulsifying (0801)
Cetostearyl alcohol (type B), emulsifying (0802)
Cetyl alcohol (0540)
Chloramphenicol (0071)
Chloramphenicol palmitate (0473)
Chloramphenicol sodium succinate (0709)
Chlorobutanol (0382)
Chlorobutanol hemihydrate (0383)
Chlorocresol (0384)
Chlortetracycline hydrochloride (0173)
Cholesterol (0993)
Ciclopirox (1407)
Ciclosporin (0994)
Cilastatin sodium (1408)
Cladribine (2174)
Clemastine fumarate (1190)
Clindamycin phosphate (0996)
Clioquinol (2111)
Clodronate disodium tetrahydrate (1777)
Clofibrate (0318)
Clonidine hydrochloride (0477)
Clopidogrel besilate (2790)
Clopidogrel hydrochloride (2791)
Clopidogrel hydrogen sulfate (2531)
Cloxacillin sodium (0661)
Codeine hydrochloride dihydrate (1412)
Codeine monohydrate (0076)
Codeine phosphate hemihydrate (0074)
Colestyramine (1775)
Colistimethate sodium (0319)
Colistin sulfate (0320)
Crospovidone (0892)
Cyclizine hydrochloride (1092)
Cysteine hydrochloride monohydrate (0895)
Cytarabine (0760)
Dacarbazine (1691)
Danaparoid sodium (2090)
Daunorubicin hydrochloride (0662)
Deferiprone oral solution (2987)
Deferoxamine mesilate (0896)
Demeclocycline hydrochloride (0176)
Desflurane (1666)
Desloratadine (2570)
Desmopressin (0712)
Detomidine hydrochloride for veterinary use (1414)
Dexchlorpheniramine maleate (1196)
Dibutyl phthalate (0762)
Diclofenac potassium (1508)
Diclofenac sodium (1002)
Dicloxacillin sodium (0663)
Dicycloverine hydrochloride (1197)
Diethyl phthalate (0897)
Diethylene glycol monoethyl ether (1198)
Dihydrostreptomycin sulfate for veterinary use (0485)
Dimetindene maleate (1417)
Docusate sodium (1418)
Doxorubicin hydrochloride (0714)
Doxycycline hyclate (0272)
Doxycycline monohydrate (0820)
Doxylamine hydrogen succinate (1589)
Duloxetine hydrochloride (2594)
Edrophonium chloride (2106)
Enalapril maleate (1420)
Enilconazole for veterinary use (1720)
Enrofloxacin for veterinary use (2229)
Epirubicin hydrochloride (1590)
Erythromycin lactobionate (1098)
Erythropoietin concentrated solution (1316)
Estrogens, conjugated (1512)
Ethacridine lactate monohydrate (1591)
Ethanol (96 per cent) (1317)
Ethanol, anhydrous (1318)
Ethylcellulose (0822)
Etofenamate (1513)
Eugenol (1100)
Everolimus (2918)
Felypressin (1634)
Fentanyl citrate (1103)
Fenticonazole nitrate (1211)
Filgrastim concentrated solution (2206)
Filgrastim injection (2848)
Flucloxacillin sodium (0668)
Folic acid hydrate (0067)
Foscarnet sodium hexahydrate (1520)
Fosfomycin sodium (1329)
Framycetin sulfate (0180)
Fulvestrant (2443)
Gadobutrol monohydrate (2735)

Gadodiamide hydrate (2225)
Gemcitabine hydrochloride (2306)
Gentamicin sulfate (0331)
Glipizide (0906)
Glucagon, human (1635)
Glycerol (0496)
Glycerol (85 per cent) (0497)
Glycerol monocaprylate (2213)
Glycerol monocaprylocaprate (2392)
Gonadorelin acetate (0827)
Gonadotrophin, equine serum, for veterinary use (0719)
Gramicidin (0907)
Guaiacol (1978)
Halothane (0393)
Heparins, low-molecular-mass (0828)
Heptaminol hydrochloride (1980)
Histidine hydrochloride monohydrate (0910)
Human coagulation factor VIIa (rDNA) concentrated solution (2534)
Human coagulation factor IX (rDNA) concentrated solution (2522)
Hyaluronidase (0912)
Hydroxychloroquine sulfate (2849)
Hydroxyethylcellulose (0336)
Hydroxypropylcellulose (0337)
Hydroxypropylcellulose, low-substituted (2083)
Hyoscyamine sulfate (0501)
Hypromellose (0348)
Imipenem monohydrate (1226)
Insulin aspart (2084)
Insulin, bovine (1637)
Insulin glargine (2571)
Insulin, human (0838)
Insulin lispro (2085)
Insulin, porcine (1638)
Insulin preparations, injectable (0854)
Interferon alfa-2 concentrated solution (1110)
Interferon beta-1a concentrated solution (1639)
Interferon gamma-1b concentrated solution (1440)
Iohexol (1114)
Iopamidol (1115)
Irinotecan hydrochloride trihydrate (2675)
Isoprenaline sulfate (0502)
Isopropyl alcohol (0970)
Isopropyl myristate (0725)
Isopropyl palmitate (0839)
Isosorbide dinitrate, diluted (1117)
Isoxsuprine hydrochloride (1119)
Kanamycin acid sulfate (0033)
Kanamycin monosulfate (0032)
Labetalol hydrochloride (0923)
Lactose (1061)
Leuprorelin (1442)
Levocabastine hydrochloride (1484)
Lincomycin hydrochloride (0583)
Lomustine (0928)
Loratadine (2124)
Lynestrenol (0558)
Macrogol isotridecyl ether (2730)
Macrogol lauryl ether (1124)
Macrogol poly(vinyl alcohol) grafted copolymer (2523)
Magnesium aspartate dihydrate (1445)
Magnesium stearate (0229)
Maize starch (0344)
Meldonium dihydrate (2624)
Menadione (0507)
Mepivacaine hydrochloride (1242)
Mepyramine maleate (0278)
Meropenem trihydrate (2234)
Metacresol (2077)
Methadone hydrochloride (0408)
Methanol (1989)
Methyl salicylate (0230)
Methylcellulose (0345)
Methylene chloride (0932)
*N*-Methylpyrrolidone (1675)
Metoclopramide hydrochloride monohydrate (0674)
Mianserin hydrochloride (0846)
Minocycline hydrochloride dihydrate (1030)
Molgramostim concentrated solution (1641)
Naftidrofuryl hydrogen oxalate (1594)
Nandrolone decanoate (1992)
Naphazoline hydrochloride (0730)
Naphazoline nitrate (0147)
Neomycin sulfate (0197)
Neostigmine bromide (0046)
Neostigmine metilsulfate (0626)
Netilmicin sulfate (1351)
Nevirapine hemihydrate (2479)
Nicardipine hydrochloride (2776)
Norflurane (2257)
Nystatin (0517)
Octyldodecanol (1136)
Oleyl alcohol (2073)
Olsalazine sodium (1457)
Orphenadrine citrate (1759)
Orphenadrine hydrochloride (1760)
Oseltamivir phosphate (2422)
Oxacillin sodium monohydrate (2260)
Oxeladin hydrogen citrate (1761)
Oxolinic acid (1353)
Oxytetracycline dihydrate (0199)
Oxytocin (0780)
Oxytocin concentrated solution (0779)
Paclitaxel (1794)
Papaverine hydrochloride (0102)
Pemetrexed disodium heptahydrate (2637)
Permethrin (25:75) (1762)
Phentolamine mesilate (1138)
Phytosterol (1911)
Piperacillin sodium (1168)
Piperazine hydrate (0425)
Poloxamers (1464)
Polymyxin B sulfate (0203)
Polyoxypropylene stearyl ether (2602)
Polysorbate 80 (0428)
Poly(vinyl acetate) (1962)
Poly(vinyl acetate) dispersion 30 per cent (2152)
Potassium clavulanate (1140)
Potassium dihydrogen phosphate (0920)
Pramipexole dihydrochloride monohydrate (2416)
Praziquantel (0855)

Propanol (2036)
Propofol (1558)
Protirelin (1144)
Pyrantel embonate (1680)
Pyridostigmine bromide (1255)
Pyrrolidone (2180)
Rabeprazole sodium (2868)
Rabeprazole sodium hydrate (2331)
Raltegravir potassium (2887)
Ranitidine hydrochloride (0946)
Remifentanil hydrochloride (2644)
Reserpine (0528)
Rifamycin sodium (0432)
Rilmenidine dihydrogen phosphate (2020)
Rivastigmine hydrogen tartrate (2630)
Rupatadine fumarate (2888)
Saccharin (0947)
Saccharin sodium (0787)
Salmeterol xinafoate (1765)
Sertraline hydrochloride (1705)
Sevoflurane (2269)
Sildenafil citrate (2270)
Sitagliptin phosphate monohydrate (2778)
Sitagliptin tablets (2927)
Sodium aminosalicylate dihydrate (1993)
Sodium aurothiomalate (1994)
Sodium cetostearyl sulfate (0847)
Sodium cyclamate (0774)
Sodium hyaluronate (1472)
Sodium (*S*)-lactate solution (2033)
Sodium phenylbutyrate (2183)
Sodium propionate (2041)
Sodium stearyl fumarate (1567)
Solifenacin succinate (2779)
Somatostatin (0949)
Somatropin (0951)
Somatropin concentrated solution (0950)
Somatropin for injection (0952)
Somatropin solution for injection (2370)
Spectinomycin dihydrochloride pentahydrate (1152)
Spectinomycin sulfate tetrahydrate for veterinary use (1658)
Spiramycin (0293)
Starch, hydroxypropyl (2165)
Starch, hydroxypropyl, pregelatinised (2645)
Starches, hydroxyethyl (1785)
Stearyl alcohol (0753)
Streptokinase concentrated solution (0356)
Streptomycin sulfate (0053)
Sufentanil citrate (1269)
Sulbactam sodium (2209)
Sulfadimethoxine sodium for veterinary use (2745)
Sulfaguanidine (1476)
Sulfamerazine (0358)
Sulfobutylbetadex sodium (2804)
Sultamicillin (2211)
Sultamicillin tosilate dihydrate (2212)
Sumatriptan succinate (1573)
Tacalcitol monohydrate (2272)
Tacrolimus monohydrate (2244)
Tadalafil (2606)
Tamsulosin hydrochloride (2131)
Teriparatide (2829)
Terpin monohydrate (2940)
Testosterone decanoate (1736)
Testosterone enantate (1048)
Testosterone isocaproate (1737)
Tetracycline hydrochloride (0210)
Tetryzoline hydrochloride (2101)
Thiamazole (1706)
Thiamine hydrochloride (0303)
Thiamine nitrate (0531)
Thiocolchicoside crystallised from ethanol (2896)
Thiocolchicoside hydrate (2814)
Thiomersal (1625)
Tianeptine sodium (2022)
Tiapride hydrochloride (1575)
Ticarcillin sodium (0956)
Tigecycline (2825)
Tizanidine hydrochloride (2578)
Tobramycin (0645)
all-*rac*-α-Tocopherol (0692)
*RRR*-α-Tocopherol (1256)
all-*rac*-α-Tocopheryl acetate (0439)
*RRR*-α-Tocopheryl acetate (1257)
α-Tocopheryl acetate concentrate (powder form) (0691)
DL-α-Tocopheryl hydrogen succinate (1258)
*RRR*-α-Tocopheryl hydrogen succinate (1259)
Tolterodine tartrate (2781)
Tosylchloramide sodium (0381)
Tributyl acetylcitrate (1770)
Tri-*n*-butyl phosphate (1682)
Triethyl citrate (1479)
Trimebutine maleate (2182)
Trimetazidine dihydrochloride (1741)
Trimethoprim (0060)
Trolamine (1577)
Troxerutin (2133)
Tuberculin purified protein derivative, avian (0535)
Tuberculin purified protein derivative, bovine (0536)
Tylosin for veterinary use (1273)
Tylosin phosphate for veterinary use (2802)
Tylosin tartrate for veterinary use (1274)
Vancomycin hydrochloride (1058)
Vardenafil hydrochloride trihydrate (2782)
Vecuronium bromide (1769)
Vinblastine sulfate (0748)
Vincristine sulfate (0749)
Vindesine sulfate (1276)
Voriconazole (2576)
Wool alcohols (0593)
Wool fat (0134)
Wool fat, hydrogenated (0969)
Xylitol (1381)
Ziprasidone mesilate trihydrate (2649)

# TEXTS WHOSE TITLE HAS CHANGED

*The titles of the following texts have been changed for the 10th Edition.*

**GENERAL CHAPTERS**

2.6.33. Residual pertussis toxin (*previously Residual pertussis toxin and irreversibility of pertussis toxoid*)

**MONOGRAPHS**

**Vaccines for veterinary use**

Enteric redmouth disease vaccine (inactivated) for rainbow trout (1950) (*previously Yersiniosis vaccine (inactivated) for salmonids*)

**Sutures for human use**

Sutures for human use: introduction (90004) (*previously Introduction*)

**Herbal drugs and herbal drug preparations**

Herbal drugs: introduction (90029) (*previously Introduction*)

**Homoeopathic preparations**

Homoeopathic preparations: introduction (90006) (*previously Introduction*)

# TEXTS WHOSE NUMBERING HAS CHANGED

*The numbering of the following texts has been changed for the 10th Edition following the modification of the structure of section 3 and the creation of chapter 3.3. Containers for human blood and blood components, and materials used in their manufacture; transfusion sets and materials used in their manufacture; syringes. Chapter 3.3 contains the following texts, which were previously in chapters 3.1. Materials used for the manufacture of containers and 3.2. Containers.*

**GENERAL CHAPTERS**

3.3.1. Materials for containers for human blood and blood components (*previously 3.1.1*)

3.3.2. Materials based on plasticised poly(vinyl chloride) for containers for human blood and blood components (*previously 3.1.1.1*)

3.3.3. Materials based on plasticised poly(vinyl chloride) for tubing used in sets for the transfusion of blood and blood components (*previously 3.1.1.2*)

3.3.4. Sterile plastic containers for human blood and blood components (*previously 3.2.3*)

3.3.5. Empty sterile containers of plasticised poly(vinyl chloride) for human blood and blood components (*previously 3.2.4*)

3.3.6. Sterile containers of plasticised poly(vinyl chloride) for human blood containing anticoagulant solution (*previously 3.2.5*)

3.3.7. Sets for the transfusion of blood and blood components (*previously 3.2.6*)

3.3.8. Sterile single-use plastic syringes (*previously 3.2.8*)

# 1. General notices

1. General notices.. ..... 3

**07/2014:10000**
**corrected 10.0**

# 1. GENERAL NOTICES

1.1. GENERAL STATEMENTS

The General Notices apply to all monographs and other texts of the European Pharmacopoeia.

The official texts of the European Pharmacopoeia are published in English and French. Translations in other languages may be prepared by the signatory States of the European Pharmacopoeia Convention. In case of doubt or dispute, the English and French versions are alone authoritative.

In the texts of the European Pharmacopoeia, the word 'Pharmacopoeia' without qualification means the European Pharmacopoeia. The official abbreviation Ph. Eur. may be used to indicate the European Pharmacopoeia.

The use of the title or the subtitle of a monograph implies that the article complies with the requirements of the relevant monograph. Such references to monographs in the texts of the Pharmacopoeia are shown using the monograph title and reference number in *italics*.

A preparation must comply throughout its period of validity; a distinct period of validity and/or specifications for opened or broached containers may be decided by the competent authority. The subject of any other monograph must comply throughout its period of use. The period of validity that is assigned to any given article and the time from which that period is to be calculated are decided by the competent authority in light of experimental results of stability studies.

Unless otherwise indicated in the General Notices or in the monographs, statements in monographs constitute mandatory requirements. General chapters become mandatory when referred to in a monograph, unless such reference is made in a way that indicates that it is not the intention to make the text referred to mandatory but rather to cite it for information.

The active substances, excipients, pharmaceutical preparations and other articles described in the monographs are intended for human and veterinary use (unless explicitly restricted to one of these uses).

**Quality systems**. The quality standards represented by monographs are valid only where the articles in question are produced within the framework of a suitable quality system. The quality system must assure that the articles consistently meet the requirements of the Pharmacopoeia.

**Alternative methods**. The tests and assays described are the official methods upon which the standards of the Pharmacopoeia are based. With the agreement of the competent authority, alternative methods of analysis may be used for control purposes, provided that the methods used enable an unequivocal decision to be made as to whether compliance with the standards of the monographs would be achieved if the official methods were used. In the event of doubt or dispute, the methods of analysis of the Pharmacopoeia are alone authoritative.

**Demonstration of compliance with the Pharmacopoeia**

(1) An article is not of Pharmacopoeia quality unless it complies with all the requirements stated in the monograph. This does not imply that performance of all the tests in a monograph is necessarily a prerequisite for a manufacturer in assessing compliance with the Pharmacopoeia before release of a product. The manufacturer may obtain assurance that a product is of Pharmacopoeia quality on the basis of its design, together with its control strategy and data derived, for example, from validation studies of the manufacturing process.

(2) An enhanced approach to quality control could utilise process analytical technology (PAT) and/or real-time release testing (including parametric release) strategies as alternatives to end-product testing alone. Real-time release testing in circumstances deemed appropriate by the competent authority is thus not precluded by the need to comply with the Pharmacopoeia.

(3) Reduction of animal testing: the European Pharmacopoeia is dedicated to phasing out the use of animals for test purposes, in accordance with the 3Rs (Replacement, Reduction, Refinement) set out in the European Convention for the Protection of Vertebrate Animals used for Experimental and Other Scientific Purposes. In demonstrating compliance with the Pharmacopoeia as indicated above (1), manufacturers may consider establishing additional systems to monitor consistency of production. With the agreement of the competent authority, the choice of tests performed to assess compliance with the Pharmacopoeia when animal tests are prescribed is established in such a way that animal usage is minimised as much as possible.

**Grade of materials**. Certain materials that are the subject of a pharmacopoeial monograph may exist in different grades suitable for different purposes. Unless otherwise indicated in the monograph, the requirements apply to all grades of the material. In some monographs, particularly those on excipients, a list of functionality-related characteristics that are relevant to the use of the substance may be appended to the monograph for information. Test methods for determination of one or more of these characteristics may be given, also for information.

**General monographs**. Substances and preparations that are the subject of an individual monograph are also required to comply with relevant, applicable general monographs. Cross-references to applicable general monographs are not normally given in individual monographs.

General monographs apply to all substances and preparations within the scope of the Definition section of the general monograph, except where a preamble limits the application, for example to substances and preparations that are the subject of a monograph of the Pharmacopoeia.

General monographs on dosage forms apply to all preparations of the type defined. The requirements are not necessarily comprehensive for a given specific preparation and requirements additional to those prescribed in the general monograph may be imposed by the competent authority.

General monographs and individual monographs are complementary. If the provisions of a general monograph do not apply to a particular product, this is expressly stated in the individual monograph.

**Validation of pharmacopoeial methods**. The test methods given in monographs and general chapters have been validated in accordance with accepted scientific practice and current recommendations on analytical validation. Unless otherwise stated in the monograph or general chapter, validation of the test methods by the analyst is not required.

**Implementation of pharmacopoeial methods**. When implementing a pharmacopoeial method, the user must assess whether and to what extent the suitability of the method under the actual conditions of use needs to be demonstrated according to relevant monographs, general chapters and quality systems.

**Conventional terms**. The term 'competent authority' means the national, supranational or international body or organisation vested with the authority for making decisions concerning the issue in question. It may, for example, be a national pharmacopoeia authority, a licensing authority or an official control laboratory.

The expression 'unless otherwise justified and authorised' means that the requirements have to be met, unless the

competent authority authorises a modification or an exemption where justified in a particular case.

Statements containing the word 'should' are informative or advisory.

In certain monographs or other texts, the terms 'suitable' and 'appropriate' are used to describe a reagent, micro-organism, test method etc.; if criteria for suitability are not described in the monograph, suitability is demonstrated to the satisfaction of the competent authority.

*Medicinal product*. (a) Any substance or combination of substances presented as having properties for treating or preventing disease in human beings and/or animals; or (b) any substance or combination of substances that may be used in or administered to human beings and/or animals with a view either to restoring, correcting or modifying physiological functions by exerting a pharmacological, immunological or metabolic action, or to making a medical diagnosis.

*Herbal medicinal product*. Any medicinal product, exclusively containing as active ingredients one or more herbal drugs or one or more herbal drug preparations, or one or more such herbal drugs in combination with one or more such herbal drug preparations.

*Active substance*. Any substance intended to be used in the manufacture of a medicinal product and that, when so used, becomes an active ingredient of the medicinal product. Such substances are intended to furnish a pharmacological activity or other direct effect in the diagnosis, cure, mitigation, treatment or prevention of disease, or to affect the structure and function of the body.

*Excipient* (auxiliary substance). Any constituent of a medicinal product that is not an active substance. Adjuvants, stabilisers, antimicrobial preservatives, diluents, antioxidants, for example, are excipients.

**Interchangeable methods**. Certain general chapters contain a statement that the text in question is harmonised with the corresponding text of the Japanese Pharmacopoeia and/or the United States Pharmacopeia and that these texts are interchangeable. This implies that if a substance or preparation is found to comply with a requirement using an interchangeable method from one of these pharmacopoeias it complies with the requirements of the European Pharmacopoeia. In the event of doubt or dispute, the text of the European Pharmacopoeia is alone authoritative.

**References to regulatory documents**. Monographs and general chapters may contain references to documents issued by regulatory authorities for medicines, for example directives and notes for guidance of the European Union. These references are provided for information for users for the Pharmacopoeia. Inclusion of such a reference does not modify the status of the documents referred to, which may be mandatory or for guidance.

### 1.2. OTHER PROVISIONS APPLYING TO GENERAL CHAPTERS AND MONOGRAPHS

**Quantities**. In tests with numerical limits and assays, the quantity stated to be taken for examination is approximate. The amount actually used, which may deviate by not more than 10 per cent from that stated, is accurately weighed or measured and the result is calculated from this exact quantity. In tests where the limit is not numerical, but usually depends upon comparison with the behaviour of a reference substance in the same conditions, the stated quantity is taken for examination. Reagents are used in the prescribed amounts.

Quantities are weighed or measured with an accuracy commensurate with the indicated degree of precision. For weighings, the precision corresponds to plus or minus 5 units after the last figure stated (for example, 0.25 g is to be interpreted as 0.245 g to 0.255 g). For the measurement of volumes, if the figure after the decimal point is a zero or ends in a zero (for example, 10.0 mL or 0.50 mL), the volume is measured using a pipette, a volumetric flask or a burette, as appropriate; otherwise, a graduated measuring cylinder or a graduated pipette may be used. Volumes stated in microlitres are measured using a micropipette or microsyringe.

It is recognised, however, that in certain cases the precision with which quantities are stated does not correspond to the number of significant figures stated in a specified numerical limit. The weighings and measurements are then carried out with a sufficiently improved accuracy.

**Apparatus and procedures**. Volumetric glassware complies with Class A requirements of the appropriate International Standard issued by the International Organisation for Standardisation.

Unless otherwise prescribed, analytical procedures are carried out at a temperature between 15 °C and 25 °C.

Unless otherwise prescribed, comparative tests are carried out using identical tubes of colourless, transparent, neutral glass with a flat base; the volumes of liquid prescribed are for use with tubes having an internal diameter of 16 mm, but tubes with a larger internal diameter may be used provided the volume of liquid used is adjusted (*2.1.5*). Equal volumes of the liquids to be compared are examined down the vertical axis of the tubes against a white background, or if necessary against a black background. The examination is carried out in diffuse light.

Any solvent required in a test or assay in which an indicator is to be used is previously neutralised to the indicator, unless a blank test is prescribed.

**Water-bath**. The term 'water-bath' means a bath of boiling water unless water at another temperature is indicated. Other methods of heating may be substituted provided the temperature is near to but not higher than 100 °C or the indicated temperature.

**Drying and ignition to constant mass**. The terms 'dried to constant mass' and 'ignited to constant mass' mean that 2 consecutive weighings do not differ by more than 0.5 mg, the 2nd weighing following an additional period of drying or of ignition respectively appropriate to the nature and quantity of the residue.

Where drying is prescribed using one of the expressions 'in a desiccator' or '*in vacuo*', it is carried out using the conditions described in chapter *2.2.32. Loss on drying*.

**Reagents**. The proper conduct of the analytical procedures described in the Pharmacopoeia and the reliability of the results depend, in part, upon the quality of the reagents used. The reagents are described in general chapter *4*. It is assumed that reagents of analytical grade are used; for some reagents, tests to determine suitability are included in the specifications.

**Solvents**. Where the name of the solvent is not stated, the term 'solution' implies a solution in water.

Where the use of water is specified or implied in the analytical procedures described in the Pharmacopoeia or for the preparation of reagents, water complying with the requirements of the monograph *Purified water (0008)* is used, except that for many purposes the requirements for bacterial endotoxins (*Purified water in bulk*) and microbial contamination (*Purified water in containers)* are not relevant. The term 'distilled water' indicates purified water prepared by distillation.

The term 'ethanol' without qualification means anhydrous ethanol. The term 'alcohol' without qualification means ethanol (96 per cent). Other dilutions of ethanol are indicated by the term 'ethanol' or 'alcohol' followed by a statement of the percentage by volume of ethanol ($C_2H_6O$) required.

**Expression of content**. In defining content, the expression 'per cent' is used according to circumstances with one of 2 meanings:

– per cent *m/m* (percentage, mass in mass) expresses the number of grams of substance in 100 g of final product;

– per cent *V/V* (percentage, volume in volume) expresses the number of millilitres of substance in 100 mL of final product.

The expression 'parts per million' (or ppm) refers to mass in mass, unless otherwise specified.

**Temperature**. Where an analytical procedure describes temperature without a figure, the general terms used have the following meaning:

– in a deep-freeze: below – 15 °C;

– in a refrigerator: 2 °C to 8 °C;

– cold or cool: 8 °C to 15 °C;

– room temperature: 15 °C to 25 °C.

## 1.3. GENERAL CHAPTERS

**Containers**. Materials used for containers are described in general chapter *3.1*. General names used for materials, particularly plastic materials, each cover a range of products varying not only in the properties of the principal constituent but also in the additives used. The test methods and limits for materials depend on the formulation and are therefore applicable only for materials whose formulation is covered by the preamble to the specification. The use of materials with different formulations, and the test methods and limits applied to them, are subject to agreement by the competent authority.

The specifications for containers in general chapter *3.2* have been developed for general application to containers of the stated category, but in view of the wide variety of containers available and possible new developments, the publication of a specification does not exclude the use, in justified circumstances, of containers that comply with other specifications, subject to agreement by the competent authority.

Reference may be made within the monographs of the Pharmacopoeia to the definitions and specifications for containers provided in chapter *3.2. Containers*. The general monographs for pharmaceutical dosage forms may, under the heading Definition/Production, require the use of certain types of container; certain other monographs may, under the heading Storage, indicate the type of container that is recommended for use.

## 1.4. MONOGRAPHS

*TITLES*

Monograph titles are in English and French in the respective versions and there is a Latin subtitle.

*RELATIVE ATOMIC AND MOLECULAR MASSES*

The relative atomic mass ($A_r$) or the relative molecular mass ($M_r$) is shown, as and where appropriate, at the beginning of each monograph. The relative atomic and molecular masses and the molecular and graphic formulae do not constitute analytical standards for the substances described.

*CHEMICAL ABSTRACTS SERVICE (CAS) REGISTRY NUMBER*

CAS registry numbers are included for information in monographs, where applicable, to provide convenient access to useful information for users. CAS Registry Number® is a registered trademark of the American Chemical Society.

*DEFINITION*

Statements under the heading Definition constitute an official definition of the substance, preparation or other article that is the subject of the monograph.

**Limits of content**. Where limits of content are prescribed, they are those determined by the method described under Assay.

**Herbal drugs**. In monographs on herbal drugs, the definition indicates whether the subject of the monograph is, for example, the whole drug or the drug in powdered form. Where a monograph applies to the drug in several states, for example both to the whole drug and the drug in powdered form, the definition states this.

*PRODUCTION*

Statements under the heading Production draw attention to particular aspects of the manufacturing process but are not necessarily comprehensive. They constitute mandatory requirements for manufacturers, unless otherwise stated. They may relate, for example, to source materials; to the manufacturing process itself and its validation and control; to in-process testing; or to testing that is to be carried out by the manufacturer on the final article, either on selected batches or on each batch prior to release. These statements cannot necessarily be verified on a sample of the final article by an independent analyst. The competent authority may establish that the instructions have been followed, for example, by examination of data received from the manufacturer, by inspection of manufacture or by testing appropriate samples.

The absence of a Production section does not imply that attention to features such as those referred to above is not required.

**Choice of vaccine strain, Choice of vaccine composition**. The Production section of a monograph may define the characteristics of a vaccine strain or vaccine composition. Unless otherwise stated, test methods given for verification of these characteristics are provided for information as examples of suitable methods. Subject to approval by the competent authority, other test methods may be used without validation against the method shown in the monograph.

*POTENTIAL ADULTERATION*

Due to the increasing number of fraudulent activities and cases of adulteration, information may be made available to Ph. Eur. users to help detect adulterated materials (i.e. active substances, excipients, intermediate products, bulk products and finished products).

To this purpose, a method for the detection of potential adulterants and relevant limits, together with a reminder that all stages of production and sourcing are subjected to a suitable quality system, may be included in this section of monographs on substances for which an incident has occurred or that present a risk of deliberate contamination. The frequency of testing by manufacturers or by users (e.g. manufacturers of intermediate products, bulk products and finished products, where relevant) depends on a risk assessment, taking into account the level of knowledge of the whole supply chain and national requirements.

This section constitutes requirements for the whole supply chain, from manufacturers to users (e.g. manufacturers of intermediate products, bulk products and finished products, where relevant). The absence of this section does not imply that attention to features such as those referred to above is not required.

*CHARACTERS*

The statements under the heading Characters are not to be interpreted in a strict sense and are not requirements.

**Solubility**. In statements of solubility in the Characters section, the terms used have the following significance, referred to a temperature between 15 °C and 25 °C.

| Descriptive term | Approximate volume of solvent in millilitres per gram of solute | | | |
|---|---|---|---|---|
| Very soluble | less than | 1 | | |
| Freely soluble | from | 1 | to | 10 |
| Soluble | from | 10 | to | 30 |
| Sparingly soluble | from | 30 | to | 100 |
| Slightly soluble | from | 100 | to | 1000 |
| Very slightly soluble | from | 1000 | to | 10 000 |
| Practically insoluble | more than | | | 10 000 |

The term 'partly soluble' is used to describe a mixture where only some of the components dissolve. The term 'miscible' is used to describe a liquid that is miscible in all proportions with the stated solvent.

*IDENTIFICATION*

**Scope**. The tests given in the Identification section are not designed to give a full confirmation of the chemical structure or composition of the product; they are intended to give confirmation, with an acceptable degree of assurance, that the article conforms to the description on the label.

**First and second identifications**. Certain monographs have subdivisions entitled 'First identification' and 'Second identification'. The test or tests that constitute the 'First identification' may be used in all circumstances. The test or tests that constitute the 'Second identification' may be used in pharmacies provided it can be demonstrated that the substance or preparation is fully traceable to a batch certified to comply with all the other requirements of the monograph.

Certain monographs give two or more sets of tests for the purpose of the first identification, which are equivalent and may be used independently. One or more of these sets usually contain a cross-reference to a test prescribed in the Tests section of the monograph. It may be used to simplify the work of the analyst carrying out the identification and the prescribed tests. For example, one identification set cross-refers to a test for enantiomeric purity while the other set gives a test for specific optical rotation: the intended purpose of the two is the same, that is, verification that the correct enantiomer is present.

**Powdered herbal drugs**. Monographs on herbal drugs may contain schematic drawings of the powdered drug. These drawings complement the description given in the relevant identification test.

*TESTS AND ASSAYS*

**Scope**. The requirements are not framed to take account of all possible impurities. It is not to be presumed, for example, that an impurity that is not detectable by means of the prescribed tests is tolerated if common sense and good pharmaceutical practice require that it be absent. See also below under Impurities.

**Calculation**. Where the result of a test or assay is required to be calculated with reference to the dried or anhydrous substance or on some other specified basis, the determination of loss on drying, water content or other property is carried out by the method prescribed in the relevant test in the monograph. The words 'dried substance' or 'anhydrous substance' etc. appear in parentheses after the result. Where a quantitative determination of a residual solvent is carried out and a test for loss on drying is not carried out, the content of residual solvent is taken into account for the calculation of the assay content of the substance, the specific optical rotation and the specific absorbance. No further indication is given in the specific monograph.

**Limits**. The limits prescribed are based on data obtained in normal analytical practice; they take account of normal analytical errors, of acceptable variations in manufacture and compounding and of deterioration to an extent considered acceptable. No further tolerances are to be applied to the limits prescribed to determine whether the article being examined complies with the requirements of the monograph.

In determining compliance with a numerical limit, the calculated result of a test or assay is first rounded to the number of significant figures stated, unless otherwise prescribed. The limits, regardless of whether the values are expressed as percentages or as absolute values, are considered significant to the last digit shown (for example 140 indicates 3 significant figures). The last figure of the result is increased by one when the part rejected is equal to or exceeds one half-unit, whereas it is not modified when the part rejected is less than a half-unit.

**Indication of permitted limit of impurities**. The acceptance criteria for related substances are expressed in monographs either in terms of comparison of peak areas (comparative tests) or as numerical values. For comparative tests, the approximate content of impurity tolerated, or the sum of impurities, may be indicated in brackets for information only. Acceptance or rejection is determined on the basis of compliance or non-compliance with the stated test. If the use of a reference substance for the named impurity is not prescribed, this content may be expressed as a nominal concentration of the substance used to prepare the reference solution specified in the monograph, unless otherwise described.

**Herbal drugs**. For herbal drugs, the sulfated ash, total ash, water-soluble matter, alcohol-soluble matter, water content, content of essential oil and content of active principle are calculated with reference to the drug that has not been specially dried, unless otherwise prescribed in the monograph.

**Equivalents**. Where an equivalent is given, for the purposes of the Pharmacopoeia only the figures shown are to be used in applying the requirements of the monograph.

**Culture media**. The culture media described in monographs and general chapters have been found to be satisfactory for the intended purpose. However, the components of media, particularly those of biological origin, are of variable quality, and it may be necessary for optimal performance to modulate the concentration of some ingredients, notably:

- peptones and meat or yeast extracts, with respect to their nutritive properties;
- buffering substances;
- bile salts, bile extract, deoxycholate, and colouring matter, depending on their selective properties;
- antibiotics, with respect to their activity.

*STORAGE*

The information and recommendations given under the heading Storage do not constitute a pharmacopoeial requirement but the competent authority may specify particular storage conditions that must be met.

The articles described in the Pharmacopoeia are stored in such a way as to prevent contamination and, as far as possible, deterioration. Where special conditions of storage are recommended, including the type of container (see section 1.3. General chapters) and limits of temperature, they are stated in the monograph.

The following expressions are used in monographs under Storage with the meaning shown.

*In an airtight container* means that the product is stored in an airtight container (*3.2*). Care is to be taken when the container is opened in a damp atmosphere. A low moisture content may be maintained, if necessary, by the use of a desiccant in the container provided that direct contact with the product is avoided.

*Protected from light* means that the product is stored either in a container made of a material that absorbs actinic light sufficiently to protect the contents from change induced by such light, or in a container enclosed in an outer cover that provides such protection, or is stored in a place from which all such light is excluded.

*LABELLING*

In general, labelling of medicines is subject to supranational and national regulation and to international agreements. The statements under the heading Labelling are not therefore comprehensive and, moreover, for the purposes of the Pharmacopoeia only those statements that are necessary to demonstrate compliance or non-compliance with the monograph are mandatory. Any other labelling statements are included as recommendations. When the term 'label' is used in the Pharmacopoeia, the labelling statements may appear on the container, the package, a leaflet accompanying the package, or a certificate of analysis accompanying the article, as decided by the competent authority.

*WARNINGS*

Materials described in monographs and reagents specified for use in the Pharmacopoeia may be injurious to health unless adequate precautions are taken. The principles of good quality control laboratory practice and the provisions of any appropriate regulations are to be observed at all times. Attention is drawn to particular hazards in certain monographs by means of a warning statement; absence of such a statement is not to be taken to mean that no hazard exists.

*IMPURITIES*

A list of all known and potential impurities that have been shown to be detected by the tests in a monograph may be given. See also chapter *5.10. Control of impurities in substances for pharmaceutical use*. The impurities are designated by a letter or letters of the alphabet. Where a letter appears to be missing, the impurity designated by this letter has been deleted from the list during monograph development prior to publication or during monograph revision.

*FUNCTIONALITY-RELATED CHARACTERISTICS OF EXCIPIENTS*

Monographs on excipients may have a section on functionality-related characteristics. The characteristics, any test methods for determination and any tolerances are not mandatory requirements; they may nevertheless be relevant for use of the excipient and are given for information (see also section 1.1. General statements).

*REFERENCE STANDARDS*

Certain monographs require the use of reference standards (chemical reference substances, herbal reference standards, biological reference preparations, reference spectra). See also chapter *5.12. Reference standards*. The European Pharmacopoeia Commission establishes the official reference standards, which are alone authoritative in case of arbitration. These reference standards are available from the European Directorate for the Quality of Medicines & HealthCare (EDQM). Information on the available reference standards and a batch validity statement can be obtained via the EDQM website.

## 1.5. ABBREVIATIONS AND SYMBOLS

| | |
|---|---|
| $A$ | Absorbance |
| $A_{1\ \mathrm{cm}}^{1\ \mathrm{per\ cent}}$ | Specific absorbance |
| $A_r$ | Relative atomic mass |
| $[\alpha]_D^{20}$ | Specific optical rotation |
| bp | Boiling point |
| BRP | Biological reference preparation |
| CRS | Chemical reference substance |
| $d_{20}^{20}$ | Relative density |
| λ | Wavelength |
| HRS | Herbal reference standard |
| IU | International Unit |
| M | Molarity |
| $M_r$ | Relative molecular mass |
| mp | Melting point |
| $n_D^{20}$ | Refractive index |
| Ph. Eur. U. | European Pharmacopoeia Unit |
| ppb | Parts per billion (micrograms per kilogram) |
| ppm | Parts per million (milligrams per kilogram) |
| R | Substance or solution defined under *4. Reagents* |
| $R_F$ | Retardation factor (see chapter *2.2.46*) |
| $R_{st}$ | Used in chromatography to indicate the ratio of the distance travelled by a substance to the distance travelled by a reference substance |
| RV | Substance used as a primary standard in volumetric analysis (chapter *4.2.1*) |

**Abbreviations used in the monographs on immunoglobulins, immunosera and vaccines**

| | |
|---|---|
| CFU | Colony-forming units |
| $LD_{50}$ | The statistically determined quantity of a substance that, when administered by the specified route, may be expected to cause the death of 50 per cent of the test animals within a given period |
| MLD | Minimum lethal dose |
| L+/10 dose | The smallest quantity of a toxin that, in the conditions of the test, when mixed with 0.1 IU of antitoxin and administered by the specified route, causes the death of the test animals within a given period |
| L+ dose | The smallest quantity of a toxin that, in the conditions of the test, when mixed with 1 IU of antitoxin and administered by the specified route, causes the death of the test animals within a given period |
| lr/100 dose | The smallest quantity of a toxin that, in the conditions of the test, when mixed with 0.01 IU of antitoxin and injected intracutaneously causes a characteristic reaction at the site of injection within a given period |
| Lp/10 dose | The smallest quantity of toxin that, in the conditions of the test, when mixed with 0.1 IU of antitoxin and administered by the specified route, causes paralysis in the test animals within a given period |
| Lo/10 dose | The largest quantity of a toxin that, in the conditions of the test, when mixed with 0.1 IU of antitoxin and administered by the specified route, does not cause symptoms of toxicity in the test animals within a given period |
| Lf dose | The quantity of toxin or toxoid that flocculates in the shortest time with 1 IU of antitoxin |

| | |
|---|---|
| $CCID_{50}$ | The statistically determined quantity of virus that may be expected to infect 50 per cent of the cell cultures to which it is added |
| $EID_{50}$ | The statistically determined quantity of virus that may be expected to infect 50 per cent of the fertilised eggs into which it is inoculated |
| $ID_{50}$ | The statistically determined quantity of a virus that may be expected to infect 50 per cent of the animals into which it is inoculated |
| $PD_{50}$ | The statistically determined dose of a vaccine that, in the conditions of the test, may be expected to protect 50 per cent of the animals against a challenge dose of the micro-organisms or toxins against which it is active |
| $ED_{50}$ | The statistically determined dose of a vaccine that, in the conditions of the test, may be expected to induce specific antibodies in 50 per cent of the animals for the relevant vaccine antigens |
| PFU | Pock-forming units or plaque-forming units |
| SPF | Specified-pathogen-free |

## 1.6. UNITS OF THE INTERNATIONAL SYSTEM (SI) USED IN THE PHARMACOPOEIA AND EQUIVALENCE WITH OTHER UNITS

*INTERNATIONAL SYSTEM OF UNITS (SI)*

The International System of Units comprises 2 main classes of units, namely base units and derived units[(1)]. The base units are the metre, the kilogram, the second, the ampere, the kelvin, the mole and the candela.

The derived units are formed as products of powers of the base units according to the algebraic relationships linking the corresponding quantities. Some of these derived units have special names and symbols. The derived units used in the Pharmacopoeia are shown in Table 1.6.-1.

Some important and widely used units outside the International System are shown in Table 1.6.-2.

The prefixes shown in Table 1.6.-3 are used to form the names and symbols of the decimal multiples and submultiples of SI units.

Table 1.6.-1. – *Derived units used in the European Pharmacopoeia and equivalence with other units*

| Quantity | | Unit | | | | Conversion of other units into SI units |
|---|---|---|---|---|---|---|
| Name | Symbol | Name | Symbol | Expression in SI base units | Expression in other SI units | |

| Catalytic activity | *Z* | katal | kat | $mol \cdot s^{-1}$ | | |

*NOTES*

1. In the Pharmacopoeia, the Celsius temperature is used (symbol *t*). This is defined by the following equation:

$$t = T - T_0$$

where $T_0$ = 273.15 K by definition. The Celsius or centigrade temperature is expressed in degrees Celsius (symbol °C). The unit 'degree Celsius' is equal to the unit 'kelvin'.

2. The practical expressions of concentrations used in the Pharmacopoeia are defined in the General Notices.

3. The radian is the plane angle between two radii of a circle that cut off on the circumference an arc equal in length to the radius.

4. In the Pharmacopoeia, conditions of centrifugation are defined by reference to the acceleration due to gravity (*g*):

$$g = 9.806\ 65\ m \cdot s^{-2}$$

5. Certain quantities without dimensions are used in the Pharmacopoeia: relative density (*2.2.5*), absorbance (*2.2.25*), specific absorbance (*2.2.25*) and refractive index (*2.2.6*).

6. The microkatal is defined as the enzymic activity that, under defined conditions, produces the transformation (e.g. hydrolysis) of 1 micromole of the substrate per second.

## 2.1.1. DROPPERS

The term 'drops' means standard drops delivered from a standard dropper as described below.

Standard droppers (Figure 2.1.1.-1) are constructed of practically colourless glass. The lower extremity has a circular orifice in a flat surface at right angles to the axis.

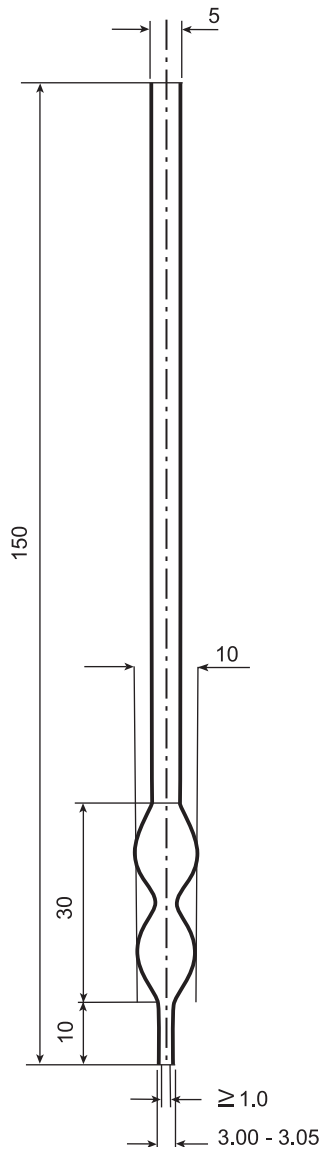

Figure 2.1.1.-1. – *Standard dropper*
*Dimensions in millimetres*

Other droppers may be used provided they comply with the following test.

20 drops of *water R* at 20 ± 1 °C flowing freely from the dropper held in the vertical position at a constant rate of 1 drop per second weighs 1000 ± 50 mg.

The dropper must be carefully cleaned before use. Carry out 3 determinations on any given dropper. No result may deviate by more than 5 per cent from the mean of the 3 determinations.

01/2008:20102

## 2.1.2. COMPARATIVE TABLE OF POROSITY OF SINTERED-GLASS FILTERS[1]

| 40 - 100 | Fine filtration, filtration of mercury, fine dispersion of gases |
| 100 - 160 | Filtration of coarse materials, dispersion and washing of gases, support for other filter materials |
| 160 - 500 | Filtration of very coarse materials, dispersion and washing of gases. |

01/2008:20103

## 2.1.3. ULTRAVIOLET RAY LAMPS FOR ANALYTICAL PURPOSES

Mercury vapour in quartz lamps is used as the source of ultraviolet light. A suitable filter may be fitted to eliminate the visible part of the spectrum emitted by the lamp. When the Pharmacopoeia prescribes in a test the use of ultraviolet light of wavelength 254 nm or 365 nm, an instrument consisting of a mercury vapour lamp and a filter which gives an emission band with maximum intensity at about 254 nm or 365 nm is used. The lamp used should be capable of revealing without doubt a standard spot of sodium salicylate with a diameter of about 5 mm on a support of *silica gel G R*, the spot being examined while in a position normal to the radiation.

(1) The given limits are only approximate.
(2) The European Pharmacopoeia has adopted the system proposed by the International Organization for Standardization (ISO).

For this purpose apply 5 µL of a 0.4 g/L solution of *sodium salicylate R* in *alcohol R*[3] for lamps of maximum output at 254 nm and 5 µL of a 2 g/L solution in *alcohol R*[3] for lamps of maximum output at 365 nm. The distance between the lamp and the chromatographic plate under examination used in a pharmacopoeial test should never exceed the distance used to carry out the above test.

**01/2008:20104**

## 2.1.4. SIEVES

Sieves are constructed of suitable materials with square meshes. For purposes other than analytical procedures, sieves with circular meshes may be used, the internal diameters of which are 1.25 times the aperture of the square mesh of the corresponding sieve size. There must be no reaction between the material of the sieve and the substance being sifted. Degree of comminution is prescribed in the monograph using the sieve number, which is the size of the mesh in micrometres, given in parenthesis after the name of the substance (Table 2.1.4.-1).

Maximum tolerance[4] for an aperture (+ *X*): no aperture size shall exceed the nominal size by more than *X*, where:

$$X = \frac{2(w^{0.75})}{3} + 4(w^{0.25})$$

*w* = width of aperture.

Tolerance for mean aperture (± *Y*): the average aperture size shall not depart from the nominal size by more than ± *Y*, where:

$$Y = \frac{w^{0.98}}{27} + 1.6$$

Intermediary tolerance (+ *Z*): not more than 6 per cent of the total number of apertures shall have sizes between "nominal + *X*" and "nominal + *Z*", where:

$$Z = \frac{X + Y}{2}$$

Wire diameter *d*: the wire diameters given in Table 2.1.4.-1 apply to woven metal wire cloth mounted in a frame. The nominal sizes of the wire diameters may depart from these values within the limits $d_{max}$ and $d_{min}$. The limits define a permissible range of choice ± 15 per cent of the recommended nominal dimensions. The wires in a test sieve shall be of a similar diameter in warp and weft directions.

Table 2.1.4.-1 (*values in micrometers*)

| Sieve numbers (Nominal dimensions of apertures) | Tolerances for apertures | | | Wire diameters | | |
|---|---|---|---|---|---|---|
| | Maximum tolerance for an aperture | Tolerance for mean aperture | Intermediary tolerance | Recommended nominal dimensions | Admissible limits | |
| | + *X* | ± *Y* | + *Z* | *d* | $d_{max}$ | $d_{min}$ |
| 11 200 | 770 | 350 | 560 | 2500 | 2900 | 2100 |
| 8000 | 600 | 250 | 430 | 2000 | 2300 | 1700 |

| 45 | 22 | 3.1 | 13 | 32 | 37 | 27 |
| 38 | – | – | – | 30 | 35 | 24 |

(3) The *alcohol R* used must be free from fluorescence.
(4) See the International Standard ISO 3310/1 (1975).

01/2008:20105

## 2.1.5. TUBES FOR COMPARATIVE TESTS

Tubes used for comparative tests are matched tubes of colourless glass with a uniform internal diameter. The base is transparent and flat.

A column of the liquid is examined down the vertical axis of the tube against a white background, or if necessary, against a black background. The examination is carried out in diffused light.

It is assumed that tubes with an internal diameter of 16 mm will be used. Tubes with a larger internal diameter may be used instead but the volume of liquid examined must then be increased so that the depth of liquid in the tubes is not less than where the prescribed volume of liquid and tubes 16 mm in internal diameter are used.

01/2018:20106

## 2.1.6. GAS DETECTOR TUBES

Gas detector tubes are cylindrical, sealed tubes consisting of an inert transparent material and are constructed to allow the passage of gas. They contain reagents adsorbed onto inert substrates that are suitable for the visualisation of the substance to be detected and, if necessary, they also contain preliminary layers and/or adsorbent filters to eliminate substances that interfere with the substance to be detected. The layer of indicator contains either a single reagent for the detection of a given impurity or several reagents for the detection of several substances (monolayer tube or multilayer tube).

The test is carried out by passing the required volume of the gas to be examined through the indicator tube. The length of the coloured layer or the intensity of a colour change on a graduated scale gives an indication of the impurities present.

The calibration of the detector tubes is verified according to the manufacturer's instructions.

*Operating conditions*. Examine according to the manufacturer's instructions or proceed as follows.

The gas supply is connected to a suitable pressure regulator and needle valve. Connect the flexible tubing fitted with a Y-piece to the valve and adjust the flow of gas to be examined to purge the tubing in order to obtain an appropriate flow (Figure 2.1.6.-1). Prepare the indicator tube and fit to the metering pump, following the manufacturer's instructions. Connect the open end of the indicator tube to the short leg of the tubing and operate the pump by the appropriate number of strokes to pass a suitable volume of gas to be examined through the tube. Read the value corresponding to the length of the coloured layer or the intensity of the colour on the graduated scale. If a negative result is achieved, indicator tubes can be verified with a calibration gas containing the appropriate impurity.

In view of the wide variety of available compressor oils, it is necessary to verify the reactivity of the oil detector tubes for the oil used. Information on the reactivity for various oils is given in the leaflet supplied with the tube. If the oil used is not cited in the leaflet, the tube manufacturer must verify the reactivity and if necessary provide a tube specific for this oil.

**Arsine detector tube**. Sealed glass tube containing adsorbent filters and suitable supports for the gold salt or other appropriate indicator. The minimum value indicated is 0.25 ppm or less, with a relative standard deviation of at most 20 per cent.

**Carbon dioxide detector tube**. Sealed glass tube containing adsorbent filters and suitable supports for hydrazine and crystal violet indicators. The minimum value indicated is 100 ppm with a relative standard deviation of at most 15 per cent.

**Carbon monoxide detector tube**. Sealed glass tube containing adsorbent filters and suitable supports for di-iodine pentoxide, selenium dioxide and fuming sulfuric acid indicators. The minimum value indicated is 5 ppm or less, with a relative standard deviation of at most 15 per cent.

**Hydrogen sulfide detector tube**. Sealed glass tube containing adsorbent filters and suitable supports for an appropriate lead salt indicator. The minimum value indicated is 0.2 ppm or less, with a relative standard deviation of at most 10 per cent.

**Nitrogen monoxide and nitrogen dioxide detector tube**. Sealed glass tube containing adsorbent filters and suitable supports for an oxidising layer (Cr(VI) salt) and the diphenylbenzidine indicator. The minimum value indicated is 0.5 ppm with a relative standard deviation of at most 15 per cent.

**Oil detector tube**. Sealed glass tube containing adsorbent filters and suitable supports for the sulfuric acid indicator. The minimum value indicated is 0.1 mg/m$^3$ with a relative standard deviation of at most 30 per cent.

**Phosphine detector tube**. Sealed glass tube containing adsorbent filters and suitable supports for the gold salt or other appropriate indicator. The minimum value indicated is 0.2 ppm or less, with a relative standard deviation of at most 20 per cent.

**Sulfur dioxide detector tube**. Sealed glass tube containing adsorbent filters and suitable supports for the iodine and starch indicator. The minimum value indicated is 0.5 ppm with a relative standard deviation of at most 15 per cent.

**Water vapour detector tube**. Sealed glass tube containing adsorbent filters and suitable supports for the magnesium perchlorate indicator. The minimum value indicated is 67 ppm or less, with a relative standard deviation of at most 20 per cent.

# 2.2. PHYSICAL AND PHYSICO-CHEMICAL METHODS

07/2017:20201

## 2.2.1. CLARITY AND DEGREE OF OPALESCENCE OF LIQUIDS

Opalescence is the effect of light being absorbed or scattered by submicroscopic particles or optical density inhomogeneities. The absence of any particles or inhomogeneities in a solution results in a clear solution.

A liquid is considered *clear* if its clarity is the same as that of *water R* or of the solvent used, or if its opalescence is not more pronounced than that of reference suspension I (see Table 2.2.1.-1), when examined under the conditions described below.

Requirements in monographs are expressed in terms of the visual method by comparing with the defined reference suspensions (see Table 2.2.1.-1). However, instrumental methods may also be used for determining compliance with monograph requirements once the suitability of the instrument has been established as described below and calibration with reference suspensions I-IV and with *water R* or the solvent used has been performed.

VISUAL METHOD

Using identical test-tubes of colourless, transparent, neutral glass with a flat base and an internal diameter of 15-25 mm, compare the liquid to be examined with a reference suspension freshly prepared as described below. Ensure that the depths of the layers in the 2 test-tubes are the same (about 40 mm).

Compare the liquids in diffused daylight 5 min after preparation of the reference suspension, viewing vertically against a black background.

*System suitability*. The diffusion of light must be such that reference suspension I can readily be distinguished from *water R*, and that reference suspension II can readily be distinguished from reference suspension I (see Table 2.2.1.-1).

INSTRUMENTAL METHOD

The instrumental assessment of clarity and opalescence provides a more discriminatory test that does not depend on the visual acuity of the analyst. Numerical results are more useful for process control and quality monitoring, especially in stability studies. For example, previous numerical data on stability can be extrapolated to determine whether a given batch of a preparation will exceed shelf-life limits prior to the expiry date.

*TURBIDIMETRY AND NEPHELOMETRY*

When a suspension is viewed at right angles to the direction of the incident light, the system appears opalescent due to the scattering of light by the particles of the suspension (Tyndall effect). A certain portion of the light beam entering a turbid liquid is transmitted, another portion is absorbed and the remaining portion is scattered by the suspended particles. The light-scattering effect of suspended particles can be measured either indirectly by observation of the transmitted light (turbidimetry) or directly by measuring the scattered light (nephelometry). Turbidimetry and nephelometry are more reliable in low turbidity ranges, where there is a linear relationship between turbidity values and detector signals.

As the degree of turbidity increases, not all the particles are exposed to the incident light and the scattered or the transmitted radiation of other particles is hindered on its way to the detector.

For quantitative measurements, the construction of calibration curves is essential. Linearity must be based on at least 4 levels of concentrations. Reference suspensions must show a sufficiently stable degree of turbidity and must be produced under well-defined conditions.

*MEASUREMENTS IN RATIO MODE*

The determination of opalescence of coloured liquids is done using instruments with ratio mode, since colour provides a negative interference, attenuating both incident and scattered light and lowering the turbidity value. The effect is so great, even for moderately coloured samples, that conventional nephelometers cannot be used.

In turbidimetry or nephelometry with ratio mode, the ratio of the transmission measurement to the 90° scattered light measurement is determined. This procedure compensates for the light that is diminished by the colour of the sample. Instruments with ratio mode use as light source a tungsten lamp with spectral sensitivity at about 550 nm operating at a filament colour temperature of 2700 K. Other suitable light sources may also be used. Silicon photodiodes and photomultipliers are commonly used as detectors and record changes in light scattered or transmitted by the sample. The light scattered at 90 ± 2.5° is measured by the primary detector. Other detectors measure back and forward scatter (reflected light) as well as transmitted light. The results are obtained by calculating the ratio of the 90° scattered light measured to the sum of the components of forward scattered and transmitted light values.

The instruments used are calibrated against standards of known turbidity and are capable of automatic measurement of turbidity. The test results are obtained directly from the instrument and compared to the specifications in the individual monograph.

Alternatively, the influence of the colour of the sample may also be eliminated by using an infrared light-emitting diode (IR LED) having an emission maximum at 860 nm with a 60 nm spectral bandwidth as the light source of the instrument.

*INSTRUMENT REQUIREMENTS*

Instruments complying with the following characteristics and verified using reference suspensions as described below may be used instead of visual examination for determination of compliance with monograph requirements.

- *Measuring unit*: NTU (nephelometric turbidity units). NTU is based on the turbidity of a primary standard of formazin. FTU (formazin turbidity units) or FNU (formazin nephelometric units) are also used, and are equivalent to NTU in regions of low turbidity (up to 40 NTU). These units are used in all 3 instrumental methods (nephelometry, turbidimetry and in ratio mode).
- *Measuring range*: 0.01-1100 NTU.
- *Resolution*: 0.01 NTU within the range 0-9.99 NTU; 0.1 NTU within the range 10.0-99.9 NTU; and 1 NTU for the range > 100 NTU.
- *Accuracy*: ± (10 per cent of reading + 0.01 NTU) within the range 0-20 NTU; ± 7.5 per cent within the range 20-1100 NTU.
- *Repeatability*: ± 0.05 NTU within the range 0-20 NTU; ± 2 per cent of the reading within the range 20-1100 NTU.

Instruments with measuring range or resolution, accuracy and repeatability capabilities other than those mentioned above may be used provided they are sufficiently validated and are capable for the intended use.

*CONTROL OF INSTRUMENT PERFORMANCE*

– *Calibration*: performed with at least 4 reference suspensions of formazin covering the measuring range of interest. Reference suspensions described in this chapter or suitable reference standards calibrated against the primary reference suspensions may be used.
– *Stray light*: < 0.15 NTU within the range 0-10 NTU; < 0.5 NTU within the range 10-1100 NTU. Stray light is defined as that light that reaches the nephelometric detector without being a result of scatter from the sample. Stray light is always a positive interference and is a significant source of error in low-range turbidity measurements. Sources of stray light include: imperfections in and scratches on sample cells, internal reflections of the optical system, contamination of the optics or sample cell chamber with dust, and electronic noise. Instrument design can also affect stray light. The influence of stray light becomes negligible in ratio mode measurements.

The test methodology for the specific substance/product to be analysed must also be verified to demonstrate its analytical capability. The instrument and methodology shall be consistent with the attributes of the substance to be examined.

Measurements of standards and samples should be carried out under the same temperature conditions, preferably between 20 °C and 25 °C.

REFERENCE SUSPENSIONS

Formazin has several desirable characteristics that make it an excellent turbidity standard. It can be reproducibly prepared from assayed raw materials. The physical characteristics make it a desirable light-scatter calibration standard. The formazin polymer consists of chains of different lengths, which fold into random configurations. This results in a wide variety of particle shapes and sizes, which allows the analysis of different particle sizes and shapes that are found in real samples. Stabilised formazin suspensions that can be used to prepare stable, diluted turbidity standards are commercially available and may be used after comparison with the standards prepared as described.

All steps of the preparation of reference suspensions as described below are carried out at 25 ± 3 °C.

**Hydrazine sulfate solution**. Dissolve 1.0 g of *hydrazine sulfate R* in *water R* and dilute to 100.0 mL with the same solvent. Allow to stand for 4-6 h.

**Primary opalescent suspension (formazin suspension)**. In a 100 mL ground-glass-stoppered flask, dissolve 2.5 g of *hexamethylenetetramine R* in 25.0 mL of *water R*. Add 25.0 mL of the hydrazine sulfate solution. Mix and allow to stand for 24 h. This suspension is stable for 2 months, provided it is stored in a glass container free from surface defects. The suspension must not adhere to the glass and must be mixed thoroughly before use.

**Standard of opalescence**. Dilute 15.0 mL of the primary opalescent suspension to 1000.0 mL with *water R*. This suspension is freshly prepared and may be stored for up to 24 h.

**Reference suspensions**. Prepare the reference suspensions according to Table 2.2.1.-1. Mix and shake before use.

Table 2.2.1.-1

| | I | II | III | IV |
|---|---|---|---|---|
| Standard of opalescence | 5.0 mL | 10.0 mL | 30.0 mL | 50.0 mL |
| *Water R* | 95.0 mL | 90.0 mL | 70.0 mL | 50.0 mL |

Measurements of reference suspensions I-IV in ratio mode show a linear relationship between the concentrations and measured NTU values (see Table 2.2.1.-2).

Table 2.2.1.-2

| Formazin suspensions | Opalescent values (NTU) |
|---|---|
| Reference suspension I | 3 |
| Reference suspension II | 6 |
| Reference suspension III | 18 |
| Reference suspension IV | 30 |
| Standard of opalescence | 60 |
| Primary opalescent suspension | 4000 |

**01/2008:20202**

# 2.2.2. DEGREE OF COLORATION OF LIQUIDS

The examination of the degree of coloration of liquids in the range brown-yellow-red is carried out by one of the 2 methods below, as prescribed in the monograph.

A solution is *colourless* if it has the appearance of *water R* or the solvent or is not more intensely coloured than reference solution $B_9$.

METHOD I

Using identical tubes of colourless, transparent, neutral glass of 12 mm external diameter, compare 2.0 mL of the liquid to be examined with 2.0 mL of *water R* or of the solvent or of the reference solution (see Tables of reference solutions) prescribed in the monograph. Compare the colours in diffused daylight, viewing horizontally against a white background.

METHOD II

Using identical tubes of colourless, transparent, neutral glass with a flat base and an internal diameter of 15 mm to 25 mm, compare the liquid to be examined with *water R* or the solvent or the reference solution (see Tables of reference solutions) prescribed in the monograph, the depth of the layer being 40 mm. Compare the colours in diffused daylight, viewing vertically against a white background.

REAGENTS

**Primary solutions**

*Yellow solution*. Dissolve 46 g of *ferric chloride R* in about 900 mL of a mixture of 25 mL of *hydrochloric acid R* and 975 mL of *water R* and dilute to 1000.0 mL with the same mixture. Titrate and adjust the solution to contain 45.0 mg of $FeCl_3,6H_2O$ per millilitre by adding the same acidic mixture. Protect the solution from light.

Titration. Place in a 250 mL conical flask fitted with a ground-glass stopper, 10.0 mL of the solution, 15 mL of *water R*, 5 mL of *hydrochloric acid R* and 4 g of *potassium iodide R*, close the flask, allow to stand in the dark for 15 min and add 100 mL of *water R*. Titrate the liberated iodine with *0.1 M sodium thiosulfate*, using 0.5 mL of *starch solution R*, added towards the end of the titration, as indicator.

1 mL of *0.1 M sodium thiosulfate* is equivalent to 27.03 mg of $FeCl_3,6H_2O$.

*Red solution*. Dissolve 60 g of *cobalt chloride R* in about 900 mL of a mixture of 25 mL of *hydrochloric acid R* and 975 mL of *water R* and dilute to 1000.0 mL with the same mixture. Titrate and adjust the solution to contain 59.5 mg of $CoCl_2,6H_2O$ per millilitre by adding the same acidic mixture.

Titration. Place in a 250 mL conical flask fitted with a ground-glass stopper, 5.0 mL of the solution, 5 mL of *dilute hydrogen peroxide solution R* and 10 mL of a 300 g/L solution

of *sodium hydroxide R*. Boil gently for 10 min, allow to cool and add 60 mL of *dilute sulfuric acid R* and 2 g of *potassium iodide R*. Close the flask and dissolve the precipitate by shaking gently. Titrate the liberated iodine with *0.1 M sodium thiosulfate*, using 0.5 mL of *starch solution R*, added towards the end of the titration, as indicator. The end-point is reached when the solution turns pink.

1 mL of *0.1 M sodium thiosulfate* is equivalent to 23.79 mg of $CoCl_2,6H_2O$.

*Blue primary solution.* Dissolve 63 g of *copper sulfate pentahydrate R* in about 900 mL of a mixture of 25 mL of *hydrochloric acid R* and 975 mL of *water R* and dilute to 1000.0 mL with the same mixture. Titrate and adjust the solution to contain 62.4 mg of $CuSO_4,5H_2O$ per millilitre by adding the same acidic mixture.

Titration. Place in a 250 mL conical flask fitted with a ground-glass stopper, 10.0 mL of the solution, 50 mL of *water R*, 12 mL of *dilute acetic acid R* and 3 g of *potassium iodide R*. Titrate the liberated iodine with *0.1 M sodium thiosulfate*, using 0.5 mL of *starch solution R*, added towards the end of the titration, as indicator. The end-point is reached when the solution shows a slight pale brown colour.

1 mL of *0.1 M sodium thiosulfate* is equivalent to 24.97 mg of $CuSO_4,5H_2O$.

**Standard solutions**

Using the 3 primary solutions, prepare the 5 standard solutions as follows (Table 2.2.2.-1):

Table 2.2.2.-1

| Standard solution | Volume in millilitres | | | |
|---|---|---|---|---|
| | Yellow solution | Red solution | Blue solution | Hydrochloric acid (10 g/L HCl) |
| B (brown) | 3.0 | 3.0 | 2.4 | 1.6 |
| BY (brownish-yellow) | 2.4 | 1.0 | 0.4 | 6.2 |
| Y (yellow) | 2.4 | 0.6 | 0.0 | 7.0 |
| GY (greenish-yellow) | 9.6 | 0.2 | 0.2 | 0.0 |
| R (red) | 1.0 | 2.0 | 0.0 | 7.0 |

**Reference solutions for Methods I and II**

Using the 5 standard solutions, prepare the following reference solutions.

Table 2.2.2.-2. - *Reference solutions B*

| Reference solution | Volumes in millilitres | |
|---|---|---|
| | Standard solution B | Hydrochloric acid (10 g/L HCl) |
| $B_1$ | 75.0 | 25.0 |
| $B_2$ | 50.0 | 50.0 |
| $B_3$ | 37.5 | 62.5 |
| $B_4$ | 25.0 | 75.0 |
| $B_5$ | 12.5 | 87.5 |
| $B_6$ | 5.0 | 95.0 |
| $B_7$ | 2.5 | 97.5 |

**Storage**

For Method I, the reference solutions may be stored in sealed tubes of colourless, transparent, neutral glass of 12 mm external diameter, protected from light.

For Method II, prepare the reference solutions immediately before use from the standard solutions.

07/2016:20203

# 2.2.3. POTENTIOMETRIC DETERMINATION OF pH

The pH of an aqueous solution is defined as the negative logarithm of the activity of its hydrogen ions, expressed conventionally as the hydrogen ion concentration of the solution. For practical purposes, its definition is an experimental one. The pH of a solution to be examined is related to that of a reference solution ($pH_s$) by the following equation:

$$pH = pH_s - \frac{E - E_s}{k}$$

in which $E$ is the potential, expressed in volts, of the cell containing the solution to be examined and $E_s$ is the potential, expressed in volts, of the cell containing the solution of known pH ($pH_s$), $k$ is the change in potential per unit change in pH, expressed in volts and calculated from the Nernst equation.

Table 2.2.3.-1. – *Values of k at different temperatures*

| Temperature (°C) | *k* (V) |
|---|---|
| 15 | 0.0572 |
| 20 | 0.0582 |
| 25 | 0.0592 |
| 30 | 0.0601 |
| 35 | 0.0611 |

The potentiometric determination of pH is made by measuring the potential difference between 2 appropriate electrodes immersed in the solution to be examined; 1 of these electrodes is sensitive to hydrogen ions (usually a glass electrode) and the other is the reference electrode (e.g. a silver-silver chloride electrode). They are often combined as 1 compact electrode, together with a temperature probe.

*Apparatus.* The measuring apparatus is usually a voltmeter with an input resistance at least 100 times that of the electrodes used. It is normally graduated in pH units and has a sensitivity such that discrimination of at least 0.05 pH unit or at least 0.003 V may be achieved.

Recent pH meters are microprocessor-controlled and are operated using the manufacturer's firmware or software, according to given instructions.

*Management of electrodes.* The electrodes are stored appropriately and according to the manufacturer's recommendations (e.g. in an electrolyte solution or a suitable storage solution). Before measurement, the electrodes are visually checked. Refillable electrodes are checked for the absence of air bubbles in the glass bulb and to ensure that the inner electrolyte solution level is satisfactory. The filling orifice has to remain open during the measurement. It is also recommended that the diaphragm of the reference electrode is checked. Before first use, or if the electrode has been stored out of electrolyte solution, it is usually necessary to condition it, according to the recommendations of the manufacturer. If pH stabilisation is too slow (i.e. a long response time), or a zero point shift, reduced slope or any other difficulties in calibration are observed, the electrode will probably need to be cleaned or replaced. The cleaning is performed depending on the type of sample and as prescribed in the manufacturer's manual. Regular cleaning is recommended.

*Calibration and measurement conditions.* Unless otherwise prescribed in the monograph, all measurements are carried out at the same temperature as that used for calibration (± 2.5 °C), usually between 20 °C and 25 °C. Table 2.2.3.-2 shows the variation of pH with respect to temperature of a number of reference buffer solutions used for calibration. Follow the manufacturer's instructions for temperature correction.

The calibration consists of the determination of the slope (e.g. 95-105 per cent) and the offset of the measuring system. Most commercial pH meters offer a "self test" or "start-up test" where, for example, the slope and asymmetry potential are tested and compared to the manufacturer's specifications. The apparatus is calibrated using at least 2 buffer solutions chosen so that the expected pH value of the solution to be examined lies between the pH values of the buffer solutions. The range must be at least 2 pH units. The pH of another buffer solution of intermediate pH, read from the scale, must not differ by more than 0.05 pH units from the value corresponding to that solution.

Reference buffer solutions are preferably commercially available certified reference materials. Alternatively, buffer solutions can be prepared in-house according to Table 2.2.3.-2. These solutions must be traceable to primary standards. Calibration has to be performed on a regular basis, preferably each day of use or before each series of measurements.

Immerse the electrodes in the solution to be examined and take the reading in the same conditions as those applied for the reference buffer solutions.

If suspensions, emulsions or solutions of non-aqueous or partially non-aqueous character are measured on a system calibrated as described above, the pH reading can only be considered to be an approximation of the true value. Suitable electrodes have to be used for pH measurements of such mixtures.

Table 2.2.3.-2. – *pH of reference buffer solutions at various temperatures*

| Temperature (°C) | Potassium tetraoxalate 0.05 M | Potassium hydrogen tartrate saturated at 25 °C | Potassium dihydrogen citrate 0.05 M | Potassium hydrogen phthalate 0.05 M | Potassium dihydrogen phosphate 0.025 M + Disodium hydrogen phosphate 0.025 M | Potassium dihydrogen phosphate 0.0087 M + Disodium hydrogen phosphate 0.0303 M | Disodium tetraborate 0.01 M | Sodium carbonate 0.025 M + Sodium bicarbonate 0.025 M | Calcium hydroxide, saturated at 25°C |

PREPARATION OF REFERENCE BUFFER SOLUTIONS

**Potassium tetraoxalate 0.05 M**. Dissolve 12.61 g of $C_4H_3KO_8,2H_2O$ in *carbon dioxide-free water R* and dilute to 1000.0 mL with the same solvent.

**Potassium hydrogen tartrate, saturated at 25 °C**. Shake an excess of $C_4H_5KO_6$ vigorously with *carbon dioxide-free water R* at 25 °C. Filter or decant. Prepare immediately before use.

**Potassium dihydrogen citrate 0.05 M**. Dissolve 11.41 g of $C_6H_7KO_7$ in *carbon dioxide-free water R* and dilute to 1000.0 mL with the same solvent. Prepare immediately before use.

**Potassium hydrogen phthalate 0.05 M**. Dissolve 10.13 g of $C_8H_5KO_4$, previously dried for 1 h at 110 ± 2 °C, in *carbon dioxide-free water R* and dilute to 1000.0 mL with the same solvent.

**Potassium dihydrogen phosphate 0.025 M + Disodium hydrogen phosphate 0.025 M**. Dissolve 3.39 g of $KH_2PO_4$ and 3.53 g of $Na_2HPO_4$, both previously dried for 2 h at 120 ± 2 °C, in *carbon dioxide-free water R* and dilute to 1000.0 mL with the same solvent.

**Potassium dihydrogen phosphate 0.0087 M + Disodium hydrogen phosphate 0.0303 M**. Dissolve 1.18 g of $KH_2PO_4$ and 4.30 g of $Na_2HPO_4$, both previously dried for 2 h at 120 ± 2 °C, in *carbon dioxide-free water R* and dilute to 1000.0 mL with the same solvent.

**Disodium tetraborate 0.01 M**. Dissolve 3.80 g of $Na_2B_4O_7,10H_2O$ in *carbon dioxide-free water R* and dilute to 1000.0 mL with the same solvent. Store protected from atmospheric carbon dioxide.

**Sodium carbonate 0.025 M + Sodium hydrogen carbonate 0.025 M**. Dissolve 2.64 g of $Na_2CO_3$ and 2.09 g of $NaHCO_3$ in *carbon dioxide-free water R* and dilute to 1000.0 mL with the same solvent. Store protected from atmospheric carbon dioxide.

**Calcium hydroxide, saturated at 25 °C**. Shake an excess of *calcium hydroxide R* with *carbon dioxide-free water R* and decant at 25 °C. Store protected from atmospheric carbon dioxide.

STORAGE OF BUFFER SOLUTIONS

Store buffer solutions in suitable chemically-resistant, airtight containers, such as type I glass bottles or plastic containers suitable for aqueous solutions.

**01/2016:20204**

## 2.2.4. APPROXIMATE pH OF SOLUTIONS

Determine the approximate pH using a *pH indicator strip R*. Alternatively, pH indicators such as those described in Table 2.2.4.-1 can be used.

Table 2.2.4.-1

| Reaction | pH | Indicator |
|---|---|---|
| **Alkaline** | > 8 | *Red litmus paper R* |
| Slightly alkaline | 8 – 10 | *Phenolphthalein solution R* |
| | | *Thymol blue solution R* |
| Strongly alkaline | > 10 | *Phenolphthalein paper R* |
| | | *Thymol blue solution R* |
| **Neutral** | 6 – 8 | *Methyl red solution R* |
| | | *Phenol red solution R* |
| **Acid** | < 6 | *Methyl red solution R* |
| | | *Bromothymol blue solution R1* |
| Slightly acid | 4 – 6 | *Methyl red solution R* |
| | | *Bromocresol green solution R* |
| Strongly acid | < 4 | *Congo red paper R* |

**01/2008:20205 corrected 10.0**

## 2.2.5. RELATIVE DENSITY

The relative density $d_{t_2}^{t_1}$ of a substance is the ratio of the mass of a certain volume of a substance at temperature $t_1$ to the mass of an equal volume of water at temperature $t_2$.

Unless otherwise indicated, the relative density $d_{20}^{20}$ is used.

Relative density is also commonly expressed as $d_4^{20}$. Density $\rho_{20}$, defined as the mass of a unit volume of the substance at 20 °C

may also be used, expressed in kilograms per cubic metre or grams per cubic centimetre ($1\ kg{\cdot}m^{-3} = 10^{-3}\ g{\cdot}cm^{-3}$). These quantities are related by the following equations where density is expressed in grams per cubic centimetre:

$$\rho_{20} = 0.998203 \times d_{20}^{20} \text{ or } d_{20}^{20} = 1.00180 \times \rho_{20}$$

$$\rho_{20} = 0.999972 \times d_{4}^{20} \text{ or } d_{4}^{20} = 1.00003 \times \rho_{20}$$

$$d_{4}^{20} = 0.998230 \times d_{20}^{20}$$

Relative density or density is measured according to the number of decimals prescribed in the monograph using a density bottle (solids or liquids), a hydrostatic balance (solids), a hydrometer (liquids) or a digital density meter with an oscillating transducer (liquids and gases). When the determination is made by weighing, the buoyancy of air is disregarded, which may introduce an error of 1 unit in the 3rd decimal place. When using a density meter, the buoyancy of air has no influence.

*Oscillating transducer density meter.* The apparatus consists of:

- a U-shaped tube, usually of borosilicate glass, which contains the liquid to be examined;
- a magneto-electrical or piezo-electrical excitation system that causes the tube to oscillate as a cantilever oscillator at a characteristic frequency depending on the density of the liquid to be examined;
- a means of measuring the oscillation period ($T$), which may be converted by the apparatus to give a direct reading of density, or used to calculate density using the constants $A$ and $B$ described below.

The resonant frequency ($f$) is a function of the spring constant ($c$) and the mass ($m$) of the system:

$$f^2 = \frac{1}{T^2} = \frac{c}{m} \times \frac{1}{4\pi^2}$$

Hence:

$$T^2 = \left(\frac{M}{c} + \frac{\rho \times V}{c}\right) \times 4\pi^2$$

$M$ = mass of the tube;

$V$ = inner volume of the tube.

Introduction of 2 constants $A = c / (4\pi^2 \times V)$ and $B = M / V$, leads to the classical equation for the oscillating transducer:

$$\rho = A \times T^2 - B$$

The constants $A$ and $B$ are determined by operating the instrument with the U-tube filled with 2 different samples of known density, for example, degassed *water R* and air. Control measurements are made daily using degassed *water R*. The results displayed for the control measurement using degassed *water R* shall not deviate from the reference value ($\rho_{20} = 0.998203\ g{\cdot}cm^{-3}$, $d_{20}^{20} = 1.000000$) by more than its specified error. For example, an instrument specified to $\pm 0.0001\ g{\cdot}cm^{-3}$ shall display $0.9982 \pm 0.0001\ g{\cdot}cm^{-3}$ in order to be suitable for further measurement. Otherwise a re-adjustment is necessary. Calibration with certified reference materials is carried out regularly. Measurements are made using the same procedure as for calibration. The liquid to be examined is equilibrated in a thermostat at 20 °C before introduction into the tube, if necessary, to avoid the formation of bubbles and to reduce the time required for measurement.

Factors affecting accuracy include:

- temperature uniformity throughout the tube;
- non-linearity over a range of density;
- parasitic resonant effects;
- viscosity, whereby solutions with a higher viscosity than the calibrant have a density that is apparently higher than the true value.

The effects of non-linearity and viscosity may be avoided by using calibrants that have density and viscosity close to those of the liquid to be examined (± 5 per cent for density, ± 50 per cent for viscosity). The density meter may have functions for automatic viscosity correction and for correction of errors arising from temperature changes and non-linearity.

Precision is a function of the repeatability and stability of the oscillator frequency, which is dependent on the stability of the volume, mass and spring constant of the cell.

Density meters are able to achieve measurements with an error of the order of $1 \times 10^{-3}\ g{\cdot}cm^{-3}$ to $1 \times 10^{-5}\ g{\cdot}cm^{-3}$ and a repeatability of $1 \times 10^{-4}\ g{\cdot}cm^{-3}$ to $1 \times 10^{-6}\ g{\cdot}cm^{-3}$.

**01/2008:20206**

## 2.2.6. REFRACTIVE INDEX

The refractive index of a medium with reference to air is equal to the ratio of the sine of the angle of incidence of a beam of light in air to the sine of the angle of refraction of the refracted beam in the given medium.

Unless otherwise prescribed, the refractive index is measured at 20 ± 0.5 °C, with reference to the wavelength of the D-line of sodium (λ = 589.3 nm); the symbol is then $n_D^{20}$.

Refractometers normally determine the critical angle. In such apparatus the essential part is a prism of known refractive index in contact with the liquid to be examined.

Calibrate the apparatus using certified reference materials.

When white light is used, the refractometer is provided with a compensating system. The apparatus gives readings accurate to at least the third decimal place and is provided with a means of operation at the temperature prescribed. The thermometer is graduated at intervals of 0.5 °C or less.

**07/2018:20207**

## 2.2.7. OPTICAL ROTATION

PRINCIPLE

Optical rotation (also known as optical activity) is the property displayed by chiral substances of rotating the plane of polarisation of linearly polarised light.

Optical rotation is considered to be positive (+) for dextrorotatory substances (i.e. those that rotate the plane of polarisation in a clockwise direction when viewed in the direction facing the oncoming light beam) and negative (−) for laevorotatory substances (i.e. anticlockwise rotation).

The angle of optical rotation $\alpha$ of a liquid is the angle of rotation of the plane of polarisation, expressed in degrees (°), at the wavelength of the D-line of sodium (λ = 589.3 nm) measured at 20 °C through the liquid when using a path length of 1.00 dm.

The specific optical rotation $[\alpha]_D^{20}$ of a substance in solution is calculated from the angle of optical rotation, as defined above, with reference to a path length of 1.00 dm and a concentration of the substance to be examined of 1 g/mL. The specific optical rotation of a substance in solution is always expressed with reference to a given solvent and concentration.

As some equipment may not use sodium lamps, the wavelength of measurement is given as 589 nm instead of 589.3 nm.

In certain cases specified in the monograph, the angle of optical rotation is measured at other temperatures, other wavelengths and/or in cells with a path length other than 1.00 dm.

In the conventional system adopted by the Pharmacopoeia, the specific optical rotation is expressed by its value without units; the actual units, degree millilitres per decimetre gram [(°)·ml·dm$^{-1}$·g$^{-1}$] are understood.

EQUIPMENT

The polarimeter typically consists of:

- a light source, for example a sodium discharge lamp, a light-emitting diode (LED) or another light source capable of providing radiation at the desired wavelength (589 nm unless otherwise prescribed in the monograph); if the light source is polychromatic, a means of isolating the required wavelength is necessary, e.g. an optical filter;
- a polariser and an analyser;
- a sample cell with a path length of 1.00 dm, unless otherwise specified in the monograph;
- a detection system to measure the angle of optical rotation, which must be capable of giving readings to at least the nearest 0.01°, unless otherwise specified in the monograph;
- a temperature control system that indicates the temperature with a readability of 0.1 °C; it may be embedded in the polarimeter (e.g. a Peltier system) or be an external unit (e.g. a cycle-cryostat), and must be able to maintain the temperature of the liquid to within ± 0.5 °C of that prescribed.

EQUIPMENT PERFORMANCE

The accuracy of the scale is checked near the value to be measured or over an appropriate range, usually by means of certified quartz plates. Other certified reference materials may also be suitable (e.g. sucrose solutions).

Optical rotation measurements may be used to quantify the amount of an enantiomer or the ratio of enantiomers present in a sample. For that purpose, the linearity must be checked, for example using sucrose solutions.

PROCEDURE

Determine the zero of the polarimeter and the angle of rotation of the liquid at a wavelength of 589 nm and a temperature of 20 ± 0.5 °C, unless otherwise prescribed. The zero of the polarimeter is determined with the sample cell closed.

For neat liquids, the zero is determined with an empty sample cell.

For solutions, the zero is determined with the sample cell filled with the same solvent as that used for the solution to be examined and measured at the same temperature. The sample preparation procedure is prescribed in the monograph.

Calculate the specific optical rotation at temperature $t$ and wavelength $\lambda$ using the following formulae.

For neat liquids, the density of the liquid is taken into account:

$$[\alpha]_{\lambda}^{t} = \frac{\alpha}{l \cdot \rho_t}$$

For solutions:

$$[\alpha]_{\lambda}^{t} = \frac{1000\alpha}{l \cdot c}$$

$\alpha$ = angle of rotation measured at temperature $t$ and wavelength $\lambda$, in degrees;

$l$ = path length of the polarimeter sample cell, in decimetres;

$\rho_t$ = density determined at the temperature of measurement $t$, in grams per cubic centimetre; for the purposes of the Pharmacopoeia, density is replaced by relative density (*2.2.5*);

$c$ = concentration of the solution, in grams per litre.

When the limits for optical rotation or specific optical rotation are expressed as the dried substance, the anhydrous substance or the solvent-free substance, the result must be corrected for loss on drying (*2.2.32*), water content (*2.5.12* or *2.5.32*) or content of solvent as appropriate.

**04/2018:20208**

## 2.2.8. VISCOSITY

The *dynamic* viscosity or *viscosity coefficient* $\eta$ is the tangential force per unit surface, known as *shearing stress* $\tau$ and expressed in pascals, necessary to move, parallel to the sliding plane, a layer of liquid of 1 square metre at a rate ($v$) of 1 metre per second relative to a parallel layer at a distance ($x$) of 1 metre.

The ratio d$v$/d$x$ is a speed gradient giving the *rate of shear D* expressed in reciprocal seconds (s$^{-1}$), so that $\eta = \tau/D$.

The unit of dynamic viscosity is the pascal second (Pa·s). The most commonly used submultiple is the millipascal second (mPa·s).

The *kinematic viscosity* $\nu$, expressed in square metres per second, is obtained by dividing the dynamic viscosity $\eta$ by the density $\rho$ expressed in kilograms per cubic metre, of the liquid measured at the same temperature, i.e. $\nu = \eta/\rho$. The kinematic viscosity is usually expressed in square millimetres per second.

A capillary viscometer may be used for determining the viscosity of Newtonian liquids and a rotating viscometer for determining the viscosity of Newtonian and non-Newtonian liquids. Other viscometers may be used provided that the accuracy and precision are at least as satisfactory as those obtained with the viscometers described in the related chapters.

**01/2019:20209**

## 2.2.9. CAPILLARY VISCOMETER METHOD

PRINCIPLE

The determination of viscosity is carried out using a suspended-level (Ubbelohde-type) capillary viscometer of appropriate size at a temperature of 20.0 ± 0.1 °C, unless otherwise prescribed. The time required for the level of the liquid to drop from one mark to the other is measured.

EQUIPMENT

The principal components of an Ubbelohde-type capillary viscometer(1). are shown in Figure 2.2.9.-1.

(1) The European Pharmacopoeia describes the system proposed by the International Organization for Standardization (ISO)

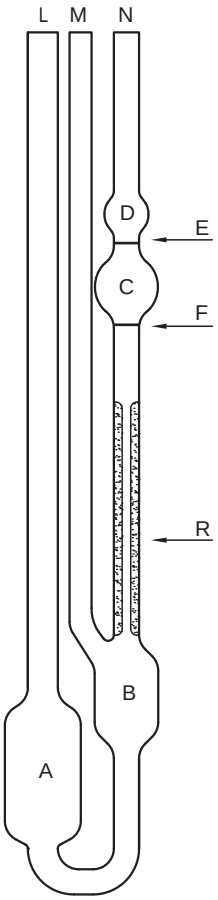

Figure 2.2.9.-1. – *Suspended-level (Ubbelohde-type) capillary viscometer*

PROCEDURE

Select a capillary viscometer of appropriate size to obtain a minimum flow time of 200 s.

**Calibration**

Capillary viscometers are calibrated at regular intervals as defined in the quality management system and dictated by the frequency of use of the equipment and the application.

Calibrate the instrument at the temperature used for the measurement by using at least 2 certified reference materials matching the viscosity range of the viscometer.

Calculate the viscometer constant ($k$) in square millimetres per second squared, using the following expression:

$$k = \frac{\eta}{\rho t}$$

$\eta$ = dynamic viscosity of the certified reference material, in millipascal seconds;

$\rho$ = density of the certified reference material, in milligrams per cubic millimetre;

$t$ = flow time for the certified reference material to drop from the upper mark to the lower mark, in seconds.

Calculate the mean of the values obtained.

**Method**

Charge the viscometer (Figure 2.2.9.-1) through tube *L* with a sufficient quantity of the liquid to be examined (previously brought to 20 °C unless otherwise prescribed) to fill bulb *A* while ensuring that the level of liquid in bulb *B* is below the exit to ventilation tube *M*. Immerse the viscometer in the upright position in a water-bath at 20.0 ± 0.1 °C (unless otherwise prescribed) and allow to stand for not less than 30 min to allow the temperature to reach equilibrium. Close tube *M* and draw the level of the liquid in tube *N* up to a level about 8 mm above mark *E*. Keep the liquid at this level by closing tube *N* and opening tube *M*. Open tube *N* and, using a stopwatch, measure the time required, to at least the nearest 1/5 of a second, for the level of the liquid to drop from mark *E* to mark *F*.

The flow time of the liquid to be examined is the mean of 3 consecutive measurements. The result is valid if the relative standard deviation of the 3 measurements is not more than 2.0 per cent.

**Calculation**

Calculate the kinematic viscosity ($\nu$) (*2.2.8*), in square millimetres per second, using the following expression:

$$\nu = kt$$

$k$ = viscometer constant, in square millimetres per second squared;

$t$ = flow time of the liquid to be examined, in seconds.

Calculate the dynamic viscosity ($\eta$) (*2.2.8*), in millipascal seconds, using the following expression:

$$\eta = k\rho t$$

$\rho$ = density of the liquid to be examined at the temperature used for the viscosity measurement, in milligrams per cubic millimetre.

The density may be obtained by multiplying the relative density of the liquid to be examined by 0.99820 (measurement at 20 °C) or 0.99704 (measurement at 25 °C).

**01/2008:20210**

## 2.2.10. VISCOSITY - ROTATING VISCOMETER METHOD

The principle of the method is to measure the force acting on a rotor (torque) when it rotates at a constant angular velocity (rotational speed) in a liquid. Rotating viscometers are used for measuring the viscosity of Newtonian (shear-independent viscosity) or non-Newtonian liquids (shear dependent viscosity or apparent viscosity). Rotating viscometers can be divided in 2 groups, namely absolute and relative viscometers. In absolute viscometers the flow in the measuring geometry is well defined. The measurements result in absolute viscosity values, which can be compared with any other absolute values. In relative viscometers the flow in the measuring geometry is not defined. The measurements result in relative viscosity values, which cannot be compared with absolute values or other relative values if not determined by the same relative viscometer method.

Different measuring systems are available for given viscosity ranges as well as several rotational speeds.

APPARATUS

The following types of instruments are most common.

*CONCENTRIC CYLINDER VISCOMETERS (ABSOLUTE VISCOMETERS)*

In the concentric cylinder viscometer (coaxial double cylinder viscometer or simply coaxial cylinder viscometer), the viscosity is determined by placing the liquid in the gap between the inner cylinder and the outer cylinder. Viscosity measurement can be performed by rotating the inner cylinder (Searle type viscometer) or the outer cylinder (Couette type viscometer), as shown in Figures 2.2.10.-1 and 2.2.10.-2, respectively. For laminar flow, the viscosity (or apparent viscosity) η expressed in pascal-seconds is given by the following formula:

$$\eta = \frac{1}{\omega}\left(\frac{M}{4\pi h}\right)\left(\frac{1}{R_i^2} - \frac{1}{R_o^2}\right) = k\frac{M}{\omega}$$

$M$ = torque in newton-metres acting on the cylinder surface,
$\omega$ = angular velocity in radians per second,
$h$ = height of immersion in metres of the inner cylinder in the liquid medium,
$R_i$ = radius in metres of the inner cylinder,
$R_o$ = radius in metres of the outer cylinder,
$k$ = constant of the apparatus, expressed in radians per cubic metre.

For non-Newtonian liquids it is indispensable to specify the shear stress ($\tau$) or the shear rate ($\gamma$) at which the viscosity is measured. Under narrow gap conditions (conditions satisfied in absolute viscometers), there is a proportional relationship between $M$ and $\tau$ and also between $\omega$ and $\gamma$:

$$\tau = AM \qquad \gamma = B\omega$$

where A and B are constants for the instrument and are calculated from the following expressions:

– *for concentric surface*:

$$A = \frac{1}{4\pi h}\frac{R_i^2 + R_o^2}{R_i^2 R_o^2} \qquad B = \frac{R_i^2 + R_o^2}{R_o^2 - R_i^2}$$

– *for cone-plates*:

$$A = \frac{3}{2\pi R^3} \qquad B = \frac{1}{\alpha}$$

$M$ = torque in Newton-metres acting on the cone or cylinder surface,
$\omega$ = angular velocity in radians per second,
$R_i$ = radius in metres of the inner cylinder,
$R_o$ = radius in metres of the outer cylinder,
$R$ = radius in metres of the cone,
$h$ = height of immersion in metres of the inner cylinder in the liquid medium,
$\alpha$ = angle in radians between the flat disk and the cone,
$\tau$ = shear stress in pascals (Pa),
$\gamma$ = shear rate in reciprocal seconds ($s^{-1}$).

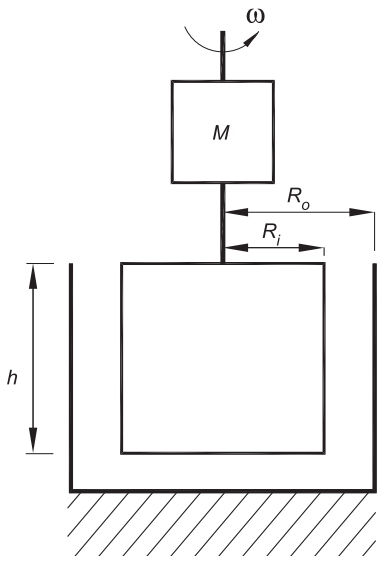

Figure 2.2.10.-1

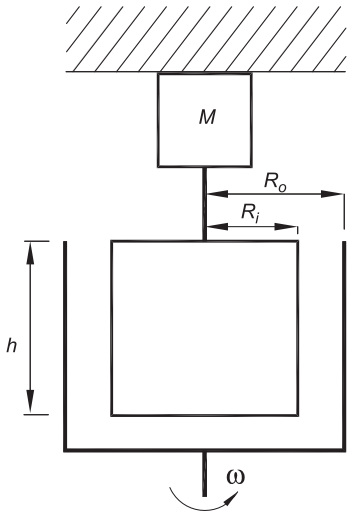

Figure 2.2.10.-2

*CONE-PLATE VISCOMETERS (ABSOLUTE VISCOMETERS)*

In the cone-plate viscometer, the liquid is introduced into the gap between a flat disc and a cone forming a define angle. Viscosity measurement can be performed by rotating the cone or the flat disc, as shown in Figures 2.2.10.-3 and 2.2.10.-4, respectively. For laminar flow, the viscosity (or apparent viscosity) $\eta$ expressed in pascal-seconds is given by the following formula:

$$\eta = \left(\frac{M}{\omega}\right)\left(\frac{3\alpha}{2\pi R^3}\right) = k\frac{M}{\omega}$$

$M$ = torque in Newton-metres acting on the flat disc or cone surface,
$\omega$ = angular velocity in radians per second,
$\alpha$ = angle in radians between the flat disc and the cone,
$R$ = radius in metres of the cone,
$k$ = constant of the apparatus, expressed in radians per cubic metre.

Constants $A$, $B$ of the apparatus (see under concentric cylinder viscometers).

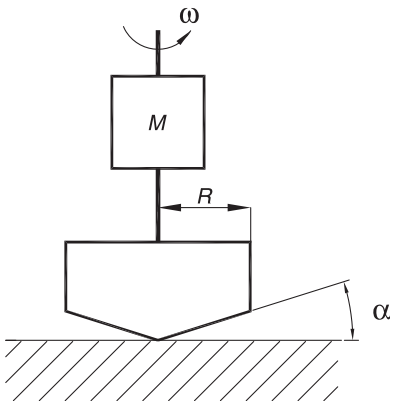

Figure 2.2.10.-3

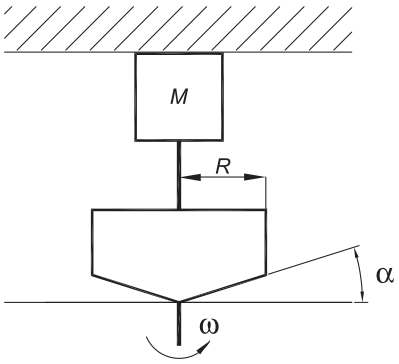

Figure 2.2.10.-4

*SPINDLE VISCOMETERS (RELATIVE VISCOMETERS)*

In the spindle viscometer, the viscosity is determined by rotating a spindle (for example, cylinder- or disc-shaped, as shown in Figures 2.2.10.-5 and 2.2.10.-6, respectively) immersed in the liquid. Relative values of viscosity (or apparent viscosity) can be directly calculated using conversion factors from the scale reading at a given rotational speed.

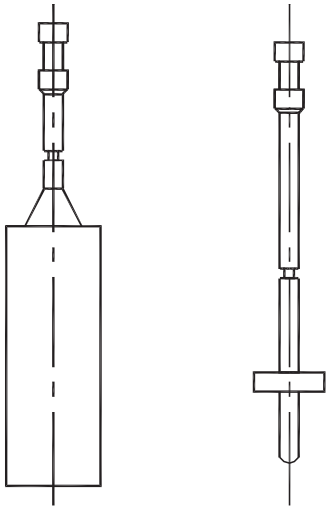

Figure 2.2.10.-5

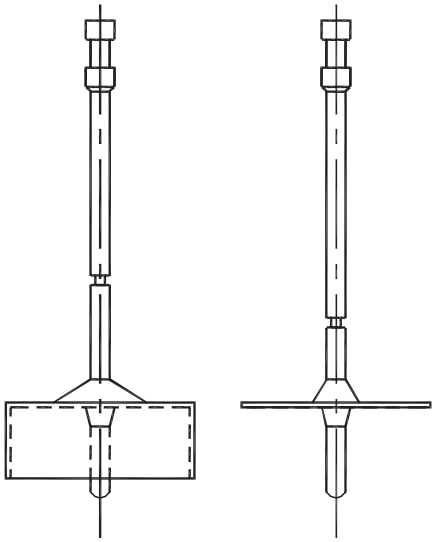

Figure 2.2.10.-6

In a general way, the constant $k$ of the apparatus may be determined at various speeds of rotation using a certified viscometer calibration liquid. The viscosity η then corresponds to the formula:

$$\eta = k\frac{M}{\omega}$$

METHOD

Measure the viscosity (or apparent viscosity) according to the instructions for the operation of the rotating viscometer. The temperature for measuring the viscosity is indicated in the monograph. For non-Newtonian systems, the monograph indicates the type of viscometer to be used and if absolute viscometers are used the angular velocity or the shear rate at which the measurement is made. If it is impossible to obtain the indicated shear rate exactly, use a shear rate slightly higher and a shear rate slightly lower and interpolate.

With relative viscometers the shear rate is not the same throughout the sample and therefore it cannot be defined. Under these conditions, the viscosity of non-Newtonian liquids determined from the previous formula has a relative character, which depends on the type of spindle and the angular velocity as well as the dimensions of the sample container (Ø = minimum 80 mm) and the depth of immersion of the spindle. The values obtained are comparable only if the method is carried out under experimental conditions that are rigorously the same.

**07/2015:20211**

## 2.2.11. DISTILLATION RANGE

The distillation range is the temperature interval, corrected for a pressure of 101.3 kPa, within which a liquid or a specified fraction of a liquid, distils under the following conditions.

*Apparatus*. The apparatus (see Figure 2.2.11.-1) consists of a distillation flask (*A*), a straight tube condenser (*B*) which fits on to the side arm of the flask and a plain-bend adaptor (*C*) attached to the end of the condenser. The lower end of the condenser may, alternatively, be bent to replace the adaptor. A thermometer is inserted in the neck of the flask so that the upper end of the bulb is 5 mm lower than the junction of the lower wall of the lateral tube. The thermometer can be read to the nearest 0.2 °C and covers a range of at least 50 °C. During the determination, the flask, including its neck, is protected from draughts by a suitable screen.

*Method*. Place in the flask (*A*) 50.0 mL of the liquid to be examined and a few pieces of porous material. Collect the distillate in a 50 mL cylinder graduated in millilitres. Cooling by circulating water is essential for liquids distilling below 150 °C. Heat the flask so that boiling is rapidly achieved and note the temperature at which the first drop of distillate falls into the cylinder. Adjust the heating to give a regular rate of distillation of 2-3 mL/min and note the temperature when the whole or the prescribed fraction of the liquid, measured at 20 °C, has distilled.

Correct the observed temperatures for barometric pressure by means of the formula:

$$t_1 = t_2 + k(101.3 - b)$$

$t_1$ = the corrected temperature,

$t_2$ = the observed temperature, at the barometric pressure $b$,

$k$ = the correction factor taken from Table 2.2.11.-1 unless the factor is given,

$b$ = the barometric pressure, expressed in kilopascals, during the distillation.

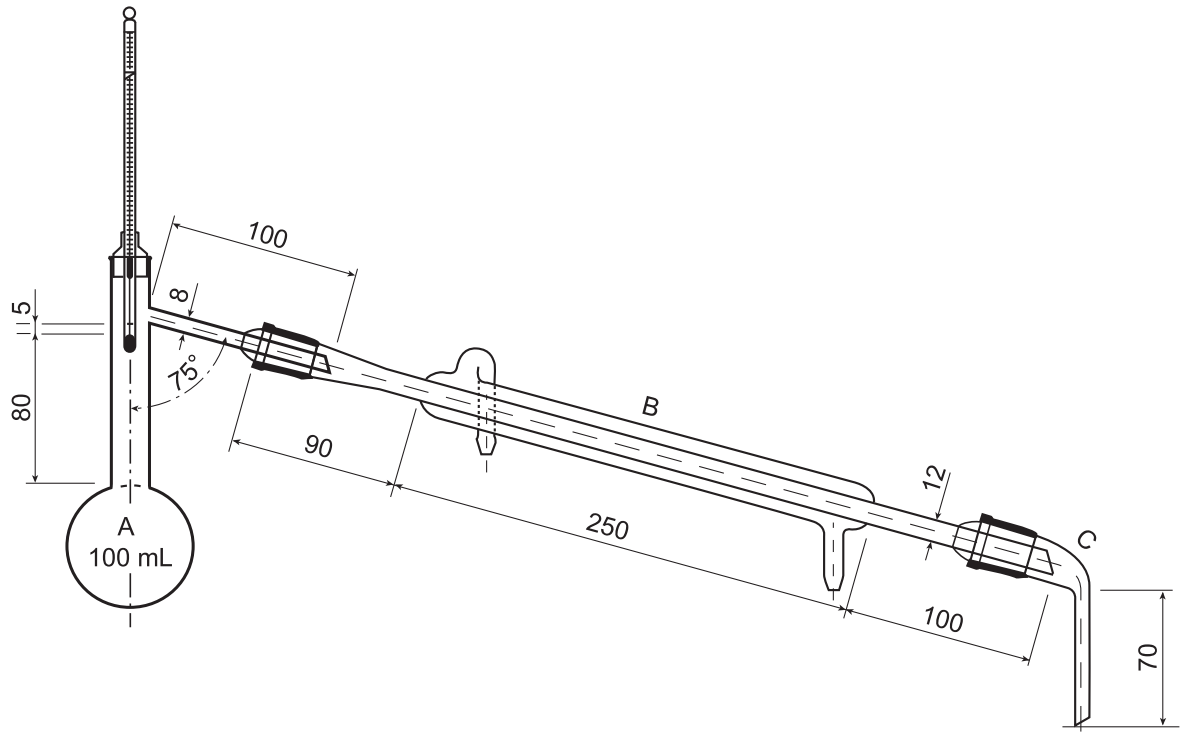

Figure 2.2.11.-1. – *Apparatus for the determination of distillation range*
*Dimensions in millimetres*

Table 2.2.11.-1. – *Temperature correction in relation to the pressure*

| Distillation temperature | Correction factor *k* |
|---|---|
| up to 100 °C | 0.30 |
| above 100 °C up to 140 °C | 0.34 |
| above 140 °C up to 190 °C | 0.38 |
| above 190 °C up to 240 °C | 0.41 |
| above 240 °C | 0.45 |

**07/2015:20212**

## 2.2.12. BOILING POINT

The boiling point is the corrected temperature at which the vapour pressure of a liquid is equal to 101.3 kPa.

*Apparatus.* The apparatus is that used for distillation range (*2.2.11*) with the exception that the thermometer is inserted in the neck of the flask so that the lower end of the bulb is level with the lower end of the neck of the distillation flask and that the flask is placed on a plate of isolating material pierced by a hole 35 mm in diameter.

*Method.* Place in the flask (*A*) 20 mL of the liquid to be examined and a few pieces of porous material. Heat the flask so that boiling is rapidly achieved and record the temperature at which liquid runs from the side-arm into the condenser.

Correct the observed temperature for barometric pressure by means of the formula:

$$t_1 = t_2 + k(101.3 - b)$$

$t_1$ = the corrected temperature,

$t_2$ = the observed temperature at barometric pressure $b$,

$k$ = the correction factor as shown in Table 2.2.11.-1 under Distillation Range,

$b$ = the barometric pressure, in kilopascals, at the time of the determination.

**01/2008:20213**

## 2.2.13. DETERMINATION OF WATER BY DISTILLATION

The apparatus (see Figure 2.2.13.-1) consists of a glass flask (*A*) connected by a tube (*D*) to a cylindrical tube (*B*) fitted with a graduated receiving tube (*E*) and reflux condenser (*C*). The receiving tube (*E*) is graduated in 0.1 mL. The source of heat is preferably an electric heater with rheostat control or an oil bath. The upper portion of the flask and the connecting tube may be insulated.

*Method.* Clean the receiving tube and the condenser of the apparatus, thoroughly rinse with water, and dry.

Introduce 200 mL of *toluene R* and about 2 mL of *water R* into the dry flask. Distil for 2 h, then allow to cool for about 30 min and read the water volume to the nearest 0.05 mL. Place in the flask a quantity of the substance, weighed with an accuracy of 1 per cent, expected to give about 2 mL to 3 mL of water. If the substance has a pasty consistency, weigh it in a boat of metal foil. Add a few pieces of porous material and heat the flask gently for 15 min. When the toluene begins to boil, distil at the rate of about two drops per second until most of the water has distilled over, then increase the rate of distillation to about four drops per second. When the water has all distilled over, rinse the inside of the condenser tube with *toluene R*. Continue the distillation for 5 min, remove the heat, allow the receiving tube to cool to room temperature and dislodge any droplets of water which adhere to the walls of the receiving

tube. When the water and toluene have completely separated, read the volume of water and calculate the content present in the substance as millilitres per kilogram, using the formula:

$$\frac{1000(n_2 - n_1)}{m}$$

$m$ = the mass in grams of the substance to be examined,

$n_1$ = the number of millilitres of water obtained in the first distillation,

$n_2$ = the total number of millilitres of water obtained in the 2 distillations.

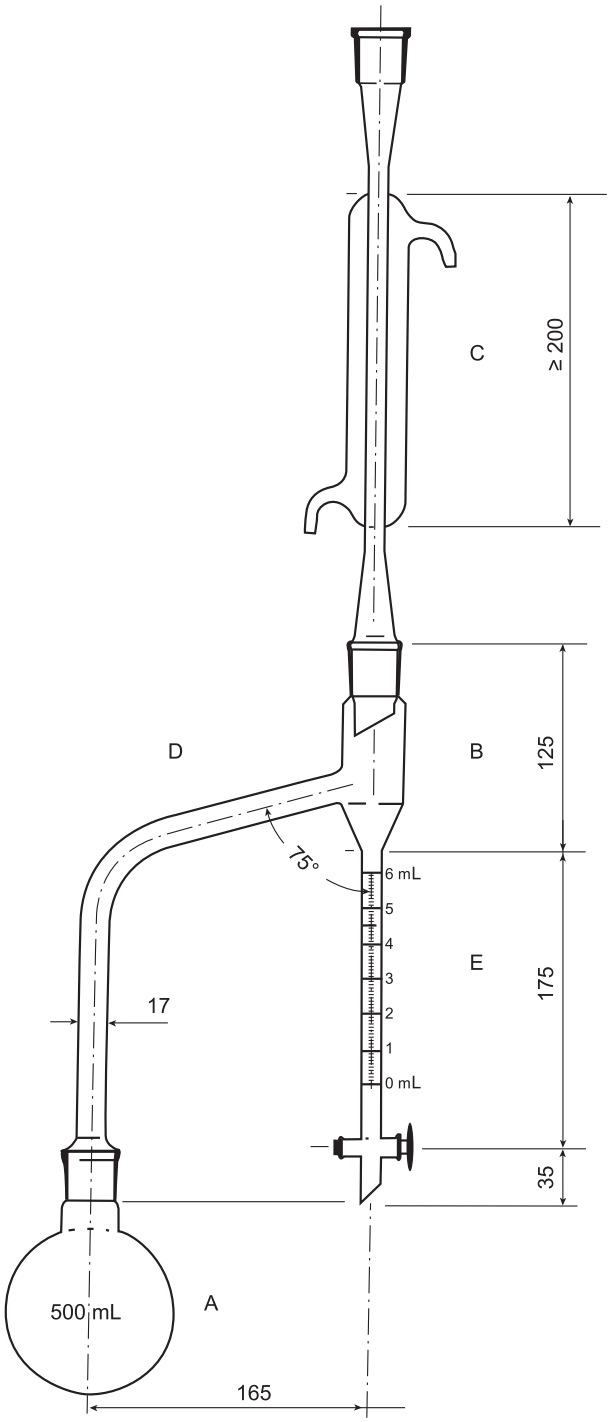

Figure 2.2.13.-1. – *Apparatus for the determination of water by distillation*

*Dimensions in millimetres*

**04/2017:20214**

# 2.2.14. MELTING POINT - CAPILLARY METHOD

The melting point determined by the capillary method is the temperature at which the last solid particle of a compact column of a substance in a tube passes into the liquid phase (i.e. clear point). The melting point determined by this method is specific to the methodology (e.g. heating rate) described in this chapter. Similarly, whenever the use of certified reference materials is required, their certified values refer to the described analytical procedure.

When prescribed in the monograph, the same apparatus and method are used for the determination of other factors, such as meniscus formation or melting range, that characterise the melting behaviour of a substance.

*Equipment.* The equipment consists of a metal heating block with 1 or more compartments for capillary tubes, or of a suitable glass vessel containing a liquid bath (e.g. water, liquid paraffin or silicone oil) and fitted with a suitable means of heating and stirring. The equipment is equipped with a temperature sensor or a suitable certified thermometer allowing readings at least to the nearest 0.1 °C.

Samples are introduced into the equipment in glass capillary tubes. The dimensions are chosen according to the manufacturer's requirements, typically with an external diameter of 1.3-1.5 mm and a wall thickness of 0.1-0.3 mm. In some equipment glass slides are used instead of capillary tubes.

The equipment is capable of heating samples at a rate of 1 °C/min or less. The accuracy of the equipment is at most ± 0.5 °C.

Detection can be performed either visually or instrumentally. In the case of instrumental detection, this is generally performed by image recording and subsequent analysis or by a photodetector that measures the transmitted or reflected light from the sample.

*Method.* The substance is previously treated as described in the monograph. Coarse crystals are to be avoided as they might lead to false results. If necessary, samples are crushed into a fine powder. Unless otherwise prescribed, dry the finely powdered substance *in vacuo* over *anhydrous silica gel R* for 24 h. Introduce a sufficient quantity into a capillary tube to give a compact column as described by the instrument manufacturer (e.g. 4-6 mm in height). Raise the temperature of the apparatus to about 5 °C below the presumed melting point. Allow the temperature to stabilise and then introduce the capillary tube into the instrument. Finally, adjust the rate of heating to about 1 °C/min unless otherwise prescribed.

In the case of instrumental detection, follow the instrument manufacturer's requirements for the determination of the melting point. For visual detection, record the temperature at which the last particle of the substance to be examined passes into the liquid phase.

Samples can be measured in parallel if the instrument allows multiple sample processing.

*System suitability.* Carry out a system suitability test before the measurements for example by choosing a suitable reference material with a melting point close to that expected for the substance to be examined.

*Qualification / Calibration of the equipment.* The qualification / calibration is carried out periodically according to the instrument manufacturer's requirements, using at least 2 certified reference materials. These are selected to cover the temperature range that is used on the equipment. Use capillary tubes with the same dimensions as those used for sample measurement.

Guidance on how to compare results obtained from certified reference materials with values from the certificates can be found on the European Reference Materials (ERM) website (Application note 1).

**01/2008:20215**

## 2.2.15. MELTING POINT - OPEN CAPILLARY METHOD

For certain substances, the following method is used to determine the melting point (also referred to as slip point and rising melting point when determined by this method).

Use glass capillary tubes open at both ends, about 80 mm long, having an external diameter of 1.4 mm to 1.5 mm and an internal diameter of 1.0 mm to 1.2 mm.

Introduce into each of 5 capillary tubes a sufficient amount of the substance, previously treated as described, to form in each tube a column about 10 mm high and allow the tubes to stand for the appropriate time and at the prescribed temperature.

Unless otherwise prescribed, substances with a waxy consistency are carefully and completely melted on a water-bath before introduction into the capillary tubes. Allow the tubes to stand at 2-8 °C for 2 h.

Attach one of the tubes to a thermometer graduated in 0.5 °C so that the substance is close to the bulb of the thermometer. Introduce the thermometer with the attached tube into a beaker so that the distance between the bottom of the beaker and the lower part of the bulb of the thermometer is 1 cm. Fill the beaker with water to a depth of 5 cm. Increase the temperature of the water gradually at a rate of 1 °C/min.

The temperature at which the substance begins to rise in the capillary tube is regarded as the melting point.

Repeat the operation with the other 4 capillary tubes and calculate the result as the mean of the 5 readings.

**07/2015:20216**

## 2.2.16. MELTING POINT - INSTANTANEOUS METHOD

The instantaneous melting point is calculated using the following expression:

$$\frac{t_1 + t_2}{2}$$

in which $t_1$ is the first temperature and $t_2$ the second temperature read under the conditions stated below.

*Apparatus.* The apparatus consists of a metal block resistant to the substance to be examined, of good heat-conducting capacity, such as brass, with a carefully polished plane upper surface. The block is uniformly heated throughout its mass by means of a micro-adjustable gas heater or an electric heating device with fine adjustment. The block has a cylindrical cavity, which is wide enough to accomodate a thermometer that is maintained in the same position during the calibration of the apparatus and the determination of the melting point of the substance to be examined. The cylindrical cavity is parallel to the upper polished surface of the block and about 3 mm from it. The apparatus is calibrated using appropriate substances of known melting point.

*Method.* Heat the block at a suitably rapid rate to a temperature about 10 °C below the presumed melting temperature, then adjust the heating rate to about 1 °C/min. At regular intervals drop a few particles of powdered and, where appropriate, dried substance, prepared as for the capillary tube method, onto the block in the vicinity of the thermometer bulb, cleaning the surface after each test. Record the temperature $t_1$ at which the substance melts instantaneously for the first time in contact with the metal. Stop the heating. During cooling drop a few particles of the substance at regular intervals on the block, cleaning the surface after each test. Record the temperature $t_2$ at which the substance ceases to melt instantaneously when it comes in contact with the metal.

*Calibration of the apparatus.* The apparatus may be calibrated using melting point reference substances such as those of the World Health Organization or other appropriate substances.

**01/2019:20217**

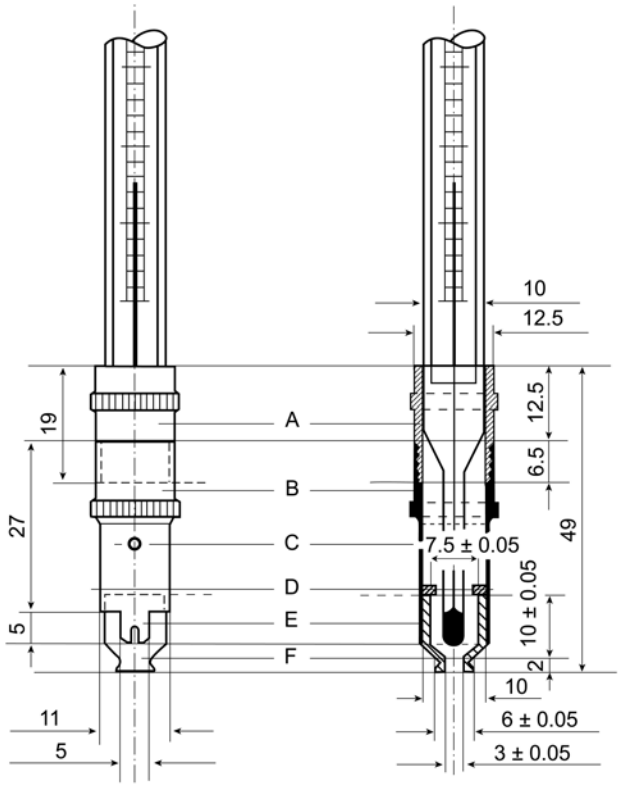
## 2.2.17. DROP POINT

The drop point is the temperature at which the first drop of the melting substance to be examined falls from a cup under defined conditions.

When a monograph does not specify the method to be used, apply method A. Any change from method A to method B is validated.

METHOD A

*Equipment.* The equipment (see Figure 2.2.17.-1) consists of 2 metal sheaths (*A* and *B*) screwed together. Sheath *A* is fixed to a thermometer. A metal cup is loosely fixed to the lower part of sheath *B* by means of 2 tightening bands. Fixed supports 2 mm long determine the exact position of the cup, and in addition are used to centre the thermometer. A hole pierced in the wall of sheath *B* is used to balance the pressure. The draining surface of the cup must be flat and the edges of the outflow orifice must be at right angles to it. The thermometer has the form and size shown in Figure 2.2.17.-1; it covers a range from 0 °C to 110 °C and on its scale a distance of 1 mm represents a difference of 1 °C. The thermometer bulb has a diameter of 3.5 ± 0.2 mm and a height of 6.0 ± 0.3 mm. The equipment is placed in the axis of a test-tube about 200 mm long and with an external diameter of about 40 mm. It is fixed to the test-tube by means of a laterally grooved stopper through which the thermometer passes. The opening of the cup is placed about 15 mm from the bottom of the test-tube. The whole device is immersed in a beaker with a capacity of about 1 L, filled with water. The bottom of the test-tube is placed about 25 mm from the bottom of the beaker. The water level reaches the upper part of sheath *A*. A stirrer is used to ensure that the temperature of the water remains uniform.



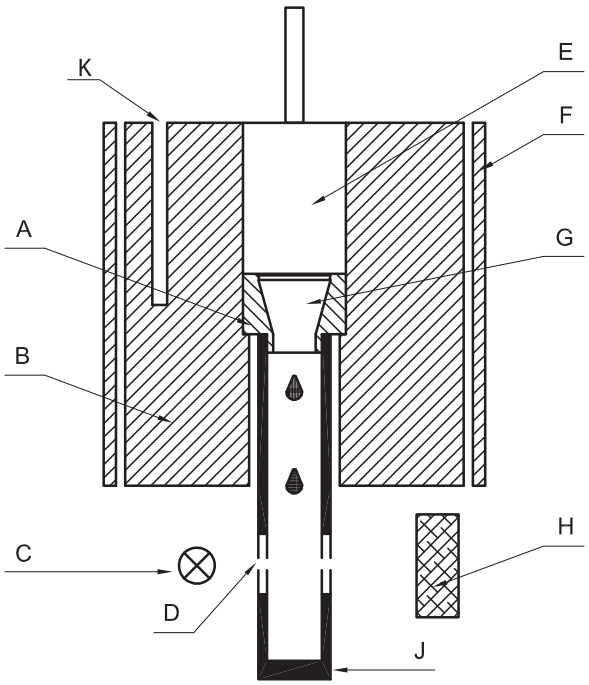
| | | |
|---|---|---|
| A. upper metal sheath | C. pressure-balancing hole | E. tightening bands |
| B. lower metal sheath | D. fixed supports | F. metal sample cup |

Figure 2.2.17.-1. – *Equipment for the determination of drop point (dimensions in millimetres)*

*Method*. Prepare the substance to be examined as described in the monograph. Fill the cup to the brim with the substance to be examined. Remove the excess substance at both ends of the cup with a spatula. When sheaths *A* and *B* have been assembled, press the cup into its housing in sheath *B* until it touches the supports. Remove with a spatula the substance pushed out by the thermometer. Place the equipment in the water-bath as described above. Heat the water-bath and, when the temperature is at about 10 °C below the presumed drop point, adjust the heating rate to about 1 °C/min. Note the temperature at the fall of the first drop. Carry out at least 3 determinations, each time with a fresh sample of the substance. The difference between the readings must not exceed 3 °C. The mean of 3 readings is the drop point of the substance.

## METHOD B - AUTOMATED METHOD

*Equipment*. The equipment (see Figure 2.2.17.-2) consists of a cartridge assembly comprising a cup holder into which the sample cup containing the sample is loosely fixed, and a collector sleeve with a horizontal light slit, which is fixed below the cup. This assembly is placed in a heating block. The block is a metal cylinder with a cylindrical hole along its vertical axis into which the cartridge assembly is placed. There is another, narrower cylindrical vertical hole in which a temperature sensor sits. This is positioned level with the sample cup. The heating block is surrounded by an electrical heating element. Below the heating block a lamp is mounted such that a beam of light shines through the light slit in the collector sleeve, and onto a photo-sensor mounted opposite. The heating element is capable of maintaining the heating block at a pre-defined temperature, and of heating at a slow and steady, pre-defined rate.



| | | | | |
|---|---|---|---|---|
| A. cup holder | C. light source | E. cartridge assembly | G. sample cup | J. collector sleeve |
| B. heating block | D. light slit | F. heating element | H. photo-sensor | K. temperature probe |

Figure 2.2.17.-2. – *Example of automated drop point equipment*

*Method*. Prepare the substance to be examined as described in the monograph, then proceed as follows or according to the manufacturer's instructions. Remove the excess substance at both ends of the cup with a spatula. Press the cup into the cup holder, and then press the collector sleeve onto the cup. Place the cartridge assembly in the heating block. Set the instrument to the initial isothermal conditions and the rate for subsequent heating as described in the monograph. Start the temperature programme. When the first drop of molten sample falls through the hole at the bottom of the sample cup, thus interrupting the light beam, a signal from the photo-sensor causes the temperature of the heating block to be recorded automatically.

*Calibration*. Use the equipment according to the manufacturer's instructions and carry out the prescribed calibrations and system performance tests at regular intervals, depending on the use of the equipment and the substances to be examined. Benzoic acid and benzophenone are usually used as certified reference materials. Other materials may be used provided they show no polymorphism. Proceed as follows or according to the manufacturer's instructions. Prepare 3 sample cups for each of 2 certified reference materials. Place the sample cups on a clean surface. Into each sample cup, introduce a small quantity of the sample and press it down with a rod (diameter about 4.5 mm). Check that the opening is completely blocked. Fill the sample cup about half full and compact the sample with a rod (diameter about 9 mm). Fill the sample cup and compact, adding more sample and compacting again if necessary, until the sample cup is completely packed.

Temperature programme for benzoic acid: start temperature = 118.0 °C; heating rate = 0.2 °C/min; end temperature = 126.0 °C. After inserting the cup at 118 °C, a waiting time of 30 s is set before heating starts.

Temperature programme for benzophenone: start temperature = 44.0 °C; heating rate = 0.2 °C/min; end temperature = 56.0 °C. After inserting the cup at 44 °C, a waiting time of 30 s is set before heating starts.

Check the 3 single results: the test is valid if the 3 results are within 0.3 °C of the mean value.

Calculate the corrected mean temperature ($T_2$) using the following expression:

$$T_1 - F$$

$T_1$ = mean drop point temperature of 3 samples, in °C;

$F$ = compensation for the difference in temperature between the sample and the point in the heating block where the temperature is measured; this will vary depending upon the design of the automatic drop point instrument and is provided by the manufacturer.

Taking into account the drop point of the certified reference material ($T_0$), the accuracy of the temperature scale is satisfactory if $|T_2 - T_0|$ is not greater than 0.3 °C.

**01/2008:20218**

## 2.2.18. FREEZING POINT

The freezing point is the maximum temperature occurring during the solidification of a supercooled liquid.

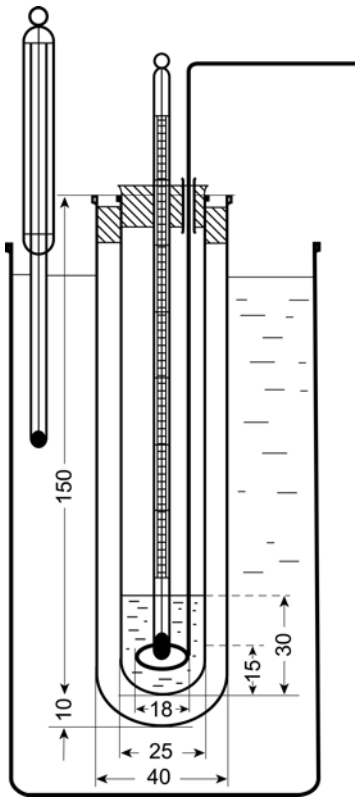


Figure 2.2.18.-1. – *Apparatus for the determination of freezing point*

*Dimensions in millimetres*

*Apparatus.* The apparatus (see Figure 2.2.18.-1) consists of a test-tube about 25 mm in diameter and 150 mm long placed inside a test-tube about 40 mm in diameter and 160 mm long. The inner tube is closed by a stopper which carries a thermometer about 175 mm long and graduated in 0.2 °C fixed so that the bulb is about 15 mm above the bottom of the tube. The stopper has a hole allowing the passage of the stem of a stirrer made from a glass rod or other suitable material formed at one end into a loop of about 18 mm overall diameter at right angles to the rod. The inner tube with its jacket is supported centrally in a 1 L beaker containing a suitable cooling liquid to within 20 mm of the top. A thermometer is supported in the cooling bath.

*Method.* Place in the inner tube sufficient quantity of the liquid or previously melted substance to be examined, to cover the thermometer bulb and determine the approximate freezing point by cooling rapidly. Place the inner tube in a bath about 5 °C above the approximate freezing point until all but the last traces of crystals are melted. Fill the beaker with water or a saturated solution of sodium chloride, at a temperature about 5 °C lower than the expected freezing point, insert the inner tube into the outer tube, ensuring that some seed crystals are present, and stir thoroughly until solidification takes place. Note the highest temperature observed during solidification.

**01/2016:20219**

## 2.2.19. AMPEROMETRIC TITRATION

In an amperometric titration, the end-point is determined by following the variation of the current measured between 2 electrodes (either one indicator electrode and one reference electrode or 2 indicator electrodes) immersed in the solution to be examined and maintained at a constant potential difference as a function of the quantity of titrant added.

The potential of the measuring electrode is sufficient to ensure a diffusion current for the electroactive substance.

*Apparatus.* The apparatus comprises an adjustable voltage source and a sensitive microammeter; the detection system generally consists of an indicator electrode (for example, a platinum electrode, a rotating-disc electrode or a carbon electrode) and a reference electrode (for example, a silver-silver chloride electrode).

A three-electrode apparatus is sometimes used, consisting of an indicator electrode, a reference electrode and a polarised auxiliary electrode.

*Method.* Set the potential of the indicator electrode as prescribed and plot a graph of the initial current and the values obtained during the titration as functions of the quantity of titrant added. Add the titrant in not fewer than 3 successive quantities equal to a total of about 80 per cent of the theoretical volume corresponding to the presumed equivalence point. The 3 values must fall on a straight line. Continue adding the titrant beyond the presumed equivalence point in not fewer than 3 successive quantities. The values obtained must fall on a straight line. The point of intersection of the 2 lines represents the end-point of the titration.

For amperometric titrations with 2 indicator electrodes, the whole titration curve is recorded and used to determine the end-point.

**01/2016:20220**

## 2.2.20. POTENTIOMETRIC TITRATION

In a potentiometric titration (volumetric titration with potentiometric end-point determination) the end-point is determined by recording the variation of the potential difference between 2 electrodes (either 1 indicator electrode and 1 reference electrode, or a combined electrode) immersed in the solution to be examined as a function of the volume of titrant added.

*Apparatus.* The apparatus used comprises a millivoltmeter. Commercial autotitrator instruments may be used and are operated in accordance with the manufacturer's instructions, using electrodes recommended for the type of titration described.

The indicator electrode to be used depends on the substance to be determined and may be a glass or metal electrode (e.g. platinum, gold or silver).

For acid-base titrations, a glass-silver-silver chloride electrode combination is generally used.

*Method.* Prepare the sample solution as described. Add the titrant in suitable aliquots paying particular attention to the rate of addition and the volume increments near the end-point. Continue the titration beyond this point to allow a clear detection of the end-point.

The end-point of the titration is reached when the maximum change in potential occurs in a plot of potential versus volume of titrant, and is expressed as the corresponding volume of titrant. Recording the first or second derivative curve can facilitate the determination of the end-point. In potentiometric titrations of weak acids or bases using non-aqueous solvents, if necessary, either carry out a blank determination or pre-neutralise the solvent mixture. Where it is impracticable to use potentiometric detection for this purpose, the solvent mixture can be pre-neutralised by titration using a suitable indicator. Some examples are given below:

| Titrant | Indicator |
|---|---|
| Perchloric acid | *Crystal violet solution R* |
| Tetrabutylammonium hydroxide | 3 g/L solution of *thymol blue R* in *methanol R* |
| Ethanolic sodium hydroxide | *Thymolphthalein solution R* |

**01/2008:20221**

## 2.2.21. FLUORIMETRY

Fluorimetry is a procedure which uses the measurement of the intensity of the fluorescent light emitted by the substance to be examined in relation to that emitted by a given standard.

*Method.* Dissolve the substance to be examined in the solvent or mixture of solvents prescribed in the monograph, transfer the solution to the cell or the tube of the fluorimeter and illuminate it with an excitant light beam of the wavelength prescribed in the monograph and as near as possible monochromatic.

Measure the intensity of the emitted light at an angle of 90° to the excitant beam, after passing it through a filter which transmits predominantly light of the wavelength of the fluorescence. Other types of apparatus may be used provided that the results obtained are identical.

For quantitative determinations, first introduce into the apparatus the solvent or mixture of solvents used to dissolve the substance to be examined and set the instrument to zero. Introduce the standard solution and adjust the sensitivity of the instrument so that the reading is greater than 50. If the second adjustment is made by altering the width of the slits, a new zero setting must be made and the intensity of the standard must be measured again. Finally introduce the solution of unknown concentration and read the result on the instrument. Calculate the concentration $c_x$ of the substance in the solution to be examined, using the formula:

$$c_x = \frac{I_x c_s}{I_s}$$

$c_x$ = concentration of the solution to be examined,

$c_s$ = concentration of the standard solution,

$I_x$ = intensity of the light emitted by the solution to be examined,

$I_s$ = intensity of the light emitted by the standard solution.

If the intensity of the fluorescence is not strictly proportional to the concentration, the measurement may be effected using a calibration curve.

In some cases, measurement can be made with reference to a fixed standard (for example a fluorescent glass or a solution of another fluorescent substance). In such cases, the concentration of the substance to be examined must be determined using a previously drawn calibration curve under the same conditions.

**01/2008:20222**

## 2.2.22. ATOMIC EMISSION SPECTROMETRY

GENERAL PRINCIPLE

Atomic emission is a process that occurs when electromagnetic radiation is emitted by excited atoms or ions. In atomic emission spectrometry the sample is subjected to temperatures high enough to cause not only dissociation into atoms, but also to cause significant amounts of collisional excitation and ionisation of the sample atoms to take place. Once the atoms and ions are in the excited states, they can decay to lower states through thermal or radiative (emission) energy transitions and electromagnetic radiation is emitted. An emission spectrum of an element contains several more lines than the corresponding absorption spectrum.

Atomic emission spectrometry is a technique for determining the concentration of an element in a sample by measuring the intensity of one of the emission lines of the atomic vapour of the element generated from the sample. The determination is carried out at the wavelength corresponding to this emission line.

In this chapter only atomisation in flame is dealt with. The method of inductively coupled plasma-atomic emission spectrometry (ICP-AES) is described in a different general chapter.

APPARATUS

This consists essentially of:

- a sample introduction and nebulisation system;
- a flame to generate the atoms to be determined;
- a monochromator;
- a detector;
- a data-acquisition unit.

Oxygen, air and a combustible gas such as hydrogen, acetylene, propane or butane may be used in flames. The atomisation source is critical, since it must provide sufficient energy to excite and atomise the atoms. The atomic spectra emitted from flames have the advantage of being simpler than those emitted from other sources, the main limitation being that the flames are not powerful enough to cause emission for many elements allowing their determination. Acidified water is the solvent of choice for preparing test and reference solutions, although organic solvents may also be used if precautions are taken to ensure that the solvent does not interfere with the stability of the flame.

INTERFERENCES

Spectral interference is reduced or eliminated by choosing an appropriate emission line for measurement or by adjusting the slit for spectral band-width. Physical interference is corrected by diluting the sample solution, by matching the matrix or by using the method of standard additions. Chemical interference is reduced by using chemical modifiers or ionisation buffers.

MEMORY EFFECT

The memory effect caused by deposit of analyte in the apparatus may be limited by thoroughly rinsing between runs, diluting the solutions to be measured if possible and thus reducing their salt content, and by aspirating the solutions through as swiftly as possible.

METHOD

Use of plastic labware is recommended wherever possible.

Operate an atomic emission spectrometer in accordance with the manufacturer's instructions at the prescribed wavelength. Optimise the experimental conditions (flame temperature, burner adjustment, use of an ionic buffer, concentration of solutions) for the specific element to be analysed and in respect of the sample matrix. Introduce a blank solution into the atomic generator and adjust the instrument reading to zero or to its blank value. Introduce the most concentrated reference solution and adjust the sensitivity to obtain a suitable reading.

It is preferable to use concentrations which fall within the linear part of the calibration curve. If this is not possible, the calibration plots may also be curved and are then to be applied with appropriate calibration software.

Determinations are made by comparison with reference solutions with known concentrations of the element to be determined either by the method of direct calibration (Method I) or the method of standard additions (Method II).

*METHOD I - DIRECT CALIBRATION*

For routine measurements 3 reference solutions of the element to be determined and a blank are prepared and examined.

Prepare the solution of the substance to be examined (test solution) as prescribed in the monograph. Prepare not fewer than 3 reference solutions of the element to be determined, the concentrations of which span the expected value in the test solution. For assay purposes, optimal calibration levels are between 0.7 and 1.3 times the expected content of the element to be determined or the limit prescribed in the monograph. For purity determination, calibration levels are between the limit of detection and 1.2 times the limit specified for the element to be determined. Any reagents used in the preparation of the test solution are added to the reference solutions and to the blank solution at the same concentration.

Introduce each of the solutions into the instrument using the same number of replicates for each solution, to obtain a steady reading.

**Calculation**. Prepare a calibration curve from the mean of the readings obtained with the reference solutions by plotting the means as a function of concentration. Determine the concentration of the element in the test solution from the curve obtained.

*METHOD II - STANDARD ADDITIONS*

Add to at least 3 similar volumetric flasks equal volumes of the solution of the substance to be examined (test solution) prepared as prescribed. Add to all but 1 of the flasks progressively larger volumes of a reference solution containing a known concentration of the element to be determined to produce a series of solutions containing steadily increasing concentrations of that element known to give responses in the linear part of the curve, if at all possible. Dilute the contents of each flask to volume with solvent.

Introduce each of the solutions into the instrument using the same number of replicates for each solution, to obtain a steady reading.

**Calculation**. Calculate the linear equation of the graph using a least-squares fit, and derive from it the concentration of the element to be determined in the test solution.

VALIDATION OF THE METHOD

Satisfactory performance of methods prescribed in monographs is verified at suitable time intervals.

*LINEARITY*

Prepare and analyse not fewer than 4 reference solutions over the calibration range and a blank solution. Perform not fewer than 5 replicates.

The calibration curve is calculated by least-square regression from all measured data. The regression curve, the means, the measured data and the confidence interval of the calibration curve are plotted. The operating method is valid when:

- the correlation coefficient is at least 0.99,
- the residuals of each calibration level are randomly distributed around the calibration curve.

Calculate the mean and relative standard deviation for the lowest and highest calibration level.

When the ratio of the estimated standard deviation of the lowest and the highest calibration level is less than 0.5 or greater than 2.0, a more precise estimation of the calibration curve may be obtained using weighted linear regression. Both linear and quadratic weighting functions are applied to the data to find the most appropriate weighting function to be employed. If the means compared to the calibration curve show a deviation from linearity, two-dimensional linear regression is used.

*ACCURACY*

Verify the accuracy preferably by using a certified reference material (CRM). Where this is not possible, perform a test for recovery.

**Recovery**. For assay determinations a recovery of 90 per cent to 110 per cent is to be obtained. For other determinations, for example for trace element determination, the test is not valid if recovery is outside of the range 80 per cent to 120 per cent at the theoretical value. Recovery may be determined on a suitable reference solution (matrix solution) which is spiked with a known quantity of analyte (middle concentration of the calibration range).

*REPEATABILITY*

The repeatability is not greater than 3 per cent for an assay and not greater than 5 per cent for an impurity test.

*LIMIT OF QUANTIFICATION*

Verify that the limit of quantification (for example, determined using the 10 σ approach) is below the value to be measured.

# 2.2.23. ATOMIC ABSORPTION SPECTROMETRY

GENERAL PRINCIPLE

Atomic absorption is a process that occurs when a ground state-atom absorbs electromagnetic radiation of a specific wavelength and is elevated to an excited state. The atoms in the ground state absorb energy at their resonant frequency and the electromagnetic radiation is attenuated due to resonance absorption. The energy absorption is virtually a direct function of the number of atoms present.

This chapter provides general information and defines the procedures used in element determinations by atomic absorption spectrometry, either atomisation by flame, by electrothermal vaporisation in a graphite furnace, by hydride generation or by cold vapour technique for mercury.

Atomic absorption spectrometry is a technique for determining the concentration of an element in a sample by measuring the absorption of electromagnetic radiation by the atomic vapour of the element generated from the sample. The determination is carried out at the wavelength of one of the absorption (resonance) lines of the element concerned. The amount of radiation absorbed is, according to the Lambert-Beer law, proportional to the element concentration.

## APPARATUS

This consists essentially of:

- a source of radiation;
- a sample introduction device;
- a sample atomiser;
- a monochromator or polychromator;
- a detector;
- a data-acquisition unit.

The apparatus is usually equipped with a background correction system. Hollow-cathode lamps and electrodeless discharge lamps (EDL) are used as radiation source. The emission of such lamps consists of a spectrum showing very narrow lines with half-width of about 0.002 nm of the element being determined.

There are 3 types of sample atomisers:

- Flame technique

  A flame atomiser is composed of a nebulisation system with a pneumatic aerosol production accessory, a gas-flow regulation and a burner. Fuel-oxidant mixtures are commonly used to produce a range of temperatures from about 2000 K to 3000 K. Fuel gases include propane, hydrogen and acetylene; air and nitrous oxide are used as oxidants. The configuration of the burner is adapted to the gases used and the gas flow is adjustable. Samples are nebulised, acidified water being the solvent of choice for preparing test and reference solutions. Organic solvents may also be used if precautions are taken to ensure that the solvent does not interfere with the stability of the flame.

- Electrothermal atomisation technique

  An electrothermal atomiser is generally composed of a graphite tube furnace and an electric power source. Electrothermal atomisation in a graphite tube furnace atomises the entire sample and retains the atomic vapour in the light path for an extended period. This improves the detection limit. Samples, liquid as well as solid, are introduced directly into the graphite tube furnace, which is heated in a programmed series of steps to dry the sample and remove major matrix components by pyrolysis and to then atomise all of the analyte. The furnace is cleaned using a final temperature higher than the atomisation temperature. The flow of an inert gas during the pyrolysis step in the graphite tube furnace allows a better performance of the subsequent atomisation process.

- Cold vapour and hydride technique

  The atomic vapour may also be generated outside the spectrometer. This is notably the case for the cold-vapour method for mercury or for certain hydride-forming elements such as arsenic, antimony, bismuth, selenium and tin. For mercury, atoms are generated by chemical reduction with stannous chloride or sodium borohydride and the atomic vapour is swept by a stream of an inert gas into a cold quartz cell mounted in the optical path of the instrument. Hydrides thus generated are swept by an inert gas into a heated cell in which they are dissociated into atoms.

## INTERFERENCES

Chemical, physical, ionisation and spectral interferences are encountered in atomic absorption measurements. Chemical interference is compensated by addition of matrix modifiers, of releasing agents or by using high temperature produced by a nitrous oxide-acetylene flame; the use of specific ionisation buffers (for example, lanthanum and caesium) compensates for ionisation interference; by dilution of the sample, through the method of standard additions or by matrix matching, physical interference due to high salt content or viscosity is eliminated. Spectral interference results from the overlapping of resonance lines and can be avoided by using a different resonance line. The use of Zeeman background correction also compensates for spectral interference and interferences from molecular absorption, especially when using the electrothermal atomisation technique. The use of multi-element hollow-cathode lamps may also cause spectral interference. Specific or non-specific absorption is measured in a spectral range defined by the band-width selected by the monochromator (0.2-2 nm).

## BACKGROUND CORRECTION

Scatter and background in the flame or the electrothermal atomisation technique increase the measured absorbance values. Background absorption covers a large range of wavelengths, whereas atomic absorption takes place in a very narrow wavelength range of about 0.005-0.02 nm. Background absorption can in principle be corrected by using a blank solution of exactly the same composition as the sample, but without the specific element to be determined, although this method is frequently impracticable. With the electrothermal atomisation technique the pyrolysis temperature is to be optimised to eliminate the matrix decomposition products causing background absorption. Background correction can also be made by using 2 different light sources, the hollow-cathode lamp that measures the total absorption (element + background) and a deuterium lamp with a continuum emission from which the background absorption is measured. Background is corrected by subtracting the deuterium lamp signal from the hollow-cathode lamp signal. This method is limited in the spectral range on account of the spectra emitted by a deuterium lamp from 190-400 nm. Background can also be measured by taking readings at a non-absorbing line near the resonance line and then subtracting the results from the measurement at the resonance line. Another method for the correction of background absorption is the Zeeman effect (based on the Zeeman splitting of the absorption line in a magnetic field). This is particularly useful when the background absorption shows fine structure. It permits an efficient background correction in the range of 185-900 nm.

## CHOICE OF THE OPERATING CONDITIONS

After selecting the suitable wavelength and slit width for the specific element, the need for the following has to be ascertained:

- correction for non-specific background absorption,
- chemical modifiers or ionisation buffers to be added to the sample as well as to blank and reference solutions,
- dilution of the sample to minimise, for example, physical interferences,
- details of the temperature programme, preheating, drying, pyrolysis, atomisation, post-atomisation with ramp and hold times,
- inert gas flow,
- matrix modifiers for electrothermal atomisation (furnace),
- chemical reducing reagents for measurements of mercury or other hydride-forming elements along with cold vapour cell or heating cell temperature,
- specification of furnace design (tank, L'vov platform, etc).

## METHOD

Use of plastic labware is recommended wherever possible. The preparation of the sample may require a dissolution, a digestion (mostly microwave-assisted), an ignition step or a combination thereof in order to clear up the sample matrix

and/or to remove carbon-containing material. If operating in an open system, the ignition temperature should not exceed 600 °C, due to the volatility of some metals, unless otherwise stated in the monograph.

Operate an atomic absorption spectrometer in accordance with the manufacturer's instructions at the prescribed wavelength. Introduce a blank solution into the atomic generator and adjust the instrument reading so that it indicates maximum transmission. The blank value may be determined by using solvent to zero the apparatus. Introduce the most concentrated reference solution and adjust the sensitivity to obtain a maximum absorbance reading. Rinse in order to avoid contamination and memory effects. After completing the analysis, rinse with *water R* or acidified water.

If a solid sampling technique is applied, full details of the procedure are provided in the monograph.

Ensure that the concentrations to be determined fall preferably within the linear part of the calibration curve. If this is not possible, the calibration plots may also be curved and are then to be applied with appropriate calibration software.

Determinations are made by comparison with reference solutions with known concentrations of the element to be determined either by the method of direct calibration (Method I) or the method of standard additions (Method II).

*METHOD I - DIRECT CALIBRATION*

For routine measurements 3 reference solutions and a blank solution are prepared and examined.

Prepare the solution of the substance to be examined (test solution) as prescribed in the monograph. Prepare not fewer than 3 reference solutions of the element to be determined, the concentrations of which span the expected value in the test solution. For assay purposes, optimal calibration levels are between 0.7 and 1.3 times the expected content of the element to be determined or the limit prescribed in the monograph. For purity determination, calibration levels are the limit of detection and 1.2 times the limit specified for the element to be determined. Any reagents used in the preparation of the test solution are added to the reference and blank solutions at the same concentration.

Introduce each of the solutions into the instrument using the same number of replicates for each of the solutions to obtain a steady reading.

**Calculation**. Prepare a calibration curve from the mean of the readings obtained with the reference solutions by plotting the means as a function of concentration. Determine the concentration of the element in the test solution from the curve obtained.

*METHOD II - STANDARD ADDITIONS*

Add to at least 3 similar volumetric flasks equal volumes of the solution of the substance to be examined (test solution) prepared as prescribed. Add to all but 1 of the flasks progressively larger volumes of a reference solution containing a known concentration of the element to be determined to produce a series of solutions containing steadily increasing concentrations of that element known to give responses in the linear part of the curve, if possible. Dilute the contents of each flask to volume with solvent.

Introduce each of the solutions into the instrument, using the same number of replicates for each of the solutions, to obtain a steady reading.

**Calculation**. Calculate the linear equation of the graph using a least-squares fit and derive from it the concentration of the element to be determined in the test solution.

VALIDATION OF THE METHOD

Satisfactory performance of methods prescribed in monographs is verified at suitable time intervals.

*LINEARITY*

Prepare and analyse not fewer than 4 reference solutions over the calibration range and a blank solution. Perform not fewer than 5 replicates.

The calibration curve is calculated by least-square regression from all measured data. The regression curve, the means, the measured data and the confidence interval of the calibration curve are plotted. The operating method is valid when:

- the correlation coefficient is at least 0.99,
- the residuals of each calibration level are randomly distributed around the calibration curve.

Calculate the mean and relative standard deviation for the lowest and highest calibration level.

When the ratio of the estimated standard deviation of the lowest and the highest calibration level is less than 0.5 or greater than 2.0, a more precise estimation of the calibration curve may be obtained using weighted linear regression. Both linear and quadratic weighting functions are applied to the data to find the most appropriate weighting function to be employed. If the means compared to the calibration curve show a deviation from linearity, two-dimensional linear regression is used.

*ACCURACY*

Verify the accuracy preferably by using a certified reference material (CRM). Where this is not possible, perform a test for recovery.

**Recovery**. For assay determinations a recovery of 90 per cent to 110 per cent is to be obtained. For other determinations, for example, for trace element determination the test is not valid if recovery is outside of the range 80 per cent to 120 per cent at the theoretical value. Recovery may be determined on a suitable reference solution (matrix solution) which is spiked with a known quantity of analyte (middle concentration of the calibration range).

*REPEATABILITY*

The repeatability is not greater than 3 per cent for an assay and not greater than 5 per cent for an impurity test.

*LIMIT OF QUANTIFICATION*

Verify that the limit of quantification (for example, determined using the 10 σ approach) is below the value to be measured.

## 2.2.24. ABSORPTION SPECTROPHOTOMETRY, INFRARED

PRINCIPLE

Infrared absorption spectrophotometry (also known as infrared (IR) spectroscopy) is based on the interaction of infrared radiation with matter, which affects the vibrational energy of molecules and induces intermolecular and intramolecular vibrations at specific frequencies. This results in an infrared absorption spectrum with characteristic bands that correspond to the functional groups of the molecule.

The infrared wavelength region can be further divided into 3 subregions, namely near-infrared, mid-infrared and far-infrared. These subregions have wavelength ranges that are generally accepted by convention to be 0.8-2.5 µm, 2.5-25 µm and 25-1000 µm respectively. However, in IR spectroscopy, wavenumber is more commonly used than wavelength, and can be calculated using the following equation:

$$\tilde{\nu} = \frac{1}{\lambda} \cdot 10^4$$

where $\tilde{\nu}$ is the wavenumber in reciprocal centimetres ($cm^{-1}$) and λ is the wavelength in micrometres. Thus 12 500-4000 $cm^{-1}$ is near-infrared, 4000-400 $cm^{-1}$ is mid-infrared and 400-10 $cm^{-1}$ is far-infrared.

This chapter concerns only spectroscopy in the mid-infrared region, i.e. 4000-400 $cm^{-1}$ (2.5-25 µm), which hereafter is referred to as infrared for simplicity. This region is where the fundamental molecular vibrations of functional groups appear in the spectrum as absorption bands. The region below 1500 $cm^{-1}$ is known as the 'fingerprint region', a very complex and informative part of the spectrum which characterises the molecule being investigated.

The mid-infrared region is flanked by the near-infrared region, where overtones and combinations of fundamental vibrations, mainly C-H, N-H and O-H functional groups, are detected (*2.2.40*) and the far-infrared region, where absorption bands associated with crystal lattice modes, hydrogen bonds, angle deformation vibrations of heavy atoms and molecular rotations are observed.

## APPLICATIONS

As the absorption bands in IR spectra are characteristic of the constituent functional groups of a compound, IR spectroscopy is widely used to identify substances and provide information on their structure. It can also be used for quantitative applications, which requires establishing a mathematical relationship between the intensity of the radiation absorbed by the sample and the concentration of the investigated component in the sample.

IR spectroscopy is widely used in the pharmaceutical field for chemical and physical analysis in the laboratory, and has a wide variety of applications during the manufacturing process as outlined below. IR spectroscopy thereby enables the application of Process Analytical Technology (PAT) as part of an advanced control strategy.

*Chemical analysis*:

- identification of active substances, excipients, dosage forms, manufacturing intermediates, chemicals and packaging materials;
- quality assessment of active substances, excipients, dosage forms, manufacturing intermediates and packaging materials, including batch-to-batch spectral comparison and supplier change assessment;
- quantification of active substances in a sample matrix, determination of water and solvent content;
- quantification of impurities, e.g. in gases, inorganic materials;
- reaction monitoring, e.g. chemical synthesis.

*Physical analysis*:

- determination of solid-state properties such as polymorphism.

## LIMITATIONS

Notable limitations to the use of IR spectroscopy include the following:

- it may be necessary to use additional techniques to unambiguously identify a substance;
- pure enantiomers of a substance cannot be discriminated;
- it may not be a suitable method for trace analysis;
- sample preparation conditions (e.g. pressure, solvent) may change the crystalline form of a substance that exhibits polymorphism;
- for heterogeneous samples, the limited sampling volume may be problematic.

## MEASUREMENT MODES

IR measurements are based on passing radiation through or into a sample and measuring the attenuation of the emerging beam at various wavelengths. This corresponds to 2 main measurement modes, i.e. transmission and attenuated total reflection (ATR). However, other modes also exist for specific applications (e.g. diffuse and specular reflection).

*TRANSMISSION MODE*

This mode is based on determination of the transmittance (*T*), namely the ability of the sample to transmit IR radiation at a given wavelength (wavenumber). It is defined by the following ratio:

$$T = \frac{I}{I_0}$$

$I_0$ = intensity of incident radiation;
$I$ = intensity of transmitted radiation.

The resulting spectrum is presented in terms of transmittance (*T*) on the y-axis versus wavelength or wavenumber on the x-axis. It can also be presented in terms of absorbance (*A*) on the y-axis, which is related to transmittance (*T*) by the following equation:

$$A = \log_{10}\left(\frac{1}{T}\right) = \log_{10}\left(\frac{I_0}{I}\right) = a \cdot b \cdot c$$

$a$ = molar absorption coefficient of the sample, in square centimetres per mole ($cm^2 \cdot mol^{-1}$);
$b$ = sample thickness, in centimetres;
$c$ = sample concentration, in moles per cubic centimetre ($mol \cdot cm^{-3}$).

*ATTENUATED TOTAL REFLECTION MODE*

ATR mode is based on the phenomenon of total internal reflection. The sample, with a refractive index $n_2$, is brought into close contact with a crystal (diamond, germanium, zinc selenide or any other suitable material), having a refractive index $n_1$ which is greater than $n_2$. A beam of IR light is then passed through the crystal. When the angle α between the incident beam and the sample-crystal interface exceeds a critical value $\alpha_c$, theoretically all of the radiation is reflected (total internal reflection). However, an evanescent wave is produced which slightly penetrates the sample and part of the energy is absorbed. The total reflection is attenuated, which makes it possible to generate an absorption spectrum. In practice, multiple internal reflections are often used to amplify the absorption intensity, although some accessories allow absorption measurements with a single reflection.
The penetration depth $d_p$ is usually of the order of a few micrometres and is given for a wavelength λ by the following equation:

$$d_p = \frac{\lambda / n_1}{2\pi\sqrt{sin^2\,\alpha - (n_2 / n_1)^2}}$$

where $d_p$ is the penetration depth, λ is the wavelength, α is the angle of incidence and $n_1$, $n_2$ are the refractive indices of the reflection element and the sample, respectively.

Due to the relationship between these parameters, the absorption intensity in ATR is greater at higher wavelengths (i.e. smaller wavenumbers) and slight band shifts occur compared to the corresponding transmission spectrum. It is therefore not advisable to compare ATR spectra with transmission spectra when identifying compounds.

## EQUIPMENT

The most commonly used IR spectrometers are Fourier-transform (FT-IR) spectrometers which typically consist of:

- a suitable polychromatic light source, e.g. a conducting ceramic rod;
- an interferometer;
- a sample presentation accessory, e.g. a sample holder;
- a detector;

– appropriate software for controlling the spectrometer, and for spectral evaluation and data processing.

Other spectrometers based on alternative principles may also be used if the requirements described under Control of equipment performance are fulfilled.

IR spectrometers can also be used in association with a microscope for the study of a small part of the sample or for chemical imaging.

IR spectroscopy can be coupled to other analytical techniques such as thermal analysis or chromatography.

## CONTROL OF EQUIPMENT PERFORMANCE

Accuracy of wavenumber scale and spectral resolution are critical parameters and must be verified. The tests described below can be used for the control of instrument performance and for qualification. They can also be used as system suitability tests.

These parameters are checked using suitable reference materials which are selected and presented depending on the measurement mode (e.g. transmission or ATR).

For quantitative analysis, appropriate assessment criteria for the control of absorption intensity must also be defined.

*WAVENUMBER SCALE*

The wavenumber scale is typically verified using a polystyrene film that exhibits IR absorption bands at the wavenumbers shown in Table 2.2.24.-1.

Table 2.2.24.-.1 - *Band positions and associated acceptable tolerances of the polystyrene film used to verify wavenumber accuracy*

| Band position ($cm^{-1}$) | | Tolerance ($cm^{-1}$) |
|---|---|---|
| **Transmission** | **ATR** | |
| 906.6 | 906.1 | ± 1.0 |
| 1028.3 | 1027.7 | ± 1.0 |
| 1601.2 | 1601.0 | ± 1.0 |
| 3060.0 | 3059.7 | ± 1.0 |

For measurement modes other than transmission or ATR, reference materials must be defined by the user.

*SPECTRAL RESOLUTION*

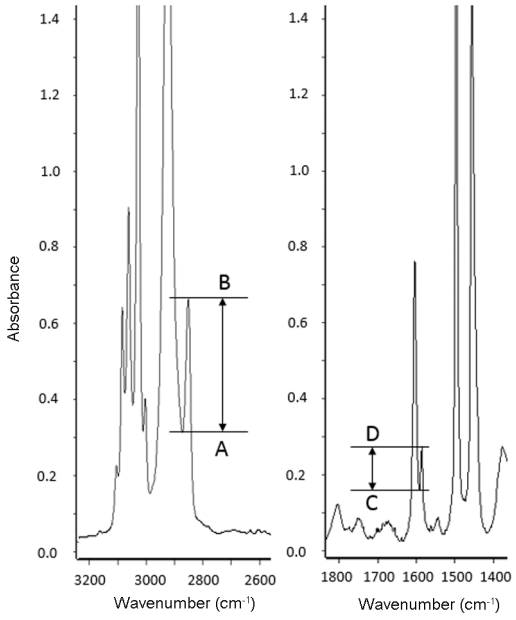

Figure 2.2.24.-1. – *Typical IR absorbance spectrum of polystyrene used to verify spectral resolution*

**Spectra recorded in transmission mode**. The spectral resolution is typically verified using a polystyrene film approximately 35 µm thick.

*Acceptance criteria (see Figure 2.2.24.-1)*: the difference between the absorbance values at the absorption minimum at 2870 $cm^{-1}$ (*A*) and the absorption maximum at 2849.5 $cm^{-1}$ (*B*) is greater than 0.33; the difference between the absorbance values at the absorption minimum at 1589 $cm^{-1}$ (*C*) and the absorption maximum at 1583 $cm^{-1}$ (*D*) is greater than 0.08.

**Spectra recorded in ATR mode**. Appropriate assessment criteria for the control of spectral resolution according to the specifications of each instrument need to be defined.

For measurement modes other than transmission or ATR, reference materials have to be defined by the user.

## PROCEDURE

*SAMPLE PREPARATION AND PRESENTATION*

Sample preparation and presentation vary according to the physical state of the sample and the measurement mode. Transmission mode is applied to transparent samples, such as neat liquids, solutions, gases or suitably prepared mulls and alkali halide discs. For liquids and gases, cells with fixed or variable pathlength and IR transparent windows can be used. For alkali-halide disks, specific sample holders are used. Reflection mode, e.g. ATR, is appropriate for the measurement of a wide range of samples in the solid and liquid state.

Some preparation modes (e.g. for discs and mulls in transmission mode or for solids in ATR mode) involve grinding and/or the application of pressure, which may induce unexpected crystal modifications.

**Transmission mode**

Prepare the substance by one of the following methods depending on the sample state (solid, liquid or gas). If sample bands in a spectrum have a minimum transmission lower than 5 per cent, this spectrum is not used for further data analysis.

*Liquids*. Examine liquids either in the form of a film between 2 plates transparent to infrared radiation or in a cell of suitable pathlength with windows that are transparent to infrared radiation.

*Liquids or solids in solution*. Prepare a solution of the substance to be examined in a suitable solvent. Choose a concentration and a pathlength that give a satisfactory spectrum. Generally, good results are obtained with concentrations of 10-100 g/L for a pathlength of 0.5-0.1 mm. The absorption due to the solvent is usually compensated by successively recording the spectra of the solvent and the sample solution and subtracting the solvent absorption bands from the spectrum of the sample solution.

*Solids dispersed in a solid (disc)*. Grind the substance to be examined taking into consideration any possible changes (e.g. crystalline form) and mix with a suitable amount of finely powdered and dried *potassium bromide R* or *potassium chloride R*, unless otherwise specified. A mixture of a few milligrams (e.g. 1-2 mg) of the substance to be examined in a few hundred milligrams (e.g. 300-400 mg) of halide is normally sufficient to give a disc of 10-15 mm diameter and a spectrum of suitable intensity. If the substance is a hydrochloride salt, it is recommended to use *potassium chloride R*. Carefully grind the mixture, spread it uniformly in a suitable die and apply a suitable pressure. A compacting force of about 800 MPa is generally sufficient to prepare a disc. For substances that are unstable under normal atmospheric conditions or are hygroscopic, the disc may be pressed under vacuum. Several factors may cause the formation of faulty discs, such as insufficient or excessive grinding, humidity or impurities in the dispersion medium. For example, any water in either the sample or the potassium bromide will cause clouding of the disc and produce a low transmission spectrum. A disc is rejected if visual examination shows a lack of uniform transparency or when, in the absence of a specific

absorption band, the transmittance is less than 60 per cent or the absorbance is more than 0.22 at about 2000 $cm^{-1}$ (5 µm) and without compensation, unless otherwise prescribed.

*Solids dispersed in a liquid (mull).* Triturate a small quantity of the substance to be examined with the minimum quantity of *liquid paraffin R* or other suitable liquid. A mixture of a few milligrams (e.g. 5-10 mg) of the substance to be examined in 1 drop of *liquid paraffin R* is generally sufficient to make an adequate mull. Compress the mull between 2 plates transparent to infrared radiation. A mull is rejected if a visual examination shows lack of uniform transparency or where the spectrum shows features such as:

- low transmission at 4000 $cm^{-1}$;
- a strongly sloping baseline between 4000 and about 2500 $cm^{-1}$;
- a ratio of relative intensities of some absorption bands that is less than expected.

*Molten solids.* If prescribed in the monograph, make a film of a molten mass and fix it on a suitable mount.

*Evaporated solution.* If prescribed in the monograph, dissolve the substance to be examined in a suitable solvent. Prepare a film by evaporating the solvent on a suitable carrier and fix it on a suitable mount.

*Gases.* Use a suitable cell transparent to infrared radiation. Evacuate the air from the cell and fill to the desired pressure through a stopcock or needle valve using a suitable gas transfer line between the cell and the container of the gas to be examined. If necessary, adjust the pressure in the cell to atmospheric pressure using a gas transparent to infrared radiation (e.g. *nitrogen R* or *argon R*), or purge with carbon dioxide-free air. An appropriate measurement protocol must be followed to compensate for water, carbon dioxide or other atmospheric gases.

**ATR mode**

ATR is suitable for liquid and solid samples, and requires no preparation apart from simple treatments such as the grinding of large crystals and coarse material. Proceed as follows depending on the sample state (liquid or solid).

*Liquids.* Place the sample in contact with the crystal.

*Solids.* Ensure close and uniform contact between the substance to be examined and the whole crystal surface, either by applying pressure or by dissolving the substance in an appropriate solvent, then covering the crystal with the resulting solution and evaporating to dryness.

*METHODS*

Infrared spectroscopy is mostly used to identify substances, but it may also be carried out for quantitative applications. Quantitative analysis (based on the Beer-Lambert law, which relates the absorbance of a sample to its concentration) will not be described in this chapter.

The measurement is performed on an appropriately prepared sample. The data is then processed and evaluated, either to identify substances or quantify them (e.g. based on integration of IR-absorption bands).

Spectral quality may be enhanced by mathematical pretreatments. In practice, these are limited to spectral normalisation and subtraction of bands caused by carbon-dioxide and water vapour. The same pretreatments are performed on both the sample and the reference spectra.

**Identification**

Prepare the substance to be examined appropriately and record the spectra between 4000 and 650 $cm^{-1}$, unless otherwise prescribed.

Identification testing is performed by comparing the spectrum of the substance to be examined with the spectrum obtained from a Ph. Eur. chemical reference substance (CRS) or with a Ph. Eur. reference spectrum.

The spectrum of the current batch of the Ph. Eur. CRS may be recorded for immediate use or stored, for example, in a spectral library for future consultation. A stored spectrum may be used, provided traceability to the current batch of CRS is ensured.

In the case of substances that are not covered by individual monographs, a suitable reference standard may be used.

In all cases, spectra must be recorded using the same operating conditions and procedure, and especially the same measurement mode.

When comparison of the spectra recorded in the solid state show differences (see below), treat the substance to be examined and the reference substance in the same manner so that they recrystallise or are produced in the same crystalline form, or proceed as prescribed in the monograph, then record the spectra again. However, this procedure must only be done for substances where the monograph does not cover a particular form of a substance that exhibits polymorphism.

Several comparison procedures may be used, and the analyst must document and justify the method used and the specific acceptance criteria that allow a conclusion for identification. The spectra can be compared either by overlaying the spectra (in the whole spectral range or in the region of interest specified in the monograph) or by using mathematical calculations from the software. It is possible for example to perform:

- visual comparison based on band positions and relative intensities unless otherwise specified - the transmission minima (or absorption maxima) in the spectrum obtained with the substance to be examined correspond in position and relative size to those of the reference;
- calculation of the correlation coefficient between the 2 spectra - this value is calculated by the software and the identification threshold is defined by the user;
- evaluation by chemometric methods (e.g. Euclidean distance, Mahalanobis distance, classification methods); these methods involve the set-up, assessment and validation of the chemometric model by the analyst (see *5.21. Chemometric methods applied to analytical data*).

**Impurities in gases**

For the analysis of impurities, use a cell transparent to infrared radiation and of suitable optical pathlength (e.g. 1-20 m). Fill the cell as prescribed under Gases. For detection and quantification of the impurities, proceed as prescribed in the monograph.

**01/2020:20225**

# 2.2.25. ABSORPTION SPECTROPHOTOMETRY, ULTRAVIOLET AND VISIBLE

PRINCIPLE

Ultraviolet and visible (UV-Vis) spectroscopy (or spectrophotometry) is based on the ability of atoms, molecules and ions to absorb light at specific wavelengths in the ultraviolet (approximately 180-400 nm) and visible (approximately 400-800 nm) range. This absorption is associated with changes in electronic energy in the form of temporary transitions of electrons to an excited state at a higher energy orbital. As each energy level of a molecule or molecular ion also has associated vibrational and rotational sub-levels, this results in many permitted transitions, which are generally impossible to separate, thereby producing absorption bands rather than sharp lines. These bands are characteristic of the functional groups and bonds in a molecule.

UV-Vis spectroscopy measurements involve exposing a sample to light and measuring the attenuation and/or scattering of the emerging (transmitted or reflected) light either at a single wavelength or over a specified wavelength range.

## APPLICATIONS

UV-Vis spectroscopy is traditionally used for the quantitative and qualitative analysis of liquid samples, but is also suitable for solid and gaseous analytes and has other applications such as the determination of physical or chemical properties.

UV-Vis spectroscopy as described in this chapter can be applied in various ways:

- when a monograph or general chapter refers to this chapter, the requirements described in the relevant paragraphs of this chapter are mandatory;
- when used as the detection method in chromatographic systems as described in general chapter *2.2.46*, the requirements listed in the relevant paragraphs of this chapter are mandatory;
- when used as a process analytical technology (PAT) tool for PAT applications similar to the applications described in this chapter, the provisions herein apply; for other PAT applications, the principles are the same, however the criteria are established bearing in mind the intended purpose of the analysis, using a risk-based approach.

## EQUIPMENT

Spectrophotometers used for carrying out measurements in the UV-Vis region typically consist of:

- a suitable light source (such as a deuterium lamp for the UV region, a tungsten-halogen lamp for the visible region or a xenon lamp to cover the entire UV-Vis range); UV-Vis spectrophotometers often have 2 sources;
- a monochromator such as a grating system;
- other optical components, such as lenses or mirrors, that relay light through the instrument and that may also be used to generate more than one beam of light, i.e. in double-beam spectrophotometers, as opposed to single-beam spectrophotometers;
- a sample container, holder or sampling device; examples include conventional cuvettes, fibre-optic probes and immersed transmission cells (e.g. high-purity quartz or sapphire transparent to UV-Vis radiation); the choice depends on the intended application, paying particular attention to its suitability for the type of sample to be analysed;
- a single-channel (e.g. photomultiplier, photodiode) or multi-channel detector (e.g. photodiode array (PDA) or charge-coupled device (CCD));
- suitable computerised data processing and evaluation systems.

**Control of cuvettes**. For benchtop instruments, cuvettes or cells with a defined path length are used. These can be made of different materials such as quartz or glass. The tolerance for the path length of quartz and glass cuvettes is ± 0.5 per cent (e.g. ± 0.005 cm for a 1 cm cuvette). Plastic cuvettes may also be used but the tolerance interval is wider; therefore, their use must be thoroughly justified and based on a risk assessment.

The following method may be applied to check the cleanliness of optical cuvette windows and any significant differences in their thickness or parallelism: fill the cuvette with *water R* and measure its apparent absorbance against air at 240 nm for quartz cuvettes and 650 nm for glass cuvettes; rotate the cuvette 180° in its holder and measure the apparent absorbance again at the same wavelength.

When using scanning instruments, it is recommended to scan over the optical region of interest.

When using double-beam spectrophotometers, measures should be taken (e.g. matching the cuvettes) to ensure that any difference between the absorbance of the cuvettes will not have a significant impact on the analysis to be performed.

*Acceptance criteria*:

- the apparent absorbance is not greater than 0.093 for 1 cm quartz cuvettes (UV region) and 0.035 for 1 cm glass cuvettes (visible region);
- the absorbance measured after rotation (180°) does not differ by more than 0.005 from the value previously obtained.

## MEASUREMENT

**Transmission mode**. Transmission mode provides a measure of the transmittance ($T$), at a given UV-Vis wavelength, of a sample placed between the light source and the detector. Transmittance is the ratio of the intensity of the transmitted light to the intensity of the incident light and is given by the following equation:

$$T = \frac{I}{I_0}$$

$I$ = intensity of transmitted radiation;

$I_0$ = intensity of incident radiation.

A spectrum may be obtained by plotting the variation in transmittance ($T$) or absorbance ($A$) as a function of wavelength.

The absorbance is defined as the logarithm to base 10 of the reciprocal of the transmittance for monochromatic radiation. It is a dimensionless quantity expressed in absorbance units (AU), given by the following equation:

$$A = \log_{10}\left(\frac{1}{T}\right) = \log_{10}\left(\frac{I_0}{I}\right)$$

According to the Beer-Lambert law, which applies to clear diluted solutions, in the absence of interfering physico-chemical factors, the absorbance ($A$) is proportional to the path length ($l$) of the radiation through the sample, and to the concentration ($c$) of the substance in solution in accordance with the following equation:

$$A = \varepsilon c l$$

$\varepsilon$ = molar absorption coefficient, in litres per mole per centimetre;

$c$ = molar concentration of the substance in solution, in moles per litre;

$l$ = absorption path length, in centimetres.

The specific absorbance ($A_{1\ \mathrm{cm}}^{1\ \mathrm{per\ cent}}$) of the substance is generally used in monographs and is related to absorbance ($A$) as follows:

$$A = A_{1\ \mathrm{cm}}^{1\ \mathrm{per\ cent}} \times c_m \times l$$

$c_m$ = mass concentration of the substance in solution, in grams per 100 millilitres.

$A_{1\ \mathrm{cm}}^{1\ \mathrm{per\ cent}}$ represents the specific absorbance of a dissolved substance and refers to the absorbance of a 1 g/100 mL (or 1 per cent *m/V*) solution in a 1 cm cuvette or cell and is measured at a defined wavelength. The relationship between $A_{1\ \mathrm{cm}}^{1\ \mathrm{per\ cent}}$ and $\varepsilon$ is:

$$A_{1\ \mathrm{cm}}^{1\ \mathrm{per\ cent}} = \frac{10\varepsilon}{M_r}$$

$M_r$ = relative molecular mass.

Transmittance or absorbance measurements are generally used for liquids (dispersions and solutions), but can also be used for solids (including tablets and capsules). For measurements of solids, a suitable sample accessory is used. Liquid samples are examined using a cell or cuvette with a suitable path length (typically 0.01-1 cm) and made of a material that is transparent to UV-Vis radiation, or by using a fibre-optic probe of a suitable configuration immersed in the liquid.

**Diffuse reflection mode**. Diffuse reflection mode provides a measure of reflectance ($R$), which is given by the following equation:

$$R = \frac{I}{I_0}$$

$I$ = intensity of light reflected and/or scattered from the sample;

$I_0$ = intensity of light reflected and/or scattered from a blank or reference reflective surface.

Depending on the chemical composition and physical characteristics of the sample, the UV-Vis radiation may be absorbed as it passes through the sample. In diffuse reflection mode, it is the non-absorbed radiation which is partially reflected and/or scattered back from the sample that is measured by the detector. UV-Vis reflectance spectra are typically obtained by calculating and plotting $\log_{10}(1/R)$ as a function of the wavelength.

This measurement mode is generally selected for solids. The sample is examined either in a suitable device (e.g. a sample holder) or in direct contact with a probe. For process monitoring, the material can be analysed through a polished window interface (e.g. quartz or sapphire), or in-line using a probe. Care must be taken to ensure that the measurement conditions are as reproducible as possible from one sample to another.

**Operation of the equipment**. The factors below affect the spectral response and must always be taken into account.

Choose a measurement mode that is appropriate for the intended application and the sample type.

Define the measuring conditions taking into account the sample size and sample probe in such a way as to obtain a satisfactory signal-to-noise ratio (e.g. beam size, measurement time and number of measurements). For scanning spectrophotometers, also select the scan range, scan rate and slit-width that provide the necessary optical resolution for the intended application without losing the required signal-to-noise ratio or the linearity of the analytical method. When using spectrophotometers with array sensors, there is no need to adjust the beam size, scan range, scan rate or slit-width since the optical resolution is typically fixed and the full spectrum is always recorded.

Before an absorbance measurement is carried out, the zero position of the absorption (baseline correction) should be set or determined for the wavelengths of interest or over the appropriate range of wavelengths.

For PAT applications, when measuring moving materials or samples, ensure that there is no fouling of the sensor (e.g. no contamination or build-up of material).

Unless otherwise prescribed in the monograph, measure the absorbance using a path length of 1 cm at the prescribed wavelength. If a single value for the position of an absorption maximum or minimum is given in a monograph, the user must determine the wavelength position. The value obtained may differ by not more than ± 2 nm, unless otherwise prescribed.

Quantitative measurements relying on absorption values above 2.0 should be avoided.

**Background correction**. Select a suitable spectroscopic blank (e.g. air, blank solvent, solid material). Unless otherwise prescribed, all measurements are carried out with reference to the same solvent or the same mixture of solvents (blank).

Measure the blank and the sample within a short time-frame either in parallel in double-beam spectrophotometers or sequentially in single-beam spectrophotometers. The absorbance values of both blank and sample must be in the working range of the equipment as specified by the manufacturer.

For benchtop instruments, the absorbance of the solvent measured against air and at the prescribed wavelength must not exceed 0.4 and is preferably less than 0.2.

For chromatographic systems, the transmittance of the mobile phase may be used as the blank.

In some PAT applications, it may be impossible to remove the probe for background data collection. Various options are therefore to be considered, including the use of internal references, measurement of a blank using a second detector, etc. Only spectra measured against a blank possessing the same optical properties can be directly compared with one another.

For reflectance measurements, common reflectance blank samples include ceramics, fluoropolymers such as polytetrafluoroethylene (PTFE) and powders such as barium sulfate ($BaSO_4$) and magnesium oxide (MgO), but other suitable materials may also be used.

## MATHEMATICAL TREATMENT OF SPECTRAL DATA

In the case of single wavelength analysis used to determine the concentration of an unknown sample (e.g. as prescribed in monographs), mathematical treatment consists in determining the regression of the photometric reading (absorbance) on the concentration of the standard samples.

In the case of full range spectra, data for both diffuse reflection and transmission modes may have to be treated before a classification or calibration model can be developed. The aim can be, for example, to reduce baseline drift or to correct for scatter caused by particle size changes in solid samples. For example, first-, second- or higher-order derivative spectra can typically be used to improve resolution or sensitivity. This pretreatment may be a useful means of simplifying the data and thereby reducing the variations that may cause interference in subsequently applied mathematical models.

A wide range of treatment methods, such as scaling, smoothing, normalisation and derivatisation, can be applied either singly or in combination. More information is available in general chapter *5.21. Chemometric methods applied to analytical data*.

## CONTROL OF EQUIPMENT PERFORMANCE

Spectrophotometer performance is controlled (automatically or manually) at regular intervals as defined in the quality management system and dictated by the use of the equipment and the application. For example, equipment exposed to variations in temperature and humidity may need more frequent performance testing.

Requirements for control of equipment performance for the various measurement modes are summarised in Table 2.2.25.-1. Further such tests may be performed if appropriate.

Wavelength accuracy, absorbance accuracy and linearity are controlled using either certified reference materials such as solid filters or liquid filters in appropriate sealed cells, or solutions prepared in the laboratory as described below.

Table 2.2.25.-1. – *Minimum tests to be carried out for the control of equipment performance*

| Purpose | Method | Wavelength accuracy | Absorbance accuracy | Photometric linearity | Stray light | Resolution/spectral bandwidth |
|---|---|---|---|---|---|---|
| Quantitative or limit test | Based on measurement of the absorbance at one or more identified wavelengths (e.g. assay or impurities test) | X | X | X | X | If required in the monograph |
| Identification test | Based on wavelength of absorption maxima and minima | X | - | - | X | - |
| | Based on absorption measurement and wavelength of absorption maxima | X | X | - | X | - |
| | Based on comparison of spectrum with that of reference substance | X | X | - | - | - |

**Control of wavelength accuracy**. Control the wavelength accuracy of an appropriate number of bands in the intended spectral range using one or more reference materials; for example, use solid or liquid filters (e.g. *holmium perchlorate solution R*) to verify the position of absorption bands, or measure the emission from a light source to check emission-line position. Table 2.2.25.-2 shows examples of wavelengths used to check wavelength accuracy. When certified reference materials are used, the reference wavelength is that stated on the corresponding certificate.

Some instruments may have an automatic or inbuilt wavelength accuracy control feature.

Table 2.2.25.-2. – *Examples of wavelengths used for the control of wavelength accuracy*
*Note: the wavelength varies with the resolution of the instrument

| Material | | Wavelengths (nm)* |
|---|---|---|
| Solutions | Cerium in sulfuric acid | 201.1; 211.4; 222.6; 240.4; 253.7 |
| | Didymium in perchloric acid | 511.8; 731.6; 794.2 |
| | Holmium in perchloric acid | 241.1; 287.2; 361.3; 451.4; 485.2; 536.6; 640.5 |
| Solid filters | Didymium glass | 513.5 |
| | Holmium glass | 279.3; 360.9; 453.4; 637.5 |
| Lamps | Deuterium | 486.0; 656.1 |
| | Mercury (low pressure) | 184.9; 253.7; 312.5; 365.0; 404.7; 435.8; 546.1; 577.0; 579.1 |
| | Neon | 717.4 |
| | Xenon | 541.9; 688.2; 764.2 |

For chromatographic systems, it is also possible to control wavelength accuracy by measuring the absorbance of a 0.05 mg/mL solution of *caffeine R* in *methanol R*; the absorption maximum is obtained at 272 nm and the minimum at 244 nm.

*Acceptance criteria*

It is recommended to test at least 2 wavelengths that bracket the intended spectral range.

For benchtop instruments, the tolerance for wavelength accuracy of UV-Vis spectroscopy in cuvettes is ± 1 nm at wavelengths below 400 nm and ± 3 nm at wavelengths of 400 nm and above.

For chromatographic systems, the tolerance for wavelength accuracy is ± 2 nm for the whole UV-Vis range.

For PAT applications, a tolerance of ± 2 nm for the UV-Vis range is recommended. However, wider tolerance intervals may be needed for some PAT applications, in which case the requisite wavelength accuracy must be defined by the user depending on the intended purpose, and using a risk-based approach.

The instrument parameters (especially the entrance optics such as slit-width or optical fibre diameter) influence the resolution and must be the same as those intended for the actual measurements.

**Control of absorbance accuracy**. Control the absorbance accuracy at an appropriate number of wavelengths in the intended spectral range, using suitable solid or liquid filters to check that the absorbance measured at the test wavelength matches the certified absorbance of the filter or the absorbance value that is calculated from a certified specific absorbance. *Nicotinic acid for equipment qualification CRS* may be used.

It is recommended to test absorbance accuracy at selected wavelengths using one or more solid or liquid filters with different absorbance levels; as a minimum, values at approximately the 2 limits of the expected absorbance range should be verified.

For chromatographic systems and PAT applications, the testing of absolute absorbance accuracy may not be necessary, providing that a standard curve is measured as required.

For measurements using *nicotinic acid for equipment qualification CRS*, the certified specific absorbance is given in the corresponding leaflet.

The solution of nicotinic acid can be prepared as follows: dissolve 57.0-63.0 mg of *nicotinic acid for equipment qualification CRS* in a 0.1 M hydrochloric acid solution prepared from *hydrochloric acid R* and dilute to 200.0 mL with the same acid solution; dilute 2.0 mL of the solution to 50.0 mL with the same acid solution to obtain a final concentration of 12 mg/L. These volumes can be adjusted to obtain nicotinic acid solutions with other concentrations (up to about 40 mg/L), for the purposes of testing different absorbance levels. The absorbance is measured at 213 nm and 261 nm.

*Acceptance criteria*

The difference between the measured absorbance and the absorbance of the certified material is ± 0.010 or ± 1 per cent, whichever is greater, for each combination of wavelength and absorbance assessed (applies to absorbance values not greater than 2). Tolerances for higher absorbance values should be defined on the basis of a risk assessment.

**Control of photometric linearity**. Control the photometric linearity in the intended spectral range. In the ultraviolet range, the filters used to control absorbance accuracy may be used, as can solutions of nicotinic acid or caffeine. In the visible range, neutral glass filters may be used. Prior to performing the test, ensure that the absorbance of the standards is compatible with the intended linear range.

Solutions with increasing concentrations (e.g. 5-40 mg/L) of *nicotinic acid for equipment qualification CRS* in a 0.1 M hydrochloric acid solution prepared from *hydrochloric acid R* may be used. The absorbance is measured at 213 nm and 261 nm.

For chromatographic systems, it is also possible to check photometric linearity using 0.5-50 mg/L solutions of *caffeine R* in *water for chromatography R*. The absorbance is measured at 273 nm.

*Acceptance criterion*

The coefficient of determination ($R^2$) is not less than 0.999.

**Limit of stray light**. Stray light is determined at an appropriate wavelength using suitable solid or liquid filters or solutions prepared in-house. The instrument parameters used for the test, such as slit-width and type of light source (e.g. deuterium or tungsten lamp), must be the same as those intended for the actual measurements.

*Acceptance criterion*

The acceptance criterion depends on the filters or solutions used, for example:

- the absorbance is not less than 3.0 when using a 10 g/L solution of *sodium iodide R* at 220 nm, a 10 g/L solution of *potassium iodide R* at 250 nm or a 50 g/L solution of *sodium nitrite R* at 340 nm and 370 nm;
- the absorbance is not less than 2.0 when using a 12 g/L solution of *potassium chloride R* at 198 nm.

These values apply when using a 1 cm cell and *water R* as the compensation liquid.

**Control of resolution**. Where prescribed in a monograph, measure the resolution of the equipment either using suitable certified reference materials, or by recording the spectrum of a 0.02 per cent *V/V* solution of *toluene R* in *hexane R* or *heptane R*, with respectively *hexane R* or *heptane R* as the compensation liquid.

*Acceptance criterion*

For measurements taken with a solution prepared as described above, the minimum ratio of the absorbance at the maximum (269 nm) to that at the minimum (266 nm) is stated in the monograph.

SYSTEM SUITABILITY

System suitability tests may be required prior to sample measurement to verify critical parameters that may have an impact on the result.

These tests may cover wavelength accuracy, absorbance accuracy, stray light and photometric linearity. System functionality tests, for example those performed as part of equipment autotesting, may be considered part of the system suitability tests.

In the case of UV-Vis detection for chromatographic systems, additional system suitability tests are applicable if prescribed in the monograph and/or in general chapter *2.2.46. Chromatographic separation techniques*.

**01/2008:20226**

# 2.2.26. PAPER CHROMATOGRAPHY

ASCENDING PAPER CHROMATOGRAPHY

*Apparatus*. The apparatus consists of a glass tank of suitable size for the chromatographic paper used, ground at the top to take a closely fitting lid. In the top of the tank is a device which suspends the chromatographic paper and is capable of being lowered without opening the chamber. In the bottom of the tank is a dish to contain the mobile phase into which the paper may be lowered. The chromatographic paper consists of suitable filter paper, cut into strips of sufficient length and not less than 2.5 cm wide; the paper is cut so that the mobile phase runs in the direction of the grain of the paper.

*Method*. Place in the dish a layer 2.5 cm deep of the mobile phase prescribed in the monograph. If prescribed in the monograph, pour the stationary phase between the walls of the tank and the dish. Close the tank and allow to stand for 24 h at 20 °C to 25 °C. Maintain the tank at this temperature throughout the subsequent procedure. Draw a fine pencil line horizontally across the paper 3 cm from one end. Using a micro pipette, apply to a spot on the pencil line the volume of the solution prescribed in the monograph. If the total volume to be applied would produce a spot more than 10 mm in diameter, apply the solution in portions allowing each to dry before the next application. When more than one chromatogram is to be run on the same strip of paper, space the solutions along the pencil line at points not less than 3 cm apart. Insert the paper into the tank, close the lid and allow to stand for 1 h 30 min. Lower the paper into the mobile phase and allow elution to proceed for the prescribed distance or time. Remove the paper from the tank and allow to dry in air. Protect the paper from bright light during the elution process.

DESCENDING PAPER CHROMATOGRAPHY

*Apparatus*. The apparatus consists of a glass tank of suitable size for the chromatographic paper used, ground at the top to take a closely fitting glass lid. The lid has a central hole about 1.5 cm in diameter closed by a heavy glass plate or a stopper. In the upper part of the tank is suspended a solvent trough with a device for holding the chromatographic paper. On each side of the trough, parallel to and slightly above its upper edges, are two glass guide rods to support the paper in such a manner that no part of it is in contact with the walls of the tank. The chromatographic paper consists of suitable filter paper, cut into strips of sufficient length, and of any convenient width between 2.5 cm and the length of the trough; the paper is cut so that the mobile phase runs in the direction of the grain of the paper.

*Method*. Place in the bottom of the tank a layer 2.5 cm deep of the solvent prescribed in the monograph, close the tank and allow to stand for 24 h at 20 °C to 25 °C. Maintain the tank at this temperature throughout the subsequent procedure. Draw a fine pencil line horizontally across the paper at such a distance from one end that when this end is secured in the solvent trough and the remainder of the paper is hanging freely over the guide rod, the line is a few centimetres below the guide rod and parallel with it. Using a micro-pipette, apply on the pencil line the volume of the solution prescribed in the monograph. If the total volume to be applied would produce a spot more than 10 mm in diameter, apply the solution in portions, allowing each to dry before the next application. When more than one chromatogram is to be run on the same strip of paper, space the solutions along the pencil line at points not less than 3 cm apart. Insert the paper in the tank, close the lid, and allow to stand for 1 h 30 min. Introduce into the solvent trough, through the hole in the lid, a sufficient quantity of the mobile phase, close the tank and allow elution

to proceed for the prescribed distance or time. Remove the paper from the tank and allow to dry in air. The paper should be protected from bright light during the elution process.

**01/2008:20227**
**corrected 9.0**

## 2.2.27. THIN-LAYER CHROMATOGRAPHY

Thin-layer chromatography is a separation technique in which a stationary phase consisting of an appropriate material is spread in a uniform thin layer on a support (plate) of glass, metal or plastic. Solutions of analytes are deposited on the plate prior to development. The separation is based on adsorption, partition, ion-exchange or on combinations of these mechanisms and is carried out by migration (development) of solutes (solutions of analytes) in a solvent or a suitable mixture of solvents (mobile phase) through the thin-layer (stationary phase).

### APPARATUS

**Plates**. The chromatography is carried out using pre-coated plates as described under *Reagents* (*4.1.1*). The particle size of the silica gel is indicated after the name of the reagent in the tests where it is used.

*Pre-treatment of the plates*. It may be necessary to wash the plates prior to separation. This can be done by migration of an appropriate solvent. The plates may also be impregnated by procedures such as development, immersion or spraying. At the time of use, the plates may be activated, if necessary, by heating in an oven at 120 °C for 20 min.

**Chromatographic tank** with a flat bottom or twin trough, of inert, transparent material, of a size suitable for the plates used and provided with a tightly fitting lid. For horizontal development the tank is provided with a trough for the mobile phase and it additionally contains a device for directing the mobile phase to the stationary phase.

**Micropipettes, microsyringes, calibrated disposable capillaries** or other application devices suitable for the proper application of the solutions.

**Fluorescence detection device** to measure direct fluorescence or the inhibition of fluorescence.

**Visualisation devices and reagents**. Suitable devices are used for derivatisation to transfer to the plate reagents by spraying, immersion or exposure to vapour and, where applicable, to facilitate heating for visualisation of separated components.

**Documentation**. A device may be used to provide documentation of the visualised chromatogram, for example a photograph or a computer file.

### METHOD

**Sample application**. Apply the prescribed volume of the solutions at a suitable distance from the lower edge and from the sides of the plate and on a line parallel to the lower edge; allow an interval of at least 10 mm (5 mm on high-performance plates) between the centres of circular spots and 5 mm (2 mm on high-performance plates) between the edges of bands. Apply the solutions in sufficiently small portions to obtain circular spots 2-5 mm in diameter (1-2 mm on high-performance plates) or bands 10-20 mm (5-10 mm on high-performance plates) by 1-2 mm.

In a monograph, where both normal and high-performance plates may be used, the working conditions for high-performance plates are given in the brackets [ ] after those for normal plates.

**Vertical development**. Line the walls of the chromatographic tank with filter paper. Pour into the chromatographic tank a sufficient quantity of the mobile phase for the size of the tank to give after impregnation of the filter paper a layer of appropriate depth related to the dimension of the plate to be used. For saturation of the chromatographic tank, replace the lid and allow to stand at 20-25 °C for 1 h. Unless otherwise indicated in the monograph, the chromatographic separation is performed in a saturated tank. Apply the prescribed volume of solutions as described above. When the solvent has evaporated from the applied solutions, place the plate in the chromatographic tank, ensuring that the plate is as vertical as possible and that the spots or bands are above the surface of the mobile phase. Close the chromatographic tank, maintain it at 20-25 °C and protect from sunlight. Remove the plate when the mobile phase has moved over the prescribed distance, measured between the points of application and the solvent front. Dry the plate and visualise the chromatograms as prescribed.

For two-dimensional chromatography, dry the plates after the first development and carry out a second development in a direction perpendicular to that of the first development.

**Horizontal development**. Apply the prescribed volume of the solutions as described above. When the solvent has evaporated from the applied solutions, introduce a sufficient quantity of the mobile phase into the trough of the chamber using a syringe or pipette, place the plate in the chamber after verifying that the latter is horizontal and connect the mobile phase direction device according to the manufacturer's instructions. If prescribed, develop the plate starting simultaneously at both ends. Close the chamber and maintain it at 20-25 °C. Remove the plate when the mobile phase has moved over the distance prescribed in the monograph. Dry the plate and visualise the chromatograms as prescribed.

For two-dimensional chromatography, dry the plates after the first development and carry out a second development in a direction perpendicular to that of the first development.

### VISUAL EVALUATION

**Identification**. The principal spot in the chromatogram obtained with the test solution is visually compared to the corresponding spot in the chromatogram obtained with the reference solution by comparing the colour, the size and the retardation factor ($R_F$) of both spots.

The retardation factor ($R_F$) is defined as the ratio of the distance from the point of application to the centre of the spot and the distance travelled by the solvent front from the point of application.

*Verification of the separating power for identification*. Normally the performance given by the suitability test described in *Reagents* (*4.1.1*) is sufficient. Only in special cases an additional performance criterion is prescribed in the monograph.

**Related substances test**. The secondary spot(s) in the chromatogram obtained with the test solution is (are) visually compared to either the corresponding spot(s) in the chromatogram obtained with the reference solution containing the impurity(ies) or the spot in the chromatogram obtained with the reference solution prepared from a dilution of the test solution.

*Verification of the separating power*. The requirements for the verification of the separating power are prescribed in the monographs concerned.

*Verification of the detecting power*. The detecting power is satisfactory if a spot or band is clearly visible in the chromatogram obtained with the most dilute reference solution.

### QUANTITATIVE MEASUREMENT

The requirements for resolution and separation are prescribed in the monographs concerned.

Substances separated by thin-layer chromatography and responding to UV-Vis irradiation can be determined directly on the plate, using appropriate instrumentation. While moving the plate or the measuring device, examine the plate by measuring the reflectance of the incident light. Similarly, fluorescence may be measured using an appropriate optical system. Substances containing radionuclides can be quantified in 3 ways: either directly by moving the plate alongside a suitable counter or vice versa (see *Radiopharmaceutical preparations (0125)*), by cutting the plates into strips and measuring the radioactivity on each individual strip using a suitable counter or by scraping off the stationary phase, dissolving it in a suitable scintillation cocktail and measuring the radioactivity using a liquid scintillation counter.

**Apparatus**. The apparatus for direct measurement on the plate consists of:

- a device for exact positioning and reproducible dispensing of the amount of substances onto the plate;
- a mechanical device to move the plate or the measuring device along the *x*-axis or the *y*-axis;
- a recorder and a suitable integrator or a computer;
- *for substances responding to UV-Vis irradiation*: a photometer with a source of light, an optical device able to generate monochromatic light and a photo cell of adequate sensitivity are used for the measurement of reflectance or transmittance; if fluorescence is measured, a suitable filter is required to prevent light used for excitation from reaching the detector while permitting emitted light or a specific portion thereof to pass;
- *for substances containing radionuclides*: a suitable counter for radioactivity. The linearity range of the counting device is to be verified.

**Method**. Prepare the solution of the substance to be examined (test solution) as prescribed in the monograph and, if necessary, prepare the reference solutions of the substance to be determined using the same solvent as in the test solution. Apply the same volume of each solution to the plate and develop.

*Substances responding to UV-Vis irradiation*. Prepare and apply not fewer than 3 reference solutions of the substance to be examined, the concentrations of which span the expected value in the test solution (about 80 per cent, 100 per cent and 120 per cent). Treat with the prescribed reagent, if necessary, and record the reflectance, the transmittance or fluorescence in the chromatograms obtained with the test and reference solutions. Use the measured results for the calculation of the amount of substance in the test solution.

*Substances containing radionuclides*. Prepare and apply a test solution containing about 100 per cent of the expected value. Determine the radioactivity as a function of the path length and report the radioactivity in each resulting peak as a percentage of the total amount of radioactivity.

Criteria for assessing the suitability of the system are described in the chapter on *Chromatographic separation techniques* (*2.2.46*). The extent to which adjustments of parameters of the chromatographic system can be made to satisfy the criteria of system suitability are also given in this chapter.

**01/2019:20228**

# 2.2.28. GAS CHROMATOGRAPHY

PRINCIPLE

Gas chromatography (GC) is a chromatographic separation technique based on the difference in the distribution of species between 2 non-miscible phases in which the mobile phase is a carrier gas moving through or passing the stationary phase contained in a column. It is applicable to substances or their derivatives which are volatilised under the temperatures employed.

GC is mainly based on mechanisms of adsorption or mass distribution.

EQUIPMENT

The equipment typically consists of:

- an injector;
- a chromatographic column contained in an oven;
- one or more detector(s);
- a data acquisition system.

The carrier gas flows through the column and then through the detector at a controlled rate or pressure.

The chromatography is carried out either at a constant temperature or according to a given temperature programme.

*INJECTORS*

Injection may be carried out either into a vaporisation chamber which may be equipped with a stream splitter, or directly at the head of the column using a syringe or an injection valve.

*Injections of vapour phase* may be effected by static or dynamic head-space injection systems.

*Dynamic head-space* (purge and trap) injection systems include a sparging device by which volatile substances in solution are swept into an absorbent column maintained at a low temperature. Retained substances are then desorbed into the mobile phase by rapid heating of the absorbent column.

*Static head-space* injection systems include a thermostatically controlled sample heating chamber in which closed vials containing solid or liquid samples are placed for a fixed period of time to allow equilibration of the volatile components of the sample between the non-gaseous phase and the vapour phase. After equilibration, a predetermined amount of the head-space of the vial is flushed into the gas chromatograph.

*STATIONARY PHASES*

Stationary phases are contained in columns which may be:

- a capillary column whose stationary phase may be a solid coating the inner surface of the column (e.g. macrogol 20 000), or a liquid deposited on the inner surface (e.g. dimethylpolysiloxane); in the latter case it may be chemically bonded to the inner surface;
- a column packed with the stationary phase which may be a solid phase (e.g. alumina, silica) or an inert solid support (usually a porous polymer) impregnated or coated with a liquid.

Capillary columns, made of fused silica, are 0.1 mm to 0.53 mm in internal diameter (Ø) and at least 5 m in length. The stationary phase is a film 0.1 µm to 5.0 µm thick.

Packed columns, made of glass or metal, are usually 1 m to 3 m in length with an internal diameter (Ø) of 2 mm to 4 mm.

*MOBILE PHASES*

Retention time and peak efficiency depend on the carrier gas flow rate; retention time is directly proportional to column length and resolution is proportional to the square root of the column length.

The carrier gas flow rate is usually expressed in millilitres per minute at atmospheric pressure and at the stated temperature. Flow rate is measured at the detector outlet, either with a calibrated mechanical device or with a bubble tube, while the column is at operating temperature.

The linear velocity of the carrier gas through a column is inversely proportional to the square of the internal diameter of the column for a given flow volume.

Helium, nitrogen and hydrogen are commonly used carrier gases.

*DETECTORS*

Flame-ionisation detectors are usually employed but other detectors such as electron-capture, nitrogen-phosphorus, mass spectrometric, thermal conductivity or infrared spectrophotometric detectors may also be used.

PROCEDURE

Equilibrate the column, the injector and the detector at the temperatures and the gas flow rates/pressures specified in the monograph until a stable baseline is achieved. Prepare the test solution(s) and the reference solution(s) as prescribed. The solutions injected must be free from solid particles.

Criteria for assessing the suitability of the system are described in general chapter *2.2.46 Chromatographic separation techniques*. The extent to which adjustments of parameters of the chromatographic system can be made to satisfy the criteria of system suitability are also given in this general chapter.

## Static head-space gas chromatography

Static head-space gas chromatography is a technique particularly suitable for separating and determining volatile compounds present in solid or liquid samples. The method is based on the analysis of the vapour phase in equilibrium with the solid or liquid phase.

EQUIPMENT

The equipment consists of a gas chromatograph provided with a sample-introduction device that may be connected to a module that automatically controls the pressure and the temperature. If necessary, a device for eliminating solvents can be added.

The sample to be analysed is introduced into a container fitted with a suitable stopper and a valve-system which permits the passage of the carrier gas. The container is placed in a thermostatically controlled chamber at a temperature set according to the substance to be examined.

The sample is held at this temperature long enough to allow equilibration between the solid or liquid phase and the vapour phase.

The carrier gas is introduced into the container and, after the prescribed time, a suitable valve is opened so that the gas expands towards the chromatographic column taking the volatilised compounds with it.

Instead of using a chromatograph specifically equipped for the introduction of samples, it is also possible to use airtight syringes and a conventional chromatograph. Equilibration is then carried out in a separate chamber and the vapour phase is carried onto the column, while necessary precautions are taken to avoid any changes in the equilibrium.

PROCEDURE

Using the reference preparations, determine suitable instrument settings to produce an adequate response.

*DIRECT CALIBRATION*

Introduce into separate, identical containers the preparation to be examined and each of the reference preparations, as prescribed in the monograph, avoiding contact between the sampling device and the samples.

Close the containers hermetically and place in the thermostatically controlled chamber set to the temperature and pressure prescribed in the monograph; after equilibration, carry out the chromatography under the prescribed conditions.

*STANDARD ADDITIONS*

Add to a set of identical suitable containers equal volumes of the preparation to be examined. Add to all but one of the containers, suitable quantities of a reference preparation containing a known concentration of the substance to be determined so as to produce a series of preparations containing steadily increasing concentrations of the substance.

Close the containers hermetically and place in the thermostatically controlled chamber set to the temperature and pressure prescribed in the monograph; after equilibration, carry out the chromatography under the prescribed conditions.

Calculate the linear equation of the graph using a least-squares fit, and derive from it the concentration of the substance to be determined in the preparation to be examined.

Alternatively, plot on a graph the mean of readings against the added quantity of the substance to be determined. Extrapolate the line joining the points on the graph until it meets the concentration axis. The distance between this point and the intersection of the axes represents the concentration of the substance to be determined in the preparation to be examined.

**corrected 10.0**

# 2.2.29. LIQUID CHROMATOGRAPHY

PRINCIPLE

Liquid chromatography (LC) is a method of chromatographic separation based on the difference in the distribution of species between 2 non-miscible phases, in which the mobile phase is a liquid which percolates through a stationary phase contained in a column.

LC is mainly based on mechanisms of adsorption, mass distribution, ion exchange, size exclusion or stereochemical interaction.

Unless otherwise specified, all the information below is valid for both standard LC and LC using reduced particle-size columns (e.g. sub-2 µm).

The latter requires instrumentation that is able to withstand higher pressures (typically up to 100 MPa, i.e. about 15 000 psi), generates lower extra-column band broadening, provides improved gradient mixing and allows a higher sampling rate in the detection system.

EQUIPMENT

The equipment typically consists of:

- a pumping system;
- an injector;
- a chromatographic column (a column temperature controller may be used);
- 1 or more detector(s);
- a data acquisition system.

The mobile phase is supplied from 1 or more reservoirs and is pumped to the injector, then through the column, usually at a constant rate, and then through the detector(s).

*PUMPING SYSTEMS*

LC pumping systems deliver the mobile phase at a controlled flow rate. Pressure fluctuations are to be minimised, for example by passing the pressurised solvent through a pulse-dampening device. Tubing and connections are capable of withstanding the pressures developed by the pumping system. LC pumps may be fitted with a facility for 'bleeding' the system of entrapped air bubbles.

Microprocessor-controlled pumping systems are capable of accurately delivering a mobile phase of either constant (isocratic elution) or varying composition (gradient elution), according to a defined programme. In the case of gradient elution, pumping systems which deliver solvent(s) from several reservoirs are available and solvent mixing can be achieved on either the low or high-pressure side of the pump(s).

*INJECTORS*

The sample solution is introduced into the flowing mobile phase at or near the head of the column using an injection system which can operate at high pressure. Fixed-loop

and variable volume devices operated manually or by an autosampler are used. Partial filling of loops during manual injection may adversely affect injection volume precision.

*STATIONARY PHASES*

There are many types of stationary phases employed in LC, including:

- silica or alumina, commonly used in normal-phase LC (polar stationary phase and non-polar mobile phase), where the separation is based on differences in adsorption on the stationary phase and/or mass distribution between the mobile phase and the stationary phase (partition chromatography);
- a variety of chemically modified supports prepared from polymers, silica or porous graphite, used in normal-phase and reversed-phase LC (non-polar stationary phase and polar mobile phase), where the separation is based principally on partition of the molecules;
- resins or polymers with acidic or basic groups, used in ion-exchange chromatography, where separation is based on competition between the ions to be separated and those in the mobile phase;
- porous silica or polymers, used in size-exclusion chromatography (*2.2.30*), where separation is based on differences between the volumes of the molecules, corresponding to steric exclusion;
- specially modified stationary phases, e.g. cellulose or amylose derivatives, proteins or peptides, cyclodextrins etc., for the separation of enantiomers (chiral chromatography).

Most separations are based on reversed-phase LC utilising chemically modified silica as the stationary phase. The surface of the support, i.e. the silanol groups of silica, is reacted with various silane reagents to produce covalently bound silyl derivatives covering a varying number of active sites on the surface of the support. The nature of the bonded phase is an important parameter for determining the separation properties of the chromatographic system.

Unless otherwise stated by the manufacturer, silica-based reversed-phase columns are considered to be stable in mobile phases having an apparent pH in the range 2.0 to 8.0. Columns containing porous graphite or particles of polymeric materials such as styrene-divinylbenzene copolymer are stable over a wider pH range.

Analysis using normal-phase LC with unmodified silica or polar chemically modified silica (e.g. cyanopropyl or diol) as the stationary phase, with a non-polar mobile phase is applicable in certain cases.

For analytical separations, the particle size of the most commonly used stationary phases varies between 2 and 10 µm. The particles may be spherical or irregular, and of varying porosity and specific surface area. These properties contribute to the chromatographic behaviour of a particular stationary phase. In the case of reversed phases, the nature of the stationary phase, the extent of bonding, e.g. expressed as the carbon loading, and whether the stationary phase is end-capped (i.e. part of the residual silanol groups are silylated) are additional determining factors. Tailing of peaks, particularly of basic substances, can occur when residual silanol groups are present.

In addition to porous particles, superficially porous or monolithic materials may be used.

Unless otherwise prescribed in the monograph, columns made of stainless steel of varying length and internal diameter (Ø) are used for analytical chromatography. Columns with internal diameters of less than 2 mm are often referred to as microbore columns.

The temperature of the mobile phase and the column must be kept constant during the analysis. Most separations are performed at room temperature, but some require a different temperature for optimal performance.

*MOBILE PHASES*

For normal-phase LC, low-polarity organic solvents are generally employed. The residual water content of the solvents used in the mobile phase is to be strictly controlled to obtain reproducible results.

In reversed-phase LC, aqueous mobile phases, usually with organic solvents and/or modifiers, are employed.

The components of the mobile phase are usually filtered to remove particles greater than 0.45 µm in size (or greater than 0.2 µm when the stationary phase is made of sub-2 µm particles, and when special detectors, e.g. light scattering detectors, are used). Multicomponent mobile phases are prepared by measuring the required volumes (unless masses are specified) of the individual components, followed by mixing. Alternatively, the solvents may be delivered by individual pumps controlled by proportioning valves, by which mixing is performed according to the desired proportion. Solvents are normally degassed before pumping by sparging with helium, sonication and/or using in-line membrane/vacuum modules to avoid the creation of gas bubbles in the detector cell.

Solvents for the preparation of the mobile phase are normally free of stabilisers and, if an ultraviolet detector is employed, are transparent at the wavelength of detection. Solvents and other components employed are to be of appropriate quality. In particular, *water for chromatography R* is used for the preparation of mobile phases when water, or an aqueous solution, is 1 of the components. Any necessary adjustments of the pH are made to the aqueous component of the mobile phase and not the mixture. If buffer solutions or saline solutions are used, adequate rinsing of the system is carried out with a mixture of water and a small proportion of the organic part of the mobile phase (5 per cent *V/V*) to prevent crystallisation of salts after completion of the analysis.

Mobile phases may contain other components, for example a counter-ion for ion-pair chromatography or a chiral selector for chiral chromatography using an achiral stationary phase.

*DETECTORS*

Ultraviolet/visible (UV/Vis) spectrophotometers (including diode array detectors) (*2.2.25*), are the most commonly employed detectors. Fluorescence spectrophotometers, differential refractometers (RI), electrochemical detectors (ECD), light scattering detectors, charged aerosol detectors (CAD), mass spectrometers (MS) (*2.2.43*), radioactivity detectors, multi-angle light scattering (MALS) detectors or other detectors may be used.

PROCEDURE

Equilibrate the column with the prescribed mobile phase and flow rate, at room temperature or at the temperature specified in the monograph, until a stable baseline is achieved. Prepare the solution(s) of the substance to be examined and the reference solution(s) required. The solutions must be free from solid particles.

Criteria for assessing the suitability of the system are described in general chapter *2.2.46. Chromatographic separation techniques*. The extent to which adjustments of parameters of the chromatographic system can be made to satisfy the criteria of system suitability are also given in this chapter.

01/2019:20230

## 2.2.30. SIZE-EXCLUSION CHROMATOGRAPHY

PRINCIPLE

Size-exclusion chromatography is a liquid chromatography (*2.2.29*) technique which separates molecules in solution according to their size. With organic mobile phases, the technique is known as gel-permeation chromatography and with aqueous mobile phases it is known as gel-filtration chromatography. The sample is introduced into a column, which is filled with a gel or a porous particle packing material, and is carried by the mobile phase through the column. The size separation takes place by repeated exchange of the solute molecules between the solvent of the mobile phase and the same solvent in the stagnant liquid phase (stationary phase) within the pores of the packing material. The pore-size range of the packing material determines the molecular-size range within which separation can occur.

Molecules small enough to penetrate all the pore spaces elute at the total mobile phase volume $V_t$ (also known as total permeation volume). Molecules apparently larger than the maximum pore size of the packing material migrate along the column only through the spaces between the particles of the packing material without being retained and elute at the retention volume of an unretained compound $V_0$ (also known as exclusion volume or void volume). Separation according to molecular size occurs between the retention volume of an unretained compound and the total mobile phase volume, with useful separation usually occurring in the first two thirds of this range.

EQUIPMENT

The equipment consists essentially of a chromatographic column of varying length and internal diameter (Ø), if necessary temperature-controlled, packed with a separation material that is capable of fractionation in the appropriate range of molecular sizes. The packing material may be a soft support such as a swollen gel or a rigid support composed of a material such as glass, silica or a solvent-compatible, cross-linked organic polymer. Rigid supports usually require pressurised systems giving faster separations.

One end of the column is usually fitted with a suitable device for applying the sample such as a flow adapter, a syringe through a septum or an injection valve and may also be connected to a suitable pump for controlling the flow of the eluent. Alternatively, the sample may be applied directly to the drained bed surface or, where the sample is denser than the eluent, it may be layered beneath the eluent.

The mobile phase is chosen according to sample type, separation medium and method of detection. The eluent is passed through the column at a constant rate.

The outlet of the column is usually connected to a suitable detector fitted with an automatic recorder which enables the monitoring of the relative concentrations of separated components of the sample. Ultraviolet/visible spectrophotometers (*2.2.25*), differential refractometers (RI), luminescent detectors, multi-angle light scattering (MALS) detectors and other detectors may be used. An automatic fraction collector may be attached, if necessary.

PROCEDURE

Before carrying out the separation, the packing material is treated, and the column is packed, as described in the monograph, or according to the manufacturer's instructions. Criteria for assessing the suitability of the system are described in general chapter *2.2.46. Chromatographic separation techniques*. The extent to which adjustments of parameters of the chromatographic system can be made to satisfy the criteria of system suitability are also given in this general chapter.

*DETERMINATION OF RELATIVE COMPONENT COMPOSITION OF MIXTURES*

Carry out the separation as stated in the monograph. If possible, monitor the elution of the components continuously and measure the corresponding peak areas. If the sample is monitored by a physico-chemical property to which all the components of interest exhibit equivalent responses (for example if they have the same specific absorbance), calculate the relative amount of each component by dividing the respective peak area by the sum of the peak areas of all the components of interest. If the responses to the property used for detection of the components of interest are not equivalent, calculate the content by means of calibration curves obtained with the calibration standards prescribed in the monograph.

*DETERMINATION OF MOLECULAR MASSES*

Size-exclusion chromatography may be used to determine molecular masses by comparison with appropriate calibration standards specified in the monograph. The retention volumes of the calibration standards may be plotted against the logarithm of their molecular masses. The plot usually approximates a straight line within the exclusion and total permeation limits for the separation medium used. From the calibration curve, molecular masses may be estimated. The molecular-mass calibration is valid only for the particular macromolecular solute/solvent system used under the specified experimental conditions.

*DETERMINATION OF MOLECULAR SIZE DISTRIBUTION OF POLYMERS*

Size-exclusion chromatography may be used to determine the distribution of the molecular size of polymers. However, sample comparison may be valid only for results obtained under the same experimental conditions. The reference standards used for the calibration and the methods for determination of the distribution of molecular sizes of polymers are specified in the monograph.

## 2.2.31. ELECTROPHORESIS[(2)]

♦1. GENERAL PRINCIPLE

Under the influence of an electrical field, charged particles dissolved or dispersed in an electrolyte solution migrate in the direction of the electrode bearing the opposite polarity. In gel electrophoresis, the movements of the particles are retarded by interactions with the surrounding gel matrix, which acts as a molecular sieve. The opposing interactions of the electrical force and molecular sieving result in differential migration rates according to sizes, shapes and charges of particles. Because of their different physico-chemical properties, different macromolecules of a mixture will migrate at different speeds during electrophoresis and will thus be separated into discrete fractions. Electrophoretic separations can be conducted in systems without support phases (e.g. free solution separation in capillary electrophoresis) and in stabilising media such as thin-layer plates, films or gels.

2. FREE OR MOVING BOUNDARY ELECTROPHORESIS

This method is mainly used for the determination of mobility, the experimental characteristics being directly measurable and reproducible. It is chiefly employed with substances of high

(2) This chapter has undergone pharmacopoeial harmonisation. See chapter 5.8. *Pharmacopoeial harmonisation*.

relative molecular mass and low diffusibility. The boundaries are initially located by a physical process such as refractometry or conductimetry. After applying a given electric field for an accurately measured time, the new boundaries and their respective positions are observed. The operating conditions must be such as to make it possible to determine as many boundaries as there are components.

3. ZONE ELECTROPHORESIS USING A SUPPORTING MEDIUM

This method requires the use of small samples only.

The nature of the support, such as paper, agar gel, cellulose acetate, starch, agarose, methacrylamide, mixed gel, introduces a number of additional factors modifying the mobility:

a) owing to channelling in the supporting medium, the apparent distance covered is less than the real distance,

b) some supporting media are not electrically neutral. As the medium is a stationary phase it may sometimes give rise to a considerable electro-endosmotic flow,

c) any heating due to the joule effect may cause some evaporation of the liquid from the supporting medium which, by capillarity, causes the solution to move from the ends towards the centre. The ionic strength therefore tends to increase gradually.

The rate of migration then depends on four main factors: the mobility of the charged particle, the electro-endosmotic flow, the evaporation flow, and the field strength. Hence it is necessary to operate under clearly defined experimental conditions and to use, wherever possible, reference substances.

An *apparatus* for electrophoresis consists of:

– a *generator supplying direct current* whose voltage can be controlled and, preferably, stabilised,

– an *electrophoresis chamber*. This is usually rectangular and made of glass or rigid plastic, with 2 separate compartments, the anodic and the cathodic, containing the electrolyte solution. In each compartment is immersed an electrode, for example of platinum or graphite. These are connected by means of an appropriately isolated circuit to the corresponding terminal of the power supply to form the anode and the cathode. The level of the liquid in the 2 compartments is kept equal to prevent siphoning.

  The electrophoresis chamber is fitted with an airtight lid which maintains a moisture-saturated atmosphere during operation and reduces evaporation of the solvent. A safety device may be used to cut off the power when the lid is removed. If the electrical power measured across the strip exceeds 10 W, it is preferable to cool the support.

– a *support-carrying device*:

  *Strip electrophoresis*. The supporting strip, previously wetted with the same conducting solution and dipped at each end into an electrode compartment is appropriately tightened and fixed on to a suitable carrier designed to prevent diffusion of the conducting electrolyte, such as a horizontal frame, inverted-V stand or a uniform surface with contact points at suitable intervals.

  *Gel electrophoresis*. The device consists essentially of a glass plate (for example, a microscope slide) over the whole surface of which is deposited a firmly adhering layer of gel of uniform thickness. The connection between the gel and the conducting solution is effected in various ways according to the type of apparatus used. Precautions must be taken to avoid condensation of moisture or drying of the solid layer.

– measuring *device or means of detection*.

*Method*. Introduce the electrolyte solution into the electrode compartments. Place the support suitably impregnated with electrolyte solution in the chamber under the conditions prescribed for the type of apparatus used. Locate the starting line and apply the sample. Apply the electric current for the prescribed time. After the current has been switched off, remove the support from the chamber, dry and visualise.

4. POLYACRYLAMIDE ROD GEL ELECTROPHORESIS

In polyacrylamide rod gel electrophoresis, the stationary phase is a gel which is prepared from a mixture of acrylamide and *N,N´*-methylenebisacrylamide. Rod gels are prepared in tubes 7.5 cm long and 0.5 cm in internal diameter, one solution being applied to each rod.

*Apparatus*. This consists of 2 buffer solution reservoirs made of suitable material such as poly(methyl methacrylate) and mounted vertically one above the other. Each reservoir is fitted with a platinum electrode. The electrodes are connected to a power supply allowing operation either at constant current or at constant voltage. The apparatus has in the base of the upper reservoir a number of holders equidistant from the electrode.

*Method*. The solutions should usually be degassed before polymerisation and the gels used immediately after preparation. Prepare the gel mixture as prescribed and pour into suitable glass tubes, stoppered at the bottom, to an equal height in each tube and to about 1 cm from the top, taking care to ensure that no air bubbles are trapped in the tubes. Cover the gel mixture with a layer of *water R* to exclude air and allow to set. Gel formation usually takes about 30 min and is complete when a sharp interface appears between the gel and the water layer. Remove the water layer. Fill the lower reservoir with the prescribed buffer solution and remove the stoppers from the tubes. Fit the tubes into the holders of the upper reservoir and adjust so that the bottom of the tubes are immersed in the buffer solution in the lower reservoir. Carefully fill the tubes with the prescribed buffer solution. Prepare the test and reference solutions containing the prescribed marker dye and make them dense by dissolving in them *sucrose R*, for example. Apply the solutions to the surface of a gel using a different tube for each solution. Add the same buffer to the upper reservoir. Connect the electrodes to the power supply and allow electrophoresis to proceed at the prescribed temperature and using the prescribed constant voltage or current. Switch off the power supply when the marker dye has migrated almost into the lower reservoir. Immediately remove each tube from the apparatus and extrude the gel. Locate the position of the bands in the electropherogram as prescribed. ♦

5. SODIUM DODECYL SULFATE POLYACRYLAMIDE GEL ELECTROPHORESIS (SDS-PAGE)

5-1. *SDS-PAGE - UNIFORM PERCENTAGE GELS*

**Scope**. Polyacrylamide gel electrophoresis is used for the qualitative characterisation of proteins in biological preparations, for control of purity and for quantitative determinations.

**Purpose**. Analytical gel electrophoresis is an appropriate method with which to identify and to assess the homogeneity of proteins in pharmaceutical preparations. The method is routinely used for the estimation of protein subunit molecular masses and for determination of the subunit compositions of purified proteins.

Ready-to-use gels and reagents are commercially available and can be used instead of those described in this text, provided that they give equivalent results and that they meet the validity requirements given below under Validation of the test.

5-1-1. **Characteristics of polyacrylamide gels**

The sieving properties of polyacrylamide gels are established by the three-dimensional network of fibres and pores which is formed as the bifunctional bisacrylamide cross-links adjacent polyacrylamide chains. Polymerisation is usually catalysed by a free radical-generating system composed of ammonium persulfate and *N,N,N´,N´*-tetramethylethylenediamine (TEMED).

As the acrylamide concentration of a gel increases, its effective pore size decreases. The effective pore size of a gel is operationally defined by its sieving properties, i.e. by the resistance it imparts to the migration of macromolecules. There are limits on the acrylamide concentrations that can be used. At high acrylamide concentrations, gels break much more easily and are difficult to handle. As the pore size of a gel decreases, the migration rate of a protein through the gel decreases. By adjusting the pore size of a gel, through manipulating the acrylamide concentration, the resolution of the method can be optimised for a given protein product. Thus, a given gel is physically characterised by its respective composition of acrylamide and bisacrylamide.

In addition to the composition of the gel, the state of the protein is an important component to the electrophoretic mobility. In the case of proteins, the electrophoretic mobility is dependent on the pK value of the charged groups and the size of the molecule. It is influenced by the type, the concentration and the pH of the buffer, by the temperature and the field strength, and by the nature of the support material.

5-1-2. **Denaturing polyacrylamide gel electrophoresis**

The method cited as an example is limited to the analysis of monomeric polypeptides with a mass range of 14 000 to 100 000 daltons. It is possible to extend this mass range using various techniques (e.g. gradient gels, particular buffer system). For instance, tricine-SDS gels, with tricine as the trailing ion in the electrophoresis running-buffer (instead of glycine as in the method described here), can separate very small proteins and peptides under 10 000 to 15 000 daltons.

Denaturing polyacrylamide gel electrophoresis using glycine-SDS is the most common mode of electrophoresis used in assessing the pharmaceutical quality of protein products and will be the focus of the example method. Typically, analytical electrophoresis of proteins is carried out in polyacrylamide gels under conditions that ensure dissociation of the proteins into their individual polypeptide subunits and that minimise aggregation. Most commonly, the strongly anionic detergent SDS is used in combination with heat to dissociate the proteins before they are loaded on the gel. The denatured polypeptides bind to SDS, become negatively charged and exhibit a consistent charge-to-mass ratio regardless of protein type. Because the amount of SDS bound is almost always proportional to the molecular mass of the polypeptide and is independent of its sequence, SDS-polypeptide complexes migrate through polyacrylamide gels with mobilities dependent on the size of the polypeptide.

The electrophoretic mobilities of the resultant detergent-polypeptide complexes all assume the same functional relationship to their molecular masses. SDS complexes will migrate toward the anode in a predictable manner, with low-molecular-mass complexes migrating faster than larger ones. The molecular mass of a protein can therefore be estimated from its relative mobility in calibrated SDS-PAGE, and the intensity of a single band relative to other undesired bands in such a gel can be a measure of purity.

Modifications to the polypeptide backbone, such as *N*- or *O*-linked glycosylation, can change the apparent molecular mass of a protein since SDS does not bind to a carbohydrate moiety in a manner similar to a polypeptide; therefore, a consistent charge-to-mass ratio is not maintained.

Depending on the extent of glycosylation and other post-translational modifications, the apparent molecular mass of proteins may not be a true reflection of the mass of the polypeptide chain.

**Reducing conditions**. Polypeptide subunits and three-dimensional structure are often maintained in proteins by the presence of disulfide bonds. A goal of SDS-PAGE analysis under reducing conditions is to disrupt this structure by reducing disulfide bonds. Complete denaturation and dissociation of proteins by treatment with 2-mercaptoethanol (2-ME) or dithiothreitol (DTT) will result in unfolding of the polypeptide backbone and subsequent complexation with SDS. Using these conditions, the molecular mass of the polypeptide subunits can reasonably be calculated by linear regression (or, more accurately, by non-linear regression) with the aid of suitable molecular-mass standards.

**Non-reducing conditions**. For some analyses, complete dissociation of the protein into subunit peptides is not desirable. In the absence of treatment with reducing agents such as 2-ME or DTT, disulfide covalent bonds remain intact, preserving the oligomeric form of the protein. Oligomeric SDS-protein complexes migrate more slowly than their SDS-polypeptide subunits. In addition, non-reduced proteins may not be completely saturated with SDS and, hence, may not bind the detergent in a constant mass ratio. Moreover, intra-chain disulfide bonds constrain the molecular shape, usually in such a way as to reduce the Stokes radius of the molecule, thereby reducing the apparent molecular mass $M_r$. This makes molecular-mass determinations of these molecules by SDS-PAGE less straightforward than analyses of fully denatured polypeptides, since it is necessary that both standards and unknown proteins be in similar configurations for valid comparisons.

5-1-3. **Characteristics of discontinuous buffer system gel electrophoresis**

The most popular electrophoretic method for the characterisation of complex mixtures of proteins uses a discontinuous buffer system involving 2 contiguous, but distinct gels: a resolving or separating (lower) gel and a stacking (upper) gel. The 2 gels are cast with different porosities, pH, and ionic strengths. In addition, different mobile ions are used in the gel and electrode buffers. The buffer discontinuity acts to concentrate large volume samples in the stacking gel, resulting in improved resolution. When power is applied, a voltage drop develops across the sample solution which drives the proteins into the stacking gel. Glycinate ions from the electrode buffer follow the proteins into the stacking gel. A moving boundary region is rapidly formed with the highly mobile chloride ions in the front and the relatively slow glycinate ions in the rear. A localised high-voltage gradient forms between the leading and trailing ion fronts, causing the SDS-protein complexes to form into a thin zone (stack) and migrate between the chloride and glycinate phases. Within broad limits, regardless of the height of the applied sample, all SDS-proteins condense into a very narrow region and enter the resolving gel as a well-defined, thin zone of high protein density. The large-pore stacking gel does not retard the migration of most proteins and serves mainly as an anti-convective medium. At the interface of the stacking and resolving gels, the proteins undergo a sharp increase in retardation due to the restrictive pore size of the resolving gel and the buffer discontinuity, which also contributes to the focusing of the proteins. Once in the resolving gel, proteins continue to be slowed by the sieving of the matrix. The glycinate ions overtake the proteins, which then move in a space of uniform pH formed by the tris(hydroxymethyl)aminomethane and glycine. Molecular sieving causes the SDS-polypeptide complexes to separate on the basis of their molecular masses.

5-1-4. **Preparing vertical discontinuous buffer SDS polyacrylamide gels**

This section describes the preparation of gels using particular instrumentation. This does not apply to pre-cast gels. For pre-cast gels or any other commercially available equipment, the manufacturer's instructions must be used for guidance.

The use of commercial reagents that have been purified in solution is recommended. When this is not the case and where the purity of the reagents used is not sufficient, a pre-treatment is applied. For instance, any solution sufficiently impure to require filtration must also be deionised with a mixed-bed (anion/cation exchange) resin to remove acrylic acid and

other charged degradation products. When stored according to recommendations, acrylamide/bisacrylamide solutions and solid persulfate are stable for long periods.

**Assembling the gel moulding cassette**. Clean the 2 glass plates (e.g. 10 cm by 8 cm in size), the polytetrafluoroethylene comb, the 2 spacers and the silicone rubber tubing (e.g. 0.6 mm in diameter by 35 cm) with mild detergent and rinse extensively with water, followed by anhydrous ethanol, and allow the plates to dry at room temperature. Lubricate the spacers and the tubing with non-silicone grease. Apply the spacers along each of the 2 short sides of the glass plate 2 mm away from the edges and 2 mm away from the long side corresponding to the bottom of the gel. Begin to lay the tubing on the glass plate by using one spacer as a guide. Carefully twist the tubing at the bottom of the spacer and follow the long side of the glass plate. While holding the tubing with 1 finger along the long side, twist again the tubing and lay it on the second short side of the glass plate, using the spacer as a guide. Place the second glass plate in perfect alignment and hold the mould together by hand pressure. Apply 2 clamps on each of the 2 short sides of the mould. Carefully apply four clamps on the longer side of the gel mould thus forming the bottom of the gel mould. Verify that the tubing runs along the edge of the glass plates and has not been extruded while placing the clamps. The gel mould is now ready for pouring the gel.

**Preparation of the gel**. In a discontinuous buffer SDS polyacrylamide gel, it is recommended to pour the resolving gel, let the gel set, and then pour the stacking gel since the composition of the 2 gels in acrylamide-bisacrylamide, buffer and pH are different.

*Preparation of the resolving gel*. In a conical flask, prepare the appropriate volume of solution containing the desired concentration of acrylamide for the resolving gel, using the values given in Table 2.2.31.-1. Mix the components in the order shown. Where appropriate, before adding the ammonium persulfate solution and the TEMED, filter the solution if necessary under vacuum through a cellulose acetate membrane (pore diameter 0.45 µm). Keep the solution under vacuum, while swirling the filtration unit, until no more bubbles are formed in the solution. Add appropriate amounts of ammonium persulfate solution and TEMED as indicated in Table 2.2.31.-1, swirl and pour immediately into the gap between the 2 glass plates of the mould. Leave sufficient space for the stacking gel (the length of the teeth of the comb plus 1 cm). Using a tapered glass pipette, carefully overlay the solution with water-saturated isobutanol. Leave the gel in a vertical position at room temperature to allow polymerisation.

Table 2.2.31.-1. – *Preparation of resolving gel*

| Solution components | Component volumes (mL) per gel mould volume of | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | 5 mL | 10 mL | 15 mL | 20 mL | 25 mL | 30 mL | 40 mL | 50 mL |
| **6 per cent acrylamide** | | | | | | | | |

| TEMED(5) | 0.002 | 0.004 | 0.006 | 0.008 | 0.01 | 0.012 | 0.016 | 0.02 |

(1) Acrylamide solution: *30 per cent acrylamide/bisacrylamide (29:1) solution R.*

(2) 1.5 M Tris (pH 8.8): *1.5 M tris-hydrochloride buffer solution pH 8.8 R.*

(3) 100 g/L SDS: a 100 g/L solution of *sodium dodecyl sulfate R.*

(4) 100 g/L APS: a 100 g/L solution of *ammonium persulfate R.* Ammonium persulfate provides the free radicals that drive polymerisation of acrylamide and bisacrylamide. Since ammonium persulfate solution decomposes rapidly, fresh solutions must be prepared daily.

(5) TEMED: *tetramethylethylenediamine R.*

*Preparation of the stacking gel.* After polymerisation is complete (about 30 min), pour off the isobutanol and wash the top of the gel several times with water to remove the isobutanol overlay and any unpolymerised acrylamide. Drain as much fluid as possible from the top of the gel, and then remove any remaining water with the edge of a paper towel.

In a conical flask, prepare the appropriate volume of solution containing the desired concentration of acrylamide, using the values given in Table 2.2.31.-2. Mix the components in the order shown. Where appropriate, before adding the ammonium persulfate solution and the TEMED, filter the solution if necessary under vacuum through a cellulose acetate membrane (pore diameter 0.45 µm). Keep the solution under vacuum, while swirling the filtration unit, until no more bubbles are formed in the solution. Add appropriate amounts of ammonium persulfate solution and TEMED as indicated in Table 2.2.31.-2. Swirl and pour immediately into the gap between the 2 glass plates of the mould directly onto the surface of the polymerised resolving gel. Immediately insert a clean polytetrafluoroethylene comb into the stacking gel solution, being careful to avoid trapping air bubbles. Add more stacking gel solution to fill the spaces of the comb completely. Leave the gel in a vertical position and allow to polymerise at room temperature.

**Preparation of the samples**. Unless otherwise stated in the specific monograph, the samples can be prepared as follows:

*Preparation of the samples (non-reducing conditions).* Mix equal volumes of a mixture comprising *water R* plus the preparation to be examined or the reference preparation, and *concentrated SDS-PAGE sample buffer R.*

*Preparation of the samples (reducing conditions).* Mix equal volumes of a mixture comprising *water R* plus the preparation to be examined or the reference preparation, and *concentrated SDS-PAGE sample buffer for reducing conditions R* containing 2-ME (or DTT) as the reducing agent.

The concentration prescribed in the monograph can vary depending on the protein and staining method.

Sample treatment: keep for 5 min in a water-bath or in a block heater set at 100 °C, then cool. The temperature and time in the monograph may vary as protein cleavage may occur during the heat treatment.

Table 2.2.31.-2. – *Preparation of stacking gel*

| Solution components | Component volumes (mL) per gel mould volume of | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| | 1 mL | 2 mL | 3 mL | 4 mL | 5 mL | 6 mL | 8 mL | 10 mL |
| *Water R* | 0.68 | 1.4 | 2.1 | 2.7 | 3.4 | 4.1 | 5.5 | 6.8 |
| Acrylamide solution(1) | 0.17 | 0.33 | 0.5 | 0.67 | 0.83 | 1.0 | 1.3 | 1.7 |
| 1.0 M Tris (pH 6.8)(2) | 0.13 | 0.25 | 0.38 | 0.5 | 0.63 | 0.75 | 1.0 | 1.25 |
| 100 g/L SDS(3) | 0.01 | 0.02 | 0.03 | 0.04 | 0.05 | 0.06 | 0.08 | 0.1 |
| 100 g/L APS(4) | 0.01 | 0.02 | 0.03 | 0.04 | 0.05 | 0.06 | 0.08 | 0.1 |
| TEMED(5) | 0.001 | 0.002 | 0.003 | 0.004 | 0.005 | 0.006 | 0.008 | 0.01 |

(1) Acrylamide solution: *30 per cent acrylamide/bisacrylamide (29:1) solution R.*

(2) 1.0 M Tris (pH 6.8): *1 M tris-hydrochloride buffer solution pH 6.8 R.*

(3) 100 g/L SDS: a 100 g/L solution of *sodium dodecyl sulfate R.*

(4) 100 g/L APS: a 100 g/L solution of *ammonium persulfate R.* Ammonium persulfate provides the free radicals that drive polymerisation of acrylamide and bisacrylamide. Since ammonium persulfate solution decomposes rapidly, fresh solutions must be prepared daily.

(5) TEMED: *tetramethylethylenediamine R.*

**Mounting the gel in the electrophoresis apparatus and electrophoretic separation**. After polymerisation is complete (about 30 min), remove the polytetrafluoroethylene comb carefully. Rinse the wells immediately with water or with the *SDS-PAGE running buffer R* to remove any unpolymerised acrylamide. If necessary, straighten the teeth of the stacking gel with a blunt hypodermic needle attached to a syringe. Remove the clamps on one short side, carefully pull out the tubing and replace the clamps. Proceed similarly on the other short side. Remove the tubing from the bottom part of the gel. Mount the gel in the electrophoresis apparatus. Add the electrophoresis buffers to the top and bottom reservoirs. Remove any bubbles that become trapped at the bottom of the gel between the glass plates. This is best done with a bent hypodermic needle attached to a syringe. Never pre-run the gel before loading the samples, since this will destroy the discontinuity of the buffer systems. Before loading the sample carefully rinse each well with *SDS-PAGE running buffer R*. Prepare the test and reference solutions in the recommended sample buffer and treat as specified in the individual monograph. Apply the appropriate volume of each solution to the stacking gel wells.

Start the electrophoresis using the conditions recommended by the manufacturer of the equipment. Manufacturers of SDS-PAGE equipment may provide gels of different surface area and thickness and electrophoresis running time and current/voltage may vary in order to achieve optimal separation. Check that the dye front is moving into the resolving gel. When the dye is near the bottom of the gel, stop the electrophoresis. Remove the gel assembly from the apparatus and carefully separate the glass plates. Remove the spacers, cut off and discard the stacking gel and immediately proceed with staining.

5-2. *SDS-PAGE - GRADIENT CONCENTRATION GELS*

Gradient gels (resolving gels) are prepared with an increasing concentration of acrylamide from the top to the bottom. Preparation of gradient gels requires a gradient-forming apparatus. Ready-to-use gradient gels are commercially available with specific recommended protocols.

Gradient gels offer some advantages, as some proteins which co-migrate on fixed-concentration gels can be resolved within gradient gels. During electrophoresis, the proteins migrate until the pore size prevents further progress and a stacking effect therefore occurs, resulting in sharper bands. As shown in Table 2.2.31.-3, gradient gels also allow separation of proteins with a wider range of molecular masses compared to a single fixed concentration gel.

The table gives suggested compositions of the linear gradient, relating the range of acrylamide concentrations to the appropriate protein molecular mass ranges. Note that other gradient shapes (e.g. concave) can be prepared for specific applications.

Table 2.2.31.-3

| Acrylamide (per cent) | Protein range (kDa) |
|---|---|
| 5 - 15 | 20 - 250 |
| 5 - 20 | 10 - 200 |
| 10 - 20 | 10 - 150 |
| 8 - 20 | 8 - 150 |

Gradient gels are also used for the determination of molecular mass and protein purity.

5-3. *DETECTION OF PROTEINS IN GELS*

Coomassie and silver staining are the most common protein staining methods and are described in more detail below. Several other commercial stains, detection methods and commercial kits are available. For example, fluorescent stains are visualised using a fluorescent imager and often provide a linear response over a wide range of protein concentrations, often several orders of magnitude depending on the protein. Coomassie staining has a protein detection level of approximately 1 µg to 10 µg of protein per band. Silver staining is the most sensitive method for staining proteins in gels and a band containing 10 ng to 100 ng can be detected. These figures are considered robust in the context of these gels. Improved sensitivity of 1 or 2 orders of magnitude has sometimes been reported in the literature.

Coomassie staining responds in a more linear manner than silver staining; however, the response and range depend on the protein and development time. Both Coomassie and silver staining can be less reproducible if staining is stopped in a subjective manner, i.e. the point at which the staining is deemed satisfactory. The use of dynamic ranges of reference proteins is very important as they help assess the intra-experimental sensitivity and linearity. All gel staining steps are carried out while wearing gloves, at room temperature, with gentle shaking (e.g. on an orbital shaker platform) and using any convenient container.

**Coomassie staining**. Immerse the gel in a large excess of *Coomassie staining solution R* and allow to stand for at least 1 h. Remove the staining solution.

Destain the gel with a large excess of *destaining solution R*. Change the destaining solution several times, until the stained protein bands are clearly distinguishable on a clear background. The more thoroughly the gel is destained, the smaller is the amount of protein that can be detected by the method. Destaining can be speeded up by including a few grams of anion-exchange resin or a small sponge in the *destaining solution R*.

*NOTE: the acid-alcohol solutions used in this procedure do not completely fix proteins in the gel. This can lead to losses of some low-molecular-mass proteins during the staining and destaining of thin gels. Permanent fixation is obtainable by allowing the gel to stand in a mixture of 1 volume of trichloroacetic acid R, 4 volumes of methanol R and 5 volumes of water R for 1 h before it is immersed in the Coomassie staining solution R.*

**Silver staining**. Immerse the gel in a large excess of *fixing solution R* and allow to stand for 1 h. Remove the fixing solution, add fresh fixing solution and incubate either for at least 1 h or overnight, if convenient. Discard the fixing solution and wash the gel in a large excess of *water R* for 1 h. Soak the gel for 15 min in a 1 per cent *V/V* solution of *glutaraldehyde R*. Wash the gel twice for 15 min in a large excess of *water R*. Soak the gel in fresh *silver nitrate reagent R* for 15 min, in darkness. Wash the gel three times for 5 min in a large excess of *water R*. Immerse the gel for about 1 min in *developer solution R* until satisfactory staining has been obtained. Stop the development by incubation in the *blocking solution R* for 15 min. Rinse the gel with *water R*.

5-4. *RECORDING OF THE RESULTS*

Gels are photographed or scanned while they are still wet or after an appropriate drying procedure. Currently, gel scanning systems with data analysis software are commercially available to immediately photograph and analyse the wet gel.

Depending on the staining method used, gels are treated in a slightly different way. For Coomassie staining, after the destaining step, allow the gel to stand in a 100 g/L solution of *glycerol R* for at least 2 h (overnight incubation is possible). For silver staining, add to the final rinsing a step of 5 min in a 20 g/L solution of *glycerol R*.

Drying of stained SDS polyacrylamide gels is one of the methods used to obtain permanent documentation. This method frequently results in the cracking of gel during drying between cellulose films.

Immerse 2 sheets of porous cellulose film in *water R* and incubate for 5 min to 10 min. Place one of the sheets on a drying frame. Carefully lift the gel and place it on the cellulose film. Remove any trapped air bubbles and pour a few millilitres of *water R* around the edges of the gel. Place

the second sheet on top and remove any trapped air bubbles. Complete the assembly of the drying frame. Place in an oven or leave at room temperature until dry.

5-5. *MOLECULAR-MASS DETERMINATION*

Molecular masses of proteins are determined by comparison of their mobilities with those of several marker proteins of known molecular weight. Mixtures of pre-stained and unstained proteins with precisely known molecular masses blended for uniform staining are available for calibrating gels. They are available in various molecular mass ranges. Concentrated stock solutions of proteins of known molecular mass are diluted in the appropriate sample buffer and loaded on the same gel as the protein sample to be examined.

Immediately after the gel has been run, the position of the bromophenol blue tracking dye is marked to identify the leading edge of the electrophoretic ion front. This can be done by cutting notches in the edges of the gel or by inserting a needle soaked in India ink into the gel at the dye front. After staining, measure the migration distances of each protein band (markers and unknowns) from the top of the resolving gel. Divide the migration distance of each protein by the distance travelled by the tracking dye. The normalised migration distances are referred to as the relative mobilities of the proteins (relative to the dye front), or $R_F$. Construct a plot of the logarithm of the relative molecular masses ($M_r$) of the protein standards as a function of the $R_F$ values. Unknown molecular masses can be estimated by linear regression analysis (or more accurately by non-linear regression analysis) or interpolation from the curves of log $M_r$ against $R_F$ if the values obtained for the unknown samples are positioned along the approximately linear part of the graph.

5-6. *VALIDATION OF THE TEST*

The test is not valid unless the target resolution range of the gel has been demonstrated by the distribution of appropriate molecular mass markers, e.g. across 80 per cent of the length of the gel. The separation obtained for the expected proteins must show a linear relationship between the logarithm of the molecular mass and the $R_F$. If the plot has a sigmoidal shape, then only data from the linear region of the curve can be used in the calculations. Additional validation requirements with respect to the test sample may be specified in individual monographs.

Sensitivity must also be validated. A reference protein control corresponding to the desired concentration limit that is run in parallel with the test samples can serve to establish system suitability.

5-7. *QUANTIFICATION OF IMPURITIES*

SDS-PAGE is often used as a limit test for impurities. When impurities are quantified by normalisation to the main band using an integrating densitometer or image analysis, the responses must be validated for linearity. Note that depending on the detection method and protein as described in the introduction of section 5-3, the linear range can vary but can be assessed within each run by using one or more control samples containing an appropriate range of protein concentration.

Where the impurity limit is specified in the individual monograph, a reference solution corresponding to that level of impurity should be prepared by diluting the test solution. For example, where the limit is 5 per cent, a reference solution would be a 1:20 dilution of the test solution. No impurity (any band other than the main band) in the electropherogram obtained with the test solution may be more intense than the main band obtained with the reference solution.

Under validated conditions, impurities may be quantified by normalisation to the main band using an integrating densitometer or by image analysis.

**07/2019:20232**

# 2.2.32. LOSS ON DRYING

PRINCIPLE

Loss on drying is the loss of mass after drying under specified conditions, calculated as a percentage (*m/m*).

Drying to constant mass means that 2 consecutive weighings do not differ by more than 0.5 mg, the 2nd weighing following an additional period of at least 30 min of drying under the conditions prescribed for the substance to be examined.

EQUIPMENT

The equipment typically consists of:

- weighing bottles that are made of suitable inert material and can easily be dried to constant mass; their diameter is large enough so that the layer of the substance to be examined does not exceed about 5 mm;
- an analytical balance by which it is possible to determine a change in mass of 0.1 mg;
- depending on the procedure to be applied, a desiccator, a vacuum cabinet, a vacuum oven or an ordinary laboratory oven; in any case, the temperature of ovens is adjustable to the specified temperature ± 2 °C; vacuum ovens in which the pressure can at least be reduced to about 2 kPa are suitable; ovens are qualified according to established quality system procedures, for example by using a suitable certified reference material (*sodium aminosalicylate dihydrate for equipment qualification CRS* may be used).

Equipment using other means of drying such as microwaves, halogen lamps, infrared lamps or mixed technologies may be used provided they are demonstrated to be fit for purpose.

PROCEDURE

It is recommended to perform the test in an environment that has minimal impact on sample measurement (e.g. humidity).

Weigh an empty weighing bottle that has been previously dried under the conditions prescribed for the substance to be examined for at least 30 min, then weigh the weighing bottle filled with the prescribed quantity of substance to be examined. Dry to constant mass or for the prescribed time. Where the drying temperature is indicated by a single value rather than a range, drying is carried out at the prescribed temperature ± 2 °C. Use one of the following procedures, unless otherwise prescribed in the monograph.

- In a desiccator: the drying is carried out over about 100 g of *molecular sieve R* at atmospheric pressure and at room temperature.
- *In vacuo*: the drying is carried out over about 100 g of *molecular sieve R* at a pressure not exceeding 2.5 kPa, at room temperature or at the temperature prescribed in the monograph.
- In an oven at a specified temperature: the drying is carried out at atmospheric pressure in an oven at the temperature prescribed in the monograph.

After drying in an oven, allow the weighing bottle and the sample to cool to room temperature in a desiccator and weigh the weighing bottle containing the dried sample.

The mass of the sample is the difference between the mass of the filled weighing bottle and the mass of the dried empty weighing bottle.

The loss on drying is the difference in the mass of the sample before and after drying, expressed as a percentage, *m/m* being implicit.

# 2.2.33. NUCLEAR MAGNETIC RESONANCE SPECTROMETRY

## INTRODUCTION

Nuclear magnetic resonance (NMR) spectrometry is an analytical method in particular suitable for the elucidation of the chemical structure of organic molecules by means of interpretation of their NMR spectra, arising from, for example, $^{1}H$ or the X-nuclei $^{13}C$, $^{19}F$, $^{15}N$, $^{31}P$. The spectra can be used for qualitative and quantitative purposes.

Under suitable experimental conditions, the integrated NMR intensities of the signals are directly proportional to the number of nuclear spins of the molecular group responsible for the signal. These integrals can be used for quantitative analysis.

## GENERAL PRINCIPLES

Placing an ensemble of nuclei with angular momentum and a magnetic moment in a static magnetic field ($B_0$) causes the nuclei to arrange themselves in different, quantum-mechanically controlled orientations in relation to the axis of the magnetic field. These orientations are different in energy. An oscillating high-frequency magnetic field ($B_1$), perpendicular to $B_0$, will cause transitions between these orientations with net energy absorption. According to the resonance condition $\omega_0 = \gamma B_0$ ($\gamma$ = gyromagnetic ratio, $\omega_0$ = Larmor frequency), either the $B_0$ magnetic field or the frequency ($\omega_1$) of the $B_1$ field may be varied to achieve a spectrum (continuous wave (CW) method). Nowadays the $B_1$ irradiation is achieved by the use of a radiofrequency (RF) pulse (Fourier transform (FT) method). The coherent radiation emitted during the return to the initial state is observed in the form of a decay curve, called the free induction decay (FID). Subsequent Fourier transformation gives the spectrum in the frequency domain, providing information about the molecular structure. Additional radiofrequency fields may be applied during acquisition of the FID signal to suppress scalar (through-bond) interactions between nuclei (called 'decoupling'). One- and multi-dimensional techniques can be applied for qualitative and quantitative purposes, on samples in either the liquid or the solid state.

Important structural information is derived from the following spectroscopic features:

| | |
|---|---|
| resonance frequency | kind of nuclei observed |
| number of resonance signals (singlets, multiplets) | number of chemically distinct groups of nuclei |
| chemical shift δ (ppm) | chemical nature and environment of the structural group observed |
| intensity of resonance signals | relative number of resonant nuclei per chemically distinct group |
| multiplicity of coupling pattern | number of nuclei that are scalar coupled to the observed nucleus |
| coupling constant $^{n}J$ (Hz) | number of bonds in the coupling pathway, and its geometry |

Correlations of different spectral parameters (e.g. chemical shift and coupling constant, or chemical shifts of different nuclei within one molecular system) can be performed by homo- and hetero-nuclear two- and higher-dimensional methods. Information about the relaxation times $T_1$ and $T_2$, nuclear Overhauser effects (NOEs) and the kinetics of time-dependent processes are also accessible from appropriate experiments.

## APPARATUS

A high-resolution NMR spectrometer consists of at least the following parts:

- a magnet to deliver the constant magnetic field $B_0$;
- a temperature-controlled probe to contain the sample, to deliver the radiofrequency pulse and to detect radiation emitted by the sample;
- an electronic console to generate high-power radiofrequency pulses and to collect and digitise the FID signal; this unit also maintains the stability of the instrument electronics;
- a data acquisition and processing unit (computer);

and may also include:

- a continuous flow cell for coupled liquid chromatographic-NMR or flow injection analysis;
- a system for pulsed field gradient NMR.

The high magnetic field is generated by a superconducting coil in a Dewar flask filled with liquid helium. The probe typically contains the sample in a 5 mm-outer-diameter sample tube or in a flow cell, and is connected to the electronics cabinet by RF cables carrying lock, $^{1}H$-, and X-nucleus frequencies. Additional devices for tuning and matching the electronic circuits are essential, and sample temperature control is often used.

The NMR spectrometer should be demonstrated to be operating correctly. Appropriate tests to demonstrate this are, typically, measurement of linewidths at half height for defined peaks under defined acquisition conditions, signal-to-noise ratios (*S/N*) for standard mixtures, pulse power (measured as a 90° pulse width), and pulse reproducibility. All instrument manufacturers publish specifications and measurement protocols for these parameters for specific instrument/probe combinations, and compliance with these specifications should be demonstrated.

## FOURIER TRANSFORM NMR (FT-NMR)

Contemporary spectrometers generally operate according to the Fourier transform (FT) principle: after exciting the sample with a radiofrequency pulse of appropriate frequency (ν), amplitude ($B_1$) and duration ($\tau_p$) and a succeeding short dead time ($t_d$) (to enable the electronics to recover), the amplified analogue FID signal is sampled during the acquisition time ($t_{ac}$) and digitised with an analogue-to-digital converter (ADC), and the results are stored in the spectrometer memory. The receiver output is amplified prior to digitisation to maximise sensitivity without saturating the ADC. In case of observation of X-nuclei, the standard experiment includes, if necessary, broadband $^{1}H$ decoupling, i.e. irradiation of all the protons during the experiment. To increase the *S/N*, multiple FID signals may be accumulated coherently and summed. Fourier transformation of this time-domain data gives the frequency-domain spectrum.

### *PARAMETERS*

The following acquisition parameters influence the result of an FT experiment, and should be adjusted and controlled.

**Pulse width ($\tau_p$).** The excitation pulse is directed along the x-axis of the so-called rotating frame, its duration (or 'width', $\tau_p$) determines the flip angle (θ) and thus the intensity (*I*) of the resonance signal:

$$\theta = \gamma' \times B_1 \times \tau_p \quad (1)$$

$$M_y = M_o \times \sin\theta \quad (2)$$

The observed magnetisation $M_y$ is maximum at θ = 90°. The pulse duration should be short to guarantee that all signals in the spectral width (*SW*) are excited to a similar degree. The magnetisation decays due to relaxation processes.

**Dead time ($t_d$).** The dead time is the time between the end of the pulse and start of the acquisition, it is necessary for technical reasons and care should be taken as it may influence signal intensities and peak phase. Rapidly decaying signals

(giving rise to broad spectral lines) are reduced in intensity by more than slowly decaying signals (which give rise to narrow spectral lines).

**Acquisition time ($t_{ac}$)**. The acquisition time ($t_{ac}$) is related to the spectral width (i.e. the whole observed region) and the number of digital data points (*DP*) collected during signal acquisition.

$$t_{ac} = \frac{DP}{2SW} \qquad (3)$$

Maximal signal intensity and signal-to-noise ratio will be achieved if $t_{ac} \approx 1.2/(\pi\nu_{1/2})$, where $\nu_{1/2}$ is the full width at half-height (*fwhh*), but it should be set to greater than $5/(\pi\nu_{1/2})$ to minimise signal distortion.

**Repetition time ($t_r$)**. The spin-lattice relaxation ($T_1$) governs the time required for the spin system to return to equilibrium after a pulse. Relaxation can be reduced by the use of special reagents. For quantitative purposes, the repetition time used should be set relative to $T_1$ and θ to avoid saturation effects.

**Receiver gain**. The analogue signal detected by the probe is amplified prior to digitisation and storage. The amplification, or receiver gain, should be set, either automatically or manually, so that the signal does not overload the ADC, which causes signal distortion, but allows random noise generated in the probe to be digitised (i.e. is non-zero).

*OPTIMISATION OF ACQUISITION AND PROCESSING PARAMETERS FOR QUANTITATIVE PURPOSES*

Besides the acquisition parameters, signal intensity is also influenced by several processing parameters. After collecting a sufficient number of scans, the resulting FID is Fourier transformed. For reliable quantitative purposes the following parameters have to be optimised.

**Digital resolution**. The digital resolution is the frequency separation between data points. The processed signal should have at least 5 digital points above half-height of the signals to be integrated. To improve the digital resolution additional points of zero intensity may be added to the end of the experimental FID before transformation ('zero filling').

**Signal-to-noise ratio (*S/N*)**. This is the ratio between the intensities (as peak height) of a specified signal in the NMR spectrum and the random fluctuations in that signal, which is usually measured in a region of the spectrum that contains no signals from the analyte. A poor signal-to-noise ratio (*S/N*) limits the accuracy of peak integrations and quantitative analyses. An *S/N* equal to or greater than 150:1 allows peak integrations with a standard deviation of less than 1 per cent. Contemporary spectrometers have software algorithms to report the *S/N* of appropriate peaks. A sufficiently high *S/N* can be difficult to obtain when analysing dilute solutions, and especially when detecting nuclei other than $^1$H. Methods to enhance the *S/N* include:

- increasing the number of accumulated scans (*n*), as *S/N* increases with $\sqrt{n}$;
- use of exponentional multiplication on the FID signal before Fourier transformation; the exponentional multiplication factor should be in the order of the peak full width at half-height (*fwhh*);
- use of spectrometers with a higher magnetic field $B_0$, since *S/N* is proportional to $B_0^{3/2}$;
- use of digital filtering to reduce noise;
- use of probes that maximise the filling factor;
- use of cryoprobes that reduce thermal noise.

**Integration region**. The intensity of the NMR signals is obtained by a quasi-analogue signal integration either by a stepped-line plot or, more accurately, by separate line integration and digital data presentation. In liquid state, NMR signals have Lorentzian line shape. Unless otherwise specified in the monograph or when peak overlap occurs, the same integration range, expressed as a multiple of the peak *fwhh*, should be used for the monitored peak and the reference peak.

**Dynamic range**. The dynamic range of the analogue-to-digital converter (ADC) determines the minimum intensity line that can be observed or quantified when integrating 2 signals with the same linewidth in a spectrum. A 16-bit ADC allows identification of a signal of 0.003 per cent intensity relative to a strong signal completely filling the dynamic range of the ADC.

*NMR OF SAMPLES IN SOLUTION*

Most NMR experiments are performed on dilute solutions (about 1 per cent) of the analyte in an appropriate solvent, which can be spiked with a suitable standard for chemical shift calibration.

**Solvents**. The solvent should be able to dissolve the analyte without further interaction if not otherwise intended. To minimise the intense solvent signals, fully deuterated solvents (*deuterium oxide R*, *deuterated chloroform R*, *deuterated dimethyl sulfoxide R*, *deuterated acetone R*, *deuterated methanol R*, etc.) should be used. The solvent atoms give signals that are easily identified by their chemical shift and can be used to calibrate the chemical shift axis (secondary reference).

**Referencing**. The spectral feature most dependent on the chemical environment of the atom in the molecule is the chemical shift, designated as δ and reported in parts per million. The chemical shift between the resonance for an NMR active nucleus X ($\delta_{X,sample}$) is measured in parts per million as the difference between the resonance frequency of that nucleus ($\nu_{X,sample}$) and that of an internal shift reference standard ($\nu_{X,reference}$), both in hertz, divided by the basic spectrometer operating frequency ($\nu_{X,reference}$), in megahertz, at a given $B_0$:

$$\delta_{X,sample} = \frac{(\nu_{X,sample} - \nu_{X,reference})}{\nu_{X,reference}} \qquad (4)$$

By convention, the standard for exact chemical shift referencing is the $^1$H resonance of *tetramethylsilane R* (TMS), setting $\delta_{TMS}$ = 0 ppm. Formally, once the $^1$H shift scale has been referenced relative to TMS, the exact frequency of any other X resonance can be calculated and its chemical shift scale calibrated. The frequency of a (secondary) reference standard at $\delta_X$ = 0 ppm ($\nu_{X,reference}$) is calculated from the $^1$H frequency of TMS ($\nu_{H,TMS}$) and a tabulated value of the ratio ($\Xi_{X,reference}$) of the isotope-specific frequency in relation to that of $^1$H in TMS:

$$\nu_{X,reference} = \nu_{H,TMS} \times \Xi_{X,reference} \qquad (5)$$

Reference standards at $\delta_X$ = 0 ppm and corresponding $\Xi_{X,reference}$ values are shown below:

| Nucleus | Water[a] | $\Xi_{X,reference}$ | Other solvents | $\Xi_{X,reference}$ |
|---|---|---|---|---|
| $^1$H | DSS[b] | 1.00000000 | TMS | 1.00000000 |
| $^{13}$C | DSS[b] | 0.25144953 | TMS | 0.25145020 |
| $^{15}$N | $NH_3$ | 0.10132912 | $CH_3NO_2$ | 0.10136767 |
| $^{19}$F | $CF_3COOH$ | not reported | $CCl_3F$ | 0.94094011 |
| $^{31}$P | $H_3PO_4$ (85 per cent) | 0.40480742 | $(CH_3O)_3PO$ | 0.40480864 |
| [a]chemical shift depends on pH | | | | |
| [b]DSS = sodium 2,2-dimethyl-2-silapentane-5-sulfonate | | | | |

In practice, X chemical shifts are referenced directly using an appropriate standard. In $^1$H and $^{13}$C NMR, internal referencing is mainly used, where the reference is added directly to

the system under study. In $^{15}N$, $^{19}F$ and $^{31}P$ NMR, external referencing is often suitable, involving sample and reference contained separately in coaxial cylindrical sample tubes.

**Lock**. In order to prevent drifting of the spectrum over time, a stabilising procedure, called field-frequency locking, is performed. The $^{2}H$ (deuterium) signal arising from deuterated solvents is used to achieve this, unless otherwise specified in the monograph.

*QUALITATIVE ANALYSIS*

The principal use for qualitative NMR spectra is as an identity test, in which the $^{1}H$ or $^{13}C$ spectrum of a test sample is compared to the spectrum of a reference sample or, less commonly, with a published reference spectrum. Spectra of reference and test samples should be acquired using the same procedure and operational conditions. The peaks in the 2 spectra, or characteristic regions of the spectra, should correspond in position, intensity and multiplicity. In appropriate cases, mathematical comparison, such as calculation of a correlation coefficient, may be appropriate. In the absence of a reference standard, an in-house reference may be used, whose identity has been demonstrated by alternative methods, or the demonstration that the NMR spectrum is fully consistent with the reported structure for that material.

*QUANTITATIVE ANALYSIS*

Signal intensity in the basic NMR experiment is the integrated area under the signal curve measured. Only when 2 signals have equal *fwhh* and the same multiplicity may signal height serve as a measure of intensity. Under conditions of essentially complete relaxation between scans, the signal intensity ($I_A$) is a true measure of the number ($N_A$) of nuclei responsible for the respective signal:

$$I_A = K_S \times N_A \tag{6}$$

The constant $K_S$ includes fundamental constants, properties of the sample and receiver parameters, and can be omitted in cases where signal intensities are compared, giving the direct relation between the numbers of nuclei in the 2 compared structure groups A and B:

$$\frac{I_A}{I_B} = \frac{N_A}{N_B} \tag{7}$$

The numbers ($N_i$) of nuclei belonging to different structure groups of 1 molecule are small integers. The values measured are rounded to the closest integer numbers. However, the proper operation of acquisition and processing of the spectrometer is easily checked by comparing exact intensities within a spectrum of any suitable organic compound of known structure.

In addition to the fact that the intensities of signals arising from each component in a mixture are related to each other by small integer numbers, the relative molar amounts of these components can be measured by comparison of the normalised intensities of resonances from different components. The molar ratio of 2 components of a mixture is calculated according to the following equation:

$$\frac{n_A}{n_B} = \frac{I_A}{I_B} \times \frac{N_B}{N_A} \tag{8}$$

The determination is only valid in cases where the structure of the molecules for which $I_A$ and $I_B$ are determined are known (or at least the values of $N$ for the monitored groups). Determinations are made using either an internal standard method or a peak-normalisation procedure.

**Internal standard method**. The mass ($m_A$) of an analyte (A) can be determined if a known mass ($m_B$) of a substance (B) with a known percentage content ($P_B$) is added to the solution as an intensity standard. Equation (8) can be converted to equation (9):

$$m_A = \frac{I_A}{I_B} \times \frac{N_B}{N_A} \times \frac{M_A}{M_B} \times m_B \times \frac{P_B}{100} \tag{9}$$

Here, $M_i$ are the molecular masses.

The intensity standard has to be carefully chosen; it should be completely soluble in the solvent used for the analyte, should produce only a small number of signals, and the 'monitor group' should have a signal in an empty spectral region. A compound of high purity and with a relatively high molecular mass is recommended for this purpose.

**Normalisation procedure**. The relative proportions of components in a mixture, the degree of substitution in a structurally modified polymer, or the amount of a contaminant can be determined by comparison of the relative intensities of resonances present.

The experimental method should be validated to ensure that there is no overlap of the relevant signals. When the contaminant is of poorly defined structure or molecular mass (e.g. an emulsifier), addition of known amounts of that material to the NMR tube will allow a calibration curve to be constructed.

METHOD

**Sample handling**. Dissolve the sample in the solvent to which the appropriate reference material may have been added to calibrate chemical shift, as prescribed in the monograph. For quantitative analysis, the solutions must be free from solid particles. Some quantitative analyses may require an internal standard to be included, so that integrations of resonances from the test sample and the reference material can be compared. Appropriate references and concentrations are indicated in the specific monographs. In other quantitative analyses, the result is obtained by comparing the relative intensities of 2 or all of the resonances that arise from the test sample. After loading the sample into a tube and capping, the sample is introduced into the NMR magnet, the experimental parameters are loaded and the experiment is executed. Key experimental parameters are indicated in the monograph.

**The measurement procedure**. Equilibrate the sample in the probe, and optimise the instrument to achieve best resonance conditions and to maximise the *S/N* by tuning and matching the probe, and make adjustments to maximise magnetic field homogeneity over the sample volume (called 'shimming'). Record, or save to computer, the parameter settings. An experiment may be composed of multiple pulse-acquisition-delay sequences, and the individual FIDs are summed in the computer memory, with random noise being averaged out. When an appropriate *S/N* has been achieved, the FID is stored and the frequency-domain spectrum is generated by Fourier transformation of the summed FIDs.

NMR IN THE SOLID STATE

Samples in the solid state can be analysed using NMR spectrometers specially equipped for that purpose. Certain technical procedures make observable individual lines for individual atomic sites with a valuable extension of the applicability of NMR to inorganic materials as well.

One technique is the rapid rotation (4-30 kHz) of the powdered sample in a rotor (about 4 mm outer diameter) inclined at an angle of 54.7° (the 'magic angle') to the direction of the $B_0$ magnetic field axis. This technique is named magic angle spinning (MAS). Another effective tool is high-power decoupling and a 3rd method is the transfer of polarisation from easily excitable nuclei towards less-polarisable nuclei, i.e. cross polarisation (CP). The combination of these techniques makes available high-resolution spectra containing much information about chemical and structural details in solid glassy, amorphous, and crystalline materials of ceramic, polymeric or mineralogical origin.

If NMR is applied to a solid, full details of the procedure are provided in the monograph.

# 2.2.34. THERMAL ANALYSIS[3]

Thermal analysis is a group of techniques in which the variation of a physical property of a substance is measured as a function of temperature. The most commonly used techniques are those which measure changes in the mass or energy of a sample of a substance.

These techniques have different applications:

- determination of phase changes;
- determination of changes in chemical composition;
- determination of purity.

## THERMOGRAVIMETRY

Thermogravimetry (TG) or thermogravimetric analysis (TGA) is a technique in which the mass of a sample of a substance is recorded as a function of temperature according to a controlled temperature programme.

**Instrument**. The essential components of a thermobalance are a device for heating or cooling the substance according to a given temperature programme, a sample holder in a controlled atmosphere, an electrobalance and a means of electronic signal output to a recorder or a computer.

**Temperature calibration**. The temperature sensor close to or in contact with the sample is calibrated using the Curie temperature of a ferromagnetic substance such as nickel. In the case of an instrument capable of simultaneously conducting TG/TGA and differential thermal analysis (DTA) or differential scanning calorimetry (DSC), the same certified reference materials as those for DTA and DSC may be used, for example, indium, tin and/or zinc.

**Calibration of the electrobalance**. Place an appropriate quantity of a suitable certified reference material (e.g. *calcium oxalate monohydrate CRS*) in the sample holder and record the mass. Set the heating rate according to the manufacturer's instructions (e.g. 5 °C/min) and start the temperature increase. Record the thermogravimetric curve as a graph with temperature or time on the abscissa, increasing from left to right, and mass on the ordinate, decreasing downwards. Stop the temperature increase at about 250 °C. Measure the difference on the graph between the initial and final mass-temperature or mass-time plateaux, which corresponds to the loss of mass. The declared loss of mass for the certified reference material is stated on the label.

**Method**. Apply the same procedure to the substance to be examined using the conditions prescribed in the monograph. Calculate the loss of mass of the substance to be examined from the difference measured in the graph obtained. Express the loss of mass as $\Delta m/m$ (per cent).

If the instrument is in frequent use, carry out temperature calibration regularly. Otherwise, calibration is carried out before each measurement.

As the operating conditions are critical, the following parameters are noted for each measurement: pressure or flow rate, gas composition, mass of the sample, heating rate, temperature range and sample pre-treatment including any isothermal period.

## DIFFERENTIAL SCANNING CALORIMETRY

Differential scanning calorimetry (DSC) is a technique that can be used to demonstrate the energy phenomena produced during heating (or cooling) of a substance (or a mixture of substances) and to determine the changes in enthalpy and specific heat and the temperatures at which these occur. The technique is used to determine the difference in heat flow (with reference to the temperature) evolved or absorbed by the test sample compared with the reference cell, as a function of the temperature. Two types of DSC instruments are available, those using power compensation to maintain a null temperature difference between sample and reference and those that apply a constant rate of heating and detect temperature differential as a difference in heat flow between sample and reference.

**Instrument**. The instrument for power compensation DSC consists of a furnace containing a sample holder with a reference cell and a test cell. The instrument for heat flow DSC consists of a furnace containing a single cell with a sample holder for the reference crucible and the test crucible.

A temperature-programming device, thermal detector(s) and a recording system which can be connected to a computer are attached. The measurements are carried out under a controlled atmosphere.

**Calibration of the instrument**. Calibrate the instrument for temperature and enthalpy change, using suitable certified materials or reference standards.

*Temperature calibration*. It can be performed using certified reference materials having an intrinsic thermal property, such as the melting point of pure metals or organic substances, or the phase transition point of crystalline inorganic salts or oxides. Melting points of indium, tin and/or zinc are usually employed for calibration.

*Heat-quantity calibration*. For accurate estimation of the quantity of heat change (enthalpic change) of a test sample, caused by a certain physical change accompanying a temperature change, it is necessary to calibrate the instrument using suitable certified reference materials. Similar to temperature calibration, heat-quantity calibration may be performed using suitable certified reference materials showing a known definite enthalpic change caused by physical changes, such as the melting of pure metals and/or organic substances, or the phase transition of crystalline inorganic salts. The heats of fusion of indium, tin and/or zinc are usually employed for calibration.

**Operating procedure**. Weigh in a suitable crucible an appropriate quantity of the substance to be examined and place it in the sample holder. Place an empty crucible in the reference holder. Set the initial and final temperatures, and the heating rate according to the operating conditions prescribed in the monograph.

Begin the analysis and record the DSC curve with the temperature or time on the abscissa (values increasing from left to right) and the energy change on the ordinate (specify whether the change is endothermic or exothermic).

The temperature at which the phenomenon occurs (the onset temperature) corresponds to the intersection (A) of the extension of the baseline with the tangent at the point of greatest slope (inflexion point) of the curve (see Figure 2.2.34.-1). The end of the thermal phenomenon is indicated by the peak of the curve.

The enthalpy of the phenomenon is proportional to the area under the curve limited by the baseline; the proportionality factor is determined from the measurement of the heat of fusion of a known substance (e.g. indium) under the same operating conditions.

Each thermogram may be accompanied by the following data: conditions employed, record of last calibration, mass of the sample and identification (including thermal history), container, atmosphere (identity, flow rate, pressure), direction and rate of temperature change, instrument and recorder sensitivity.

(3) This chapter has undergone pharmacopoeial harmonisation. See chapter *5.8 Pharmacopoeial harmonisation*.

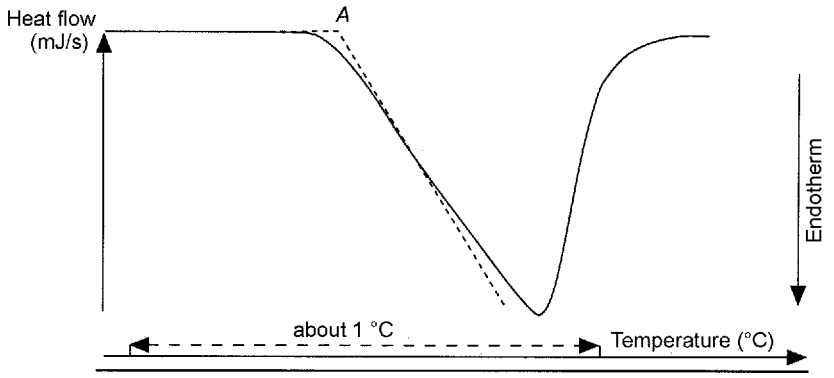

Figure 2.2.34.-1. – *Thermogram*

**Applications**

*Phase changes.* Determination of the temperature, heat capacity change and enthalpy of phase changes undergone by a substance as a function of temperature. The transitions that may be observed include those shown in Table 2.2.34.-1.

Table 2.2.34.-1.

| | |
|---|---|
| solid - solid transition: | allotropy - polymorphism<br>desolvation<br>amorphous-crystalline |
| solid - liquid transition: | melting<br>glass-transition |
| solid - gas transition: | sublimation |
| liquid - solid transition: | freezing<br>recrystallisation<br>glass-transition |
| liquid - gas transition: | evaporation |

*Changes in chemical composition.* Measurement of heat and temperatures of reaction under given experimental conditions, so that, for example, the kinetics of decomposition or desolvation can be determined.

*Application to phase diagrams.* Establishment of phase diagrams for solid mixtures. The establishment of a phase diagram may be an important step in the preformulation and optimisation of the freeze-drying process.

*Determination of purity.* The measurements of the fraction of substance melted at a given temperature and the heat of fusion by DSC enable the impurity content of a substance to be determined from a single thermal diagram, requiring the use of only a few milligrams of sample with no need for repeated accurate measurements of the true temperature.

In theory, the melting of an entirely crystalline, pure substance at constant pressure is characterised by a heat of fusion $\Delta H_f$ in an infinitely narrow range, corresponding to the melting point $T_0$. A broadening of this range is a sensitive indicator of impurities. Therefore, samples of the same substance, whose impurity contents vary by a few tenths of a per cent, give thermal diagrams that are visually distinct (see Figure 2.2.34.-2).

The determination of molar purity by DSC is based on the use of a mathematical approximation of the integrated form of the van't Hoff equation applied to the concentrations (not the activities) in a binary system [ $\ln(1 - x_2) \approx -x_2$ and $T \times T_0 \approx T_0^2$ ]. For low amounts of impurities ( $x_2 \ll 1$) and for temperatures close to the melting point $T_0$ the equation can be written as follows, in which $T$ and $x_2$ are variables:

$$T = T_0 - \frac{RT_0^2}{\Delta H_f} \times x_2 \qquad (1)$$

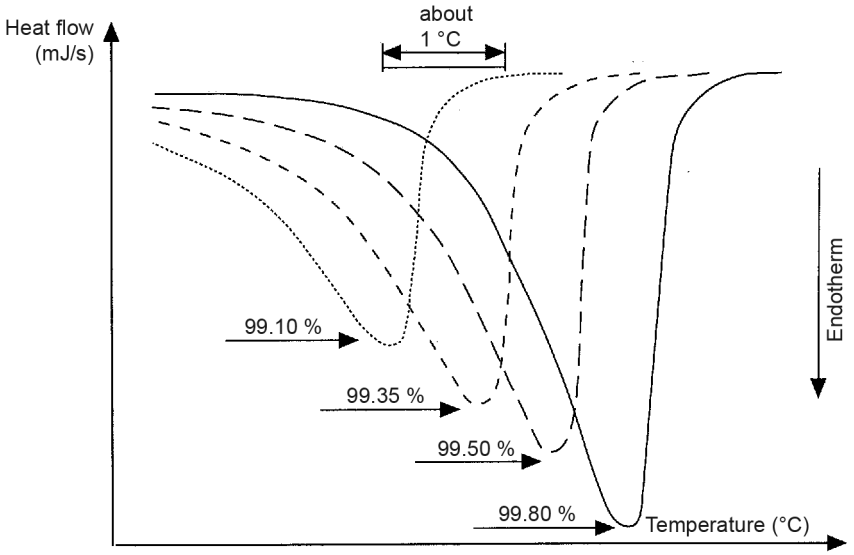

Figure 2.2.34.-2. – *Thermal diagrams according to purity*

$T$ = temperature of the sample, in kelvins;

$T_0$ = melting point of the chemically pure substance, in kelvins;

$R$ = gas constant for ideal gases, in joules·kelvin$^{-1}$·mole$^{-1}$;

$\Delta H_f$ = molar heat of fusion of the pure substance, in joules·mole$^{-1}$;

$x_2$ = mole fraction of the impurity, i.e., the number of molecules of the impurity divided by the total number of molecules in the liquid phase (or molten phase) at temperature $T$ (expressed in kelvins).

Hence, the determination of purity by DSC is limited to the detection of impurities forming a eutectic mixture with the principal compound and present at a mole fraction of typically less than 2 per cent in the substance to be examined.

This method cannot be applied to:

- amorphous substances;
- solvates or polymorphic compounds that are unstable within the experimental temperature range;
- impurities forming solid solutions with the principal substance;
- impurities that are insoluble in the liquid phase or in the melt of the principal substance.

During the heating of the substance to be examined, the impurity melts completely at the eutectic temperature. Above this temperature, the solid phase contains only the pure substance. As the temperature increases progressively from the eutectic temperature to the melting point of the pure substance, the mole fraction of the impurity in the liquid phase decreases, since the quantity of liquefied pure substance increases.

For all temperatures above the eutectic point:

$$x_2 = \frac{1}{F} \times x_2^* \qquad (2)$$

$F$ = molten fraction of the analysed sample;

$x_2^*$ = mole fraction of the impurity in the analysed sample.

When the entire sample has melted, $F = 1$ and $x_2 = x_2^*$.

If equation (2) is combined with equation (1), the following equation is obtained:

$$T = T_0 - \frac{RT_0^2}{\Delta H_f} \times \frac{1}{F} \times x_2^*$$

The value of the heat of fusion of the pure substance is obtained by integrating the melting peak.

The melting point $T_0$ of the pure substance is extrapolated from the plot of temperature $T$ (expressed in kelvins) versus $1/F$. The slope α of the curve (obtained after linearisation, if necessary) corresponding to $RT_0^2 \frac{x_2^*}{\Delta H_f}$, allows $x_2^*$ to be evaluated.

The fraction $x_2^*$ multiplied by 100 gives the mole fraction in per cent for total eutectic impurities.

**07/2019:20235**

# 2.2.35. OSMOLALITY

PRINCIPLE

*GENERAL*

Osmolality is a measure of the total number of chemical entities per kilogram of solvent, and thus provides an indication of the osmotic pressure of the solution. Osmolality is dependent on the molal concentration of the solute(s) in the solution, on their dissociation and on the deviation of the solution from ideal behaviour (Raoult's law).

The unit of osmolality is the osmole per kilogram (osmol/kg), but the submultiple milliosmole per kilogram (mosmol/kg) is more commonly used.

The osmolality ($\xi_m$) of a solution containing $i$ solutes is given by the expression:

$$\xi_m = \sum \nu_i m_i \Phi_{m,i}$$

$\nu_i$ = number of entities formed by the dissociation of one molecule of the $i^{th}$ solute; if the solute is non-ionic (non-dissociating), $\nu_i$ equals 1,

$m_i$ = molality of the $i^{th}$ solute in the solution, in moles per kilogram of solvent,

$\Phi_{m,i}$ = molal osmotic coefficient, a dimensionless factor.

The molal osmotic coefficient is a measure of the deviation of the solution from ideal behaviour. For an ideal solution, osmolality equals molality ($\Phi$=1).

In the case of a real, non-ideal solution, the molal osmotic coefficient is influenced by the interactions occurring amongst the components (i.e. molecules, ions, solvent) of the solution. The more complex the composition of the solution, the harder it becomes to determine $\Phi$.

For this reason, the measurement of a colligative property such as the freezing-point depression is used as a practical means of determining osmolality by obtaining an overall measure of the contribution of the various solutes present in a solution.

*PRINCIPLE OF MEASUREMENT*

Unless otherwise prescribed, osmolality is determined by measuring the freezing-point depression ($\Delta T_f$) of a solution. The relationship between osmolality and freezing-point depression is given by the expression:

$$\Delta T_f = k_f \xi_m$$

where $k_f$ is the molal cryoscopic constant, which is solvent-dependent. For water, the value of $k_f$ is 1.86 K/osmol (i.e. adding 1 mol of a non-dissociating solute to 1 kg of water results in a decrease in freezing-point of 1.86 K).

EQUIPMENT

An osmometer for freezing-point depression measurement typically consists of:

- an appropriate sample container;
- a means of cooling the sample;
- a temperature-sensitive resistor (thermistor), with an appropriate current or potential difference measurement device that can indicate a temperature depression or give osmolality values directly;
- a means of mixing the sample and/or inducing solidification when supercooling occurs.

PROCEDURE

*CALIBRATION*

Prepare reference solutions as specified in Table 2.2.35.-1, as necessary, using dried *sodium chloride R*. Commercially available certified solutions for osmometer calibration, with osmolalities equal or similar to those listed in Table 2.2.35.-1, may be used. Calibrate the equipment according to the manufacturer's instructions using *water R* to determine the zero value and at least 2 of the reference solutions listed in Table 2.2.35.-1. Confirm the calibration using at least one additional reference solution with a known osmolality (see Table 2.2.35.-1). Select a reference solution preferably with an osmolality within ± 50 mosmol/kg of the expected value for the solution to be examined or close to the centre of the expected osmolality range of the solutions to be examined. It is recommended that the reading is within ± 4 mosmol/kg of the osmolality of the chosen reference solution.

Table 2.2.35.-1. – *Reference solutions for osmometer calibration*

| Mass of *sodium chloride R* in *water R* (g/kg) | Osmolality, $\xi_m$ (mosmol/kg) | Freezing-point depression, $\Delta T_f$ (K) |
|---|---|---|
| 3.087 | 100 | 0.186 |
| 6.260 | 200 | 0.372 |
| 9.463 | 300 | 0.558 |
| 12.684 | 400 | 0.744 |
| 15.916 | 500 | 0.930 |
| 19.147 | 600 | 1.116 |
| 22.380 | 700 | 1.302 |

*METHOD*

Rinse the sample container with the solution to be examined before each measurement. Programme the device inducing solidification to start at a defined temperature below the expected freezing-point of the solution to be examined. Introduce an appropriate volume of the solution to be examined into the sample container according to the manufacturer's instructions, and start the cooling system. The equipment indicates when equilibrium has been reached.

Perform the test under the conditions (cooling temperature and volume) used to calibrate the equipment. Depending on the type of equipment, the osmolality can be read directly or can be calculated from the measured freezing-point depression.

The test is not valid unless the measured osmolality of the solution to be examined lies within the calibrated osmolality range.

# 2.2.36. POTENTIOMETRIC DETERMINATION OF IONIC CONCENTRATION USING ION-SELECTIVE ELECTRODES

Ideally, the potential $E$ of an ion-selective electrode varies linearly with the logarithm of the activity $a_i$ of a given ion, as expressed by the Nernst equation:

$$E = E_0 + 2.303\frac{RT}{z_i F}\log_{10} a_i$$

$E_0$ = part of the constant potential due to the apparatus used,

R = gas constant,

$T$ = absolute temperature,

F = Faraday's number,

$z_i$ = charge number of the ion including its sign.

At a constant ionic strength, the following holds:

$$E = E_0 + \frac{k}{z_i}\log_{10} fC_i$$

$C_i$ = molar concentration of the ion,

$f$ = the activity coefficient $(a_i = fC_i)$,

$k$ = $\dfrac{RT}{F}$

If: $E_0 + \dfrac{k}{z_i}\log_{10} f = E'_0$ and $S = \dfrac{k}{z_i}$

$S$ = slope of the calibration curve of the electrode,

the following holds: $E = E'_0 + S\log_{10} C_i$

and for $-\log_{10} C_i = pC_i$: $E = E'_0 - SpC_i$.

The potentiometric determination of the ion concentration is carried out by measuring the potential difference between two suitable electrodes immersed in the solution to be examined; the indicator electrode is selective for the ion to be determined and the other is a reference electrode.

*Apparatus.* Use a voltmeter allowing measurements at least to the nearest 0.1 millivolt and whose input impedance is at least one hundred times greater than that of the electrodes used.

Ion-selective electrodes may be primary electrodes with a crystal or non-crystal membrane or with a rigid matrix (for example, glass electrodes), or electrodes with charged (positive or negative) or uncharged mobile carriers, or sensitised electrodes (enzymatic-substrate electrodes, gas-indicator electrodes). The reference electrode is generally a silver–silver chloride electrode with suitable junction liquids producing no interference.

*Procedure.* Carry out each measurement at a temperature constant to ± 0.5 °C, taking into account the variation of the slope of the electrode with temperature (see Table 2.2.36.-1). Adjust the ionic strength and possibly the pH of the solution to be analysed using the buffer reagent described in the monograph and equilibrate the electrode by immersing it in the solution to be analysed, under slow and uniform stirring, until a constant reading is obtained.

Table 2.2.36.-1. – *Values of k at different temperatures*

| Temperature (°C) | *k* |
|---|---|
| 20 | 0.0582 |
| 25 | 0.0592 |
| 30 | 0.0602 |

If the electrode system is used frequently, check regularly the repeatability and the stability of responses, and the linearity of the calibration curve or the calculation algorithm in the range of concentrations of the test solution; if not, carry out the test before each set of measurements. The response of the electrode may be regarded as linear if the slope $S$ of the calibration curve is approximately equal to $k/z_i$, per unit of $pC_i$.

METHOD I (DIRECT CALIBRATION)

Measure at least three times in succession the potential of at least three reference solutions spanning the expected concentration of the test solution. Calculate the calibration curve, or plot on a chart the mean potential E obtained against the concentration of the ion to be determined expressed as $-\log_{10} C_i$ or $pC_i$.

Prepare the test solution as prescribed in the monograph; measure the potential three times and, from the mean potential, calculate the concentration of the ion to be determined using the calibration curve.

METHOD II (MULTIPLE STANDARD ADDITIONS)

Prepare the test solution as prescribed in the monograph. Measure the potential at equilibrium $E_T$ of a volume $V_T$ of this solution of unknown concentration $C_T$ of the ion to be determined. Make at least three consecutive additions of a volume $V_S$ negligible compared to $V_T$ ($V_S \leq 0.01 V_T$) of a reference solution of a concentration $C_S$ known to be within the linear part of the calibration curve. After each addition, measure the potential and calculate the difference of potential $\Delta E$ between the measured potential and $E_T$. $\Delta E$ is related to the concentration of the ion to be determined by the equation:

$$\Delta E = S\log_{10}\left(1 + \frac{C_S V_S}{C_T V_T}\right)$$

or

$$10^{\frac{\Delta E}{S}} = 1 + \frac{C_S V_S}{C_T V_T}$$

$V_T$ = volume of the test solution,

$C_T$ = concentration of the ion to be determined in the test solution,

$V_S$ = added volume of the reference solution,

$C_S$ = concentration of the ion to be determined in the reference solution,

$S$ = slope of the electrode determined experimentally, at constant temperature, by measuring the difference between the potentials obtained with two reference solutions whose concentrations differ by a factor of ten and are situated within the range where the calibration curve is linear.

Plot on a graph $10^{\frac{\Delta E}{S}}$ ($y$-axis) against $V_S$ ($x$-axis) and extrapolate the line obtained until it intersects the $x$-axis. At the intersection, the concentration $C_T$ of the ion to be determined in the test solution is given by the equation:

$$C_T = -\frac{C_S V_S}{V_T}$$

METHOD III (SINGLE STANDARD ADDITION)

To a volume $V_T$ of the test solution prepared as prescribed in the monograph, add a volume $V_S$ of a reference solution containing an amount of the ion to be determined known to give a response situated in the linear part of the calibration curve. Prepare a blank solution in the same conditions. Measure at least three times the potentials of the test solution and the blank solution, before and after adding the reference solution. Calculate the concentration $C_T$ of the ion to be analysed using the following equation and making the necessary corrections for the blank:

$$C_T = \frac{C_S V_S}{10^{\frac{\Delta E}{S}}(V_T + V_S) - V_T}$$

$V_T$ = volume of the test solution or the blank,

$C_T$ = concentration of the ion to be determined in the test solution,

$V_S$ = added volume of the reference solution,

$C_S$ = concentration of the ion to be determined in the reference solution,

$\Delta E$ = difference between the average potentials measured before and after adding $V_S$,

$S$ = slope of the electrode determined experimentally, at constant temperature, by measuring the difference between the potentials obtained from two reference solutions whose concentrations differ by a factor of ten and are situated within the range where the calibration curve is linear.

**01/2018:20237**

# 2.2.37. X-RAY FLUORESCENCE SPECTROMETRY

PRINCIPLE OF THE TECHNIQUE

X-ray fluorescence (XRF) analysis is based on measurements of the X-rays emitted by the constituent atoms of a sample when it is excited by an external source of radiation. If sufficiently energetic radiation impinges on an atom of the sample material, it may eject 1 of the inner-shell electrons of that atom. The vacancy created is filled by 1 of the electrons from an outer, higher-energy shell. The energy difference between the 2 electron shells involved in the process is released in the form of fluorescent X-rays. These X-rays are characteristic since their energy is specific to each element (atom). By measuring their energy and intensity, qualitative and quantitative data about the elemental composition of the test material is obtained.

XRF spectrometry is suitable for liquid, solid and powdered materials and is widely used as a means of screening pharmaceutical ingredients and products for toxic elements or elemental impurities, for quality control and in-process testing. It is also used to identify inorganic foreign elements within falsified medicinal products. As XRF can be non-invasive, it lends itself to process analytical technology (PAT) applications, such as the analysis of an unwanted trace catalyst in an active pharmaceutical ingredient.

EQUIPMENT

An XRF spectrometer (or analyser) consists of 3 essential components:

- a source of exciting radiation (e.g. an X-ray tube, an electron beam if a scanning electron microscope is used or, more rarely, a radioisotope);
- a means for reproducible sample presentation;
- a detector.

Depending on the X-ray detection method employed, either a wavelength-dispersive (WD) or an energy-dispersive (ED) XRF spectrometer is used.

In a WD-XRF spectrometer the X-rays from the sample are directed at a crystal, which diffracts them at precise angles depending on their energy. The intensity of the diffracted X-rays is measured sequentially by a detector counter.

In an ED-XRF spectrometer the X-rays from the sample are directed at a solid-state detector, which generates an electric pulse of an amplitude proportional to the energy of each X-ray photon detected. During measurement, the spectrometer acquires an X-ray spectrum of the sample that contains complete information about its composition. An ED-XRF spectrometer can also be combined with a scanning electron microscope (SEM). Substantial advances in miniaturisation and automation have led to the development of hand-held ED-XRF spectrometers for field measurements.

Some instruments are supplied with an initial factory-set calibration that allows semi-quantitative analyses to be carried out.

MATRIX EFFECTS AND INTERFERENCE

The intensity of the characteristic X-rays of the analysed elements is not necessarily linear with concentration, owing to matrix effects. The intensity of the fluorescence measured for a given element depends not only on the concentration of that element in the sample but also on the absorption of the incident and fluorescent radiations by the matrix. The presence and concentration of other elements (analytes) in the sample, the composition of the sample matrix, and the particle size of the sample material are known to contribute to matrix effects. The presence of matrix effects must be taken into account in any calibration method utilised for quantitative determination.

At low concentrations the linearity is usually well preserved, which greatly facilitates calibration of the spectrometer. The intensity of the fluorescent radiation emitted by an element in a given matrix and at a given wavelength is then proportional to the concentration of that element and inversely proportional to the mass absorption coefficient of the matrix at that wavelength.

SAMPLE PREPARATION

It is essential that the sample is sufficiently thick that the intensities of characteristic X-rays measured are not affected by variations in sample thickness.

*Liquid samples*. Samples are analysed 'as is', provided that the solution consists of a clear, single phase and has sufficiently low volatility. A special liquid-sample holder and a commercially available support window composed of a suitable polymer film (transparent to X-rays and solvent resistant) are required. Alternatively, liquid samples can be transferred onto the surface of a disc and dried before analysis.

*Powdered samples*. Samples may be analysed 'as is' in special X-ray sample cups with bottoms made of a thin polymer film, transparent to X-rays. After transferring the powder to a sample cup, the cup is tapped gently until no further settling of the powder is observed. If necessary, more powder can be added to the cup after tapping. Another alternative for preparation of a powdered sample, which is better suited to WD-XRF analysis, is to press the sample powder into a pellet, with a binder (for example cellulose powder, wax or ethylcellulose) or without a binder. The mass of reference material and sample material must be about the same and the resulting pellets must be approximatively 5 mm thick or more.

*Solid samples*. Samples are analysed by placing them directly on the spectrometer measuring window, making sure they cover it completely. Solid samples for WD-XRF may need to be cut into a uniform shape with a flat surface for reproducible analysis, whereas samples can be measured 'as is' when using ED-XRF, provided there is adequate sample depth.

*Fusion*. The fusion bead method can be used to prepare solid and powdered samples (e.g. minerals or oxides) if the element of interest is not volatile. The sample is homogeneously mixed with a flux reagent (e.g. dilithium tetraborate) and transferred to a platinum vessel; a releasing agent and/or oxidising agent may be added if necessary, for example to prevent damage of the vessel. The mixture is heated at an appropriate temperature while swirling the vessel until a homogeneous melt is obtained. If necessary, the melt is then transferred to a flat-bottomed mould, kept in a horizontal position and cooled under conditions maintaining its property as a glass.

PROCEDURE

**Measuring conditions**. The instrument is set up and used in accordance with the manufacturer's instructions. The measurements may be carried out under vacuum, nitrogen or helium to improve the sensitivity of the method for the quantitation of light elements.

**Reference standards**. Standards required for the calibration, system suitability or control of equipment performance are prepared from certified reference materials (CRMs). Standards with a high carbon load may be more representative for pharmaceutical applications.

**Calibration**. The calibration model selected must be fit for purpose. Various calibration methods are available, including the 'fundamental parameters' approach, empirical calibration, Compton/Rayleigh normalisation and multiple linear regression (MLR).

**System suitability test**. This test must be carried out before the analysis to ensure that the performance of the measurement system is satisfactory. It may also be performed to verify the calibration of the system.

*Acceptance criteria*: the measurement system is suitable if the concentration obtained for a check material containing the element(s) of interest within the used concentration range does not differ from the actual concentration by more than 5 per cent for an assay, and 20 per cent for impurity tests; when using concentrations determined from reference methods such as atomic absorption spectrometry, the accuracy of the XRF calibration should be aligned to that of the reference method; in this case an acceptance criterion of 10 per cent for the assay can be more realistic.

**Analysis**. The samples are measured with the same parameters as used during calibration of the instrument.

CONTROL OF EQUIPMENT PERFORMANCE

*These parameters are also applicable for equipment qualification.*

Specific procedures, acceptance criteria and time intervals for characterising XRF performance depend on the instrument and its intended application. Demonstrating stable instrument performance over extended periods of time provides some assurance that reliable measurements can be obtained.

The following tests may be carried out at appropriate intervals defined according to the user's quality system procedures to ensure the adequate performance of the XRF instrument.

***x*- and *y*-axes**

It is recommended that the *x*-axis (energy or peak angle) and *y*-axis (intensity) are verified at least on installation and thereafter at appropriate intervals that are defined according to the user's quality system procedures. Consideration is to be given to peak position in ED-XRF and to peak angle in WD-XRF when verifying the *x*-axis, and to the count rate when verifying the *y*-axis.

**Detector resolution**

Calculate the resolution (total width at half-height) at the energy used during calibration of the instrument.

*Acceptance criteria*: the resolution value does not deviate by more than 20 per cent for an assay, and 25 per cent for identity and elemental impurities tests, from the value determined during calibration of the instrument.

VALIDATION REQUIREMENTS

The objective of an XRF method validation is to demonstrate that the measurement procedure is fit for purpose (assay, content uniformity, limit tests and identification tests). Where sample preparation is necessary, it is essential that test materials are spiked before any preparatory steps. For example, if a test material is to be digested, the material must be spiked at the beginning of the digestion procedure.

For the determination of impurities, the validation requirements are given in general chapter *2.4.20*. For other purposes, validation is performed according to the relevant ICH guidelines.

**01/2019:20238**

# 2.2.38. CONDUCTIVITY[4]

INTRODUCTION

This general chapter provides information on how to carry out electrical conductivity measurements (hereafter referred to as 'conductivity') of fluids, including pure liquids. It is intended for fluid applications when conductivity is used to measure, monitor or control chemical dispensing (e.g. chemical purity or ionic concentration), and other applications where the ionic character of the fluid needs to be known or controlled.

Applications include, but are not limited to, solutions that may be used in clean-in-place, chromatography detection, ionic solution preparations, end point detection, dosing, fermentation and buffer production. In some cases, conductivity measurements can be extended to pure organic

(4) This general chapter has undergone pharmacopoeial harmonisation. See chapter *5.8. Pharmacopoeial harmonisation*.

fluids such as alcohols and glycols where a weak conductivity signal exists, and the signal can be significantly increased if the organic fluids become contaminated with water or salts.

Conductivity is the measurement of the ability of a fluid to conduct electricity via its ions. The ability of any ion to electrically conduct is directly related to its ion mobility. Conductivity is directly proportional to the concentrations of ions in the fluid according to the following equation:

$$\kappa = 1000 \sum_{i}^{all\ ions} C_i \lambda_i$$

$\kappa$ = conductivity, in siemens per centimetre;

$C_i$ = concentration of ion *i*, in moles per litre;

$\lambda_i$ = specific molar conductance of ion *i*, in siemens square centimetres per mole ($S \cdot cm^2 \cdot mol^{-1}$).

Although siemens per metre is the appropriate SI unit for conductivity, historically the unit siemens per centimetre has been selected by industry as the accepted unit.

Based on this equation, conductivity is not ion-selective because it responds to all ions. Furthermore, the specific molar conductance of each ion is different. As a result, unless the percentage composition of ions in the solution is limited and known, the precise concentrations of ionic species cannot be determined from conductivity measurements. However, for examples such as a solution of a single salt, acid or base (e.g. a caustic solution used in cleaning) the precise concentration can be directly determined. Despite the lack of ionic specificity, conductivity is a valuable laboratory and process tool for measurement and control of total ionic content because it is proportional to the sum of the concentrations of all ionic species (anions and cations) for diluted solutions, as described in the equation above. At higher concentrations, conductivity measurements are not perfectly linear with concentration. Conductivity measurements cannot be applied to solids or gases, but they can be applied to the condensate of gases.

Another variable that influences conductivity measurements is the fluid temperature. As fluid temperature increases, the ion conductance increases, making this physico-chemical phenomenon the predominant reason for the temperature-compensation requirement when testing conductive fluids.

The conductivity ($\kappa$) is proportional to the conductance ($G$), of a fluid between 2 electrodes:

$$\kappa = G \times \left(\frac{d}{A}\right) = G \times K$$

$\kappa$ = conductivity, in siemens per centimetre;

$G$ = conductance, in siemens;

$d$ = distance between the electrodes, in centimetres;

$A$ = area of the conducting electrodes, in square centimetres;

$K$ = cell constant, in reciprocal centimetres, which is also equal to the ratio of $d/A$.

The resistivity $\rho$, expressed in ohm centimetres, of the fluid is, by definition, the reciprocal of the conductivity:

$$\rho = \frac{1}{\kappa} = \frac{1}{G \times K} = \frac{R}{K}$$

$\rho$ = resistivity, in ohm centimetres;

$\kappa$ = conductivity, in siemens per centimetre;

$G$ = conductance, in siemens;

$R$ = resistance, in ohms, which is the reciprocal of the conductance ($G$);

$K$ = cell constant, in reciprocal centimetres.

EQUIPMENT

An electrical conductivity measurement consists of the determination of resistance of the fluid between and around the electrodes of the conductivity sensor. To achieve this measurement, the primary instrumentation is the resistance-measuring circuit and the conductivity sensor, and they are usually connected by a cable when the sensor and the user interface are separated.

The resistance measurement is made by applying an AC (alternating current, meaning the flow of electric charge periodically reverses direction) voltage (or current) to the electrodes, measuring the current (or voltage), and calculating the resistance according to Ohm's law. The alternating source is utilised to prevent polarisation (collection of ions) at the electrodes. Depending on the equipment, the frequency of the measuring system adjusts automatically according to the measuring conditions of the instrument, and there may be multiple resistance-measuring circuits embedded in the measuring system. The resistance-measurement circuit may be embedded in the transmitter or in the sensor.

The conductivity sensor consists of at least 2 electrical conductors of a fixed size and geometry, separated by an electrical insulator. The electrodes, insulator and any other wetted components are constructed of materials that are unreactive to fluids with which they may come into contact. In addition, the sensor construction must be able to withstand the environmental conditions (process or ambient temperature, pressure, cleaning applications) that it would be subjected to.

Most conductivity sensors have temperature devices such as a platinum RTD (resistance temperature device) or NTC (negative temperature coefficient) thermistor embedded inside the sensor, although external temperature measurement is possible. The purpose of the temperature measurement is for temperature compensation of the conductivity measurement.

CELL CONSTANT DETERMINATION

The purpose of the sensor's cell constant is to normalise the conductance (or resistance) measurement for the geometrical construction of the 2 electrodes.

The cell constant is determined by immersing the conductivity sensor in a solution of known conductivity. Solutions of known conductivity can be obtained by preparation of specific recipes according to national authoritative sources, or procurement of commercially available certified and traceable standard solutions. These recipes or certified solutions can range from 5 to 200 000 $\mu S \cdot cm^{-1}$ depending on the level of accuracy desired. Alternatively, the cell constant is determined by comparison to other reference conductivity measuring systems (also available as an accredited calibration service). (*NOTE*: conductivity measurements are not perfectly linear with concentration.)

The measured cell constant of the conductivity sensor must be within 5 per cent of the nominal value indicated by the sensor certificate, unless otherwise prescribed.

Modern conductivity sensors normally do not change their cell constant over their lifetime. If a change in the cell constant is detected during calibration, cleaning of the sensor according to the manufacturer's recommendations is appropriate, followed by a repeat of the calibration procedure. Sometimes 'memory effects' appear, particularly when changing from high to low concentrations if the sensor is not well flushed.

CALIBRATION OF TEMPERATURE

In addition to verifying the sensor's cell constant, the embedded temperature device (or external temperature device) must be appropriately calibrated for the application, in order to apply the temperature compensation algorithm accurately. The temperature accuracy that is required depends on the criticality of the temperature to the application. An accuracy of ± 1 °C typically suffices.

CALIBRATION OF MEASUREMENT ELECTRONICS

The measurement circuit of the system is fundamentally an AC resistance measuring device. Appropriate verification and/or calibration of the measuring circuit is required for measurement systems with signal transfer via analog cable. This is accomplished by disconnecting the measuring circuit from the sensor's electrodes, attaching traceable resistors of known value to the measuring circuit using the same measurement system cable, and verifying that the measured resistance agrees with the resistor value to an acceptable level. A typical acceptance criterion for the resistance accuracy is below 2 per cent of the reading at resistances greater than 100 Ω, and increasing to 5 per cent at lower resistances. However, it is recommended that the application criticality ultimately determines the desired accuracy.

For conductivity systems that cannot have the resistance-measuring circuit disconnected from the electrodes (e.g. measurement circuit and electrodes in 1 mutual housing), it may be difficult to directly adjust or verify the circuit accuracy, depending on the sensor design. An alternative method of verifying the measurement system integrity is a system calibration according to the procedures for cell constant determination for each measuring circuit that is intended to be used.

If verification/calibration of the sensor's cell constant, temperature device and measuring circuit are done at the same service interval, it is recommended to verify the measuring circuit first, the temperature device next and the cell constant last. Because all of these parameters are typically very stable due to modern electronics and stable sensor construction, frequent calibration (such as daily) is not usually required. Comparison to qualified reference systems is also a suitable means of calibration. Calibration is performed at appropriate intervals as defined in the quality management system.

TEMPERATURE COMPENSATION

As the conductivity of a fluid is temperature dependent, temperature compensation of the conductivity measurement is necessary unless otherwise prescribed (e.g. purified water, water for injection). An appropriate temperature compensation algorithm will ensure that changes in the conductivity measurements can be ascribed to concentration changes and not temperature changes. Conductivity measurements are normally referenced to 25 °C. A common form of linear temperature compensation uses a temperature coefficient according to the following equation:

$$\kappa_{25} = \frac{\kappa_T}{[1 + \alpha(T - 25)]}$$

$\kappa_{25}$ = conductivity compensated to 25 °C;

$\kappa_T$ = conductivity at $T$;

$\alpha$ = temperature coefficient of conductivity;

$T$ = measured temperature.

A temperature coefficient of 2.1 per cent per degree Celsius is commonly used for many salt solutions. Most salt-based solutions have temperature coefficients of conductivity ranging from 1.9 to 2.2 per cent per degree Celsius. Depending on the fluid samples, other forms of temperature compensation may be appropriate. Non-linear temperature compensation data for a variety of solutions is widely available, e.g. as described in ISO 7888 *Water Quality – Determination of electrical conductivity*. In cases of very low conductivity (below 10 $\mu S \cdot cm^{-1}$), for example, purified water for pharmaceutical use, 2 compensations need to be made. One is for the intrinsic conductivity of water, and the other is for the other ionic species in water. These compensations are normally combined and embedded in the microprocessor-controlled conductivity measurement systems. This is not supplied in all conductivity measurement technologies.

CONDUCTIVITY MEASUREMENT OF FLUIDS

For off-line batch measurements, rinse the cleaned sensor with the fluid to be measured, then perform the measurement. Ensure that the position of the sensor in the container does not impact the conductivity measurement, as the container walls can impact the measurement for some electrode designs. Record the temperature and the temperature-compensated conductivity as required.

For continuous on-line or at-line measurements, install the cleaned sensor into the pipe, tank or other containment vessel, and flush if necessary. Make sure proper installation procedures are applied to prevent bubbles or particles from collecting between the electrodes. Ensure that the position of the sensor in the pipe or tank does not impact the conductivity measurement, as the nearby surfaces can affect the measurement for some electrode designs. Record the temperature and the temperature-compensated conductivity as required.

For all batch or continuous measurements, ensure that the wetted components of the sensor are compatible with the fluid and the temperature to be measured.

## 2.2.39. MOLECULAR MASS DISTRIBUTION IN DEXTRANS

Examine by size-exclusion chromatography (*2.2.30*).

*Test solution.* Dissolve 0.200 g of the substance to be examined in the mobile phase and dilute to 10 mL with the mobile phase.

*Marker solution.* Dissolve 5 mg of *glucose R* and 2 mg of *dextran $V_0$ CRS* in 1 mL of the mobile phase.

*Calibration solutions.* Dissolve separately in 1 mL of the mobile phase 15 mg of *dextran 4 for calibration CRS*, 15 mg of *dextran 10 for calibration CRS*, 20 mg of *dextran 40 for calibration CRS*, 20 mg of *dextran 70 for calibration CRS* and 20 mg of *dextran 250 for calibration CRS*.

*System suitability solution.* Dissolve either 20 mg of *dextran 40 for performance test CRS* (for dextran 40) or 20 mg of *dextran 60/70 for performance test CRS* (for dextran 60 and dextran 70) in 1 mL of the mobile phase.

The chromatographic procedure may be carried out using:

- a column 0.3 m long and 10 mm in internal diameter, packed with *cross-linked agarose for chromatography R* or a series of columns, 0.3 m long and 10 mm in internal diameter, packed with *polyether hydroxylated gel for chromatography R*,
- as the mobile phase, at a flow rate of 0.5-1 mL/min, kept constant to ± 1 per cent per hour, a solution containing 7 g of *anhydrous sodium sulfate R* and 1 g of *chlorobutanol R* in 1 L of *water R*,
- as detector a differential refractometer,
- a 100 µL to 200 µL loop injector,

maintaining the system at a constant temperature (± 0.1 °C).

CALIBRATION OF THE CHROMATOGRAPHIC SYSTEM

Carry out replicate injections of the chosen volume of the marker solution. The chromatogram shows 2 peaks, the first of which corresponds to *dextran $V_0$ CRS* and the second of which corresponds to *glucose R*. From the elution volume of the peak corresponding to dextran $V_0$, calculate the void volume $V_0$ and from the peak corresponding to dextrose, calculate the total volume $V_t$.

Inject the chosen volume of each of the calibration solutions. Draw carefully the baseline of each of the chromatograms. Divide each chromatogram into $p$ (at least 60) equal vertical sections (corresponding to equal elution volumes). In each section $i$, corresponding to an elution volume $V_i$ measure the height ($y_i$) of the chromatogram line above the baseline and calculate the coefficient of distribution $K_i$ using the expression:

$$\frac{(V_i - V_0)}{(V_t - V_0)} \qquad (1)$$

$V_0$ = void volume of the column, determined using the peak corresponding to *dextran $V_0$ CRS* in the chromatogram obtained with the marker solution,

$V_t$ = total volume of the column, determined using the peak corresponding to glucose in the chromatogram obtained with the marker solution,

$V_i$ = elution volume of section $i$ in the chromatogram obtained with each of the calibration solutions.

Carry out the calibration using either of the following methods.

**Calibration by plotting of the curve**. For each of the dextrans for calibration calculate the coefficient of distribution $K_{max}$ corresponding to the maximum height of the chromatographic line, using expression (1). Plot on semilogarithmic paper the values of $K_{max}$ (on the $x$-axis) against the declared molecular mass at the maximum height of the chromatographic line ($M_{max}$) of each of the dextrans for calibration and glucose. Draw a first calibration curve through the points obtained, extrapolating it from the point $K_{max}$ obtained with *dextran 250 for calibration CRS* to the lowest $K$ value obtained for this CRS (Figure 2.2.39.-1). Using this first calibration curve, transform, for each chromatogram, all $K_i$ values into the corresponding molecular mass $M_i$, thus obtaining the molecular mass distribution. Calculate for each dextran for calibration the average molecular mass $M_w$ using equation (3) below. If the calculated values for $M_w$ do not differ by more than 5 per cent from those declared for each of the dextrans for calibration and the mean difference is within ± 3 per cent, the calibration curve is approved. If not, move the calibration curve along the y-axis and repeat the procedure above until the calculated and the declared values for $M_w$ do not differ by more than 5 per cent.

**Calibration by calculation of the curve**. Calculate from equations (2) and (3) below, using a suitable method[(5)], values for $b_1$, $b_2$, $b_3$, $b_4$ and $b_5$ that give values of $M_w$ within 5 per cent of the declared values of each of the dextrans for calibration and 180 ± 2 for glucose:

$$M_i = b_5 + e^{(b_4 + b_1 K_i + b_2 K_i^2 + b_3 K_i^3)} \qquad (2)$$

$$\overline{M}_w = \frac{\sum_{i=1}^{p} (y_i M_i)}{\sum_{i=1}^{p} y_i} \qquad (3)$$

$p$ = number of sections dividing the chromatograms,

$y_i$ = height of the chromatographic line above the baseline in section $i$,

$M_i$ = molecular mass in section $i$.

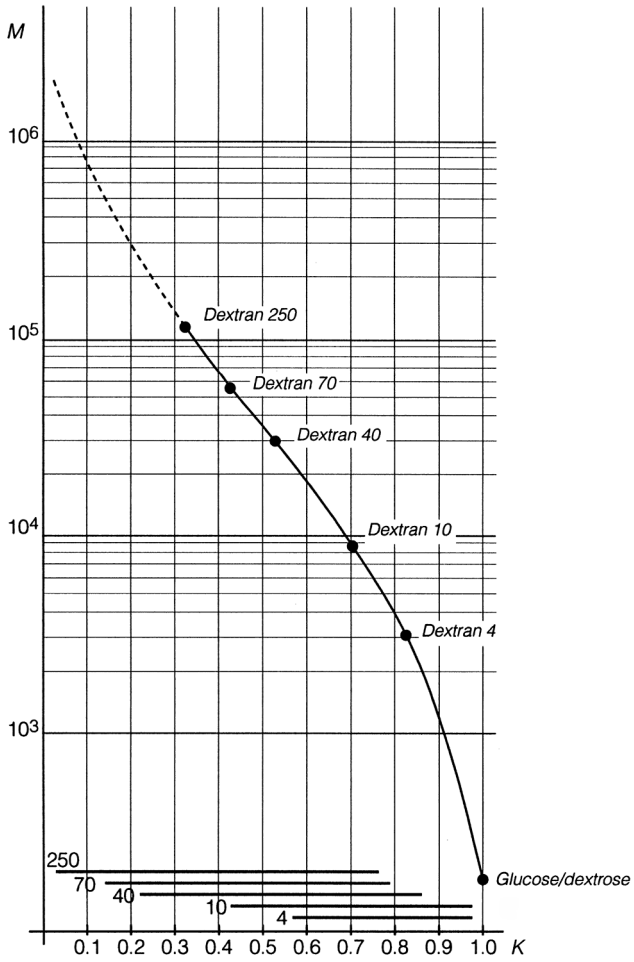

Figure 2.2.39.-1. - *Example of a calibration curve.*

*The dotted line corresponds to the part of the curve that is extrapolated. Horizontal lines at the bottom of the figure represent the width and the position of the chromatographic line obtained with each of the dextrans for calibration.*

SYSTEM SUITABILITY

Inject the chosen volume of the appropriate system suitability solution.

**Average molecular mass of dextran for performance test CRS**. Calculate the average molecular mass $M_w$ as indicated under Calibration of the chromatographic system, using either the plotted calibration curve or the values obtained above for $b_1$, $b_2$, $b_3$, $b_4$ and $b_5$. The test is not valid unless $M_w$ is:

- 41 000 to 47 000 (*dextran 40 for performance test CRS*),
- 67 000 to 75 000 (*dextran 60/70 for performance test CRS*).

(5) An iterative method such as the Gauss-Newton method modified by Hartley is suitable (see O. Hartley, Tecnometrics, 3 (1961) and G. Nilsson and K. Nilsson, J. Chromat. 101, 137 (1974)). A curve-fitting programme for microcomputers, capable of non-linear regression, may be used.

**Average molecular mass of the 10 per cent high-fraction dextran**. Calculate $M_w$ for the 10 per cent high-fraction dextran eluted through section $n$ using the equation:

$$M_w = \frac{\sum_{i=1}^{n}(y_i M_i)}{\sum_{i=1}^{n} y_i} \quad (4)$$

in which $n$ is defined by the expressions:

$$\sum_{i=1}^{n} y_i \leq 0.1\left(\sum_{i=1}^{p} y_i\right) \quad (5)$$

$$\sum_{i=1}^{n+1} y_i > 0.1\left(\sum_{i=1}^{p} y_i\right) \quad (6)$$

$p$ = number of sections dividing the chromatograms,

$y_i$ = height of the chromatographic line above the baseline in section $i$,

$M_i$ = molecular mass in section $i$.

The test is not valid unless $M_w$ of the 10 per cent high fraction dextran is:

– 110 000 to 130 000 (*dextran 40 for performance test CRS*),

– 190 000 to 230 000 (*dextran 60/70 for performance test CRS*).

**Average molecular mass of the 10 per cent low-fraction dextran**. Calculate $M_w$ for the 10 per cent low-fraction dextran eluted in and after section $m$ using the expression:

$$M_w = \frac{\sum_{i=m}^{p}(y_i M_i)}{\sum_{i=m}^{p} y_i} \quad (7)$$

in which $m$ is defined by the expressions:

$$\sum_{i=m}^{p} y_i \leq 0.1\left(\sum_{i=1}^{p} y_i\right) \quad (8)$$

$$\sum_{i=m-1}^{p} y_i > 0.1\left(\sum_{i=1}^{p} y_i\right) \quad (9)$$

$p$ = number of sections dividing the chromatograms,

$y_i$ = height of the chromatographic line above the baseline in section $i$,

$M_i$ = molecular mass in section $i$.

The test is not valid unless $M_w$ of the 10 per cent low-fraction dextran is:

– 6000 to 8500 (*dextran 40 for performance test CRS*),

– 7000 to 11 000 (*dextran 60/70 for performance test CRS*).

MOLECULAR MASS DISTRIBUTION OF THE DEXTRAN TO BE ANALYSED

Inject the chosen volume of the test solution and calculate $M_w$ of the total molecular mass distribution, $M_w$ of the 10 per cent high-fraction dextran and $M_w$ of the 10 per cent low-fraction dextran as indicated under System suitability.

01/2014:20240

# 2.2.40. NEAR-INFRARED SPECTROSCOPY

Near-infrared (NIR) spectroscopy is a technique with wide and varied applications in pharmaceutical analysis. The NIR spectral range extends from 780 nm to 2500 nm (from 12 800 $cm^{-1}$ to 4000 $cm^{-1}$). NIR spectra are dominated by C-H, N-H, O-H and S-H overtones and combinations of fundamental mid-infrared (MIR) vibrations. They contain composite chemical and physical information and in most cases this information can be extracted by suitable mathematical data treatment. NIR bands are much weaker than the fundamental MIR vibrations from which they originate. Because absorptivities in the NIR range are low, radiation can penetrate up to several millimetres into materials, including solids. Furthermore, many materials such as glass are relatively transparent in this region.

Measurements can be made directly *in situ*, in addition to standard sampling and testing procedures. NIR measurements can be performed off-line, and also at-line or in-line, and on-line for process analytical technology (PAT). Suitable chemometric methods may be required for identification. However, when the specificity criteria for a qualitative method are met, chemical identification or solid-state characterisation is possible by direct comparison of the untreated or pre-treated spectra obtained with the chemical substance being examined with a spectrum of a reference substance.

NIR spectroscopy has a wide variety of applications for chemical, physical and process analysis, for example:

*Chemical analysis*:

– identification of active substances, excipients, dosage forms, manufacturing intermediates, chemical materials and packaging materials;

– qualification of active substances, excipients, dosage forms, manufacturing intermediates and packaging materials, including batch-to-batch spectral comparison and supplier change assessment;

– quantification of active substances in a sample matrix, determination of chemical values such as hydroxyl value, determination of absolute water content, determination of degree of hydroxylation and control of solvent content.

*Physical analysis*:

– crystalline form and crystallinity, polymorphism, solvates, particle size;

– disintegration, hardness;

– film properties.

*Process analysis*:

– monitoring of unit operations such as synthesis, crystallisation, blending, drying, granulation and coating, for the purpose of process control;

– control and endpoint detection.

Measurements in the NIR region are influenced by many chemical and physical factors as described below; the reproducibility and relevance of results depend on control of these factors and measurements are usually valid only for a defined calibration model.

APPARATUS

All NIR measurements are based on passing light through or into a sample and measuring the attenuation of the emerging (transmitted or reflected) beam. Spectrometers for measurement in the NIR region consist of a suitable light source (such as a highly-stable quartz-tungsten lamp), a monochromator or interferometer, and a detector. Common monochromators are acousto-optic tunable filters (AOTF),

gratings or prisms. Traditionally, many NIR instruments have a single-beam design, though some process instruments use internal referencing and can therefore be dual-beam (for example in diode array instruments). Silicon, lead sulfide, and indium gallium arsenide are examples of detector materials. Conventional cuvette sample holders, fibre-optic probes, transmission dip cells, neutral borosilicate vials and spinning or traversing sample holders are a few examples of sampling devices. The selection is based on the intended application, paying particular attention to the suitability of the sampling system for the type of sample to be analysed. Suitable data processing and evaluation units (e.g. software and computer) are usually part of the system.

It is common to express the wavelength (λ) in nanometres and the wavenumber ($\nu$) in reciprocal centimetres ($cm^{-1}$), depending on the measurement technique and apparatus. Conversion between nm and $cm^{-1}$ is performed according to the following expression:

$$\nu_{cm^{-1}} = 10^7 \times \frac{1}{\lambda_{nm}}$$

MEASUREMENT METHODS

**Transmission mode**. Transmittance ($T$) is a measure of the decrease in radiation intensity at given wavelengths when radiation is passed through the sample. The sample is placed in the optical beam between the source and the detector. The arrangement is analogous to that in many conventional spectrometers. The resulting spectrum can be presented directly in terms of transmittance ($T$) and/or absorbance ($A$) (y-axis) versus the wavelength or wavenumber (x-axis).

$$T = \frac{I}{I_0}$$

$I_0$ = intensity of incident radiation;

$I$ = intensity of transmitted radiation;

$$A = -\log_{10} T = \log_{10}\left(\frac{1}{T}\right) = \log_{10}\left(\frac{I_0}{I}\right)$$

**Diffuse reflection mode**. The diffuse reflection mode gives a measure of reflectance ($R$), the ratio of the intensity of light reflected from the sample ($I$) to that reflected from a background or reference reflective surface ($I_r$). Depending on the chemical composition and physical characteristics of the sample, NIR radiation can penetrate a more or less substantial distance into the sample, where it can be absorbed by the overtones and combinations of the fundamental vibrations of the analyte species present in the sample. Non-absorbed radiation is partially reflected back from the sample to the detector. NIR reflectance spectra are typically obtained by calculating and plotting $\log_{10}(1/R)$ (y-axis) versus the wavelength or wavenumber (x-axis).

$$R = \frac{I}{I_r}$$

$I$ = intensity of light diffusively reflected from the sample;

$I_r$ = intensity of light reflected from the background or reference reflective surface;

$$A_R = \log_{10}\left(\frac{1}{R}\right) = \log_{10}\left(\frac{I_r}{I}\right)$$

**Transflection mode**. This mode is a combination of transmittance and reflectance. In the measurement of transflectance ($T^*$), a mirror or a diffuse reflectance surface is used to reflect the transmitted radiation back through the sample, thus doubling the pathlength. Non-absorbed radiation is reflected back from the sample to the detector. The resulting spectrum can be presented directly in terms of transflectance ($T^*$) and/or absorbance ($A^*$) (y-axis) versus the wavelength or wavenumber (x-axis).

$$T^* = \frac{I}{I_T}$$

$I$ = intensity of transflected radiation measured from the sample;

$I_T$ = intensity of transflected radiation of the reference material as background;

$$A^* = \log_{10}\left(\frac{1}{T^*}\right) = \log_{10}\left(\frac{I_T}{I}\right)$$

SAMPLE PREPARATION/PRESENTATION

Sample preparation and presentation may vary according to the measurement mode. The following requirements are necessary for all sampling techniques:

- optimise the measuring time and number of scans to optimise the signal-to-noise ratio;
- find the best suitable measurement mode for the intended application (transmission, diffuse reflection or transflection);
- find the best orientation of the sample (e.g. to minimise the impact of debossing on tablets);
- find the best suitable accessory (e.g. transmission cell or immersion probe);
- optimise pathlength in transmission and transflection modes;
- find a suitable spectroscopic background reference material;
- show that the background reference material is reliable over time and that the measurement of the background is reproducible and stable over time;
- when measuring moving materials or samples (for process-related measurements) it is important to obtain a representative spectrum (e.g. by adjusting the measuring time, the number of scans, co-adding individual spectra, or increasing the beam size);
- ensure there is no fouling of the sensor, for example with build-up of material or contamination;
- the measuring conditions (measuring time, beam size) in relation to the minimal sample size should be justified.

In some process analysis situations it may be impossible to remove a probe for reference background data collection; various options are therefore to be considered, including internal referencing, measurement of a background reference using a 2nd detector, etc. Only spectra measured against a background possessing the same optical properties can be directly compared with one another.

**Transmission mode**. The measurement of transmittance ($T$) is dependent on a background transmittance spectrum for its calculation. Examples of background references include air, a polymeric disc, an empty cell, a solvent blank or in special cases a reference sample. The method generally applies to liquids (diluted or undiluted), dispersions, solutions and solids (including tablets and capsules). For transmittance measurements of solids, a suitable sample accessory is used. Liquid samples are examined in a cell of suitable pathlength (typically 0.5-4 mm), transparent to NIR radiation, or alternatively by immersion of a fibre-optic probe of a suitable configuration.

**Diffuse reflection mode**. This mode generally applies to solids. The sample is examined directly, or in a suitable device (for example a sample holder), or in direct contact with a fibre-optic probe. For process monitoring, material can be analysed through a polished window interface (e.g. sapphire), or using an in-line fibre-optic probe. Care must be taken to ensure that the measuring conditions are as reproducible as

possible from one sample to another. The reflected radiation of a background reference is scanned to obtain the baseline, and then the reflectance of one or more analytical samples is measured. Common reflectance references include ceramic, thermoplastic resins and gold. Other suitable materials may be used.

**Transflection mode**. This mode generally applies to liquids, suspensions and clear plastic materials. A reflector is placed behind the sample so as to double the pathlength. This configuration can be adopted to share the same instrument geometry with reflectance and fibre-optic probe systems where the source and the detector are on the same side of the sample. The sample is examined through a cell with a mirror or a suitable diffusive reflector, made either of metal or of an inert substance (for example, dried titanium dioxide) not absorbing in the NIR region. Liquids can also be measured using in-line transflectance probes.

FACTORS AFFECTING SPECTRAL RESPONSE

**Environment**. The environment temperature and humidity must be taken into consideration before carrying out measurements.

**Sample presentation area**. The sample presentation area or probe end must be clean of residue prior to measurement. Similarly, the in-line or on-line interface to the sample should not have significant product or contamination build-up, which would interfere with the desired measurement.

**Sample temperature**. This parameter is important for aqueous solutions and many liquids, where a difference of a few degrees can result in measurable spectral changes which may have a significant effect on the analysis. Temperature is also an important parameter for solids and powders containing water.

**Moisture and solvent residues**. Moisture and solvent residues present in the samples will contribute significant absorption bands in the NIR region.

**Sample thickness**. Sample thickness is a known source of spectral variability and must be assessed and/or controlled, particularly for tablet and capsule analysis in transmittance mode. For the measurement of compressed powders, an infinite thickness is typically reached after 5 mm of sample depth (e.g. in a vial).

**Sample optical properties**. In solids, both surface and bulk scattering properties of samples must be taken into account. Spectra of physically, chemically or optically heterogeneous samples may require increasing the beam size, or examining multiple samples or spinning the sample to obtain a representative spectrum of the sample. Certain factors such as differing degree of compaction or particle size in powdered materials and surface finish can cause significant spectral differences.

**Solid-state forms**. Variations in solid-state forms (polymorphs, hydrates, solvates and amorphous forms) influence vibrational spectra. Hence, different crystalline forms as well as the amorphous form of a solid may be distinguished from one another on the basis of their NIR spectra. Where multiple crystalline forms are present, care must be taken to ensure that the calibration samples have a distribution of forms relevant to the intended application.

**Age of samples**. Samples may exhibit changes in their chemical, physical or optical properties over time. Depending on the storage conditions, solid samples may either absorb or desorb water, and portions of amorphous material may crystallise. Materials used for NIR calibration should be representative of future samples and their matrix variables.

PRE-TREATMENT OF NIR SPECTRAL DATA

In many cases, and particularly for reflection mode spectra, some form of mathematical pre-treatment of the spectrum may be useful prior to the development of a classification or calibration model. The aim can be, for example, to reduce baseline variations, to reduce the impact of known variations that are interfering in the subsequent mathematical models, or to simplify data before use. In some cases spectra may also be normalised or corrected for scatter, for example using standard normal variate (SNV) transformation. Spectral pre-treatment techniques may include, for example, windowing and noise reduction and the numerical calculation of the first- or second-order derivative of the spectrum. Higher-order derivatives are not recommended because of increased spectral noise.

CONTROL OF INSTRUMENT PERFORMANCE

Use the apparatus according to the manufacturer's instructions and carry out the prescribed verification at regular intervals, according to the use of the apparatus and the application. For in-line and on-line applications, the use of alternative means of control of instrument performance must be scientifically justified. For example, utilise the standards built into the instrument or separate channels/probes to demonstrate instrument performance (pending practicality).

System suitability tests may be required prior to sample scanning, and the instrument attributes with potential impact on suitability of the final measurement (typically photometric noise and wavelength accuracy) must be tested. The frequency at which each performance test is carried out must be risk-assessed depending on the instrument type and its environment. For example, instruments placed in harsh environments with variations in temperature and humidity may need frequent performance testing. Cases where the measurement system cannot be removed such as an in-line probe or flow cell are also to be considered.

Some accessories are custom designed and therefore require adequate performance testing.

*Verification and calibration of the wavelength or wavenumber scale (except for filter apparatus)*. Verify the wavelength scale employed, generally in the region between 780 nm and 2500 nm ( 12 800 $cm^{-1}$ to 4000 $cm^{-1}$) or in the intended spectral range using one or more suitable wavelength standards which have characteristic maxima or minima within the wavelength range to be used. For example, *methylene chloride R*, *talc R*, wavelength reference lamps or a mixture of rare-earth oxides are suitable reference materials. Other suitable standards may also be used. Obtain a spectrum and measure the position of at least 3 peaks distributed over the range used. For rare-earth oxides, the National Institute of Standards and Technology (NIST) provides suitable reference materials. Fourier transform (FT) instruments have a linear frequency range, therefore wavelength certification at a single frequency is sufficient.

*Verification and calibration of photometric linearity*. The photometric linearity is demonstrated with a set of transmittance or reflectance standards with known percentage values of transmittance or reflectance. For reflectance measurements, carbon-doped polymer standards are available. Ensure that the absorbance of the materials used is relevant to the intended linear working range of the method. Subsequent verifications of photometric linearity can use the initial observed absorbance values as the reference values. Non-linear calibration models and hence non-linear responses are acceptable with understanding demonstrated by the user.

Spectra obtained from reflectance and transmittance standards are subject to variability due to the differences between the experimental conditions under which they were factory-calibrated and those under which they are subsequently put to use. Hence, the percentage reflectance values supplied with a set of calibration standards may not be useful in the attempt to establish an 'absolute' calibration for a given instrument. As long as the standards do not change chemically or physically and the same reference background is used as was used to obtain the certified values, subsequent measurements of the same standards under

identical conditions, including precise sample positioning, give information on long-term stability of the photometric response. A tolerance of ± 2 per cent of the absorbance value is acceptable for long-term stability; this verification is only necessary if the spectra are used without pre-treatment.

Recommendations for the conditions used to control instrument performance for the various measurement modes are summarised in Table 2.2.40.-1.

Table 2.2.40.-1 – *Control of instrument performance*

| Measurement mode | Reflection | Transflection | Transmission |
|---|---|---|---|
| *Verification of wavelength scale (except for filter apparatus)* | Typical tolerances for agreement with standard values are:<br>± 1.0 nm at 780 nm (± 16 $cm^{-1}$ at 12 800 $cm^{-1}$);<br>± 1.0 nm at 1200 nm (± 8 $cm^{-1}$ at 8300 $cm^{-1}$);<br>± 1.0 nm at 1600 nm (± 6 $cm^{-1}$ at 6250 $cm^{-1}$);<br>± 1.5 nm at 2000 nm (± 4 $cm^{-1}$ at 5000 $cm^{-1}$);<br>± 1.5 nm at 2500 nm (± 2 $cm^{-1}$ at 4000 $cm^{-1}$).<br>For the reference material used, apply the tolerance for the nearest wavelength or wavenumber for each peak used. For diode array instruments, most often the pixel resolution (wavelength between pixels) can be as large as 10 nm. The pixel resolution must be adapted to match the spectral resolution. The peak-finding algorithms are critical to wavelength accuracy. Practically, ± 2 nm is appropriate for peak wavelength accuracy using such instrumentation. Alternatively, refer to manufacturer's specifications for acceptance. | | |
| Bench/mobile instrument | Measure *talc R* via a suitable medium or by fibre-optic probe. *Talc R* has characteristic peaks at 948 nm, 1391 nm and 2312 nm suitable for calibration.<br>Alternatively, other suitable standards may also be used that ensure wavelength accuracy in the region of working methodology. For example, measure an internal polystyrene standard if built-in, or measure a NIST standard or other traceable material, and assess 3 peaks across the wavelength range for calibration. | A suspension of 1.2 g of dry *titanium dioxide R* in about 4 mL of *methylene chloride R* is used directly with a cell or a probe. Titanium dioxide has no absorption in the NIR range. Spectra are recorded with a maximum nominal instrument bandwidth of 10 nm at 2500 nm (16 $cm^{-1}$ at 4000 $cm^{-1}$). Methylene chloride has characteristic sharp bands at 1155 nm, 1366 nm, 1417 nm, 1690 nm, 1838 nm, 1894 nm, 2068 nm and 2245 nm. Choose 3 peaks across the wavelength range for calibration. Other suitable standards may also be used, such as a liquid transflection standard mixed with titanium dioxide or some other reflective medium. | *Methylene chloride R* may be used and has characteristic sharp bands at 1155 nm, 1366 nm, 1417 nm, 1690 nm, 1838 nm, 1894 nm, 2068 nm and 2245 nm. Choose 3 peaks across the wavelength range for calibration. Other suitable standards may also be used. |
| Process instrument | If it is not practically possible to measure a traceable reference material at the point of sample measurement, use internal material such as polystyrene, fibreglass or solvent and/or water vapour. Alternatively, adopt a second external channel/probe.<br>For FT instruments, the calibration of the wavenumber scale may be performed using a narrow, isolated water-vapour line, for example, the line at 7306.74 $cm^{-1}$, or 7299.45 $cm^{-1}$, or 7299.81 $cm^{-1}$ or a narrow line from a certified reference material. | | |
| *Verification of wavelength repeatability (except for filter apparatus)* | The standard deviation of the wavelength is consistent with the specifications of the instrument manufacturer, or otherwise scientifically justified. | | |
| Bench/mobile instrument | Verify the wavelength repeatability using a suitable external or internal standard. | | |
| Process instrument | Verify the wavelength repeatability using a suitable external or internal standard. | | |
| *Verification of photometric linearity and response stability*(1) | Measure 4 photometric standards across the working method absorbance range. | | |
| Bench/mobile instrument | Analyse 4 reflectance standards, for example in the range of 10-99 per cent, including 10 per cent, 20 per cent, 40 per cent and 80 per cent. In some circumstances 2 per cent may be appropriate. Evaluate the observed absorbance values against the reference absorbance values, for example perform a linear regression. Acceptable tolerances are 1.00 ± 0.05 for the slope and 0.00 ± 0.05 for the intercept for the 1st verification of photometric linearity of an instrument. Subsequent verifications of photometric linearity can use the initial observed absorbance values as the reference values. | Transflection measurements can use appropriate reflectance or transmittance standards and criteria. | Analyse 4 transmittance standards to cover the absorbance values over the working absorbance range of the modelled data. Evaluate the observed absorbance values against the reference absorbance values, for example perform a linear regression. Acceptable tolerances are 1.00 ± 0.05 for the slope and 0.00 ± 0.05 for the intercept for the 1st verification of photometric linearity of an instrument. Subsequent verifications of photometric linearity can use the initial observed absorbance values as the reference values. |

| Measurement mode | Reflection | Transflection | Transmission |
|---|---|---|---|
| Process instrument | If photometric reflectance and transmittance standards cannot be measured at the point of sample measurement, use the photometric standards built into the instrument.<br>Process instruments can use internal photometric standards for photometric linearity. Follow the manufacturer's verified tolerances in such cases. | | |

| | | |
|---|---|---|
| *Verification of photometric noise*[(1)] | Determine the photometric noise at a relevant photometric region of the spectrum using a suitable reflectance standard, for example, white reflective ceramic tiles or carbon-doped polymer standards. Follow the manufacturer's methodology and specifications. | |
| Bench/mobile instrument | Scan the reflectance low flux standard (e.g. 5 or 10 per cent, carbon-doped polymer standard) over a suitable wavelength range in accordance with the manufacturer's recommendation and calculate the photometric noise as peak-to-peak noise. | Scan the transmittance high flux standard (e.g. 90 or 99 per cent, carbon-doped polymer standard) over a suitable wavelength/wavenumber range in accordance with the manufacturer's recommendation and calculate the photometric noise as peak-to-peak noise. |
| Process instrument | As above, or if not practically possible, use the standard built into the instrument for noise testing and manufacturer specifications. | As above, or if not practically possible, use the standard built into the instrument for noise testing and manufacturer specifications. |

(1) *Verification of photometric linearity* and *Verification of photometric noise* are not required for instruments using methods to perform simple identifications which do not use the photometric absorbances as part of model strategy (for example, simple correlation with absorbing wavelengths).

QUALITATIVE ANALYSIS (IDENTIFICATION AND CHARACTERISATION)

**Establishment of a spectral reference library**. Record the spectra of a suitable number of representative samples of the substance which have known, traceable identities, and that exhibit the variation typical for the substance to be analysed (for example, solid-state form, particle size, etc.). Libraries are built using representative samples under appropriate environmental conditions. The set of spectra obtained represents the information which can be used for identification of the sample to be analysed.

The collection of spectra in the library may be represented in different ways defined by the mathematical technique used for identification. These may be:

- all individual spectra representing the substance;
- a mean spectrum of the measured batches for each chemical substance;
- if necessary, a description of the variability within the substance spectra.

The number of substances in the library depends on the specific application. All spectra in the library used have the same:

- spectral range and number of data points;
- technique of measurement;
- data pre-treatment.

If sub-groups (sub-libraries) are created, the above criteria are applied independently for each group. Sub-libraries are individually validated. Original spectral data for the preparation of the spectral library must be archived. Caution must be exercised when performing any mathematical transformation, as artefacts can be introduced or essential information (important with qualification methods) can be lost. The suitability of the algorithm used should be demonstrated by successful method validation and in all cases the rationale for the use of transform must be documented.

**Direct comparison of substance and reference spectra**. Direct comparison of representative spectra of the substance to be examined and of a reference substance for qualitative chemical or physical identification purposes may not require use of a reference spectral library where specificity permits.

**Data evaluation**. Direct comparison of the representative spectrum of the substance to be examined is made with the individual or mean reference spectra of all substances in the database on the basis of their mathematical correlation or other suitable algorithms. A set of known reference mean spectra and the variability around this mean can be used with an algorithm for classification; alternatively, this can be achieved visually by overlaying spectral data if specificity is inherent. There are different techniques available, such as principal component analysis (PCA), cluster analysis, and soft independent modelling by class analogy (SIMCA). The reliability of the technique chosen for a particular application has to be validated according to the following:

**Validation of the model**. Identification methods using direct spectral comparison must be validated in accordance with identification method validation procedures.

The validation parameters for qualitative methods are robustness and specificity.

LIMIT ANALYSIS

**Relative comparison of spectra**. A calibration is not required when comparing a set of spectra for limit analysis purposes, such as the maximum or minimum absorbance at which an analyte absorbs. Also, dryer end point control may use a qualitative approach around a specific absorbing wavelength. Appropriate spectral ranges and pre-treatments (if used) must be shown to be fit for purpose.

**Specificity**. The relative discriminatory power for a limit test must be demonstrated. The extent of specificity testing is dependent on the application and the risks being controlled. Variations in matrix concentrations within the operating range of the method must not affect the measurement.

TREND ANALYSIS

**Relative comparison of spectra**. A calibration is not necessarily required when comparing a set of spectra for trend analysis purposes, such as the moving block approach to estimate statistical parameters such as mean, median and standard deviation. For example, blend uniformity monitoring using NIR spectroscopy has adopted such data analysis approaches. Appropriate spectral ranges and algorithms must be used for trend analyses.

**Specificity**. The relative discriminatory power for trend analysis must be demonstrated. The extent of specificity testing is dependent on the application and the risks being controlled. Variations in matrix concentrations within the operating range of the method must not affect the trend analysis.

QUANTITATIVE ANALYSIS

**Establishment of a spectral reference library for a calibration model**. Calibration is the process of constructing a mathematical model to relate the response from a sample scanned using an analytical instrument to the properties of the samples. Any calibration model that can be clearly defined in a mathematical expression and gives suitable results can be used. Record the spectra of a suitable number of representative samples with known or future-established values of the attribute of interest throughout the range to be measured (for example, content of water). The number of samples for calibration will depend on the complexity of the sample matrix and interferences (e.g. temperature, particle size, etc.). All samples must give quantitative results within a calibration interval as defined by the intended purpose of the method. Multiple linear regression (MLR), principal component regression (PCR) and partial least squares regression (PLS) are commonly used algorithms. For PLS or PCR calibrations, the regression coefficients and/or the loadings should be plotted and the regions of large coefficients or loadings compared with the spectrum of the analyte. Predicted residual error sum of squares (PRESS) plots (or similar) are useful to facilitate the optimising of the number of PCR or PLS factors.

**Pre-treatment of data**. Wavelength selection or excluding certain wavelength ranges may enhance the accuracy and robustness of calibration models. Wavelength compression (wavelength averaging) techniques may be applied to the data.

**Model validation parameters**. Analytical performance characteristics to be considered for demonstrating the validation of NIR methods are similar to those required for any analytical procedure. Specific acceptance criteria for each validation parameter must be consistent with the intended use of the method. Validation parameters for quantitative methods are accuracy, linearity, precision (repeatability and intermediate precision), robustness and specificity.

ONGOING MODEL EVALUATION

NIR models validated for use are subjected to ongoing performance evaluation and monitoring of validation parameters.

TRANSFER OF DATABASES

When databases are transferred to another instrument, spectral range, number of data points, spectral resolution and other parameters have to be taken into consideration. Further procedures and criteria must be applied to demonstrate that the model remains valid with the new database or new instrument.

**01/2008:20241**

# 2.2.41. CIRCULAR DICHROISM

The difference in absorbance of optically active substances within an absorption band for left and right circularly polarised light is referred to as circular dichroism.

Direct measurement gives a mean algebraic value:

$$\Delta A = A_L - A_R$$

$\Delta A$ = circular dichroic absorbance,

$A_L$ = absorbance of left circularly polarised light,

$A_R$ = absorbance of right circularly polarised light.

Circular dichroism is calculated using the equation:

$$\Delta\varepsilon = \varepsilon_L - \varepsilon_R = \frac{\Delta A}{c \times l}$$

$\Delta\varepsilon$ = molar circular dichroism or molar differential dichroic absorptivity expressed in litre·mole$^{-1}$·cm$^{-1}$,

$\varepsilon_L$ = molar absorptivity (*2.2.25*) of left circularly polarised light,

$\varepsilon_R$ = molar absorptivity of right circularly polarised light,

$c$ = concentration of the test solution in mole·litre$^{-1}$,

$l$ = optical path of the cell in centimetres.

The following units may also be used to characterise circular dichroism:

*Dissymmetry factor*:

$$g = \frac{\Delta\varepsilon}{\varepsilon}$$

$\varepsilon$ = molar absorptivity (*2.2.25*).

*Molar ellipticity*:

Certain types of instruments display directly the value of ellipticity Θ, expressed in degrees. When such instruments are used, the molar ellipticity [Θ] may be calculated using the following equation:

$$[\Theta] = \frac{\Theta \times M}{c \times l \times 10}$$

[Θ] = molar ellipticity, expressed in degrees·cm$^2$·decimole$^{-1}$,

Θ = value of ellipticity given by the instrument,

$M$ = relative molecular mass of the substance to be examined,

$c$ = concentration of the solution to be examined in g/mL,

$l$ = optical path of the cell in centimetres.

Molar ellipticity is also related to molar circular dichroism by the following equation:

$$[\Theta] = 2.303\Delta\varepsilon\frac{4500}{\pi} \approx 3300\Delta\varepsilon$$

Molar ellipticity is often used in the analysis of proteins and nucleic acids. In this case, molar concentration is expressed in terms of monomeric residue, calculated using the expression:

$$\frac{\text{molecular mass}}{\text{number of amino acids}}$$

The mean relative molecular mass of the monomeric residue is 100 to 120 (generally 115) for proteins and about 330 for nucleic acids (as the sodium salt).

**Apparatus**. The light source (S) is a xenon lamp (Figure 2.2.41.-1); the light passes through a double monochromator (M) equipped with quartz prisms (P1, P2).

The linear beam from the first monochromator is split into 2 components polarised at right angles in the second monochromator. The exit slit of the monochromator eliminates the extraordinary beam.

The polarised and monochromatic light passes through a birefringent modulator (Cr): the result is alternating circularly polarised light.

The beam then passes through the sample to be examined (C) and reaches a photomultiplier (PM) followed by an amplifier circuit which produces 2 electrical signals: one is a direct current $V_c$ and the other is an alternating current at the modulation frequency $V_{ac}$ characteristic of the sample to be examined. The phase gives the sign of the circular dichroism. The ratio $V_{ac}/V_c$ is proportional to the differential absorption $\Delta A$ which created the signal. The region of wavelengths normally covered by a dichrograph is 170 nm to 800 nm.

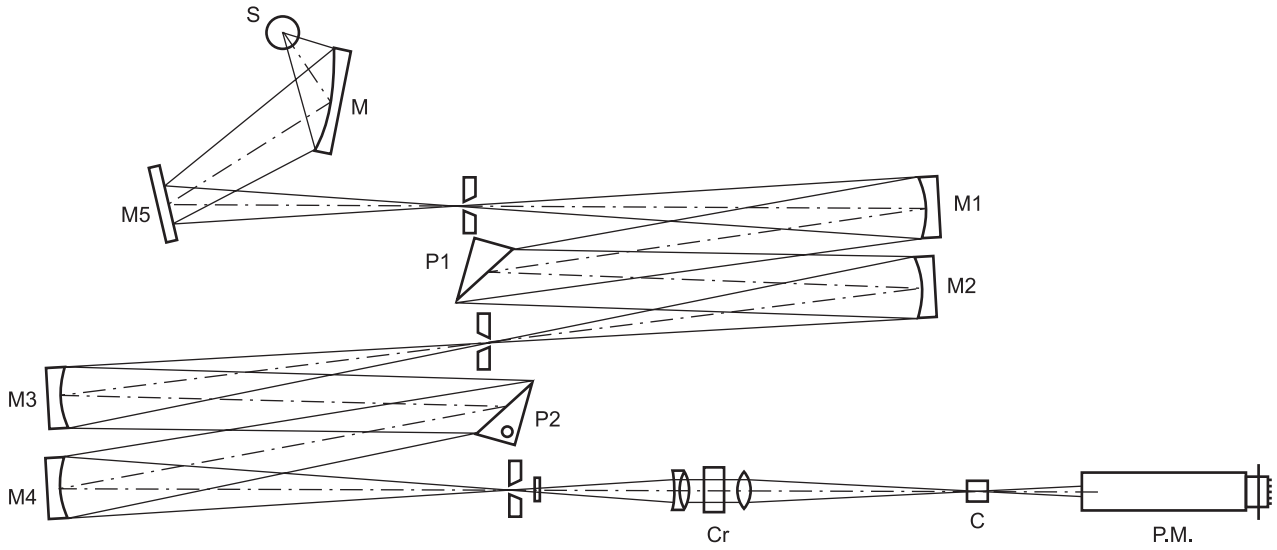

Figure 2.2.41.-1. – *Optical scheme of a dichrograph*

**Calibration of the apparatus**

*Accuracy of absorbance scale*. Dissolve 10.0 mg of *isoandrosterone R* in *dioxan R* and dilute to 10.0 mL with the same solvent. Record the circular dichroism spectrum of the solution between 280 nm and 360 nm. Measured at the maximum at 304 nm, $\Delta\varepsilon$ is + 3.3.

The solution of *(1S)-(+)-10-camphorsulfonic acid R* may also be used.

*Linearity of modulation*. Dissolve 10.0 mg of *(1S)-(+)-10-camphorsulfonic acid R* in *water R* and dilute to 10.0 mL with the same solvent. Determine the exact concentration of camphorsulfonic acid in the solution by ultraviolet spectrophotometry (*2.2.25*), taking the specific absorbance to be 1.49 at 285 nm.

Record the circular dichroism spectrum between 185 nm and 340 nm. Measured at the maximum at 290.5 nm, $\Delta\varepsilon$ is + 2.2 to + 2.5. Measured at the maximum at 192.5 nm, $\Delta\varepsilon$ is − 4.3 to − 5.

*(1S)-(+)-* or antipodal *(1R)-(−)-ammonium 10-camphorsulfonate R* can also be used.

**01/2010:20242**

# 2.2.42. DENSITY OF SOLIDS

The density of solids corresponds to their average mass per unit volume and typically is expressed in grams per cubic centimetre (g/cm$^3$) although the International Unit is the kilogram per cubic metre (1 g/cm$^3$ = 1000 kg/m$^3$).

Unlike gases and liquids whose density depends only on temperature and pressure, the density of a solid also depends on its assembly and therefore varies with the crystal structure and degree of crystallinity.

When a solid is amorphous or partially amorphous, its density may further depend upon the history of preparation, treatment and storage.

Therefore, unlike fluids, the densities of 2 chemically equivalent solids may be different, and this difference reflects a difference in solid-state structure. The density of constituent particles is an important physical characteristic of pharmaceutical powders.

The density of a solid particle can assume different values depending on the method used to measure the volume of the particle. It is useful to distinguish 3 levels of expression of density:

- the *true density*, which only includes the solid fraction of the material; in case of crystalline material, the true density is also called *crystal density*;
- the *particle density*, which also includes the volume due to intraparticulate pores;
- the *bulk density*, which further includes the interparticulate void volume formed in the powder bed.

TRUE DENSITY

The true density of a substance is the ratio of the mass to the volume of the unit cell, exclusive of all voids that are not a fundamental part of the molecular packing arrangement. It is an intrinsic property of the specified crystal structure of substance, and hence should be independent of the method of determination. The true density is determined by calculation.

It is obtained using crystallographic data (volume and composition of the unit cell) from, for example, X-ray diffraction data, either on a single crystal or by refinement of the crystalline structure from X-ray powder diffraction data.

PARTICLE DENSITY

The particle density takes into account both the true density and the intraparticulate porosity (sealed and/or experimentally non-accessible open pores). Thus, particle density depends on the value of the volume determined, which in turn depends on the method of measurement. The particle density can be determined using one of the 2 following methods.

The gas *pycnometric density* is determined by measuring the volume occupied by a known mass of powder, which is equivalent to the volume of gas displaced by the powder using a gas displacement pycnometer (*2.9.23*). In gas pycnometric density measurements, the volume determined excludes the volume occupied by open pores; however, it includes the volume occupied by sealed pores or pores inaccessible to the gas. Due to the high diffusivity of helium, which is the preferred choice of gas, most open pores are accessible to the gas. Therefore, the gas pycnometric density of a finely milled powder is generally not very different from the true density. Hence, this density is the best estimate of the true density of an amorphous or partially crystalline sample and is therefore widely applicable for processed pharmaceutical powder samples.

The *mercury porosimeter density* is also called *granular density*. With this method the volume determined includes the volume occupied by sealed pores or pores inaccessible to mercury; however, it includes the volume only from open pores smaller than some size limit. This pore-size limit or minimal access diameter depends on the maximal mercury intrusion pressure applied during the measurement, and under normal

operating pressures the mercury does not penetrate the finest pores accessible to helium. Various granular densities can be obtained from one sample since, for each applied mercury intrusion pressure, a density can be determined that corresponds to the pore-size limit at that pressure.

BULK AND TAPPED DENSITY

The bulk density of a powder includes the contribution of interparticulate void volume. Hence, the bulk density depends on both the density of powder particles and the spatial arrangement of particles in the powder bed.

The bulk density of a powder is often very difficult to measure with good reproducibility since the slightest disturbance of the bed may result in a new density. Thus, it is essential in reporting bulk density to specify how the determination was made.

The bulk density and the tapped density are determined as mentioned in chapter *2.9.34. Bulk density and tapped density*.

**01/2008:20243**

# 2.2.43. MASS SPECTROMETRY

Mass spectrometry is based on the direct measurement of the ratio of the mass to the number of positive or negative elementary charges of ions (*m*/*z*) in the gas phase obtained from the substance to be analysed. This ratio is expressed in atomic mass units (1 a.m.u. = one twelfth the mass of $^{12}C$) or in daltons (1 Da = the mass of the hydrogen atom).

The ions, produced in the ion *source* of the apparatus, are accelerated and then separated by the *analyser* before reaching the *detector*. All of these operations take place in a chamber where a pumping system maintains a vacuum of $10^{-3}$ to $10^{-6}$ Pa.

The resulting spectrum shows the relative abundance of the various ionic species present as a function of *m*/*z*. The signal corresponding to an ion will be represented by several peaks corresponding to the statistical distribution of the various isotopes of that ion. This pattern is called the *isotopic profile* and (at least for small molecules) the peak representing the most abundant isotopes for each atom is called the *monoisotopic peak*.

Information obtained in mass spectrometry is essentially qualitative (determination of the molecular mass, information on the structure from the fragments observed) or quantitative (using internal or external standards) with limits of detection ranging from the picomole to the femtomole.

INTRODUCTION OF THE SAMPLE

The very first step of an analysis is the introduction of the sample into the apparatus without overly disturbing the vacuum. In a common method, called *direct liquid introduction*, the sample is placed on the end of a cylindrical rod (in a quartz crucible, on a filament or on a metal surface). This rod is introduced into the spectrometer after passing through a vacuum lock where a primary intermediate vacuum is maintained between atmospheric pressure and the secondary vacuum of the apparatus.

Other introduction systems allow the components of a mixture to be analysed as they are separated by an appropriate apparatus connected to the mass spectrometer.

**Gas chromatography/mass spectrometry**. The use of suitable columns (capillary or semi-capillary) allows the end of the column to be introduced directly into the source of the apparatus without using a separator.

**Liquid chromatography/mass spectrometry**. This combination is particularly useful for the analysis of polar compounds, which are insufficiently volatile or too heat-labile to be analysed by gas chromatography coupled with mass spectrometry. This method is complicated by the difficulty of obtaining ions in the gas phase from a liquid phase, which requires very special interfaces such as:

- *direct liquid introduction*: the mobile phase is nebulised, and the solvent is evaporated in front of the ion source of the apparatus,
- *particle-beam interface*: the mobile phase, which may flow at a rate of up to 0.6 mL/min, is nebulised in a desolvation chamber such that only the analytes, in neutral form, reach the ion source of the apparatus; this technique is used for compounds of relatively low polarity with molecular masses of less than 1000 Da,
- *moving-belt interface*: the mobile phase, which may flow at a rate of up to 1 mL/min, is applied to the surface of a moving belt; after the solvent evaporates, the components to be analysed are successively carried to the ion source of the apparatus where they are ionised; this technique is rather poorly suited to very polar or heat-labile compounds.

Other types of coupling (electrospray, thermospray, atmospheric-pressure chemical ionisation) are considered to be ionisation techniques in their own right and are described in the section on modes of ionisation.

**Supercritical fluid chromatography/mass spectrometry**. The mobile phase, usually consisting of supercritical carbon dioxide enters the gas state after passing a heated restrictor between the column and the ion source.

**Capillary electrophoresis/mass spectrometry**. The eluent is introduced into the ion source, in some cases after adding another solvent so that flow rates of the order of a few microlitres per minute can be attained. This technique is limited by the small quantities of sample introduced and the need to use volatile buffers.

MODES OF IONISATION

**Electron impact**. The sample, in the gas state, is ionised by a beam of electrons whose energy (usually 70 eV) is greater than the ionisation energy of the sample. In addition to the molecular ion $M^+$, fragments characteristic of the molecular structure are observed. This technique is limited mainly by the need to vaporise the sample. This makes it unsuited to polar, heat-labile or high molecular mass compounds. Electron impact is compatible with the coupling of gas chromatography to mass spectrometry and sometimes with the use of liquid chromatography.

**Chemical ionisation**. This type of ionisation involves a reagent gas such as methane, ammonia, nitrogen oxide, nitrogen dioxide or oxygen. The spectrum is characterised by ions of the $(M + H)^+$ or $(M - H)^-$ types, or adduct ions formed from the analyte and the gas used. Fewer fragments are produced than with electron impact. A variant of this technique is used when the substance is heat-labile: the sample, applied to a filament, is very rapidly vaporised by the Joule-Thomson effect (desorption chemical ionisation).

**Fast-atom bombardment (FAB) or fast-ion bombardment ionisation (liquid secondary-ion mass spectrometry LSIMS)**. The sample, dissolved in a viscous matrix such as glycerol, is applied to a metal surface and ionised by a beam of neutral atoms such as argon or xenon or high-kinetic-energy caesium ions. Ions of the $(M + H)^+$ or $(M - H)^-$ types or adduct ions formed from the matrix or the sample are produced. This type of ionisation, well suited to polar and heat-labile compounds, allows molecular masses of up to 10 000 Da to be obtained. The technique can be combined with liquid chromatography by adding 1 per cent to 2 per cent of glycerol to the mobile phase; however, the flow rates must be very low (a few microlitres per minute). These ionisation techniques also allow thin-layer chromatography plates to be analysed by applying a thin layer of matrix to the surface of these plates.

**Field desorption and field ionisation**. The sample is vaporised near a tungsten filament covered with microneedles (*field ionisation*) or applied to this filament (*field desorption*). A voltage of about 10 kV, applied between this filament and a counter-electrode, ionises the sample. These two techniques mainly produce molecular ions $M^+$, and $(M + H)^+$ ions and are used for low polarity and/or heat-labile compounds.

**Matrix-assisted laser desorption ionisation (MALDI)**. The sample, in a suitable matrix and deposited on a metal support, is ionised by a pulsed laser beam whose wavelength may range from UV to IR (impulses lasting from a picosecond to a few nanoseconds). This mode of ionisation plays an essential role in the analysis of very high molecular mass compounds (more than 100 000 Da) but is limited to time-of flight analysers (see below).

**Electrospray**. This mode of ionisation is carried out at atmospheric pressure. The samples, in solution, are introduced into the source through a capillary tube, the end of which has a potential of the order of 5 kV. A gas can be used to facilitate nebulisation. Desolvation of the resulting microdroplets produces singly or multiply charged ions in the gas phase. The flow rates vary from a few microlitres per minute to 1 mL/min. This technique is suited to polar compounds and to the investigation of biomolecules with molecular masses of up to 100 000 Da. It can be coupled to liquid chromatography or capillary electrophoresis.

**Atmospheric-pressure chemical ionisation (APCI)**. Ionisation is carried out at atmospheric pressure by the action of an electrode maintained at a potential of several kilovolts and placed in the path of the mobile phase, which is nebulised both by thermal effects and by the use of a stream of nitrogen. The resulting ions carry a single charge and are of the $(M + H)^+$ type in the positive mode and of the $(M - H)^-$ type in the negative mode. The high flow rates that can be used with this mode of ionisation (up to 2 mL/min) make this an ideal technique for coupling to liquid chromatography.

**Thermospray**. The sample, in the mobile phase consisting of water and organic modifiers and containing a volatile electrolyte (generally ammonium acetate) is introduced in nebulised form after having passed through a metal capillary tube at controlled temperature. Acceptable flow rates are of the order of 1 mL/min to 2 mL/min. The ions of the electrolyte ionise the compounds to be analysed. This ionisation process may be replaced or enhanced by an electrical discharge of about 800 volts, notably when the solvents are entirely organic. This technique is compatible with the use of liquid chromatography coupled with mass spectrometry.

## ANALYSERS

Differences in the performance of analysers depend mainly on two parameters:

- the range over which $m/z$ ratios can be measured, ie, the *mass range*,
- their *resolving power* characterised by the ability to separate two ions of equal intensity with $m/z$ ratios differing by $\Delta M$, and whose overlap is expressed as a given percentage of valley definition; for example, a resolving power $(M/\Delta M)$ of 1000 with 10 per cent valley definition allows the separation of $m/z$ ratios of 1000 and 1001 with the intensity returning to 10 per cent above baseline. However, the resolving power may in some cases (time-of-flight analysers, quadrupoles, ion-trap analysers) be defined as the ratio between the molecular mass and peak width at half height (50 per cent valley definition).

**Magnetic and electrostatic analysers**. The ions produced in the ion source are accelerated by a voltage $V$, and focused towards a magnetic analyser (magnetic field $B$) or an electrostatic analyser (electrostatic field $E$), depending on the configuration of the instrument. They follow a trajectory of radius $r$ according to Laplace's law:

$$\frac{m}{z} = \frac{B^2 r^2}{2V}$$

Two types of scans can be used to collect and measure the various ions produced by the ion source: a scan of $B$ holding $V$ fixed or a scan of $V$ with constant $B$. The magnetic analyser is usually followed by an electric sector that acts as a kinetic energy filter and allows the resolving power of the instrument to be increased appreciably. The maximum resolving power of such an instrument (double sector) ranges from 10 000 to 150 000 and in most cases allows the value of $m/z$ ratios to be calculated accurately enough to determine the elemental composition of the corresponding ions. For monocharged ions, the mass range is from 2000 Da to 15 000 Da. Some ions may decompose spontaneously (metastable transitions) or by colliding with a gas (collision-activated dissociation (CAD)) in field-free regions between the ion source and the detector. Examination of these decompositions is very useful for the determination of the structure as well as the characterisation of a specific compound in a mixture and involves tandem mass spectrometry. There are many such techniques depending on the region where these decompositions occur:

- *daughter-ion mode* (determination of the decomposition ions of a given parent ion): $B/E$ = constant, *MIKES (Mass-analysed Ion Kinetic Energy Spectroscopy)*,
- *parent-ion mode* (determination of all ions which by decomposition give an ion with a specific $m/z$ ratio): $B^2/E$ = constant,
- *neutral-loss mode* (detection of all the ions that lose the same fragment):

  $B/E(1 - E/E_0)^{1/2}$ = constant, where $E_0$ is the basic voltage of the electric sector.

**Quadrupoles**. The analyser consists of four parallel metal rods, which are cylindrical or hyperbolic in cross-section. They are arranged symmetrically with respect to the trajectory of the ions; the pairs diagonally opposed about the axis of symmetry of rods are connected electrically. The potentials to the two pairs of rods are opposed. They are the resultant of a constant component and an alternating component. The ions produced at the ion source are transmitted and separated by varying the voltages applied to the rods so that the ratio of continuous voltage to alternating voltage remains constant. The quadrupoles usually have a mass range of 1 a.m.u. to 2000 a.m.u., but some may range up to 4000 a.m.u. Although they have a lower resolving power than magnetic sector analysers, they nevertheless allow the monoisotopic profile of single charged ions to be obtained for the entire mass range. It is possible to obtain spectra using three quadrupoles arranged in series, $Q_1$, $Q_2$, $Q_3$ ($Q_2$ serves as a collision cell and is not really an analyser; the most commonly used collision gas is argon).

The most common types of scans are the following:

- *daughter-ion mode*: $Q_1$ selects an $m/z$ ion whose fragments obtained by collision in $Q_2$ are analysed by $Q_3$,
- *parent-ion mode*: $Q_3$ filters only a specific $m/z$ ratio, while $Q_1$ scans a given mass range. Only the ions decomposing to give the ion selected by $Q_3$ are detected,
- *neutral loss mode*: $Q_1$ and $Q_3$ scan a certain mass range but at an offset corresponding to the loss of a fragment characteristic of a product or family of compounds.

It is also possible to obtain spectra by combining quadrupole analysers with magnetic or electrostatic sector instruments; such instruments are called *hybrid mass spectrometers*.

**Ion-trap analyser**. The principle is the same as for a quadrupole, this time with the electric fields in three dimensions. This type of analyser allows product-ion spectra over several generations ($MS^n$) to be obtained.

**Ion-cyclotron resonance analysers**. Ions produced in a cell and subjected to a uniform, intense magnetic field move in circular orbits at frequencies which can be directly correlated to their *m*/*z* ratio by applying a Fourier transform algorithm. This phenomenon is called ion-cyclotron resonance. Analysers of this type consist of superconducting magnets and are capable of very high resolving power (up to 1000 000 and more) as well as $MS^n$ spectra. However, very low pressures are required (of the order of $10^{-7}$ Pa).

**Time-of-flight analysers**. The ions produced at the ion source are accelerated at a voltage *V* of 10 kV to 20 kV. They pass through the analyser, consisting of a field-free tube, 25 cm to 1.5 m long, generally called a *flight tube*. The time (*t*) for an ion to travel to the detector is proportional to the square root of the *m*/*z* ratio. Theoretically the mass range of such an analyser is infinite. In practice, it is limited by the ionisation or desorption method. Time-of-flight analysers are mainly used for high molecular mass compounds (up to several hundred thousand daltons). This technique is very sensitive (a few picomoles of product are sufficient). The accuracy of the measurements and the resolving power of such instruments may be improved considerably by using an electrostatic mirror (reflectron).

SIGNAL ACQUISITION

There are essentially three possible modes.

**Complete spectrum mode**. The entire signal obtained over a chosen mass range is recorded. The spectrum represents the relative intensity of the different ionic species present as a function of *m*/*z*. The results are essentially qualitative. The use of spectral reference libraries for more rapid identification is possible.

**Fragmentometric mode (Selected-ion monitoring)**. The acquired signal is limited to one (single-ion monitoring (SIM)) or several (multiple-ion monitoring (MIM)) ions characteristic of the substance to be analysed. The limit of detection can be considerably reduced in this mode. Quantitative or semiquantitative tests can be carried out using external or internal standards (for example, deuterated standards). Such tests cannot be carried out with time-of-flight analysers.

**Fragmentometric double mass spectrometry mode (multiple reaction monitoring (MRM))**. The unimolecular or bimolecular decomposition of a chosen precursor ion characteristic of the substance to be analysed is followed specifically. The selectivity and the highly specific nature of this mode of acquisition provide excellent sensitivity levels and make it the most appropriate for quantitative studies using suitable internal standards (for example, deuterated standards). This type of analysis can be performed only on apparatus fitted with three quadrupoles in series, ion-trap analysers or cyclotron-resonance analysers.

CALIBRATION

Calibration allows the corresponding *m*/*z* value to be attributed to the detected signal. As a general rule, this is done using a reference substance. This calibration may be external (acquisition file separate from the analysis) or internal (the reference substance(s) are mixed with the substance to be examined and appear on the same acquisition file). The number of ions or points required for reliable calibration depends on the type of analyser and on the desired accuracy of the measurement, for example, in the case of a magnetic analyser where the *m*/*z* ratio varies exponentially with the value of the magnetic field, there should be as many points as possible.

SIGNAL DETECTION AND DATA PROCESSING

Ions separated by an analyser are converted into electric signals by a detection system such as a photomultiplier or an electron multiplier. These signals are amplified before being re-converted into digital signals for data processing, allowing various functions such as calibration, reconstruction of spectra, automatic quantification, archiving, creation or use of libraries of mass spectra. The various physical parameters required for the functioning of the apparatus as a whole are controlled by computer.

**01/2008:20244**

# 2.2.44. TOTAL ORGANIC CARBON IN WATER FOR PHARMACEUTICAL USE

Total organic carbon (TOC) determination is an indirect measure of organic substances present in water for pharmaceutical use. TOC determination can also be used to monitor the performance of various operations in the preparation of medicines.

A variety of acceptable methods is available for determining TOC. Rather than prescribing a given method to be used, this general chapter describes the procedures used to qualify the chosen method and the interpretation of results in limit tests. A standard solution is analysed at suitable intervals, depending on the frequency of measurements; the solution is prepared with a substance that is expected to be easily oxidisable (for example, sucrose) at a concentration adjusted to give an instrument response corresponding to the TOC limit to be measured. The suitability of the system is determined by analysis of a solution prepared with a substance expected to be oxidisable with difficulty (for example, 1,4-benzoquinone).

The various types of apparatus used to measure TOC in water for pharmaceutical use have in common the objective of completely oxidising the organic molecules in the sample water to produce carbon dioxide followed by measurement of the amount of carbon dioxide produced, the result being used to calculate the carbon concentration in the water.

The apparatus used must discriminate between organic and inorganic carbon, the latter being present as carbonate. The discrimination may be effected either by measuring the inorganic carbon and subtracting it from the total carbon, or by purging inorganic carbon from the sample before oxidisation. Purging may also entrain organic molecules, but such purgeable organic carbon is present in negligible quantities in water for pharmaceutical use.

*Apparatus*. Use a calibrated instrument installed either on-line or off-line. Verify the system suitability at suitable intervals as described below. The apparatus must have a limit of detection specified by the manufacturer of 0.05 mg or less of carbon per litre.

*TOC water*. Use highly purified water complying with the following specifications:

- conductivity: not greater than 1.0 µS·cm$^{-1}$ at 25 °C,
- total organic carbon: not greater than 0.1 mg/L.

Depending on the type of apparatus used, the content of heavy metals and copper may be critical. The manufacturer's instructions should be followed.

*Glassware preparation*. Use glassware that has been scrupulously cleaned by a method that will remove organic matter. Use *TOC water* for the final rinse of glassware.

*Standard solution*. Dissolve *sucrose R*, dried at 105 °C for 3 h in *TOC water* to obtain a solution containing 1.19 mg of sucrose per litre (0.50 mg of carbon per litre).

*Test solution*. Using all due care to avoid contamination, collect water to be tested in an airtight container leaving minimal head-space. Examine the water with minimum delay to reduce contamination from the container and its closure.

*System suitability solution*. Dissolve *1,4-benzoquinone R* in *TOC water* to obtain a solution having a concentration of 0.75 mg of 1,4-benzoquinone per litre (0.50 mg of carbon per litre).

*TOC water control.* Use *TOC water* obtained at the same time as that used to prepare the standard solution and the system suitability solution.

*Control solutions.* In addition to the *TOC water control*, prepare suitable blank solutions or other solutions needed for establishing the baseline or for calibration adjustments following the manufacturer's instructions; run the appropriate blanks to zero the instrument.

*System suitability.* Run the following solutions and record the responses: *TOC water* ($r_w$); *standard solution* ($r_s$); *system suitability solution* ($r_{ss}$). Calculate the percentage response efficiency using the expression:

$$\frac{r_{ss} - r_w}{r_s - r_w} \times 100$$

The system is suitable if the response efficiency is not less than 85 per cent and not more than 115 per cent of the theoretical response.

*Procedure.* Run the test solution and record the response ($r_u$). The test solution complies with the test if $r_u$ is not greater than $r_s - r_w$.

The method can also be applied using on-line instrumentation that has been adequately calibrated and shown to have acceptable system suitability. The location of instrumentation must be chosen to ensure that the responses are representative of the water used.

**01/2008:20245**

## 2.2.45. SUPERCRITICAL FLUID CHROMATOGRAPHY

Supercritical fluid chromatography (SFC) is a method of chromatographic separation in which the mobile phase is a fluid in a supercritical or a subcritical state. The stationary phase, contained in a column, consists of either finely divided solid particles, such as a silica or porous graphite, a chemically modified stationary phase, as used in liquid chromatography, or, for capillary columns, a cross-linked liquid film evenly coated on the walls of the column.

SFC is based on mechanisms of adsorption or mass distribution.

APPARATUS

The apparatus usually consists of a cooled pumping system, an injector, a chromatographic column, contained in an oven, a detector, a pressure regulator and a data acquisition device (or an integrator or a chart recorder).

**Pumping system**

Pumping systems are required to deliver the mobile phase at a constant flow rate. Pressure fluctuations are to be minimised, e.g. by passing the pressurised solvent through a pulse-damping device. Tubing and connections are capable of withstanding the pressures developed by the pumping system.

Microprocessor controlled systems are capable of accurately delivering a mobile phase in either constant or varying conditions, according to a defined programme. In the case of gradient elution, pumping systems which deliver solvent(s) from several reservoirs are available and solvent mixing can be achieved on either the low or high-pressure side of the pump(s).

**Injectors**

Injection may be carried out directly at the head of the column using a valve.

**Stationary phases**

Stationary phases are contained in columns which have been described in the chapters on *Liquid chromatography* (*2.2.29*) (packed columns) and *Gas chromatography* (*2.2.28*) (capillary columns). A capillary column has a maximum internal diameter (Ø) of 100 µm.

**Mobile phases**

Usually the mobile phase is carbon-dioxide which may contain a polar modifier such as methanol, 2-propanol or acetonitrile. The composition, pressure (density), temperature and flow rate of the prescribed mobile phase may either be constant throughout the whole chromatographic procedure (isocratic, isodense, isothermic elution) or may vary according to a defined programme (gradient elution of the modifier, pressure (density), temperature or flow rate).

**Detectors**

Ultraviolet/visible (UV/Vis) spectrophotometers and flame ionisation detectors are the most commonly employed detectors. Light scattering detectors, infrared absorption spectrophotometers, thermal conductivity detectors or other special detectors may be used.

METHOD

Prepare the test solution(s) and the reference solution(s) as prescribed. The solutions must be free from solid particles.

Criteria for assessing the suitability of the system are described in the chapter on *Chromatographic separation techniques* (*2.2.46*). The extent to which adjustments of parameters of the chromatographic system can be made to satisfy the criteria of system suitability are also given in this chapter.

**07/2016:20246**
**corrected 9.2**

## 2.2.46. CHROMATOGRAPHIC SEPARATION TECHNIQUES

Chromatographic separation techniques are multi-stage separation methods in which the components of a sample are distributed between 2 phases, one of which is stationary, while the other is mobile. The stationary phase may be a solid or a liquid supported on a solid or a gel. The stationary phase may be packed in a column, spread as a layer, or distributed as a film, etc. The mobile phase may be gaseous or liquid or supercritical fluid. The separation may be based on adsorption, mass distribution (partition), ion-exchange, etc., or may be based on differences in the physico-chemical properties of the molecules such as size, mass, volume, etc.

This chapter contains definitions and calculations of common parameters and generally applicable requirements for system suitability. Principles of separation, apparatus and methods are given in the following general methods:

- paper chromatography (*2.2.26*);
- thin-layer chromatography (*2.2.27*);
- gas chromatography (*2.2.28*);
- liquid chromatography (*2.2.29*);
- size-exclusion chromatography (*2.2.30*);
- supercritical fluid chromatography (*2.2.45*).

DEFINITIONS

*The system suitability and acceptance criteria in monographs have been set using parameters as defined below. With some equipment, certain parameters, such as the signal-to-noise ratio and resolution, can be calculated using software provided by the manufacturer. It is the responsibility of the user to ensure that the calculation methods used in the software are equivalent to the requirements of the European Pharmacopoeia and to make any necessary corrections if this is not the case.*

**Chromatogram**

A graphical or other representation of detector response, effluent concentration or other quantity used as a measure of effluent concentration, versus time or volume. Idealised chromatograms are represented as a sequence of Gaussian peaks on a baseline (Figure 2.2.46.-1).

**Peak**

The portion of a chromatogram recording the detector response when a single component (or 2 or more unresolved components) is eluted from the column.

The peak may be defined by the peak area, or the peak height ($h$) and the peak width at half-height ($w_h$), or the peak height ($h$) and the peak width between the points of inflection ($w_i$). In Gaussian peaks (Figure 2.2.46.-1) there is the following relationship:

$$w_h = 1.18 w_i$$

**Retention time ($t_R$)**

Time required for elution of a component (Figure 2.2.46.-1, baseline scale being in minutes).

**Retention volume ($V_R$)**

Volume of the mobile phase required for elution of a component. It may be calculated from the retention time and the flow rate ($F$) in millilitres per minute using the following equation:

$$V_R = t_R \times F$$

**Hold-up time ($t_M$)**

Time required for elution of an unretained component (Figure 2.2.46.-1, baseline scale being in minutes). In size-exclusion chromatography, the symbol $t_0$ (see below) is used.

**Hold-up volume ($V_M$)**

Volume of the mobile phase required for elution of an unretained component. It may be calculated from the hold-up time and the flow rate ($F$) in millilitres per minute using the following equation:

$$V_M = t_M \times F$$

In size-exclusion chromatography, the symbol $V_0$ (see below) is used.

**Retention factor ($k$)**

The retention factor (also known as mass distribution ratio ($D_m$) or capacity factor ($k'$)) is defined as:

$$k = \frac{\text{amount of component in stationary phase}}{\text{amount of component in mobile phase}} = K_C \frac{V_s}{V_M}$$

$K_C$ = distribution constant (also known as equilibrium distribution coefficient);

$V_S$ = volume of the stationary phase;

$V_M$ = volume of the mobile phase.

The retention factor of a component may be determined from the chromatogram using the following equation:

$$k = \frac{t_R - t_M}{t_M}$$

**Total mobile phase time ($t_t$)**

In size-exclusion chromatography, retention time of a component whose molecules are smaller than the smallest gel pores (Figure 2.2.46.-2).

**Total mobile phase volume ($V_t$)**

In size-exclusion chromatography, retention volume of a component whose molecules are smaller than the smallest gel pores. It may be calculated from the total mobile phase time and the flow rate ($F$) in millilitres per minute using the following equation:

$$V_t = t_t \times F$$

**Retention time of an unretained compound ($t_0$)**

In size-exclusion chromatography, retention time of a component whose molecules are larger than the largest gel pores (Figure 2.2.46.-2).

**Retention volume of an unretained compound ($V_0$)**

In size-exclusion chromatography, retention volume of a component whose molecules are larger than the largest gel pores. It may be calculated from the retention time of an unretained compound and the flow rate ($F$) in millilitres per minute using the following equation:

$$V_0 = t_0 \times F$$

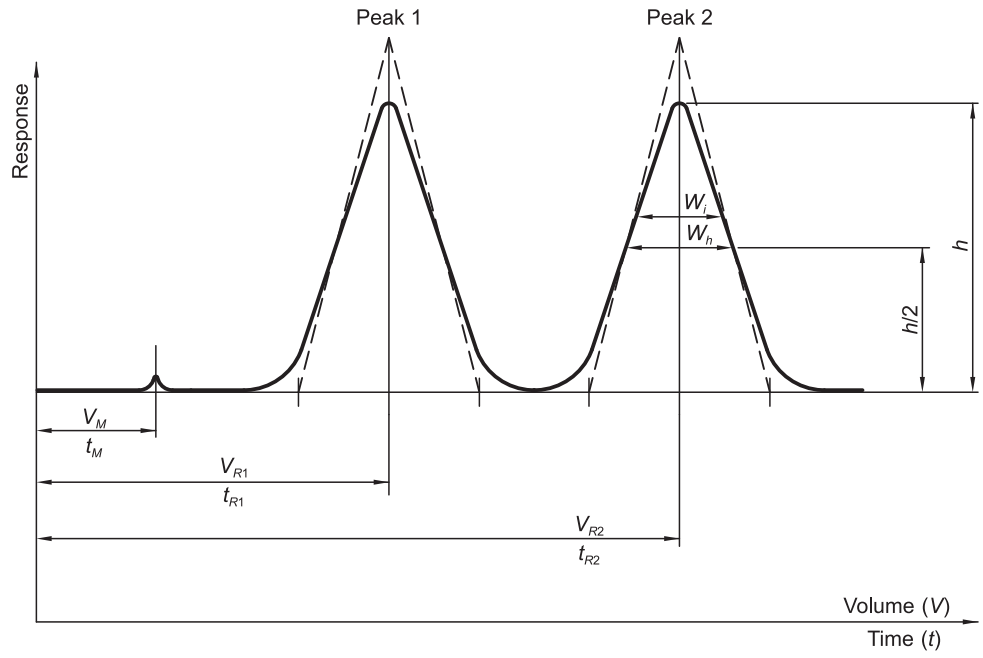

Figure 2.2.46.-1.

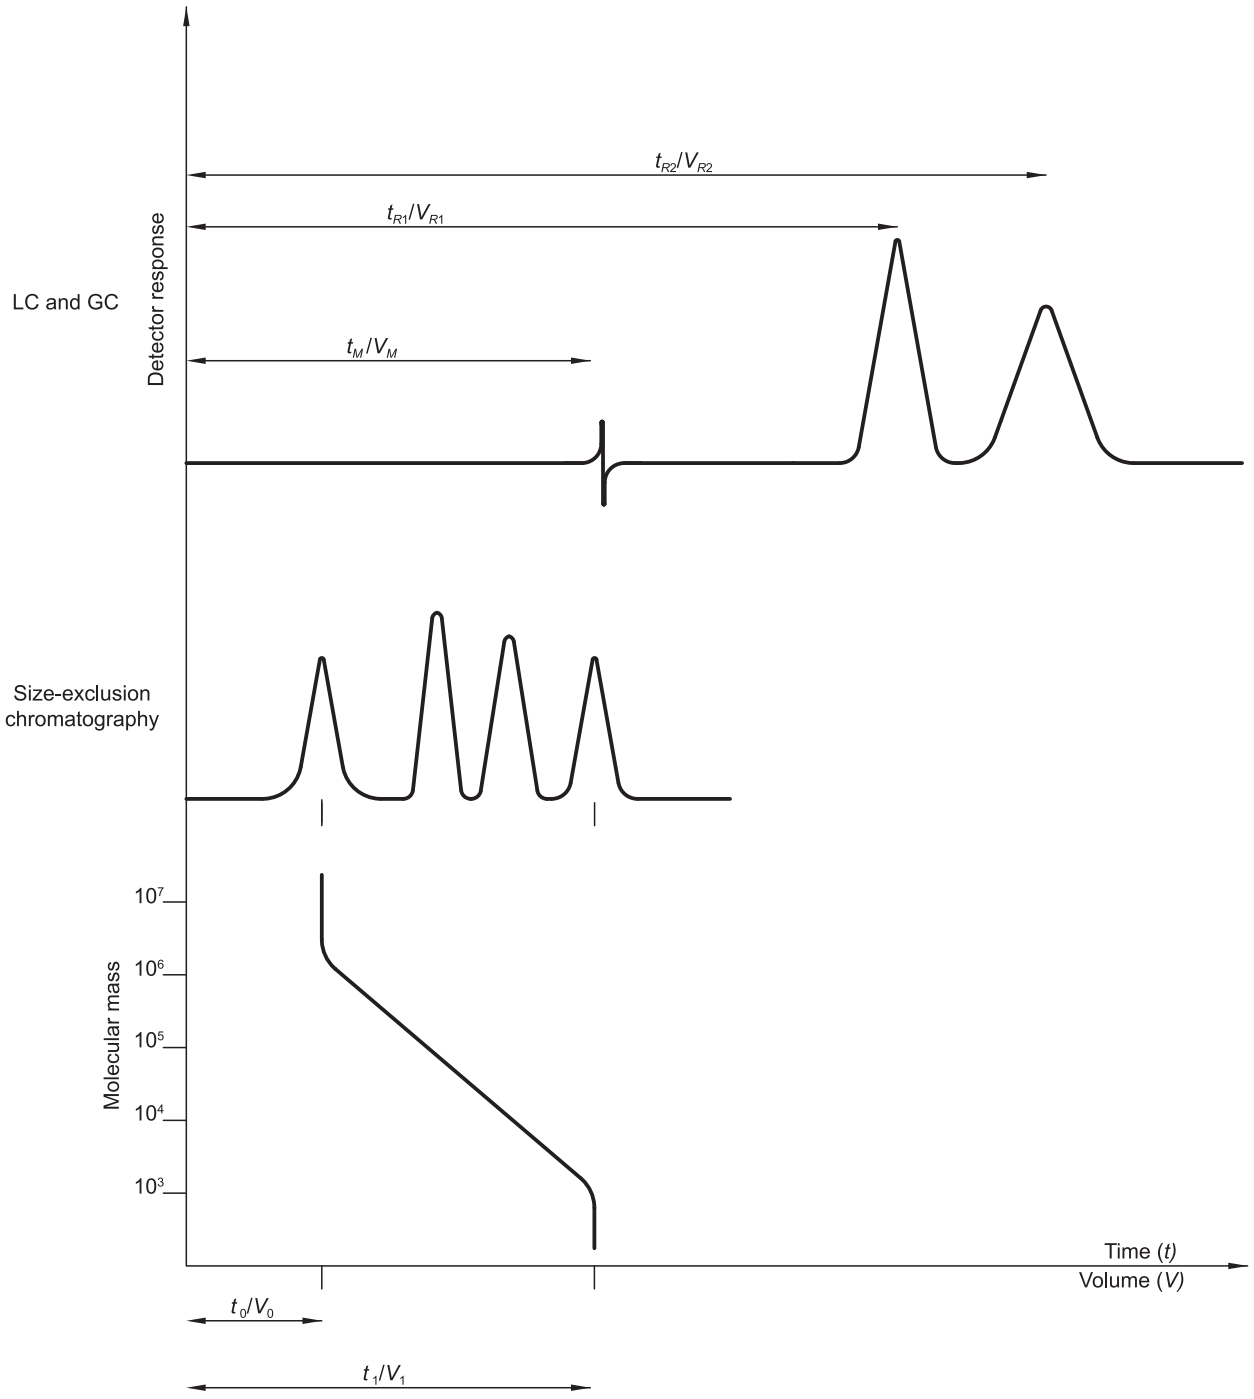

Figure 2.2.46.-2.

**Distribution constant ($K_0$)**

In size-exclusion chromatography, the elution characteristics of a component in a particular column may be given by the distribution constant (also referred to as distribution coefficient), which is calculated using the following equation:

$$K_0 = \frac{t_R - t_0}{t_t - t_0}$$

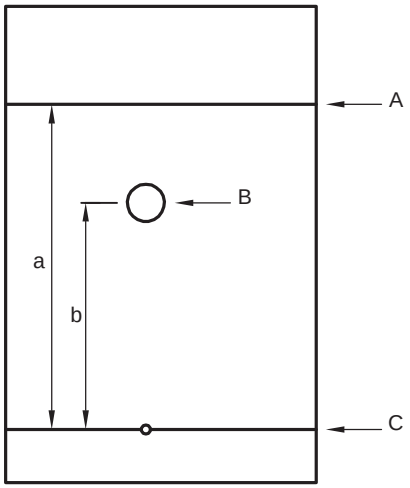
**Retardation factor ($R_F$)**

The retardation factor (also known as retention factor ($R_f$)), used in planar chromatography, is the ratio of the distance from the point of application to the centre of the spot and the distance travelled by the solvent front from the point of application (Figure 2.2.46.-3).

$$R_F = \frac{b}{a}$$

$b$ = migration distance of the component;

$a$ = migration distance of the solvent front.



A. mobile phase front B. spot C. line of application

Figure 2.2.46.-3.

**Plate number (*N*)**

The column performance (apparent efficiency) may be calculated from data obtained under either isothermal, isocratic or isodense conditions, depending on the technique, as the plate number (also referred to as number of theoretical plates), using the following equation, the values of $t_R$ and $w_h$ being expressed in the same units:

$$N = 5.54\left(\frac{t_R}{w_h}\right)^2$$

$t_R$ = retention time of the peak corresponding to the component;

$w_h$ = width of the peak at half-height.

The plate number varies with the component as well as with the column, the column temperature, the mobile phase and the retention time.

**Dwell volume (*D*)**

The dwell volume (also known as gradient delay volume) is the volume between the point at which the eluents meet and the top of the column. It can be determined using the following procedure.

*Column*: replace the chromatographic column by an appropriate capillary tubing (e.g. 1 m × 0.12 mm).

*Mobile phase*:

– *mobile phase A*: *water R*;

– *mobile phase B*: 0.1 per cent *V/V* solution of *acetone R*;

| Time (min) | Mobile phase A (per cent *V/V*) | Mobile phase B (per cent *V/V*) |
|---|---|---|
| 0 - 20 | 100 → 0 | 0 → 100 |
| 20 - 30 | 0 | 100 |

*Flow rate*: set to obtain sufficient back-pressure (e.g. 2 mL/min).

*Detection*: spectrophotometer at 265 nm.

Determine the time ($t_{0.5}$) in minutes when the absorbance has increased by 50 per cent (Figure 2.2.46.-4).

$$D = t_D \times F$$

$t_D$ = $t_{0.5} - 0.5t_G$ (in minutes);

$t_G$ = pre-defined gradient time (= 20 min);

$F$ = flow rate (in millilitres per minute).

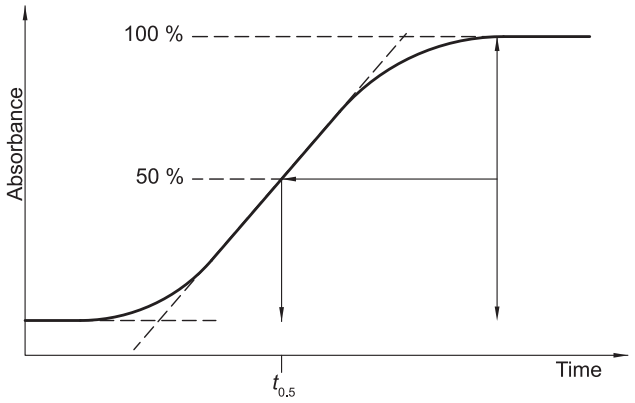


Figure 2.2.46.-4

**Symmetry factor ($A_s$)**

The symmetry factor of a peak (Figure 2.2.46.-5) is calculated using the following equation:

$$A_s = \frac{w_{0.05}}{2d}$$

$w_{0.05}$ = width of the peak at one-twentieth of the peak height;

$d$ = distance between the perpendicular dropped from the peak maximum and the leading edge of the peak at one-twentieth of the peak height.

An $A_s$ value of 1.0 signifies symmetry. When $A_s > 1.0$, the peak is tailing. When $A_s < 1.0$, the peak is fronting.

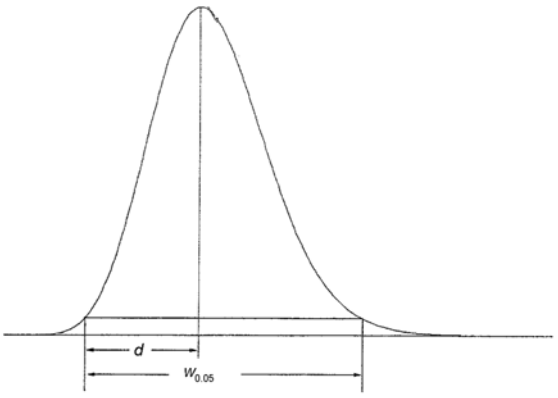

Figure 2.2.46.-5

**Resolution ($R_s$)**

The resolution between peaks of 2 components (Figure 2.2.46.-1) may be calculated using the following equation:

$$R_s = \frac{1.18(t_{R2} - t_{R1})}{w_{h1} + w_{h2}}$$

$t_{R2} > t_{R1}$

$t_{R1}$, $t_{R2}$ = retention times of the peaks;

$w_{h1}$, $w_{h2}$ = peak widths at half-height.

In quantitative planar chromatography, using densitometry, the migration distances are used instead of retention times and the resolution between peaks of 2 components may be calculated using the following equation:

$$R_s = \frac{1.18a(R_{F2} - R_{F1})}{w_{h1} + w_{h2}}$$

$R_{F1}$, $R_{F2}$ = retardation factors of the peaks;

$w_{h1}$, $w_{h2}$ = peak widths at half-height;

$a$ = migration distance of the solvent front.

**Peak-to-valley ratio (*p/v*)**

The peak-to-valley ratio may be employed as a system suitability criterion in a test for related substances when baseline separation between 2 peaks is not achieved (Figure 2.2.46.-6).

$$p / v = \frac{H_p}{H_v}$$

$H_p$ = height above the extrapolated baseline of the minor peak;

$H_v$ = height above the extrapolated baseline at the lowest point of the curve separating the minor and major peaks.

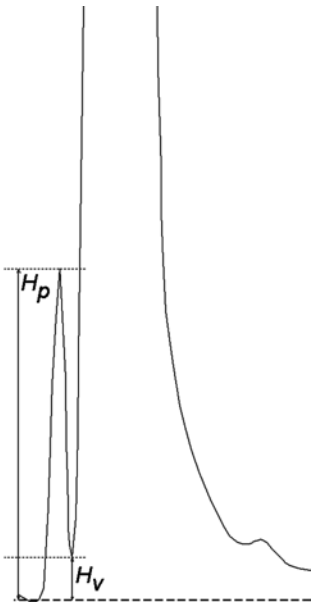

Figure 2.2.46.-6

**Relative retention (*r*)**

Relative retention is calculated as an estimate using the following equation:

$$r = \frac{t_{Ri} - t_M}{t_{Rst} - t_M}$$

$t_{Ri}$ = retention time of the peak of interest;

$t_{Rst}$ = retention time of the reference peak (usually the peak corresponding to the substance to be examined);

$t_M$ = hold-up time.

The unadjusted relative retention ($r_G$) is calculated using the following equation:

$$r_G = \frac{t_{Ri}}{t_{Rst}}$$

Unless otherwise indicated, values for relative retention stated in monographs correspond to unadjusted relative retention.

In planar chromatography, the retardation factors $R_{Fst}$ and $R_{Fi}$ are used instead of $t_{Rst}$ and $t_{Ri}$.

**Signal-to-noise ratio (*S/N*)**

The short-term noise influences the precision of quantification. The signal-to-noise ratio is calculated using the following equation:

$$S / N = \frac{2H}{h}$$

$H$ = height of the peak (Figure 2.2.46.-7) corresponding to the component concerned, in the chromatogram obtained with the prescribed reference solution, measured from the maximum of the peak to the extrapolated baseline of the signal observed over a distance equal to at least 5 times the width at half-height;

$h$ = range of the noise in a chromatogram obtained after injection or application of a blank, observed over a distance equal to at least 5 times the width at half-height of the peak in the chromatogram obtained with the prescribed reference solution and, if possible, situated equally around the place where this peak would be found.

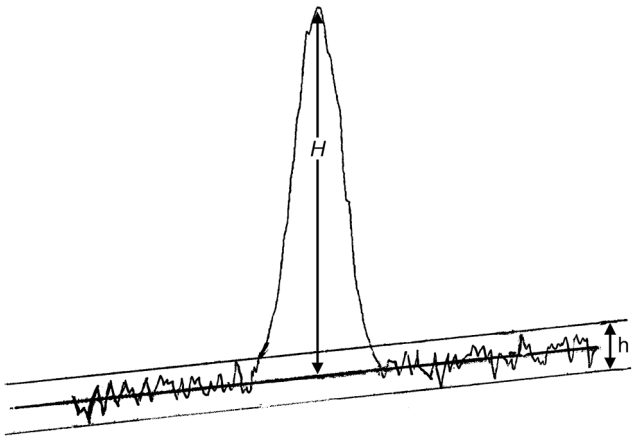

Figure 2.2.46.-7.

**System repeatability**

The repeatability of response is expressed as an estimated percentage relative standard deviation ($s_r$(%)) of a consecutive series of measurements for not fewer than 3 injections or applications of a reference solution, and is calculated using the following equation:

$$s_r(\%) = \frac{100}{\overline{y}} \sqrt{\frac{\sum (y_i - \overline{y})^2}{n - 1}}$$

$y_i$ = individual values expressed as peak area, peak height, or ratio of areas by the internal standardisation method;

$\overline{y}$ = mean of individual values;

$n$ = number of individual values.

SYSTEM SUITABILITY

The various components of the equipment employed must be qualified and be capable of achieving the performance required to conduct the test or assay.

The system suitability tests represent an integral part of the method and are used to ensure adequate performance of the chromatographic system. Apparent efficiency, retention factor (mass distribution ratio), resolution and symmetry factor are the parameters that are usually employed in assessing the performance of the column. Factors that may affect the chromatographic behaviour include:

- the composition, ionic strength, temperature and apparent pH of the mobile phase;
- flow rate, column dimensions, column temperature and pressure;
- stationary phase characteristics including type of chromatographic support (particle-based or monolithic), particle or macropore size, porosity, specific surface area;
- reversed-phase and other surface-modification of the stationary phases, the extent of chemical modification (as expressed by end-capping, carbon loading etc.).

The following requirements and any supplementary requirements given in the individual monograph are to be fulfilled unless otherwise prescribed:

- in a related substances test or assay, for a peak in the chromatogram obtained with a reference solution used for quantification, the symmetry factor is 0.8 to 1.5, unless otherwise prescribed;
- in an assay of an active substance where the value is 100 per cent for a pure substance, the maximum permitted relative standard deviation ($s_r(\%)_{max}$) for the defined limits is calculated for a series of injections of the reference solution using the following equation:

$$s_r(\%)_{max} = \frac{KB\sqrt{n}}{t_{90\%,n-1}}$$

$K$ = constant (0.349), obtained from the expression $K = \frac{0.6}{\sqrt{2}} \times \frac{t_{90\%,5}}{\sqrt{6}}$ in which $\frac{0.6}{\sqrt{2}}$ represents the required percentage relative standard deviation after 6 injections for $B = 1.0$;

$B$ = upper limit given in the definition of the individual monograph minus 100 per cent;

$n$ = number of replicate injections of the reference solution ($3 \leq n \leq 6$);

$t_{90\%,n-1}$ = Student's $t$ at the 90 per cent probability level (double sided) with $n-1$ degrees of freedom.

Unless otherwise prescribed, the maximum permitted relative standard deviation does not exceed the appropriate value given in Table 2.2.46.-1. This requirement does not apply to tests for related substances.

Table 2.2.46.-1. – *Repeatability requirements*

| | Number of individual injections | | | |
|---|---|---|---|---|
| | 3 | 4 | 5 | 6 |
| ***B* (per cent)** | **Maximum permitted relative standard deviation** | | | |
| 2.0 | 0.41 | 0.59 | 0.73 | 0.85 |
| 2.5 | 0.52 | 0.74 | 0.92 | 1.06 |
| 3.0 | 0.62 | 0.89 | 1.10 | 1.27 |

- in a related substances test, the limit of quantification (corresponding to a signal-to-noise ratio of 10) is equal to or less than the disregard limit.

Compliance with the system suitability criteria is required throughout the chromatographic procedure. Depending on various factors, such as the frequency of use of the procedure and experience with the chromatographic system, the analyst chooses an appropriate verification scheme to monitor this.

ADJUSTMENT OF CHROMATOGRAPHIC CONDITIONS

The extent to which the various parameters of a chromatographic test may be adjusted to satisfy the system suitability criteria without fundamentally modifying the methods are listed below. Adjustment of conditions with gradient elutions is more critical than with isocratic elutions, since it may lead to shifts in peaks to a different step of the gradient, thus leading to the incorrect assignment of peaks, and to the masking of peaks or a shift such that elution occurs beyond the prescribed elution time. Changes other than those indicated require revalidation of the method. The chromatographic conditions described have been validated during the elaboration of the monograph.

The system suitability tests are included to verify that the separation required for satisfactory performance of the test or assay is achieved. Nonetheless, since the stationary phases are described in a general way and there is such a variety available commercially, with differences in chromatographic behaviour, some adjustments of the chromatographic conditions may be necessary to achieve the prescribed system suitability requirements. With reversed-phase liquid chromatographic methods in particular, adjustment of the various parameters will not always result in satisfactory chromatography. In that case, it may be necessary to replace the column with another of the same type (e.g. octadecylsilyl silica gel), which exhibits the desired chromatographic behaviour. The Knowledge database on the EDQM website usually contains information on the column(s) used during monograph elaboration.

For critical parameters the adjustments are defined clearly in the monograph to ensure the system suitability.

**Thin-layer chromatography and paper chromatography**

*Composition of the mobile phase*: the amount of the minor solvent component may be adjusted by ± 30 per cent relative or ± 2 per cent absolute, whichever is the larger; for a minor component at 10 per cent of the mobile phase, a 30 per cent relative adjustment allows a range of 7-13 per cent whereas a 2 per cent absolute adjustment allows a range of 8-12 per cent, the relative value therefore being the larger; for a minor component at 5 per cent of the mobile phase, a 30 per cent relative adjustment allows a range of 3.5-6.5 per cent whereas a 2 per cent absolute adjustment allows a range of 3-7 per cent, the absolute value being the larger in this case; no other component is altered by more than 10 per cent absolute.

*pH of the aqueous component of the mobile phase*: ± 0.2 pH, unless otherwise prescribed, or ± 1.0 pH when non-ionisable substances are to be examined.

*Concentration of salts in the buffer component of a mobile phase*: ± 10 per cent.

*Application volume*: 10-20 per cent of the prescribed volume if using fine particle size plates (2-10 µm).

**Liquid chromatography: isocratic elution**

*Composition of the mobile phase*: the amount of the minor solvent component may be adjusted by ± 30 per cent relative or ± 2 per cent absolute, whichever is the larger (see example above); no other component is altered by more than 10 per cent absolute.

*pH of the aqueous component of the mobile phase*: ± 0.2 pH, unless otherwise prescribed, or ± 1.0 pH when non-ionisable substances are to be examined.

*Concentration of salts in the buffer component of a mobile phase*: ± 10 per cent.

*Flow rate*: ± 50 per cent; a larger adjustment is acceptable when changing the column dimensions (see the formula below).

*Column parameters*

*Stationary phase*:

- no change of the identity of the substituent of the stationary phase permitted (e.g. no replacement of C18 by C8);
- *particle size*: maximum reduction of 50 per cent; no increase permitted.

*Column dimensions*:

- *length*: ± 70 per cent;
- *internal diameter*: ± 25 per cent.

When column dimensions are changed, the flow rate may be adjusted as necessary using the following equation:

$$F_2 = F_1 \frac{l_2 d_2^2}{l_1 d_1^2}$$

$F_1$ = flow rate indicated in the monograph, in millilitres per minute;

$F_2$ = adjusted flow rate, in millilitres per minute;

$l_1$ = length of the column indicated in the monograph, in millimetres;

$l_2$ = length of the column used, in millimetres;

$d_1$ = internal diameter of the column indicated in the monograph, in millimetres;

$d_2$ = internal diameter of the column used, in millimetres.

*Temperature*: ± 10 °C, where the operating temperature is specified, unless otherwise prescribed.

*Detector wavelength*: no adjustment permitted.

*Injection volume*: may be decreased, provided detection and repeatability of the peak(s) to be determined are satisfactory; no increase permitted.

**Liquid chromatography: gradient elution**

Adjustment of chromatographic conditions for gradient systems requires greater caution than for isocratic systems.

*Composition of the mobile phase/gradient elution*: minor adjustments of the composition of the mobile phase and the gradient are acceptable provided that:

- the system suitability requirements are fulfilled;
- the principal peak(s) elute(s) within ± 15 per cent of the indicated retention time(s);
- the final composition of the mobile phase is not weaker in elution power than the prescribed composition.

Where compliance with the system suitability requirements cannot be achieved, it is often preferable to consider the dwell volume or to change the column.

*Dwell volume.* The configuration of the equipment employed may significantly alter the resolution, retention time and relative retentions described. Should this occur, it may be due to excessive dwell volume. Monographs preferably include an isocratic step before the start of the gradient programme so that an adaptation can be made to the gradient time points to take account of differences in dwell volume between the system used for method development and that actually used. It is the user's responsibility to adapt the length of the isocratic step to the analytical equipment used. If the dwell volume used during the elaboration of the monograph is given in the monograph, the time points ($t$ min) stated in the gradient table may be replaced by adapted time points ($t_c$ min), calculated using the following equation:

$$t_c = t - \frac{(D - D_0)}{F}$$

$D$ = dwell volume, in millilitres;

$D_0$ = dwell volume used for development of the method, in millilitres;

$F$ = flow rate, in millilitres per minute.

The isocratic step introduced for this purpose may be omitted if validation data for application of the method without this step is available.

*pH of the aqueous component of the mobile phase*: no adjustment permitted.

*Concentration of salts in the buffer component of a mobile phase*: no adjustment permitted.

*Flow rate*: adjustment is acceptable when changing the column dimensions (see the formula below).

*Column parameters*

*Stationary phase*:

- no change of the identity of the substituent of the stationary phase permitted (e.g. no replacement of C18 by C8);
- *particle size*: no adjustment permitted.

*Column dimensions*:

- *length*: ± 70 per cent;
- *internal diameter*: ± 25 per cent.

When column dimensions are changed, the flow rate may be adjusted as necessary using the following equation:

$$F_2 = F_1 \frac{l_2 d_2^2}{l_1 d_1^2}$$

$F_1$ = flow rate indicated in the monograph, in millilitres per minute;

$F_2$ = adjusted flow rate, in millilitres per minute;

$l_1$ = length of the column indicated in the monograph, in millimetres;

$l_2$ = length of the column used, in millimetres;

$d_1$ = internal diameter of the column indicated in the monograph, in millimetres;

$d_2$ = internal diameter of the column used, in millimetres.

*Temperature*: ± 5 °C, where the operating temperature is specified, unless otherwise prescribed.

*Detector wavelength*: no adjustment permitted.

*Injection volume*: may be decreased, provided detection and repeatability of the peak(s) to be determined are satisfactory; no increase permitted.

**Gas chromatography**

*Column parameters*

*Stationary phase*:

- *particle size*: maximum reduction of 50 per cent; no increase permitted (packed columns);
- *film thickness*: – 50 per cent to + 100 per cent (capillary columns).

*Column dimensions*:

- *length*: ± 70 per cent;
- *internal diameter*: ± 50 per cent.

*Flow rate*: ± 50 per cent.

*Temperature*: ± 10 per cent.

*Injection volume and split volume*: may be adjusted, provided detection and repeatability are satisfactory.

**Supercritical fluid chromatography**

*Composition of the mobile phase*: for packed columns, the amount of the minor solvent component may be adjusted by ± 30 per cent relative or ± 2 per cent absolute, whichever is the larger; no adjustment is permitted for a capillary column system.

*Detector wavelength*: no adjustment permitted.

*Column parameters*

*Stationary phase*:

– *particle size*: maximum reduction of 50 per cent; no increase permitted (packed columns).

*Column dimensions*:

– *length*: ± 70 per cent;

– *internal diameter*:

± 25 per cent (packed columns);

± 50 per cent (capillary columns).

*Flow rate*: ± 50 per cent.

*Temperature*: ± 5 °C, where the operating temperature is specified.

*Injection volume*: may be decreased, provided detection and repeatability are satisfactory; no increase permitted.

QUANTIFICATION

Peaks due to solvents and reagents or arising from the mobile phase or the sample matrix are disregarded during quantification.

– *Detector sensitivity*. The detector sensitivity is the signal output per unit concentration or unit mass of a substance in the mobile phase entering the detector. The relative detector response factor, commonly referred to as *response factor*, expresses the sensitivity of a detector for a given substance relative to a standard substance. The *correction factor* is the reciprocal of the response factor.

– *External standard method*. The concentration of the component(s) to be analysed is determined by comparing the response(s) (peak(s)) obtained with the test solution to the response(s) (peak(s)) obtained with a reference solution.

– *Internal standard method*. Equal amounts of a component that will be resolved from the substance to be examined (the internal standard) are introduced into the test solution and a reference solution. The internal standard is chosen such that it does not react with the substance to be examined, is stable and does not contain impurities with the same retention time as that of the substance to be examined. The concentration of the substance to be examined is determined by comparing the ratio of the peak areas or peak heights due to the substance to be examined and the internal standard in the test solution with the ratio of the peak areas or peak heights due to the substance to be examined and the internal standard in the reference solution.

– *Normalisation procedure*. The percentage content of a component of the substance to be examined is calculated by determining the area of the corresponding peak as a percentage of the total area of all the peaks, excluding those due to solvents or reagents or arising from the mobile phase or the sample matrix, and those at or below the disregard limit.

– *Calibration procedure*. The relationship between the measured or evaluated signal ($y$) and the quantity (concentration, mass, etc.) of substance ($x$) is determined and the calibration function is calculated. The analytical results are calculated from the measured signal or evaluated signal of the analyte by means of the inverse function.

In tests for related substances for both the external standard method, when a dilution of the test solution is used for comparison, and the normalisation procedure, any correction factors indicated in the monograph are applied (i.e. when the response factor is outside the range 0.8-1.2).

When the related substances test prescribes the total of impurities or there is a quantitative determination of an impurity, it is important to choose an appropriate threshold setting and appropriate conditions for the integration of the peak areas. In such tests the *disregard limit*, i.e. the limit at or below which a peak is disregarded, is generally 0.05 per cent. Integration of the peak area of any impurity that is not completely separated from the principal peak is preferably performed by valley-to-valley extrapolation (tangential skim).

# 2.2.47. CAPILLARY ELECTROPHORESIS(6)

GENERAL PRINCIPLES

Capillary electrophoresis is a physical method of analysis based on the migration, inside a capillary, of charged analytes dissolved in an electrolyte solution, under the influence of a direct-current electric field.

The migration velocity of an analyte under an electric field of intensity $E$, is determined by the electrophoretic mobility of the analyte and the electro-osmotic mobility of the buffer inside the capillary. The electrophoretic mobility of a solute ($\mu_{ep}$) depends on the characteristics of the solute (electric charge, molecular size and shape) and those of the buffer in which the migration takes place (type and ionic strength of the electrolyte, pH, viscosity and additives). The electrophoretic velocity ($v_{ep}$) of a solute, assuming a spherical shape, is given by the equation:

$$v_{ep} = \mu_{ep} \times E = \left(\frac{q}{6\pi\eta r}\right) \times \left(\frac{V}{L}\right)$$

$q$ = effective charge of the solute,

$\eta$ = viscosity of the electrolyte solution,

$r$ = Stoke's radius of the solute,

$V$ = applied voltage,

$L$ = total length of the capillary.

When an electric field is applied through the capillary filled with buffer, a flow of solvent is generated inside the capillary, called electro-osmotic flow. The velocity of the electro-osmotic flow depends on the electro-osmotic mobility ($\mu_{eo}$) which in turn depends on the charge density on the capillary internal wall and the buffer characteristics. The electro-osmotic velocity ($v_{eo}$) is given by the equation:

$$v_{eo} = \mu_{eo} \times E = \left(\frac{\varepsilon\zeta}{\eta}\right) \times \left(\frac{V}{L}\right)$$

$\varepsilon$ = dielectric constant of the buffer,

$\zeta$ = zeta potential of the capillary surface.

The velocity of the solute ($v$) is given by:

$$v = v_{ep} + v_{eo}$$

The electrophoretic mobility of the analyte and the electro-osmotic mobility may act in the same direction or in opposite directions, depending on the charge of the solute. In normal capillary electrophoresis, anions will migrate in the opposite direction to the electro-osmotic flow and their velocities will be smaller than the electro-osmotic velocity. Cations will migrate in the same direction as the electro-osmotic flow and their velocities will be greater than the electro-osmotic velocity. Under conditions in which

(6) This chapter has undergone pharmacopoeial harmonisation. See chapter *5.8. Pharmacopoeial harmonisation.*

there is a fast electro-osmotic velocity with respect to the electrophoretic velocity of the solutes, both cations and anions can be separated in the same run.

The time ($t$) taken by the solute to migrate the distance ($l$) from the injection end of the capillary to the detection point (capillary effective length) is given by the expression:

$$t = \frac{l}{v_{ep} + v_{eo}} = \frac{l \times L}{\left(\mu_{ep} + \mu_{eo}\right) \times V}$$

In general, uncoated fused-silica capillaries above pH 3 have negative charge due to ionised silanol groups in the inner wall. Consequently, the electro-osmotic flow is from anode to cathode. The electro-osmotic flow must remain constant from run to run if good reproducibility is to be obtained in the migration velocity of the solutes. For some applications, it may be necessary to reduce or suppress the electro-osmotic flow by modifying the inner wall of the capillary or by changing the concentration, composition and/or pH of the buffer solution.

After the introduction of the sample into the capillary, each analyte ion of the sample migrates within the background electrolyte as an independent zone, according to its electrophoretic mobility. Zone dispersion, that is the spreading of each solute band, results from different phenomena. Under ideal conditions the sole contribution to the solute-zone broadening is molecular diffusion of the solute along the capillary (longitudinal diffusion). In this ideal case the efficiency of the zone, expressed as the number of theoretical plates ($N$), is given by:

$$N = \frac{\left(\mu_{ep} + \mu_{eo}\right) \times V \times l}{2 \times D \times L}$$

$D$ = molecular diffusion coefficient of the solute in the buffer.

In practice, other phenomena such as heat dissipation, sample adsorption onto the capillary wall, mismatched conductivity between sample and buffer, length of the injection plug, detector cell size and unlevelled buffer reservoirs can also significantly contribute to band dispersion.

Separation between 2 bands (expressed as the resolution, $R_s$) can be obtained by modifying the electrophoretic mobility of the analytes, the electro-osmotic mobility induced in the capillary and by increasing the efficiency for the band of each analyte, according to the equation:

$$R_s = \frac{\sqrt{N}\left(\mu_{epb} - \mu_{epa}\right)}{4\left(\overline{\mu}_{ep} + \mu_{eo}\right)}$$

$\mu_{epa}$ and $\mu_{epb}$ = electrophoretic mobilities of the 2 analytes separated,

$\overline{\mu}_{ep}$ = mean electrophoretic mobility of the 2 analytes $\overline{\mu}_{ep} = \frac{1}{2}\left(\mu_{epb} + \mu_{epa}\right)$.

## APPARATUS

An apparatus for capillary electrophoresis is composed of:

- a high-voltage, controllable direct-current power supply;
- 2 buffer reservoirs, held at the same level, containing the prescribed anodic and cathodic solutions;
- 2 electrode assemblies (the cathode and the anode), immersed in the buffer reservoirs and connected to the power supply;
- a separation capillary (usually made of fused-silica) which, when used with some specific types of detectors, has an optical viewing window aligned with the detector. The ends of the capillary are placed in the buffer reservoirs. The capillary is filled with the solution prescribed in the monograph;
- a suitable injection system;
- a detector able to monitor the amount of substances of interest passing through a segment of the separation capillary at a given time; it is usually based on absorption spectrophotometry (UV and visible) or fluorimetry, but conductimetric, amperometric or mass spectrometric detection can be useful for specific applications; indirect detection is an alternative method used to detect non-UV-absorbing and non-fluorescent compounds;
- a thermostatic system able to maintain a constant temperature inside the capillary is recommended to obtain a good separation reproducibility;
- a recorder and a suitable integrator or a computer.

The definition of the injection process and its automation are critical for precise quantitative analysis. Modes of injection include gravity, pressure or vacuum injection and electrokinetic injection. The amount of each sample component introduced electrokinetically depends on its electrophoretic mobility, leading to possible discrimination using this injection mode.

Use the capillary, the buffer solutions, the preconditioning method, the sample solution and the migration conditions prescribed in the monograph of the considered substance. The employed electrolytic solution is filtered to remove particles and degassed to avoid bubble formation that could interfere with the detection system or interrupt the electrical contact in the capillary during the separation run. A rigorous rinsing procedure should be developed for each analytical method to achieve reproducible migration times of the solutes.

## CAPILLARY ZONE ELECTROPHORESIS

*PRINCIPLE*

In capillary zone electrophoresis, analytes are separated in a capillary containing only buffer without any anticonvective medium. With this technique, separation takes place because the different components of the sample migrate as discrete bands with different velocities. The velocity of each band depends on the electrophoretic mobility of the solute and the electro-osmotic flow in the capillary (see General Principles). Coated capillaries can be used to increase the separation capacity of those substances adsorbing on fused-silica surfaces.

Using this mode of capillary electrophoresis, the analysis of both small ($M_r$ < 2000) and large molecules (2000 < $M_r$ < 100 000) can be accomplished. Due to the high efficiency achieved in capillary zone electrophoresis, separation of molecules having only minute differences in their charge-to-mass ratio can be effected. This separation mode also allows the separation of chiral compounds by addition of chiral selectors to the separation buffer.

*OPTIMISATION*

Optimisation of the separation is a complex process where several separation parameters can play a major role. The main factors to be considered in the development of separations are instrumental and electrolytic solution parameters.

**Instrumental parameters**

*Voltage.* A Joule heating plot is useful in optimising the applied voltage and capillary temperature. Separation time is inversely proportional to applied voltage. However, an increase in the voltage used can cause excessive heat production, giving rise to temperature and, as a result thereof, viscosity gradients in the buffer inside the capillary. This effect causes band broadening and decreases resolution.

*Polarity.* Electrode polarity can be normal (anode at the inlet and cathode at the outlet) and the electro-osmotic flow will move toward the cathode. If the electrode polarity is reversed, the electro-osmotic flow is away from the outlet and only charged analytes with electrophoretic mobilities greater than the electro-osmotic flow will pass to the outlet.

*Temperature*. The main effect of temperature is observed on buffer viscosity and electrical conductivity, and therefore on migration velocity. In some cases, an increase in capillary temperature can cause a conformational change in proteins, modifying their migration time and the efficiency of the separation.

*Capillary*. The dimensions of the capillary (length and internal diameter) contribute to analysis time, efficiency of separations and load capacity. Increasing both effective length and total length can decrease the electric fields (working at constant voltage) which increases migration time. For a given buffer and electric field, heat dissipation, and hence sample band-broadening, depend on the internal diameter of the capillary. The latter also affects the detection limit, depending on the sample volume injected and the detection system employed.

Since the adsorption of the sample components on the capillary wall limits efficiency, methods to avoid these interactions should be considered in the development of a separation method. In the specific case of proteins, several strategies have been devised to avoid adsorption on the capillary wall. Some of these strategies (use of extreme pH and adsorption of positively charged buffer additives) only require modification of the buffer composition to prevent protein adsorption. In other strategies, the internal wall of the capillary is coated with a polymer, covalently bonded to the silica, that prevents interaction between the proteins and the negatively charged silica surface. For this purpose, ready-to-use capillaries with coatings consisting of neutral-hydrophilic, cationic and anionic polymers are available.

**Electrolytic solution parameters**

*Buffer type and concentration*. Suitable buffers for capillary electrophoresis have an appropriate buffer capacity in the pH range of choice and low mobility to minimise current generation.

Matching buffer-ion mobility to solute mobility, whenever possible, is important for minimising band distortion. The type of sample solvent used is also important to achieve on-column sample focusing, which increases separation efficiency and improves detection.

An increase in buffer concentration (for a given pH) decreases electro-osmotic flow and solute velocity.

*Buffer pH*. The pH of the buffer can affect separation by modifying the charge of the analyte or additives, and by changing the electro-osmotic flow. In protein and peptide separation, changing the pH of the buffer from above to below the isoelectric point (pI) changes the net charge of the solute from negative to positive. An increase in the buffer pH generally increases the electro-osmotic flow.

*Organic solvents*. Organic modifiers (methanol, acetonitrile, etc.) may be added to the aqueous buffer to increase the solubility of the solute or other additives and/or to affect the degree of ionisation of the sample components. The addition of these organic modifiers to the buffer generally causes a decrease in the electro-osmotic flow.

*Additives for chiral separations*. For the separation of optical isomers, a chiral selector is added to the separation buffer. The most commonly used chiral selectors are cyclodextrins, but crown ethers, polysaccharides and proteins may also be used. Since chiral recognition is governed by the different interactions between the chiral selector and each of the enantiomers, the resolution achieved for the chiral compounds depends largely on the type of chiral selector used. In this regard, for the development of a given separation it may be useful to test cyclodextrins having a different cavity size (α-, β-, or γ-cyclodextrin) or modified cyclodextrins with neutral (methyl, ethyl, hydroxyalkyl, etc.) or ionisable (aminomethyl, carboxymethyl, sulfobutyl ether, etc.) groups. When using modified cyclodextrins, batch-to-batch variations in the degree of substitution of the cyclodextrins must be taken into account since it will influence the selectivity. Other factors controlling the resolution in chiral separations are concentration of chiral selector, composition and pH of the buffer and temperature. The use of organic additives, such as methanol or urea can also modify the resolution achieved.

## CAPILLARY GEL ELECTROPHORESIS

*PRINCIPLE*

In capillary gel electrophoresis, separation takes place inside a capillary filled with a gel that acts as a molecular sieve. Molecules with similar charge-to-mass ratios are separated according to molecular size since smaller molecules move more freely through the network of the gel and therefore migrate faster than larger molecules. Different biological macromolecules (for example, proteins and DNA fragments), which often have similar charge-to-mass ratios, can thus be separated according to their molecular mass by capillary gel electrophoresis.

*CHARACTERISTICS OF GELS*

2 types of gels are used in capillary electrophoresis: permanently coated gels and dynamically coated gels. Permanently coated gels, such as cross-linked polyacrylamide, are prepared inside the capillary by polymerisation of the monomers. They are usually bonded to the fused-silica wall and cannot be removed without destroying the capillary. If the gels are used for protein analysis under reducing conditions, the separation buffer usually contains sodium dodecyl sulfate and the samples are denatured by heating in a mixture of sodium dodecyl sulfate and 2-mercaptoethanol or dithiothreitol before injection. When non-reducing conditions are used (for example, analysis of an intact antibody), 2-mercaptoethanol and dithiothreitol are not used. Separation in cross-linked gels can be optimised by modifying the separation buffer (as indicated in the capillary zone electrophoresis section) and controlling the gel porosity during the gel preparation. For cross-linked polyacrylamide gels, the porosity can be modified by changing the concentration of acrylamide and/or the proportion of cross-linker. As a rule, a decrease in the porosity of the gel leads to a decrease in the mobility of the solutes. Due to the rigidity of these gels, only electrokinetic injection can be used.

Dynamically coated gels are hydrophilic polymers, such as linear polyacrylamide, cellulose derivatives, dextran, etc., which can be dissolved in aqueous separation buffers giving rise to a separation medium that also acts as a molecular sieve. These separation media are easier to prepare than cross-linked polymers. They can be prepared in a vial and filled by pressure in a wall-coated capillary (with no electro-osmotic flow). Replacing the gel before every injection generally improves the separation reproducibility. The porosity of the gels can be increased by using polymers of higher molecular mass (at a given polymer concentration) or by decreasing the polymer concentration (for a given polymer molecular mass). A reduction in the gel porosity leads to a decrease in the mobility of the solute for the same buffer. Since the dissolution of these polymers in the buffer gives low viscosity solutions, both hydrodynamic and electrokinetic injection techniques can be used.

## CAPILLARY ISOELECTRIC FOCUSING

*PRINCIPLE*

In isoelectric focusing, the molecules migrate under the influence of the electric field, so long as they are charged, in a pH gradient generated by ampholytes having pI values in a wide range (poly-aminocarboxylic acids), dissolved in the separation buffer.

The three basic steps of isoelectric focusing are loading, focusing and mobilisation.

**Loading step**. Two methods may be employed:
- loading in one step: the sample is mixed with ampholytes and introduced into the capillary either by pressure or vacuum;
- sequential loading: a leading buffer, then the ampholytes, then the sample mixed with ampholytes, again ampholytes alone and finally the terminating buffer are introduced into the capillary. The volume of the sample must be small enough not to modify the pH gradient.

**Focusing step**. When the voltage is applied, ampholytes migrate toward the cathode or the anode, according to their net charge, thus creating a pH gradient from anode (lower pH) to cathode (higher pH). During this step the components to be separated migrate until they reach a pH corresponding to their isoelectric point (pI) and the current drops to very low values.

**Mobilisation step**. If mobilisation is required for detection, use one of the following methods.
- in the first method, mobilisation is accomplished during the focusing step under the effect of the electro-osmotic flow; the electro-osmotic flow must be small enough to allow the focusing of the components;
- in the second method, mobilisation is accomplished by applying positive pressure after the focusing step;
- in the third method, mobilisation is achieved after the focusing step by adding salts to the cathode reservoir or the anode reservoir (depending on the direction chosen for mobilisation) in order to alter the pH in the capillary when the voltage is applied. As the pH is changed, the proteins and ampholytes are mobilised in the direction of the reservoir which contains the added salts and pass the detector.

The separation achieved, expressed as ΔpI, depends on the pH gradient (dpH / d$x$), the number of ampholytes having different pI values, the molecular diffusion coefficient ($D$), the intensity of the electric field ($E$) and the variation of the electrophoretic mobility of the analyte with the pH ($-\mathrm{d}\mu$ / dpH):

$$\Delta\mathrm{pI} = 3 \times \sqrt{\frac{D(\mathrm{dpH} / \mathrm{d}x)}{E(-\mathrm{d}\mu / \mathrm{dpH})}}$$

*OPTIMISATION*

The main parameters to be considered in the development of separations are:

**Voltage**. Capillary isoelectric focusing utilises very high electric fields, 300 V/cm to 1000 V/cm in the focusing step.

**Capillary**. The electro-osmotic flow must be reduced or suppressed depending on the mobilisation strategy (see above). Coated capillaries tend to reduce the electro-osmotic flow.

**Solutions**. The anode buffer reservoir is filled with a solution with a pH lower than the pI of the most acidic ampholyte and the cathode reservoir is filled with a solution with a pH higher than the pI of the most basic ampholyte. Phosphoric acid for the anode and sodium hydroxide for the cathode are frequently used.

Addition of a polymer, such as methylcellulose, in the ampholyte solution tends to suppress convective forces (if any) and electro-osmotic flow by increasing the viscosity. Commercial ampholytes are available covering many pH ranges and may be mixed if necessary to obtain an expanded pH range. Broad pH ranges are used to estimate the isoelectric point whereas narrower ranges are employed to improve accuracy. Calibration can be done by correlating migration time with isoelectric point for a series of protein markers.

During the focusing step precipitation of proteins at their isoelectric point can be prevented, if necessary, using buffer additives such as glycerol, surfactants, urea or zwitterionic buffers. However, depending on the concentration, urea denatures proteins.

## MICELLAR ELECTROKINETIC CHROMATOGRAPHY (MEKC)

*PRINCIPLE*

In micellar electrokinetic chromatography, separation takes place in an electrolyte solution which contains a surfactant at a concentration above the critical micellar concentration (*cmc*). The solute molecules are distributed between the aqueous buffer and the pseudo-stationary phase composed of micelles, according to the partition coefficient of the solute. The technique can therefore be considered as a hybrid of electrophoresis and chromatography. It is a technique that can be used for the separation of both neutral and charged solutes, maintaining the efficiency, speed and instrumental suitability of capillary electrophoresis. One of the most widely used surfactants in MEKC is the anionic surfactant sodium dodecyl sulfate, although other surfactants, for example cationic surfactants such as cetyltrimethylammonium salts, are also used.

The separation mechanism is as follows. At neutral and alkaline pH, a strong electro-osmotic flow is generated and moves the separation buffer ions in the direction of the cathode. If sodium dodecyl sulfate is employed as the surfactant, the electrophoretic migration of the anionic micelle is in the opposite direction, towards the anode. As a result, the overall micelle migration velocity is slowed down compared to the bulk flow of the electrolytic solution. In the case of neutral solutes, since the analyte can partition between the micelle and the aqueous buffer, and has no electrophoretic mobility, the analyte migration velocity will depend only on the partition coefficient between the micelle and the aqueous buffer. In the electropherogram, the peaks corresponding to each uncharged solute are always between that of the electro-osmotic flow marker and that of the micelle (the time elapsed between these two peaks is called the separation window). For electrically charged solutes, the migration velocity depends on both the partition coefficient of the solute between the micelle and the aqueous buffer, and on the electrophoretic mobility of the solute in the absence of micelle.

Since the mechanism in MEKC of neutral and weakly ionised solutes is essentially chromatographic, migration of the solute and resolution can be rationalised in terms of the retention factor of the solute ($k'$), also referred to as mass distribution ratio ($D_m$), which is the ratio of the number of moles of solute in the micelle to those in the mobile phase. For a neutral compound, $k'$ is given by:

$$k' = \frac{t_R - t_0}{t_0 \times \left(1 - \frac{t_R}{t_{mc}}\right)} = K \times \frac{V_S}{V_M}$$

$t_R$ = migration time of the solute,

$t_0$ = analysis time of an unretained solute (determined by injecting an electro-osmotic flow marker which does not enter the micelle, for instance methanol),

$t_{mc}$ = micelle migration time (measured by injecting a micelle marker, such as Sudan III, which migrates while continuously associated in the micelle),

$K$ = partition coefficient of the solute,

$V_S$ = volume of the micellar phase,

$V_M$ = volume of the mobile phase.

Likewise, the resolution between 2 closely-migrating solutes ($R_s$) is given by:

$$R_s = \frac{\sqrt{N}}{4} \times \frac{\alpha - 1}{\alpha} \times \frac{k'_b}{k'_b + 1} \times \frac{1 - \left(\frac{t_0}{t_{mc}}\right)}{1 + k'_a \times \left(\frac{t_0}{t_{mc}}\right)}$$

$N$ = number of theoretical plates for one of the solutes,
$\alpha$ = selectivity,
$k'_a$ and $k'_b$ = retention factors for both solutes, respectively ($k'_b > k'_a$).

Similar, but not identical, equations give $k'$ and $R_s$ values for electrically charged solutes.

*OPTIMISATION*

The main parameters to be considered in the development of separations by MEKC are instrumental and electrolytic solution parameters.

**Instrumental parameters**

*Voltage.* Separation time is inversely proportional to applied voltage. However, an increase in voltage can cause excessive heat production that gives rise to temperature gradients and viscosity gradients of the buffer in the cross-section of the capillary. This effect can be significant with high conductivity buffers such as those containing micelles. Poor heat dissipation causes band broadening and decreases resolution.

*Temperature.* Variations in capillary temperature affect the partition coefficient of the solute between the buffer and the micelles, the critical micellar concentration and the viscosity of the buffer. These parameters contribute to the migration time of the solutes. The use of a good cooling system improves the reproducibility of the migration time for the solutes.

*Capillary.* As in capillary zone electrophoresis, the dimensions of the capillary (length and internal diameter) contribute to analysis time and efficiency of separations. Increasing both effective length and total length can decrease the electric fields (working at constant voltage), increase migration time and improve the separation efficiency. The internal diameter controls heat dissipation (for a given buffer and electric field) and consequently the sample band broadening.

**Electrolytic solution parameters**

*Surfactant type and concentration.* The type of surfactant, in the same way as the stationary phase in chromatography, affects the resolution since it modifies separation selectivity. Also, the log $k'$ of a neutral compound increases linearly with the concentration of surfactant in the mobile phase. Since resolution in MEKC reaches a maximum when $k'$ approaches the value of $\sqrt{t_{mc} / t_0}$, modifying the concentration of surfactant in the mobile phase changes the resolution obtained.

*Buffer pH.* Although pH does not modify the partition coefficient of non-ionised solutes, it can modify the electro-osmotic flow in uncoated capillaries. A decrease in the buffer pH decreases the electro-osmotic flow and therefore increases the resolution of the neutral solutes in MEKC, resulting in a longer analysis time.

*Organic solvents.* To improve MEKC separation of hydrophobic compounds, organic modifiers (methanol, propanol, acetonitrile, etc.) can be added to the electrolytic solution. The addition of these modifiers usually decreases migration time and the selectivity of the separation. Since the addition of organic modifiers affects the critical micellar concentration, a given surfactant concentration can be used only within a certain percentage of organic modifier before the micellisation is inhibited or adversely affected, resulting in the absence of micelles and, therefore, in the absence of partition. The dissociation of micelles in the presence of a high content of organic solvent does not always mean that the separation will no longer be possible; in some cases the hydrophobic interaction between the ionic surfactant monomer and the neutral solutes forms solvophobic complexes that can be separated electrophoretically.

*Additives for chiral separations.* For the separation of enantiomers using MEKC, a chiral selector is included in the micellar system, either covalently bound to the surfactant or added to the micellar separation electrolyte. Micelles that have a moiety with chiral discrimination properties include salts of *N*-dodecanoyl-L-amino acids, bile salts, etc. Chiral resolution can also be achieved using chiral discriminators, such as cyclodextrins, added to the electrolytic solutions which contain micellised achiral surfactants.

*Other additives.* Several strategies can be carried out to modify selectivity, by adding chemicals to the buffer. The addition of several types of cyclodextrins to the buffer can also be used to reduce the interaction of hydrophobic solutes with the micelle, thus increasing the selectivity for this type of compound.

The addition of substances able to modify solute-micelle interactions by adsorption on the latter, is used to improve the selectivity of the separations in MEKC. These additives may be a second surfactant (ionic or non-ionic) which gives rise to mixed micelles or metallic cations which dissolve in the micelle and form co-ordination complexes with the solutes.

## QUANTIFICATION

Peak areas must be divided by the corresponding migration time to give the corrected area in order to:

- compensate for the shift in migration time from run to run, thus reducing the variation of the response,
- compensate for the different responses of sample constituents with different migration times.

Where an internal standard is used, verify that no peak of the substance to be examined is masked by that of the internal standard.

*CALCULATIONS*

From the values obtained, calculate the content of the component or components being examined. When prescribed, the percentage content of one or more components of the sample to be examined is calculated by determining the corrected area(s) of the peak(s) as a percentage of the total of the corrected areas of all peaks, excluding those due to solvents or any added reagents (normalisation procedure). The use of an automatic integration system (integrator or data acquisition and processing system) is recommended.

## SYSTEM SUITABILITY

In order to check the behaviour of the capillary electrophoresis system, system suitability parameters are used. The choice of these parameters depends on the mode of capillary electrophoresis used. They are: retention factor ($k'$) (only for micellar electrokinetic chromatography), apparent number of theoretical plates ($N$), symmetry factor ($A_s$) and resolution ($R_s$). In previous sections, the theoretical expressions for $N$ and $R_s$ have been described, but more practical equations that allow these parameters to be calculated from the electropherograms are given below.

*APPARENT NUMBER OF THEORETICAL PLATES*

The apparent number of theoretical plates ($N$) may be calculated using the expression:

$$N = 5.54 \times \left( \frac{t_R}{w_h} \right)^2$$

$t_R$ = migration time or distance along the baseline from the point of injection to the perpendicular dropped from the maximum of the peak corresponding to the component,
$w_h$ = width of the peak at half-height.

*RESOLUTION*

The resolution ($R_s$) between peaks of similar height of 2 components may be calculated using the expression:

$$R_s = \frac{1.18 \times (t_{R2} - t_{R1})}{w_{h1} + w_{h2}}$$

$$t_{R2} > t_{R1}$$

$t_{R1}$ and $t_{R2}$ = migration times or distances along the baseline from the point of injection to the perpendiculars dropped from the maxima of two adjacent peaks,

$w_{h1}$ and $w_{h2}$ = peak widths at half-height.

When appropriate, the resolution may be calculated by measuring the height of the valley ($H_v$) between 2 partly resolved peaks in a standard preparation and the height of the smaller peak ($H_p$) and calculating the peak-to-valley ratio:

$$\frac{p}{v} = \frac{H_p}{H_v}$$

*SYMMETRY FACTOR*

The symmetry factor ($A_s$) of a peak may be calculated using the expression:

$$A_s = \frac{w_{0.05}}{2d}$$

$w_{0.05}$ = width of the peak at one-twentieth of the peak height,

$d$ = distance between the perpendicular dropped from the peak maximum and the leading edge of the peak at one-twentieth of the peak height.

Tests for area repeatability (standard deviation of areas or of the area/migration-time ratio) and for migration time repeatability (standard deviation of migration time) are introduced as suitability parameters. Migration time repeatability provides a test for the suitability of the capillary washing procedures. An alternative practice to avoid the lack of repeatability of the migration time is to use migration time relative to an internal standard.

A test for the verification of the signal-to-noise ratio for a standard preparation (or the determination of the limit of quantification) may also be useful for the determination of related substances.

*SIGNAL-TO-NOISE RATIO*

The detection limit and quantification limit correspond to signal-to-noise ratios of 3 and 10 respectively. The signal-to-noise ratio ($S/N$) is calculated using the expression:

$$\frac{S}{N} = \frac{2H}{h}$$

$H$ = height of the peak corresponding to the component concerned, in the electropherogram obtained with the prescribed reference solution, measured from the maximum of the peak to the extrapolated baseline of the signal observed over a distance equal to twenty times the width at half-height,

$h$ = range of the background in an electropherogram obtained after injection of a blank, observed over a distance equal to twenty times the width at the half-height of the peak in the electropherogram obtained with the prescribed reference solution and, if possible, situated equally around the place where this peak would be found.

**04/2016:20248**

# 2.2.48. RAMAN SPECTROSCOPY

In Raman spectroscopy a sample is irradiated with an intense monochromatic light source (usually a laser). Most of the radiation is scattered from the sample at the same wavelength as that of the incident light; this process is known as Rayleigh scattering or elastic light scattering. Only $10^{-6}$ to $10^{-8}$ of the incident photons are scattered from the sample at wavelengths shifted from the original source wavelength; this scattered light is known as Raman scatter or inelastic light scatter. The differences between the incident light source wavelength and the Raman scattered wavelengths are known as the Raman shifts and are related to the molecular vibrations within the sample. The scattered light with lower energy is called Stokes scatter and with higher energy is called anti-Stokes scatter. Typically, Stokes scatter is analysed.

A Raman spectrum can be obtained from liquid, solid and even gaseous samples. Raman spectroscopy is a suitable non-invasive method for determination of solid-state properties and for chemical identification, for example, detecting changes in polymorphic form. Raman spectroscopy encompasses many methodologies, including backscattering, transmittance, resonance Raman (RR) spectroscopy, surface-enhanced Raman spectroscopy (SERS), tip-enhanced Raman spectroscopy (TERS), spatially offset Raman spectroscopy (SORS), Raman optical activity (ROA), coherent anti-Stokes Raman spectroscopy (CARS), stimulated Raman spectroscopy (SRS) and confocal Raman (CF) spectroscopy. It also lends itself to imaging techniques.

Raman spectroscopy is complementary to infrared spectroscopy. Both techniques probe the fundamental molecular vibrations in a material. However, Raman and infrared spectroscopy have different sensitivities for different functional groups within a material. Raman spectroscopy is particularly useful in examining non-polar bonds, functional groups and vibrations that are highly symmetrical (e.g. C-C single or multiple bonds); but is less sensitive to polar bonds (e.g. C=O) and vibrations that are asymmetrical. For example, water, which strongly influences infrared spectra, exhibits weak Raman scattering and therefore has minimal interference on the resulting spectrum. Raman can therefore be used for aqueous solutions.

A major difficulty of Raman spectroscopy is that the material examined or impurities in the material may exhibit fluorescence, which can overcome the Raman signal. Fluorescence may be avoided by choosing a longer excitation wavelength, for example in the near-infrared region.

Raman spectroscopy is a rapid and non-invasive analytical method and can be performed off-line and also at-line, on-line or in-line for process analytical technology (PAT). Raman spectrometers can be situated at a great distance from the point of measurement when using long-distance optical fibres for sample interfacing. Raman spectroscopy has a wide variety of applications for chemical, physical and process analysis and can also be used for counterfeit detection and quality control, for example:

- *chemical analysis*: identification and quantification of active substances, excipients;
- *physical analysis*: identification and quantification of solid forms (e.g. polymorphs and solvates) and crystallinity;
- *process analysis*: monitoring of biological and chemical reactions, synthesis, crystallisation, granulation, mixing, drying, lyophilisation, extrusion, encapsulation and coating.

APPARATUS

There are different types of spectrometers for recording Raman spectra, the most common are benchtop dispersive instruments, including microscope-coupled Raman spectrometers, Fourier transform (FT) and hand-held Raman spectrometers.

Raman spectrometers typically consist of the following components:

- a monochromatic light source, typically a laser, with a wavelength in the ultraviolet, visible or near-infrared region; selection of laser frequency and intensity should be considered depending on the intended application and material to be examined;
- suitable optics (lens, mirrors or optical-fibre assembly) that direct the monochromatic light to and collect the Raman scattered light from the material to be examined;
- an optical device (monochromator or filter) that transmits the frequency-shifted Raman scattering and prevents the intense incident frequency of Rayleigh scattering from reaching the detector; and
- a dispersing device (grating and/or prism polychromator) combined with wavelength-selecting slits and a single or multi-channel detector (e.g. a charge-coupled device) or
- an interferometer with a detector that records the intensity of the scattered light over time, and a data-handling device (e.g. computer and appropriate software) that converts this data to the frequency or wavenumber domain by a Fourier-transform calculation.

PREPARATION OF THE SAMPLE

Raman spectra can be obtained from solids, liquids and gases either directly or in suitable containers such as glass vials, generally without prior sample preparation or dilution.

When using Raman spectroscopy, the measured sample area and volume may be small (in particular for microscope-coupled devices) and care must be taken to ensure the measurement is representative. This can be achieved by, for example, rotation of the sample, performing multiple measurements on different preparations of the sample, increasing the area of illumination by reducing the magnification (focus), by demagnification (defocusing) of the laser beam or by changing the focal length between measurements to scan at different depths.

It is not always possible to consider Raman as a non-destructive technique. The energy transmitted by the laser depends on the duration of exposure and the wavelength. It may change the physical state and may destroy the sample.

CONTROL OF INSTRUMENT PERFORMANCE

Carry out the prescribed calibrations and/or system performance tests according to the manufacturer's instructions at regular intervals, depending on the use of the apparatus. Wavenumber calibration of Fourier transform systems is maintained with an internal laser (He-Ne). For dispersive systems, emission spectra of a low pressure lamp exhibiting characteristic maxima at wavenumbers over the whole spectral range of the instrument can usually be used for calibration (e. g. neon lamps or less frequently mercury, argon, krypton or xenon lamps).

*Verification of the wavenumber scale.* Verify the wavenumber scale of the Raman shift using a suitable standard that has characteristic maxima at the wavenumbers under investigation, for example an organic substance such as polystyrene, paracetamol or cyclohexane (see Table 2.2.48.-1).

A minimum of 3 wavenumber shifts covering the working range of the instrument intended for measurements should be chosen. For dispersive Raman spectrometers that use multiple gratings for different spectral resolutions, the wavenumber scale should be verified at the same optical resolution that will occur for sample collection. All gratings used for Raman measurements should be verified for accuracy of Raman-shift.

*Verification of the response-intensity scale.* The absolute and relative intensities of the Raman bands are affected by variations in several factors including:

- polarisation of the irradiating light;
- polarisation of the Raman scattered light;
- intensity of the irradiating light;
- instrument response;
- focus and geometry at sample;
- packing density for solid samples;
- refractive index $n$ or change of $n$ ($\Delta n$) between analyte and the environment;
- the particle size and particle-size distribution;
- the scattering cross-section;
- the absorption cross-section.

Appropriate acceptance criteria will vary with the application but a day-to-day variation of ± 10 per cent or less in relative band intensities is achievable in most cases. Response calibration may involve the use of white-light standards or luminescent glass (e.g. NIST SRM 2241), usually applied by the manufacturer of Raman spectrometers.

QUALITATIVE METHODS

Since the frequency shift position is employed for identification, identical laser intensity for both the reference standard and the material to be examined may not be necessary. The material to be examined is measured in the same physical state (e.g. liquid, solid) as the reference or library material. Raman techniques offer the advantage of non-invasive measurements of the material to be examined without removal from the packaging. However, some packaging materials may alter the measurement. This is especially the case when the packaging absorbs at the laser's excitation wavelength.

*Identification using a reference standard.* Prepare the material to be examined and the reference standard by the same procedure and record the spectra under the same instrumental conditions. The maxima in the spectrum obtained with the material to be examined correspond in position and if applicable in relative intensity to those in the spectrum obtained with the reference standard. When the spectra recorded in the solid state show differences in the positions of the maxima, treat the material to be examined and the reference standard in the same manner so that they crystallise or are produced in the same solid form, or proceed as described in the monograph, then record the spectra.

*Identification using a spectral reference library.* Record the spectra of a suitable number of materials which exhibit typical variation (manufacturer, batch, particle size, impurity profile, etc.) and comply with the requirements of the monograph or established specifications. The number and selection of samples in the database depends on the specific application. A suitable mathematical transformation of the Raman spectrum may facilitate qualitative comparison of spectra (e.g. baseline correction, min-max normalisation, vector normalisation, derivatives). The selectivity of the database that makes it possible to identify a given material and distinguish it adequately from other materials in the database is to be confirmed during the validation procedure.

QUANTITATIVE METHODS

Quantitative determination requires that the reference standard and the material to be examined are measured at the same laser intensity and frequency. Ensure the material to be examined is measured in the same physical state (e.g. liquid, solid) and concentration range as the reference standard used for calibration. While Beer-Lambert's law is not valid for Raman spectroscopy, Raman intensity is directly proportional

Table 2.2.48.-1. – *Wavenumber shifts (and acceptable tolerances) of polystyrene, paracetamol and cyclohexane*

| | Wavenumber shifts[A] [$cm^{-1}$] | Tolerances | |
|---|---|---|---|
| | | Benchtop [$cm^{-1}$] | Hand-held [$cm^{-1}$] |
| Polystyrene[B] | 620.9 | ± 1.5 | ± 2.5 |
| | 1001.4 | ± 1.5 | ± 2.0 |
| | 1031.8 | ± 1.5 | ± 2.0 |
| | 1602.3 | ± 1.5 | ± 3.0 |
| | 3054.3 | ± 3.0 | NA[E] |
| Paracetamol[C] | 797.2 | ± 1.5 | ± 2.5 |
| | 857.9 | ± 1.5 | ± 2.0 |
| | 1168.5 | ± 1.5 | ± 2.0 |
| | 1236.8 | ± 1.5 | ± 2.0 |
| | 1323.9 | ± 1.5 | ± 2.5 |
| | 1648.4 | ± 1.5 | ± 3.0 |
| | 2931.1 | ± 2.0 | NA[E] |
| Cyclohexane[D] | 801.3 | ± 1.5 | ± 2.5 |
| | 1028.3 | ± 1.0 | ± 2.0 |
| | 1266.4 | ± 1.0 | ± 2.0 |

to the concentration of the Raman scattering analytes, however for solid samples and suspensions the Raman intensity could be affected by the matrix (e.g. fluorescence and self-absorption). The Raman signal is influenced by the refractive index of the material, the particle size and the particle-size distribution (where the small particles give a relatively more intense Raman scattering than large particles), the packing density, the scattering cross-section, the absorption cross-section, etc. (see also under Verification of the response-intensity scale).

## 2.2.49. FALLING BALL AND AUTOMATIC ROLLING BALL VISCOMETER METHODS

The determination of dynamic viscosity of Newtonian liquids using a falling ball or rolling ball viscometer is performed at 20.0 ± 0.1 °C, unless otherwise prescribed in the monograph. The time required for a test ball to fall or roll in the liquid to be examined from one ring mark or sensor to the other is determined.

METHOD A - FALLING BALL VISCOMETER

*Apparatus.* The falling ball viscometer consists of: a glass tube enclosed in a mantle, which allows precise control of temperature; 6 balls made of glass, nickel-iron or steel with different densities and diameters. The tube is fixed in such a way that the axis is inclined by 10 ± 1° with regard to the vertical. The tube has 2 ring marks that define the distance the ball has to fall. Commercially available apparatuses are supplied with tables giving the constants, the density of the balls and the suitability of the different balls for the expected viscosity range.

*Method.* Fill the clean, dry tube of the viscometer, previously brought to 20.0 ± 0.1 °C, with the liquid to be examined, avoiding bubbles. Choose the ball that is suitable for the viscosity range of the liquid so as to obtain a falling time (run time) not less than 30 s. Place it in the tube, close the tube and maintain the solution at 20.0 ± 0.1 °C for at least 15 min. Let the ball run through the liquid between the 2 ring marks once without measurement. Let it run again and measure with a stop-watch, to at least the nearest 1/5 s, the time required for the ball to fall from the upper to the lower ring mark. Repeat the test run at least 3 times to obtain a minimum of 4 run times. The result is only valid if 2 consecutive run times do not differ by more than 1.5 per cent.

Use the mean of the run times to calculate the dynamic viscosity ($\eta$) in millipascal seconds using the formula:

$$\eta = k(\rho_1 - \rho_2) \times t$$

$k$ = constant, in square millimetres per second squared;

$\rho_1$ = density of the ball used, in grams per cubic centimetre;

$\rho_2$ = density of the liquid to be examined, in grams per cubic centimetre, obtained by multiplying its relative density ($d_{20}^{20}$) by 0.9982;

$t$ = mean of the run times of the ball, in seconds.

METHOD B – AUTOMATIC ROLLING BALL VISCOMETER

*Apparatus*. The automatic rolling ball viscometer consists of: several capillaries made of glass or other suitable materials with different diameters enclosed in a thermostatically controlled block, which allows precise control of the temperature; balls made of stainless steel (optionally coated) or other suitable materials; a motor drive that positions the capillary at an inclination angle from 10.0 ± 0.2° to 80.0 ± 0.2° with regard to the vertical. The apparatus has at least 2 sensors to measure the run time of the ball over a predefined distance. Commercially available apparatuses are supplied with tables giving the constants, the density of the balls and the suitability of the different capillaries for the expected viscosity range. Temperature control, control of the inclination angle, run-time determination, repetitions of runs and calculations of the mean and relative standard deviation are performed by the apparatus software.

*Method*. Set the instrument software to perform a measurement with at least 4 run times (2 forward/backward cycles) and a maximum relative standard deviation of 0.5 per cent. Choose the capillary, the ball and the inclination angle that are suitable for the expected viscosity range of the liquid to be examined so as to obtain a rolling time (run time) not less than 20 s over the 100 mm distance or a proportional time over other distances. If no digital density meter is connected to the viscometer, ensure that the density value of the liquid to be examined has been specified in the apparatus software. Fill the clean, dry capillary of the viscometer with the liquid to be examined, avoiding bubbles. Start the measurement immediately after filling the capillary.

The instrument calculates automatically the dynamic viscosity ($\eta$) in millipascal seconds and the kinematic viscosity ($\nu$) in square millimetres per second.

## 2.2.54. ISOELECTRIC FOCUSING[7]

GENERAL PRINCIPLES

Isoelectric focusing (IEF) is a method of electrophoresis that separates proteins according to their isoelectric point. Separation is carried out in a slab of polyacrylamide or agarose gel that contains a mixture of amphoteric electrolytes (ampholytes). When subjected to an electric field, the ampholytes migrate in the gel to create a pH gradient. In some cases gels containing an immobilised pH gradient, prepared by incorporating weak acids and bases to specific regions of the gel network during the preparation of the gel, are used. When the applied proteins reach the gel fraction that has a pH that is the same as their isoelectric point (pI), their charge is neutralised and migration ceases. Gradients can be made over various ranges of pH, according to the mixture of ampholytes chosen.

THEORETICAL ASPECTS

When a protein is at the position of its isoelectric point, it has no net charge and cannot be moved in a gel matrix by the electric field. It may, however, move from that position by diffusion. The pH gradient forces a protein to remain in its isoelectric point position, thus concentrating it; this concentrating effect is called "focusing". Increasing the applied voltage or reducing the sample load result in improved separation of bands. The applied voltage is limited by the heat generated, which must be dissipated. The use of thin gels and an efficient cooling plate controlled by a thermostatic circulator prevents the burning of the gel whilst allowing sharp focusing. The separation is estimated by determining the minimum pI difference (ΔpI), which is necessary to separate 2 neighbouring bands:

$$\Delta\mathrm{pI} = 3 \times \sqrt{\frac{D(\mathrm{dpH} / \mathrm{d}x)}{E(-\mathrm{d}\mu / \mathrm{dpH})}}$$

$D$ = diffusion coefficient of the protein,

$\frac{\mathrm{dpH}}{\mathrm{d}x}$ = pH gradient,

$E$ = intensity of the electric field, in volts per centimetre,

$-\frac{\mathrm{d}\mu}{\mathrm{dpH}}$ = variation of the solute mobility with the pH in the region close to the pI.

Since $D$ and $-\frac{\mathrm{d}\mu}{\mathrm{dpH}}$ for a given protein cannot be altered, the separation can be improved by using a narrower pH range and by increasing the intensity of the electric field.

Resolution between protein bands on an IEF gel prepared with carrier ampholytes can be quite good. Improvements in resolution may be achieved by using immobilised pH gradients where the buffering species, which are analogous to carrier ampholytes, are copolymerised within the gel matrix. Proteins exhibiting pIs differing by as little as 0.02 pH units may be resolved using a gel prepared with carrier ampholytes while immobilised pH gradients can resolve proteins differing by approximately 0.001 pH units.

PRACTICAL ASPECTS

Special attention must be paid to sample characteristics and/or preparation. Having salt in the sample can be problematic and it is best to prepare the sample, if possible, in deionised water or 2 per cent ampholytes, using dialysis or gel filtration if necessary.

The time required for completion of focusing in thin-layer polyacrylamide gels is determined by placing a coloured protein (e.g. haemoglobin) at different positions on the gel surface and by applying the electric field: the steady state is reached when all applications give an identical band pattern. In some protocols the completion of the focusing is indicated by the time elapsed after the sample application.

The IEF gel can be used as an identity test when the migration pattern on the gel is compared to a suitable standard preparation and IEF calibration proteins, the IEF gel can be used as a limit test when the density of a band on IEF is compared subjectively with the density of bands appearing in a standard preparation, or it can be used as a quantitative test when the density is measured using a densitometer or similar instrumentation to determine the relative concentration of protein in the bands subject to validation.

(7) This chapter has undergone pharmacopoeial harmonisation. See chapter *5.8. Pharmacopoeial harmonisation*.

APPARATUS

An apparatus for IEF consists of:

- a controllable generator for constant potential, current and power; potentials of 2500 V have been used and are considered optimal under a given set of operating conditions; a supply of up to 30 W of constant power is recommended;
- a rigid plastic IEF chamber that contains a cooled plate, of suitable material, to support the gel;
- a plastic cover with platinum electrodes that are connected to the gel by means of paper wicks of suitable width, length and thickness, impregnated with solutions of anodic and cathodic electrolytes.

ISOELECTRIC FOCUSING IN POLYACRYLAMIDE GELS: DETAILED PROCEDURE

*The following method is a detailed description of an IEF procedure in thick polyacrylamide slab gels, which is used unless otherwise stated in the monograph.*

*PREPARATION OF THE GELS*

**Mould**. The mould (see Figure 2.2.54.-1) is composed of a glass plate (A) on which a polyester film (B) is placed to facilitate handling of the gel, one or more spacers (C), a second glass plate (D) and clamps to hold the structure together.

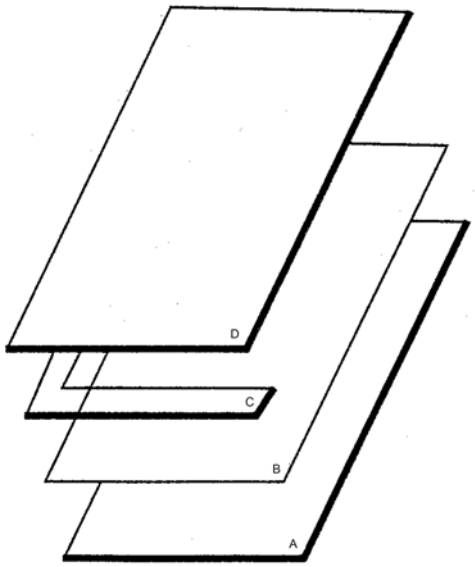

Figure 2.2.54.-1 – *Mould*

**7.5 per cent polyacrylamide gel**. Dissolve 29.1 g of *acrylamide R* and 0.9 g of *methylenebisacrylamide R* in 100 mL of *water R*. To 2.5 volumes of this solution, add the mixture of ampholytes specified in the monograph and dilute to 10 volumes with *water R*. Mix carefully and degas the solution.

**Preparation of the mould**. Place the polyester film on the lower glass plate, apply the spacer, place the second glass plate and fit the clamps. Before use, place the solution on a magnetic stirrer and add 0.25 volumes of a 100 g/L solution of *ammonium persulfate R* and 0.25 volumes of *tetramethylethylenediamine R*. Immediately fill the space between the glass plates of the mould with the solution.

*METHOD*

Dismantle the mould and, making use of the polyester film, transfer the gel onto the cooled support, wetted with a few millilitres of a suitable liquid, taking care to avoid forming air bubbles. Prepare the test solutions and reference solutions as specified in the monograph. Place strips of paper for sample application, about 10 mm × 5 mm in size, on the gel and impregnate each with the prescribed amount of the test and reference solutions. Also apply the prescribed quantity of a solution of proteins with known isoelectric points as pH markers to calibrate the gel. In some protocols the gel has pre-cast slots where a solution of the sample is applied instead of using impregnated paper strips. Cut 2 strips of paper to the length of the gel and impregnate them with the electrolyte solutions: acid for the anode and alkaline for the cathode. The compositions of the anode and cathode solutions are given in the monograph. Apply these paper wicks to each side of the gel several millimetres from the edge. Fit the cover so that the electrodes are in contact with the wicks (respecting the anodic and cathodic poles). Proceed with the isoelectric focusing by applying the electrical parameters described in the monograph. Switch off the current when the migration of the mixture of standard proteins has stabilised. Using forceps, remove the sample application strips and the 2 electrode wicks. Immerse the gel in *fixing solution for isoelectric focusing in polyacrylamide gel R*. Incubate with gentle shaking at room temperature for 30 min. Drain off the solution and add 200 mL of *destaining solution R*. Incubate with shaking for 1 h. Drain the gel, add *coomassie staining solution R*. Incubate for 30 min. Destain the gel by passive diffusion with *destaining solution R* until the bands are well visualised against a clear background. Locate the position and intensity of the bands in the electropherogram as prescribed in the monograph.

VARIATIONS TO THE DETAILED PROCEDURE (SUBJECT TO VALIDATION)

Where reference to the general method on isoelectric focusing is made, variations in methodology or procedure may be made subject to validation. These include:

- the use of commercially available pre-cast gels and of commercial staining and destaining kits,
- the use of immobilised pH gradients,
- the use of rod gels,
- the use of gel cassettes of different dimensions, including ultra-thin (0.2 mm) gels,
- variations in the sample application procedure, including different sample volumes or the use of sample application masks or wicks other than paper,
- the use of alternate running conditions, including variations in the electric field depending on gel dimensions and equipment, and the use of fixed migration times rather than subjective interpretation of band stability,
- the inclusion of a pre-focusing step,
- the use of automated instrumentation,
- the use of agarose gels.

VALIDATION OF ISO-ELECTRIC FOCUSING PROCEDURES

Where alternative methods to the detailed procedure are employed they must be validated. The following criteria may be used to validate the separation:

- formation of a stable pH gradient of desired characteristics, assessed for example using coloured pH markers of known isoelectric points,
- comparison with the electropherogram provided with the chemical reference substance for the preparation to be examined,
- any other validation criteria as prescribed in the monograph.

SPECIFIED VARIATIONS TO THE GENERAL METHOD

Variations to the general method required for the analysis of specific substances may be specified in detail in monographs. These include:

- the addition of urea in the gel (3 M concentration is often satisfactory to keep protein in solution but up to 8 M can be used): some proteins precipitate at their isoelectric point; in this case, urea is included in the gel formulation to keep the protein in solution; if urea is used, only fresh solutions should be used to prevent carbamylation of the protein;

– the use of alternative staining methods;
– the use of gel additives such as non-ionic detergents (e.g. octylglucoside) or zwitterionic detergents (e.g., CHAPS or CHAPSO), and the addition of ampholyte to the sample, to prevent proteins from aggregating or precipitating.

POINTS TO CONSIDER

Samples can be applied to any area on the gel, but to protect the proteins from extreme pH environments samples should not be applied close to either electrode. During method development the analyst can try applying the protein in 3 positions on the gel (i.e. middle and both ends); the pattern of a protein applied at opposite ends of the gel may not be identical.

A phenomenon known as cathodic drift, where the pH gradient decays over time, may occur if a gel is focused too long. Although not well understood, electroendoosmosis and absorption of carbon dioxide may be factors that lead to cathodic drift. Cathodic drift is observed as focused protein migrating off the cathode end of the gel. Immobilised pH gradients may be used to address this problem.

Efficient cooling (approximately 4 °C) of the bed that the gel lies on during focusing is important. High field strengths used during isoelectric focusing can lead to overheating and affect the quality of the focused gel.

**01/2010:20255**

## 2.2.55. PEPTIDE MAPPING[8]

Peptide mapping is an identity test for proteins, especially those obtained by rDNA technology. It involves the chemical or enzymatic treatment of a protein resulting in the formation of peptide fragments followed by separation and identification of these fragments in a reproducible manner. It is a powerful test that is capable of identifying almost any single amino acid changes resulting from events such as errors in the reading of complementary DNA (cDNA) sequences or point mutations. Peptide mapping is a comparative procedure because the information obtained, compared to a reference substance similarly treated, confirms the primary structure of the protein, is capable of detecting whether alterations in structure have occurred, and demonstrates process consistency and genetic stability. Each protein presents unique characteristics which must be well understood so that the scientific and analytical approaches permit validated development of a peptide map that provides sufficient specificity.

This chapter provides detailed assistance in the application of peptide mapping and its validation to characterise the desired protein, to evaluate the stability of the expression construct of cells used for recombinant DNA products and to evaluate the consistency of the overall process, to assess product stability as well as to ensure the identity of the protein, or to detect the presence of protein variant.

Peptide mapping is not a general method, but involves developing specific maps for each unique protein. Although the technology is evolving rapidly, there are certain methods that are generally accepted. Variations of these methods will be indicated, when appropriate, in specific monographs.

A peptide map may be viewed as a fingerprint of a protein and is the end product of several chemical processes that provide a comprehensive understanding of the protein being analysed. 4 principal steps are necessary for the development of the procedure: isolation and purification of the protein, if the protein is part of a formulation; selective cleavage of the peptide bonds; chromatographic separation of the peptides; and analysis and identification of the peptides. A test sample is digested and assayed in parallel with a reference substance. Complete cleavage of peptide bonds is more likely to occur when enzymes such as endoproteases (e.g., trypsin) are used, instead of chemical cleavage reagents. A map must contain enough peptides to be meaningful. On the other hand, if there are too many fragments, the map might lose its specificity because many proteins will then have the same profiles.

ISOLATION AND PURIFICATION

Isolation and purification are necessary for analysis of bulk drugs or dosage forms containing interfering excipients and carrier proteins and, when required, will be specified in the monograph. Quantitative recovery of protein from the dosage form must be validated.

SELECTIVE CLEAVAGE OF PEPTIDE BONDS

The selection of the approach used for the cleavage of peptide bonds will depend on the protein under test. This selection process involves determination of the type of cleavage to be employed, enzymatic or chemical, and the type of cleavage agent within the chosen category. Several cleavage agents and their specificity are shown in Table 2.2.55.-1. This list is not all-inclusive and will be expanded as other cleavage agents are identified.

Table 2.2.55.-1. – *Examples of cleavage agents*

| Type | Agent | Specificity |
|---|---|---|
| Enzymatic | Trypsin (EC 3.4.21.4) | *C*-terminal side of Arg and Lys |
| | Chymotrypsin (EC 3.4.21.1) | *C*-terminal side of hydrophobic residues (e.g. Leu, Met, Ala, aromatics) |
| | Pepsin (EC 3.4.23.1 and 2) | Non-specific digest |
| | Lysyl endopeptidase (Lys-C endopeptidase) (EC 3.4.21.50) | *C*-terminal side of Lys |
| | Glutamyl endopeptidase (from *S. aureus* strain V8) (EC 3.4.21.19) | *C*-terminal side of Glu and Asp |
| | Peptidyl-Asp metallo-endopeptidase (endoproteinase Asp-N) | *N*-terminal side of Asp |
| | Clostripain (EC 3.4.22.8) | *C*-terminal side of Arg |
| Chemical | Cyanogen bromide | *C*-terminal side of Met |
| | 2-Nitro-5-thio-cyanobenzoic acid | *N*-terminal side of Cys |
| | *O*-Iodosobenzoic acid | *C*-terminal side of Trp and Tyr |
| | Dilute acid | Asp and Pro |
| | BNPS-skatole | Trp |

(8) This chapter has undergone pharmacopoeial harmonisation. See chapter *5.8. Pharmacopoeial harmonisation*.

**Pretreatment of sample**. Depending on the size or the configuration of the protein, different approaches in the pretreatment of samples can be used. If trypsin is used as a cleavage agent for proteins with a molecular mass greater than 100 000 Da, lysine residues must be protected by citraconylation or maleylation; otherwise, too many peptides will be generated.

**Pretreatment of the cleavage agent**. Pretreatment of cleavage agents, especially enzymatic agents, might be necessary for purification purposes to ensure reproducibility of the map. For example, trypsin used as a cleavage agent will have to be treated with tosyl-L-phenylalanine chloromethyl ketone to inactivate chymotrypsin. Other methods, such as purification of trypsin by high performance liquid chromatography (HPLC) or immobilisation of enzyme on a gel support, have been successfully used when only a small amount of protein is available.

**Pretreatment of the protein**. Under certain conditions, it might be necessary to concentrate the sample or to separate the protein from excipients and stabilisers used in formulation of the product, if these interfere with the mapping procedure. Physical procedures used for pretreatment can include ultrafiltration, column chromatography and lyophilization. Other pretreatments, such as the addition of chaotropic agents (e.g. urea) can be used to unfold the protein prior to mapping. To allow the enzyme to have full access to cleavage sites and permit some unfolding of the protein, it is often necessary to reduce and alkylate the disulfide bonds prior to digestion.

Digestion with trypsin can introduce ambiguities in the peptide map due to side reactions occurring during the digestion reaction, such as non-specific cleavage, deamidation, disulfide isomerisation, oxidation of methionine residues, or formation of pyroglutamic groups created from the deamidation of glutamine at the *N*-terminal side of a peptide. Furthermore, peaks may be produced by autohydrolysis of trypsin. Their intensities depend on the ratio of trypsin to protein. To avoid autohydrolysis, solutions of proteases may be prepared at a pH that is not optimal (e.g. at pH 5 for trypsin), which would mean that the enzyme would not become active until diluted with the digest buffer.

**Establishment of optimal digestion conditions**. Factors that affect the completeness and effectiveness of digestion of proteins are those that could affect any chemical or enzymatic reactions.

*pH of the reaction milieu.* The pH of the digestion mixture is empirically determined to ensure the optimisation of the performance of the given cleavage agent. For example, when using cyanogen bromide as a cleavage agent, a highly acidic environment (e.g. pH 2, formic acid) is necessary; however, when using trypsin as a cleavage agent, a slightly alkaline environment (pH 8) is optimal. As a general rule, the pH of the reaction milieu must not alter the chemical integrity of the protein during the digestion and must not change during the course of the fragmentation reaction.

*Temperature.* A temperature between 25 °C and 37 °C is adequate for most digestions. The temperature used is intended to minimise chemical side reactions. The type of protein under test will dictate the temperature of the reaction milieu, because some proteins are more susceptible to denaturation as the temperature of the reaction increases. For example, digestion of recombinant bovine somatropin is conducted at 4 °C, because at higher temperatures it will precipitate during digestion.

*Time.* If sufficient sample is available, a time course study is considered in order to determine the optimum time to obtain a reproducible map and avoid incomplete digestion. Time of digestion varies from 2 h to 30 h. The reaction is stopped by the addition of an acid which does not interfere in the map or by freezing.

*Amount of cleavage agent used.* Although excessive amounts of cleavage agent are used to accomplish a reasonably rapid digestion time (i.e. 6-20 hours), the amount of cleavage agent is minimised to avoid its contribution to the chromatographic map pattern. A protein to protease ratio between 20:1 and 200:1 is generally used. It is recommended that the cleavage agent is added in 2 or more stages to optimise cleavage. Nonetheless, the final reaction volume remains small enough to facilitate the next step in peptide mapping, the separation step. To sort out digestion artifacts that might interfere with the subsequent analysis, a blank determination is performed, using a digestion control with all the reagents, except the test protein.

## CHROMATOGRAPHIC SEPARATION

Many techniques are used to separate peptides for mapping. The selection of a technique depends on the protein being mapped. Techniques that have been successfully used for separation of peptides are shown in Table 2.2.55-2. In this section, a most widely used reversed-phase HPLC method is described as one of the procedures of chromatographic separation.

The purity of solvents and mobile phases is a critical factor in HPLC separation. HPLC-grade solvents and water that are commercially available, are recommended for reversed-phase HPLC. Dissolved gases present a problem in gradient systems where the solubility of the gas in a solvent may be less in a mixture than in a single solvent. Vacuum degassing and agitation by sonication are often used as useful degassing procedures. When solid particles in the solvents are drawn into the HPLC system, they can damage the sealing of pump valves or clog the top of the chromatographic column. Both pre- and post-pump filtration is also recommended.

Table 2.2.55-2. – *Techniques used for the separation of peptides*

| |
|---|
| Reversed-phase high performance liquid chromatography (HPLC) |
| Ion-exchange chromatography (IEC) |
| Hydrophobic interaction chromatography (HIC) |
| Polyacrylamide gel electrophoresis (PAGE), non-denaturating |
| Sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) |
| Capillary electrophoresis (CE) |
| Paper chromatography-high voltage (PCHV) |
| High voltage-paper electrophoresis (HVPE) |

**Chromatographic column**. The selection of a chromatographic column is empirically determined for each protein. Columns with 10 nm or 30 nm pore size with silica support can give optimal separation. For smaller peptides, *octylsilyl silica gel for chromatography R* (3-10 µm) and *octadecylsilyl silica gel for chromatography R* (3-10 µm) column packings are more efficient than *butylsilyl silica gel for chromatography R* (5-10 µm).

**Solvent**. The most commonly used solvent is water with acetonitrile as the organic modifier to which not more than 0.1 per cent trifluoroacetic acid is added. If necessary, add propyl alcohol or isopropyl alcohol to solubilise the digest components, provided that the addition does not unduly increase the viscosity of the components.

**Mobile phase**. Buffered mobile phases containing phosphate are used to provide some flexibility in the selection of pH conditions, since shifts of pH in the 3.0-5.0 range enhance the separation of peptides containing acidic residues (e.g. glutamic and aspartic acids). Sodium or potassium phosphates, ammonium acetate, phosphoric acid at a pH between 2 and 7 (or higher for polymer-based supports) have also been used with acetonitrile gradients. Acetonitrile containing trifluoroacetic acid is used quite often.

**Gradient**. Gradients can be linear, nonlinear, or include step functions. A shallow gradient is recommended in order to separate complex mixtures. Gradients are optimised to provide clear resolution of 1 or 2 peaks that will become "marker" peaks for the test.

**Isocratic elution**. Isocratic HPLC systems using a single mobile phase are used on the basis of their convenience of use and improved detector responses. Optimal composition of a mobile phase to obtain clear resolution of each peak is sometimes difficult to establish. Mobile phases for which slight changes in component ratios or in pH significantly affect retention times of peaks in peptide maps must not be used in isocratic HPLC systems.

**Other parameters**. Temperature control of the column is usually necessary to achieve good reproducibility. The flow rates for the mobile phases range from 0.1-2.0 mL/min, and the detection of peptides is performed with a UV detector at 200-230 nm. Other methods of detection have been used (e.g. post-column derivatisation), but they are not as robust or versatile as UV detection.

**Validation**. This section provides an experimental means for measuring the overall performance of the test method. The acceptance criteria for system suitability depend on the identification of critical test parameters that affect data interpretation and acceptance. These critical parameters are also criteria that monitor peptide digestion and peptide analysis. An indicator that the desired digestion endpoint has been achieved is shown by comparison with a reference standard, which is treated in the same manner as the test protein. The use of a reference substance in parallel with the test protein is critical in the development and establishment of system suitability limits. In addition, a chromatogram is included with the reference substance for additional comparison purposes. Other indicators may include visual inspection of protein or peptide solubility, the absence of intact protein, or measurement of responses of a digestion-dependent peptide. The critical system suitability parameters for peptide analysis will depend on the particular mode of peptide separation and detection and on the data analysis requirements.

When peptide mapping is used as an identification test, the system suitability requirements for the identified peptides cover selectivity and precision. In this case, as well as when identification of variant protein is done, the identification of the primary structure of the peptide fragments in the peptide map provides both a verification of the known primary structure and the identification of protein variants by comparison with the peptide map of the reference substance for the specified protein. The use of a digested reference substance for a given protein in the determination of peptide resolution is the method of choice. For an analysis of a variant protein, a characterised mixture of a variant and a reference substance can be used, especially if the variant peptide is located in a less-resolved region of the map. The index of pattern consistency can be simply the number of major peptides detected. Peptide pattern consistency can be best defined by the resolution of peptide peaks. Chromatographic parameters, such as peak-to-peak resolution, maximum peak width, peak area, peak tailing factors, and column efficiency, may be used to define peptide resolution. Depending on the protein under test and the method of separation used, single peptide or multiple peptide resolution requirements may be necessary.

The replicate analysis of the digest of the reference substance for the protein under test yields measures of precision and quantitative recovery. Recovery of the identified peptides is generally ascertained by the use of internal or external peptide standards. The precision is expressed as the relative standard deviation (RSD). Differences in the recovery and precision of the identified peptides are to be expected; therefore, the system suitability limits will have to be established for both the recovery and the precision of the identified peptides. These limits are unique for a given protein and will be specified in the individual monograph.

Visual comparison of the relative retentions, the peak responses (the peak area or the peak height), the number of peaks, and the overall elution pattern is completed initially. It is then complemented and supported by mathematical analysis of the peak response ratios and by the chromatographic profile of a 1:1 (*V/V*) mixture of sample and reference substance digest. If all peaks in the sample digest and in the reference substance digest have the same relative retentions and peak response ratios, then the identity of the sample under test is confirmed.

If peaks that initially eluted with significantly different relative retentions are then observed as single peaks in the 1:1 mixture, the initial difference would be an indication of system variability. However, if separate peaks are observed in the 1:1 mixture, this would be evidence of the nonequivalence of the peptides in each peak. If a peak in the 1:1 mixture is significantly broader than the corresponding peak in the sample and reference substance digest, it may indicate the presence of different peptides. The use of computer-aided pattern recognition software for the analysis of peptide mapping data has been proposed and applied, but issues related to the validation of the computer software preclude its use in a compendial test in the near future. Other automated approaches have been used that employ mathematical formulas, models, and pattern recognition. Such approaches are, for example, the automated identification of compounds by IR spectroscopy and the application of diode-array UV spectral analysis for identification of peptides. These methods have limitations due to inadequate resolutions, co-elution of fragments, or absolute peak response differences between reference substance and sample digest fragments.

The numerical comparison of the peak retention times and peak areas or peak heights can be done for a selected group of relevant peaks that have been correctly identified in the peptide maps. Peak areas can be calculated using 1 peak showing relatively small variation as an internal reference, keeping in mind that peak area integration is sensitive to baseline variation and likely to introduce error in the analysis. Alternatively, the percentage of each peptide peak height relative to the sum of all peak heights can be calculated for the sample under test. The percentage is then compared to that of the corresponding peak of the reference substance. The possibility of auto-hydrolysis of trypsin is monitored by producing a blank peptide map, that is, the peptide map obtained when a blank solution is treated with trypsin.

The minimum requirement for the qualification of peptide mapping is an approved test procedure that includes system suitability as a test control. In general, early in the regulatory process, qualification of peptide mapping for a protein is sufficient. As the regulatory approval process for the protein progresses, additional qualifications of the test can include a partial validation of the analytical procedure to provide assurance that the method will perform as intended in the development of a peptide map for the specified protein.

## ANALYSIS AND IDENTIFICATION OF PEPTIDES

*This section gives guidance on the use of peptide mapping during development in support of regulatory applications.*

The use of a peptide map as a qualitative tool does not require the complete characterisation of the individual peptide peaks. However, validation of peptide mapping in support of regulatory applications requires rigorous characterisation of each of the individual peaks in the peptide map. Methods to characterise peaks range from *N*-terminal sequencing of each peak followed by amino acid analysis to the use of mass spectroscopy (MS).

For characterisation purposes, when *N*-terminal sequencing and amino acids analysis are used, the analytical separation is scaled up. Since scale-up might affect the resolution of peptide peaks, it is necessary, using empirical data, to assure that there is no loss of resolution due to scale-up. Eluates corresponding to specific peptide peaks are collected, vacuum-concentrated, and chromatographed again, if necessary. Amino acid analysis of fragments may be limited by the peptide size. If the *N*-terminus is blocked, it may need to be cleared before sequencing. *C*-terminal sequencing of proteins in combination with carboxypeptidase and matrix-assisted laser desorption ionisation coupled to time-of-flight analyser (MALDI-TOF) can also be used for characterisation purposes.

The use of MS for characterisation of peptide fragments is by direct infusion of isolated peptides or by the use of on-line LC-MS for structure analysis. In general, it includes electrospray and MALDI-TOF-MS, as well as fast-atom bombardment (FAB). Tandem MS has also been used to sequence a modified protein and to determine the type of amino acid modification that has occurred. The comparison of mass spectra of the digests before and after reduction provides a method to assign the disulfide bonds to the various sulfydryl-containing peptides.

If regions of the primary structure are not clearly demonstrated by the peptide map, it might be necessary to develop a secondary peptide map. The goal of a validated method of characterisation of a protein through peptide mapping is to reconcile and account for at least 95 per cent of the theoretical composition of the protein structure.

## 2.2.56. AMINO ACID ANALYSIS[9]

Amino acid analysis refers to the methodology used to determine the amino acid composition or content of proteins, peptides, and other pharmaceutical preparations. Proteins and peptides are macromolecules consisting of covalently bonded amino acid residues organised as a linear polymer. The sequence of the amino acids in a protein or peptide determines the properties of the molecule. Proteins are considered large molecules that commonly exist as folded structures with a specific conformation, while peptides are smaller and may consist of only a few amino acids. Amino acid analysis can be used to quantify proteins and peptides, to determine the identity of proteins or peptides based on their amino acid composition, to support protein and peptide structure analysis, to evaluate fragmentation strategies for peptide mapping, and to detect atypical amino acids that might be present in a protein or peptide. It is necessary to hydrolyse a protein/peptide to its individual amino acid constituents before amino acid analysis. Following protein/peptide hydrolysis, the amino acid analysis procedure can be the same as that practiced for free amino acids in other pharmaceutical preparations. The amino acid constituents of the test sample are typically derivatised for analysis.

### APPARATUS

Methods used for amino acid analysis are usually based on a chromatographic separation of the amino acids present in the test sample. Current techniques take advantage of the automated chromatographic instrumentation designed for analytical methodologies. An amino acid analysis instrument will typically be a low-pressure or high-pressure liquid chromatograph capable of generating mobile phase gradients that separate the amino acid analytes on a chromatographic column. The instrument must have post-column derivatisation capability, unless the sample is analysed using precolumn derivatisation. The detector is usually an ultraviolet/visible or fluorescence detector depending on the derivatisation method used. A recording device (e.g., integrator) is used for transforming the analogue signal from the detector and for quantitation. It is preferred that instrumentation be dedicated particularly for amino acid analysis.

### GENERAL PRECAUTIONS

Background contamination is always a concern for the analyst in performing amino acid analysis. High purity reagents are necessary (e.g., low purity hydrochloric acid can contribute to glycine contamination). Analytical reagents are changed routinely every few weeks using only high-pressure liquid chromatography (HPLC) grade solvents. Potential microbial contamination and foreign material that might be present in the solvents are reduced by filtering solvents before use, keeping solvent reservoirs covered, and not placing amino acid analysis instrumentation in direct sunlight.

Laboratory practices can determine the quality of the amino acid analysis. Place the instrumentation in a low traffic area of the laboratory. Keep the laboratory clean. Clean and calibrate pipets according to a maintenance schedule. Keep pipet tips in a covered box; the analysts may not handle pipet tips with their hands. The analysts may wear powder-free latex or equivalent gloves. Limit the number of times a test sample vial is opened and closed because dust can contribute to elevated levels of glycine, serine, and alanine.

A well-maintained instrument is necessary for acceptable amino acid analysis results. If the instrument is used on a routine basis, it is to be checked daily for leaks, detector and lamp stability, and the ability of the column to maintain resolution of the individual amino acids. Clean or replace all instrument filters and other maintenance items on a routine schedule.

### REFERENCE MATERIAL

Acceptable amino acid standards are commercially available for amino acid analysis and typically consist of an aqueous mixture of amino acids. When determining amino acid composition, protein or peptide standards are analysed with the test material as a control to demonstrate the integrity of the entire procedure. Highly purified bovine serum albumin has been used as a protein standard for this purpose.

### CALIBRATION OF INSTRUMENTATION

Calibration of amino acid analysis instrumentation typically involves analysing the amino acid standard, which consists of a mixture of amino acids at a number of concentrations, to determine the response factor and range of analysis for each amino acid. The concentration of each amino acid in the standard is known. In the calibration procedure, the analyst dilutes the amino acid standard to several different analyte levels within the expected linear range of the amino acid analysis technique. Then, replicates at each of the different analyte levels can be analysed. Peak areas obtained for each amino acid are plotted versus the known concentration for each of the amino acids in the standard dilution. These results will allow the analyst to determine the range of amino acid concentrations where the peak area of a given amino acid is an approximately linear function of the amino acid concentration. It is important that the analyst prepare the samples for amino acid analysis so that they are within the analytical limits (e.g., linear working range) of the technique employed in order to obtain accurate and repeatable results.

4 to 6 amino acid standard levels are analysed to determine a response factor for each amino acid. The response factor is calculated as the average peak area or peak height per nanomole of amino acid present in the standard. A calibration file consisting of the response factor for each amino acid is prepared and used to calculate the concentration of each

(9) This chapter has undergone pharmacopoeial harmonisation. See chapter *5.8. Pharmacopoeial harmonisation.*

amino acid present in the test sample. This calculation involves dividing the peak area corresponding to a given amino acid by the response factor for that amino acid to give the nanomoles of the amino acid. For routine analysis, a single-point calibration may be sufficient; however, the calibration file is updated frequently and tested by the analysis of analytical controls to ensure its integrity.

REPEATABILITY

Consistent high quality amino acid analysis results from an analytical laboratory require attention to the repeatability of the assay. During analysis of the chromatographic separation of the amino acids or their derivatives, numerous peaks can be observed on the chromatogram that correspond to the amino acids. The large number of peaks makes it necessary to have an amino acid analysis system that can repeatedly identify the peaks based on retention time and integrate the peak areas for quantitation. A typical repeatability evaluation involves preparing a standard amino acid solution and analysing many replicates (e.g., 6 analyses or more) of the same standard solution. The relative standard deviation (RSD) is determined for the retention time and integrated peak area of each amino acid. An evaluation of the repeatability is expanded to include multiple assays conducted over several days by different analysts. Multiple assays include the preparation of standard dilutions from starting materials to determine the variation due to sample handling. The amino acid composition of a standard protein (e.g., bovine serum albumin) is often analysed as part of the repeatability evaluation. By evaluating the replicate variation (i.e., RSD), the laboratory can establish analytical limits to ensure that the analyses from the laboratory are under control. It is desirable to establish the lowest practical variation limits to ensure the best results. Areas to focus on to lower the variability of the amino acid analysis include sample preparation, high background spectral interference due to quality of reagents and/or laboratory practices, instrument performance and maintenance, data analysis and interpretation, and analyst performance and habits. All parameters involved are fully investigated in the scope of the validation work.

SAMPLE PREPARATION

Accurate results from amino acid analysis require purified protein and peptide samples. Buffer components (e.g., salts, urea, detergents) can interfere with the amino acid analysis and are removed from the sample before analysis. Methods that utilise post-column derivatisation of the amino acids are generally not affected by buffer components to the extent seen with pre-column derivatisation methods. It is desirable to limit the number of sample manipulations to reduce potential background contamination, to improve analyte recovery, and to reduce labour. Common techniques used to remove buffer components from protein samples include the following methods: (1) injecting the protein sample onto a reversed-phase HPLC system, removing the protein with a volatile solvent containing a sufficient organic component, and drying the sample in a vacuum centrifuge; (2) dialysis against a volatile buffer or water; (3) centrifugal ultrafiltration for buffer replacement with a volatile buffer or water; (4) precipitating the protein from the buffer using an organic solvent (e.g., acetone); (5) gel filtration.

INTERNAL STANDARDS

It is recommended that an internal standard be used to monitor physical and chemical losses and variations during amino acid analysis. An accurately known amount of internal standard can be added to a protein solution prior to hydrolysis. The recovery of the internal standard gives the general recovery of the amino acids of the protein solution. Free amino acids, however, do not behave in the same way as protein-bound amino acids during hydrolysis, whose rates of release or destruction are variable. Therefore, the use of an internal standard to correct for losses during hydrolysis may give unreliable results. It will be necessary to take this point into consideration when interpreting the results. Internal standards can also be added to the mixture of amino acids after hydrolysis to correct for differences in sample application and changes in reagent stability and flow rates. Ideally, an internal standard is an unnaturally occurring primary amino acid that is commercially available and inexpensive. It should also be stable during hydrolysis, its response factor should be linear with concentration, and it needs to elute with a unique retention time without overlapping other amino acids. Commonly used amino acid standards include norleucine, nitrotyrosine, and α-aminobutyric acid.

PROTEIN HYDROLYSIS

Hydrolysis of protein and peptide samples is necessary for amino acid analysis of these molecules. The glassware used for hydrolysis must be very clean to avoid erroneous results. Glove powders and fingerprints on hydrolysis tubes may cause contamination. To clean glass hydrolysis tubes, boil tubes for 1 h in 1 M hydrochloric acid or soak tubes in concentrated nitric acid or in a mixture of equal volumes of concentrated hydrochloric acid and nitric acid. Clean hydrolysis tubes are rinsed with high-purity water followed by a rinse with HPLC grade methanol, dried overnight in an oven, and stored covered until use. Alternatively, pyrolysis of clean glassware at 500 °C for 4 h may also be used to eliminate contamination from hydrolysis tubes. Adequate disposable laboratory material can also be used.

Acid hydrolysis is the most common method for hydrolysing a protein sample before amino acid analysis. The acid hydrolysis technique can contribute to the variation of the analysis due to complete or partial destruction of several amino acids: tryptophan is destroyed; serine and threonine are partially destroyed; methionine might undergo oxidation; and cysteine is typically recovered as cystine (but cystine recovery is usually poor because of partial destruction or reduction to cysteine). Application of adequate vacuum (less than 200 µm of mercury or 26.7 Pa) or introduction of an inert gas (argon) in the headspace of the reaction vessel can reduce the level of oxidative destruction. In peptide bonds involving isoleucine and valine the amido bonds of Ile-Ile, Val-Val, Ile-Val, and Val-Ile are partially cleaved; and asparagine and glutamine are deamidated, resulting in aspartic acid and glutamic acid, respectively. The loss of tryptophan, asparagine, and glutamine during an acid hydrolysis limits quantitation to 17 amino acids. Some of the hydrolysis techniques described are used to address these concerns. Some of the hydrolysis techniques described (i.e., Methods 4-11) may cause modifications to other amino acids. Therefore, the benefits of using a given hydrolysis technique are weighed against the concerns with the technique and are tested adequately before employing a method other than acid hydrolysis.

A time-course study (i.e., amino acid analysis at acid hydrolysis times of 24 h, 48 h and 72 h) is often employed to analyse the starting concentration of amino acids that are partially destroyed or slow to cleave. By plotting the observed concentration of labile amino acids (e.g., serine and threonine) versus hydrolysis time, the line can be extrapolated to the origin to determine the starting concentration of these amino acids. Time-course hydrolysis studies are also used with amino acids that are slow to cleave (e.g., isoleucine and valine). During the hydrolysis time course, the analyst will observe a plateau in these residues. The level of this plateau is taken as the residue concentration. If the hydrolysis time is too long, the residue concentration of the sample will begin to decrease, indicating destruction by the hydrolysis conditions.

An acceptable alternative to the time-course study is to subject an amino acid calibration standard to the same hydrolysis conditions as the test sample. The amino acid in free form may not completely represent the rate of destruction of labile amino acids within a peptide or protein during the hydrolysis. This is especially true for peptide bonds that are slow to cleave

(e.g., Ile-Val bonds). However, this technique will allow the analyst to account for some residue destruction. Microwave acid hydrolysis has been used and is rapid but requires special equipment as well as special precautions. The optimal conditions for microwave hydrolysis must be investigated for each individual protein/peptide sample. The microwave hydrolysis technique typically requires only a few minutes, but even a deviation of one minute may give inadequate results (e.g., incomplete hydrolysis or destruction of labile amino acids). Complete proteolysis, using a mixture of proteases, has been used but can be complicated, requires the proper controls, and is typically more applicable to peptides than proteins.

During initial analyses of an unknown protein, experiments with various hydrolysis time and temperature conditions are conducted to determine the optimal conditions.

*METHOD 1*

Acid hydrolysis using hydrochloric acid containing phenol is the most common procedure used for protein/peptide hydrolysis preceding amino acid analysis. The addition of phenol to the reaction prevents the halogenation of tyrosine.

**Hydrolysis solution**. 6 M hydrochloric acid containing 0.1 per cent to 1.0 per cent of phenol.

**Procedure**

*Liquid phase hydrolysis*. Place the protein or peptide sample in a hydrolysis tube, and dry (the sample is dried so that water in the sample will not dilute the acid used for the hydrolysis). Add 200 µL of hydrolysis solution per 500 µg of lyophilised protein. Freeze the sample tube in a dry ice-acetone bath, and flame seal *in vacuo*. Samples are typically hydrolysed at 110 °C for 24 h *in vacuo* or in an inert atmosphere to prevent oxidation. Longer hydrolysis times (e.g., 48 h and 72 h) are investigated if there is a concern that the protein is not completely hydrolysed.

*Vapour phase hydrolysis*. This is one of the most common acid hydrolysis procedures, and it is preferred for microanalysis when only small amounts of the sample are available. Contamination of the sample from the acid reagent is also minimised by using vapour phase hydrolysis. Place vials containing the dried samples in a vessel that contains an appropriate amount of hydrolysis solution. The hydrolysis solution does not come in contact with the test sample. Apply an inert atmosphere or vacuum (less than 200 µm of mercury or 26.7 Pa) to the headspace of the vessel, and heat to about 110 °C for a 24 h hydrolysis time. Acid vapour hydrolyses the dried sample. Any condensation of the acid in the sample vials is to be minimised. After hydrolysis, dry the test sample *in vacuo* to remove any residual acid.

*METHOD 2*

Tryptophan oxidation during hydrolysis is decreased by using mercaptoethanesulfonic acid as the reducing acid.

**Hydrolysis solution**. 2.5 M mercaptoethanesulfonic acid solution.

**Vapour phase hydrolysis**. Dry about 1 µg to 100 µg of the protein/peptide under test in a hydrolysis tube. Place the hydrolysis tube in a larger tube with about 200 µL of the hydrolysis solution. Seal the larger tube *in vacuo* (about 50 µm of mercury or 6.7 Pa) to vaporise the hydrolysis solution. Heat the hydrolysis tube to 170-185 °C for about 12.5 min. After hydrolysis, dry the hydrolysis tube *in vacuo* for 15 min to remove the residual acid.

*METHOD 3*

Tryptophan oxidation during hydrolysis is prevented by using thioglycollic acid (TGA) as the reducing acid.

**Hydrolysis solution**. 7 M hydrochloric acid containing 1 per cent of phenol, 10 per cent of trifluoroacetic acid and 20 per cent of thioglycollic acid.

**Vapour phase hydrolysis**. Dry about 10 µg to 50 µg of the protein/peptide under test in a sample tube. Place the sample tube in a larger tube with about 200 µL of the hydrolysis solution. Seal the larger tube *in vacuo* (about 50 µm of mercury or 6.7 Pa) to vaporise the TGA. Heat the sample tube to 166 °C for about 15-30 min. After hydrolysis, dry the sample tube *in vacuo* for 5 min to remove the residual acid. Recovery of tryptophan by this method may be dependent on the amount of sample present.

*METHOD 4*

Cysteine/cystine and methionine oxidation is performed with performic acid before the protein hydrolysis.

**Oxidation solution**. Use performic acid freshly prepared by mixing 1 volume of hydrogen peroxide solution (30 per cent) and 9 volumes of anhydrous formic acid and incubating at room temperature for 1 h.

**Procedure**. Dissolve the protein/peptide sample in 20 µL of anhydrous formic acid and heat at 50 °C for 5 min; then add 100 µL of the oxidation solution. Allow the oxidation to proceed for 10-30 min. In this reaction, cysteine is converted to cysteic acid and methionine is converted to methionine-sulfone. Remove the excess reagent from the sample in a vacuum centrifuge. The oxidised protein can then be acid hydrolysed using Method 1 or Method 2. This technique may cause modifications to tyrosine residues in the presence of halides.

*METHOD 5*

Cysteine/cystine oxidation is accomplished during the liquid phase hydrolysis with sodium azide.

**Hydrolysis solution**. To 6 M hydrochloric acid containing 0.2 per cent of phenol, add sodium azide to obtain a final concentration of 2 g/L. The added phenol prevents halogenation of tyrosine.

**Liquid phase hydrolysis**. Conduct the protein/peptide hydrolysis at about 110 °C for 24 h. During the hydrolysis, the cysteine/cystine present in the sample is converted to cysteic acid by the sodium azide present in the hydrolysis solution. This technique allows better tyrosine recovery than Method 4, but it is not quantitative for methionine. Methionine is converted to a mixture of the parent methionine and its 2 oxidative products, methionine-sulfoxide and methionine-sulfone.

*METHOD 6*

Cysteine/cystine oxidation is accomplished with dimethyl sulfoxide (DMSO).

**Hydrolysis solution**. To 6 M hydrochloric acid containing 0.1 per cent to 1.0 per cent of phenol, add dimethyl sulfoxide to obtain a final concentration of 2 per cent *V/V*.

**Vapour phase hydrolysis**. Conduct the protein/peptide hydrolysis at about 110 °C for 24 h. During the hydrolysis, the cysteine/cystine present in the sample is converted to cysteic acid by the DMSO present in the hydrolysis solution. As an approach to limit variability and compensate for partial destruction, it is recommended to evaluate the cysteic acid recovery from oxidative hydrolysis of standard proteins containing 1-8 mol of cysteine per mole of protein. The response factors from protein/peptide hydrolysates are typically about 30 per cent lower than those for non-hydrolysed cysteic acid standards. Because histidine, methionine, tyrosine, and tryptophan are also modified, a complete compositional analysis is not obtained with this technique.

*METHOD 7*

Cysteine/cystine reduction and alkylation is accomplished by a vapour phase pyridylethylation reaction.

**Reducing solution**. Transfer 83.3 µL of pyridine, 16.7 µL of 4-vinylpyridine, 16.7 µL of tributylphosphine, and 83.3 µL of water to a suitable container and mix.

**Procedure**. Add the protein/peptide (between 1 and 100 µg) to a hydrolysis tube, and place in a larger tube. Transfer the reducing solution to the large tube, seal *in vacuo* (about 50 µm of mercury or 6.7 Pa), and heat at about 100 °C for 5 min. Then remove the inner hydrolysis tube, and dry it in a vacuum desiccator for 15 min to remove residual reagents. The pyridylethylated sample can then be acid hydrolysed using previously described procedures. The pyridylethylation reaction is performed simultaneously with a protein standard sample containing 1-8 mol of cysteine per mole of protein to evaluate the pyridylethyl-cysteine recovery. Longer incubation times for the pyridylethylation reaction can cause modifications to the α-amino terminal group and the ε-amino group of lysine in the protein.

*METHOD 8*

Cysteine/cystine reduction and alkylation is accomplished by a liquid phase pyridylethylation reaction.

**Stock solutions**. Prepare and filter 3 solutions: 1 M Tris-hydrochloride pH 8.5 containing 4 mM disodium edetate (stock solution A), 8 M guanidine hydrochloride (stock solution B), and 10 per cent of 2-mercaptoethanol (stock solution C).

**Reducing solution**. Prepare a mixture of 1 volume of stock solution A and 3 volumes of stock solution B to obtain a buffered solution of 6 M guanidine hydrochloride in 0.25 M tris-hydrochloride.

**Procedure**. Dissolve about 10 µg of the test sample in 50 µL of the reducing solution, and add about 2.5 µL of stock solution C. Store under nitrogen or argon for 2 h at room temperature in the dark. To achieve the pyridylethylation reaction, add about 2 µL of 4-vinylpyridine to the protein solution, and incubate for an additional 2 h at room temperature in the dark. Desalt the protein/peptide by collecting the protein/peptide fraction from a reversed-phase HPLC separation. The collected sample can be dried in a vacuum centrifuge before acid hydrolysis.

*METHOD 9*

Cysteine/cystine reduction and alkylation is accomplished by a liquid phase carboxymethylation reaction.

**Stock solutions**. Prepare as directed for Method 8.

**Carboxymethylation solution**. Prepare a 100 g/L solution of iodoacetamide in alcohol.

**Buffer solution**. Use the reducing solution, prepared as described for Method 8.

**Procedure**. Dissolve the test sample in 50 µL of the buffer solution, and add about 2.5 µL of stock solution C. Store under nitrogen or argon for 2 h at room temperature in the dark. Add the carboxymethylation solution in a ratio 1.5 fold per total theoretical content of thiols, and incubate for an additional 30 min at room temperature in the dark. If the thiol content of the protein is unknown, then add 5 µL of 100 mM iodoacetamide for every 20 nmol of protein present. The reaction is stopped by adding excess of 2-mercaptoethanol. Desalt the protein/peptide by collecting the protein/peptide fraction from a reversed-phase HPLC separation. The collected sample can be dried in a vacuum centrifuge before acid hydrolysis. The *S*-carboxyamidomethyl-cysteine formed will be converted to *S*-carboxymethyl-cysteine during acid hydrolysis.

*METHOD 10*

Cysteine/cystine is reacted with dithiodiglycolic acid or dithiodipropionic acid to produce a mixed disulfide. The choice of dithiodiglycolic acid or dithiodipropionic acid depends on the required resolution of the amino acid analysis method.

**Reducing solution**. A 10 g/L solution of dithiodiglycolic acid (or dithiodipropionic acid) in 0.2 M sodium hydroxide.

**Procedure**. Transfer about 20 µg of the test sample to a hydrolysis tube, and add 5 µL of the reducing solution. Add 10 µL of isopropyl alcohol, and then remove all of the sample liquid by vacuum centrifugation. The sample is then hydrolysed using Method 1. This method has the advantage that other amino acid residues are not derivatised by side reactions, and that the sample does not need to be desalted prior to hydrolysis.

*METHOD 11*

Asparagine and glutamine are converted to aspartic acid and glutamic acid, respectively, during acid hydrolysis. Asparagine and aspartic acid residues are added and represented by *Asx*, while glutamine and glutamic acid residues are added and represented by *Glx*. Proteins/peptides can be reacted with bis(1,1-trifluoroacetoxy)iodobenzene (BTI) to convert the asparagine and glutamine residues to diaminopropionic acid and diaminobutyric acid residues, respectively, upon acid hydrolysis. These conversions allow the analyst to determine the asparagine and glutamine content of a protein/peptide in the presence of aspartic acid and glutamic acid residues.

**Reducing solutions**. Prepare and filter 3 solutions: a solution of 10 mM trifluoroacetic acid (Solution A), a solution of 5 M guanidine hydrochloride and 10 mM trifluoroacetic acid (Solution B), and a freshly prepared solution of dimethylformamide containing 36 mg of BTI per millilitre (Solution C).

**Procedure**. In a clean hydrolysis tube, transfer about 200 µg of the test sample, and add 2 mL of Solution A or Solution B and 2 mL of Solution C. Seal the hydrolysis tube *in vacuo*. Heat the sample at 60 °C for 4 h in the dark. The sample is then dialysed with water to remove the excess reagents. Extract the dialysed sample 3 times with equal volumes of butyl acetate, and then lyophilise. The protein can then be acid hydrolysed using previously described procedures. The α,β-diaminopropionic and α,γ-diaminobutyric acid residues do not typically resolve from the lysine residues upon ion-exchange chromatography based on amino acid analysis. Therefore, when using ion-exchange as the mode of amino acid separation, the asparagine and glutamine contents are the quantitative difference in the aspartic acid and glutamic acid content assayed with underivatised and BTI-derivatised acid hydrolysis. The threonine, methionine, cysteine, tyrosine, and histidine assayed content can be altered by BTI derivatisation; a hydrolysis without BTI will have to be performed if the analyst is interested in the composition of these other amino acid residues of the protein/peptide.

## METHODOLOGIES OF AMINO ACID ANALYSIS: GENERAL PRINCIPLES

Many amino acid analysis techniques exist, and the choice of any one technique often depends on the sensitivity required from the assay. In general, about one-half of the amino acid analysis techniques employed rely on the separation of the free amino acids by ion-exchange chromatography followed by post-column derivatisation (e.g., with ninhydrin or *o*-phthalaldehyde). Post-column derivatisation techniques can be used with samples that contain small amounts of buffer components, (such as salts and urea) and generally require between 5 µg and 10 µg of protein sample per analysis. The remaining amino acid techniques typically involve pre-column derivatisation of the free amino acids (e.g., phenyl isothiocyanate; 6-aminoquinolyl-*N*-hydroxysuccinimidyl carbamate or *o*-phthalaldehyde; (dimethylamino)azobenzenesulfonyl chloride; 9-fluorenylmethyl chloroformate; and 7-fluoro-4-nitrobenzo-2-oxa-1,3-diazole) followed by reversed-phase HPLC. Pre-column derivatisation techniques are very sensitive and usually require between 0.5 µg and 1.0 µg of protein sample per analysis but may be influenced by buffer

salts in the samples. Pre-column derivatisation techniques may also result in multiple derivatives of a given amino acid, which complicates the result interpretation. Post-column derivatisation techniques are generally influenced less by performance variation of the assay than pre-column derivatisation techniques.

The following methods may be used for quantitative amino acid analysis. Instruments and reagents for these procedures are available commercially. Furthermore, many modifications of these methodologies exist with different reagent preparations, reaction procedures, chromatographic systems, etc. Specific parameters may vary according to the exact equipment and procedure used. Many laboratories will use more than one amino acid analysis technique to exploit the advantages offered by each. In each of these methods, the analogue signal is visualised by means of a data acquisition system, and the peak areas are integrated for quantification purposes.

*METHOD 1 - POST-COLUMN NINHYDRIN DERIVATISATION*

Ion-exchange chromatography with post-column ninhydrin derivatisation is one of the most common methods employed for quantitative amino acid analysis. As a rule, a lithium-based cation-exchange system is employed for the analysis of the more complex physiological samples, and the faster sodium-based cation-exchange system is used for the more simplistic amino acid mixtures obtained with protein hydrolysates (typically containing 17 amino acid components). Separation of the amino acids on an ion-exchange column is accomplished through a combination of changes in pH and cation strength. A temperature gradient is often employed to enhance separation.

When the amino acid reacts with ninhydrin, the reactant has a characteristic purple or yellow colour. Amino acids, except imino acid, give a purple colour, and show an absorption maximum at 570 nm. The imino acids such as proline give a yellow colour, and show an absorption maximum at 440 nm. The post-column reaction between ninhydrin and amino acids eluted from the column is monitored at 440 nm and 570 nm, and the chromatogram obtained is used for the determination of amino acid composition.

The detection limit is considered to be 10 pmol for most of the amino acid derivatives, but 50 pmol for the proline derivative. Response linearity is obtained in the range of 20-500 pmol with correlation coefficients exceeding 0.999. To obtain good composition data, samples larger than 1 µg before hydrolysis are best suited for this amino acid analysis of protein/peptide.

*METHOD 2 - POST-COLUMN OPA DERIVATISATION*

*o*-Phthalaldehyde (OPA) reacts with primary amines in the presence of thiol compound, to form highly fluorescent isoindole products. This reaction is used for the post-column derivatisation in analysis of amino acids by ion-exchange chromatography. The rule of the separation is the same as Method 1.

Although OPA does not react with secondary amines (imino acids such as proline) to form fluorescent substances, the oxidation with sodium hypochlorite or chloramine T allows secondary amines to react with OPA. The procedure employs a strongly acidic cation-exchange column for separation of free amino acids followed by post-column oxidation with sodium hypochlorite or chloramine T and post-column derivatisation using OPA and a thiol compound such as *N*-acetyl-L-cysteine or 2-mercaptoethanol. The derivatisation of primary amino acids is not noticeably affected by the continuous supply of sodium hypochlorite or chloramine T.

Separation of the amino acids on an ion-exchange column is accomplished through a combination of changes in pH and cation strength. After post-column derivatisation of eluted amino acids with OPA, the reactant passes through the fluorometric detector. Fluorescence intensity of OPA-derivatised amino acids are monitored with an excitation wavelength of 348 nm and an emission wavelength of 450 nm.

The detection limit is considered to be a few tens of picomole level for most of the OPA-derivatised amino acids. Response linearity is obtained in the range of a few picomole level to a few tens of nanomole level. To obtain good compositional data, samples larger than 500 ng of protein/peptide before hydrolysis are recommended.

*METHOD 3 - PRE-COLUMN PITC DERIVATISATION*

Phenylisothiocyanate (PITC) reacts with amino acids to form phenylthiocarbamyl (PTC) derivatives which can be detected with high sensitivity at 254 nm. Therefore, pre-column derivatisation of amino acids with PITC followed by a reversed-phase HPLC separation with UV detection is used to analyse the amino acid composition.

After the reagent is removed under vacuum, the derivatised amino acids can be stored dry and frozen for several weeks with no significant degradation. If the solution for injection is kept cold, no noticeable loss in chromatographic response occurs after 3 days.

Separation of the PTC-amino acids on a reversed-phase HPLC with an octadecylsilyl (ODS) column is accomplished through a combination of changes in concentrations of acetonitrile and buffer ionic strength. PTC-amino acids eluted from the column are monitored at 254 nm.

The detection limit is considered to be 1 pmol for most of the PTC-amino acids. Response linearity is obtained in the range of 20-500 pmol with correlation coefficients exceeding 0.999. To obtain good compositional data, samples larger than 500 ng of protein/peptide before hydrolysis are recommended.

*METHOD 4 - PRE-COLUMN AQC DERIVITISATION*

Pre-column derivatisation of amino acids with 6-aminoquinolyl-*N*-hydroxysuccinimidyl carbamate (AQC) followed by reversed-phase HPLC separation with fluorometric detection is used.

AQC reacts with amino acids to form stable, fluorescent unsymmetric urea derivatives (AQC-amino acids) which are readily amenable to analysis by reversed-phase HPLC. Therefore, pre-column derivatisation of amino acids with AQC followed by reversed-phase HPLC separation with fluorimetric detection is used to analyse the amino acid composition.

Separation of the AQC-amino acids on a reversed-phase HPLC with an ODS column is accomplished through a combination of changes in concentrations of acetonitrile and buffer ionic strengh. Selective fluorescence detection of the derivatives with an excitation wavelength at 250 nm and an emission wavelength at 395 nm allows for the direct injection of the reaction mixture with no significant interference from the only major fluorescent reagent by-product, 6-aminoquinoline. Excess reagent is rapidly hydrolysed ($t_{1/2}$<15 s) to yield 6-aminoquinoline, *N*-hydroxysuccinimide and carbon dioxide, and after 1 min no further derivatisation can take place.

Peak areas for AQC-amino acids are essentially unchanged for at least 1 week at room temperature. Therefore AQC-amino acids have more than sufficient stability to allow for overnight automated chromatographic analysis.

The detection limit is considered to range from about 40 fmol to 320 fmol for each amino acid, except for cystein. The detection limit for cystein is approximately 800 fmol. Response linearity is obtained in the range of 2.5-200 µM with correlation coefficients exceeding 0.999. Good compositional data can be obtained from the analysis of derivatised protein hydrolysates derived from as little as 30 ng of protein/peptide.

*METHOD 5 - PRE-COLUMN OPA DERIVATISATION*

Pre-column derivatisation of amino acids with *o*-phthalaldehyde (OPA) followed by reversed-phase HPLC separation with fluorometric detection is used. This technique does not detect amino acids that exist as secondary amines (e.g., proline).

OPA in conjunction with a thiol reagent reacts with primary amine groups to form highly fluorescent isoindole products. 2-Mercaptoethanol or 3-mercaptopropionic acid can be used as the thiol. OPA itself does not fluoresce and consequently produces no interfering peaks. In addition, its solubility and stability in aqueous solution, along with the rapid kinetics for the reaction, make it amenable to automated derivatisation and analysis using an autosampler to mix the sample with the reagent. However, lack of reactivity with secondary amino acids has been a predominant drawback. This method does not detect amino acids that exist as secondary amines (e.g., proline). To compensate for this drawback, this technique may be combined with another technique described in Method 7 or Method 8.

Pre-column derivatisation of amino acids with OPA is followed by a reversed-phase HPLC separation. Because of the instability of the OPA-amino acid derivative, HPLC separation and analysis are performed immediately following derivatisation. The liquid chromatograph is equipped with a fluorometric detector for the detection of derivatised amino acids. Fluorescence intensity of OPA-derivatised amino acids is monitored with an excitation wavelength of 348 nm and an emission wavelength of 450 nm.

Detection limits as low as 50 fmol via fluorescence have been reported, although the practical limit of analysis remains at 1 pmol.

*METHOD 6 - PRE-COLUMN DABS-Cl DERIVATISATION*

Pre-column derivatisation of amino acids with (dimethylamino)azobenzenesulfonyl chloride (DABS-Cl) followed by reversed-phase HPLC separation with visible light detection is used.

DABS-Cl is a chromophoric reagent employed for the labelling of amino acids. Amino acids labelled with DABS-Cl (DABS-amino acids) are highly stable and show an absorption maximum at 436 nm.

DABS-amino acids, all naturally occurring amino acid derivatives, can be separated on an ODS column of a reversed-phase HPLC by employing gradient systems consisting of acetonitrile and aqueous buffer mixture. Separated DABS-amino acids eluted from the column are detected at 436 nm in the visible region.

This method can analyse the imino acids such as proline together with the amino acids at the same degree of sensitivity, DABS-Cl derivatisation method permits the simultaneous quantification of tryptophan residues by previous hydrolysis of the protein/peptide with sulfonic acids such as mercaptoethanesulfonic acid, *p*-toluenesulfonic acid or methanesulfonic acid described in Method 2 under Protein hydrolysis. The other acid-labile residues, asparagine and glutamine, can also be analysed by previous conversion into diaminopropionic acid and diaminobutyric acid, respectively, by treatment of protein/peptide with BTI described in Method 11 under Protein hydrolysis.

The non-proteinogenic amino acid norleucine cannot be used as an internal standard in this method as this compound is eluted in a chromatographic region crowded with peaks of primary amino acids. Nitrotyrosine can be used as an internal standard because it is eluted in a clean region.

The detection limit of DABS-amino acid is about 1 pmol. As little as 2-5 pmol of an individual DABS-amino acid can be quantitatively analysed with reliability, and only 10-30 ng of the dabsylated protein hydrolysate is required for each analysis.

*METHOD 7 - PRE-COLUMN FMOC-Cl DERIVATISATION*

Pre-column derivatisation of amino acids with 9-fluorenylmethyl chloroformate (FMOC-Cl) followed by reversed-phase HPLC separation with fluorometric detection is used.

FMOC-Cl reacts with both primary and secondary amino acids to form highly fluorescent products. The reaction proceeds under mild conditions in aqueous solution and is completed in 30 s. The derivatives are stable, only the histidine derivative showing any breakdown. Although FMOC-Cl is fluorescent itself, the reagent excess and fluorescent side-products can be eliminated without loss of FMOC-amino acids.

FMOC-amino acids are separated by a reversed-phase HPLC using an ODS column. The separation is carried out by gradient elution varied linearly from a mixture of 10 volumes of acetonitrile, 40 volumes of methanol and 50 volumes of acetic acid buffer to a mixture of 50 volumes of acetonitrile and 50 volumes of acetic acid buffer and 20 amino acid derivatives are separated in 20 min. Each derivative eluted from the column is monitored by a fluorometric detector set at an excitation wavelength of 260 nm and an emission wavelength of 313 nm.

The detection limit is in the low femtomole range. A linearity range of 0.1-50 µM is obtained for most of the amino acids.

*METHOD 8 - PRE-COLUMN NBD-F DERIVATISATION*

Pre-column derivatisation of amino acids with 7-fluoro-4-nitrobenzo-2-oxa-1,3-diazole (NBD-F) followed by reversed-phase HPLC separation with fluorometric detection is used.

NBD-F reacts with both primary and secondary amino acids to form highly fluorescent products. Amino acids are derivatised with NBD-F by heating to 60 °C for 5 min.

NBD-amino acid derivatives are separated on an ODS column of a reversed-phase HPLC by employing a gradient elution system consisting of acetonitrile and aqueous buffer mixture, and 17 amino acid derivatives are separated in 35 min. ε-Aminocaproic acid can be used as an internal standard, because it is eluted in a clean chromatographic region. Each derivative eluted from the column is monitored by a fluorometric detector set at an excitation wavelength of 480 nm and an emission wavelength of 530 nm.

The sensitivity of this method is almost the same as for the pre-column OPA derivatisation method (Method 5), excluding proline to which OPA is not reactive, and might be advantageous for NBD-F against OPA. The detection limit for each amino acid is about 10 fmol. Profile analysis can be achieved with about 1.5 mg of protein hydrolysates in the pre-column reaction mixture.

DATA CALCULATION AND ANALYSIS

When determining the amino acid content of a protein/peptide hydrolysate, it should be noted that the acid hydrolysis step destroys tryptophan and cysteine. Serine and threonine are partially destroyed by acid hydrolysis, while isoleucine and valine residues may be only partially cleaved. Methionine can undergo oxidation during acid hydrolysis, and some amino acids (e.g., glycine and serine) are common contaminants. Application of adequate vacuum (less than 200 µm of mercury or 26.7 Pa) or introduction of inert gas (argon) in the headspace of the reaction vessel during vapour phase hydrolysis can reduce the level of oxidative destruction. Therefore, the quantitative results obtained for cysteine, tryptophan, threonine, isoleucine, valine, methionine, glycine, and serine from a protein/peptide hydrolysate may be variable and may warrant further investigation and consideration.

**Amino Acid Mole Percent**. This is the number of specific amino acid residues per 100 residues in a protein. This result may be useful for evaluating amino acid analysis data when the molecular mass of the protein under investigation is unknown. This information can be used to corroborate

the identity of a protein/peptide and has other applications. Carefully identify and integrate the peaks obtained as directed for each procedure. Calculate the mole percent for each amino acid present in the test sample using the formula:

$$\frac{100r_U}{r}$$

in which $r_U$ is the peak response, in nanomoles, of the amino acid under test; and $r$ is the sum of peak responses, in nanomoles, for all amino acids present in the test sample. Comparison of the mole percent of the amino acids under test to data from known proteins can help establish or corroborate the identity of the sample protein.

**Unknown Protein Samples**. This data analysis technique can be used to estimate the protein concentration of an unknown protein sample using the amino acid analysis data. Calculate the mass, in micrograms, of each recovered amino acid using the formula:

$$\frac{mM_r}{1000}$$

in which $m$ is the recovered quantity, in nanomoles, of the amino acid under test; and $M_r$ is the average molecular mass for that amino acid, corrected for the mass of the water molecule that was eliminated during peptide bond formation. The sum of the masses of the recovered amino acids will give an estimate of the total mass of the protein analysed after appropriate correction for partially and completely destroyed amino acids. If the molecular mass of the unknown protein is available (i.e., by SDS-PAGE analysis or mass spectroscopy), the amino acid composition of the unknown protein can be predicted. Calculate the number of residues of each amino acid using the formula:

$$\frac{m}{\left(\frac{1000M}{M_{rt}}\right)}$$

in which $m$ is the recovered quantity, in nanomoles, of the amino acid under test; $M$ is the total mass, in micrograms, of the protein; and $M_{rt}$ is the molecular mass of the unknown protein.

**Known protein samples**. This data analysis technique can be used to investigate the amino acid composition and protein concentration of a protein sample of known molecular mass and amino acid composition using the amino acid analysis data. When the composition of the protein being analysed is known, one can exploit the fact that some amino acids are recovered well, while other amino acid recoveries may be compromised because of complete or partial destruction (e.g., tryptophan, cysteine, threonine, serine, methionine), incomplete bond cleavage (i.e., for isoleucine and valine) and free amino acid contamination (i.e., by glycine and serine).

Because those amino acids that are recovered best represent the protein, these amino acids are chosen to quantify the amount of protein. Well-recovered amino acids are, typically, aspartate-asparagine, glutamate-glutamine, alanine, leucine, phenylalanine, lysine, and arginine. This list can be modified based on experience with one's own analysis system. Divide the quantity, in nanomoles, of each of the well-recovered amino acids by the expected number of residues for that amino acid to obtain the protein content based on each well-recovered amino acid. Average the protein content results calculated. The protein content determined for each of the well-recovered amino acids should be evenly distributed about the mean. Discard protein content values for those amino acids that have an unacceptable deviation from the mean. Typically greater than 5 per cent variation from the mean is considered unacceptable. Recalculate the mean protein content from the remaining values to obtain the protein content of the sample. Divide the content of each amino acid by the calculated mean protein content to determine the amino acid composition of the sample by analysis.

Calculate the relative compositional error, in percentage, using the formula:

$$\frac{100m}{m_S}$$

in which $m$ is the experimentally determined quantity, in nanomoles per amino acid residue, of the amino acid under test; and $m_S$ is the known residue value for that amino acid. The average relative compositional error is the average of the absolute values of the relative compositional errors of the individual amino acids, typically excluding tryptophan and cysteine from this calculation. The average relative compositional error can provide important information on the stability of analysis run over time. The agreement in the amino acid composition between the protein sample and the known composition can be used to corroborate the identity and purity of the protein in the sample.

# 2.2.57. INDUCTIVELY COUPLED PLASMA-ATOMIC EMISSION SPECTROMETRY

GENERAL PRINCIPLE

Inductively coupled plasma-atomic emission spectrometry (ICP-AES) is an atomic emission spectrometry method that uses an inductively coupled plasma (ICP) as the excitation source.

An ICP is a highly ionised inert gas (usually argon) with equal numbers of electrons and ions sustained by a radio-frequency (RF) field. The high temperature reached in the plasma successively desolvates, vaporises, excites - atomic emission spectrometry (AES) detection - and ionises - mass spectrometry (MS) detection - atoms from the sample. Detection limits are, generally, in the lower nanogram (ICP-MS) to microgram (ICP-AES) per litre range.

The plasma is formed by a tangential stream of support gas through a 'torch', i.e. a system consisting of 3 concentric quartz tubes. A metal coil (the load coil) surrounds the top end of the torch and is connected to a radio-frequency (RF) generator. Power (usually 700-1500 W) is applied through the coil and an oscillating magnetic field corresponding to the frequency of the generator (in most cases 27 MHz, 40 MHz) is formed. The plasma forms when the support gas is made conductive by exposing it to an electric discharge, which produces seed electrons and ions. Inside the induced magnetic field, the charged particles (electrons and ions) are forced to flow in a closed annular path. As they meet resistance to their flow, heating takes place producing additional ionisation. The process occurs almost instantaneously, and the plasma expands to its full strength and dimensions. The radio-frequency oscillation of the power applied through the coil causes radio-frequency electric and magnetic fields to be set up in the area at the top of the torch. When a spark (produced by a Tesla tube or some other seeding device) is applied to the support gas flowing through the torch, some electrons are stripped from the support gas atoms. These electrons are then caught up in the magnetic field and accelerated. Adding energy to the electrons by the use of a coil is known as inductive coupling. These high-energy electrons in turn collide with other support-gas atoms, stripping off still more electrons. The collisional ionisation of the support gas continues in a chain reaction, breaking down the gas into a physical plasma consisting of support-gas atoms, electrons and support-gas ions. The plasma is then sustained within the torch and load coil as radio-frequency energy is continually transferred to it through the inductive coupling process.

The ICP appears as an intense, very bright, plume-shaped plasma. At the base the plasma is toroidal, and this is referred to as the induction region (IR), i.e. the region in which the inductive energy transfer from the load coil to the plasma takes place. The sample is introduced through the induction region into the centre of the plasma.

## APPARATUS

The apparatus consists essentially of the following elements:

- sample-introduction system consisting of a peristaltic pump delivering the solution at constant flow rate into a nebuliser;
- radio-frequency (RF) generator;
- plasma torch;
- transfer optics focussing the image of the plasma at the entrance slit of the spectrometer; radial viewing is better for difficult matrices (alkalis, organics), whereas axial viewing gives more intensity and better detection limits in simple matrices;
- wavelength dispersive devices consisting of diffraction gratings, prisms, filters or interferometers;
- detectors converting radiant energy into electrical energy;
- data-acquisition unit.

## INTERFERENCE

Interference is anything that causes the signal from an analyte in a sample to be different from the signal for the same concentration of that analyte in a calibration solution. The well-known chemical interference that is encountered in flame atomic absorption spectrometry is usually weak in ICP-AES. In rare cases where interference occurs, it may be necessary to increase the RF power or to reduce the inner support-gas flow to eliminate it. The interference in ICP-AES can be of spectral origin or even the result of high concentrations of certain elements or matrix compounds. Physical interference (due to differences in viscosity and surface tension of the sample and calibration standards) can be minimised by dilution of the sample, matrix matching, use of internal standards or through application of the method of standard additions.

Another type of interference occasionally encountered in ICP-AES is the so-called 'easily ionised elements (EIEs) effect'. The EIEs are those elements that are ionised much more easily, for example alkaline metals and alkaline earths. In samples that contain high concentrations of EIEs (more than 0.1 per cent), suppression or enhancement of emission signals is likely to occur.

**Spectral interference**. This may be due to other lines or shifts in background intensity. These lines may correspond to argon (observed above 300 nm), OH bands due to the decomposition of water (at about 300 nm), NO bands due to the interaction of the plasma with the ambient air (between 200 nm and 300 nm), and other elements in the sample, especially those present at high concentrations. The interference falls into 4 different categories: simple background shift, sloping background shift, direct spectral overlap, and complex background shift.

**Absorption interference**. This arises when part of the emission from an analyte is absorbed before it reaches the detector. This effect is observed particularly when the concentration of a strongly emitting element is so high that the atoms or ions of that element that are in the lower energy state of transition absorb significant amounts of the radiation emitted by the relevant excited species. This effect, known as self-absorption, determines the upper end of the linear working range for a given emission line.

**Multicomponent spectral fitting**. Multiple emission-line determinations are commonly used to overcome problems with spectral interferences. A better, more accurate method for performing spectral interference corrections is to use the information obtained with advanced detector systems through multicomponent spectral fitting. This quantifies not only the interference, but also the background contribution from the matrix, thereby creating a correction formula. Multicomponent spectral fitting utilises a multiple linear-squares model based on the analysis of pure analyte, the matrix and the blank, creating an interference-corrected mathematical model. This permits the determination of the analyte emission in a complex matrix with improved detection limits and accuracy.

## PROCEDURE

### *SAMPLE PREPARATION AND SAMPLE INTRODUCTION*

The basic goal for the sample preparation is to ensure that the analyte concentration falls within the working range of the instrument through dilution or preconcentration, and that the sample-containing solution can be nebulised in a reproducible manner.

Several sample-introduction systems tolerate high acid concentrations, but the use of sulfuric and phosphoric acids can contribute to background emission observed in the ICP spectra. Therefore, nitric and hydrochloric acids are preferable. The availability of hydrofluoric acid-resistant (for example perfluoroalkoxy polymer) sample-introduction systems and torches also allows the use of hydrofluoric acid. In selecting a sample-introduction method, the requirements for sensitivity, stability, speed, sample size, corrosion resistance and resistance to clogging have to be considered. The use of a cross-flow nebuliser combined with a spray chamber and torch is suitable for most requirements. The peristaltic pumps used for ICP-AES usually deliver the standard and sample solutions at a rate of 1 mL/min or less.

In the case of organic solvents being used, the introduction of oxygen must be considered to avoid organic layers.

### *CHOICE OF OPERATING CONDITIONS*

The standard operating conditions prescribed by the manufacturer are to be followed. Usually, different sets of operating conditions are used for aqueous solutions and for organic solvents. Suitable operating parameters are to be properly chosen:

- wavelength selection;
- support-gas flow rates (outer, intermediate and inner tubes of the torch);
- RF power;
- viewing position (radial or axial);
- pump speed;
- conditions for the detector (gain/voltage for photomultiplier tube detectors, others for array detectors);
- integration time (time set to measure the emission intensity at each wavelength).

## CONTROL OF INSTRUMENT PERFORMANCE

### System suitability

The following tests may be carried out with a multi-element control solution to ensure the adequate performance of the ICP-AES system:

- energy transfer (generator, torch, plasma); measurement of the ratio Mg II (280.270 nm)/Mg I (285.213 nm) may be used;
- sample transfer, by checking nebuliser efficiency and stability;
- resolution (optical system), by measuring peak widths at half height, for example As (189.042 nm), Mn (257.610 nm), Cu (324.754 nm) or Ba (455.403 nm);
- analytical performance, by calculating detection limits of selected elements over the wavelength range.

## VALIDATION OF THE METHOD

Satisfactory performance of methods prescribed in monographs is verified at suitable time intervals.

*LINEARITY*

Prepare and analyse not fewer than 4 reference solutions over the calibration range plus a blank. Perform not fewer than 5 replicates.

The calibration curve is calculated by least-square regression from all measured data of the calibration test. The regression curve, the means, the measured data and the confidence interval of the calibration curve are plotted. The operating method is valid when:

- the correlation coefficient is at least 0.99;
- the residuals of each calibration level are randomly distributed around the calibration curve.

Calculate the mean and relative standard deviation for the lowest and for the highest calibration level.

When the ratio of the estimated standard deviations of the lowest and the highest calibration level is less than 0.5 or greater than 2.0, a more precise estimation of the calibration curve may be obtained using weighted linear regression. Both linear and quadratic weighting functions are applied to the data to find the most appropriate weighting function to be employed.

If the means compared to the calibration curve show a deviation from linearity, two-dimensional linear regression is used.

*ACCURACY*

Verify the accuracy preferably by using a certified reference material (CRM). Where this is not possible, perform a test for recovery.

**Recovery**. For assay determinations a recovery of 90 per cent to 110 per cent is to be obtained. The test is not valid if recovery, for example for trace-element determination, is outside of the range 80 per cent to 120 per cent of the theoretical value. Recovery may be determined on a suitable reference solution (matrix solution) spiked with a known quantity of analyte (concentration range that is relevant to the samples to be determined).

*REPEATABILITY*

The repeatability is not greater than 3 per cent for an assay and not greater than 5 per cent for an impurity test.

*LIMIT OF QUANTIFICATION*

Verify that the limit of quantification (for example, determined using the 10 σ approach) is below the value to be measured.

**01/2008:20258**

# 2.2.58. INDUCTIVELY COUPLED PLASMA-MASS SPECTROMETRY

Inductively coupled plasma-mass spectrometry (ICP-MS) is a mass spectrometry method that uses an inductively coupled plasma (ICP) as the ionisation source. The basic principles of ICP formation are described in chapter *2.2.57* on inductively coupled plasma-atomic emission spectrometry (ICP-AES).

ICP-MS utilises the ability of the ICP to generate charged ions from the element species within a sample. These ions are then directed into a mass spectrometer, which separates them according to their mass-to-charge ratio (*m*/*z*). Most mass spectrometers have a quadrupole system or a magnetic sector. Ions are transported from the plasma through 2 cones (sampler and skimmer cones, forming the interface region) to the ion optics. The ion optics consist of an electrostatic lens, which takes ions from an area at atmospheric pressure to the mass filter at a vacuum of $10^{-8}$ Pa or less, maintained with a turbomolecular pump. After their filtration, ions of the selected mass/charge ratio are directed to a detector (channel electromultiplier, Faraday cup, dynodes), where ion currents are converted into electrical signals. The element is quantified according to the number of ions arriving and generating electrical pulses per unit time.

The sample-introduction system and data-handling techniques of an ICP-AES system are also used in ICP-MS.

APPARATUS

The apparatus consists essentially of the following elements:

- sample-introduction system, consisting of a peristaltic pump delivering the solution at constant flow rate into a nebuliser;
- radio-frequency (RF) generator;
- plasma torch;
- interface region including cones to transport ions to the ion optics;
- mass spectrometer;
- detector;
- data-acquisition unit.

INTERFERENCE

Mass interference is the major problem, for example by isobaric species that significantly overlap the mass signal of the ions of interest, especially in the central part of the mass range (for example 40-80 a.m.u.). The combination of atomic ions leads to polyatomic or molecular interferences (i.e. $^{40}Ar^{16}O$ with $^{56}Fe$ or $^{40}Ar^{40}Ar$ with $^{80}Se$). Matrix interference may also occur with some analytes. Some samples have an impact on droplet formation or on the ionisation temperature in the plasma. These phenomena may lead to the suppression of analyte signals. Physical interference is to be circumvented by using the method of internal standardisation or by standard addition. The element used as internal standard depends on the element to be measured: $^{59}Co$ and $^{115}In$, for example, can be used as internal standards.

The prime characteristic of an ICP-MS instrument is its resolution, i.e. the efficiency of separation of 2 close masses. Quadrupole instruments are, from this point of view, inferior to magnetic-sector spectrometers.

PROCEDURE

*SAMPLE PREPARATIONS AND SAMPLE INTRODUCTION*

The sample preparation usually involves a step of digestion of the matrix by a suitable method, for example in a microwave oven. Furthermore, it is important to ensure that the analyte concentration falls within the working range of the instrument through dilution or preconcentration, and that the sample-containing solution can be nebulised in a reproducible manner.

Several sample-introduction systems tolerate high acid concentrations, but the use of sulfuric and phosphoric acids can contribute to background emission. Therefore, nitric and hydrochloric acids are preferable. The availability of hydrofluoric acid-resistant (for example perfluoroalkoxy polymer) sample-introduction systems and torches also allows the use of hydrofluoric acid. In selecting a sample-introduction method, the requirements for sensitivity, stability, speed, sample size, corrosion resistance and resistance to clogging have to be considered. The use of a cross-flow nebuliser combined with a spray chamber and torch is suitable for most requirements. The peristaltic pumps usually deliver the standard and sample solutions at a rate of 20-1000 µL/min.

In the case of organic solvents being used, the introduction of oxygen must be considered to avoid organic layers.

*CHOICE OF OPERATING CONDITIONS*

The standard operating conditions prescribed by the manufacturer are to be followed. Usually, different sets of operating conditions are used for aqueous solutions and for organic solvents. Suitable operating parameters are to be properly chosen:

- selection of cones (material of sampler and skimmer);
- support-gas flow rates (outer, intermediate and inner tubes of the torch);
- RF power;
- pump speed;
- selection of one or more isotopes of the element to be measured (mass).

ISOTOPE SELECTION

Isotope selection is made using several criteria. The most abundant isotope for a given element is selected to obtain maximum sensitivity. Furthermore, an isotope with the least interference from other species in the sample matrix and from the support gas should be selected. Information about isobaric interferences and interferences from polyatomic ions of various types, for example hydrides, oxides, chlorides, etc., is usually available in the software of ICP-MS instrument manufacturers.

CONTROL OF INSTRUMENT PERFORMANCE

**System suitability**

- Tuning of the instrument allows to monitor and adjust the measurement before running samples. ICP-MS mass accuracy is checked with a tuning solution containing several isotopes covering the whole range of masses, for example $^{9}Be$, $^{59}Co$, $^{89}Y$, $^{115}In$, $^{140}Ce$ and $^{209}Bi$.
- Sensitivity and short- and long-term stability are recorded. The instrument parameters (plasma condition, ion lenses and quadrupole parameter) are to be optimised to obtain the highest possible number of counts.
- Tuning for resolution and mass axis is to be done with a solution of Li, Y and Tl to ensure an acceptable response over a wide range of masses.
- Evaluation of the efficiency of the plasma to decompose oxides has to be performed in order to minimise these interferences. The ratio Ce/CeO and/or Ba/BaO is a good indicator, and a level less than about 3 per cent is required.
- Reduction of the formation of double-charged ions is made with Ba and Ce. The ratio of the signal for double-charged ions to the assigned element should be less than 2 per cent.
- Long-term stability is checked by running a standard first and at the end of the sample sequence, controlling whether salt deposits on the cones have reduced the signal throughout the run.

VALIDATION OF THE METHOD

Satisfactory performance of methods prescribed in monographs is verified at suitable time intervals.

*LINEARITY*

Prepare and analyse not fewer than 4 reference solutions over the calibration range plus a blank. Perform not fewer than 5 replicates.

The calibration curve is calculated by least-square regression from all measured data of the calibration test. The regression curve, the means, the measured data and the confidence interval of the calibration curve are plotted. The operating method is valid when:

- the correlation coefficient is at least 0.99;
- the residuals of each calibration level are randomly distributed around the calibration curve.

Calculate the mean and relative standard deviation for the lowest and for the highest calibration level.

When the ratio of the estimated standard deviations of the lowest and the highest calibration level is less than 0.5 or greater than 2.0, a more precise estimation of the calibration curve may be obtained using weighted linear regression. Both linear and quadratic weighting functions are applied to the data to find the most appropriate weighting function to be employed.

If the means compared to the calibration curve show a deviation from linearity, two-dimensional linear regression is used.

*ACCURACY*

Verify the accuracy preferably by using a certified reference material (CRM). Where this is not possible, perform a test for recovery.

**Recovery**. For assay determinations a recovery of 90 per cent to 110 per cent is to be obtained. The test is not valid if recovery, for example for trace-element determination, is outside the range 80 per cent to 120 per cent of the theoretical value. Recovery may be determined on a suitable reference solution (matrix solution) spiked with a known quantity of analyte (concentration range that is relevant to the samples to be determined).

*REPEATABILITY*

The repeatability is not greater than 3 per cent for an assay and not greater than 5 per cent for an impurity test.

*LIMIT OF QUANTIFICATION*

Verify that the limit of quantification (for example, determined using the 10 σ approach) is below the value to be measured.

**01/2011:20259**

# 2.2.59. GLYCAN ANALYSIS OF GLYCOPROTEINS

1. INTRODUCTION

Glycan analysis is a test to analyse glycan moieties of glycoproteins. It may involve:

- whole glycoprotein analysis;
- separation and detection of protein glycoforms;
- analysis of glycopeptides obtained after enzymatic treatment of the glycoprotein;
- analysis of released glycans obtained after chemical or enzymatic treatment of the glycoprotein.

Monosaccharide analysis may complement information obtained by glycan analysis.

Glycosylation can play a predominant role in determining the function, pharmacokinetics, pharmacodynamics, stability, and immunogenicity of biotherapeutics. Glycosylation, unlike transcription, is a non-template-driven enzymatic modification process that results in glycan heterogeneity. The manufacturing procedure also has an influence on glycan heterogeneity. Glycoprotein glycan analysis may therefore be an important test to identify variations in the glycosylation pattern of the glycoprotein and/or monitor the consistency of the glycosylation pattern during production.

Glycan analysis can be a comparative procedure, because the information obtained, compared to a similarly treated reference substance, confirms product consistency.

This chapter provides approaches used for glycoprotein glycan analysis and requirements for the application of methods and validation of methods.

Glycan analysis is not a single general method, but involves the application of specific procedures and the development of specific glycan maps for each unique glycoprotein. Specific procedures are therefore indicated in relevant specific monographs.

1-1. *PROTEIN GLYCOSYLATION*

There are 3 main types of enzymatic glycosylation found in proteins:

- *N*-glycosylation, which involves the addition of oligosaccharides to the nitrogen on the terminal amide group of asparagine;
- *O*-glycosylation, which involves the addition of oligosaccharides to the hydroxyl groups of serine, threonine, and/or hydroxyproline;
- *C*-glycosylation, which involves the addition of an α-mannopyranose to the C2-carbon of the indole ring of tryptophan.

Non-enzymatic additions, also known as glycation, can occur when proteins are incubated with reducing sugars.

This chapter describes analytical methods for the *N*- and *O*-linked glycosylations, which are the most commonly found in glycoprotein medicinal products.

1-2. *HETEROGENEITY OF THE PROTEIN GLYCOSYLATION*

Different levels of glycan heterogeneity can appear during the production of glycoproteins. This heterogeneity may result from variations:

- in the degree of occupancy (full, partial, unoccupied);
- in the type of glycosylation (*N*- or *O*-linked);
- in the oligosaccharide structures (extensions, branching and linkage).

This heterogeneity in glycosylation results in a set of glycoforms for one specific glycoprotein. These variations arise because, unlike transcription and translation, glycosylation is a non-template post-translational modification process. The glycosylation pattern at a given site depends on many factors including the cell-specific and/or growth-dependent availability of glycosyltransferases and exo-glycosidases found in the Golgi apparatus and endoplasmic reticulum. Protein glycosylation is also influenced by the protein structure, the production process, the host-vector expression system and the cell culture conditions.

2. GLYCAN ANALYSIS PROCEDURES

Heterogeneity in glycosylation can be assessed by 4 distinct and complementary approaches:

- analysis of the intact glycoprotein;
- analysis of glycopeptides;
- analysis of released glycans;
- monosaccharide analysis.

The present section provides methods and general requirements used for glycan analysis of glycoproteins containing *N*- and *O*-linked glycans.

Glycan analysis is usually a multistep process. There are numerous methodologies for glycan analysis. This variety is a consequence of the diversity and complexity of glycan structures, of the available technologies and detection systems, and of the wide range of approaches depending on the level of information required.

Figure 2.2.59.-1 provides an overview of glycan analysis analytical procedures that can be employed to apply the chosen approach(es). Many variations of the same techniques and conditions are available depending on the glycan structures and origin.

**Isolation and purification**. Isolation and purification may be necessary for analysis of bulk drug substances or dosage forms containing interfering excipients, and, when required, will be described in the specific monograph.

2-1. *ANALYSIS OF INTACT GLYCOPROTEIN*

Analysis of the intact glycoprotein provides information on the overall pattern of glycosylation of the glycoprotein.

This approach provides limited information when the molecule is large and contains multiple glycosylation sites.

Methods such as capillary electrophoresis (CE) (*2.2.47*) and mass spectrometry (MS) (*2.2.43*) can be used. Size-based techniques, such as size-exclusion chromatography (*2.2.30*) and sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) (*2.2.31*), may provide information on the glycosylation status of a protein. If the degree of sialylation significantly contributes to the biological activity of the glycoprotein, ion-exchange chromatography (*2.2.46*), isoelectric focusing (IEF) (*2.2.54*) or CE (*2.2.47*) may be performed to monitor sialylation. The technique must be chosen according to its suitability to provide a reliable correlation between the degree of sialylation and the bioactivity of the product.

2-2. *ANALYSIS OF GLYCOPEPTIDES*

Analysis of glycopeptides provides information on site-specific glycosylation properties, on the degree of occupancy, and on the oligosaccharide structures. It involves proteolytic digestion of the glycoprotein. Approaches to site-specific cleavage of the protein backbone are given in general chapter *2.2.55. Peptide mapping*.

After proteolysis of the glycoprotein, the following approaches can be chosen.

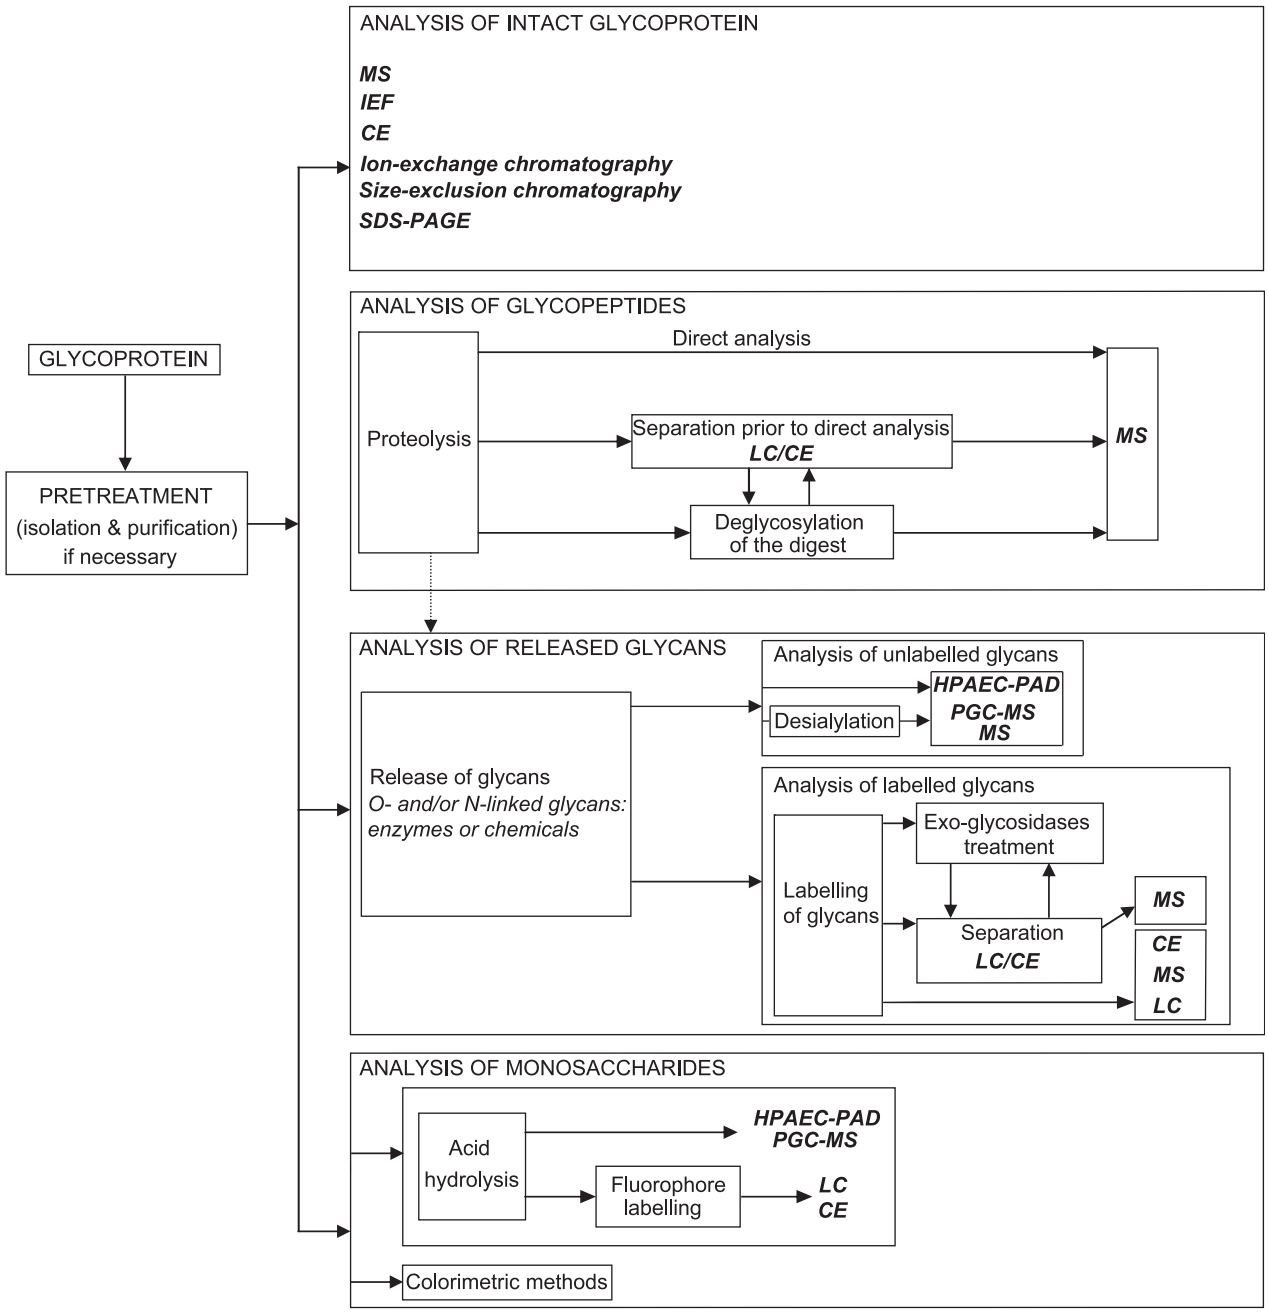
*Direct analysis by MS (2.2.43).* Care should be taken that the glycopeptide signal is not suppressed due to the presence of other peptides, where glycopeptides represent a minor portion of the total peptide mixture and where signal intensities are lower than those of non-glycosylated peptides.

*Separation prior to analysis by MS.* This additional step overcomes the problems raised above. Enrichment or fractionation techniques can be used either in parallel with or sequentially to direct analysis. Separation techniques such as liquid chromatography (LC) (*2.2.29*) and CE (*2.2.47*) are suitable. These techniques may be interfaced with MS to allow online MS measurements.

*Deglycosylation of the glycopeptides.* Identification of the different glycosylation sites of a glycoprotein is made possible by comparing peptide maps obtained by proteolytic digestion of the intact glycoprotein to those obtained when the glycoprotein is deglycosylated previously or following proteolytic digestion. The peptide mass gives information about the glycosylation sites and by calculating the mass difference between the intact glycopeptide and the deglycosylated glycopeptide, it is possible to obtain information about the attached glycans concerning composition and heterogeneity. Approaches to deglycosylation of the protein backbone are given in section 2-3-1. A separation step can be performed after or before deglycosylation.

2-3. *ANALYSIS OF RELEASED GLYCANS*

Analysis of released glycans provides a convenient way to obtain information on the various populations of glycans present on the protein (bi-, tri-, and tetra-antennary profile). The degree of sialylation can also be addressed at this stage. Depending on the chosen method, prior derivatisation/labelling may be needed to allow the detection of the glycans.



CE: Capillary electrophoresis
HPAEC-PAD: High-pH anion-exchange chromatography with pulsed amperometric detection
IEF: Isoelectric focusing
LC: Liquid chromatography
MS: Mass spectrometry
PGC: Porous graphite chromatography
SDS-PAGE: Sodium dodecyl sulfate polyacrylamide gel electrophoresis

Figure 2.2.59.-1. – *Overview of glycan analysis procedures*

Analysis of released glycans generally involves the release and purification of glycans from the reaction mixture, followed by the labelling/derivatisation of the glycans, where needed; the glycans are then profiled (fractionation or separation).

2-3-1. **Release of glycans**

The selection of the approach used for the release of glycans will depend on the glycoprotein under test. The cleavage agent to be employed is chosen according to the type of cleavage needed and level of information required. Enzymatic or chemical cleavage may be used. Table 2.2.59.-1 gives a non-exhaustive list of enzymatic cleavage agents and their specificity.

Digestion efficiency is generally dependent on the accessibility of the glycans on the protein and hence the protein can be denatured to maximise glycosylation site exposure, unless it is desirable to distinguish between surface and buried glycans.

Chemical cleavage agents might also be used, using for example hydrazine or alkaline borohydride for β-elimination.

Table 2.2.59.-1. – *Examples of enzymatic cleavage agents*

| Agents | Specificity |
|---|---|
| ***N*-linked glycans release** | |
| **Peptide-$N^4$-(*N*-acetyl-β-glucosaminyl)asparagine amidase (EC 3.5.1.52)** | **Hydrolysis of an $N^4$-(acetyl-β-D-glucosaminyl)asparagine residue in which the glucosamine residue may be further glycosylated, to yield a (substituted) *N*-acetyl-β-D-glucosaminylamine and a peptide containing an aspartate residue** |
| - Peptide *N*-glycosidase F (PNGase F) | Release of *N*-glycan chain but no release of *N*-glycan chain containing (α1-3)-linked core fucose |
| - Peptide *N*-glycosidase A (PNGase A) | Release of *N*-glycan chain containing (α1-3)-linked core fucose |
| **Mannosyl-glycoprotein endo-β-*N*-acetylglucosaminidase (EC 3.2.1.96)** | **Endohydrolysis of the *N,N′*-diacetylchitobiosyl unit in high-mannose glycopeptides/glycoproteins containing the -[Man(GlcNAc)$_2$]Asn structure** |
| - Endo-β-*N*-acetylglucosaminidase F (endo F) | Release of high-mannose, hybrid and complex oligosaccharides |
| - Endo-β-*N*-acetylglucosaminidase H (endo H) | Release of high-mannose, hybrid oligosaccharides |
| ***O*-linked glycans release** | |
| **Glycopeptide α-*N*-acetylgalactosaminidase (EC 3.2.1.97)*** | **Hydrolysis of terminal D-galactosyl-*N*-acetyl-α-D-galactosaminidic residues** |
| * This enzyme has limited usage because of its high substrate specificity. | |

2-3-2. **Analysis of glycans**

Released glycans can be analysed or profiled by chromatographic, electrophoretic and mass spectrometric techniques, and in general by a combination of these techniques. The choice of the method can be grouped according to the nature of the glycans and level of information required.

Analysis of glycans provides information on the various populations of glycans present on the protein (high-mannose, hybrid, complex). Information on the relative amounts of branched structures might be obtained by analysis of desialylated glycans.

A separation step may be required. It implies the use of LC (*2.2.29*) and CE (*2.2.47*) as intermediate techniques. LC (*2.2.29*) can be used preparatively with individual fractions being collected (usually labelling is required) or can be directly coupled to MS (*2.2.43*).

2-3-2-1. *Analysis of unlabelled glycans*

Native glycans can be analysed by high-pH anion-exchange chromatography with pulsed amperometric detection (HPAEC-PAD), porous graphite chromatography (PGC) and MS (*2.2.43*).

HPAEC-PAD has high sensitivity and can also separate some linkage isomers. Response factors of the different signals are not equal for the different oligosaccharide structures. Absolute quantification of the glycan is not possible unless an oligosaccharide reference library is available. Quantification can be obtained by comparison with a well-characterised reference standard of the substance being tested, or by relating the peak area of each glycan to the total peak area of all glycans in the map.

PGC can also be used to separate native glycans because of its higher selectivity compared to the conventional non-polar columns. A PGC-electrospray-ionisation-MS approach can be applied for direct glycan analysis.

2-3-2-2. *Analysis of labelled glycans*

*Labelling of glycans*

The type of derivatisation carried out will depend on the method used to detect glycans: UV or fluorescent.

Derivatisation with fluorescent labels is the most commonly used technique for labelling glycans at their reducing end by reductive amination. One label can be attached to every single mono- and oligo-saccharide, allowing the determination of molar quantities. Table 2.2.59.-2 gives a non-exhaustive list of commonly used fluorescent labels and suitable analytical techniques.

Table 2.2.59.-2. – *Examples of fluorescent labels and suitable techniques*

| Name | Acronym | Analytical techniques |
|---|---|---|
| 2-Aminobenzoic acid | 2-AA | LC (*2.2.29*), MS (*2.2.43*) |
| 2-Aminobenzamide | 2-AB | LC (*2.2.29*), MS (*2.2.43*) |
| 2-Aminopyridine | 2-AP | LC (*2.2.29*), MS (*2.2.43*) |
| 2-Amino-9(10*H*)-acridinone | AMAC | Gel electrophoresis (*2.2.23*) |
| Trisodium 8-aminopyrene-1,3,6-trisulfonic acid | APTS | CE (*2.2.47*) |

Permethylation of glycans may also be used when MS (*2.2.43*) is used alone for detection. It is based on the methylation of the oligosaccharides.

*Analysis of labelled glycans*

Labelled glycans can be analysed by analytical techniques such as LC (*2.2.29*), CE (*2.2.47*) and MS (*2.2.43*).

According to the separation properties of the glycans, glycans can be profiled and quantified by several LC (*2.2.29*) systems using an appropriate label: reversed-phase (separation by hydrophobicity), normal-phase (separation by size), and anion-exchange (separation by charge) LC.

2-4. *MONOSACCHARIDE ANALYSIS*

Monosaccharide analysis provides information on the monosaccharide composition of a glycoprotein. Analysis of monosaccharides can be performed using either colorimetric or separation methods.

2-4-1. **Colorimetric methods**

The colorimetric methods, which are based on chemical staining, provide information on the quantity of specific classes of sugars such as sialic acids, neutral sugars and hexosamines.

2-4-2. **Separation methods**

The separation methods generate quantitative information on the overall monosaccharide composition. The methods require acid hydrolysis pre-treatment of the oligosaccharide chains of the intact glycoprotein or released glycans, prior to analysis. To release sialic acids, mild acid hydrolysis or enzymatic treatment is employed. The hydrolysis step is a significant source of variability and may require product-specific validation.

Methods for separation and quantification of monosaccharides include:

- the use of HPAEC-PAD and PGC-MS, which allow the determination of molar quantities of native monosaccharides (sialic acids, neutral sugars and alcohol sugars);
- fluorophore labelling of monosaccharides followed by separation methods such as reversed-phase or ion-exchange chromatography, or CE.

3. EVALUATION AND ANALYSIS OF DATA

Data obtained from analytical methods for the analysis of glycans can be analysed and evaluated for 3 different purposes:

- confirmation of identity of individual structures or families of structures;
- confirmation of compliance of the substance being tested with qualitative requirements;
- confirmation of compliance of the substance being tested with quantitative requirements.

Specific considerations with respect to reference standards and method development of each level of analysis are set out in sections 4 and 5 respectively.

3-1. *CONFIRMATION OF IDENTITY OF INDIVIDUAL STRUCTURES OR FAMILIES OF STRUCTURES*

The analytical target for a glycan analysis method may be an individual monosaccharide (e.g. sialic acid, fucose), a defined oligosaccharide structure (e.g. tetra-sialylated, tetra-antennary glycan) or a family of structures sharing a common analytical feature (e.g. tetra-sialylated glycans, tri-antennary glycans, glycoprotein isoforms with the same charge). Confirmation of the identity of the analytical target is an essential step in the analysis and evaluation of data, and can be achieved absolutely, by verification of molecular structure, or comparatively, by comparison with an appropriate reference standard.

3-1-1. **Absolute confirmation of identity**

Absolute confirmation of the identity of glycan structures is typically achieved during product development, and should not necessarily be the target of routine analysis. Identity of the analytical target will be assigned by reference to a known molecular property of the molecule. Such absolute identification of individual structures can require multi-step approaches using enzymatic and chemical reactions, separation techniques and online or offline detection methods, and will most commonly use the charge-to-mass ratio of a molecular ion, determined using a suitable mass spectrometric method as the final basis for structure assignment.

3-1-2. **Comparative confirmation of identity**

During routine application of the analytical method, the identity of the analytical target may be confirmed by comparison with process or system suitability reference standards. These may be generated from known, well-characterised glycoproteins, which may be of the same general class as the product being tested (e.g. fetuin for complex *N*-linked glycoproteins), or may be derived from a well-characterised batch of the product being tested, which has been established as a reference standard. The following considerations apply to comparative assignment of structural identity:

- in the case of a validated high reproducibility of the retention times, the absolute retention times can be used for correct assignment;
- alternatively, a glycan marker can be injected at the beginning and at the end of the testing sequence and checked for any drifts in the retention times; based on these reference chromatograms the glycans of the test samples can be assigned;
- in cases where no standard is available to assign all glycan peaks in the test sample, absolute or normalised retention times can be used to monitor and label unidentified glycan peaks.

3-2. *CONFIRMATION OF COMPLIANCE OF THE SUBSTANCE BEING TESTED WITH QUALITATIVE REQUIREMENTS*

At this level of evaluation, the analytical results obtained with the product being tested are evaluated to demonstrate compliance with specifications. Typically this is achieved by comparison with data obtained in parallel using a reference standard of the substance being tested. In evaluating the data it is necessary:

- to establish that the analytical result obtained using the reference standard is broadly comparable to the expected result, to verify the suitability of the system; for example, in a glycan mapping procedure, this would be achieved by comparison of the map obtained with the reference substance with a provided specimen map obtained during establishment of the reference substance, and by ensuring compliance with all stated system suitability criteria;
- to demonstrate similarity of the maps obtained with the reference substance and the test substance, using any specific compliance criteria given in the specific monograph.

3-3. *CONFIRMATION OF COMPLIANCE OF THE SUBSTANCE BEING TESTED WITH QUANTITATIVE REQUIREMENTS*

3-3-1. **Quantitative measurement of analyte levels and expression of results**

In some cases, e.g. measurement of sialic acid or other monosaccharides, data can be expressed in order to obtain a molar ratio of sialic acid to glycoprotein. Data is calculated by reference to a reference standard for sialic acid and to a validated method of protein determination. Either the internal or external standard method may be used (see general chapter *2.2.46. Chromatographic separation techniques*).

3-3-2. **Quantitative expressions of separation profile**

Profiles or distribution patterns may be expressed numerically in a number of ways, including the normalisation procedure; the percentage content of each analytical target, e.g. glycan entity, is calculated by determining the response of the glycan entity as a percentage of the total response of all the entities, excluding those due to solvents or any added reagents, and those below the disregard limit. In addition, numerical expressions such as the *Z* number, which are method- and product-specific and defined in specific monographs, can be used.

4. REFERENCE STANDARDS

Reference standards for glycan analysis serve 2 functions: the verification of the suitability of the system and the confirmation that the article under test complies with specified requirements.

The reference standards used for system suitability may be:

- a reference substance for the substance being tested;
- glycan moities liberated from a fully characterised reference standard of the substance being tested;
- well-characterised glycan moities liberated from glycoproteins (e.g. fetuin, IgG);
- glycan markers characterised for identity and purity.

The reference standard used for compliance of the glycoprotein under test is a preparation of the substances being tested. It is noted that glycan analysis procedures described in specific monographs prescribe the use of a reference standard for the substance being tested and for which the glycan analysis procedure has been validated.

5. POINTS TO CONSIDER IN METHOD DEVELOPMENT

This section provides means for measuring the overall performance of the method during development. The extent of method development and analytical validation is selected on the basis of their suitability for a specific product. Depending on the chosen approach, several steps are necessary for glycan analysis, for example:

- isolation and purification (or desalting) of the glycoprotein;
- enzymatic (or chemical) treatment of the glycoprotein to selectively release either *N*- or *O*-linked glycans from the protein backbone;
- isolation and purification of the released glycans;
- verification of released sialic acid and monosaccharide residues;
- chromophore labelling of the released glycans;
- separation of the glycans, native or fluorescence labelled;
- glycan identification and quantification (e.g. determination of the *Z* number);

– determination of site occupancy based on relative quantities of glycosylated and non-glycosylated peptides.

**Protein isolation and purification**. Isolation and purification of the glycoprotein from its matrix may be necessary to remove all interfering substances (e.g. excipients, salts) and, when required, will be specified in the specific monograph. This must be performed in a reproducible manner in order to guarantee a quantitative recovery of the protein.

**Release and isolation of oligosaccharides**. The approach chosen for the release of glycans will depend on the protein under test and will be based on the types of glycosylation, i.e. *N*- or *O*-linked glycosylation. Non-compendial approaches available for the release of glycans must be optimised in order to ascertain a quantitative profiling of all glycan entities. Factors that impact cleavage efficiency, such as enzyme-to-protein concentration ratio, temperature, reaction time course, and denaturation of protein prior to digestion, must be optimised.

It is noteworthy that the enzymatic/chemical reaction must not alter the glycan composition, e.g. not destroy sialic acid residues. Where there is more than one glycosylation site, the enzymatic treatment should proportionally release all oligosaccharide moieties attached to the protein, independent of their structure and their individual position in the protein. Reproducible recovery of all glycan entities from the reaction mixture must be confirmed.

**Derivatisation of released glycans**. Derivatisation is usually carried out according to non-compendial protocols. Therefore, the reproducible derivatisation of all glycan entities must be verified. This may be achieved through optimisation of the reaction conditions such as amount of the derivatisation reagent, reaction temperature and time. The derivatisation reaction must not change the glycan composition, e.g. not destroy sialic acid residues.

**Separation, identification and system suitability**. The methods employed for glycan analysis must be capable of detecting and separating different glycan moieties to ascertain a reliable identification and quantification.

The acceptance criteria for system suitability, which also cover glycan cleavage, recovery and analysis, depend on the critical test parameters that affect the outcome of the result.

A comparison between the glycan map of the substance under test and that of a reference substance, being treated in the same conditions, is an indicator to evaluate the performance of the analytical procedure. In order to further confirm the obtained results, the analyses may be repeated with an orthogonal method. The use of a reference standard (e.g. reference substance of the product being examined, system suitability glycan marker) is essential in the establishment of system suitability parameters and validation of the analytical procedure.

Reproducibility of quantitative expression (e.g. *Z* number estimation) of glycan profiles must be verified.

**Determination of site occupancy based on relative quantities of glycosylated and non-glycosylated peptides**. Where site occupancy is estimated by comparison of glycosylated and non-glycosylated peptides from an enzymatically digested glycoprotein, reproducible cleavage of both forms of the peptide must be demonstrated.

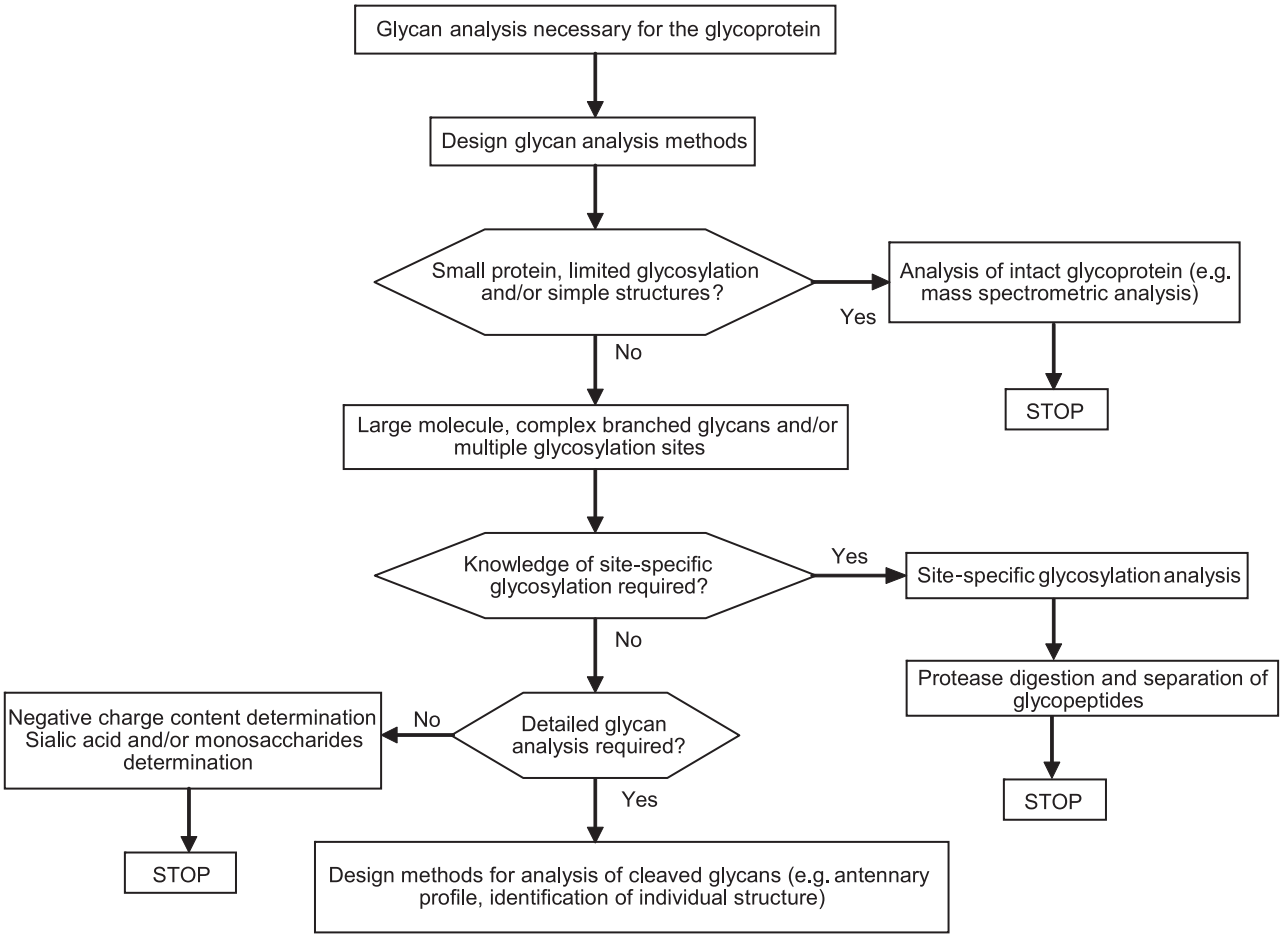


Figure 2.2.59.-2. – *Guidance on methods to be used when glycan analysis is required*

6. GLYCAN ANALYSIS DECISION-MAKING FRAMEWORK

This decision-making framework is given for information and does not constitute a mandatory part of the European Pharmacopoeia.

The choice of procedures used to analyse glycans is established according to the level of information required to ensure the quality of the glycoprotein and is set up during the development phase of the product.

Figure 2.2.59.-2 provides guidance in the choice of methods to be used when glycan analysis is required.

**01/2013:20261**

# 2.2.61. CHARACTERISATION OF CRYSTALLINE SOLIDS BY MICROCALORIMETRY AND SOLUTION CALORIMETRY

*For the purpose of this chapter, crystalline material, partially crystalline material and amorphous material are considered as solids.*

INTRODUCTION - THE CONCEPT OF CRYSTALLINITY

The perfectly ordered crystal lattice with every molecule in its expected lattice position is an ideal that is seldom, if ever, achieved. The other extreme is the amorphous state, in which a solid contains the maximum possible density of imperfections (defects of various dimensionalities), such that all long-range order is lost while only the short-range order, imposed by its nearest neighbours, remains. Real crystals lie somewhere between these 2 extremes. A crystal's position on a scale bounded by these 2 extremes is termed *crystallinity*.

All real crystals, even in the pure state, possess some lattice imperfections or defects, which increase both the energy (enthalpy under conditions of constant atmospheric pressure) and the disorder (expressed as the entropy) of the crystal lattice. A crystal with a relatively low density of imperfections is said to be highly crystalline and to possess a high crystallinity. By contrast, a particle with a relatively high density of imperfections is said to be partially amorphous and to possess a low crystallinity. In ideal terms, a totally amorphous particle corresponds to zero crystallinity. Amorphous particles may contain somewhat ordered domains that can act as nuclei for crystallisation; such so-called amorphous particles are said to possess a low-level but finite crystallinity.

The ability to detect and to quantify the amount of amorphous material within a highly crystalline substance is of great importance during the development and subsequent manufacture of a pharmaceutical preparation.

In reality, a powder probably contains particles with different degrees of crystallinity, just as it may contain particles with varying sizes and shapes. The lower the crystallinity of a solid, the greater its enthalpy and entropy. The increase in enthalpy is never totally compensated for by the increase in entropy; therefore, the Gibbs free energy, which reflects the balance between them, actually increases. Hence, the lower the crystallinity of a material (powder), and consequently the greater its amorphous character, the greater its apparent intrinsic solubility and dissolution rate, but the lower its thermodynamic stability. Because of the great relevance of these properties, crystallinity is also an important property and requires measurement by a suitable method.

In the following chapter, the crystallinity or the content of amorphous parts of a powder are measured by calorimetric methods such as microcalorimetry or solution calorimetry, although other methods could be used (e.g. see general chapter *2.9.33. Characterisation of crystalline and partially crystalline solids by X-ray powder diffraction (XRPD)*).

Many substances are capable of crystallising in more than one type of crystal lattice, which is known as polymorphism. If water or a solvent is incorporated in the crystal lattice the crystals are termed hydrates or solvates. Because of the different crystal packing, and/or molecular conformation and lattice energy, they usually exhibit different physical properties. For simplicity, calorimetry measurements for degree of crystallinity determination discussed here assume only one solid crystalline form present in the material of interest. The theory and experimental technique can be easily expanded to polymorphic systems with proper consideration of the enthalpy differences among the polymorphs.

METHOD 1 - MICROCALORIMETRY (DETERMINATION OF AMORPHOUS CONTENT)

Most chemical, physical and biological processes are associated with the exchange of heat. Microcalorimetry is a highly sensitive technique to monitor and quantify both exothermic (heat producing) and endothermic (heat absorbing) changes associated with those processes. The technique allows the determination of the rate and extent of chemical reactions, changes of phase or changes of structure.

Thermal events producing only a fraction of a microwatt can be observed using microcalorimetry. This means that temperature differences less than $10^{-6}$ K must be detectable. Microcalorimetry typically uses the heat flow (heat leakage) principle, where the heat produced (or absorbed) in a thermally defined vessel flows away (or into) in an effort to re-establish thermal equilibrium with its surroundings. Exceptional thermal stability with its surrounding has to be achieved either by a heat sink or an electronically regulated surrounding.

Heat energy from an active sample in the reaction vessel is channelled typically through Peltier elements; they act as thermoelectric generators using the Seebeck effect. The heat energy is converted into a voltage signal proportional to the heat flow.

Results are typically presented as a measure of the thermal energy produced per unit of time (Watt) as a function of time.

*APPARATUS*

Microcalorimeters are typically designed as twin systems with a measuring vessel and a reference vessel. Vessels are typically made of glass or stainless steel. For certain applications specially designed vessels which allow the addition of a gas, a liquid or a solid material may be used.

*CALIBRATION*

The microcalorimeter is calibrated for heat flow (energy per time unit) using either calibrated external or internal electrical heat sources or a suitable standard reaction.

*SENSITIVITY*

The sensitivity of the microcalorimetric method can be assessed based on an appropriate standard sample analysed according to the corresponding method in conjunction with the determination of the instrument baseline noise.

*PROCEDURE*

Weigh in a suitable vessel an appropriate quantity of the substance to be examined. Close the vessel carefully to avoid any evaporation of solvents and place the vessel in the sample holder. If appropriate, allow the vessel to equilibrate at the temperature of the measurement before placing it in the measuring position.

Begin the analysis and record the heat flow, with the time on the abscissa and the heat flow on the ordinate (specify the direction of exothermic or endothermic heat flow).

*DETECTION AND QUANTIFICATION OF AMORPHOUS CONTENT IN POWDERS*

The amorphous state is metastable with respect to the crystalline state; recrystallisation may therefore occur. The measurement of the heat of recrystallisation enables the amorphous content to be determined by the area of the recrystallisation peak. By relating the output from the microcalorimeter for a sample to that obtained from an amorphous standard, it is possible to quantify the amorphous content of the sample. The range of amorphous content covered by this method depends on the individual substance to be tested; in favourable cases limits of detection below 1 per cent can be reached.

Recrystallisation can be initiated by subjecting the sample to higher relative humidity or an atmosphere containing organic vapour. The sample is typically placed in an ampoule which also contains a small test-tube containing an aqueous saturated salt solution, an organic solvent, or a solvent mixture.

The heat of recrystallisation is typically measured using a fixed sample mass placed in a glass or steel vessel. The test-tube containing a saturated salt solution or an organic solvent is chosen to be large enough to allow a full saturation of the atmosphere above the sample. The mass of the sample and the nature of the vapour atmosphere above the sample are chosen so that recrystallisation occurs in such a way that a distinct peak is observed, clearly separated from initial thermal events caused by introduction of the sample.

The conditions under which the transition of the amorphous phase to a thermodynamically more stable crystalline state occurs will have a significant impact on the time of recrystallisation. In particular, physical mixtures of purely amorphous and crystalline material will behave differently from a partially crystalline material. These effects should be considered when developing a method.

A typical response for the recrystallisation of a mainly amorphous material is shown in Figure 2.2.61.-1. The first part of the curve represents several concurrent processes taking place simultaneously, such as the absorption of water vapour into the amorphous parts of the powder and the generation of water vapour from the test-tube. After this initial response there is a large exothermic response caused by the recrystallisation of the amorphous material. Also included, but not seen, are the expulsion of excess water from the recrystallised parts and its condensation. Thus, the area under this exothermic recrystallisation response is proportional to the heat of recrystallisation.

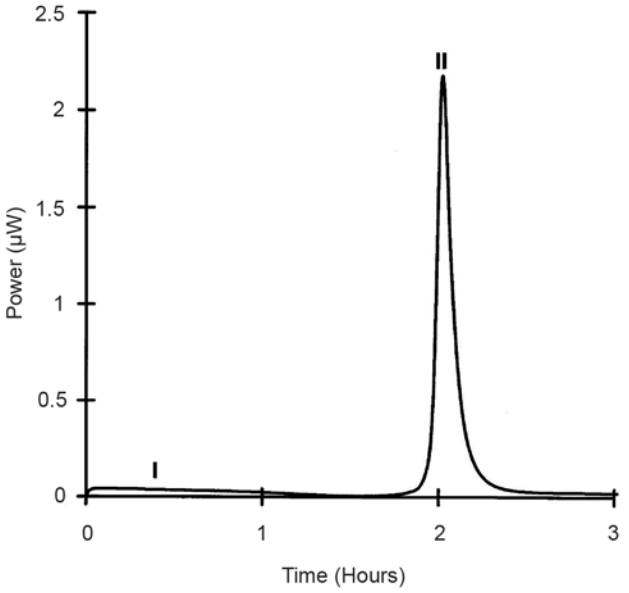

Figure 2.2.61.-1. – *Typical microcalorimetric output of power (in µW) as a function of time (in hours): amorphous collapse peak (I) and crystallisation peak (II) for mainly amorphous lactose at 25 °C and 75 per cent relative humidity*

METHOD 2 - SOLUTION CALORIMETRY (DETERMINATION OF CRYSTALLINITY)

Solution calorimetry provides a means of determining enthalpy of solution (i.e. heat of solution under constant atmospheric pressure) of a substance. Enthalpy of solution is defined as the enthalpy of the substance dissolved in the solution to a defined concentration minus the enthalpy of the original substance. The solvent for the dissolution process must be such that the mass of solid dissolves within a time frame that matches the response time of the calorimeter, as discussed below. The enthalpy of solution is proportional to the amount of solid being dissolved. This amount may be defined as 1 mol for molar enthalpy or as 1 g for specific enthalpy. If the substance possesses adequate purity (as determined by the degree of accuracy required) and if its molecular mass is known, the molar enthalpy is preferred, otherwise the specific enthalpy must be used. The enthalpy of solution is weakly dependent on both the temperature, which is usually 25.0 °C, and the final concentration of the dissolved solute.

It is usually preferred to express the crystallinity, $P_c$, of a substance on a percentage scale. This procedure requires 2 reference standards, namely a highly crystalline sample assuming 100 per cent crystallinity and having a measured enthalpy of solution of $\Delta H_c^s$, and an amorphous sample assuming 0 per cent crystallinity and having a measured enthalpy of solution of $\Delta H_a^s$. From these values and from the measured enthalpy of solution, $\Delta H_s^s$, of the solid under study, the percentage crystallinity of the solid, $P_c$, may be calculated as follows:

$$P_c(\%) = 100(\Delta H_s^s - \Delta H_a^s) / (\Delta H_c^s - \Delta H_a^s)$$

Clearly, crystallinity expressed on a percentage scale depends on 3 measured values and the enthalpies of solution may be replaced by other corresponding physical quantities that depend on crystallinity. The value of the percentage crystallinity of a sample, however, depends not only on the nature and method of preparation of the 2 reference standards, but also on the choice of the physical quantity that is measured.

The enthalpy of solution is measured either by an isoperibol (constant perimeter, i.e. jacket) solution calorimeter or by an isothermal (constant temperature) solution calorimeter. Typically, at least 3 measurements are made with each sample.

The mean of these values is then calculated. The exact requirements will depend upon the equipment capability and degree of accuracy needed.

*ISOPERIBOL SOLUTION CALORIMETRY*

In the isoperibol solution calorimeter, the heat change during the solution process causes a corresponding change in temperature of the solvent-solute system (i.e. solution). This temperature change is measured by a temperature sensor, which is wired to an electrical circuit that records an electrical signal corresponding to the temperature change. Typically, this temperature change in an electronic form is measured at precisely defined time intervals to produce temperature-time data that are collected, analysed by a computer, and then plotted. A blank run without addition of the solid solute to the solvent normally shows no discernible change in the slope of the temperature-time plot.

For isoperibol solution calorimeters, response is fairly rapid, but corrections must be made for any heat losses to or heat gains from the bath. Therefore, isoperibol solution calorimeters are more advantageous than isothermal solution calorimeters when the solution process is relatively fast. For all measurements of enthalpy of solution using isoperibol solution calorimeters, the choice of solvent is critical. The nature and mass of the solvent and the mass of sample allow the total heat change, corresponding to total dissolution of the solid, to proceed to completion within 5 min under vigorous stirring at a constant rotational speed within the range of 400-600 r/min.

The effective heat capacity of the calorimeter cell and its contents is determined for every calorimeter run. This determination is accomplished by electrical heating of the contents of the calorimeter cell. The effective heat capacity is determined according to 1 of 2 protocols: either by making 1 determination after ampoule breakage or by making 1 determination before and a 2nd determination after ampoule breakage and then averaging the 2 results. The accuracy and reliability of the electrical heating are established by the accuracy and reliability of the aforementioned chemical calibrations.

*ISOTHERMAL SOLUTION CALORIMETRY*

In the isothermal (constant temperature) solution calorimeter, the heat change during the solution process is compensated for by an equal but opposite energy change, such that the temperature of the solvent-solute system (i.e. solution) remains essentially constant. This equal but opposite energy change is measured and, when its sign is reversed, provides the enthalpy of solution. For isothermal calorimeters, response is relatively slow, but the compensation process eliminates the effects of heat losses to or heat gains from the bath. Therefore, isothermal solution calorimeters are more advantageous than isoperibol solution calorimeters when the solution process is relatively slow.

*SOLUTION CALORIMETER CALIBRATION*

To ensure the accuracy of the calorimeter, chemical calibrations must be performed on a regular basis. For an endothermic solution process, the calibration of the calorimeter is checked by measuring the heat absorbed during the dissolution of potassium chloride in distilled water at 298.15 K (25.0 °C). The established enthalpy change in this endothermic process is 235.5 J/g (17.56 kJ/mol). For an exothermic solution process, the calorimeter is checked by measuring the heat evolved during the dissolution of 5 g per litre of tromethamine [tris(hydroxymethyl)aminomethane, THAM] in a 0.1 mol/L aqueous hydrochloric acid solution at 298.15 K (25.0 °C). The established heat for the aforementioned process is – 246.0 J/g (– 29.80 kJ/mol).

*SAMPLE HANDLING*

The chemical and physical stability of solids may decrease with decreasing crystallinity. In particular, solids of low crystallinity, especially amorphous solids, tend to sorb water vapour from the atmosphere, leading to crystallisation and a corresponding gain in crystallinity. For these reasons, anhydrous samples whose crystallinity is to be determined must be stored at zero humidity or below critical humidity levels in sealed chambers containing a desiccant, preferably containing an indicator of effectiveness. If crystallinity-humidity studies are to be carried out, the sample is stored in a sealed chamber containing a saturated salt solution to provide a defined relative humidity.

# 2.2.63. DIRECT AMPEROMETRIC AND PULSED ELECTROCHEMICAL DETECTION

Direct amperometric detection and pulsed electrochemical detection (PED) are used to detect electroactive compounds by oxidation (or reduction) when coupled to a separation technique such as liquid chromatography (*2.2.29*). Electrochemical detection uses the redox potential of analytes and is therefore only valid for electroactive substances.

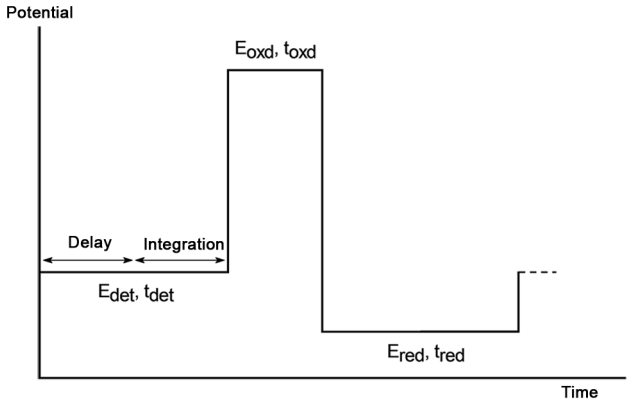
PRINCIPLE

When a constant potential is applied between 2 electrodes, the oxidation (or reduction) of an electroactive substance generates a current proportional to the amount of analyte passing the electrode surface. This analytical technique requires a supporting electrolyte, which can be added post-column if not already present in the mobile phase. Detection usually involves oxidation of the compounds of interest. The potential applied to the measuring electrode can serve as a selectivity parameter for the compounds of interest. The upper limit of the electroactivity range is defined by the oxidation curve of the mobile phase, the supporting electrolyte or the measuring electrode.

With direct amperometric detection, only a constant potential is applied. However, this method may result in the surface of the measuring electrode becoming fouled with adsorbed carbon compounds, resulting in signal variability and a decreased response. This passivation phenomenon is particularly common with sugars, thiols and phenols. The problem of electrode fouling can be resolved by the application of a series of pulses, a process known by the generic term of pulsed electrochemical detection (PED).

The most widely used PED mode is pulsed amperometric detection (PAD), which involves a 3-step series of pulses or waveform (Figure 2.2.63.-1). After applying the detection potential ($E_{det}$), a high positive potential ($E_{oxd}$) (anodic polarisation) is applied to clean the surface of the measuring electrode, followed by a negative potential ($E_{red}$) (cathodic polarisation) to restore the surface of the measuring electrode. A new cycle of the waveform can then start. Following the potential step from $E_{red}$ to $E_{det}$, background signals will originate. Although these decay quickly, a brief delay must be introduced before the analyte signal can be properly measured.

Other waveforms comprising more than 3 voltage steps have been developed.



$E_{det}$: detection potential applied during a period $t_{det}$

$E_{oxd}$: oxidation potential applied during a period $t_{oxd}$

$E_{red}$: reduction potential applied during a period $t_{red}$

Figure 2.2.63.-1. – *3-Step potential-time waveform (pulse sequence)*

EQUIPMENT

An electrochemical detection system comprises 3 electrodes: a measuring electrode (gold, platinum or glassy carbon); a reference electrode (usually silver-silver chloride); and an auxiliary electrode (e.g. titanium cell body) (Figure 2.2.63.-2).

The choice of measuring electrode depends on the substance to be examined. The electrodes are coupled to a potentiostat, which controls the potentials applied to the measuring electrode without subjecting the reference electrode to a current, the auxiliary electrode functioning as a cathode whenever the measuring electrode is operating as an anode and vice versa.

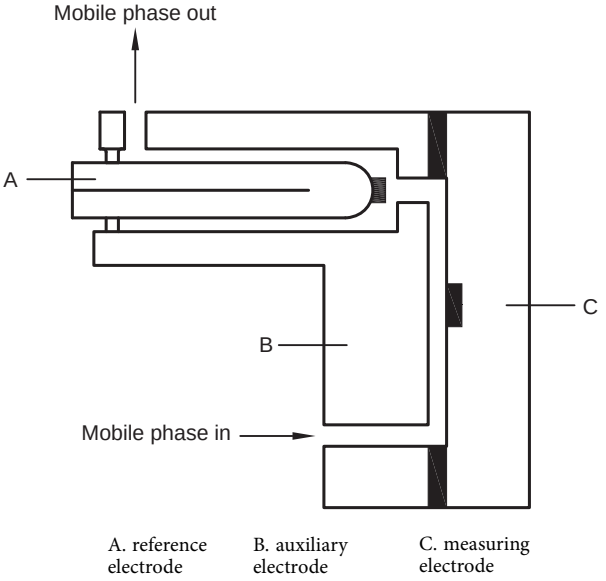


Figure 2.2.63.-2. – *Electrochemical detection system*

*EQUIPMENT PERFORMANCE*

The potentials to be applied depend on the analyte and the type of electrodes used, and the settings must therefore be adapted accordingly.

All electrodes should be in good condition and periodic replacement is recommended. When the detector is used for quantitative analysis, it is advisable to check the linear range, sensitivity and repeatability of the detector.

The quality of the reagents used is of utmost importance. It is advisable to employ reagents of the highest purity.

*ADDITIONAL INFORMATION*

*Maintenance of the electrochemical cell*

Although the application of an increased potential in PED cleans the surface of the measuring electrode effectively, it can be necessary to polish the measuring electrode mechanically from time to time when the background current increases and the sensitivity decreases. The cleaning of the measuring electrode must be carried out very carefully to avoid creating pits or scratches. It is also advisable to wipe the auxiliary electrode at the same time to remove deposited substances. The cell requires some time to stabilise after polishing.

*Sodium hydroxide solution*

Detection can be enhanced in alkaline media (at least pH 12), as is the case with aminoglycoside antibiotics. When the mobile phase is not sufficiently alkaline, this can be achieved by post-column addition of a sodium hydroxide solution to increase the pH of the column effluent. The solutions are mixed in a coil that is linked to the electrochemical cell. It is essential that the length of the mixing coil is such as to produce a homogeneous solution but with minimal peak broadening. It is important to avoid carbonates in the sodium hydroxide solution. To avoid baseline disturbances, the sodium hydroxide solution should be degassed before use, it must be added pulse-free and its flow should be constant between runs. The parts of the chromatographic system coming into contact with the sodium hydroxide-containing solutions must be alkaline resistant.

# 2.2.64. PEPTIDE IDENTIFICATION BY NUCLEAR MAGNETIC RESONANCE SPECTROMETRY

This general chapter is to be used in conjunction with general chapter *2.2.33. Nuclear magnetic resonance spectrometry* in the context of peptide identification. The approach to be followed is qualitative and consists of comparing the nuclear magnetic resonance (NMR) spectrum of a test sample with that of a reference sample acquired under identical conditions.

This general chapter mainly applies to the use of proton NMR ($^1$H NMR) spectrometry, to confirm the identity of small peptide products (up to approximately 15 amino acids). It is also applicable when using $^{13}$C NMR spectrometry with some modifications. The scope is restricted to the use of one-dimensional NMR spectrometry.

GENERAL PRINCIPLES

**Equipment**. Unless otherwise specified, an apparatus with a field strength giving an operating frequency for proton NMR of at least 300 MHz.

**Spectral acquisition conditions and their optimisation**. After introduction into the magnet, the sample is allowed to come to thermal equilibrium, especially if analysis is carried out at a temperature significantly different from room temperature: monitoring the lock signal is often a valuable visual guide to the progress of this process.

The spectral width must encompass the complete spectrum of the peptide, with an empty spectral region at each side. Typically, a spectral width of 12 ppm or 16 ppm is appropriate.

The following parameters may be optimised to improve resolution of characteristic peaks: temperature and/or pH primarily, buffer and peptide concentrations. Control of sample temperature is recommended but is not mandatory; if not used, the effect of small temperature changes on the appearance of the spectrum is validated.

The number of data points collected is such as to define peaks adequately.

Solvent suppression is not recommended but, if used, the intensities of peaks close to the solvent resonance may be affected and this has to be validated when comparing spectra.

**Chemical shift referencing**. For samples in aqueous solution, sodium 2,2-dimethyl-2-silapentane-5-sulfonate (DSS), sodium 3-(trimethylsilyl)propionate (TSP) or a deuterated analogue (TSP-$d_4$) are appropriate, and the chemical shift of the methyl signals is often set to 0 ppm. Either the reference material is added at low amounts (10-100 ppm has been found to be appropriate) to the deuterated water used to dissolve the final sample, or an easily recognised internal resonance that is consistently present (such as acetate anion) can be used as a secondary reference. In this case, a validation spectrum obtained under the same spectral conditions is used to define the chemical shift of the secondary standard.

**Sample size**. Usually a few milligrams are used. If sample sizes are variable, the effects of this variation on the appearance of the spectrum are validated.

**Sample preparation**. The test and reference samples must be comparable in terms of concentration, pH and buffer composition. Typically, samples in solution are lyophilised, and the dried samples dissolved in deuterated water or a buffer in deuterated water. It may be worthwhile to lyophilise a solution in deuterated water one or more times ('deuterium exchange') as this reduces the intensity of strong solvent signals; volatile process impurities such as ethanol will also be lost. Use of buffer for the final sample preparation can reduce aggregation and improve spectral reproducibility by reducing batch-to-batch pH variation. Some probes are intolerant to high salt concentrations, but ionic strengths up to 200 mM sodium chloride are normally tolerated. High salt concentrations tend to increase 90° pulse length.

VERIFICATION OF IDENTITY

**Determination of key spectral factors**. Use of a qualitative approach does not entail stringent requirements on spectral parameters (for example, fast pulse repetition rates can be used, as full relaxation is not required). The use of short pulse widths (for example, a 30° pulse) and fast repetition rates will have no significantly deleterious effect on spectra, and will allow faster acquisition of acceptable signal-to-noise ratios. Variation in the pulse width and acquisition time within wide limits will not affect the ability to compare spectra. The number of scans collected must give appropriate signal-to-noise ratios for low intensity resonances and therefore a minimum signal-to-noise ratio of 50:1 is recommended.

**Identification of characteristic resonances**. It is possible to compare either the complete spectrum or a portion of it. Comparison of spectra of relevant samples will highlight regions of the spectrum that are distinctive, and comparison can be constrained to these regions. It is important to define resonances from impurities, such as residual solvents, which may be essentially irrelevant to product quality and which may vary in intensity between batches.

**Spectral comparison**. See the provisions of general chapter *2.2.33*.

**01/2013:20265**

## 2.2.65. VOLTAMETRIC TITRATION

In voltametric titration the end-point of the titration is determined by following the variation of the voltage measured between 2 electrodes (either 1 indicator electrode and 1 reference electrode or 2 indicator electrodes) immersed in the solution to be examined and maintained at a constant current as a function of the quantity of titrant added.

*Apparatus*. The apparatus comprises an adjustable current source and a voltmeter; the detection system generally consists of an indicator electrode (for example, a platinum electrode, a rotating-disc electrode or a carbon electrode) and a 2nd electrode (for example, a platinum electrode, a rotating-disc electrode or a carbon electrode).

*Method*. Set the current to the indicator electrode as prescribed in the monograph and plot a graph of the initial voltage and the values obtained during the titration as functions of the quantity of titrant added. Add the titrant in not fewer than 3 successive quantities equal to a total of about 80 per cent of the theoretical volume corresponding to the presumed equivalence point. The 3 values must fall on a straight line. Continue adding the titrant beyond the presumed equivalence point in not fewer than 3 successive quantities. The values obtained must fall on another straight line. The point of intersection of the 2 lines represents the end-point of the titration.

Using titration systems for voltametric titration with 2 indicator electrodes, the whole titration curve is recorded and used to determine the end-point.

**01/2014:20266**

## 2.2.66. DETECTION AND MEASUREMENT OF RADIOACTIVITY

INTRODUCTION

Within the context of the European Pharmacopoeia, the term 'radioactivity' is used both to describe the phenomenon of radioactive decay and to express the physical quantity of this phenomenon. In the monographs on radiopharmaceutical preparations, the detection and measurement of radioactivity are performed for different purposes: verification of the characters, identification, determination of radionuclidic and radiochemical purity, as well as determination of the radioactivity in a substance (assay).

Under these assumptions, the measurement can be qualitative, quantitative or both, depending whether it is directed to the identification of the radionuclide or the determination of its activity (rate of decay) or both of them.

Radioactive sources can produce various types of emissions, such as alpha particles, electrons, positrons, gamma- and X-rays, according to the radionuclidic composition.

Each radionuclide yields characteristic emissions, with specific energies and relative intensities. Such radiations can be detected as a result of their ionising properties in an ionisation chamber but without further characterisation; when they are detected and analysed using a spectrometer, an energy spectrum is obtained. A detailed spectrum analysis is typically used to identify radionuclides present in a sample. Spectrometry can also be used for quantitative determination of the radioactivity in sources made of a single radionuclide or radionuclide mixtures or of the individual radionuclides present.

A measurement of radioactivity is generally performed by counting the number of detected decay events (emissions). Therefore, the geometry of the sample during the measurement of radioactivity and the acquisition time strongly influence the result. In general, the measurement geometry must correspond to a calibrated geometry and the acquisition time must be long enough to reach sufficient counting statistics.

A measurement of radioactivity can be done in a stand-alone mode (e.g. using an ionisation chamber or a spectrometer) or in combination with a separation technique (e.g. radiochromatography) to account for relative contributions from different radioactive chemical species that may be present in a mixture.

## MEASUREMENT OF RADIOACTIVITY

A direct determination of the radioactivity of a given sample, in becquerel (Bq), may be carried out if the decay scheme of the radionuclide is known, but in practice many corrections are required to obtain accurate results. For this reason, it is possible to carry out the measurement with the aid of a primary standard source or by using measuring instruments such as an ionisation chamber or a spectrometer calibrated using suitable standards for the particular radionuclides.

A spectrometer is used when measuring the radioactivity of radionuclides in a mixture, each radionuclide being identified by its emissions and their characteristic energies.

All measurements of radioactivity must be corrected for dead-time losses and by subtracting the background signal due to radiation in the environment and to spurious signals generated in the equipment itself.

The radioactivity of a preparation is stated at a given date. If the half-life of the radionuclide is less than 70 days, the time is also indicated. This statement of the radioactive content must be made with reference to a specified time zone. The radioactivity at other times may be calculated from the exponential decay equation or from tables.

In general, a correct measurement of radioactivity requires that consideration is given to some or all of the following:

**Dead-time losses**. Due to the finite resolving time (dead time) of the detector and its associated electronic equipment, it may be necessary to correct for losses by coincidence. The resolving time of a counter is the minimum time interval required by the counter to resolve 2 single pulses. Incident radiation events at shorter intervals may not be detected or may be detected as a single event with the summed energy. These losses are sometimes referred to as 'dead-time losses'. For a counting system with a fixed dead time $\tau$ following each count, the true count rate, per second, is calculated using the following expression:

$$\frac{N_1}{1 - N_1\tau}$$

$N_1$ = the observed count rate, per second;

$\tau$ = the dead time, in seconds.

With some equipment this correction is made automatically. Corrections for losses by coincidence must be made before the correction for background radiation.

**Correction for decay during measurement**. If the time period of an individual measurement, $t_m$, is not negligibly short compared with the half-life of the radionuclide, $T_{1/2}$, the decay during this measurement time must be taken into account. For example, there is a 5 per cent cumulative loss of counts due to decay during a counting period that is 15 per cent of the half-life of the radionuclide.

After having corrected the instrument reading (count rate, ionisation current, etc.) for background signals and, if necessary, for losses due to electronic effects, the instrument reading corrected to the beginning of the individual measurement is calculated using the following expression:

$$\frac{R(\lambda t_m)}{1 - (e^{-\lambda t_m})}$$

$R$ = instrument reading before decay correction, but already corrected for background signal, etc.;

$\lambda$ = radionuclide decay constant ($\ln 2/T_{½}$);

$e$ = base of natural logarithm;

$t_m$ = measurement duration.

**Statistics of radioactivity measurement**. The results of determinations of radioactivity show variations that derive mainly from the random nature of nuclear transformations. Counting for any finite time can yield only an estimate of the true rate of nuclear transformations. A sufficient number of counts must be registered in order to compensate for variations in the number of transformations per time. In the case of measurement of radioactivity, the standard deviation of the recorded counts is the square root of the counts, so at least 10 000 counts are necessary to obtain a relative standard deviation of not more than 1 per cent.

**Linearity**. The linearity of an instrument is the range of radioactivity for a particular radionuclide over which its efficiency remains constant.

The linear range of a radioactivity measurement assembly can be determined by repeatedly counting a radioactive sample in a fixed geometry as it decays from an activity level that is above the linear range. After correction for the background signal, the natural logarithm of the count rate data is plotted against the elapsed time after the first measurement (Figure 2.2.66.-1).

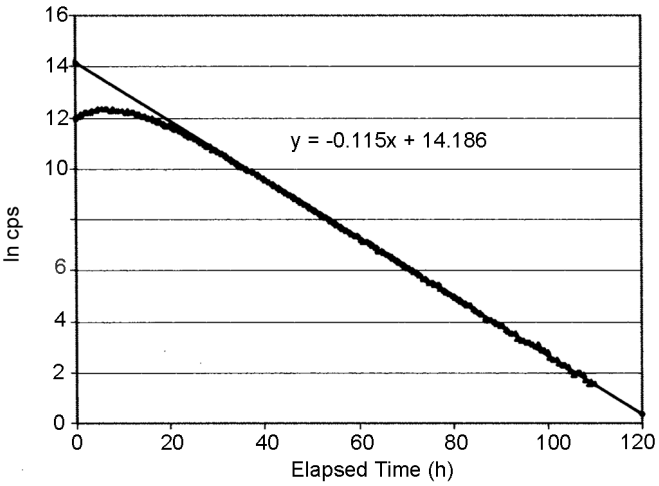

Figure 2.2.66.-1. – *Plot showing the measured and extrapolated count rate (natural logarithm of counts per second (cps)) from a technetium-99m source as a function of time, starting with a level of radioactivity above the linear range of the measuring equipment*

Linear regression analysis of the central, linear portion of the data set yields a slope which is the decay constant $\lambda$, which has a characteristic value for each radionuclide:

$$\ln \text{cps} = -\lambda t + c$$

$c$ represents the natural logarithm of the count rate at $t = 0$ of a perfectly linear instrument.

The resulting regression equation is used to calculate the theoretical count rate at each time that the actual data were recorded. Where the deviation of the measured count rate from the theoretical count rate is unacceptably high, the linear range of the measuring equipment has been exceeded.

Alternatively, a series of dilutions can be made of a radioactive solution of known radioactivity concentration. Equal volumes of each of the dilutions are then counted using standardised geometry and counter settings. The ratio of the count rate for each sample (after correction for background signals and decay) to the calculated radioactivity of the respective

sample in Bq is the counting efficiency. The range over which this ratio is constant is the useable range of the measuring equipment for the radionuclide concerned.

The limit of detection and the limit of quantification for equipment and procedures used for radioactivity measurement must be established before their routine use.

**Limit of detection**. The limit of detection (LOD) of an individual procedure is the lowest amount of radioactivity in a sample that can be detected but not necessarily quantified as an exact value. In practical terms this requires an estimate of the background signal and its standard deviation. The LOD is usually considered to be 3 times the standard deviation of the background signal.

**Limit of quantification**. The limit of quantification (LOQ) of an individual procedure is the lowest amount of radioactivity in a sample that can be quantitatively determined with suitable precision and accuracy. The LOQ is used particularly for the determination of impurities and/or degradation products. In practical terms the LOQ is usually considered to be 10 times the standard deviation of the background signal.

*MEASUREMENT OF RADIOACTIVITY USING IONISATION CHAMBERS*

**Apparatus**. Ionisation chambers (including dose calibrators) are the most common equipment for the measurement of radioactivity in the practice of radiopharmacy. It generally can measure activities from a few tens of kBq to hundreds of GBq. It usually comprises a sealed well-type ionisation chamber and built-in electronics to convert the detector signal to a measure of radioactivity.

The chamber is filled with a gas across which an electrical field is applied. When the gas is ionised by the radiation emitted by the source, the resulting ionisation current is measured and related to the radioactivity present in the ionisation chamber. The ionisation current is influenced by the applied voltage, the energy and the intensity of the radiation and the nature and pressure of the gas. The instrument settings (calibration factor) may be adjusted to keep a direct relationship between the ionisation produced by the radiation of a specific radionuclide and the radioactivity value obtained for each measurement geometry.

As an ionisation chamber measures only the current resulting from the overall ionisation produced within the chamber, it cannot discriminate between the emissions of different radionuclides.

For an accurate measurement of the radioactivity of a specific radionuclide, the measurement must be corrected for the contributions to the ionisation current caused by radionuclidic impurities present in the preparation.

The activity levels to be measured are limited by saturation considerations, the range of the amplifier and the design of the chamber itself. The linearity range of the ionisation chamber is established as described above under Linearity.

The ionisation chamber must be shielded to minimise background signals to an acceptable level.

**Method**. The sample is positioned inside the well of the ionisation chamber at a given position, using a holder. After putting the sample in the ionisation chamber, the activity reading is made once the response is stable. Measuring the sample under exactly the same geometrical conditions as the calibration source will yield the most accurate results. If necessary, dilute the preparation to be measured to the same volume as that of the calibration source.

*Calibration*. The ionisation chamber is calibrated taking into account the shape, dimensions, material of the container, volume and composition of the solution, the position within the chamber and the radionuclide being measured. Limits for uncertainty in calibration can be found in national and international regulations.

Calibrate the ionisation chamber at least once a year, by using sources of radionuclides traceable to national or international standards in the appropriate containers (vial, syringe) with regard to geometry. Establish and implement subsidiary correction factors to take account of the differing configurations of the radionuclides to be measured. Perform a linearity check of the instrument's response over the complete range of energies and activities for which the equipment is used.

For each setting and before each use (minimum once on each day of use) perform a constancy check of the ionisation chamber using standard sources of radionuclides with long half-lives to verify its calibrated state. A check with a reference source, such as caesium-137, must be performed on each day of use to verify that the ionisation chamber is still in its calibrated state.

*MEASUREMENT OF RADIOACTIVITY USING SOLID-STATE DETECTORS*

Solid-state detectors include scintillating plastic fluors and crystals, and semiconductors. Further to their application in spectrometry (see section Spectrometry), solid-state detectors can be used for the measurement of radioactivity. In particular, due to their high sensitivity, plastic and crystal scintillation detectors are used in counting low levels of radioactivity. Dead-time losses must be carefully considered with these types of detectors. Semiconductor detectors are used when a higher energy discrimination is required, for example in mixtures of radionuclides or when there are potential radionuclidic impurities with emissions of similar energy.

**Apparatus**. The equipment consists of a shielded detector comprising a plastic or crystal scintillator coupled to a photomultiplier, or a semiconductor, which are connected to an amplifier and counting electronics. The system may have an adjustable energy window, used for selecting a counting region of the radionuclide energy spectrum that may be adjusted by the operator.

Instruments have different properties of energy resolution and detection efficiency depending on the type of detector and its volume and geometry. Lower efficiency requires a longer counting time.

Samples to be measured may be placed in front of the detector or into the well of a well-type detector. Measuring chambers may be enclosed in the detector shielding and single samples may be introduced using lids or other positioning systems to ensure correct measurement geometry.

A scintillation detector can be used for dynamic radioactivity measurement when, for example, the eluate of a liquid chromatograph is directed over or through a detector, see section on Detection and measurement of radioactivity in combination with a separation technique.

**Method**. Ensure that the sample radioactivity gives a counting rate in the linearity range of the equipment. The measurement is started after any shielding is in place or the well cover is replaced and the counting time is selected to reach sufficient counts for a statistically significant value.

*Calibration*. The detector has to be calibrated by measuring its efficiency using a source of the radionuclide in question traceable to national or international standards. Calibration in terms of efficiency uses sources such as caesium-137, cobalt-60, barium-133 and others covering the desired energy range.

*MEASUREMENT OF RADIOACTIVITY USING LIQUID SCINTILLATION DETECTORS*

Liquid scintillation counting is commonly used for beta-particle emitting samples, but is also used for alpha-particle emitting samples. For the principles of the detection of radioactivity using liquid scintillation detectors see under Beta-particle spectrometry below.

*Calibration*. In order to take into account the loss of counting efficiency due to quenching, the liquid scintillation counter may make use of an external source, typically barium-133 or europium-152, which is brought close to the sample vial to release Compton electrons. The shape of the resulting spectrum is analysed automatically to compute a quench-indicating parameter. This parameter can then be related to the counting efficiency measuring sources of known activity at a determined level of quenching agent. The obtained quench curve allows the determination of the activity of an unknown sample knowing the count rate and the value of the quenching parameter.

*DETERMINATION OF HALF-LIFE*

The half-life is a characteristic of the radionuclide that may be used for its identification. The half-life is calculated by measuring the variation of radioactivity of a sample to be tested as a function of time. Perform the measurements in the linearity range of a calibrated instrument.

**Apparatus**. Half-life can be measured by using any type of quantitative radioactivity detector provided it is used within a linearity range throughout the range of activities that are present during the measurement and the geometry is not changed during the measurement.

For preparations containing a radionuclide with a short half-life and when stated in a monograph, determination of the approximate half-life contributes to the identification.

**Method**.

*Half-life*. The preparation to be examined is used as such or diluted or dried in a capsule after appropriate dilution. The radioactive sample is prepared in a manner that will avoid loss of material during handling. If it is a liquid (solution), it is contained in a closed flask or a sealed tube. If it is a residue from drying in a capsule, it is protected by a cover consisting of a sheet of adhesive cellulose acetate or of some other material.

The radioactivity of the sample must be high enough to allow measurements over a period corresponding to 3 estimated half-lives but must be, for each measurement, within the linearity range of the equipment. Correction for dead-time losses is applied if necessary.

The same source is measured in the same geometrical conditions and at intervals usually corresponding to at least half of the estimated half-life. Each value is tabulated against the time interval from the initial measurement. To avoid influence of decay during measurement, the counting time is the same for all measurements.

A graph can be drawn with time as the abscissa and the logarithm of the relative instrument reading (e.g. count rate) as the ordinate. The half-life is calculated from the slope of the best linear fit of the measured values against the time corresponding to each measurement.

*Approximate half-life*. For this purpose, not fewer than 3 measurements are made over a period of not less than 1/4 of the estimated half-life.

The sample to be examined and the instrument to be used comply with the indications given above. The data are processed in the same way as above.

SPECTROMETRY

Radionuclides can be identified by their emission spectrum. Each type of emission (i.e. alpha particles, beta particles and electrons, gamma- and X-rays) requires specific equipment to acquire an emission spectrum. Spectrometers must be calibrated in order to work properly and the following sections describe the different equipment and detail the general procedures for a reliable measurement.

*GAMMA-RAY SPECTROMETRY*

**General principles**. In gamma-ray spectrometry using a scintillation detector, absorption of gamma- and X-rays results in production of light, which is converted into an electrical pulse by a photomultiplier. In gamma-ray spectrometry using a semiconductor detector, absorption of gamma- and X-rays results in the immediate production of an electrical pulse.

In both cases the pulse amplitude is proportional to the energy of the absorbed radiation. The most common detectors for gamma- and X-ray spectrometry are thallium-activated sodium iodide (NaI(Tl)) scintillation counters and high-purity germanium (HPGe) semiconductor detectors.

A gamma-ray spectrum can be produced by collecting and analysing a sufficient number of pulses.

**Apparatus**. A gamma-ray spectrometer usually comprises a shielded measuring chamber where the sample is positioned, a detector, an electronic chain and a multichannel analyser.

The shielding of the chamber must be able to reduce the background signal to a level that allows the registration of a correct gamma-ray spectrum.

The measurement chamber has a movable cover or a drawer to allow the positioning of the sample. A sample holder may be present to ensure reproducible geometry between measurements.

The duration of measurement is related to the radioactivity of the target radionuclide and a long period of acquisition may be required to achieve the necessary counting statistics. Dead-time losses must be carefully considered with this type of detector.

The sensitivity of a NaI(Tl) detector is higher than that of a germanium detector of the same size. In general, peaks in an energy spectrum are identified with an uncertainty depending upon the full width of the peak at its half-maximum height (FWHM). The energy resolution of a solid-state scintillation detector is much poorer than that of a semiconductor detector and hence peaks obtained with a semiconductor detector are much narrower than those obtained with a scintillation detector. Figure 2.2.66.-2 shows a comparison of the spectra obtained from the same source with the 2 types of detector.

The different performances of NaI(Tl) and HPGe detectors may limit their use in some spectrometric analyses.

For the identification of the radionuclide(s) in a preparation and determination of radionuclidic purity, a risk assessment on the process of radionuclide production must assess the potential presence of other radionuclides with photon energies in the same range (± 10 per cent) as that of the radionuclide(s) present in the radiopharmaceutical.

In case radionuclidic impurities can be present that emit gamma- or X-rays with an energy in the same range as that of the photons emitted by the radionuclide in the preparation, a measured peak energy within a maximum interval of ± 2 keV or ± 2 per cent (whichever is the larger) with respect to the nominal peak energy (see *5.7. Table of physical characteristics of radionuclides)* is sufficient for peak identification.

In the case where such impurities are not expected to be present, a maximum interval of ± 10 keV or ± 6 per cent (whichever is the larger) with respect to the nominal peak energy is acceptable for peak identification.

**Method**. Ensure that the counting rate of the sample falls within the linearity range of the equipment. For liquid samples this may be achieved by appropriate dilution; for solid samples, by increasing the source-to-detector distance or by using an attenuating material. Introduce the preparation to be examined in a container into the instrument chamber and record the spectrum after closing the shielding.

Ensure that the container used for quantitative measurements is of the same shape, dimensions, volume and material as that of the calibration standard.

Ensure that the composition of the solution and the position of the container in the measuring chamber is the same for the container for the quantitative measurement as for the calibration standard.

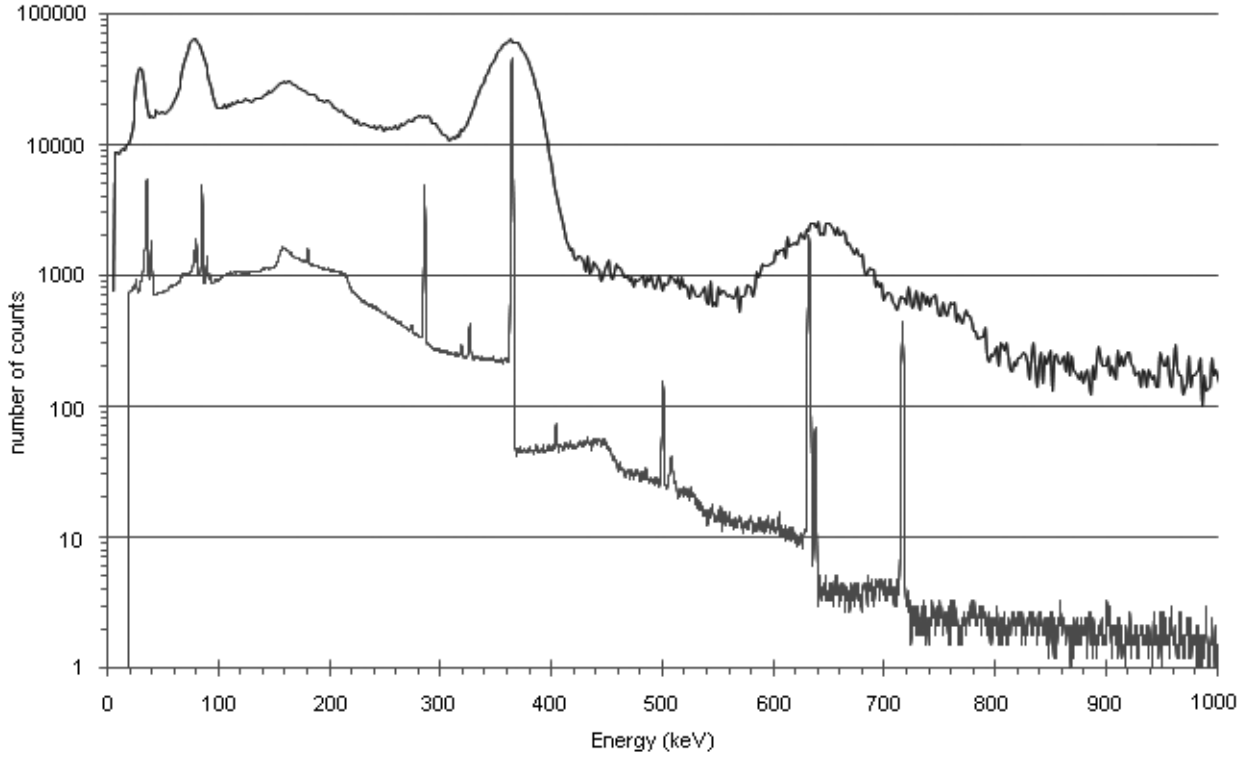

Figure 2.2.66.-2. – *Comparative pulse-height spectra recorded using a thallium-activated sodium iodide scintillator (upper curve) and a high-purity germanium semiconductor detector (lower curve). The source was gamma- and X-ray radiation from the decay of iodine-131.*

*Radionuclide identification.* Calibrate the spectrometer in relation to energy. Determination of the correspondence of the energy of the peaks detected from the sample to the energies prescribed by a monograph is a valid identification test.

*Radionuclidic purity.* Calibrate the spectrometer in relation to efficiency and energy. Determine the LOQ and resolution of the equipment and ensure that they are in line with the limits of the radionuclides to be determined. Record the spectrum of the preparation.

Identify the radionuclides present in the preparation to be examined and determine their radioactivity with the aid of chapter *5.7. Table of physical characteristics of radionuclides*. Because the level of radionuclidic impurities, expressed as a percentage of the total radioactivity, may increase or decrease with time, the measured activity of each impurity must be recalculated to the activity during the period of validity of the preparation. The activities of all radionuclidic impurities need to be summed (taking into account the limit of quantification) and related to the total radioactivity of the preparation.

The sample is placed close to the detector or within a well-type detector. All the events within a pre-set energy range are collected and displayed on a ratemeter as counts per second or accumulated over a pre-set period of time. If there is sufficient difference in photon energies emitted by the radionuclide(s), a sodium iodide detector can be suitable, given its high sensitivity. However, if there is a need to discriminate emissions of similar energy, a HPGe detector or another semiconductor detector is needed.

*Calibration.* Calibration in relation to energy is done by using the peaks of known sources traceable to national or international standards, such as cobalt-57, caesium-137, cobalt-60 and others covering the desired energy range. A calibration in relation to efficiency can be simultaneously obtained, so that not only the energy spectrum but also the activity of the sample and the radionuclide impurities can be further determined. The calibration of efficiency can be performed with a traceable radionuclide source with energy peaks covering the desired range or with the aid of a mixed, traceable radionuclide standard with gamma-ray energies covering the desired range.

To obtain the efficiency curve, the detector response as a function of the energy has to be measured using each separate sample/detector geometry. For this reason, it is possible to carry out the measurement with the aid of a primary standard source. Primary standards may not be available for radionuclides with a short half-life, e.g. some positron emitters. When measuring, the sample will mostly have to be in a container and set at a defined position in relation to the detector. The sample/detector geometry is then defined by the position of the sample relative to the detector and the characteristics of the container and sample, e.g. shape, volume and density. Figure 2.2.66.-3 shows a typical HPGe detector efficiency curve obtained for a cylindrical container placed on top of the detector.

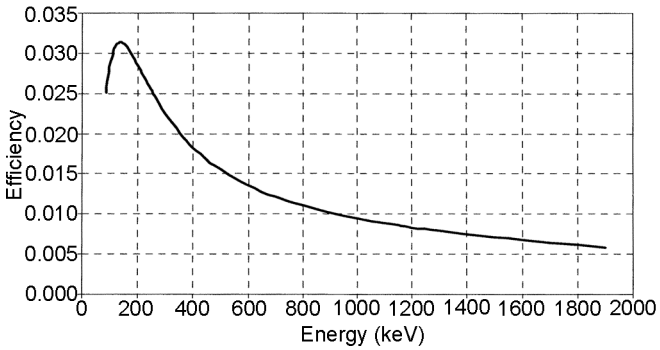

Figure 2.2.66.-3. – *Typical HPGe efficiency curve measured using a dedicated container set on top of the detector*

*BETA-PARTICLE SPECTROMETRY*

In the case of a beta-particle emitter, a beta-particle spectrometer is necessary to determine the energy distribution of the emitted beta particles. It is analogous to a gamma-ray spectrometer, but frequently uses liquid scintillators to convert the energy of the beta particles into detectable light,

which can then be analysed. Beta-particle spectrometry is mostly achieved by dissolving or suspending the sample in a liquid scintillation cocktail in transparent or translucent (glass or plastic) containers and subsequent counting of the electrical pulses generated by a photomultiplier from the emitted light. The pulse amplitude is related to the energy of the absorbed radiation. A beta-particle spectrum can be produced by collecting a sufficient number of pulses. The liquid scintillation cocktail is chosen in such a way that counting errors due to quenching, chemoluminescence, phosphorescence, etc., are minimised. Coincidence counting with 2 or more photomultipliers is also used to minimise counts from background radiation, electronics, etc.
To differentiate between alpha- and beta-particle emissions, pulse-shape discrimination is commonly used.

*Radionuclide identification.* Determination of the correspondence of the mean and/or maximum energies in the energy spectrum from the sample to the energies prescribed by a monograph is a valid identification test.

*Calibration.* A common method of energy calibration is to use an unquenched reference sample to determine the maximum energy of the beta particles emitted by the radionuclide of interest.

*ALPHA-PARTICLE SPECTROMETRY*

For the identification and assay of alpha-particle emitters, spectrometry using liquid scintillation is mostly used. The principle is explained in the previous section on beta-particle spectrometry.
For the identification and determination of radionuclidic purity of alpha-particle emitters, spectrometry using a silicon-diode semiconductor detector can be used. Using this detector, the absorption of alpha particles results in the immediate production of an electrical pulse. The movement of electron-hole pairs created by the interaction of radiation induces an electrical charge, which is amplified and measured.

The sample preparation is of crucial importance. After a chemical separation of the radionuclide of interest, the sample is electro-deposited on a stainless steel disk in the form of a very thin layer of material to minimise self-absorption. The yield of the whole procedure can be determined experimentally by adding a known amount of a tracer, which will take into account the chemical separation efficiency, the electro-deposition efficiency and the counting efficiency.

For both types of detectors, the pulse amplitude is related to the energy of the absorbed radiation. An alpha-particle spectrum can be produced by collecting a sufficient number of pulses.

*Radionuclide identification.* Determination of the correspondence of the energy of the peaks detected from the sample to the energies prescribed by a monograph is a valid identification test.

*Calibration.* An alpha-particle spectrometer has to be calibrated in relation to energy and efficiency. This is done by using the peaks from known sources covering the desired energy range, such as americium-241 and plutonium-242. Not all alpha particles emitted by the source will produce a count in the system. The probability that an emitted alpha particle will interact with the detector material and produce a count is the efficiency of the detector, which depends on the geometry.

## DETECTION AND MEASUREMENT OF RADIOACTIVITY IN COMBINATION WITH A SEPARATION TECHNIQUE

A radioactive preparation may contain the radionuclide in different chemical forms other than the intended one. Therefore it is necessary to separate the different substances containing the radionuclide and determine the percentage of radioactivity due to the radionuclide concerned associated with the stated chemical form and the contribution to the total radioactivity due to the radionuclide concerned coming from other substances. For this purpose, instruments for the detection and measurement of radioactivity are used in combination with a physico-chemical separation technique. In principle, any method of separation may be used.

Monographs for radiopharmaceutical preparations may include the combined use of radioactivity measurement with paper chromatography (*2.2.26*), thin-layer chromatography (*2.2.27*), gas chromatography (*2.2.28*), liquid chromatography (*2.2.29*), size-exclusion chromatography (*2.2.30*) or electrophoresis (*2.2.31*).

In all cases the radioactivity of each analyte is measured after the separation has been achieved using the stated method.

Radioactivity measurement may be performed using detectors mounted in series with other detectors in analytical instruments, such as liquid chromatographs, making in-line detection of analytes, or performed off-line, i.e. after the analytical separation has been completed, by measuring the radioactivity of eluate fractions obtained after liquid chromatographic separation of equal volume or as the distribution of radioactivity on paper chromatography or thin-layer chromatography supports.

*IN-LINE DETECTION AND MEASUREMENT OF RADIOACTIVITY IN COMBINATION WITH LIQUID CHROMATOGRAPHY*

**Apparatus**. Liquid chromatography (see *2.2.29*) may be used to separate the principal radioactive substance of a radiopharmaceutical preparation from radiochemical impurities or degradation products. In-line detection is usually obtained by using a scintillation detector connected to a ratemeter and recording device. The scintillating material of the detector is selected on the basis of the emission to be detected, e.g. plastic scintillator for beta-particle emissions or scintillation crystals for gamma- and X-ray radiations. The addition of a liquid scintillation cocktail before the eluate reaches the in-line radioactivity detector may also be used in the case of beta-particle-emitting radionuclides.

The simultaneous use of a radioactivity detector and other detectors (UV, refractive index, conductimetric, etc.) connected in series may be used to identify the substance, e.g. in relation to the retention time of a known standard, to determine the amount of the substance using a suitable reference standard and to measure the radioactivity associated with such a substance. When different detectors are coupled in series, correct the experimentally obtained retention times for the delay in time between the detectors.

In liquid chromatography some radiochemical impurities, such as colloidal impurities, may be retained on the column. In such cases a separate method is required for the determination of the content of the retained radiochemical impurities and the calculation formula for the expression of the total radiochemical purity takes into account the relative amount of the retained radiochemical impurities.

One possibility to evaluate such retention problems during method validation is to evaluate the radioactivity recovery from the column by measuring the total radioactivity recovered from the chromatographic equipment with and without the column.

**Method**. The sample is diluted if necessary and then applied to the column in the prescribed volume and conditions. In this respect it is important to demonstrate the LOD and LOQ, and the linearity of the detector throughout the range of activities to be measured.

*Flow-through detector.* A portion of the tubing where the eluate containing the radioactive species is flowing is placed in front of or within the detector. Counting efficiency may be increased using a longer portion of the tube (e.g. making multiple turns in front of or within the detector); however, this will reduce the ability of the system to separate 2 closely eluting peaks of radioactivity.

When the radiochemical purity test prescribes determination of the total radiochemical impurities or there is a quantitative determination of an individual impurity, it is important to choose an appropriate threshold setting and appropriate conditions for integration of the peak areas. In such tests the disregard limit, i.e. the limit at or below which a peak is disregarded, is dependent on the method and is related to the limit of detection and limit of quantification. Thus, the threshold setting of the data collection system corresponds to at least half of the disregard limit.

Record the signal of the detectors as a function of time.

Identification of peaks in the radiometric signal (radiochromatogram) is made on the basis of the retention time of the analytes. The profile from other detectors may be used for this purpose.

Quantification of the different components of chromatogram and radiochromatogram profiles is made on the basis of peak areas. Peak areas are usually obtained by direct integration of the detector signal using commercially available software.

*OFF-LINE DETECTION AND MEASUREMENT OF RADIOACTIVITY*

Liquid chromatography (*2.2.29*). Provided the retention times of the various radiochemical species are reproducibly consistent, an alternative method of radioactivity quantification is to collect the liquid chromatography effluent in a series of timed samples (fractions) for off-line analysis for radioactivity content. The radioactivity in the fractions corresponding to the peaks can be expressed as a percentage of the total of the radioactivity in all fractions, taking into account the limit of quantification.

**Method**. The sample is applied on the column in the prescribed volume and conditions. Fractions are collected at the end of the chromatographic line.

The volume between the detector used to identify the retention time of the peaks and the collection point is measured and a delay factor is calculated on the basis of the effluent flow rate and applied to each peak to estimate the time of elution of the peak at the point of collection. The fractions are collected on the basis of a fixed time interval or at the time of appearance estimated from the delay time so that any relevant peak is collected in one or more fractions.

The radioactivity of each fraction is counted using a calibrated instrument such as a dose calibrator or a scintillation detector, taking into account the limit of quantification and the linearity.

An elution profile is obtained tabulating the counts per fraction against the elution time or volume. The activity of fractions belonging to the same peak may be summed and the relative percentage calculated to define radiochemical purity.

Thin-layer chromatography (*2.2.27*) and paper chromatography (*2.2.26*). Provided a thin-layer chromatography or a paper chromatography analytical method has been validated for the separation of components of a radioactive preparation, the number and relative intensities of the separated spots can be detected and measured using a radioactivity detector that can relate the radioactivity to a specific position on the chromatographic support.

The positions of the spots (peaks) may permit chemical identification by comparison with solutions of the same chemical substances (non-radioactive), using a suitable detection method.

**Apparatus**.

*Scanning device*. The apparatus generally comprises a radioactivity detector, such as a position-sensitive proportional counter or a collimated scintillation detector placed at a fixed distance from a scanning platform where the chromatographic support to be scanned is positioned.

The radioactivity of the sample applied to the chromatography support must result in a counting rate in the linearity range of the equipment and the sample may be diluted if necessary. The area to be scanned is positioned at the reference position so that the desired lane is aligned with the detector scanning trip. Adjust the scanning time to allow enough counting time during the run.

The detector or the platform may be moved in-plane, along the *x*-axis or the *y*-axis, so that the entire surface can be scanned during a single run.

The detector is connected to a suitable counting device, so that the radioactivity revealed can be measured quantitatively and the count rate related spatially to the surface scanned.

The radioactivity is automatically reported against the development distance and the profile describes peaks having an area proportional to the number of counts per unit of distance.

*Radioactivity counter*. In the case where a maximum of only 3 radiochemical components needs to be identified and they are fully separated, the support can be cut into equal strips, each having a size not more than half the length of the support corresponding to the difference between the retardation factors of the 2 closest spots. Each single strip is numbered starting from the origin side and counted separately. Alternatively, for well-characterised systems the support may be cut into 2 or more unequal portions, folded if necessary to approximately equal geometry before counting. An ionisation chamber or a scintillation counter can be used for this purpose, provided they are used within the instrument's linearity range and above its LOQ.

*Autoradiography*. This may also be used to acquire an image of the radioactivity distribution on the chromatographic support. In this case, the response of the system used for the acquisition of the image, such as a phosphor imager or a photographic film, must be shown to be linear with respect to the radioactivity in the chromatogram. Otherwise the system must be pre-calibrated or exposed at the same time to a series of reference radioactive sources, obtained by dilution from a calibrated standard solution, covering the expected radioactivity range that may be present on the support.

**Method**. Deposit the required amount of sample at the origin of the chromatographic support, with drying if necessary to avoid spreading of the spot. Develop the chromatogram according to the prescribed method. A carrier may be added when prescribed in a particular monograph.

In paper and thin-layer chromatography, it is preferable not to dilute the preparation to be examined but it is important to avoid depositing such a quantity of radioactivity that counting losses by coincidence (dead-time losses) occur during measurement of the radioactivity.

After development, the support is dried and the positions of the radioactive areas are detected by measurement of radioactivity over the length of the chromatogram, using a suitable collimated counter, by autoradiography, or by cutting the strips into portions and counting each portion.

Radioactivity may be measured by integration using an automatic-plotting instrument or a digital counter.

The ratios of the areas under the peaks give the ratios of the percentages of radioactivity due to the respective radiochemical substances.

When the strips are cut into portions, the ratios of the quantities of radioactivity measured give the ratio of percentages of radioactivity due to the respective radiochemical species.

*Calibration*. It is important to demonstrate the limits of detection and quantification, and the linearity of the detector throughout the range of activities to be measured and in all positions on the support of the chromatographic system. This may be done by applying samples covering a range of activities from 0.1 per cent to 100 per cent of the expected range. Prepare the samples by dilution and apply equal volumes of each, with drying if necessary. After examining the radioactivity profile using the equipment's standard settings, the peak areas are integrated for comparison with the

calculated amount of radioactivity applied to each spot. Verify that the response of the detector over the complete length and width of the detector path is the same, as the response may vary with the detector position.

The peak-resolving power is influenced by the size of the spot, the total radioactivity of the radionuclide and the detector equipment. It can be checked by applying 5 µL spots separated by distances increasing from 4 mm to 20 mm in 2 mm increments. The approximate resolution of the detection system can be determined from the radioactivity profile as the distance between the 2 spots where the baseline is only just clearly separated.

## 2.3.1. IDENTIFICATION REACTIONS OF IONS AND FUNCTIONAL GROUPS

ACETATES

a) Heat the substance to be examined with an equal quantity of *oxalic acid R*. Acid vapours with the characteristic odour of acetic acid are liberated, showing an acid reaction (*2.2.4*).

b) Dissolve about 30 mg of the substance to be examined in 3 mL of *water R* or use 3 mL of the prescribed solution. Add successively 0.25 mL of *lanthanum nitrate solution R*, 0.1 mL of *0.05 M iodine* and 0.05 mL of *dilute ammonia R2*. Heat carefully to boiling. Within a few minutes a blue precipitate is formed or a dark blue colour develops.

ACETYL

In a test-tube about 180 mm long and 18 mm in external diameter, place about 15 mg of the substance to be examined, or the prescribed quantity, and 0.15 mL of *phosphoric acid R*. Close the tube with a stopper through which passes a small test-tube about 100 mm long and 10 mm in external diameter containing *water R* to act as a condenser. On the outside of the smaller tube, hang a drop of *lanthanum nitrate solution R*. Except for substances hydrolysable only with difficulty, place the apparatus in a water-bath for 5 min, then take out the smaller tube. Remove the drop and mix it with 0.05 mL of *0.01 M iodine* on a tile. Add at the edge 0.05 mL of *dilute ammonia R2*. After 1 min to 2 min, a blue colour develops at the junction of the two drops; the colour intensifies and persists for a short time.

For *substances hydrolysable only with difficulty* heat the mixture slowly to boiling over an open flame and then proceed as prescribed above.

ALKALOIDS

Dissolve a few milligrams of the substance to be examined, or the prescribed quantity, in 5 mL of *water R*, add *dilute hydrochloric acid R* until an acid reaction occurs (*2.2.4*), then 1 mL of *potassium iodobismuthate solution R*. An orange or orange-red precipitate is formed immediately.

ALUMINIUM

Dissolve about 15 mg of the substance to be examined in 2 mL of *water R* or use 2 mL of the prescribed solution. Add about 0.5 mL of *dilute hydrochloric acid R* and about 0.5 mL of *thioacetamide reagent R*. No precipitate is formed. Add dropwise *dilute sodium hydroxide solution R*. A gelatinous white precipitate is formed which dissolves on further addition of *dilute sodium hydroxide solution R*. Gradually add *ammonium chloride solution R*. The gelatinous white precipitate is re-formed.

AMINES, PRIMARY AROMATIC

Acidify the prescribed solution with *dilute hydrochloric acid R* and add 0.2 mL of *sodium nitrite solution R*. After 1 min to 2 min, add 1 mL of *β-naphthol solution R*. An intense orange or red colour and usually a precipitate of the same colour are produced.

AMMONIUM SALTS

To the prescribed solution add 0.2 g of *magnesium oxide R*. Pass a current of air through the mixture and direct the gas that escapes just beneath the surface of a mixture of 1 mL of *0.1 M hydrochloric acid* and 0.05 mL of *methyl red solution R*. The colour of the indicator changes to yellow. On addition of 1 mL of a freshly prepared 100 g/L solution of *sodium cobaltinitrite R* a yellow precipitate is formed.

AMMONIUM SALTS AND SALTS OF VOLATILE BASES

Dissolve about 20 mg of the substance to be examined in 2 mL of *water R* or use 2 mL of the prescribed solution. Add 2 mL of *dilute sodium hydroxide solution R*. On heating, the solution gives off vapour that can be identified by its odour and by its alkaline reaction (*2.2.4*).

ANTIMONY

Dissolve with gentle heating about 10 mg of the substance to be examined in a solution of 0.5 g of *sodium potassium tartrate R* in 10 mL of *water R* and allow to cool: to 2 mL of this solution, or to 2 mL of the prescribed solution, add *sodium sulfide solution R* dropwise; an orange-red precipitate is formed which dissolves on addition of *dilute sodium hydroxide solution R*.

ARSENIC

Heat 5 mL of the prescribed solution on a water-bath with an equal volume of *hypophosphorous reagent R*. A brown precipitate is formed.

BARBITURATES, NON-NITROGEN SUBSTITUTED

Dissolve about 5 mg of the substance to be examined in 3 mL of *methanol R*, add 0.1 mL of a solution containing 100 g/L of *cobalt nitrate R* and 100 g/L of *calcium chloride R*. Mix and add, with shaking, 0.1 mL of *dilute sodium hydroxide solution R*. A violet-blue colour and precipitate are formed.

BENZOATES

a) To 1 mL of the prescribed solution add 0.5 mL of *ferric chloride solution R1*. A dull-yellow precipitate, soluble in *ether R*, is formed.

b) Place 0.2 g of the substance to be examined, treated if necessary as prescribed, in a test-tube. Moisten with 0.2 mL to 0.3 mL of *sulfuric acid R*. Gently warm the bottom of the tube. A white sublimate is deposited on the inner wall of the tube.

c) Dissolve 0.5 g of the substance to be examined in 10 mL of *water R* or use 10 mL of the prescribed solution. Add 0.5 mL of *hydrochloric acid R*. The precipitate obtained, after crystallisation from warm *water R* and drying *in vacuo*, has a melting point (*2.2.14*) of 120 °C to 124 °C.

BISMUTH

a) To 0.5 g of the substance to be examined add 10 mL of *dilute hydrochloric acid R* or use 10 mL of the prescribed solution. Heat to boiling for 1 min. Cool and filter if necessary. To 1 mL of the solution obtained add 20 mL of *water R*. A white or slightly yellow precipitate is formed which on addition of 0.05 mL to 0.1 mL of *sodium sulfide solution R* turns brown.

b) To about 45 mg of the substance to be examined add 10 mL of *dilute nitric acid R* or use 10 mL of the prescribed solution. Boil for 1 min. Allow to cool and filter if necessary. To 5 mL of the solution obtained add 2 mL of a 100 g/L solution of *thiourea R*. A yellowish-orange colour or an orange precipitate is formed. Add 4 mL of a 25 g/L solution of *sodium fluoride R*. The solution is not decolorised within 30 min.

BROMIDES

a) Dissolve in 2 mL of *water R* a quantity of the substance to be examined equivalent to about 3 mg of bromide ($Br^-$) or use 2 mL of the prescribed solution. Acidify with *dilute nitric acid R* and add 0.4 mL of *silver nitrate solution R1*. Shake and allow to stand. A curdled, pale yellow precipitate is formed. Centrifuge and wash the precipitate with three quantities, each of 1 mL, of *water R*. Carry out this operation rapidly in subdued light disregarding the fact that the supernatant solution may not become perfectly clear. Suspend the precipitate obtained in 2 mL of *water R* and add 1.5 mL of *ammonia R*. The precipitate dissolves with difficulty.

b) Introduce into a small test-tube a quantity of the substance to be examined equivalent to about 5 mg of bromide ($Br^-$) or the prescribed quantity. Add 0.25 mL of *water R*, about 75 mg of *lead dioxide R*, 0.25 mL of *acetic acid R* and shake gently. Dry the inside of the upper part of the test-tube with a piece of filter paper and allow to stand for 5 min. Prepare a strip of suitable filter paper of appropriate size. Impregnate it by capillarity, by dipping the tip in a drop of *decolorised fuchsin solution R* and introduce the impregnated part immediately into the tube. Starting from the tip, a violet colour appears within 10 s that is clearly distinguishable from the red colour of fuchsin, which may be visible on a small area at the top of the impregnated part of the paper strip.

CALCIUM

a) To 0.2 mL of a neutral solution containing a quantity of the substance to be examined equivalent to about 0.2 mg of calcium ($Ca^{2+}$) per millilitre or to 0.2 mL of the prescribed solution add 0.5 mL of a 2 g/L solution of *glyoxalhydroxyanil R* in *ethanol (96 per cent) R*, 0.2 mL of *dilute sodium hydroxide solution R* and 0.2 mL of *sodium carbonate solution R*. Shake with 1 mL to 2 mL of *chloroform R* and add 1 mL to 2 mL of *water R*. The chloroform layer is coloured red.

b) Dissolve about 20 mg of the substance to be examined or the prescribed quantity in 5 mL of *acetic acid R*. Add 0.5 mL of *potassium ferrocyanide solution R*. The solution remains clear. Add about 50 mg of *ammonium chloride R*. A white, crystalline precipitate is formed.

CARBONATES AND BICARBONATES

Introduce into a test-tube 0.1 g of the substance to be examined and suspend in 2 mL of *water R* or use 2 mL of the prescribed solution. Add 3 mL of *dilute acetic acid R*. Close the tube immediately using a stopper fitted with a glass tube bent twice at right angles. The solution or the suspension becomes effervescent and gives off a colourless and odourless gas. Heat gently and collect the gas in 5 mL of *barium hydroxide solution R*. A white precipitate is formed that dissolves on addition of an excess of *hydrochloric acid R1*.

CHLORIDES

a) Dissolve in 2 mL of *water R* a quantity of the substance to be examined equivalent to about 2 mg of chloride ($Cl^-$) or use 2 mL of the prescribed solution. Acidify with *dilute nitric acid R* and add 0.4 mL of *silver nitrate solution R1*. Shake and allow to stand. A curdled, white precipitate is formed. Centrifuge and wash the precipitate with three quantities, each of 1 mL, of *water R*. Carry out this operation rapidly in subdued light, disregarding the fact that the supernatant solution may not become perfectly clear. Suspend the precipitate in 2 mL of *water R* and add 1.5 mL of *ammonia R*. The precipitate dissolves easily with the possible exception of a few large particles which dissolve slowly.

b) Introduce into a test-tube a quantity of the substance to be examined equivalent to about 15 mg of chloride ($Cl^-$) or the prescribed quantity. Add 0.2 g of *potassium dichromate R* and 1 mL of *sulfuric acid R*. Place a filter-paper strip impregnated with 0.1 mL of *diphenylcarbazide solution R* over the opening of the test-tube. The paper turns violet-red. The impregnated paper must not come into contact with the potassium dichromate.

CITRATES

Dissolve in 5 mL of *water R* a quantity of the substance to be examined equivalent to about 50 mg of citric acid or use 5 mL of the prescribed solution. Add 0.5 mL of *sulfuric acid R* and 1 mL of *potassium permanganate solution R*. Warm until the colour of the permanganate is discharged. Add 0.5 mL of a 100 g/L solution of *sodium nitroprusside R* in *dilute sulfuric acid R* and 4 g of *sulfamic acid R*. Make alkaline with *concentrated ammonia R*, added dropwise until all the sulfamic acid has dissolved. Addition of an excess of *concentrated ammonia R* produces a violet colour, turning to violet-blue.

ESTERS

To about 30 mg of the substance to be examined or the prescribed quantity add 0.5 mL of a 70 g/L solution of *hydroxylamine hydrochloride R* in *methanol R* and 0.5 mL of a 100 g/L solution of *potassium hydroxide R* in *ethanol (96 per cent) R*. Heat to boiling, cool, acidify with *dilute hydrochloric acid R* and add 0.2 mL of *ferric chloride solution R1* diluted ten times. A bluish-red or red colour is produced.

IODIDES

a) Dissolve a quantity of the substance to be examined equivalent to about 4 mg of iodide ($I^-$) in 2 mL of *water R* or use 2 mL of the prescribed solution. Acidify with *dilute nitric acid R* and add 0.4 mL of *silver nitrate solution R1*. Shake and allow to stand. A curdled, pale-yellow precipitate is formed. Centrifuge and wash with three quantities, each of 1 mL, of *water R*. Carry out this operation rapidly in subdued light disregarding the fact that the supernatant solution may not become perfectly clear. Suspend the precipitate in 2 mL of *water R* and add 1.5 mL of *ammonia R*. The precipitate does not dissolve.

b) To 0.2 mL of a solution of the substance to be examined containing about 5 mg of iodide ($I^-$) per millilitre, or to 0.2 mL of the prescribed solution, add 0.5 mL of *dilute sulfuric acid R*, 0.1 mL of *potassium dichromate solution R*, 2 mL of *water R* and 2 mL of *chloroform R*. Shake for a few seconds and allow to stand. The chloroform layer is coloured violet or violet-red.

IRON

a) Dissolve a quantity of the substance to be examined equivalent to about 10 mg of iron ($Fe^{2+}$) in 1 mL of *water R* or use 1 mL of the prescribed solution. Add 1 mL of *potassium ferricyanide solution R*. A blue precipitate is formed that does not dissolve on addition of 5 mL of *dilute hydrochloric acid R*.

b) Dissolve a quantity of the substance to be examined equivalent to about 1 mg of iron ($Fe^{3+}$) in 30 mL of *water R*. To 3 mL of this solution or to 3 mL of the prescribed solution, add 1 mL of *dilute hydrochloric acid R* and 1 mL of *potassium thiocyanate solution R*. The solution is coloured red. Take two portions, each of 1 mL, of the mixture. To one portion add 5 mL of *isoamyl alcohol R* or 5 mL of *ether R*. Shake and allow to stand. The organic layer is coloured pink. To the other portion add 2 mL of *mercuric chloride solution R*. The red colour disappears.

c) Dissolve a quantity of the substance to be examined equivalent to not less than 1 mg of iron ($Fe^{3+}$) in 1 mL of *water R* or use 1 mL of the prescribed solution. Add 1 mL of *potassium ferrocyanide solution R*. A blue precipitate is formed that does not dissolve on addition of 5 mL of *dilute hydrochloric acid R*.

LACTATES

Dissolve a quantity of the substance to be examined equivalent to about 5 mg of lactic acid in 5 mL of *water R* or use 5 mL of the prescribed solution. Add 1 mL of *bromine water R* and 0.5 mL of *dilute sulfuric acid R*. Heat on a water-bath until the colour is discharged, stirring occasionally with a glass rod. Add 4 g of *ammonium sulfate R* and mix. Add dropwise and without mixing 0.2 mL of a 100 g/L solution of *sodium nitroprusside R* in *dilute sulfuric acid R*. Still without mixing add 1 mL of *concentrated ammonia R*. Allow to stand for 30 min. A dark green ring appears at the junction of the two liquids.

LEAD

a) Dissolve 0.1 g of the substance to be examined in 1 mL of *acetic acid R* or use 1 mL of the prescribed solution. Add 2 mL of *potassium chromate solution R*. A yellow precipitate is formed that dissolves on addition of 2 mL of *strong sodium hydroxide solution R*.

b) Dissolve 50 mg of the substance to be examined in 1 mL of *acetic acid R* or use 1 mL of the prescribed solution. Add 10 mL of *water R* and 0.2 mL of *potassium iodide solution R*. A yellow precipitate is formed. Heat to boiling for 1 min to 2 min. The precipitate dissolves. Allow to cool. The precipitate is re-formed as glistening, yellow plates.

MAGNESIUM

Dissolve about 15 mg of the substance to be examined in 2 mL of *water R* or use 2 mL of the prescribed solution. Add 1 mL of *dilute ammonia R1*. A white precipitate is formed that dissolves on addition of 1 mL of *ammonium chloride solution R*. Add 1 mL of *disodium hydrogen phosphate solution R*. A white crystalline precipitate is formed.

MERCURY

a) Place about 0.1 mL of a solution of the substance to be examined on well-scraped copper foil. A dark-grey stain that becomes shiny on rubbing is formed. Dry the foil and heat in a test-tube. The spot disappears.

b) To the prescribed solution add *dilute sodium hydroxide solution R* until strongly alkaline (*2.2.4*). A dense yellow precipitate is formed (mercuric salts).

NITRATES

To a mixture of 0.1 mL of *nitrobenzene R* and 0.2 mL of *sulfuric acid R*, add a quantity of the powdered substance equivalent to about 1 mg of nitrate ($NO_3^-$) or the prescribed quantity. Allow to stand for 5 min. Cool in iced water and add slowly and with mixing 5 mL of *water R*, then 5 mL of *strong sodium hydroxide solution R*. Add 5 mL of *acetone R*. Shake and allow to stand. The upper layer is coloured deep violet.

PHOSPHATES (ORTHOPHOSPHATES)

a) To 5 mL of the prescribed solution, neutralised if necessary, add 5 mL of *silver nitrate solution R1*. A yellow precipitate is formed whose colour is not changed by boiling and which dissolves on addition of *ammonia R*.

b) Mix 1 mL of the prescribed solution with 2 mL of *molybdovanadic reagent R*. A yellow colour develops.

POTASSIUM

a) Dissolve 0.1 g of the substance to be examined in 2 mL of *water R* or use 2 mL of the prescribed solution. Add 1 mL of *sodium carbonate solution R* and heat. No precipitate is formed. Add to the hot solution 0.05 mL of *sodium sulfide solution R*. No precipitate is formed. Cool in iced water and add 2 mL of a 150 g/L solution of *tartaric acid R*. Allow to stand. A white crystalline precipitate is formed.

b) Dissolve about 40 mg of the substance to be examined in 1 mL of *water R* or use 1 mL of the prescribed solution. Add 1 mL of *dilute acetic acid R* and 1 mL of a freshly prepared 100 g/L solution of *sodium cobaltinitrite R*. A yellow or orange-yellow precipitate is formed immediately.

SALICYLATES

a) To 1 mL of the prescribed solution add 0.5 mL of *ferric chloride solution R1*. A violet colour is produced that persists after the addition of 0.1 mL of *acetic acid R*.

b) Dissolve 0.5 g of the substance to be examined in 10 mL of *water R* or use 10 mL of the prescribed solution. Add 0.5 mL of *hydrochloric acid R*. The precipitate obtained, after recrystallisation from hot *water R* and drying *in vacuo*, has a melting point (*2.2.14*) of 156 °C to 161 °C.

SILICATES

Mix the prescribed quantity of the substance to be examined in a lead or platinum crucible by means of a copper wire with about 10 mg of *sodium fluoride R* and a few drops of *sulfuric acid R* to give a thin slurry. Cover the crucible with a thin, transparent plate of plastic under which a drop of *water R* is suspended and warm gently. Within a short time a white ring is rapidly formed around the drop of water.

SILVER

Dissolve about 10 mg of the substance to be examined in 10 mL of *water R* or use 10 mL of the prescribed solution. Add 0.3 mL of *hydrochloric acid R1*. A curdled, white precipitate is formed that dissolves on addition of 3 mL of *dilute ammonia R1*.

SODIUM

a) Dissolve 0.1 g of the substance to be examined in 2 mL of *water R* or use 2 mL of the prescribed solution. Add 2 mL of a 150 g/L solution of *potassium carbonate R* and heat to boiling. No precipitate is formed. Add 4 mL of *potassium pyroantimonate solution R* and heat to boiling. Allow to cool in iced water and if necessary rub the inside of the test-tube with a glass rod. A dense white precipitate is formed.

b) Dissolve a quantity of the substance to be examined equivalent to about 2 mg of sodium ($Na^+$) in 0.5 mL of *water R* or use 0.5 mL of the prescribed solution. Add 1.5 mL of *methoxyphenylacetic reagent R* and cool in ice-water for 30 min. A voluminous, white, crystalline precipitate is formed. Place in water at 20 °C and stir for 5 min. The precipitate does not disappear. Add 1 mL of *dilute ammonia R1*. The precipitate dissolves completely. Add 1 mL of *ammonium carbonate solution R*. No precipitate is formed.

SULFATES

a) Dissolve about 45 mg of the substance to be examined in 5 mL of *water R* or use 5 mL of the prescribed solution. Add 1 mL of *dilute hydrochloric acid R* and 1 mL of *barium chloride solution R1*. A white precipitate is formed.

b) To the suspension obtained during reaction (a), add 0.1 mL of *0.05 M iodine*. The suspension remains yellow (distinction from sulfites and dithionites), but is decolorised by adding dropwise *stannous chloride solution R* (distinction from iodates). Boil the mixture. No coloured precipitate is formed (distinction from selenates and tungstates).

TARTRATES

a) Dissolve about 15 mg of the substance to be examined in 5 mL of *water R* or use 5 mL of the prescribed solution. Add 0.05 mL of a 10 g/L solution of *ferrous sulfate R* and 0.05 mL of *dilute hydrogen peroxide solution R*. A transient yellow colour is produced. After the colour has disappeared add *dilute sodium hydroxide solution R* dropwise. A violet or purple colour is produced.

b) To 0.1 mL of a solution of the substance to be examined containing the equivalent of about 15 mg of tartaric acid per millilitre or to 0.1 mL of the prescribed solution add 0.1 mL of a 100 g/L solution of *potassium bromide R*, 0.1 mL of a 20 g/L solution of *resorcinol R* and 3 mL of *sulfuric acid R*. Heat on a water-bath for 5 min to 10 min. A dark-blue colour develops. Allow to cool and pour the solution into *water R*. The colour changes to red.

XANTHINES

To a few milligrams of the substance to be examined or the prescribed quantity add 0.1 mL of *strong hydrogen peroxide solution R* and 0.3 mL of *dilute hydrochloric acid R*. Heat to dryness on a water-bath until a yellowish-red residue is obtained. Add 0.1 mL of *dilute ammonia R2*. The colour of the residue changes to violet-red.

ZINC

Dissolve 0.1 g of the substance to be examined in 5 mL of *water R* or use 5 mL of the prescribed solution. Add 0.2 mL of *strong sodium hydroxide solution R*. A white precipitate is formed. Add a further 2 mL of *strong sodium hydroxide solution R*. The precipitate dissolves. Add 10 mL of *ammonium chloride solution R*. The solution remains clear. Add 0.1 mL of *sodium sulfide solution R*. A flocculent white precipitate is formed.

**01/2019:20302 corrected 9.8**

# 2.3.2. IDENTIFICATION OF FATTY OILS BY THIN-LAYER CHROMATOGRAPHY

METHOD A

Thin-layer chromatography (*2.2.27*).

*Test solution.* Unless otherwise prescribed, dissolve about 20 mg (1 drop) of the fatty oil in 3 mL of *methylene chloride R*.

*Reference solution.* Dissolve about 20 mg (1 drop) of *maize oil R* in 3 mL of *methylene chloride R*.

*Plate*: a suitable octadecylsilyl silica gel for high-performance thin-layer chromatography as the coating substance.

*Mobile phase*:

– *mobile phase A*: *ether R*;

– *mobile phase B*: *methylene chloride R*, *glacial acetic acid R*, *acetone R* (20:40:50 *V/V/V*).

*Application*: 1 µL.

*Development*: twice over a path of 0.5 cm with mobile phase A, then twice over a path of 8 cm with mobile phase B.

*Drying*: in air.

*Detection*: spray with a 100 g/L solution of *phosphomolybdic acid R* in *ethanol (96 per cent) R*. Heat the plate at 120 °C for about 3 min and examine in daylight.

The chromatogram obtained typically shows spots comparable to those in Figure 2.3.2.-1.

METHOD B

Thin-layer chromatography (*2.2.27*).

*Test solution.* Unless otherwise prescribed, dissolve about 20 mg (1 drop) of the fatty oil in 3 mL of *methylene chloride R*.

*Reference solution.* Dissolve about 20 mg (1 drop) of *maize oil R* in 3 mL of *methylene chloride R*.

*Plate*: a suitable octadecylsilyl silica gel for high-performance thin-layer chromatography as the coating substance.

*Mobile phase*: *methylene chloride R*, *glacial acetic acid R*, *acetone R* (20:40:50 *V/V/V*).

*Application*: 1 µL as bands of 8 mm. A suitable automated apparatus may be used.

*Development*: over a path of 7 cm.

*Drying*: in air.

*Detection*: treat with a 100 g/L solution of *phosphomolybdic acid R* in *ethanol (96 per cent) R*. Heat the plate at 120 °C for 3 min and examine in daylight.

The chromatogram obtained typically shows zones comparable to those in Figure 2.3.2.-2.

## 2.3.3. IDENTIFICATION OF PHENOTHIAZINES BY THIN-LAYER CHROMATOGRAPHY

Examine by thin-layer chromatography (*2.2.27*) using *kieselguhr G R* as the coating substance. Impregnate the plate by placing it in a closed tank containing the necessary quantity of the impregnation mixture composed of a solution containing 10 per cent *V/V* of *phenoxyethanol R* and 50 g/L of *macrogol 300 R* in *acetone R* so that the plate dips about 5 mm beneath the surface of the liquid. When the impregnation mixture has risen at least 17 cm from the lower edge of the plate, remove the plate and use immediately for chromatography. Carry out the chromatography in the same direction as the impregnation.

*Test solution.* Dissolve 20 mg of the substance to be examined in *chloroform R* and dilute to 10 mL with the same solvent.

*Reference solution.* Dissolve 20 mg of the corresponding chemical reference substance (CRS) in *chloroform R* and dilute to 10 mL with the same solvent.

Apply separately to the plate 2 µL of each solution and develop in the dark over a path of 15 cm using a mixture of 50 mL of *light petroleum R* and 1 mL of *diethylamine R* saturated with *phenoxyethanol R* (i.e. add about 3 mL to 4 mL of *phenoxyethanol R* to the above mixture of solvents to give a persistent cloudiness on shaking, decant, and use the supernatant, even if it is cloudy). After development place the plate under ultraviolet light at 365 nm and examine after a few minutes. The spot in the chromatogram obtained with the test solution is similar in position, fluorescence and size to the spot in the chromatogram obtained with the reference solution. Spray with a 10 per cent *V/V* solution of *sulfuric acid R* in *alcohol R*. The spot in the chromatogram obtained with the test solution is of the same colour as that in the chromatogram obtained with the reference solution and has similar stability over a period of at least 20 min.

**01/2008:20304**

## 2.3.4. ODOUR

On a watch-glass 6 cm to 8 cm in diameter, spread in a thin layer 0.5 g to 2.0 g of the substance to be examined. After 15 min, determine the odour or verify the absence of odour.

# 2.4. LIMIT TESTS

**01/2008:20401**
**corrected 8.0**

## 2.4.1. AMMONIUM

*Unless otherwise prescribed, use method A.*

METHOD A

Introduce the prescribed solution into a test-tube or dissolve the prescribed quantity of the substance to be examined in 14 mL of *water R* in a test-tube. Make the solution alkaline if necessary by the addition of *dilute sodium hydroxide solution R*, dilute to 15 mL with *water R* and add 0.3 mL of *alkaline potassium tetraiodomercurate solution R*. Prepare a standard by mixing 10 mL of *ammonium standard solution (1 ppm $NH_4$) R*, 5 mL of *water R* and 0.3 mL of *alkaline potassium tetraiodomercurate solution R*. Stopper the test-tubes.

After 5 min, any yellow colour in the test solution is not more intense than that in the standard.

METHOD B

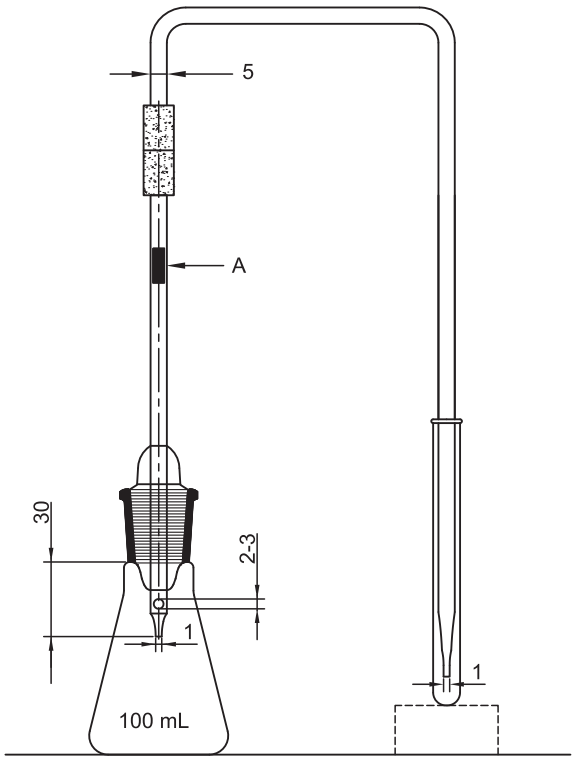
In a 25 mL jar fitted with a cap, place the prescribed quantity of the finely powdered substance to be examined and dissolve or suspend in 1 mL of *water R*. Add 0.30 g of *heavy magnesium oxide R*. Close immediately after placing a piece of *silver manganese paper R* 5 mm square, wetted with a few drops of *water R*, under the polyethylene cap. Swirl, avoiding projections of liquid, and allow to stand at 40 °C for 30 min. If the silver manganese paper shows a grey colour, it is not more intense than that of a standard prepared at the same time and in the same manner using the prescribed volume of *ammonium standard solution (1 ppm $NH_4$) R*, 1 mL of *water R* and 0.30 g of *heavy magnesium oxide R*.

**04/2018:20402**

## 2.4.2. ARSENIC

METHOD A

The apparatus (see Figure 2.4.2.-1) consists of a 100 mL conical flask closed with a ground-glass stopper through which passes a glass tube about 200 mm long and about 5 mm in internal diameter. The lower part of the tube tapers to an internal diameter of 1 mm, and about 20 mm from its tip is a lateral orifice 2-3 mm in diameter. When the tube is in position in the stopper, the lateral orifice is at least 3 mm below the lower surface of the stopper. A second glass tube of the same internal diameter is connected to the first tube. The second tube is bent twice at right angles and the free end of the tube tapers to an internal diameter of 1 mm. This end is immersed in a test-tube containing 3.0 mL of *silver diethyldithiocarbamate solution R*. Other suitable equipment may be used. Into the first tube insert 50-60 mg of *lead acetate cotton R*, loosely packed, or a small plug of cotton and a rolled piece of *lead acetate paper R* weighing 50-60 mg.



A. Lead acetate paper/cotton

Figure 2.4.2.-1. – *Apparatus for the limit test for arsenic (method A)*

*Dimensions in millimetres*

In the conical flask, dissolve the prescribed quantity of the substance to be examined in 25 mL of *water R*, or in the case of a solution adjust the prescribed volume to 25 mL with *water R*. Add 15 mL of *hydrochloric acid R*, 0.1 mL of *stannous chloride solution R* and 5 mL of *potassium iodide solution R*, allow to stand for 15 min and introduce 5 g of *activated zinc R*. Assemble the 2 parts of the apparatus immediately and immerse the flask in a water-bath at a temperature such that a uniform evolution of gas is maintained. Prepare a standard in the same manner, using 1 mL of *arsenic standard solution (1 ppm As) R*, diluted to 25 mL with *water R*. If foaming occurs, 1 mL of *2-propanol R* may be added to the flask.

After at least 2 h, the colour obtained in the test-tube with the test solution is not more intense than that obtained with the standard.

*Suitability test.* The colour obtained in the test-tube with the standard is at least as intensely coloured as 3 mL of a mixture of 3.0 mL of yellow primary solution, 0.6 mL of red primary solution and 11.40 mL of a solution of *hydrochloric acid R* (10 g/L HCl) (*2.2.2, Method I*).

METHOD B

Introduce the prescribed quantity of the substance to be examined into a test-tube containing 4 mL of *hydrochloric acid R* and about 5 mg of *potassium iodide R* and add 3 mL of *hypophosphorous reagent R*. Heat the mixture on a water-bath for 15 min, shaking occasionally. Prepare a standard in the same manner, using 0.5 mL of *arsenic standard solution (10 ppm As) R*.

After heating on the water-bath, the colour obtained in the test-tube with the test solution is not more intense than that obtained with the standard.

01/2008:20403
corrected 8.0

## 2.4.3. CALCIUM

*All solutions used for this test are prepared with distilled water R.*

To 0.2 mL of *alcoholic calcium standard solution (100 ppm Ca) R* add 1 mL of *ammonium oxalate solution R*. After 1 min add a mixture of 1 mL of *dilute acetic acid R* and 15 mL of the prescribed solution or of a solution containing the prescribed quantity of the substance to be examined, and shake. Prepare a standard in the same manner using a mixture of 10 mL of aqueous *calcium standard solution (10 ppm Ca) R*, 1 mL of *dilute acetic acid R* and 5 mL of *distilled water R*.

After 15 min, any opalescence in the test solution is not more intense than that in the standard.

01/2008:20404

## 2.4.4. CHLORIDES

To 15 mL of the prescribed solution add 1 mL of *dilute nitric acid R* and pour the mixture as a single addition into a test-tube containing 1 mL of *silver nitrate solution R2*. Prepare a standard in the same manner using 10 mL of *chloride standard solution (5 ppm Cl) R* and 5 mL of *water R*. Examine the tubes laterally against a black background.

After standing for 5 min protected from light, any opalescence in the test solution is not more intense than that in the standard.

01/2008:20405

## 2.4.5. FLUORIDES

Introduce into the inner tube of the apparatus (see Figure 2.4.5.-1) the prescribed quantity of the substance to be examined, 0.1 g of acid-washed *sand R* and 20 mL of a mixture of equal volumes of *sulfuric acid R* and *water R*. Heat the jacket containing *tetrachloroethane R* maintained at its boiling point (146 °C). Heat the steam generator and distil, collecting the distillate in a 100 mL volumetric flask containing 0.3 mL of *0.1 M sodium hydroxide* and 0.1 mL of *phenolphthalein solution R*. Maintain a constant volume (20 mL) in the tube during distillation and ensure that the distillate remains alkaline, adding *0.1 M sodium hydroxide* if necessary. Dilute the distillate to 100 mL with *water R* (test solution). Prepare a standard in the same manner by distillation, using 5 mL of *fluoride standard solution (10 ppm F) R* instead of the substance to be examined. Into two glass-stoppered cylinders introduce 20 mL of the test solution and 20 mL of the standard and 5 mL of *aminomethylalizarindiacetic acid reagent R*.

After 20 min, any blue colour in the test solution (originally red) is not more intense than that in the standard.

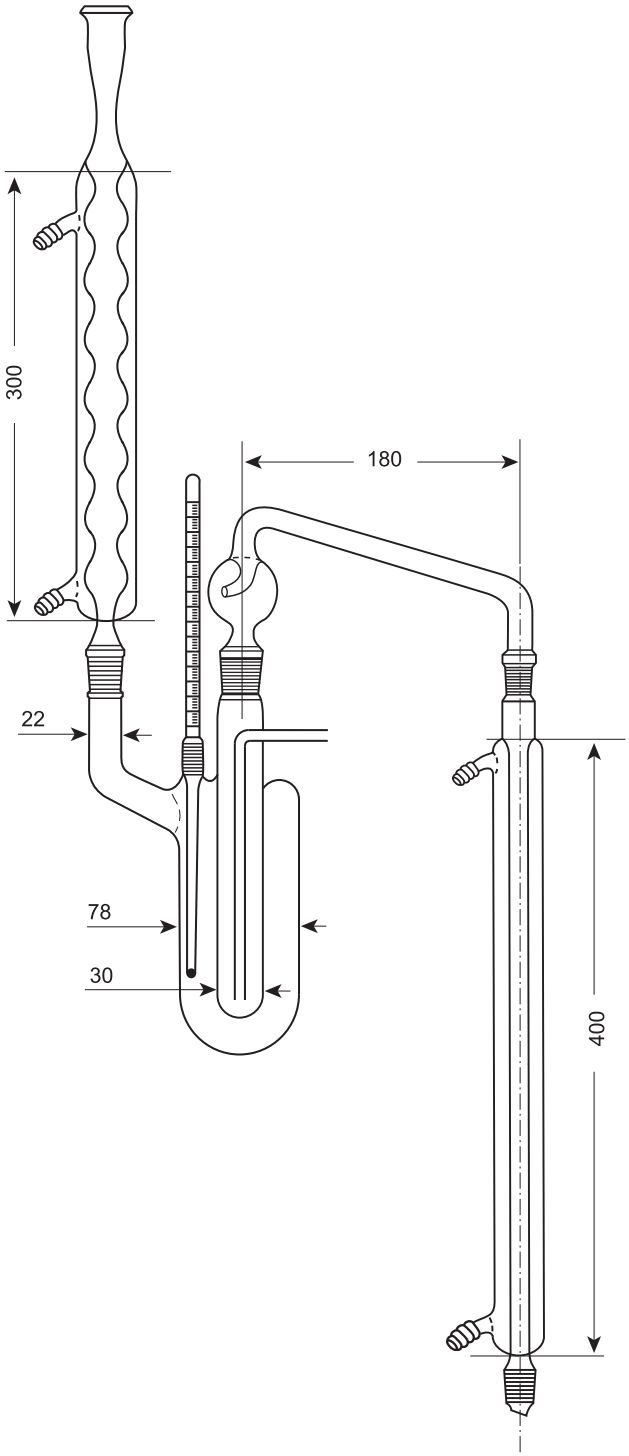


Figure 2.4.5.-1. – *Apparatus for limit test for fluorides*
*Dimensions in millimetres*

01/2008:20406

## 2.4.6. MAGNESIUM

To 10 mL of the prescribed solution add 0.1 g of *disodium tetraborate R*. Adjust the solution, if necessary, to pH 8.8 to pH 9.2 using *dilute hydrochloric acid R* or *dilute sodium hydroxide solution R*. Shake with 2 quantities, each of 5 mL, of a 1 g/L solution of *hydroxyquinoline R* in *chloroform R*, for 1 min each time. Allow to stand. Separate and discard the organic layer. To the aqueous solution add 0.4 mL of *butylamine R* and 0.1 mL of *triethanolamine R*. Adjust the

solution, if necessary, to pH 10.5 to pH 11.5. Add 4 mL of the solution of hydroxyquinoline in chloroform, shake for 1 min, allow to stand and separate. Use the lower layer for comparison. Prepare a standard in the same manner using a mixture of 1 mL of *magnesium standard solution (10 ppm Mg) R* and 9 mL of *water R*.

Any colour in the solution obtained from the substance to be examined is not more intense than that in the standard.

**01/2008:20407**

## 2.4.7. MAGNESIUM AND ALKALINE-EARTH METALS

To 200 mL of *water R* add 0.1 g of *hydroxylamine hydrochloride R*, 10 mL of *ammonium chloride buffer solution pH 10.0 R*, 1 mL of *0.1 M zinc sulfate* and about 15 mg of *mordant black 11 triturate R*. Heat to about 40 °C. Titrate with *0.01 M sodium edetate* until the violet colour changes to full blue. To the solution add the prescribed quantity of the substance to be examined dissolved in 100 mL of *water R* or use the prescribed solution. If the colour of the solution changes to violet, titrate with *0.01 M sodium edetate* until the full blue colour is again obtained.

The volume of *0.01 M sodium edetate* used in the second titration does not exceed the prescribed quantity.

**07/2010:20408**

## 2.4.8. HEAVY METALS

The methods described below require the use of *thioacetamide reagent R*. As an alternative, *sodium sulfide solution R1* (0.1 mL) is usually suitable. Since tests prescribed in monographs have been developed using *thioacetamide reagent R*, if *sodium sulfide solution R1* is used instead, it is necessary to include also for methods A, B and H a monitor solution, prepared from the quantity of the substance to be examined prescribed for the test, to which has been added the volume of lead standard solution prescribed for preparation of the reference solution. The test is invalid if the monitor solution is not at least as intense as the reference solution.

METHOD A

*Test solution.* 12 mL of the prescribed aqueous solution of the substance to be examined.

*Reference solution (standard).* A mixture of 10 mL of *lead standard solution (1 ppm Pb) R* or *lead standard solution (2 ppm Pb) R*, as prescribed, and 2 mL of the prescribed aqueous solution of the substance to be examined.

*Blank solution.* A mixture of 10 mL of *water R* and 2 mL of the prescribed aqueous solution of the substance to be examined.

To each solution, add 2 mL of *buffer solution pH 3.5 R*. Mix and add to 1.2 mL of *thioacetamide reagent R*. Mix immediately. Examine the solutions after 2 min.

*System suitability*: the reference solution shows a slight brown colour compared to the blank solution.

*Result*: any brown colour in the test solution is not more intense than that in the reference solution.

If the result is difficult to judge, filter the solutions through a suitable membrane filter (nominal pore size 0.45 µm). Carry out the filtration slowly and uniformly, applying moderate and constant pressure to the piston. Compare the spots on the filters obtained with the different solutions.

METHOD B

*Test solution.* 12 mL of the prescribed solution of the substance to be examined prepared using an organic solvent containing a minimum percentage of water (for example, dioxan containing 15 per cent of water or acetone containing 15 per cent of water).

*Reference solution (standard).* A mixture of 10 mL of lead standard solution (1 or 2 ppm Pb), as prescribed, and 2 mL of the prescribed solution of the substance to be examined in an organic solvent. Prepare the lead standard solution (1 or 2 ppm Pb) by dilution of *lead standard solution (100 ppm Pb) R* with the solvent used for the substance to be examined.

*Blank solution.* A mixture of 10 mL of the solvent used for the substance to be examined and 2 mL of the prescribed solution of the substance to be examined in an organic solvent.

To each solution, add 2 mL of *buffer solution pH 3.5 R*. Mix and add to 1.2 mL of *thioacetamide reagent R*. Mix immediately. Examine the solutions after 2 min.

*System suitability*: the reference solution shows a slight brown colour compared to the blank solution.

*Result*: any brown colour in the test solution is not more intense than that in the reference solution.

If the result is difficult to judge, filter the solutions through a suitable membrane filter (nominal pore size 0.45 µm). Carry out the filtration slowly and uniformly, applying moderate and constant pressure to the piston. Compare the spots on the filters obtained with the different solutions.

METHOD C

*Test solution.* Place the prescribed quantity (not more than 2 g) of the substance to be examined in a silica crucible with 4 mL of a 250 g/L solution of *magnesium sulfate R* in *dilute sulfuric acid R*. Mix using a fine glass rod. Heat cautiously. If the mixture is liquid, evaporate gently to dryness on a water-bath. Progressively heat to ignition and continue heating until an almost white or at most greyish residue is obtained. Carry out the ignition at a temperature not exceeding 800 °C. Allow to cool. Moisten the residue with a few drops of *dilute sulfuric acid R*. Evaporate, ignite again and allow to cool. The total period of ignition must not exceed 2 h. Take up the residue in 2 quantities, each of 5 mL, of *dilute hydrochloric acid R*. Add 0.1 mL of *phenolphthalein solution R*, then *concentrated ammonia R* until a pink colour is obtained. Cool, add *glacial acetic acid R* until the solution is decolorised and add 0.5 mL in excess. Filter if necessary and wash the filter. Dilute to 20 mL with *water R*.

*Reference solution (standard).* Prepare as described for the test solution, using the prescribed volume of *lead standard solution (10 ppm Pb) R* instead of the substance to be examined. To 10 mL of the solution obtained add 2 mL of the test solution.

*Monitor solution.* Prepare as described for the test solution, adding to the substance to be examined the volume of *lead standard solution (10 ppm Pb) R* prescribed for preparation of the reference solution. To 10 mL of the solution obtained add 2 mL of the test solution.

*Blank solution.* A mixture of 10 mL of *water R* and 2 mL of the test solution.

To 12 mL of each solution, add 2 mL of *buffer solution pH 3.5 R*. Mix and add to 1.2 mL of *thioacetamide reagent R*. Mix immediately. Examine the solutions after 2 min.

*System suitability*:

- the reference solution shows a slight brown colour compared to the blank solution,
- the monitor solution is at least as intense as the reference solution.

*Result*: any brown colour in the test solution is not more intense than that in the reference solution.

If the result is difficult to judge, filter the solutions through a suitable membrane filter (nominal pore size 0.45 µm). Carry out the filtration slowly and uniformly, applying moderate and constant pressure to the piston. Compare the spots on the filters obtained with the different solutions.

METHOD D

*Test solution.* In a silica crucible, mix thoroughly the prescribed quantity of the substance to be examined with 0.5 g of *magnesium oxide R1*. Ignite to dull redness until a homogeneous white or greyish-white mass is obtained. If after 30 min of ignition the mixture remains coloured, allow to cool, mix using a fine glass rod and repeat the ignition. If necessary repeat the operation. Heat at 800 °C for about 1 h. Take up the residue in 2 quantities, each of 5 mL, of a mixture of equal volumes of *hydrochloric acid R1* and *water R*. Add 0.1 mL of *phenolphthalein solution R* and then *concentrated ammonia R* until a pink colour is obtained. Cool, add *glacial acetic acid R* until the solution is decolorised and add 0.5 mL in excess. Filter if necessary and wash the filter. Dilute to 20 mL with *water R*.

*Reference solution (standard).* Prepare as described for the test solution using the prescribed volume of *lead standard solution (10 ppm Pb) R* instead of the substance to be examined and drying in an oven at 100-105 °C. To 10 mL of the solution obtained add 2 mL of the test solution.

*Monitor solution.* Prepare as described for the test solution, adding to the substance to be examined the volume of *lead standard solution (10 ppm Pb) R* prescribed for preparation of the reference solution and drying in an oven at 100-105 °C. To 10 mL of the solution obtained add 2 mL of the test solution.

*Blank solution.* A mixture of 10 mL of *water R* and 2 mL of the test solution.

To 12 mL of each solution, add 2 mL of *buffer solution pH 3.5 R*. Mix and add to 1.2 mL of *thioacetamide reagent R*. Mix immediately. Examine the solutions after 2 min.

*System suitability*:

- the reference solution shows a slight brown colour compared to the blank solution,
- the monitor solution is at least as intense as the reference solution.

*Result*: any brown colour in the test solution is not more intense than that in the reference solution.

If the result is difficult to judge, filter the solutions through a suitable membrane filter (nominal pore size 0.45 µm). Carry out the filtration slowly and uniformly, applying moderate and constant pressure to the piston. Compare the spots on the filters obtained with the different solutions.

METHOD E

*Test solution.* Dissolve the prescribed quantity of the substance to be examined in 30 mL of *water R* or the prescribed volume.

*Reference solution (standard).* Unless otherwise prescribed, dilute the prescribed volume of *lead standard solution (1 ppm Pb) R* to the same volume as the test solution.

Prepare the filtration apparatus by adapting the barrel of a 50 mL syringe without its piston to a support containing, on the plate, a membrane filter (nominal pore size 3 µm) and above it a prefilter (Figure 2.4.8.-1).

Transfer the test solution into the syringe barrel, put the piston in place and then apply an even pressure on it until the whole of the liquid has been filtered. In opening the support and removing the prefilter, check that the membrane filter remains uncontaminated with impurities. If this is not the case replace it with another membrane filter and repeat the operation under the same conditions.

To the prefiltrate or to the prescribed volume of the prefiltrate add 2 mL of *buffer solution pH 3.5 R*. Mix and add to 1.2 mL of *thioacetamide reagent R*. Mix immediately and allow to stand for 10 min and again filter as described above, but inverting the order of the filters, the liquid passing first through the membrane filter before passing through the prefilter (Figure 2.4.8.-1). The filtration must be carried out slowly and uniformly by applying moderate and constant pressure to the piston of the syringe. After complete filtration, open the support, remove the membrane filter, and dry using filter paper.

In parallel, treat the reference solution in the same manner as the test solution.

*Result*: the colour of the spot obtained with the test solution is not more intense than that obtained with the reference solution.

METHOD F

*Test solution.* Place the prescribed quantity or volume of the substance to be examined in a clean, dry, 100 mL long-necked combustion flask (a 300 mL flask may be used if the reaction

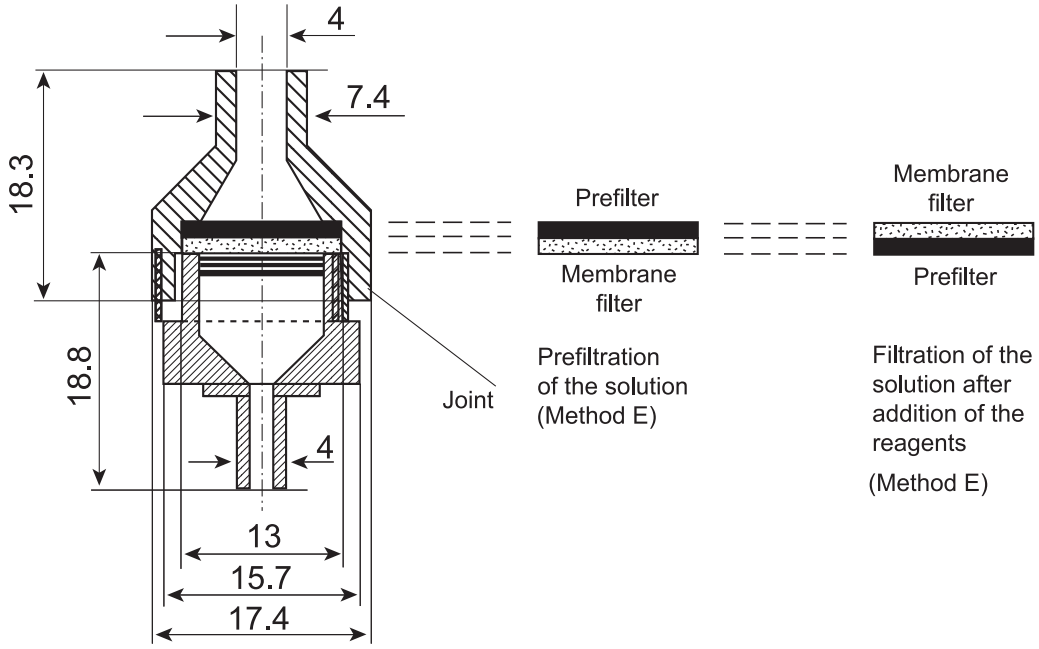

Figure 2.4.8.-1. – *Apparatus for the test for heavy metals*
*Dimensions in millimetres*

foams excessively). Clamp the flask at an angle of 45°. If the substance to be examined is a solid, add a sufficient volume of a mixture of 8 mL of *sulfuric acid R* and 10 mL of *nitric acid R* to moisten the substance thoroughly; if the substance to be examined is a liquid, add a few millilitres of a mixture of 8 mL of *sulfuric acid R* and 10 mL of *nitric acid R*. Warm gently until the reaction commences, allow the reaction to subside and add additional portions of the same acid mixture, heating after each addition, until a total of 18 mL of the acid mixture has been added. Increase the amount of heat and boil gently until the solution darkens. Cool, add 2 mL of *nitric acid R* and heat again until the solution darkens. Continue the heating, followed by the addition of *nitric acid R* until no further darkening occurs, then heat strongly until dense, white fumes are produced. Cool, cautiously add 5 mL of *water R*, boil gently until dense, white fumes are produced and continue heating to reduce to 2-3 mL. Cool, cautiously add 5 mL of *water R* and examine the colour of the solution. If the colour is yellow, cautiously add 1 mL of *strong hydrogen peroxide solution R* and again evaporate until dense, white fumes are produced and reduce to a volume of 2-3 mL. If the solution is still yellow in colour, repeat the addition of 5 mL of *water R* and 1 mL of *strong hydrogen peroxide solution R* until the solution is colourless. Cool, dilute cautiously with *water R* and rinse into a 50 mL colour comparison tube, ensuring that the total volume does not exceed 25 mL. Adjust the solution to pH 3.0-4.0, using short range pH indicator paper as external indicator, with *concentrated ammonia R1* (*dilute ammonia R1* may be used, if desired, as the specified range is approached), dilute with *water R* to 40 mL and mix. Add 2 mL of *buffer solution pH 3.5 R*. Mix and add to 1.2 mL of *thioacetamide reagent R*. Mix immediately. Dilute to 50 mL with *water R* and mix.

*Reference solution (standard).* Prepare at the same time and in the same manner as the test solution, using the prescribed volume of *lead standard solution (10 ppm Pb) R*.

*Monitor solution.* Prepare as described for the test solution, adding to the substance to be examined the volume of *lead standard solution (10 ppm Pb) R* prescribed for the preparation of the reference solution.

*Blank solution.* Prepare as described for the test solution, omitting the substance to be examined.

Examine the solutions vertically against a white background after 2 min.

*System suitability*:

- the reference solution shows a brown colour compared to the blank solution,
- the monitor solution is at least as intense as the reference solution.

*Result*: any brown colour in the test solution is not more intense than that in the reference solution.

If the result is difficult to judge, filter the solutions through a suitable membrane filter (nominal pore size 0.45 µm). Carry out the filtration slowly and uniformly, applying moderate and constant pressure to the piston. Compare the spots on the filters obtained with the different solutions.

METHOD G

*CAUTION: when using high-pressure digestion vessels the safety precautions and operating instructions given by the manufacturer must be followed. The digestion cycles have to be elaborated depending on the type of microwave oven to be used (for example, energy-controlled microwave ovens, temperature-controlled microwave ovens or high-pressure ovens). The cycle must conform to the manufacturer's instructions. The digestion cycle is suitable if a clear solution is obtained.*

*Test solution.* Place the prescribed amount of the substance to be examined (not more than 0.5 g) in a suitable, clean beaker. Add successively 2.7 mL of *sulfuric acid R*, 3.3 mL of *nitric acid R* and 2.0 mL of *strong hydrogen peroxide solution R* using a magnetic stirrer. Allow the substance to react with a reagent before adding the next one. Transfer the mixture to a dry high-pressure-resistant digestion vessel (fluoropolymer or quartz glass).

*Reference solution (standard).* Prepare as described for the test solution, using the prescribed volume of *lead standard solution (10 ppm Pb) R* instead of the substance to be examined.

*Monitor solution.* Prepare as prescribed for the test solution, adding to the substance to be examined the volume of *lead standard solution (10 ppm Pb) R* prescribed for the preparation of the reference solution.

*Blank solution.* Prepare as described for the test solution, omitting the substance to be examined.

Close the vessels and place in a laboratory microwave oven. Digest using a sequence of 2 separate suitable programmes. Design the programmes in several steps in order to control the reaction, monitoring pressure, temperature or energy depending on the type of microwave oven available. After the first programme allow the digestion vessels to cool before opening. Add to each vessel 2.0 mL of *strong hydrogen peroxide solution R* and digest using the second programme. After the second programme allow the digestion vessels to cool before opening. If necessary to obtain a clear solution, repeat the addition of *strong hydrogen peroxide solution R* and the second digestion programme.

Cool, dilute cautiously with *water R* and rinse into a flask, ensuring that the total volume does not exceed 25 mL.

Using short-range pH indicator paper as external indicator, adjust the solutions to pH 3.0-4.0 with *concentrated ammonia R1* (*dilute ammonia R1* may be used as the specified range is approached). To avoid heating of the solutions use an ice-bath and a magnetic stirrer. Dilute to 40 mL with *water R* and mix. Add 2 mL of *buffer solution pH 3.5 R*. Mix and add to 1.2 mL of *thioacetamide reagent R*. Mix immediately. Dilute to 50 mL with *water R*, mix and allow to stand for 2 min.

Filter the solutions through a suitable membrane filter (nominal pore size 0.45 µm). Carry out the filtration slowly and uniformly, applying moderate and constant pressure to the piston. Compare the spots on the filters obtained with the different solutions.

*System suitability*:

- the spot obtained with the reference solution shows a brown colour compared to the spot obtained with the blank solution,
- the spot obtained with the monitor solution is at least as intense as the spot obtained with the reference solution.

*Result*: the brown colour of the spot obtained with the test solution is not more intense than that of the spot obtained with the reference solution.

METHOD H

*Test solution.* Dissolve the prescribed quantity of the substance to be examined in 20 mL of the solvent or solvent mixture prescribed.

*Reference solution.* Dilute the prescribed volume of *lead standard solution (10 ppm Pb) R* to 20 mL with the solvent or solvent mixture prescribed.

*Blank solution.* 20 mL of the solvent or solvent mixture prescribed.

To each solution, add 2 mL of *buffer solution pH 3.5 R*. Mix. *(In some cases precipitation occurs, in which case the specific monograph would describe re-dissolution in a defined volume of a given solvent.)* Add to 1.2 mL of *thioacetamide reagent R*. Mix immediately and allow to stand for 2 min. Filter the solutions through a suitable membrane filter (nominal pore size 0.45 µm). Compare the spots on the filters obtained with the different solutions.

*System suitability*: the spot obtained with the reference solution shows a brownish-black colour compared to the spot obtained with the blank solution.

*Result*: the brownish-black colour of the spot obtained with the test solution is not more intense than that of the spot obtained with the reference solution.

**01/2008:20409**

## 2.4.9. IRON

Dissolve the prescribed quantity of the substance to be examined in *water R* and dilute to 10 mL with the same solvent or use 10 mL of the prescribed solution. Add 2 mL of a 200 g/L solution of *citric acid monohydrate R* and 0.1 mL of *thioglycollic acid R*. Mix, make alkaline with *ammonia R* and dilute to 20 mL with *water R*. Prepare a standard in the same manner, using 10 mL of *iron standard solution (1 ppm Fe) R*.

After 5 min, any pink colour in the test solution is not more intense than that in the standard.

**01/2008:20410**

## 2.4.10. LEAD IN SUGARS

Determine the lead by atomic absorption spectrometry (*2.2.23, Method II*).

*Test solution.* Dissolve 20.0 g of the substance to be examined in a mixture of equal volumes of *dilute acetic acid R* and *water R* and dilute to 100.0 mL with the same mixture of solvents. Add 2.0 mL of a clear 10 g/L solution of *ammonium pyrrolidinedithiocarbamate R* and 10.0 mL of *methyl isobutyl ketone R* and then shake for 30 s protected from bright light. Allow the layers to separate and use the methyl isobutyl ketone layer.

*Reference solutions.* Prepare 3 reference solutions in the same manner as the test solution but adding 0.5 mL, 1.0 mL and 1.5 mL respectively of *lead standard solution (10 ppm Pb) R* in addition to the 20.0 g of the substance to be examined.

Set the zero of the instrument using *methyl isobutyl ketone R* treated as described for the test solution without the substance to be examined. Measure the absorbance at 283.3 nm using a lead hollow-cathode lamp as source of radiation and an air-acetylene flame.

The substance to be examined contains not more than 0.5 ppm of lead, unless otherwise prescribed.

**01/2008:20411**

## 2.4.11. PHOSPHATES

To 100 mL of the solution prepared and, if necessary, neutralised as prescribed add 4 mL of *sulfomolybdic reagent R3*. Shake and add 0.1 mL of *stannous chloride solution R1*. Prepare a standard in the same manner using 2 mL of *phosphate standard solution (5 ppm $PO_4$) R* and 98 mL of *water R*. After 10 min, compare the colours using 20 mL of each solution.

Any colour in the test solution is not more intense than that in the standard.

**01/2008:20412**

## 2.4.12. POTASSIUM

To 10 mL of the prescribed solution add 2 mL of a freshly prepared 10 g/L solution of *sodium tetraphenylborate R*. Prepare a standard in the same manner using a mixture of 5 mL of *potassium standard solution (20 ppm K) R* and 5 mL of *water R*.

After 5 min, any opalescence in the test solution is not more intense than that in the standard.

**01/2008:20413 corrected 8.0**

## 2.4.13. SULFATES

*All solutions used for this test must be prepared with distilled water R.*

Add 3 mL of a 250 g/L solution of *barium chloride R* to 4.5 mL of *sulfate standard solution (10 ppm $SO_4$) R1*. Shake and allow to stand for 1 min. To 2.5 mL of this suspension add 15 mL of the prescribed solution and 0.5 mL of *acetic acid R*. Prepare a standard in the same manner using 15 mL of *sulfate standard solution (10 ppm $SO_4$) R* instead of the prescribed solution.

After 5 min, any opalescence in the test solution is not more intense than that in the standard.

**04/2010:20414**

## 2.4.14. SULFATED ASH[(1)]

Ignite a suitable crucible (for example, silica, platinum, porcelain or quartz) at 600 ± 50 °C for 30 min, allow to cool in a desiccator over silica gel or other suitable desiccant and weigh. Place the prescribed amount of the substance to be examined in the crucible and weigh. Moisten the substance to be examined with a small amount of *sulfuric acid R* (usually 1 mL) and heat gently at as low a temperature as practicable until the sample is thoroughly charred. After cooling, moisten the residue with a small amount of *sulfuric acid R* (usually 1 mL), heat gently until white fumes are no longer evolved and ignite at 600 ± 50 °C until the residue is completely incinerated. Ensure that flames are not produced at any time during the procedure. Allow the crucible to cool in a desiccator over silica gel or other suitable desiccant, weigh it again and calculate the percentage of residue.

If the amount of the residue so obtained exceeds the prescribed limit, repeat the moistening with *sulfuric acid R* and ignition, as previously, for 30 min periods until 2 consecutive weighings do not differ by more than 0.5 mg or until the percentage of residue complies with the prescribed limit.

The amount of substance used for the test (usually 1-2 g) is chosen so that at the prescribed limit the mass of the residue (usually about 1 mg) can be measured with sufficient accuracy.

(1) This chapter has undergone pharmacopoeial harmonisation. See chapter *5.8. Pharmacopoeial harmonisation*.

**01/2008:20415 corrected 7.0**

## 2.4.15. NICKEL IN POLYOLS

Determine the nickel by atomic absorption spectrometry (*2.2.23, Method II*).

*Test solution.* Dissolve 20.0 g of the substance to be examined in a mixture of equal volumes of *dilute acetic acid R* and *water R* and dilute to 100.0 mL with the same mixture of solvents. Add 2.0 mL of a saturated solution of *ammonium pyrrolidinedithiocarbamate R* (about 10 g/L) and 10.0 mL of *methyl isobutyl ketone R* and then shake for 30 s protected from bright light. Allow the layers to separate and use the methyl isobutyl ketone layer.

*Reference solutions.* Prepare 3 reference solutions in the same manner as the test solution but adding 0.5 mL, 1.0 mL and 1.5 mL respectively of *nickel standard solution (10 ppm Ni) R* in addition to the 20.0 g of the substance to be examined.

Set the zero of the instrument using *methyl isobutyl ketone R* treated as described for preparation of the test solution omitting the substance to be examined. Measure the absorbance at 232.0 nm using a nickel hollow-cathode lamp as source of radiation and an air-acetylene flame.

The substance to be examined contains not more than 1 ppm of nickel, unless otherwise prescribed.

**01/2008:20416**

## 2.4.16. TOTAL ASH

Heat a silica or platinum crucible to redness for 30 min, allow to cool in a desiccator and weigh. Unless otherwise prescribed, evenly distribute 1.00 g of the substance or the powdered herbal drug to be examined in the crucible. Dry at 100 °C to 105 °C for 1 h and ignite to constant mass in a muffle furnace at 600 °C ± 25 °C, allowing the crucible to cool in a desiccator after each ignition. Flames should not be produced at any time during the procedure. If after prolonged ignition the ash still contains black particles, take up with hot water, filter through an ashless filter paper and ignite the residue and the filter paper. Combine the filtrate with the ash, carefully evaporate to dryness and ignite to constant mass.

**01/2008:20417**

## 2.4.17. ALUMINIUM

Place the prescribed solution in a separating funnel and shake with 2 quantities, each of 20 mL, and then with one 10 mL quantity of a 5 g/L solution of *hydroxyquinoline R* in *chloroform R*. Dilute the combined chloroform solutions to 50.0 mL with *chloroform R* (test solution).

Prepare a standard in the same manner using the prescribed reference solution.

Prepare a blank in the same manner using the prescribed blank solution.

Measure the intensity of the fluorescence (*2.2.21*) of the test solution ($I_1$), of the standard ($I_2$) and of the blank ($I_3$) using an excitant beam at 392 nm and a secondary filter with a transmission band centred on 518 nm or a monochromator set to transmit at this wavelength.

The fluorescence ($I_1 - I_3$) of the test solution is not greater than that of the standard ($I_2 - I_3$).

**01/2008:20418**

## 2.4.18. FREE FORMALDEHYDE

Use method A, unless otherwise prescribed. Method B is suitable for vaccines where sodium metabisulfite has been used to neutralise excess formaldehyde.

METHOD A

For vaccines for human use, prepare a 1 in 10 dilution of the vaccine to be examined. For bacterial toxoids for veterinary use, prepare a 1 in 25 dilution of the vaccine to be examined.

To 1 mL of the dilution, add 4 mL of *water R* and 5 mL of *acetylacetone reagent R1*. Place the tube in a water-bath at 40 °C for 40 min. Examine the tubes down their vertical axes. The solution is not more intensely coloured than a standard, prepared at the same time and in the same manner, using 1 mL of a dilution of *formaldehyde solution R* containing 20 µg of formaldehyde ($CH_2O$) per millilitre, instead of the dilution of the vaccine to be examined.

METHOD B

*Test solution.* Prepare a 1 in 200 dilution of the vaccine to be examined with *water R*. If the vaccine is an emulsion, prepare an equivalent dilution using the aqueous phase separated by a suitable procedure (see below). If one of the methods described below is used for separation of the aqueous phase, a 1 in 20 dilution of the latter is used.

*Reference solutions.* Prepare solutions containing 0.25 g/L, 0.50 g/L, 1.00 g/L and 2.00 g/L of $CH_2O$ by dilution of *formaldehyde solution R* with *water R*. Prepare a 1 in 200 dilution of each solution with *water R*.

To 0.5 mL of the test solution and of each of the reference solutions in test-tubes, add 5.0 mL of a freshly prepared 0.5 g/L solution of *methylbenzothiazolone hydrazone hydrochloride R*. Close the tubes, shake and allow to stand for 60 min. Add 1 mL of *ferric chloride-sulfamic acid reagent R* and allow to stand for 15 min. Measure the absorbance (*2.2.25*) of the solutions at 628 nm. Calculate the content of formaldehyde in the vaccine to be examined from the calibration curve established using the reference solutions. The test is invalid if the correlation coefficient ($r$) of the calibration curve is less than 0.97.

*Emulsions.* If the vaccine to be examined is an emulsion, the aqueous phase is separated using a suitable procedure and used for preparation of the test solution. The following procedures have been found suitable.

(a) Add 1.0 mL of the vaccine to be examined to 1.0 mL of *isopropyl myristate R* and mix. Add 1.3 mL of *1 M hydrochloric acid*, 2.0 mL of *chloroform R* and 2.7 mL of a 9 g/L solution of *sodium chloride R*. Mix thoroughly. Centrifuge at 15 000 *g* for 60 min. Transfer the aqueous phase to a 10 mL volumetric flask and dilute to volume with *water R*. If this procedure fails to separate the aqueous phase, add 100 g/L of *polysorbate 20 R* to the sodium chloride solution and repeat the procedure but centrifuge at 22 500 *g*.

(b) Add 1.0 mL of the vaccine to be examined to 1.0 mL of a 100 g/L solution of *sodium chloride R* and mix. Centrifuge at 1000 *g* for 15 min. Transfer the aqueous phase to a 10 mL volumetric flask and dilute to volume with *water R*.

(c) Add 1.0 mL of the vaccine to be examined to 2.0 mL of a 100 g/L solution of *sodium chloride R* and 3.0 mL of *chloroform R* and mix. Centrifuge at 1000 *g* for 5 min. Transfer the aqueous phase to a 10 mL volumetric flask and dilute to volume with *water R*.

01/2008:20419

## 2.4.19. ALKALINE IMPURITIES IN FATTY OILS

In a test-tube mix 10 mL of recently distilled *acetone R* and 0.3 mL of *water R* and add 0.05 mL of a 0.4 g/L solution of *bromophenol blue R* in *alcohol R*. Neutralise the solution if necessary with *0.01 M hydrochloric acid* or *0.01 M sodium hydroxide*. Add 10 mL of the oil to be examined, shake and allow to stand. Not more than 0.1 mL of *0.01 M hydrochloric acid* is required to change the colour of the upper layer to yellow.

07/2018:20420
corrected 9.6

## 2.4.20. DETERMINATION OF ELEMENTAL IMPURITIES

INTRODUCTION

This chapter describes the general approach for the determination of elemental impurities in medicinal products or substances for pharmaceutical use. As the chemical composition of the considered samples and the specification limits for the element(s) of interest vary considerably, it is not possible to describe all suitable sample preparation and measurement methods. Therefore, any method that fulfils the requirements described in this chapter may be used.

The results of the analysis are acceptable only if the system suitability has been demonstrated by a suitable test. Before the initial use of a method, the analyst must ensure that the method is appropriate for the samples and instruments used. This is accomplished by applying a validation procedure to methods not described in the individual monograph or by a system suitability test for methods which are described in the monograph. Decision trees for the choice of the sample preparation and the measurement procedures are presented in Figures 2.4.20.-1 and 2.4.20.-2.

PROCEDURES

As a reference procedure is not provided for each element, matrix and concentration, the choice of procedure according to Figures 2.4.20.-1 and 2.4.20.-2, including sample preparation, detection technique and instrument parameters, is the responsibility of the user.

Use the flow chart in Figure 2.4.20.-1 to define the sample preparation method and the flow chart in Figure 2.4.20.-2 to define the measurement method. The sample preparation method should yield a sufficient quantity of sample to allow quantification of each element at the specified limit stated in the individual monograph or the general chapter.

All suitable sample preparation methods and measurement techniques (e.g. *2.2.22. Atomic emission spectrometry* (AES), *2.2.23. Atomic absorption spectrometry* (AAS), *2.2.37. X-ray fluorescence spectrometry* (XRFS), *2.2.57. Inductively coupled plasma-atomic emission spectrometry* (ICP-AES), *2.2.58. Inductively coupled plasma-mass spectrometry* (ICP-MS), *2.4.2. Arsenic*, *2.4.8. Heavy metals*, *2.4.9. Iron*, *2.4.10. Lead in sugars*, *2.4.15. Nickel in polyols*, *2.4.31. Nickel in hydrogenated vegetable oils*) can be used for the determination of elemental impurities, if the method has been verified before the initial use by a system suitability test or a validation procedure according to this chapter.

If no sample preparation and/or measurement method is described in the individual monograph, a suitable sample preparation and/or measurement method must be developed and validated (see Figures 2.4.20.-1 and 2.4.20.-2).

*SAMPLE PREPARATION*

Sample preparation is critical to the success of elemental analysis. Many techniques not using direct measurement are heavily dependent on sample transport.

If an atomisation system is used, the most conventional means by which samples are introduced into the atomisation system is by solution nebulisation. In this case, solid samples must be dissolved in order to be introduced into the atomisation system. Samples may be dissolved in any appropriate solvent. The use of aqueous or dilute nitric acid solutions is strongly recommended, due to minimal interference with these solvents compared to other solvents. Hydrochloric acid, hydrofluoric acid, perchloric acid, sulfuric acid and hydrogen peroxide, at various concentrations, can be used to dissolve the samples. The viscosity of sulfuric acid is greater than that of the other acids and is to be taken into account as it can affect the overall fluidity of the solution.

The choice of solvents also includes, but is not limited to, the use of dilute bases, straight or diluted organic solvents, combinations of acids or bases, and combinations of organic solvents.

Acids, bases, and hydrogen peroxide of high purity must be used, especially when ICP-MS is employed. For aqueous solutions, use *deionised distilled water R*. Diluents must be checked for interference if they are used in an analysis. Because it is not always possible to obtain organic solvents that are free from elemental impurities, organic solvents of the highest purity possible with regard to these contaminants must be used. Specifically for ICP techniques, where samples are introduced into the plasma via solution nebulisation, it is important to consider the potential matrix effects and interferences that might arise from the solvent. The use of an appropriate internal standard and/or matching the standard matrix with samples should be applied for ICP-AES and ICP-MS analyses in cases where accuracy and precision are not sufficient. In any case, the selection of an appropriate internal standard should take into account the element(s) of interest, ionisation energy, wavelengths or masses, and the nature of the sample matrix.

Where a sample is found not to be soluble in any acceptable solvent, a variety of digestion or incineration techniques can be employed. These include hot-plate digestion, incineration and microwave-assisted digestions, using an open- or closed-vessel.

The decision regarding the type of digestion technique to be used depends on the nature of the sample being digested, as well as on the element(s) of interest and the concentration range of the elements to be quantified. Open-vessel digestion is not recommended for the analysis of volatile elements. The suitability of a digestion technique, whether open- or closed-vessel, should be supported by spike recovery experiments in order to verify that, within an acceptable tolerance, volatile elements have not been lost during sample preparation. The digestion cycle is suitable if a clear solution is obtained.

It is important to consider the selection of the type, the material of construction, the pretreatment, and the cleaning of analytical labware used in elemental analyses. The material must be inert and, depending on the specific application, resistant to caustics, acids, and/or organic solvents. For some analyses, care must be exercised to prevent the adsorption of elemental impurities onto the surface of a vessel, particularly in ultra-trace analyses. Contamination of sample solutions by elemental impurities and ions present in the container can also lead to inaccurate results.

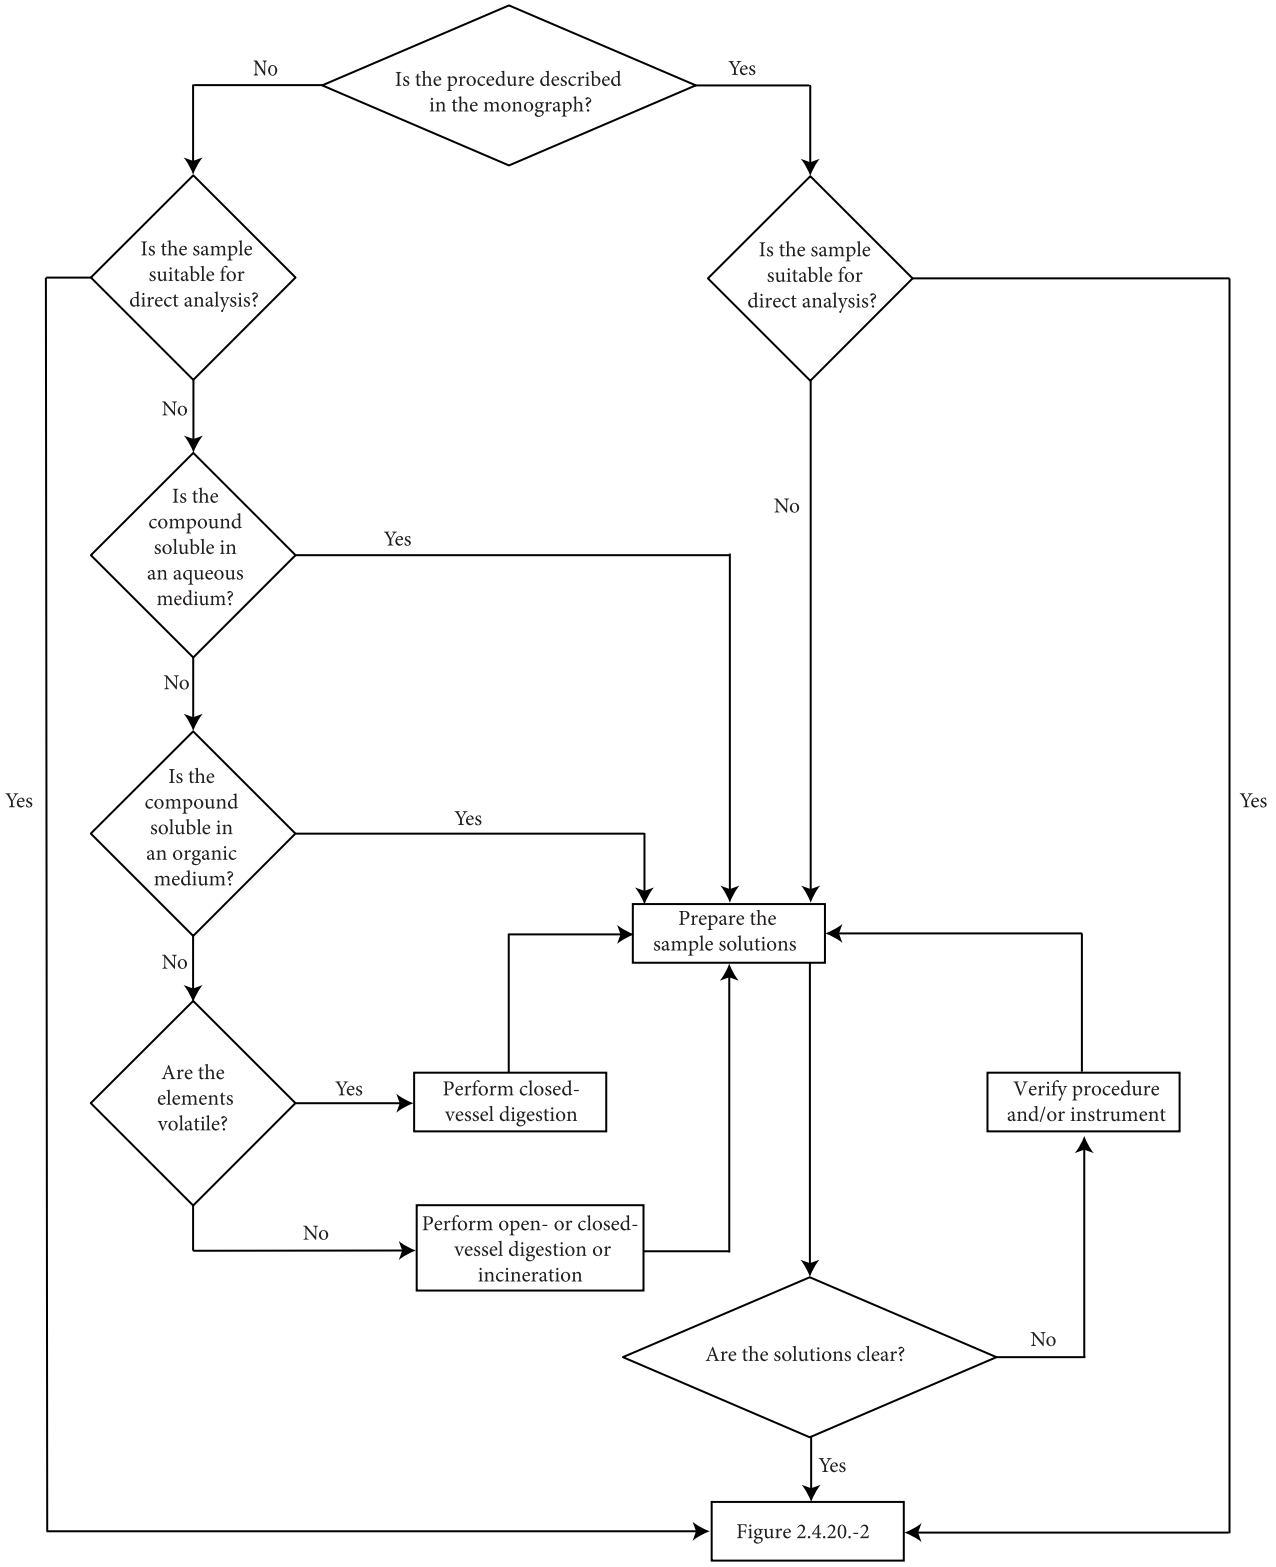

Figure 2.4.20.-1. – *Elemental impurities decision tree: sample preparation*

The use of volumetric glassware that does not comply with Class A requirements of the appropriate International Standard of the International Organization for Standardization (ISO) is acceptable if the validation or the system suitability test of the method using such glassware have experimentally demonstrated that the method is suitable for the intended purpose.

*CAUTION: when using high-pressure digestion vessels and microwave laboratory equipment, the safety precautions and operating instructions given by the manufacturer must be followed.*

*MEASUREMENT*

**Method**. The choice of the techniques depends mainly on the sample matrix and the characteristics and specification limits of the element(s) of interest. Analyse according to the instructions of the manufacturer of the equipment regarding program and wavelength.

**System suitability**. A system suitability test must be carried out on the day of the analysis to ensure that the sample preparation and measurement system are appropriate.

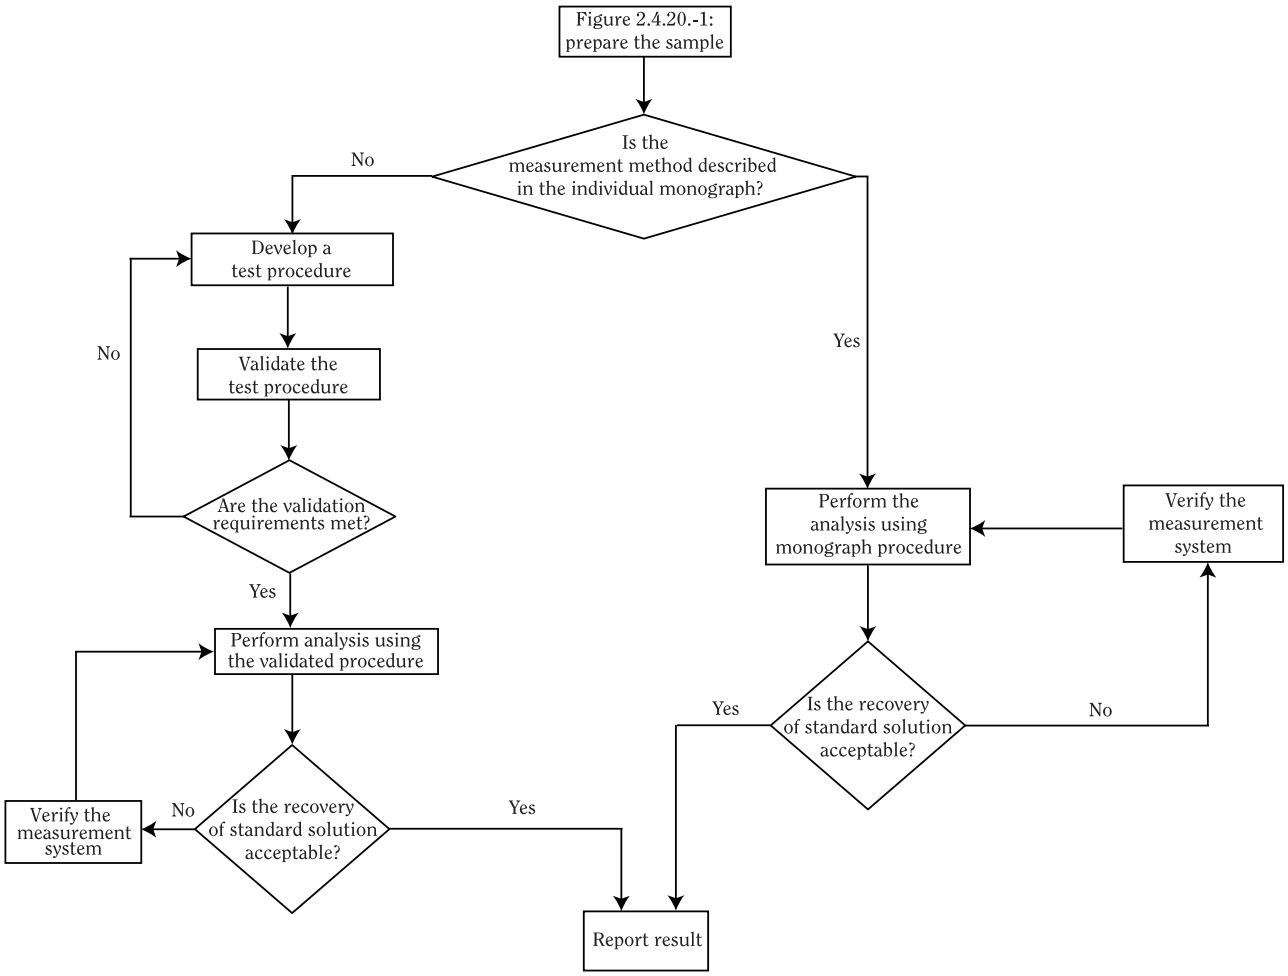

Figure 2.4.20.-2. – *Elemental impurities decision tree: measurement*

*Acceptance criterion for preparation of sample solution*: a clear solution is obtained.

*Acceptance criterion for measurement system*: the measured concentration of a standard solution of the element at a concentration within the range of the used calibration curve does not differ from the actual concentration by more than 20 per cent.

**Calculation**. The blank value of reagents must be taken into account for the calculation of the content. Upon completion of the analysis, the concentration of a given element in the sample is calculated by the software of the instrument from the concentration of the element in the test solution. If no calculation software is available or no indication for calculation is given in the general chapter corresponding to the method used, the concentration of a given element in the sample can be calculated from the concentration of the element in the solution using the following expression:

$$C = A \times \frac{V_1}{m} \times \frac{V_2}{V_3}$$

$C$ = concentration of element in the analysed sample, in micrograms per gram;

$A$ = instrument reading of the concentration of the element in the sample solution, in micrograms per millilitre;

$m$ = mass of the sample in the initial sample solution, in grams;

$V_1$ = volume of the initial sample preparation, in millilitres;

$V_2$ = total volume of any dilution performed, in millilitres;

$V_3$ = volume of initial sample preparation used in any dilution performed, in millilitres.

VALIDATION REQUIREMENTS

Some validation requirements provided below may differ from those provided in general chapters of the Ph. Eur. (e.g. *2.2.22* (AES), *2.2.23* (AAS), *2.2.57* (ICP-AES), *2.2.58* (ICP-MS)).

Before the initial use of the selected procedure, the analyst must ensure that the sample preparation and measurement method are appropriate for the element(s) of interest, sample matrix and instrument used. This is accomplished by following the validation procedure before the initial use and the system suitability test on the day of the analysis.

For elemental impurities, validation of a limit test must include specificity and limit of detection.

The following section defines the characteristics for the acceptability of a quantitative procedure. It must be demonstrated experimentally that such a procedure complies with the validation requirements, with an appropriate system suitability test using material spiked with a suitable reference material. The test materials must be spiked before any sample preparation steps. For example, if a test material is to be digested, the material must be spiked at the beginning of the digestion procedure.

*SPECIFICITY*

Specificity is the ability to ensure that the analytical procedure (sample preparation and measurement) allows a reliable determination of the element(s) of interest in the presence of components (e.g. carrier gas, impurities, matrix) that may be expected to be present.

*Acceptance criteria*: the procedure must be able to assess unequivocally each elemental impurity to be determined with this procedure in the presence of components that may be expected to be present, including other elemental impurities, matrix components and other sources of interference; specificity is demonstrated by complying with the accuracy requirement for the element(s) to be determined.

*RANGE*

*Acceptance criterion*: range is demonstrated by complying with the recovery requirement.

*ACCURACY*

Verify the accuracy using a certified reference material or by performing a test for recovery. *Elemental impurity solutions CRS* may be used.

The recovery may be determined on a sample of the substance to be examined, spiked with a known quantity of a reference standard of the element of interest (3 concentration levels in the range of 50-150 per cent of the intended specification limit, even if the original concentration of the reference standard is at the specified value), in triplicate.

*Acceptance criterion*: spike recovery is within 70 per cent and 150 per cent for the mean of 3 replicates at each concentration.

*REPEATABILITY*

*Test samples*: either 6 independent samples of the substance to be examined spiked with a suitable reference standard at the specified concentration level, or 3 concentration levels prepared in triplicate.

*Acceptance criterion*: the relative standard deviation is in both cases not more than 20 per cent.

*INTERMEDIATE PRECISION*

The effect of random events (intra-laboratory variations) on the analytical precision of the method must be established. Acceptable experiments for establishing intermediate precision include performing the repeatability analysis on different days, or with different instrumentation, or by different analysts. Only 1 of the 3 experiments is required to demonstrate intermediate precision.

*Acceptance criterion*: the relative standard deviation is not more than 25 per cent.

*LIMIT OF QUANTIFICATION*

Use the results from the accuracy study. Determine the lowest concentration meeting the acceptance criterion.

*Acceptance criterion*: the limit of quantification is below the specification limit.

*LIMIT OF DETECTION (ONLY APPLICABLE TO LIMIT TESTS)*

Determine the lowest concentration giving a signal clearly distinct from that obtained with a blank solution.

*Acceptance criterion*: the limit of detection is not more than 0.5 times the concentration of the specification limit.

**01/2008:20421**

## 2.4.21. FOREIGN OILS IN FATTY OILS BY THIN-LAYER CHROMATOGRAPHY

Examine by thin-layer chromatography (*2.2.27*) using *kieselguhr G R* as the coating substance. Impregnate a plate by placing it in a chromatographic tank containing the necessary quantity of a mixture of 10 volumes of *liquid paraffin R* and 90 volumes of *light petroleum R* so that the plate dips about 5 mm beneath the surface of the liquid. When the impregnation mixture has risen by at least 12 cm from the lower edge of the plate, remove the plate and allow the solvent to evaporate for 5 min. Carry out the chromatography in the same direction as the impregnation.

*Preparation of the mixture of fatty acids.* Heat 2 g of the oil with 30 mL of *0.5 M alcoholic potassium hydroxide* under a reflux condenser for 45 min. Add 50 mL of *water R*, allow to cool, transfer to a separating funnel and extract with three quantities, each of 50 mL, of *ether R*. Discard the ether extracts, acidify the aqueous layer with *hydrochloric acid R* and extract with three quantities, each of 50 mL, of *ether R*. Combine the ether extracts and wash with three quantities, each of 10 mL, of *water R*; discard the washings, dry the ether over *anhydrous sodium sulfate R* and filter. Evaporate the ether on a water-bath. Use the residue to prepare the test solution. The fatty acids may also be obtained from the soap solution prepared during the determination of the unsaponifiable matter.

*Test solution.* Dissolve 40 mg of the mixture of fatty acids obtained from the substance to be examined in 4 mL of *chloroform R*.

*Reference solution.* Dissolve 40 mg of the mixture of fatty acids obtained from a mixture of 19 volumes of *maize oil R* and 1 volume of *rapeseed oil R* in 4 mL of *chloroform R*.

Apply to the plate 3 µL of each solution. Develop over a path of 8 cm using a mixture of 10 volumes of *water R* and 90 volumes of *glacial acetic acid R*. Dry the plate at 110 °C for 10 min. Allow to cool and, unless otherwise prescribed, place the plate in a chromatographic chamber, with a tightly fitting lid, that has previously been saturated with iodine vapour by placing *iodine R* in an evaporating dish at the bottom of the chamber. After some time brown or yellowish-brown spots become visible. Remove the plate and allow to stand for a few minutes. When the brown background colour has disappeared, spray with *starch solution R*. Blue spots appear which may become brown on drying and again become blue after spraying with *water R*. The chromatogram obtained with the test solution always shows a spot with an $R_F$ of about 0.5 (oleic acid) and a spot with an $R_F$ of about 0.65 (linoleic acid) corresponding to the spots in the chromatogram obtained with the reference solution. With some oils a spot with an $R_F$ of about 0.75 may be present (linolenic acid). By comparison with the spot in the chromatogram obtained with the reference solution, verify the absence in the chromatogram obtained with the test solution of a spot with an $R_F$ of about 0.25 (erucic acid).

**07/2016:20422**

## 2.4.22. COMPOSITION OF FATTY ACIDS BY GAS CHROMATOGRAPHY

The test for foreign oils is carried out on the methyl esters of the fatty acids contained in the oil to be examined by gas chromatography (*2.2.28*).

METHOD A

*This method is not applicable to oils that contain glycerides of fatty acids with an epoxy-, hydroepoxy-, hydroperoxy-, cyclopropyl or cyclopropenyl group, or those that contain a large proportion of fatty acids of chain length less than 8 carbon atoms or to oils with an acid value greater than 2.0.*

*Test solution.* When prescribed in the monograph, dry the oil to be examined before the methylation step. Weigh 1.0 g of the oil into a 25 mL round-bottomed flask with a ground-glass neck fitted with a reflux condenser and a gas port into the flask. Add 10 mL of *anhydrous methanol R* and 0.2 mL of a 60 g/L solution of *potassium hydroxide R* in *methanol R*. Attach the

reflux condenser, pass *nitrogen R* through the mixture at a rate of about 50 mL/min, shake and heat to boiling. When the solution is clear (usually after about 10 min), continue heating for a further 5 min. Cool the flask under running water and transfer the contents to a separating funnel. Rinse the flask with 5 mL of *heptane R* and transfer the rinsings to the separating funnel and shake. Add 10 mL of a 200 g/L solution of *sodium chloride R* and shake vigorously. Allow to separate and transfer the organic layer to a vial containing *anhydrous sodium sulfate R*. Allow to stand, then filter.

*Reference solution (a).* Prepare 0.50 g of the mixture of calibrating substances with the composition described in one of the 2.4.22 tables, as prescribed in the individual monograph (if the monograph does not mention a specific solution, use the composition described in Table 2.4.22.-1). Dissolve in *heptane R* and dilute to 50.0 mL with the same solvent.

*Reference solution (b).* Dilute 1.0 mL of reference solution (a) to 10.0 mL with *heptane R*.

*Reference solution (c).* Prepare 0.50 g of a mixture of fatty acid methyl esters that corresponds in composition to the mixture of fatty acids indicated in the monograph of the substance to be examined. Dissolve in *heptane R* and dilute to 50.0 mL with the same solvent. Commercially available mixtures of fatty acid methyl esters may also be used.

*Column*:

- *material*: fused silica, glass or quartz;
- *size*: *l* = 10-30 m, Ø = 0.2-0.8 mm;
- *stationary phase*: *macrogol 20 000 R* (film thickness 0.1-0.5 µm) or another suitable stationary phase.

*Carrier gas*: *helium for chromatography R* or *hydrogen for chromatography R*.

*Flow rate*: 1.3 mL/min (for a column Ø = 0.32 mm).

*Split ratio*: 1:100 or less, according to the internal diameter of the column used (1:50 when Ø = 0.32 mm).

*Temperature*:

- *column*: in isothermal conditions, 160-200 °C, according to the length and type of column used (200 °C for a column 30 m long and coated with a layer of *macrogol 20 000 R*); if a linear temperature programming is necessary, raise the temperature of the column at a rate of 3 °C/min from 170 °C to 230 °C, for example;
- *injection port*: 250 °C;
- *detector*: 250 °C.

*Detection*: flame ionisation.

*Injection*: 1 µL.

*System suitability* when using the mixture of calibrating substances in Table 2.4.22.-1 or Table 2.4.22.-3:

- *resolution*: minimum 1.8 between the peaks due to methyl oleate and methyl stearate in the chromatogram obtained with reference solution (a);
- *signal-to-noise ratio*: minimum 5 for the peak due to methyl myristate in the chromatogram obtained with reference solution (b);
- *number of theoretical plates*: minimum 30 000, calculated for the peak due to methyl stearate in the chromatogram obtained with reference solution (a).

*System suitability* when using the mixture of calibrating substances in Table 2.4.22.-2:

- *resolution*: minimum 4.0 between the peaks due to methyl caprylate and methyl decanoate in the chromatogram obtained with reference solution (a);
- *signal-to-noise ratio*: minimum 5 for the peak due to methyl caproate in the chromatogram obtained with reference solution (b);
- *number of theoretical plates*: minimum 15 000, calculated for the peak due to methyl decanoate in the chromatogram obtained with reference solution (a).

*ASSESSMENT OF CHROMATOGRAMS*

Avoid working conditions tending to give masked peaks (presence of constituents with small differences between retention times, for example linolenic acid and arachidic acid).

**Qualitative analysis**. Identify the peaks in the chromatogram obtained with reference solution (c) (isothermal operating conditions or linear temperature programming).

When using isothermal operating conditions, the peaks may also be identified by drawing calibration curves using the chromatogram obtained with reference solution (a) and the information given in Tables 2.4.22.-1, 2.4.22.-2 or 2.4.22.-3.

Table 2.4.22.-1. – *Mixture of calibrating substances (for gas chromatography with capillary column and split inlet system, it is recommended that the component with the longest chain length of the mixture to be examined be added to the calibration mixture, when the qualitative analysis is done using calibration curves)*

| Mixture of the following substances | Composition (per cent *m/m*) |
|---|---|
| *Methyl laurate R* | 5 |
| *Methyl myristate R* | 5 |
| *Methyl palmitate R* | 10 |
| *Methyl stearate R* | 20 |
| *Methyl arachidate R* | 40 |
| *Methyl oleate R* | 20 |

Table 2.4.22.-2. – *Mixture of calibrating substances (for gas chromatography with capillary column and split inlet system, it is recommended that the component with the longest chain length of the mixture to be examined be added to the calibration mixture, when the qualitative analysis is done using calibration curves)*

| Mixture of the following substances | Composition (per cent *m/m*) |
|---|---|
| *Methyl caproate R* | 10 |
| *Methyl caprylate R* | 10 |
| *Methyl decanoate R* | 20 |
| *Methyl laurate R* | 20 |
| *Methyl myristate R* | 40 |

Table 2.4.22.-3. – *Mixture of calibrating substances (for gas chromatography with capillary column and split inlet system, it is recommended that the component with the longest chain length of the mixture to be examined be added to the calibration mixture, when the qualitative analysis is done using calibration curves)*

| Mixture of the following substances | Composition (per cent *m/m*) |
|---|---|
| *Methyl myristate R* | 5 |
| *Methyl palmitate R* | 10 |
| *Methyl stearate R* | 15 |
| *Methyl arachidate R* | 20 |
| *Methyl oleate R* | 20 |
| *Methyl eicosenoate R* | 10 |
| *Methyl behenate R* | 10 |
| *Methyl lignocerate R* | 10 |

Measure the reduced retention time ($t'_R$) of each peak in the chromatogram obtained with reference solution (a). $t'_R$ is the retention time measured from the solvent peak and not from the time of injection. Plot the straight line:

$$\log_{10}(t'_R) = f(\text{equivalent chain length})$$

The logarithms of $t'_R$ of unsaturated acids are situated on this line at points corresponding to non-integer values of carbon atoms known as 'equivalent chain lengths'; the equivalent chain length is the length of the theoretical saturated chain that would have the same $t'_R$ as the fatty acid to be identified. For example, linoleic acid has the same $t'_R$ as the theoretical saturated fatty acid having 18.8 carbon atoms.

Identify the peaks in the chromatogram obtained with the test solution by means of the straight line and the reduced retention times. Equivalent chain lengths are given in Table 2.4.22.-4.

Table 2.4.22.-4. – *Equivalent chain lengths (this value, which is to be calculated using calibration curves, is given as an example for a column of macrogol 20 000 R)*

| Fatty acid | Equivalent chain length |
|---|---|
| Caproic acid | 6.0 |
| Caprylic acid | 8.0 |
| Capric acid | 10.0 |
| Lauric acid | 12.0 |
| Myristic acid | 14.0 |
| Palmitic acid | 16.0 |
| Palmitoleic acid | 16.3 |
| Margaric acid | 17.0 |
| Stearic acid | 18.0 |
| Oleic acid | 18.3 |
| Linoleic acid | 18.8 |
| Gamma-linolenic acid | 19.0 |
| Alpha-linolenic acid | 19.2 |
| Arachidic acid | 20.0 |
| Eicosenoic acid (gondoic acid) | 20.2 |
| Arachidonic acid | 21.2 |
| Behenic acid | 22.0 |
| Erucic acid | 22.2 |
| 12-Oxostearic acid | 22.7 |
| Ricinoleic acid | 23.9 |
| 12-Hydroxystearic acid | 23.9 |
| Lignoceric acid | 24.0 |
| Nervonic acid | 24.2 |

**Quantitative analysis**. In general, the normalisation procedure is used in which the sum of the areas of the peaks in the chromatogram, except that of the solvent, is set at 100 per cent. The content of a constituent is calculated by determining the area of the corresponding peak as a percentage of the sum of the areas of all the peaks. Disregard any peak with an area less than 0.05 per cent of the total area.

In certain cases, for example in the presence of fatty acids with 12 or less carbon atoms, correction factors can be prescribed in the individual monograph to convert peak areas in per cent *m/m*.

METHOD B

*This method is not applicable to oils that contain glycerides of fatty acids with an epoxy-, hydroepoxy-, hydroperoxy-, cyclopropyl or cyclopropenyl group or to oils with an acid value greater than 2.0.*

*Test solution.* Introduce 0.100 g of the substance to be examined into a 10 mL centrifuge tube with a screw cap. Dissolve with 1 mL of *heptane R* and 1 mL of *dimethyl carbonate R* and mix vigorously under gentle heating (50-60 °C). Add, while still warm, 1 mL of a 12 g/L solution of *sodium R* in *anhydrous methanol R*, prepared with the necessary precautions, and mix vigorously for about 5 min. Add 3 mL of *distilled water R* and mix vigorously for about 30 s. Centrifuge for 15 min at 1500 *g*. Inject 1 µL of the organic phase.

*Reference solutions and assessment of chromatograms.* Where there is no specific prescription in the individual monograph, proceed as described under Method A.

*Column*:

- *material*: fused silica;
- *size*: *l* = 30 m, Ø = 0.25 mm;
- *stationary phase*: *macrogol 20 000 R* (film thickness 0.25 µm).

*Carrier gas*: *helium for chromatography R*.

*Flow rate*: 0.9 mL/min.

*Split ratio*: 1:100.

*Temperature*:

| | Time (min) | Temperature (°C) |
|---|---|---|
| Column | 0 - 15 | 100 |
| | 15 - 36 | 100 → 225 |
| | 36 - 61 | 225 |
| Injection port | | 250 |
| Detector | | 250 |

*Detection*: flame ionisation.

*Injection*: 1 µL.

METHOD C

*This method is not applicable to oils that contain glycerides of fatty acids with epoxy-, hydroepoxy-, hydroperoxy-, aldehyde, ketone, cyclopropyl and cyclopropenyl groups, and conjugated polyunsaturated and acetylenic compounds because of partial or complete destruction of these groups.*

*Test solution.* Dissolve 0.10 g of the substance to be examined in 2 mL of a 20 g/L solution of *sodium hydroxide R* in *methanol R* in a 25 mL conical flask and boil under a reflux condenser for 30 min. Add 2.0 mL of *boron trifluoride-methanol solution R* through the condenser and boil for 30 min. Add 4 mL of *heptane R* through the condenser and boil for 5 min. Cool and add 10.0 mL of *saturated sodium chloride solution R*, shake for about 15 s and add a quantity of *saturated sodium chloride solution R* such that the upper phase is brought into the neck of the flask. Collect 2 mL of the upper phase, wash with 3 quantities, each of 2 mL, of *water R* and dry over *anhydrous sodium sulfate R*.

*Reference solutions, chromatographic procedure and assessment of chromatograms.* Where there is no specific prescription in the individual monograph, proceed as described under Method A.

corrected 10.0

# 2.4.23. STEROLS IN FATTY OILS

*When the monograph does not specify the method to be used, method A is applied. Any change from method A to method B must be validated.*

METHOD A

**Separation of the sterol fraction (TLC)**

Prepare the unsaponifiable matter and then isolate the sterol fraction of the fatty oil by thin-layer chromatography (*2.2.27*), using a *TLC silica gel plate R* with a 0.2 mm to 0.5 mm layer.

*Test solution (a).* In a 150 mL flask fitted with a reflux condenser, place a volume of a 2 g/L solution of *betulin R* in *methylene chloride R* containing betulin corresponding to about 10 per cent of the sterol content of the sample used for the determination (e.g. in the case of olive oil add 500 µL, in the case of other vegetable oils add 1500 µL of the betulin solution). If the monograph requires the percentage content of the individual sterols in the sterol fraction, the addition of betulin may be omitted. Evaporate to dryness under a current of *nitrogen R*. Add 5.00 g (*m*) of the substance to be examined. Add 50 mL of *2 M alcoholic potassium hydroxide R* and heat on a water-bath for 1 h, swirling frequently. Cool to a temperature below 25 °C and transfer the contents of the flask to a separating funnel with 100 mL of *water R*. Shake the liquid carefully with 3 quantities, each of 100 mL, of *peroxide-free ether R*. Combine the ether layers in another separating funnel containing 40 mL of *water R*, shake gently for a few minutes, allow to separate and reject the aqueous phase. Wash the ether phase with several quantities, each of 40 mL, of *water R*, until the aqueous phase is no longer alkaline to phenolphthalein. Transfer the ether phase to a tared flask, washing the separating funnel with *peroxide-free ether R*. Distil off the ether with suitable precautions and add 6 mL of *acetone R* to the residue. Carefully remove the solvent in a current of *nitrogen R*. Dry to constant mass at 100-105 °C. Allow to cool in a desiccator and weigh. Transfer the residue to a small test tube with *methylene chloride R*. Evaporate under a stream of *nitrogen R* to a volume of about 1 mL. Depending on the unsaponifiable content of the oil, adapt the final concentration of the solution to 25-50 mg/mL.

*Test solution (b).* Treat 5.00 g of *rapeseed oil R* as prescribed for the substance to be examined, beginning at the words "Add 50 mL of *2 M alcoholic potassium hydroxide R*".

*Test solution (c).* Treat 5.00 g of *sunflower oil R* as prescribed for the substance to be examined, beginning at the words "Add 50 mL of *2 M alcoholic potassium hydroxide R*".

*Reference solution.* Dissolve 25 mg of *cholesterol R* and 10 mg of *betulin R* in 1 mL of *methylene chloride R*.

Use a separate plate for each test solution. Apply as a band of 10 mm, at 20 mm from the base and 10 mm from the left edge, 10 µL of the reference solution and as bands of 150 mm, at 20 mm from the base, 0.5 mL of test solutions (a), (b) or (c). Develop over a path of 17 cm using a mixture of 35 volumes of *ether R* and 65 volumes of *hexane R*. Dry the plates in a current of *nitrogen R*. Spray the plates with a 2 g/L solution of *dichlorofluorescein R* in *anhydrous ethanol R* and examine in ultraviolet light at 254 nm. The chromatogram obtained with the reference solution shows bands due to cholesterol and betulin. The chromatograms obtained with the test solutions show bands with similar $R_F$ values due to sterols. From each of the chromatograms, remove an area of coating corresponding to the area occupied by the sterol bands and additionally the area of the zones 2-3 mm above and below the visible zones corresponding to the reference solution. Place separately in three 50 mL flasks. To each flask add 15 mL of *methylene chloride R* and heat under reflux with stirring, for 15 min. Filter each solution through a sintered-glass filter (40) (*2.1.2*) or suitable filter paper and wash each filter with 3 quantities, each of 15 mL, of *methylene chloride R*. Place the combined filtrate and washings from each filter separately in 3 flasks, evaporate under a stream of *nitrogen R* to 5-10 mL. Transfer to a small test tube and evaporate to dryness under a stream of *nitrogen R*.

**Determination of the sterols (GC)**

Gas chromatography (*2.2.28*). *Carry out the operations protected from humidity and prepare the solutions immediately before use.*

*Test solution.* To the sterols separated from the substance to be examined by thin-layer chromatography add a freshly prepared mixture of 0.04 mL of *chlorotrimethylsilane R*, 0.1 mL of *hexamethyldisilazane R* and 0.5 mL of *anhydrous pyridine R*. Allow to stand for at least 5 min and use the liquid phase.

*Reference solution (a).* To 9 parts of the sterols separated from *rapeseed oil R* by thin-layer chromatography add 1 part of *cholesterol R*. To the mixture add a freshly prepared mixture of 0.04 mL of *chlorotrimethylsilane R*, 0.1 mL of *hexamethyldisilazane R* and 0.5 mL of *anhydrous pyridine R*. Allow to stand for at least 5 min and use the liquid phase.

*Reference solution (b).* To the sterols separated from *sunflower oil R* by thin-layer chromatography add a freshly prepared mixture of 0.04 mL of *chlorotrimethylsilane R*, 0.1 mL of *hexamethyldisilazane R* and 0.5 mL of *anhydrous pyridine R*. Allow to stand for at least 5 min and use the liquid phase.

*Column*:

- *material*: fused silica;
- *size*: *l* = 20-30 m, Ø = 0.25-0.32 mm;
- *stationary phase*: *phenyl(5)methyl(95)polysiloxane R* or *cyanopropyl(7)phenyl(7)methyl(86)polysiloxane R* (film thickness 0.25 µm).

*Carrier gas*: *hydrogen for chromatography R* or *helium for chromatography R*.

*Linear velocity*: 30-50 cm/s (hydrogen) or 20-35 cm/s (helium).

*Split ratio*: 1:50 (hydrogen) or 1:100 (helium).

*Temperature*:

- *column*: 260 °C;
- *injection port*: 280 °C;
- *detector*: 290 °C.

*Detection*: flame ionisation.

*Injection*: 1 µL.

*Identification of peaks*: the chromatogram obtained with reference solution (a) shows 4 principal peaks corresponding to cholesterol, brassicasterol, campesterol and β-sitosterol and the chromatogram obtained with reference solution (b) shows 4 principal peaks corresponding to campesterol, stigmasterol, β-sitosterol and Δ7-stigmastenol. The relative retentions of the sterols with reference to β-sitosterol (main peak) are given in Table 2.4.23.-1.

Table 2.4.23.-1. – *Relative retentions of sterols with reference to β-sitosterol for 2 different columns*

| | Cyanopropyl(7)-(phenyl)(7)-(methyl)(86)polysiloxane | Phenyl(5)methyl(95)-polysiloxane |
|---|---|---|
| Cholesterol | 0.64 | 0.63 |
| Brassicasterol | 0.70 | 0.71 |
| 24-Methylenecholesterol | 0.79 | 0.80 |
| Campesterol | 0.82 | 0.81 |
| Campestanol | 0.83 | 0.82 |
| Stigmasterol | 0.87 | 0.87 |
| Δ7-Campesterol | 0.93 | 0.92 |
| Δ5,23-Stigmastadienol | 0.95 | 0.95 |
| Clerosterol | 0.96 | 0.96 |
| β-Sitosterol | 1 | 1 |
| Sitostanol | 1.01 | 1.02 |
| Δ5-Avenasterol | 1.03 | 1.03 |
| Δ5,24-Stigmastadienol | 1.09 | 1.08 |
| Δ7-Stigmastenol(1) | 1.13 | 1.12 |
| Δ7-Avenasterol | 1.18 | 1.16 |
| Betulin | 1.4 | 1.4 |

(1) This sterol may also be referred to as Δ7-stigmasterol in literature.

The peak due to the internal standard (betulin) must be clearly separated from the peaks due to the sterols to be determined.

For the chromatogram obtained with the test solution, identify the peaks and calculate the percentage content of each sterol in the sterol fraction of the substance to be examined using the following expression:

$$\frac{A}{S} \times 100$$

$A$ = area of the peak due to the component to be determined;

$S$ = sum of the areas of the peaks due to the components indicated in Table 2.4.23.-1; disregard the peak due to betulin.

If required in the monograph, calculate the content of each sterol in milligrams per 100 grams of the substance to be examined using the following expression:

$$\frac{A \times m' \times 100}{A' \times m}$$

$A$ = area of the peak due to the component to be determined;

$A'$ = area of the peak due to betulin;

$m$ = mass of the sample of the substance to be examined, in grams;

$m'$ = mass of *betulin R* added, in milligrams.

METHOD B

**Preparation of the unsaponifiable matter**

Prepare the unsaponifiable matter according to the method stated in the test for unsaponifiable matter of the monograph on the substance to be examined. Failing this, prepare the unsaponifiable matter according to the method described in chapter *2.5.7. Unsaponifiable matter*. After the final neutralisation step, evaporate the ethanol, then add 6 mL of *acetone R* and evaporate the solvent. Dry the residue at 100-105 °C. It is not necessary to dry to constant mass.

Simultaneously prepare under the same conditions the unsaponifiable matter of *sunflower oil R*. This will in particular serve to locate the sterol fraction to be collected.

**Separation of the sterol fraction (LC)**

Liquid chromatography (*2.2.29*).

*Test solution.* Take up the residue with 3 quantities, each of 4 mL, of the solvent used during the preparation of the unsaponifiable matter (generally *ether R* or *light petroleum R*) and transfer to a 15 mL tube. Evaporate to dryness under a current of *nitrogen R*. Dissolve the residue in a volume of mobile phase sufficient to obtain a solution with an approximate concentration of 40 mg/mL. Add a few drops of *2-propanol R1* to improve the solubility (3 drops are normally sufficient to ensure complete solubilisation). Filter through a membrane filter (nominal pore size 0.45 µm).

*Reference solution.* Proceed as described for the test solution with the unsaponifiable matter obtained with *sunflower oil R*.

*Precolumn*:

- *size*: *l* = 5 mm, Ø = 4.6 mm;
- *stationary phase*: *silica gel for chromatography R* (5 µm) with a pore size of 6 nm.

*Column*:

- *size*: *l* = 0.25 m, Ø = 4.6 mm;
- *stationary phase*: *silica gel for chromatography R* (5 µm) with a pore size of 6 nm.

*Mobile phase*: *2-propanol R1*, *hexane R* (1:99 *V/V*).

*Flow rate*: 1 mL/min.

*Detection*: spectrophotometer at 210 nm.

*Injection*: 50 µL.

*Identification of the peaks due to sterols*: the sterol fraction elutes at the end of the chromatogram. Locate the fraction to be collected using the chromatogram obtained with the reference solution, which shows 2 principal peaks eluting approximately between 23 min and 32 min. Collect the fraction at the detector outlet in a 15 mL tube with a screw cap. Evaporate the solvent under a current of *nitrogen R*.

**Determination of the sterols (GC)**

Gas chromatography (*2.2.28*).

*Test solution.* Dissolve the residue of the sterol fraction obtained with the test solution in the previous LC step in 0.2 mL of *anhydrous pyridine R* and 0.2 mL of a mixture of 1 volume of *chlorotrimethylsilane R* and 99 volumes of *N,O-bis(trimethylsilyl)trifluoroacetamide R*. Stopper the tube tightly and heat at 80 °C for 20 min. Allow to cool and use the liquid phase.

*Reference solution.* Dissolve the residue of the sterol fraction obtained with the reference solution in the previous LC step in 0.2 mL of *anhydrous pyridine R* and 0.2 mL of a mixture of 1 volume of *chlorotrimethylsilane R* and 99 volumes of *N,O-bis(trimethylsilyl)trifluoroacetamide R*. Stopper the tube tightly and heat at 80 °C for 20 min. Allow to cool and use the liquid phase.

A standard of cholesterol (*cholesterol R*) may also be used, alone or as a mixture with the sterol fraction of sunflower oil. Proceed with derivatisation as described for the test solution.

*Column*:

- *material*: fused silica;
- *size*: *l* = 30 m, Ø = 0.25 mm;
- *stationary phase*: *phenyl(5)methyl(95)polysiloxane R* (film thickness 0.25 µm).

*Carrier gas*: *helium for chromatography R*.

*Flow rate*: 2.6 mL/min.

*Split ratio*: 1:25.

*Temperature*:

| | Time (min) | Temperature (°C) |
|---|---|---|
| Column | 0 - 38 | 260 |
| | 38 - 44 | 260 → 290 |
| | 44 - 49 | 290 |
| Injection port | | 290 |
| Detector | | 290 |

*Detection*: flame ionisation.

*Injection*: 1-3 µL (depending on the expected amount of sterols in the substance to be examined).

*Identification of peaks*: use the chromatogram obtained with the reference solution to identify the peaks due to campesterol, stigmasterol, β-sitosterol and Δ7-stigmastenol. Identify the peaks due to the sterols in the chromatogram obtained with the test solution using the chromatogram obtained with the reference solution and the relative retentions with reference to β-sitosterol (main peak) given in Table 2.4.23.-1.

*System suitability*: reference solution:

– *resolution*: minimum 4.0 between the peaks due to campesterol and stigmasterol.

Calculate the percentage content of each sterol in the sterol fraction of the substance to be examined using the following expression:

$$\frac{A}{S} \times 100$$

*A* = area of the peak due to the component to be determined;

*S* = sum of the areas of the peaks due to the components indicated in Table 2.4.23.-1, except betulin.

**01/2017:20424**

# 2.4.24. IDENTIFICATION AND CONTROL OF RESIDUAL SOLVENTS

The test procedures described in this general method may be used:

i. for the identification of the majority of Class 1 and Class 2 residual solvents in an active substance, excipient or medicinal product when the residual solvents are unknown;

ii. as a limit test for Class 1 and Class 2 solvents when present in an active substance, excipient or medicinal product;

iii. for the quantification of Class 2 solvents when the limits are greater than 1000 ppm (0.1 per cent) or for the quantification of Class 3 solvents when required.

Class 1, Class 2 and Class 3 residual solvents are listed in general chapter *5.4. Residual solvents*.

Three diluents are described for sample preparation and the conditions to be applied for head-space injection of the gaseous sample onto the chromatographic system. Two chromatographic systems are prescribed but System A is preferred whilst System B is employed normally for confirmation of identity. The choice of sample preparation procedure depends on the solubility of the substance to be examined and in certain cases the residual solvents to be controlled.

The following residual solvents are not readily detected by the head-space injection conditions described: formamide, 2-ethoxyethanol, 2-methoxyethanol, ethylene glycol, *N*-methylpyrrolidone and sulfolane. Other appropriate procedures should be employed for the control of these residual solvents.

When the test procedure is applied quantitatively to control residual solvents in a substance, then it must be validated.

PROCEDURE

Examine by gas chromatography with static head-space injection (*2.2.28*).

**Sample preparation 1**. This is intended for the control of residual solvents in water-soluble substances.

*Sample solution (1).* Dissolve 0.200 g of the substance to be examined in *water R* and dilute to 20.0 mL with the same solvent.

**Sample preparation 2**. This is intended for the control of residual solvents in water-insoluble substances.

*Sample solution (2).* Dissolve 0.200 g of the substance to be examined in *dimethylformamide R* (DMF) and dilute to 20.0 mL with the same solvent.

**Sample preparation 3**. This is intended for the control of *N,N*-dimethylacetamide and/or *N,N*-dimethylformamide, when it is known or suspected that one or both of these substances are present in the substance to be examined.

*Sample solution (3).* Dissolve 0.200 g of the substance to be examined in *1,3-dimethyl-2-imidazolidinone R* (DMI) and dilute to 20.0 mL with the same solvent.

In some cases none of the above sample preparation procedures are appropriate, in which case the diluent to be used for the preparation of the sample solution and the static head-space conditions to be employed must be demonstrated to be suitable.

*Solvent solution (a).* To 1.0 mL of *Class 1 residual solvent solution CRS*, add 9 mL of *dimethyl sulfoxide R* and dilute to 100.0 mL with *water R*. Dilute 1.0 mL of this solution to 100 mL with *water R*. Dilute 1.0 mL of this solution to 10.0 mL with *water R*.

The reference solutions correspond to the following limits:

– benzene: 2 ppm,
– carbon tetrachloride: 4 ppm,
– 1,2-dichloroethane: 5 ppm,
– 1,1-dichloroethene: 8 ppm,
– 1,1,1-trichloroethane: 10 ppm.

*Solvent solution (b).* Dissolve appropriate quantities of the Class 2 residual solvents in *dimethyl sulfoxide R* and dilute to 100.0 mL with the same solvent. Dilute in *water R* to give a concentration of 1/20 of the limits stated in Table 2 (see *5.4. Residual solvents*).

*Solvent solution (c).* Dissolve 1.00 g of the solvent or solvents present in the substance to be examined in *dimethyl sulfoxide R* or *water R*, if appropriate, and dilute to 100.0 mL with *water R*. Dilute to give a concentration of 1/20 of the limit(s) stated in Table 1 or 2 (see *5.4. Residual solvents*).

*Blank solution.* Prepare as described for solvent solution (c) but without the addition of solvent(s) (used to verify the absence of interfering peaks).

*Test solution.* Introduce 5.0 mL of the sample solution and 1.0 mL of the blank solution into an injection vial.

*Reference solution (a) (Class 1).* Introduce 1.0 mL of solvent solution (a) and 5.0 mL of the appropriate diluent into an injection vial.

*Reference solution ($a_1$) (Class 1).* Introduce 5.0 mL of the sample solution and 1.0 mL of solvent solution (a) into an injection vial.

*Reference solution (b) (Class 2).* Introduce 1.0 mL of solvent solution (b) and 5.0 mL of the appropriate diluent into an injection vial.

*Reference solution (c).* Introduce 5.0 mL of the sample solution and 1.0 mL of solvent solution (c) into an injection vial.

*Reference solution (d).* Introduce 1.0 mL of the blank solution and 5.0 mL of the appropriate diluent into an injection vial.

*Close the vials with a tight rubber membrane stopper coated with polytetrafluoroethylene and secure with an aluminium crimped cap. Shake to obtain a homogeneous solution.*

The following static head-space injection conditions may be used:

| | Sample preparation procedure | | |
|---|---|---|---|
| **Operating parameters** | **1** | **2** | **3** |
| Equilibration temperature (°C) | 80 | 105 | 80 |
| Equilibration time (min) | 60 | 45 | 45 |
| Transfer-line temperature (°C) | 85 | 110 | 105 |
| Carrier gas: *Nitrogen for chromatography R* or *Helium for chromatography R* at an appropriate pressure | | | |
| Pressurisation time (s) | 30 | 30 | 30 |
| Injection volume (mL) | 1 | 1 | 1 |

The chromatographic procedure may be carried out using:

*SYSTEM A*

- a fused-silica capillary or wide-bore column 30 m long and 0.32 mm or 0.53 mm in internal diameter coated with cross-linked 6 per cent polycyanopropylphenylsiloxane and 94 per cent polydimethylsiloxane (film thickness: 1.8 µm or 3 µm),
- *nitrogen for chromatography R* or *helium for chromatography R* as the carrier gas, split ratio 1:5 with a linear velocity of about 35 cm/s,
- a flame-ionisation detector (a mass spectrometer may also be used or an electron-capture detector for the chlorinated residual solvents of Class 1),

maintaining the temperature of the column at 40 °C for 20 min, then raising the temperature at a rate of 10 °C per min to 240 °C and maintaining it at 240 °C for 20 min and maintaining the temperature of the injection port at 140 °C and that of the detector at 250 °C, or, where there is interference from the matrix, use:

*SYSTEM B*

- a fused-silica capillary or wide-bore column 30 m long and 0.32 mm or 0.53 mm in internal diameter coated with *macrogol 20 000 R* (film thickness: 0.25 µm),
- *nitrogen for chromatography R* or *helium for chromatography R* as the carrier gas, split ratio 1:5 with a linear velocity of about 35 cm/s.
- a flame-ionisation detector (a mass spectrophotometer may also be used or an electron-capture detector for the chlorinated residual solvents of Class 1),

maintaining the temperature of the column at 50 °C for 20 min, then raising the temperature at a rate of 6 °C per min to 165 °C and maintaining it at 165 °C for 20 min and maintaining the temperature of the injection port at 140 °C and that of the detector at 250 °C.

Inject 1 mL of the gaseous phase of reference solution (a) onto the column described in System A and record the chromatogram under such conditions that the signal-to-noise ratio for 1,1,1-trichloroethane can be measured. The signal-to-noise ratio must be at least 5. A typical chromatogram is shown in Figure 2.4.24.-1.

Inject 1 mL of the gaseous phase of reference solution ($a_1$) onto the column described in System A. The peaks due to the Class 1 residual solvents are still detectable.

Inject 1 mL of the gaseous phase of reference solution (b) onto the column described in System A and record the chromatogram under such conditions that the resolution between acetonitrile and methylene chloride can be determined. The system is suitable if the chromatogram obtained resembles the chromatogram shown in Figure 2.4.24.-2 and the resolution between acetonitrile and methylene chloride is at least 1.0.

Inject 1 mL of the gaseous phase of the test solution onto the column described in System A. If in the chromatogram obtained, there is no peak which corresponds to one of the residual solvent peaks in the chromatograms obtained with reference solution (a) or (b), then the substance to be examined meets the requirements of the test. If any peak in the chromatogram obtained with the test solution corresponds to any of the residual solvent peaks obtained with reference solution (a) or (b) then System B is to be employed.

Inject 1 mL of the gaseous phase of reference solution (a) onto the column described in System B and record the chromatogram under such conditions that the signal-to-noise ratio for benzene can be measured. The signal-to-noise ratio must be at least 5. A typical chromatogram is shown in Figure 2.4.24.-3.

Inject 1 mL of the gaseous phase of reference solution ($a_1$) onto the column described in System B. The peaks due to the Class 1 residual solvents are still detectable.

Inject 1 mL of the gaseous phase of reference solution (b) onto the column described in System B and record the chromatogram under such conditions that the resolution between acetonitrile and trichloroethene can be determined. The system is suitable if the chromatogram obtained resembles the chromatogram shown in Figure 2.4.24.-4 and the resolution between acetonitrile and trichloroethene is at least 1.0.

Inject 1 mL of the gaseous phase of the test solution onto the column described in System B. If in the chromatogram obtained, there is no peak which corresponds to any of the residual solvent peaks in the chromatogram obtained with the reference solution (a) or (b), then the substance to be examined meets the requirements of the test. If any peak in the chromatogram obtained with the test solution corresponds to any of the residual solvent peaks obtained with reference solution (a) or (b) and confirms the correspondence obtained when using System A, then proceed as follows.

Inject 1 mL of the gaseous phase of reference solution (c) onto the column described for System A or System B. If necessary, adjust the sensitivity of the system so that the height of the peak corresponding to the identified residual solvent(s) is at least 50 per cent of the full scale of the recorder.

Inject 1 mL of the gaseous phase of reference solution (d) onto the column. No interfering peaks should be observed.

Inject 1 mL of the gaseous phase of the test solution and 1 mL of the gaseous phase of reference solution (c) on to the column. Repeat these injections twice more.

The mean area of the peak of the residual solvent(s) in the chromatograms obtained with the test solution is not greater than half the mean area of the peak of the corresponding residual solvent(s) in the chromatograms obtained with reference solution (c). The test is not valid unless the relative standard deviation of the differences in areas between the analyte peaks obtained from 3 replicate paired injections of reference solution (c) and the test solution, is at most 15 per cent.

A flow diagram of the procedure is shown in Figure 2.4.24.-5.

When a residual solvent (Class 2 or Class 3) is present at a level of 0.1 per cent or greater then the content may be quantitatively determined by the method of standard additions.

**04/2015:20425 corrected 10.0**

# 2.4.25. ETHYLENE OXIDE AND DIOXAN

The test is intended for the determination of residual ethylene oxide and dioxan in samples soluble in water or dimethylacetamide. For substances that are insoluble or insufficiently soluble in these solvents, the preparation of the sample solution and the head-space conditions to be employed are given in the individual monograph.

Head-space gas chromatography (*2.2.28*).

A. For samples soluble in or miscible with water, the following procedure may be used.

*Test solution.* Weigh 1.00 g ($M_T$) of the substance to be examined in a 10 mL vial (other sizes may be used depending on the operating conditions) and add 1.0 mL of *water R*. Close and mix to obtain a homogeneous solution. Allow to stand at 70 °C for 45 min.

*Reference solution (a).* Weigh 1.00 g ($M_R$) of the substance to be examined into an identical 10 mL vial, add 0.50 mL of *dioxan solution R2* and 0.50 mL of *ethylene oxide solution R3*. Close and mix to obtain a homogeneous solution. Allow to stand at 70 °C for 45 min.

*Reference solution (b).* To 0.50 mL of *ethylene oxide solution R3* in a 10 mL vial add 0.1 mL of a freshly prepared 10 mg/L solution of *acetaldehyde R* and 0.10 mL of *dioxan solution R1*. Close and mix to obtain a homogeneous solution. Allow to stand at 70 °C for 45 min.

B. For samples soluble in or miscible with dimethylacetamide, the following procedure may be used.

*Test solution.* Weigh 1.00 g ($M_T$) of the substance to be examined in a 10 mL vial (other sizes may be used depending on the operating conditions) and add 0.20 mL of *water R* and 1.0 mL of *dimethylacetamide R*. Close and mix to obtain a homogeneous solution. Allow to stand at 90 °C for 45 min.

*Reference solution (a).* Weigh 1.00 g ($M_R$) of the substance to be examined into an identical 10 mL vial, add 0.10 mL of *dioxan solution R1*, 0.10 mL of *ethylene oxide solution R2* and 1.0 mL of *dimethylacetamide R*. Close and mix to obtain a homogeneous solution. Allow to stand at 90 °C for 45 min.

*Reference solution (b).* To 0.10 mL of *ethylene oxide solution R2* in a 10 mL vial, add 0.1 mL of a freshly prepared 10 mg/L solution of *acetaldehyde R* and 0.10 mL of *dioxan solution R1*. Close and mix to obtain a homogeneous solution. Allow to stand at 70 °C for 45 min.

*Column*:

- *material*: glass or fused silica;
- *size*: *l* = 30 m, Ø = 0.32 mm;
- *stationary phase*: *methylpolysiloxane R* (film thickness 1.0 µm).

*Carrier gas*: *helium for chromatography R* or *nitrogen for chromatography R*.

*Linear velocity*: 20 cm/s.

*Split ratio*: 1:20.

*Static head-space conditions that may be used*:

- *equilibration temperature*: 70 °C (90 °C for solutions in dimethylacetamide);
- *equilibration time*: 45 min;
- *transfer-line temperature*: 75 °C (150 °C for solutions in dimethylacetamide);
- *carrier gas*: *helium for chromatography R*;
- *pressurisation time*: 1 min;
- *injection time*: 12 s.

*Temperature*:

| | Time (min) | Temperature (°C) |
|---|---|---|
| Column | 0 - 5 | 50 |
| | 5 - 31 | 50 → 180 |
| | 31 - 32.5 | 180 → 230 |
| | 32.5 - 37.5 | 230 |
| Injection port | | 150 |
| Detector | | 250 |

*Detection*: flame ionisation.

*Injection*: a suitable volume, for example 1.0 mL, of the gaseous phase of the test solution and of reference solutions (a) and (b). Repeat the procedure twice more.

*System suitability*: reference solution (b):

- *resolution*: minimum 2.0 between the peaks due to acetaldehyde and ethylene oxide;
- *signal-to-noise ratio*: minimum 5 for the peaks due to ethylene oxide and dioxan.

*Verification of precision*

For each pair of injections, calculate for ethylene oxide and for dioxan the difference in area between the peaks obtained with the test solution and reference solution (a). The test is not valid unless the relative standard deviation of the 3 values obtained for ethylene oxide is not greater than 15 per cent and the relative standard deviation of the 3 values obtained for dioxan is not greater than 15 per cent. If the weighings used for the test solution and reference solution (a) differ from 1.00 g by more than 0.5 per cent, the appropriate corrections must be made.

Calculate the content of ethylene oxide or dioxan in parts per million from the following expressions:

$$\frac{A_T \times C}{(A_R \times M_T) - (A_T \times M_R)}$$

$A_T$ = area of the peak due to ethylene oxide in the chromatogram obtained with the test solution;

$A_R$ = area of the peak due to ethylene oxide in the chromatogram obtained with reference solution (a);

$M_T$ = mass of the substance to be examined in the test solution, in grams;

$M_R$ = mass of the substance to be examined in reference solution (a), in grams;

$C$ = amount of ethylene oxide added to reference solution (a), in micrograms.

$$\frac{D_T \times C}{(D_R \times M_T) - (D_T \times M_R)}$$

$D_T$ = area of the peak due to dioxan in the chromatogram obtained with the test solution;

$D_R$ = area of the peak due to dioxan in the chromatogram obtained with reference solution (a);

$C$ = amount of dioxan added to reference solution (a) in micrograms.

**01/2008:20426 corrected 10.0**

## 2.4.26. *N,N*-DIMETHYLANILINE

METHOD A

Examine by gas chromatography (*2.2.28*), using *N,N-diethylaniline R* as the internal standard.

*Internal standard solution.* Dissolve 50 mg of *N,N-diethylaniline R* in 4 mL of *0.1 M hydrochloric acid* and dilute to 50 mL with *water R*. Dilute 1 mL of this solution to 100 mL with *water R*.

*Test solution.* Dissolve in a ground-glass-stoppered tube 0.50 g of the substance to be examined in 30.0 mL of *water R*. Add 1.0 mL of the internal standard solution. Adjust the solution to a temperature of 26-28 °C. Add 1.0 mL of *strong sodium hydroxide solution R* and mix until completely dissolved. Add 2.0 mL of *trimethylpentane R*. Shake for 2 min and allow the phases to separate. Use the upper layer.

*Reference solution.* Dissolve 50.0 mg of *N,N-dimethylaniline R* in 4.0 mL of *0.1 M hydrochloric acid* and dilute to 50.0 mL with *water R*. Dilute 1.0 mL of this solution to 100.0 mL with *water R*. Dilute 1.0 mL of this solution to 30.0 mL with *water R*. Add 1.0 mL of the internal standard solution and 1.0 mL of *strong sodium hydroxide solution R*. Add 2.0 mL of *trimethylpentane R*. Shake for 2 min and allow the phases to separate. Use the upper layer.

The chromatographic procedure may be carried out using:

- a fused-silica capillary column 25 m long and 0.32 mm in internal diameter coated with *phenyl(50)methyl(50)polysiloxane R* (film thickness 0.52 µm),
- *helium for chromatography R* as the carrier gas with a split ratio 1:20, a column head pressure of 50 kPa and a split vent of 20 mL/min,
- a flame-ionisation detector,
- a split-liner consisting of a column about 1 cm long packed with *diatomaceous earth for gas chromatography R* impregnated with 10 per cent *m/m* of *methylpolysiloxane R*,

maintaining the temperature of the column at 150 °C for 5 min, then raising the temperature at a rate of 20 °C per min to 275 °C and maintaining it at 275 °C for 3 min and maintaining the temperature of the detector at 300 °C and that of the injection port at 220 °C.

The retention times are: *N,N*-dimethylaniline about 3.6 min, *N,N*-diethylaniline about 5.0 min.

Inject 1 µL of the test solution and 1 µL of the reference solution.

METHOD B

Examined by gas chromatography (*2.2.28*), using *naphthalene R* as the internal standard.

*Internal standard solution.* Dissolve 50 mg of *naphthalene R* in *cyclohexane R* and dilute to 50 mL with the same solvent. Dilute 5 mL of this solution to 100 mL with *cyclohexane R*.

*Test solution.* To 1.00 g of the substance to be examined in a ground-glass-stoppered tube add 5 mL of *1 M sodium hydroxide* and 1.0 mL of the internal standard solution. Stopper the tube and shake vigorously for 1 min. Centrifuge if necessary and use the upper layer.

*Reference solution.* To 50.0 mg of *N,N-dimethylaniline R* add 2 mL of *hydrochloric acid R* and 20 mL of *water R*, shake to dissolve and dilute to 50.0 mL with *water R*. Dilute 5.0 mL of this solution to 250.0 mL with *water R*. To 1.0 mL of the latter solution in a ground-glass-stoppered tube add 5 mL of *1 M sodium hydroxide* and 1.0 mL of the internal standard solution. Stopper the tube and shake vigorously for 1 min. Centrifuge if necessary and use the upper layer.

The chromatographic procedure may be carried out using:

- a glass column 2 m long and 2 mm in internal diameter packed with *silanised diatomaceous earth for gas chromatography R* impregnated with 3 per cent *m/m* of *phenyl(50)methyl(50)polysiloxane R*,
- *nitrogen for chromatography R* as the carrier gas at a flow rate of 30 mL/min,
- a flame-ionisation detector,

maintaining the temperature of the column at 120 °C and that of the injection port and of the detector at 150 °C.

Inject 1 µL of the test solution and 1 µL of the reference solution.

**07/2014:20427**

## 2.4.27. HEAVY METALS IN HERBAL DRUGS AND HERBAL DRUG PREPARATIONS

*CAUTION: when using closed high-pressure digestion vessels and microwave laboratory equipment, be familiar with the safety and operating instructions given by the manufacturer.*

APPARATUS

The apparatus typically consists of the following:

- as digestion flasks, polytetrafluoroethylene, perfluoroalkoxy polymer, quartz or glass flasks with a volume of 20-150 mL, fitted with an airtight closure, a valve to adjust the pressure inside the container and a polytetrafluoroethylene tube to allow release of gas;
- a system to make flasks airtight, using the same torsional force for each of them;
- a programmable microwave oven (e.g. with a magnetron frequency of 2450 MHz, with a selectable output from 0 to 1500 ± 70 W in 1 per cent increments), a polytetrafluoroethylene-coated microwave cavity with a variable speed exhaust fan, a rotating turntable drive system and exhaust tubing to vent fumes;
- an atomic absorption spectrometer (*2.2.23*), an inductively coupled plasma-atomic emission spectrometer (*2.2.57*), or an inductively coupled plasma-mass spectrometer (*2.2.58*).

METHOD

Examine by atomic absorption spectrometry (AAS) (*2.2.23*), inductively coupled plasma-atomic emission spectrometry (ICP-AES) (*2.2.57*), or inductively coupled plasma-mass spectrometry (ICP-MS) (*2.2.58*).

Deviations from the experimental parameters of the sample preparation procedure and the method description below are acceptable provided that the validation requirements are met and the system suitability test is fulfilled on the day of the analysis.

**Sample preparation**

Clean all the glassware and laboratory equipment with a 10 g/L solution of *nitric acid R* before use.

*Test solution.* In a digestion flask, place the prescribed quantity of the substance to be examined (about 0.50 g of powdered herbal drug (1400) (*2.9.12*)). Add 4 mL of *heavy metal-free hydrochloric acid R* and 6 mL of *heavy metal-free nitric acid R*. Make the flask airtight.

Place the digestion flasks in the microwave oven. Carry out the digestion in 3 steps according to the following programme, used for 7 flasks each containing the test solution: 80 per cent power for 15 min, 100 per cent power for 5 min, 80 per cent power for 20 min.

At the end of the cycle, allow the flasks to cool in air or water. After cooling, open each digestion flask and introduce the clear, colourless solution obtained into a 50 mL volumetric flask. Rinse each digestion flask with 2 quantities, each of 15 mL, of *heavy metal-free dilute nitric acid R*, collect the rinsings in the volumetric flask and dilute to 50.0 mL with *water R*. Modifiers (e.g. in the case of AAS with electrothermal atomisation, 1.0 mL of a 10 g/L solution of *magnesium nitrate R* and 1.0 mL of a 100 g/L solution of *ammonium dihydrogen phosphate R*) and stabilising agents may be used, if necessary.

*Blank solution.* Mix 4 mL of *heavy metal-free hydrochloric acid R* and 6 mL of *heavy metal-free nitric acid R* in a digestion flask. Carry out the digestion in the same manner as for the test solution.

*DETERMINATION OF ARSENIC, CADMIUM, COPPER, NICKEL AND LEAD USING AAS (2.2.23) WITH ELECTROTHERMAL ATOMISATION*

Measure the content of arsenic, cadmium, copper, nickel and lead by direct calibration (*2.2.23, Method I*) or by the standard additions method (*2.2.23, Method II*), using reference solutions of each heavy metal and the instrumental parameters recommended in Table 2.4.27.-1.

The absorbance value of the blank solution is subtracted from the value obtained with the test solution.

Table 2.4.27.-1. – *Instrumental parameters for AAS with electrothermal atomisation*

| | | As | Cd | Cu | Ni | Pb |
|---|---|---|---|---|---|---|
| Wavelength | nm | 193.7 | 228.8 | 324.8 | 232 | 283.5 |
| Slit width | nm | 0.5 | 0.5 | 0.5 | 0.2 | 0.5 |
| Lamp current | mA | 10 | 6 | 7 | 10 | 5 |
| Ignition temperature | °C | 1400 | 800 | 800 | 800 | 800 |
| Atomisation temperature | °C | 2600 | 1800 | 2300 | 2500 | 2200 |
| Gas flow rate | L/min | 3 | 3 | 3 | 3 | 3 |

*DETERMINATION OF ARSENIC AND MERCURY USING AAS (2.2.23) WITH COLD-VAPOUR OR HYDRIDE ATOMISATION*

Measure the content of arsenic and mercury by direct calibration (*2.2.23, Method I*) or by the standard additions method (*2.2.23, Method II*), using reference solutions of arsenic or mercury and an automated continuous-flow hydride vapour generation system.

The absorbance value of the blank solution is subtracted from the value obtained with the test solution.

**Arsenic**

*Sample solution.* To 19.0 mL of the test solution or of the blank solution as prescribed above, add 1 mL of a 200 g/L solution of *potassium iodide R*. Allow the test solution to stand at room temperature for about 50 min or at 70 °C for about 4 min.

*Acid reagent. Heavy metal-free hydrochloric acid R.*

*Reducing reagent.* 6 g/L solution of *sodium tetrahydroborate R* in a 5 g/L solution of *sodium hydroxide R*.

The recommended instrumental parameters in Table 2.4.27.-2 may be used.

**Mercury**

*Sample solution.* Test solution or blank solution, as prescribed above.

*Acid reagent.* 515 g/L solution of *heavy metal-free hydrochloric acid R*.

*Reducing reagent.* 10 g/L solution of *stannous chloride R* in *heavy metal-free dilute hydrochloric acid R*.

The recommended instrumental parameters in Table 2.4.27.-2 may be used.

Table 2.4.27.-2. – *Instrumental parameters for AAS with cold-vapour or hydride atomisation*

| | | As | Hg |
|---|---|---|---|
| Wavelength | nm | 193.7 | 253.7 |
| Slit width | nm | 0.2 | 0.5 |
| Lamp current | mA | 10 | 4 |
| Acid reagent flow rate | mL/min | 1.0 | 1.0 |
| Reducing reagent flow rate | mL/min | 1.0 | 1.0 |
| Sample solution flow rate | mL/min | 7.0 | 7.0 |
| Absorption cell | | Quartz (heated) | Quartz (unheated) |
| Nitrogen flow rate | L/min | 0.1 | 0.1 |

*DETERMINATION OF ARSENIC, CADMIUM, COPPER, MERCURY, NICKEL AND LEAD USING ICP-AES (2.2.57)*

Measure the content of arsenic, cadmium, copper, mercury, nickel and lead by direct calibration (*2.2.23, Method I*), using reference solutions of each heavy metal or a mixture of all measured metals, and the instrumental parameters recommended in Table 2.4.27.-3.

The emission value of the blank solution is subtracted from the value obtained with the test solution.

*DETERMINATION OF ARSENIC, CADMIUM, COPPER, MERCURY, NICKEL AND LEAD USING ICP-MS (2.2.58)*

Measure the content of arsenic, cadmium, copper, mercury, nickel and lead by direct calibration (*2.2.23, Method I*) using reference solutions of each heavy metal and the analytical isotopes and additional masses recommended in Table 2.4.27.-4.

The signal intensity of the blank solution is subtracted from the value obtained with the test solution.

SYSTEM SUITABILITY

A system suitability test must be carried out on the day of the analysis to ensure that the sample preparation and measurement system are appropriate.

Table 2.4.27.-3. – *Instrumental parameters for ICP-AES*

| | | As | Cd | Cu | Hg | Ni | Pb |
|---|---|---|---|---|---|---|---|
| Wavelength | nm | 193.696/ 197.197/ 189.042 | 214.438/ 226.502/ 228.802 | 324.754/ 327.396/ 224.700 | 184.950/ 253.652/ 435.835 | 231.604/ 231.997/ 352.454 | 220.351/ 283.306/ 168.215 |
| Ar, Monitorline | nm | 430.010 | 430.010 | 430.010 | 430.010 | 430.010 | 430.010 |
| Plasma energy | W | 1200 | 1200 | 1200 | 1200 | 1200 | 1200 |
| Peak algorithm with background correction | | yes | yes | yes | yes | yes | yes |

*Acceptance criterion for preparation of sample solution*: a clear solution is obtained.

*Acceptance criterion for measurement system*: the measured concentration of a standard solution of the metal at a concentration within the range of the used calibration curve does not differ from the actual concentration by more than 20 per cent.

Table 2.4.27.-4. – *Recommended analytical isotopes and additional masses for ICP-MS*

| Isotope | Element of Interest |
|---|---|
| 75 | Arsenic |
| 106, 108, 111, 114 | Cadmium |
| 63, 65 | Copper |
| 202 | Mercury |
| 60, 62 | Nickel |
| 206, 207, 208 | Lead |

VALIDATION REQUIREMENTS

The analytical procedures used must be validated in accordance with the relevant general methods AAS (*2.2.23*), ICP-AES (*2.2.57*) and ICP-MS (*2.2.58*). Additionally, the following criteria must be fulfilled.

*SPECIFICITY*

Specificity is the ability to ensure that the analytical procedures for sample preparation and measurement allow a reliable determination of the metal(s) in the presence of components (e.g. carrier gas, impurities, matrix) that may be expected to be present.

*Acceptance criteria*: the procedure must be able to assess unequivocally each heavy metal to be determined with this procedure in the presence of components that may be expected to be present, including other heavy metals, matrix components and other sources of interference; specificity is demonstrated by complying with the accuracy requirement for the metal(s) to be determined.

*RANGE*

The calibration range of each metal is within the linear range of the method; test solutions containing residues at a level outside the calibration range may be diluted to concentrations within the calibration range.

*Acceptance criterion*: range is demonstrated by complying with the recovery requirement.

*ACCURACY*

Verify the accuracy using a certified reference material (CRM) or by performing a test for recovery.

**Recovery**. Recovery may be determined on a sample of the substance to be examined, spiked with a known quantity of a reference standard of the metal (3 concentration levels in the range of 50-150 per cent of the intended specification limit, even if the original concentration of the reference standard is at the specified value), in triplicate.

*Acceptance criterion*: spike recovery is within 70 per cent and 150 per cent for the mean of 3 replicates at each concentration.

*REPEATABILITY*

*Test samples*: either 6 independent samples of the substance to be examined spiked with a suitable reference standard at the specified concentration level, or 3 concentration levels prepared in triplicate.

*Acceptance criterion*: the relative standard deviation is in both cases not greater than the value indicated in Table 2.4.27.-5.

*INTERMEDIATE PRECISION*

The effect of random events (intra-laboratory variations) on the analytical precision of the method must be established. Acceptable experiments for establishing intermediate precision include performing the repeatability analysis on different days, or with different instrumentation, or with different analysts. Only 1 of the 3 experiments is required to demonstrate intermediate precision.

*Acceptance criterion*: the relative standard deviation is not greater than the value indicated in Table 2.4.27.-5.

*LIMIT OF QUANTIFICATION*

Determine the lowest concentration meeting the acceptance criterion. Use the results from the accuracy study.

*Acceptance criterion*: the limit of quantification is below the specification limit.

Table 2.4.27.-5

| Concentration range of the metal (mg/kg) | Repeatability (RSD) (per cent) | Intermediate precision (RSD) (per cent) |
|---|---|---|
| 0.01 - 1 | 20 | 32 |
| > 1 | 10 | 16 |

*LIMIT OF DETECTION (ONLY APPLICABLE TO LIMIT TESTS)*

Determine the lowest concentration giving a signal clearly distinct from that obtained with a blank solution.

*Acceptance criterion*: the limit of detection is not more than 0.1 times the concentration of the specification limit.

**01/2008:20428**

# 2.4.28. 2-ETHYLHEXANOIC ACID

Examine by gas chromatography (*2.2.28*), using *3-cyclohexylpropionic acid R* as the internal standard.

*Internal standard solution.* Dissolve 100 mg of *3-cyclohexylpropionic acid R* in *cyclohexane R* and dilute to 100 mL with the same solvent.

*Test solution.* To 0.300 g of the substance to be examined, add 4.0 mL of a 33 per cent *V/V* solution of *hydrochloric acid R*. Shake vigorously for 1 min with 1.0 mL of the internal standard solution. Allow the phases to separate (if necessary, centrifuge for a better separation). Use the upper layer.

*Reference solution.* Dissolve 75.0 mg of *2-ethylhexanoic acid R* in the internal standard solution and dilute to 50.0 mL with the same solution. To 1.0 mL of the solution add 4.0 mL of a 33 per cent *V/V* solution of *hydrochloric acid R*. Shake vigorously for 1 min. Allow the phases to separate (if necessary, centrifuge for a better separation). Use the upper layer.

The chromatographic procedure may be carried out using:

- a wide-bore fused-silica column 10 m long and 0.53 mm in internal diameter coated with *macrogol 20 000 2-nitroterephthalate R* (film thickness 1.0 µm),
- *helium for chromatography R* as the carrier gas at a flow rate of 10 mL/min,
- a flame-ionisation detector,

with the following temperature programme:

| | Time (min) | Temperature (°C) | Rate (°C/min) | Comment |
|---|---|---|---|---|
| Column | 0 - 2 | 40 | – | isothermal |
| | 2 - 7.3 | 40 → 200 | 30 | linear gradient |
| | 7.3 - 10.3 | 200 | – | isothermal |
| Injection port | | 200 | | |
| Detector | | 300 | | |

Inject 1 µL of the test solution and 1 µL of the reference solution.

The test is not valid unless the resolution between the peaks due to 2-ethylhexanoic acid (first peak) and the internal standard is at least 2.0.

Calculate the percentage content of 2-ethylhexanoic acid from the expression:

$$\frac{A_T \times I_R \times m_R \times 2}{A_R \times I_T \times m_T}$$

$A_T$ = area of the peak due to 2-ethylhexanoic acid in the chromatogram obtained with the test solution,

$A_R$ = area of the peak due to 2-ethylhexanoic acid in the chromatogram obtained with the reference solution,

$I_T$ = area of the peak due to the internal standard in the chromatogram obtained with the test solution,

$I_R$ = area of the peak due to the internal standard in the chromatogram obtained with the reference solution,

$m_T$ = mass of the substance to be examined in the test solution, in grams,

$m_R$ = mass of 2-ethylhexanoic acid in the reference solution, in grams.

**04/2019:20429**

# 2.4.29. COMPOSITION OF FATTY ACIDS IN OILS RICH IN OMEGA-3 ACIDS

*The assay may be used for quantitative determination of the eicosapentaenoic acid (EPA), docosahexaenoic acid (DHA) and total omega-3-acids content in products from fish oil containing omega-3 acids in different concentrations. The method is applicable to triglycerides or ethyl esters. The former includes fish oils/fish-liver oils and omega-3-concentrates in triglyceride form. The results are expressed as triglycerides or ethyl esters, respectively.*

EPA AND DHA

Gas chromatography (*2.2.28*). *Carry out the operations as rapidly as possible, avoiding exposure to actinic light, oxidising agents, oxidation catalysts (for example, copper and iron) and air.*

The assay is carried out on the methyl esters (after derivatisation of triglycerides - see step B below) or ethyl esters of (*all-Z*)-eicosa-5,8,11,14,17-pentaenoic acid (EPA; 20:5 n-3) and (*all-Z*)-docosa-4,7,10,13,16,19-hexaenoic acid (DHA; 22:6 n-3) in the substance to be examined.

*Internal standard*: *methyl tricosanoate R*.

*Test solutions*: prepare all test solutions in duplicate.

**Step A**

– *Test solution (a).* Dissolve a quantity of the sample to be examined according to Table 2.4.29.-1 and 70.0 mg of the internal standard in a 50 mg/L solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 mL with the same solution. Gentle heating (up to 60 °C) may be applied to dissolve the internal standard. Ethyl esters are now ready for analysis. For triglycerides continue as described in step B.

Table 2.4.29.-1

| Approximate sum EPA + DHA (per cent) | Mass of sample to be examined (g) |
|---|---|
| 30 - 50 | 0.4 - 0.5 |
| 50 - 70 | 0.3 |
| 70 - 90 | 0.25 |

– *Test solution (b).* Dissolve a quantity of the sample to be examined according to Table 2.4.29.-1 in a 50 mg/mL solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 mL with the same solution. Ethyl esters are now ready for analysis. For triglycerides continue as described in step B.

**Step B**

Introduce 2.0 mL of test solutions (a) and (b) obtained in step A into separate quartz tubes and evaporate the solvent with a gentle current of *nitrogen R*. Add 1.5 mL of a 20 g/L solution of *sodium hydroxide R* in *methanol R*, cover with *nitrogen R*, cap tightly with a polytetrafluoroethylene-lined cap, mix and heat on a water-bath for 7 min. Allow to cool. Add 2 mL of *boron trichloride-methanol solution R*, cover with *nitrogen R*, cap tightly, mix and heat on a water-bath for 30 min. Cool to 40-50 °C, add 1 mL of *trimethylpentane R*, cap and shake vigorously for at least 30 s. Immediately add 5 mL of a *saturated sodium chloride solution R*, cover with *nitrogen R*, cap and shake thoroughly for at least 15 s. Transfer the upper layer to a separate tube. Shake the methanol layer once more with 1 mL of *trimethylpentane R*. Wash the combined trimethylpentane extracts with 2 quantities, each of 1 mL, of *water R* and dry over *anhydrous sodium sulfate R*.

*Reference solutions*: prepare reference solutions ($a_1$) and ($a_2$) in duplicate; reference solution (c) only has to be prepared for triglycerides, and only if tetracos-15-enoic acid methyl ester is not clearly observed in the chromatogram obtained with test solution (a).

– *Reference solution ($a_1$).* Dissolve 70.0 mg of the internal standard and 90.0 mg of *eicosapentaenoic acid ethyl ester CRS* in a 50 mg/L solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 mL with the same solution. Gentle heating (up to 60 °C) may be applied to dissolve the internal standard.

– *Reference solution ($a_2$).* Dissolve 60.0 mg of *docosahexaenoic acid ethyl ester CRS* and 70.0 mg of the internal standard in a 50 mg/L solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 mL with the same solution. Gentle heating (up to 60 °C) may be applied to dissolve the internal standard.

For ethyl ester samples, reference solutions ($a_1$) and ($a_2$) are ready for analysis. For analysis of triglycerides, continue with step B in the same manner as for test solutions (a) and (b).

– *Reference solution (b).* Dissolve 0.300 g of *methyl arachidate R*, 0.300 g of *methyl behenate R*, 0.300 g of *methyl palmitate R* and 0.300 g of *methyl stearate R* in a 50 mg/L solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 mL with the same solution.

– *Reference solution (c).* Dissolve a mixture containing 55.0 mg of *docosahexaenoic acid methyl ester R* and 5.0 mg of *tetracos-15-enoic acid methyl ester R* in a 50 mg/L solution of *butylhydroxytoluene R* in *trimethylpentane R* and dilute to 10.0 mL with the same solution.

*Column*:

– *material*: fused silica;

– *dimensions*: *l* = at least 25 m, Ø = 0.25 mm;

– *stationary phase*: *macrogol 20 000 R* (film thickness 0.2 µm).

*Carrier gas*: *hydrogen for chromatography R* or *helium for chromatography R*.

*Flow rate*: 1 mL/min.

*Split ratio*: 1:200, alternatively splitless with temperature control (sample solutions need to be diluted 1/200 with a 50 mg/L solution of *butylhydroxytoluene R* in *trimethylpentane R* before injection).

If necessary, adapt the split ratio and/or sample dilution to obtain a symmetry factor of 0.8-1.5 for the peaks due to the methyl or ethyl esters of eicosapentaenoic acid and docosahexaenoic acid, while at the same time observing that for test solution (b) any peaks due to the corresponding esters of linolenic acid (C18:3; n-3), stearidonic acid (C18:4; n-3),

eicosatetraenoic acid (C20:4; n-3), heneicosapentaenoic acid (C21:5; n-3), and docosapentaenoic acid (C22:5; n-3) are clearly detectable. If both requirements are unachievable, then the clear detection of the corresponding esters mentioned above for test solution (b) takes precedence.

If necessary, adapt the split ratio and/or sample dilution to obtain a symmetry factor of 0.8-1.5 for the peaks due to the components of reference solution (b).

*Temperature*:

| | Split injection | | Splitless injection | |
|---|---|---|---|---|
| | Time (min) | Temperature (°C) | Time (min) | Temperature (°C) |
| Column | 0 - 2 | 170 | 0 - 2 | 90 |
| | 2 - 25.7 | 170 → 240 | 2 - 4.7 | 90 → 170 |
| | 25.7 - 28 | 240 | 4.7 - 28 | 170 → 240 |
| | | | 28 - 30 | 240 |
| Injection port | | 250 | | 90 - 250* |
| Detector | | 270 | | 270 |

*90 °C for on-column injection

*Detection*: flame ionisation.

*Injection*: 1 µL.

*System suitability*:

– in the chromatogram obtained with reference solution (b), multiply the area of the peaks due to methyl palmitate, methyl stearate, methyl arachidate and methyl behenate by the corresponding response factors in Table 2.4.29.-2; normalise the corrected areas of the peaks of the fatty acid methyl esters to a sum of 100 per cent; the normalised area percentage of each fatty acid methyl ester is to be within ± 1.0 percentage units of the corresponding weight percentage;

Table 2.4.29.-2

| Fatty acid methyl ester | Theoretical response factor |
|---|---|
| Methyl palmitate | 1.049 |
| Methyl stearate | 1.029 |
| Methyl arachidate | 1.013 |
| Methyl behenate | 1.000 |

– *resolution*:
  – *ethyl esters*: minimum 1.2 between the peaks due to methyl tricosanoate and heneicosapentaenoic acid ethyl ester in the chromatogram obtained with test solution (a);
  – *triglycerides*: minimum 1.2 between the peaks due to docosahexaenoic acid methyl ester and tetracos-15-enoic acid methyl ester in the chromatogram obtained with test solution (a) or with reference solution (c);
– in the chromatogram obtained with test solution (a), the peaks due to methyl tricosanoate and any heneicosapentaenoic acid methyl ester present when compared with the chromatogram obtained with test solution (b) are clearly separated.

Calculate the percentage content of EPA and DHA using the following expression and taking into account the assigned value of the reference substances:

$$\frac{A_x \times m_1}{A_1 \times m_2} \times Rf \times C \times 100$$

$Rf$ = response factor for EPA and DHA as given by the expression:

$$\frac{A_{x,3} \times m_{x,r}}{A_{x,r} \times m_{x,3}}$$

$m_1$ = mass of the internal standard in test solution (a), in milligrams;

$m_2$ = mass of the sample to be examined in test solution (a), in milligrams;

$m_{x,3}$ = mass of the internal standard in reference solution ($a_1$) (EPA determination), or in reference solution ($a_2$) (DHA determination), in milligrams;

$m_{x,r}$ = mass of *eicosapentaenoic acid ethyl ester CRS* in reference solution ($a_1$) or *docosahexaenoic acid ethyl ester CRS* in reference solution ($a_2$), in milligrams;

$A_x$ = area of the peak due to eicosapentaenoic acid ester or docosahexaenoic acid ester in the chromatogram obtained with test solution (a);

$A_{x,r}$ = area of the peak due to eicosapentaenoic acid ester in the chromatogram obtained with reference solution ($a_1$) or docosahexaenoic acid ester in the chromatogram obtained with reference solution ($a_2$);

$A_1$ = area of the peak due to the internal standard in the chromatogram obtained with test solution (a);

$A_{x,3}$ = area of the peak due to the internal standard in the chromatogram obtained with reference solution ($a_1$) (EPA determination) or with reference solution ($a_2$) (DHA determination);

$C$ = conversion factor between ethyl ester and triglycerides:

Ethyl esters: $C = 1.00$;

Triglycerides: $C = 0.954$ for EPA;

$C = 0.957$ for DHA.

TOTAL OMEGA-3 ACIDS

From the assay for EPA and DHA, calculate the percentage content of the total omega-3 acids using the following expression and identifying the peaks from the chromatograms:

$$EPA + DHA + \frac{A_{n-3}\,(EPA + DHA)}{A_{\mathrm{EPA}} + A_{\mathrm{DHA}}}$$

$EPA$ = percentage content of EPA;

$DHA$ = percentage content of DHA;

$A_{\text{n-3}}$ = sum of the areas of the peaks due to linolenic acid (C18:3; n-3), stearidonic acid (C18:4; n-3), eicosatetraenoic acid (C20:4; n-3), heneicosapentaenoic acid (C21:5; n-3), and docosapentaenoic acid (C22:5; n-3) in the chromatogram obtained with test solution (b);

$A_{\mathrm{EPA}}$ = area of the peak due to EPA ester in the chromatogram obtained with test solution (b);

$A_{\mathrm{DHA}}$ = area of the peak due to DHA ester in the chromatogram obtained with test solution (b).

01/2008:20430

## 2.4.30. ETHYLENE GLYCOL AND DIETHYLENE GLYCOL IN ETHOXYLATED SUBSTANCES

*Ethoxylated substances may contain varied amounts of ethylene glycol and diethylene glycol, as a result of the manufacturing process. The following method may be used for the quantitative determination of these substances, in particular in the case of the following surfactants: macrogolglycerol ricinoleate, macrogolglycerol hydroxystearate, macrogol 15 hydroxystearate, nonoxinol 9 and macrogol cetostearyl ether.*

Gas chromatography (*2.2.28*).

*Internal standard solution.* Dissolve 30.0 mg of *1,2-pentanediol R* in *acetone R* and dilute to 30.0 mL with the same solvent. Dilute 1.0 mL of this solution to 20.0 mL with *acetone R*.

*Test solution.* Dissolve 0.500 g of the substance to be examined in the internal standard solution and dilute to 10.0 mL with the same solution.

*Reference solution (a).* Mix 30.0 mg of *ethylene glycol R* with *acetone R* and dilute to 100.0 mL with the same solvent. Dilute 1.0 mL to 10.0 mL with the internal standard solution.

*Reference solution (b).* Prepare a solution of *diethylene glycol R* with a concentration corresponding to the prescribed limit and using the same solvents as for the preparation of reference solution (a).

*Column*:

– *material*: fused silica,
– *size*: *l* = 30 m, Ø = 0.53 mm,
– *stationary phase*: *macrogol 20 000 R* (film thickness 1 µm).

*Carrier gas*: *helium for chromatography R*.

*Flow rate*: 10 mL/min.

*Split ratio*: 1:3.

*Temperature*:

| | Time (min) | Temperature (°C) |
|---|---|---|
| Column | 0 - 40 | 80 → 200 |
| | 40 - 45 | 200 → 230 |
| | 45 - 65 | 230 |
| Injection port | | 250 |
| Detector | | 250 |

*Detection*: flame ionisation.

*Injection*: 2 µL.

*Relative retention* with reference to 1,2-pentanediol (retention time = about 19 min): ethylene glycol = about 0.7; diethylene glycol = about 1.3.

04/2018:20431

## 2.4.31. NICKEL IN HYDROGENATED VEGETABLE OILS

Atomic absorption spectrometry (*2.2.23, Method I*).

*The reagents magnesium nitrate R and ammonium dihydrogen phosphate R must be controlled for nickel before use. The actual nickel content is taken into account in the calculation of the nickel content of the sample.*

*Test solution.* Weigh 0.250 g (*m*) of the substance to be examined into a suitable high-pressure-resistant digestion vessel (fluoropolymer or quartz glass), add 6.0 mL of *nickel-free nitric acid R* and 2.0 mL of *strong hydrogen peroxide solution R*. Prepare a blank solution in the same manner. Place the closed vessels in a laboratory microwave oven and digest with an appropriate programme, e.g. 1000 W for 40 min. Allow the digestion vessels to cool before opening. Add 2.0 mL of *strong hydrogen peroxide solution R* and repeat the digestion step. Allow the digestion vessels to cool before opening. Quantitatively transfer to a 25 mL flask, add 0.5 mL of a 10 g/L solution of *magnesium nitrate R* and 0.5 mL of a 100 g/L solution of *ammonium dihydrogen phosphate R*, dilute to 25.0 mL with *water for chromatography R* and mix.

*Reference solutions.* Into 4 volumetric flasks, introduce 25 µL, 50 µL, 75 µL and 100 µL of *nickel standard solution (5 ppm Ni) R*. To each flask, add 0.5 mL of a 10 g/L solution of *magnesium nitrate R*, 0.5 mL of a 100 g/L solution of *ammonium dihydrogen phosphate R* and 6.0 mL of *nickel-free nitric acid R* and dilute to 25.0 mL with *water for chromatography R*. Mix to obtain reference solutions containing respectively 5 ng/mL, 10 ng/mL, 15 ng/mL and 20 ng/mL (ppb) of nickel.

*Zero solution.* In a volumetric flask, introduce 1.0 mL of a 10 g/L solution of *magnesium nitrate R*, 1.0 mL of a 100 g/L solution of *ammonium dihydrogen phosphate R* and 12.0 mL of *nickel-free nitric acid R*. Dilute to 50.0 mL with *water for chromatography R* and mix.

*Method.* Determine the absorbance of each solution at 232.0 nm using a suitable graphite furnace atomic absorption (GFAA) spectrometer equipped with a background compensation system, a pyrolytically-coated tube and a nickel hollow-cathode lamp. The optimal temperature programme may be different for each instrument, so the programme recommended by the spectrometer manufacturer may be used. The following temperature parameters for GFAA analysis are given as an example: maintain the drying temperature of the furnace at 120 °C for 35 s after a 5 s ramp, the ashing temperature at 1100 °C for 10 s after a 30 s ramp, the cooling temperature at 800 °C for 5 s after a 5 s decrease, and the atomisation temperature at 2600 °C for 7 s. Use the zero solution to set the instrument to zero. Using the calibration curve, determine the concentrations of the test solution and the blank solution from the corresponding absorptions. If necessary, dilute with the zero solution to obtain a reading within the calibrated absorbance range.

Calculate the content of Ni in micrograms per gram (ppm) using the following expression:

$$\frac{c \times f}{m \times 40}$$

$c$ = measured concentration of Ni, in nanograms per millilitre;

$f$ = dilution factor of the test solution;

$m$ = mass of the substance to be examined, in grams.

07/2016:20432 corrected 10.0

## 2.4.32. TOTAL CHOLESTEROL IN OILS RICH IN OMEGA-3 ACIDS

*This method may be used for the quantitative determination of the sum of free and esterified cholesterol in products of fish oils rich in omega-3 acids (as ethyl esters or triglycerides).*

Gas chromatography (*2.2.28*).

*Internal standard stock solution.* Dissolve 0.15 g of *(5α)-cholestane R* in *heptane R* and dilute to 50.0 mL with the same solvent. The solution may be stored in a deep-freeze for up to 6 months.

*Internal standard working solution. Prepare the solution immediately before use.* Dilute 1.0 mL of the internal standard stock solution to 10.0 mL with *heptane R*.

*Cholesterol stock solution.* Dissolve 50.0 mg of *cholesterol R* in *heptane R* and dilute to 100.0 mL with the same solvent. The solution may be stored in a deep-freeze for up to 6 months.

*Cholesterol working solution. Prepare the solution immediately before use.* Dilute 1.0 mL of the cholesterol stock solution to 10.0 mL with *heptane R*.

*Cholesterol and α-tocopherol stock solution.* Dissolve 50.0 mg of *cholesterol R* and 50.0 mg of *α-tocopherol R* in *heptane R* and dilute to 100.0 mL with the same solvent. The solution may be stored at room temperature for up to 3 months.

*Reference solution. Prepare the solution on the day of use.* Dilute 1.0 mL of the cholesterol and α-tocopherol stock solution to 100.0 mL with *heptane R*.

*Calibration solutions.* See Table 2.4.32.-1. *Prepare the solutions on the day of use.* Dilute each solution to 20.0 mL with a 10 per cent *V/V* solution of *ethyl acetate R* in *heptane R*.

For high levels of cholesterol (3.0-20.0 mg/g), use all 5 calibration solutions.

For low levels of cholesterol (0.2-3.0 mg/g), use the following calibration solutions: 0.2 mg/g, 1.0 mg/g and 3.0 mg/g.

*Test solution.* Weigh 0.100 g of the substance to be examined into a 15 mL quartz tube (for fish oils and cod-liver oils, shake the oil to be examined vigorously in a suitable container, allow to stand for 10-15 min and while maintaining the container upright, remove a sample from the middle layer of the oil for weighing). Add 1.0 mL of the internal standard working solution. Evaporate the solvent on a heating block at 50 °C under a gentle stream of *nitrogen R*. Add 0.5 mL of a 50 per cent *m/m* solution of *potassium hydroxide R* and 3.0 mL of *ethanol (96 per cent) R*. Fill the tube with *nitrogen R*, cap and homogenise. Heat on the heating block at 100 °C for 1 h. Cool for about 10 min, add 6.0 mL of *distilled water R* and homogenise. Condition a 20 mL solid phase extraction (SPE) column containing 1 g of *end-capped octadecylsilyl silica gel for chromatography R* (particles with a diameter of 55 µm and a pore size of 7 nm) with 5 mL of a 50 per cent *V/V* solution of *ethanol (96 per cent) R* in *distilled water R*. Transfer 5.0 mL of the saponified sample to the SPE column ensuring that the column does not dry out. Wash the column with 5.0 mL of a 50 per cent *V/V* solution of *ethanol (96 per cent) R* in *distilled water R*. Elute the column using 20.0 mL of a 10 per cent *V/V* solution of *ethyl acetate R* in *heptane R*. Collect the eluate and use it as the test solution.

*Column*:

- *material*: fused silica;
- *size*: *l* = 15 m, Ø = 0.25 mm;
- *stationary phase*: *phenyl(5)methyl(95)polysiloxane R* (film thickness 0.25 µm).

*Carrier gas*: *helium for chromatography R*.

*Pressure*: 48 kPa (corresponding to a flow rate of about 0.6 mL/min at 200 °C and about 0.4 mL/min at 330 °C).

*Split ratio*: 1:5.

*Temperature*:

| | Time (min) | Temperature (°C) |
|---|---|---|
| Column | 0 - 1 | 200 |
| | 1 - 7.5 | 200 → 330 |
| | 7.5 - 10 | 330 |
| Injection port | | 250 |
| Detector | | 340 |

Prior to analysis, heat the column at 340 °C for at least 30 min using the indicated pressure.

*Detection*: flame ionisation.

*Injection*: 1 µL.

*Retention time*: (5α)-cholestane = about 7.5 min; cholesterol = about 9 min.

Plot the calibration curve. The x-axis represents the nominal concentration of cholesterol in milligrams per gram of the substance to be examined in each calibration solution. The y-axis represents the ratio of the area of the peak due to cholesterol to the area of the peak due to (5α)-cholestane in the chromatogram obtained with each calibration solution. Calculate the slope (*S*) and the intercept with the y-axis (*Y*).

*System suitability*:

- *resolution*: minimum 1.5 between the peaks due to cholesterol and α-tocopherol in the chromatogram obtained with the reference solution;
- the coefficient of determination ($r^2$) of the calibration curve is not less than 0.995.

Calculate the content of total cholesterol, expressed in milligrams of cholesterol per gram of substance to be examined, using the following expression:

$$\frac{\frac{A_1}{A_2} - Y}{m_1 \times S} \times 0.100$$

$A_1$ = area of the peak due to cholesterol in the chromatogram obtained with the test solution;

$A_2$ = area of the peak due to (5α)-cholestane in the chromatogram obtained with the test solution;

$m_1$ = mass of the substance to be examined in the test solution, in grams;

$Y$ = intercept of the calibration curve with the y-axis;

$S$ = slope of the calibration curve, in grams per milligram.

Table 2.4.32.-1. – *Preparation of calibration solutions*

| Calibration solutions | | Cholesterol stock solution (mL) | Cholesterol working solution (mL) | Internal standard working solution (mL) |
|---|---|---|---|---|
| Cholesterol concentration (mg/mL) | Cholesterol concentration (mg/g)[a] | | | |
| 0.1 | 20.0 | 4.0 | | 1.0 |
| 0.05 | 10.0 | 2.0 | | 1.0 |
| 0.015 | 3.0 | 0.60 | | 1.0 |
| 0.005 | 1.0 | | 2.0 | 1.0 |
| 0.001 | 0.2 | | 0.40 | 1.0 |

(a)Based on a sample weight of 0.100 g of the substance to be examined.

# 2.5. ASSAYS

01/2008:20501
corrected 8.6

## 2.5.1. ACID VALUE

The acid value $I_A$ is the number that expresses, in milligrams the quantity of potassium hydroxide required to neutralise the free acids present in 1 g of the substance.

Dissolve 10.00 g of the substance to be examined, or the quantity prescribed, (*m* g), in 50 mL of a mixture of equal volumes of *ethanol (96 per cent) R* and *light petroleum R3*, previously neutralised with *0.1 M potassium hydroxide* or *0.1 M sodium hydroxide*, unless otherwise specified, using 0.5 mL of *phenolphthalein solution R1* as indicator. If necessary, heat to about 90 °C to dissolve the substance to be examined. When the substance to be examined has dissolved, titrate with *0.1 M potassium hydroxide* or *0.1 M sodium hydroxide* until the pink colour persists for at least 15 s (*n* mL of titrant). When heating has been applied to aid dissolution, maintain the temperature at about 90 °C during the titration.

$$I_A = \frac{5.611n}{m}$$

01/2008:20502

## 2.5.2. ESTER VALUE

The ester value $I_E$ is the number that expresses in milligrams the quantity of potassium hydroxide required to saponify the esters present in 1 g of the substance. It is calculated from the saponification value $I_S$ and the acid value $I_A$:

$$I_E = I_S - I_A$$

01/2008:20503

## 2.5.3. HYDROXYL VALUE

The hydroxyl value $I_{OH}$ is the number that expresses in milligrams the quantity of potassium hydroxide required to neutralise the acid combined by acylation in 1 g of the substance.

METHOD A

Introduce the quantity of the substance to be examined shown in Table 2.5.3.-1 (*m* g) into a 150 mL acetylation flask fitted with an air condenser, unless another quantity is prescribed in the monograph. Add the quantity of *acetic anhydride solution R1* stated in Table 2.5.3.-1 and attach the air condenser.

Table 2.5.3.-1

| Presumed value $I_{OH}$ | Quantity of sample (g) | Volume of acetylating reagent (mL) |
|---|---|---|
| 10 - 100 | 2.0 | 5.0 |
| 100 - 150 | 1.5 | 5.0 |
| 150 - 200 | 1.0 | 5.0 |
| 200 - 250 | 0.75 | 5.0 |
| 250 - 300 | 0.60 or 1.20 | 5.0 or 10.0 |
| 300 - 350 | 1.0 | 10.0 |
| 350 - 700 | 0.75 | 15.0 |
| 700 - 950 | 0.5 | 15.0 |

Heat the flask in a water-bath for 1 h keeping the level of the water about 2.5 cm above the level of the liquid in the flask. Withdraw the flask and allow to cool. Add 5 mL of *water R* through the upper end of the condenser. If a cloudiness appears add sufficient *pyridine R* to clear it, noting the volume added. Shake the flask and replace in the water-bath for 10 min. Withdraw the flask and allow to cool. Rinse the condenser and the walls of the flask with 5 mL of *alcohol R*, previously neutralised to *phenolphthalein solution R1*. Titrate with *0.5 M alcoholic potassium hydroxide* using 0.2 mL of *phenolphthalein solution R1* as indicator ($n_1$ mL of *0.5 M alcoholic potassium hydroxide*). Carry out a blank test under the same conditions ($n_2$ mL of *0.5 M alcoholic potassium hydroxide*).

$$I_{OH} = \frac{28.05(n_2 - n_1)}{m} + I_A$$

METHOD B

Introduce the prescribed quantity of the substance to be examined (*m* g) into a perfectly dry 5 mL conical flask fitted with a ground-glass or suitable plastic stopper and add 2.0 mL of *propionic anhydride reagent R*. Close the flask and shake gently to dissolve the substance. Allow to stand for 2 h unless otherwise prescribed. Remove the stopper and transfer the flask and its contents into a wide-mouthed 500 mL conical flask containing 25.0 mL of a 9 g/L solution of *aniline R* in *cyclohexane R* and 30 mL of *glacial acetic acid R*. Swirl the contents of the flask, allow to stand for 5 min, add 0.05 mL of *crystal violet solution R* and titrate with *0.1 M perchloric acid* until an emerald-green colour is obtained ($n_1$ mL of *0.1 M perchloric acid*). Carry out a blank test under the same conditions ($n_2$ mL of *0.1 M perchloric acid*).

$$I_{OH} = \frac{5.610(n_1 - n_2)}{m}$$

To take account of any water present, determine this (*y* per cent) by the semi-micro determination of water (*2.5.12*).

The hydroxyl value is then given by the equation:

$$I_{OH} = \text{(hydroxyl value as determined)} - 31.1y$$

01/2008:20504

## 2.5.4. IODINE VALUE

The iodine value $I_I$ is the number that expresses in grams the quantity of halogen, calculated as iodine, that can be fixed in the prescribed conditions by 100 g of the substance.

*When the monograph does not specify the method to be used, method A is applied. Any change from method A to method B is validated.*

METHOD A

Unless otherwise prescribed, use the following quantities (Table 2.5.4.-1) for the determination.

Table 2.5.4.-1

| Presumed value $I_I$ | Quantity of sample (g) |
|---|---|
| less than 20 | 1.0 |
| 20 - 60 | 0.5 - 0.25 |
| 60 - 100 | 0.25 - 0.15 |
| more than 100 | 0.15 - 0.10 |

Introduce the prescribed quantity of the substance to be examined ($m$ g) into a 250 mL flask fitted with a ground-glass stopper and previously dried or rinsed with *glacial acetic acid R*, and dissolve it in 15 mL of *chloroform R* unless otherwise prescribed. Add very slowly 25.0 mL of *iodine bromide solution R*. Close the flask and keep it in the dark for 30 min unless otherwise prescribed, shaking frequently. Add 10 mL of a 100 g/L solution of *potassium iodide R* and 100 mL of *water R*. Titrate with *0.1 M sodium thiosulfate*, shaking vigorously until the yellow colour is almost discharged. Add 5 mL of *starch solution R* and continue the titration adding the *0.1 M sodium thiosulfate* dropwise until the colour is discharged ($n_1$ mL of *0.1 M sodium thiosulfate*). Carry out a blank test under the same conditions ($n_2$ mL of *0.1 M sodium thiosulfate*).

$$I_I = \frac{1.269\ (n_2 - n_1)}{m}$$

METHOD B

Unless otherwise prescribed, use the following quantities (Table 2.5.4.-2) for the determination.

Table 2.5.4.-2

| Presumed value $I_I$ | Mass (g) (corresponding to an excess of 150 per cent ICl) | Mass (g) (corresponding to an excess of 100 per cent ICl) | Iodine chloride solution (mL) |
|---|---|---|---|
| <3 | 10 | 10 | 25 |
| 3 | 8.4613 | 10.5760 | 25 |
| 5 | 5.0770 | 6.3460 | 25 |
| 10 | 2.5384 | 3.1730 | 20 |
| 20 | 0.8461 | 1.5865 | 20 |
| 40 | 0.6346 | 0.7935 | 20 |
| 60 | 0.4321 | 0.5288 | 20 |
| 80 | 0.3173 | 0.3966 | 20 |
| 100 | 0.2538 | 0.3173 | 20 |
| 120 | 0.2115 | 0.2644 | 20 |
| 140 | 0.1813 | 0.2266 | 20 |
| 160 | 0.1587 | 0.1983 | 20 |
| 180 | 0.1410 | 0.1762 | 20 |
| 200 | 0.1269 | 0.1586 | 20 |

The mass of the sample is such that there will be an excess of *iodine chloride solution R* of 50 per cent to 60 per cent of the amount added, i.e. 100 per cent to 150 per cent of the amount absorbed.

Introduce the prescribed quantity of the substance to be examined ($m$ g) into a 250 mL flask fitted with a ground-glass stopper and previously rinsed with *glacial acetic acid R* or dried, and dissolve it in 15 mL of a mixture of equal volumes of *cyclohexane R* and *glacial acetic acid R*, unless otherwise prescribed. If necessary, melt the substance before dissolution (melting point greater than 50 °C). Add very slowly the volume of *iodine chloride solution R* stated in Table 2.5.4.-2. Close the flask and keep it in the dark for 30 min, unless otherwise prescribed, shaking frequently. Add 10 mL of a 100 g/L solution of *potassium iodide R* and 100 mL of *water R*. Titrate with *0.1 M sodium thiosulfate*, shaking vigorously until the yellow colour is almost discharged. Add 5 mL of *starch solution R* and continue the titration adding the *0.1 M sodium thiosulfate* dropwise until the colour is discharged ($n_1$ mL of *0.1 M sodium thiosulfate*). Carry out a blank test under the same conditions ($n_2$ mL of *0.1 M sodium thiosulfate*).

$$I_I = \frac{1.269\ (n_2 - n_1)}{m}$$

**01/2016:20505**

## 2.5.5. PEROXIDE VALUE

The peroxide value $I_P$ is the number that expresses in milliequivalents of active oxygen the quantity of peroxide contained in 1000 g of the substance, as determined by the methods described below.

*When the monograph does not specify the method to be used, method A is applied. Any change from method A to method B is validated.*

METHOD A

Place 5.00 g of the substance to be examined ($m$ g) in a 250 mL conical flask fitted with a ground-glass stopper. Add 30 mL of a mixture of 2 volumes of *chloroform R* and 3 volumes of *glacial acetic acid R*. Shake to dissolve the substance and add 0.5 mL of *saturated potassium iodide solution R*. Shake for exactly 1 min then add 30 mL of *water R*. Titrate with *0.01 M sodium thiosulfate*, adding the titrant slowly with continuous vigorous shaking, until the yellow colour is almost discharged. Add 5 mL of *starch solution R* and continue the titration, shaking vigorously, until the colour is discharged ($n_1$ mL of *0.01 M sodium thiosulfate*). Carry out a blank test under the same conditions ($n_2$ mL of *0.01 M sodium thiosulfate*). The volume of *0.01 M sodium thiosulfate* used in the blank titration must not exceed 0.1 mL.

$$I_P = \frac{10(n_1 - n_2)}{m}$$

METHOD B

*Carry out the operations avoiding exposure to actinic light.*

Place 50 mL of a mixture of 2 volumes of *trimethylpentane R* and 3 volumes of *glacial acetic acid R* in a conical flask and replace the stopper. Swirl the flask until the substance to be examined ($m$ g; see Table 2.5.5.-1) has dissolved. Using a suitable volumetric pipette, add 0.5 mL of *saturated potassium iodide solution R* and replace the stopper. Allow the solution to stand for 60 ± 1 s, thoroughly shaking the solution continuously, then add 30 mL of *water R*.

Table 2.5.5.-1

| Expected peroxide value $I_P$ | Mass of substance to be examined (g) |
|---|---|
| 0 to 12 | 5.00 to 2.00 |
| 12 to 20 | 2.00 to 1.20 |
| 20 to 30 | 1.20 to 0.80 |
| 30 to 50 | 0.800 to 0.500 |
| 50 to 90 | 0.500 to 0.300 |

Titrate the solution with *0.01 M sodium thiosulfate* ($V_1$ mL), adding it gradually and with constant, vigorous shaking, until the yellow iodine colour has almost disappeared. Add about 0.5 mL of *starch solution R1* and continue the titration, with

constant shaking especially near the end-point, to liberate all of the iodine from the solvent layer. Add the sodium thiosulfate solution dropwise until the blue colour just disappears.

Depending on the volume of *0.01 M sodium thiosulfate* used, it may be necessary to titrate with *0.1 M sodium thiosulfate*.

*NOTE*: there is a 15 s to 30 s delay in neutralising the starch indicator for peroxide values of 70 and greater, due to the tendency of trimethylpentane to float on the surface of the aqueous medium and the time necessary to adequately mix the solvent and the aqueous titrant, thus liberating the last traces of iodine. It is recommended to use *0.1 M sodium thiosulfate* for peroxide values greater than 150. A small amount (0.5 per cent to 1.0 per cent *m/m*) of high HLB emulsifier (for example polysorbate 60) may be added to the mixture to retard the phase separation and decrease the time lag in the liberation of iodine.

Carry out a blank determination ($V_0$ mL). If the result of the blank determination exceeds 0.1 mL of titration reagent, replace the reagents and repeat the determination.

$$I_p = \frac{1000(V_1 - V_0)c}{m}$$

c = concentration of the sodium thiosulfate solution, in moles per litre.

**01/2008:20506**

## 2.5.6. SAPONIFICATION VALUE

The saponification value $I_S$ is the number that expresses in milligrams the quantity of potassium hydroxide required to neutralise the free acids and to saponify the esters present in 1 g of the substance.

Unless otherwise prescribed, use the quantities indicated in Table 2.5.6.-1 for the determination.

Table 2.5.6.-1

| Presumed value $I_S$ | Quantity of sample (g) |
|---|---|
| <3 | 20 |
| 3 to 10 | 12 to 15 |
| 10 to 40 | 8 to 12 |
| 40 to 60 | 5 to 8 |
| 60 to 100 | 3 to 5 |
| 100 to 200 | 2.5 to 3 |
| 200 to 300 | 1 to 2 |
| 300 to 400 | 0.5 to 1 |

Introduce the prescribed quantity of the substance to be examined (*m* g) into a 250 mL borosilicate glass flask fitted with a reflux condenser. Add 25.0 mL of *0.5 M alcoholic potassium hydroxide* and a few glass beads. Attach the condenser and heat under reflux for 30 min, unless otherwise prescribed. Add 1 mL of *phenolphthalein solution R1* and titrate immediately (while still hot) with *0.5 M hydrochloric acid* ($n_1$ mL of *0.5 M hydrochloric acid*). Carry out a blank test under the same conditions ($n_2$ mL of *0.5 M hydrochloric acid*).

$$I_S = \frac{28.05(n_2 - n_1)}{m}$$

**01/2008:20507**

## 2.5.7. UNSAPONIFIABLE MATTER

The term "unsaponifiable matter" is applied to the substances non-volatile at 100-105 °C obtained by extraction with an organic solvent from the substance to be examined after it has been saponified. The result is calculated as per cent *m/m*.

*Use ungreased ground-glass glassware.*

Introduce the prescribed quantity of the substance to be examined (*m* g) into a 250 mL flask fitted with a reflux condenser. Add 50 mL of *2 M alcoholic potassium hydroxide R* and heat on a water-bath for 1 h, swirling frequently. Cool to a temperature below 25 °C and transfer the contents of the flask to a separating funnel with the aid of 100 mL of *water R*. Shake the liquid carefully with 3 quantities, each of 100 mL, of *peroxide-free ether R*. Combine the ether layers in another separating funnel containing 40 mL of *water R*, shake gently for a few minutes, allow to separate and reject the aqueous phase. Wash the ether phase with 2 quantities, each of 40 mL, of *water R* then wash successively with 40 mL of a 30 g/L solution of *potassium hydroxide R* and 40 mL of *water R*; repeat this procedure 3 times. Wash the ether phase several times, each with 40 mL of *water R*, until the aqueous phase is no longer alkaline to phenolphthalein. Transfer the ether phase to a tared flask, washing the separating funnel with *peroxide-free ether R*.

Distil off the ether with suitable precautions and add 6 mL of *acetone R* to the residue. Carefully remove the solvent in a current of air. Dry to constant mass at 100-105 °C. Allow to cool in a desiccator and weigh (*a* g).

$$\text{Unsaponifiable matter} = \frac{100a}{m} \text{ per cent}$$

Dissolve the residue in 20 mL of *alcohol R*, previously neutralised to *phenolphthalein solution R* and titrate with *0.1 M ethanolic sodium hydroxide*. If the volume of *0.1 M ethanolic sodium hydroxide* used is greater than 0.2 mL, the separation of the layers has been incomplete; the residue weighed cannot be considered as "unsaponifiable matter". In case of doubt, the test must be repeated.

**01/2008:20508**

## 2.5.8. DETERMINATION OF PRIMARY AROMATIC AMINO-NITROGEN

Dissolve the prescribed quantity of the substance to be examined in 50 mL of *dilute hydrochloric acid R* or in another prescribed solvent and add 3 g of *potassium bromide R*. Cool in ice-water and titrate by slowly adding *0.1 M sodium nitrite* with constant stirring.

Determine the end-point electrometrically or by the use of the prescribed indicator.

01/2008:20509

## 2.5.9. DETERMINATION OF NITROGEN BY SULFURIC ACID DIGESTION

SEMI-MICRO METHOD

Place a quantity of the substance to be examined (*m* g) containing about 2 mg of nitrogen in a combustion flask, add 4 g of a powdered mixture of 100 g of *dipotassium sulfate R*, 5 g of *copper sulfate pentahydrate R* and 2.5 g of *selenium R*, and three glass beads. Wash any adhering particles from the neck into the flask with 5 mL of *sulfuric acid R*, allowing it to run down the sides of the flask, and mix the contents by rotation. Close the mouth of the flask loosely, for example by means of a glass bulb with a short stem, to avoid excessive loss of sulfuric acid. Heat gradually at first, then increase the temperature until there is vigorous boiling with condensation of sulfuric acid in the neck of the flask; precautions should be taken to prevent the upper part of the flask from becoming overheated. Continue the heating for 30 min, unless otherwise prescribed. Cool, dissolve the solid material by cautiously adding to the mixture 25 mL of *water R*, cool again and place in a steam-distillation apparatus. Add 30 mL of *strong sodium hydroxide solution R* and distil immediately by passing steam through the mixture. Collect about 40 mL of distillate in 20.0 mL of *0.01 M hydrochloric acid* and enough *water R* to cover the tip of the condenser. Towards the end of the distillation, lower the receiver so that the tip of the condenser is above the surface of the acid. Take precautions to prevent any water on the outer surface of the condenser from reaching the contents of the receiver. Titrate the distillate with *0.01 M sodium hydroxide*, using *methyl red mixed solution R* as indicator ($n_1$ mL of *0.01 M sodium hydroxide*).

Repeat the test using about 50 mg of *glucose R* in place of the substance to be examined ($n_2$ mL of *0.01 M sodium hydroxide*).

$$\text{Content of nitrogen} = \frac{0.01401(n_2 - n_1)}{m} \text{ per cent}$$

01/2008:20510

## 2.5.10. OXYGEN-FLASK METHOD

Unless otherwise prescribed the combustion flask is a conical flask of at least 500 mL capacity of borosilicate glass with a ground-glass stopper fitted with a suitable carrier for the sample, for example in platinum or platinum-iridium.

Finely grind the substance to be examined, place the prescribed quantity in the centre of a piece of filter paper measuring about 30 mm by 40 mm provided with a small strip about 10 mm wide and 30 mm long. If paper impregnated with lithium carbonate is prescribed, moisten the centre of the paper with a saturated solution of *lithium carbonate R* and dry in an oven before use. Envelop the substance to be examined in the paper and place it in the sample carrier. Introduce into the flask *water R* or the prescribed solution designed to absorb the combustion products, displace the air with oxygen by means of a tube having its end just above the liquid, moisten the neck of the flask with *water R* and close with its stopper. Ignite the paper strip by suitable means with the usual precautions. Keep the flask firmly closed during the combustion. Shake the flask vigorously to completely dissolve the combustion products. Cool and after about 5 min, unless otherwise prescribed, carefully unstopper the flask. Wash the ground parts and the walls of the flask, as well as the sample carrier, with *water R*. Combine the combustion products and the washings and proceed as prescribed in the monograph.

corrected 8.0

## 2.5.11. COMPLEXOMETRIC TITRATIONS

ALUMINIUM

Introduce 20.0 mL of the prescribed solution into a 500 mL conical flask, add 25.0 mL of *0.1 M sodium edetate* and 10 mL of a mixture of equal volumes of a 155 g/L solution of *ammonium acetate R* and *dilute acetic acid R*. Boil for 2 min, then cool. Add 50 mL of *ethanol R* and 3 mL of a freshly prepared 0.25 g/L solution of *dithizone R* in *ethanol R*. Titrate the excess of sodium edetate with *0.1 M zinc sulfate* until the colour changes from greenish-blue to reddish-violet.

1 mL of *0.1 M sodium edetate* is equivalent to 2.698 mg of Al.

BISMUTH

Introduce the prescribed solution into a 500 mL conical flask. Dilute to 250 mL with *water R* and then, unless otherwise prescribed, add dropwise, with shaking, *concentrated ammonia R* until the mixture becomes cloudy. Add 0.5 mL of *nitric acid R*. Heat to about 70 °C until the cloudiness disappears completely. Add about 50 mg of *xylenol orange triturate R* and titrate with *0.1 M sodium edetate* until the colour changes from pinkish-violet to yellow.

1 mL of *0.1 M sodium edetate* is equivalent to 20.90 mg of Bi.

CALCIUM

Introduce the prescribed solution into a 500 mL conical flask, and dilute to 300 mL with *water R*. Add 6.0 mL of *strong sodium hydroxide solution R* and about 200 mg of *calconecarboxylic acid triturate R*. Titrate with *0.1 M sodium edetate* until the colour changes from violet to full blue.

1 mL of *0.1 M sodium edetate* is equivalent to 4.008 mg of Ca.

MAGNESIUM

Introduce the prescribed solution into a 500 mL conical flask and dilute to 300 mL with *water R*. Add 10 mL of *ammonium chloride buffer solution pH 10.0 R* and about 50 mg of *mordant black 11 triturate R*. Heat to about 40 °C then titrate at this temperature with *0.1 M sodium edetate* until the colour changes from violet to full blue.

1 mL of *0.1 M sodium edetate* is equivalent to 2.431 mg of Mg.

LEAD

Introduce the prescribed solution into a 500 mL conical flask and dilute to 200 mL with *water R*. Add about 50 mg of *xylenol orange triturate R* and *hexamethylenetetramine R* until the solution becomes violet-pink. Titrate with *0.1 M sodium edetate* until the violet-pink colour changes to yellow.

1 mL of *0.1 M sodium edetate* is equivalent to 20.72 mg of Pb.

ZINC

Introduce the prescribed solution into a 500 mL conical flask and dilute to 200 mL with *water R*. Add about 50 mg of *xylenol orange triturate R* and *hexamethylenetetramine R* until the solution becomes violet-pink. Add 2 g of *hexamethylenetetramine R* in excess. Titrate with *0.1 M sodium edetate* until the violet-pink colour changes to yellow.

1 mL of *0.1 M sodium edetate* is equivalent to 6.54 mg of Zn.

04/2018:20512

## 2.5.12. WATER: SEMI-MICRO DETERMINATION

The semi-micro determination of water is based upon the quantitative reaction of water with sulfur dioxide and iodine in a suitable anhydrous medium in the presence of a base with sufficient buffering capacity.

APPARATUS

The apparatus consists of a titration vessel with:

- 2 identical platinum electrodes;
- tight inlets for introduction of solvent and titrant;
- an inlet for introduction of air via a desiccant;
- a sample inlet fitted with a stopper or, for liquids, a septum.

Inlet systems for introduction of dry nitrogen or for aspiration of solvents may also be fitted.

The titration is carried out according to the instrument supplier's instructions. Care is taken throughout the determination to avoid exposure of reagents and solvents to atmospheric moisture. The end-point is determined using 2 identical indicator electrodes connected to an electrical source that maintains between the electrodes either a constant current (*2.2.65. Voltametric titration*) or a constant voltage (*2.2.19. Amperometric titration*). Where direct titration is used (method A), addition of titrant causes either a decrease in voltage where constant current is maintained or an increase in current where constant voltage is maintained, until the end-point is reached. Instruments with automatic end-point detection are commonly used. Instrument qualification is carried out according to established quality system procedures, for example using a suitable certified reference material (*sodium aminosalicylate dihydrate for equipment qualification CRS* may be used).

STANDARDISATION

To the titration vessel, add *methanol R*, dried if necessary, or the solvent recommended by the supplier of the titrant. Where applicable for the apparatus used, eliminate residual water from the measurement cell or carry out a pre-titration. Introduce a suitable amount of water in an appropriate form (*water R* or a certified reference material) and carry out the titration, stirring for the necessary time. The water equivalent is not less than 80 per cent of that indicated by the supplier. Standardise the titrant before the first use and at suitable intervals thereafter.

Unless otherwise prescribed, use Method A.

METHOD A

Introduce into the titration vessel *methanol R*, or the solvent indicated in the monograph or recommended by the supplier of the titrant. Where applicable for the apparatus used, eliminate residual water from the measurement cell or carry out a pre-titration. Introduce the substance to be examined rapidly and carry out the titration, stirring for the necessary extraction time.

METHOD B

Introduce into the titration vessel *methanol R*, or the solvent indicated in the monograph or recommended by the supplier of the titrant. Where applicable for the apparatus used, eliminate residual water from the measurement cell or carry out a pre-titration. Introduce the substance to be examined rapidly and in a suitable state of division. Add an accurately measured volume of the titrant, sufficient to give an excess of about 1 mL or the prescribed volume. Allow to stand protected from light for 1 min or the prescribed time, with stirring. Titrate the excess of reagent using *methanol R* or the prescribed solvent, containing an accurately known quantity of water.

SUITABILITY

The accuracy of the determination with the chosen titrant must be verified for each combination of substance, titrant and solvent to be examined. The following procedure, given as an example, is suitable for samples containing 2.5-25 mg of water.

The water content of the substance to be examined is determined using the reagent/solvent system chosen. Thereafter, in the same titration vessel, sequential known amounts of water, corresponding to about 50-100 per cent of the amount found in the substance to be examined, are added in an appropriate form (at least 5 additions) and the water content is determined after each addition. Calculate the percentage recovery ($r$) after each addition using the following expression:

$$r = 100\frac{W_2}{W_1}$$

$W_1$ = amount of water added, in milligrams;

$W_2$ = amount of water found, in milligrams.

Calculate the mean percentage recovery ($\bar{r}$). The reagent/solvent system is considered to be acceptable if $\bar{r}$ is between 97.5 per cent and 102.5 per cent.

Calculate the regression line. The $x$-axis represents the cumulative water added whereas the $y$-axis represents the sum of the initial water content determined for the substance ($M$) and the cumulative water determined after each addition. Calculate the slope ($b$), the intercept with the $y$-axis ($a$) and the intercept of the extrapolated calibration line with the $x$-axis ($d$).

Calculate the percentage errors ($e_1$ and $e_2$) using the following expressions:

$$e_1 = 100\frac{a - M}{M}$$

$$e_2 = 100\frac{|d| - M}{M}$$

$a$ = the $y$-axis intercept, in milligrams of water;

$d$ = the $x$-axis intercept, in milligrams of water;

$M$ = water content of the substance, in milligrams of water.

The reagent/solvent system is considered to be acceptable if:

- $|e_1|$ and $|e_2|$ are not greater than 2.5 per cent;
- $b$ is between 0.975 and 1.025.

01/2008:20513

## 2.5.13. ALUMINIUM IN ADSORBED VACCINES

Homogenise the preparation to be examined and transfer a suitable quantity, presumed to contain 5 mg to 6 mg of aluminium, to a 50 mL combustion flask. Add 1 mL of *sulfuric acid R*, 0.1 mL of *nitric acid R* and some glass beads. Heat the solution until thick, white fumes are evolved. If there is charring at this stage add a few more drops of *nitric acid R* and continue boiling until the colour disappears. Allow to cool for a few minutes, carefully add 10 mL of *water R* and boil until a clear solution is obtained. Allow to cool, add 0.05 mL of *methyl orange solution R* and neutralise with *strong sodium hydroxide solution R* (6.5 mL to 7 mL). If a

precipitate forms dissolve it by adding, dropwise, sufficient *dilute sulfuric acid R*. Transfer the solution to a 250 mL conical flask, rinsing the combustion flask with 25 mL of *water R*. Add 25.0 mL of *0.02 M sodium edetate*, 10 mL of *acetate buffer solution pH 4.4 R* and a few glass beads and boil gently for 3 min. Add 0.1 mL of *pyridylazonaphthol solution R* and titrate the hot solution with *0.02 M copper sulfate* until the colour changes to purplish-brown. Carry out a blank titration omitting the vaccine.

1 mL of *0.02 M sodium edetate* is equivalent to 0.5396 mg of Al.

**01/2008:20514**

## 2.5.14. CALCIUM IN ADSORBED VACCINES

*All solutions used for this test must be prepared using water R.*

Determine the calcium by atomic emission spectrometry (*2.2.22, Method I*). Homogenise the preparation to be examined. To 1.0 mL add 0.2 mL of *dilute hydrochloric acid R* and dilute to 3.0 mL with *water R*. Measure the absorbance at 620 nm.

**01/2008:20515**

## 2.5.15. PHENOL IN IMMUNOSERA AND VACCINES

Homogenise the preparation to be examined. Dilute an appropriate volume with *water R* so as to obtain a solution presumed to contain 15 µg of phenol per millilitre. Prepare a series of reference solutions with *phenol R* containing 5 µg, 10 µg, 15 µg, 20 µg and 30 µg of phenol per millilitre respectively. To 5 mL of the solution to be examined and to 5 mL of each of the reference solutions respectively, add 5 mL of *buffer solution pH 9.0 R*, 5 mL of *aminopyrazolone solution R* and 5 mL of *potassium ferricyanide solution R*. Allow to stand for 10 min and measure the intensity of colour at 546 nm.

Plot the calibration curve and calculate the phenol content of the preparation to be examined.

**01/2008:20516**

## 2.5.16. PROTEIN IN POLYSACCHARIDE VACCINES

*Test solution.* Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Place 1 mL of the solution in a glass tube and add 0.15 mL of a 400 g/L solution of *trichloroacetic acid R*. Shake, allow to stand for 15 min, centrifuge for 10 min at 5000 r/min and discard the supernatant. Add 0.4 mL of *0.1 M sodium hydroxide* to the centrifugation residue.

*Reference solutions.* Dissolve 0.100 g of *bovine albumin R* in 100 mL of *0.1 M sodium hydroxide* (stock solution containing 1 g of protein per litre). Dilute 1 mL of the stock solution to 20 mL with *0.1 M sodium hydroxide* (working dilution 1 : 50 mg of protein per litre). Dilute 1 mL of the stock solution to 4 mL with *0.1 M sodium hydroxide* (working dilution 2 : 250 mg of protein per litre). Place in 6 glass tubes 0.10 mL, 0.20 mL and 0.40 mL of working dilution 1 and 0.15 mL, 0.20 mL and 0.25 mL of working dilution 2. Make up the volume in each tube to 0.40 mL using *0.1 M sodium hydroxide*.

Prepare a blank using 0.40 mL of *0.1 M sodium hydroxide*.

Add 2 mL of *cupri-tartaric solution R3* to each tube, shake and allow to stand for 10 min. Add to each tube 0.2 mL of a mixture of equal volumes of *phosphomolybdotungstic reagent R* and *water R*, prepared immediately before use. Stopper the tubes, mix by inverting and allow to stand in the dark for 30 min. The blue colour is stable for 60 min. If necessary, centrifuge to obtain clear solutions.

Measure the absorbance (*2.2.25*) of each solution at 760 nm using the blank as the compensation liquid. Draw a calibration curve from the absorbances of the 6 reference solutions and the corresponding protein contents and read from the curve the content of protein in the test solution.

**01/2008:20517**

## 2.5.17. NUCLEIC ACIDS IN POLYSACCHARIDE VACCINES

*Test solution.* Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*.

Dilute the test solution if necessary to obtain an absorbance value suitable for the instrument used. Measure the absorbance (*2.2.25*) at 260 nm using *water R* as the compensation liquid.

The absorbance of a 1 g/L solution of nucleic acid at 260 nm is 20.

**01/2008:20518**

## 2.5.18. PHOSPHORUS IN POLYSACCHARIDE VACCINES

*Test solution.* Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volume used in the test (1 mL) contains about 6 µg of phosphorus. Transfer 1.0 mL of the solution to a 10 mL ignition tube.

*Reference solutions.* Dissolve 0.2194 g of *potassium dihydrogen phosphate R* in 500 mL of *water R* to give a solution containing the equivalent of 0.1 mg of phosphorus per millilitre. Dilute 5.0 mL of the solution to 100.0 mL with *water R*. Introduce 0.5 mL, 1.0 mL and 2.0 mL of the dilute solution into 3 ignition tubes.

Prepare a blank solution using 2.0 mL of *water R* in an ignition tube.

To all the tubes add 0.2 mL of *sulfuric acid R* and heat in an oil bath at 120 °C for 1 h and then at 160 °C until white fumes appear (about 1 h). Add 0.1 mL of *perchloric acid R* and heat at 160 °C until the solution is decolorised (about 90 min). Cool and add to each tube 4 mL of *water R* and 4 mL of *ammonium molybdate reagent R*. Heat in a water-bath at 37 °C for 90 min and cool. Adjust the volume to 10.0 mL with *water R*. The blue colour is stable for several hours.

Measure the absorbance (*2.2.25*) of each solution at 820 nm using the blank solution as the compensation liquid. Draw a calibration curve with the absorbances of the 3 reference

solutions as a function of the quantity of phosphorus in the solutions and read from the curve the quantity of phosphorus in the test solution.

**01/2008:20519 corrected 10.0**

## 2.5.19. *O*-ACETYL IN POLYSACCHARIDE VACCINES

*Test solution.* Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volumes used in the test contain 30 µg to 600 µg of acetylcholine chloride (*O*-acetyl). Introduce 0.3 mL, 0.5 mL and 1.0 mL in duplicate into 6 tubes (3 reaction solutions and 3 correction solutions).

*Reference solutions.* Dissolve 0.150 g of *acetylcholine chloride R* in 10 mL of *water R* (stock solution containing 15 g of acetylcholine chloride per litre). Immediately before use, dilute 1 mL of the stock solution to 50 mL with *water R* (working dilution 1: 300 µg of acetylcholine chloride per millilitre). Immediately before use, dilute 1 mL of the stock solution to 25 mL with *water R* (working dilution 2: 600 µg of acetylcholine chloride per millilitre). Introduce 0.1 mL and 0.4 mL of working dilution 1 in duplicate (reaction and correction solutions) into 4 tubes and 0.6 mL and 1.0 mL of working dilution 2 in duplicate (reaction and correction solutions) into another 4 tubes.

Prepare a blank using 1 mL of *water R*.

Make up the volume in each tube to 1 mL with *water R*. Add 1.0 mL of a 4 M solution of hydrochloric acid prepared from *hydrochloric acid R* to each of the correction tubes and to the blank. Add 2.0 mL of *alkaline hydroxylamine solution R* to each tube. Allow the reaction to proceed for exactly 2 min and add 1.0 mL of the 4 M solution of hydrochloric acid to each of the reaction tubes. To each tube, add 1.0 mL of a 100 g/L solution of *ferric chloride R* in a 0.1 M solution of hydrochloric acid prepared from *hydrochloric acid R*, stopper the tubes and shake vigorously to remove bubbles.

Measure the absorbance (*2.2.25*) of each solution at 540 nm using the blank as the compensation liquid. For each reaction solution, subtract the absorbance of the corresponding correction solution. Draw a calibration curve from the corrected absorbances for the 4 reference solutions and the corresponding content of acetylcholine chloride and read from the curve the content of acetylcholine chloride in the test solution for each volume tested. Calculate the mean of the 3 values.

1 mole of acetylcholine chloride (181.7 g) is equivalent to 1 mole of *O*-acetyl (43.05 g).

**01/2008:20520**

## 2.5.20. HEXOSAMINES IN POLYSACCHARIDE VACCINES

*Test solution.* Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volumes used in the test contain 125 µg to 500 µg of glucosamine (hexosamine). Introduce 1.0 mL of the diluted solution into a graduated tube.

*Reference solutions.* Dissolve 60 mg of *glucosamine hydrochloride R* in 100 mL of *water R* (stock solution containing 0.500 g of glucosamine per litre). Introduce 0.25 mL, 0.50 mL, 0.75 mL, and 1.0 mL of the working dilution into 4 graduated tubes.

Prepare a blank using 1 mL of *water R*.

Make up the volume in each tube to 1 mL with *water R*. Add 1 mL of a solution of *hydrochloric acid R* (292 g/L) to each tube. Stopper the tubes and place in a water-bath for 1 h. Cool to room temperature. Add to each tube 0.05 mL of a 5 g/L solution of *thymolphthalein R* in *alcohol R*; add a solution of *sodium hydroxide R* (200 g/L) until a blue colour is obtained and then *1 M hydrochloric acid* until the solution is colourless. Dilute the volume in each tube to 10 mL with *water R* (neutralised hydrolysates).

In a second series of 10 mL graduated tubes, place 1 mL of each neutralised hydrolysate. Add 1 mL of acetylacetone reagent (a mixture, prepared immediately before use, of 1 volume of *acetylacetone R* and 50 volumes of a 53 g/L solution of *anhydrous sodium carbonate R*) to each tube. Stopper the tubes and place in a water-bath at 90 °C for 45 min. Cool to room temperature. Add to each tube 2.5 mL of *alcohol R* and 1.0 mL of dimethylaminobenzaldehyde solution (immediately before use dissolve 0.8 g of *dimethylaminobenzaldehyde R* in 15 mL of *alcohol R* and add 15 mL of *hydrochloric acid R*) and dilute the volume in each tube to 10 mL with *alcohol R*. Stopper the tubes, mix by inverting and allow to stand in the dark for 90 min. Measure the absorbance (*2.2.25*) of each solution at 530 nm using the blank as the compensation liquid.

Draw a calibration curve from the absorbances for the 4 reference solutions and the corresponding content of hexosamine and read from the curve the quantity of hexosamine in the test solution.

**01/2008:20521**

## 2.5.21. METHYLPENTOSES IN POLYSACCHARIDE VACCINES

*Test solution.* Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volumes used in the test contain 2 µg to 20 µg of rhamnose (methylpentoses). Introduce 0.25 mL, 0.50 mL and 1.0 mL of the diluted solution into 3 tubes.

*Reference solutions.* Dissolve 0.100 g of *rhamnose R* in 100 mL of *water R* (stock solution containing 1 g of methylpentose per litre). Immediately before use, dilute 1 mL of the stock solution to 50 mL with *water R* (working dilution: 20 mg of methylpentose per litre). Introduce 0.10 mL, 0.25 mL, 0.50 mL, 0.75 mL and 1.0 mL of the working dilution into 5 tubes.

Prepare a blank using 1 mL of *water R*.

Make up the volume in each tube to 1 mL with *water R*. Place the tubes in iced water and add dropwise and with continuous stirring to each tube 4.5 mL of a cooled mixture of 1 volume of *water R* and 6 volumes of *sulfuric acid R*. Warm the tubes to room temperature and place in a water-bath for a few minutes. Cool to room temperature. Add to each tube 0.10 mL of a 30 g/L solution of *cysteine hydrochloride R*, prepared immediately before use. Shake and allow to stand for 2 h.

Measure the absorbance (*2.2.25*) of each solution at 396 nm and at 430 nm using the blank as compensation liquid. For each solution, calculate the difference between the absorbance measured at 396 nm and that measured at 430 nm. Draw a calibration curve from the absorbance differences for the 5 reference solutions and the corresponding content

of methylpentose and read from the curve the quantity of methylpentose in the test solution for each volume tested. Calculate the mean of the 3 values.

**01/2008:20522**

## 2.5.22. URONIC ACIDS IN POLYSACCHARIDE VACCINES

*Test solution.* Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volumes used in the test contain 4 µg to 40 µg of glucuronic acid (uronic acids). Introduce 0.25 mL, 0.50 mL and 1.0 mL of the diluted solution into 3 tubes.

*Reference solutions.* Dissolve 50 mg of *sodium glucuronate R* in 100 mL of *water R* (stock solution containing 0.4 g of glucuronic acid per litre). Immediately before use, dilute 5 mL of the stock solution to 50 mL with *water R* (working dilution: 40 mg of glucuronic acid per litre). Introduce 0.10 mL, 0.25 mL, 0.50 mL, 0.75 mL, and 1.0 mL of the working dilution into 5 tubes.

Prepare a blank using 1 mL of *water R*.

Make up the volume in each tube to 1 mL with *water R*. Place the tubes in iced water and add dropwise and with continuous stirring to each tube 5.0 mL of *borate solution R*. Stopper the tubes and place in a water-bath for 15 min. Cool to room temperature. Add 0.20 mL of a 1.25 g/L solution of *carbazole R* in *ethanol R* to each tube. Stopper the tubes and place in a water-bath for 15 min. Cool to room temperature. Measure the absorbance (*2.2.25*) of each solution at 530 nm using the blank as the compensation liquid.

Draw a calibration curve from the absorbances for the 5 reference solutions and the corresponding content of glucuronic acid and read from the curve the quantity of glucuronic acid in the test solution for each volume tested. Calculate the mean of the 3 values.

**01/2008:20523**

## 2.5.23. SIALIC ACID IN POLYSACCHARIDE VACCINES

*Test solution.* Transfer quantitatively the contents of one or several containers to a volumetric flask of a suitable volume that will give a solution with a known concentration of about 250 µg per millilitre of polysaccharide and dilute to volume with *water R*. Using a syringe, transfer 4.0 mL of this solution to a 10 mL ultrafiltration cell suitable for the passage of molecules of relative molecular mass less than 50 000. Rinse the syringe twice with *water R* and transfer the rinsings to the ultrafiltration cell. Carry out the ultrafiltration, with constant stirring, under *nitrogen R* at a pressure of about 150 kPa. Refill the cell with *water R* each time the volume of liquid in it has decreased to 1 mL and continue until 200 mL has been filtered and the remaining volume in the cell is about 2 mL. Using a syringe, transfer this residual liquid to a 10 mL volumetric flask. Wash the cell with 3 quantities, each of 2 mL, of *water R*, transfer the washings to the flask and dilute to 10.0 mL with *water R* (test solution). In each of 2 test-tubes place 2.0 mL of the test solution.

*Reference solutions.* Use the reference solutions prescribed in the monograph.

Prepare 2 series of 3 test-tubes, place in the tubes of each series 0.5 mL, 1.0 mL and 1.5 mL respectively, of the reference solution corresponding to the type of vaccine to be examined and adjust the volume in each tube to 2.0 mL with *water R*.

Prepare blank solutions using 2.0 mL of *water R* in each of 2 test-tubes.

To all the tubes add 5.0 mL of *resorcinol reagent R*. Heat at 105 °C for 15 min, cool in cold water and transfer the tubes to a bath of iced water. To each tube add 5 mL of *isoamyl alcohol R* and mix thoroughly. Place in the bath of iced water for 15 min. Centrifuge the tubes and keep them in the bath of iced water until the examination by absorption spectrophotometry. Measure the absorbance (*2.2.25*) of each supernatant solution at 580 nm and 450 nm using *isoamyl alcohol R* as the compensation liquid. For each wavelength, calculate the absorbance as the mean of the values obtained with 2 identical solutions. Subtract the mean value for the blank solution from the mean values obtained for the other solutions.

Draw a graph showing the difference between the absorbances at 580 nm and 450 nm of the reference solutions as a function of the content of *N*-acetylneuraminic acid and read from the graph the quantity of *N*-acetylneuraminic acid (sialic acid) in the test solution.

**01/2011:20524**

## 2.5.24. CARBON DIOXIDE IN GASES

Gases absorb light at one or more specific wavelengths. This property is widely used to allow highly selective measurement of their concentrations.

**Description and principle of measurement**. The concentration of carbon dioxide in other gases can be determined using an infrared analyser.

The infrared analyser generally consists of a light source emitting broadband infrared radiation, an optical device, a sample cell and a detector. The optical device may be positioned either before or after the sample cell and it consists of one or several optical filters, through which the broadband radiation is passed. The optical device in this case is selected for carbon dioxide. The measurement light beam passes through the sample cell and may also pass through a reference cell if the analyser integrates such a feature (some use an electronic system instead of a reference cell).

When carbon dioxide is present in the sample cell, absorption of energy in the measurement light beam will occur according to the Beer-Lambert law and this produces a change in the detector signal. This measurement signal is compared to a reference signal to generate an output related to the concentration of carbon dioxide. The generated signal is linearised in order to obtain the carbon dioxide concentration. To prevent the entry of particles into the sensors, which could cause stray-light phenomena, the apparatus is fitted with a suitable filter.

**Required technical specifications**. When used for a limit test, the infrared analyser meets the following technical specifications:

- *limit of detection*: (generally defined as a signal-to-noise ratio of 2) maximum 20 per cent of the maximum admissible concentration;
- *repeatability*: maximum relative standard deviation of 10 per cent of the maximum admissible concentration, determined on 6 measurements;

– *linearity*: maximum 10 per cent of the maximum admissible concentration.

The technical specifications must be met in the presence of the other gas impurities in the sample.

**01/2011:20525**

## 2.5.25. CARBON MONOXIDE IN GASES

METHOD I

*Apparatus.* The apparatus (Figure 2.5.25.-1) consists of the following parts connected in series:

– a U-tube ($U_1$) containing *anhydrous silica gel R* impregnated with *chromium trioxide R*;

– a wash bottle ($F_1$) containing 100 mL of a 400 g/L solution of *potassium hydroxide R*;

– a U-tube ($U_2$) containing pellets of *potassium hydroxide R*;

– a U-tube ($U_3$) containing *diphosphorus pentoxide R* dispersed on previously granulated, fused pumice;

– a U-tube ($U_4$) containing 30 g of *recrystallised iodine pentoxide R* in granules, previously dried at 200 °C and kept at a temperature of 120 °C ($T$) during the test; the iodine pentoxide is packed in the tube in 1 cm columns separated by 1 cm columns of glass wool to give an effective length of 5 cm;

– a reaction tube ($F_2$) containing 2.0 mL of *potassium iodide solution R* and 0.15 mL of *starch solution R*.

*Method.* Flush the apparatus with 5.0 L of *argon R* and, if necessary, discharge the blue colour in the iodide solution by adding the smallest necessary quantity of freshly prepared *0.002 M sodium thiosulfate*. Continue flushing until not more than 0.045 mL of *0.002 M sodium thiosulfate* is required after passage of 5.0 L of *argon R*. Pass the gas to be examined from the cylinder through the apparatus, using the prescribed volume and the flow rate. Flush the last traces of liberated iodine into the reaction tube by passing through the apparatus 1.0 L of *argon R*. Titrate the liberated iodine with *0.002 M sodium thiosulfate*. Carry out a blank test, using the prescribed volume of *argon R*. The difference between the volumes of *0.002 M sodium thiosulfate* used in the titrations is not greater than the prescribed limit.

METHOD II

Gases absorb light at one or more specific wavelengths. This property is widely used to allow highly selective measurement of their concentrations.

**Description and principle of measurement**. The concentration of carbon monoxide in other gases can be determined using an infrared analyser.

The infrared analyser generally consists of a light source emitting broadband infrared radiation, an optical device, a sample cell and a detector. The optical device may be positioned either before or after the sample cell; it consists of one or several optical filters, through which the broadband radiation is passed. The optical device in this case is selected for carbon monoxide. The measurement light beam passes through the sample cell and may also pass through a reference cell if the analyser integrates such a feature (some use an electronic system instead of a reference cell).

When carbon monoxide is present in the sample cell, absorption of energy in the measurement light beam will occur according to the Beer-Lambert law and this produces a change in the detector signal. This measurement signal is compared to a reference signal to generate an output related to the concentration of carbon monoxide. The generated signal is linearised in order to obtain the carbon monoxide concentration. To prevent the entry of particles into the sensors, which could cause stray-light phenomena, the apparatus is fitted with a suitable filter.

**Required technical specifications**. When used for a limit test, the carbon monoxide infrared analyser meets the following technical specifications:

– *limit of detection*: (generally defined as a signal-to-noise ratio of 2) maximum 20 per cent of the maximum admissible concentration;

– *repeatability*: maximum relative standard deviation of 10 per cent of the maximum admissible concentration, determined on 6 measurements;

– *linearity*: maximum 10 per cent of the maximum admissible concentration.

The technical specifications must be met in the presence of the other gas impurities in the sample.

## 2.5.26. NITROGEN MONOXIDE AND NITROGEN DIOXIDE IN GASES

Nitrogen monoxide and nitrogen dioxide in gases are determined using a chemiluminescence analyser (Figure 2.5.26.-1).

The apparatus consists of the following:

- a device for filtering, checking and controlling the flow of the gas to be examined,
- a converter that reduces nitrogen dioxide to nitrogen monoxide, to determine the combined content of nitrogen monoxide and nitrogen dioxide. The efficiency of the converter has to be verified prior to use,
- a controlled-flow-rate ozone generator; the ozone is produced by high-voltage electric discharges across two electrodes; the ozone generator is supplied with pure oxygen or with dehydrated ambient air and the concentration of ozone obtained must greatly exceed the maximum content of any detectable nitrogen oxides,
- a chamber in which nitrogen monoxide and ozone can react,
- a system for detecting light radiation emitted at a wavelength of 1.2 µm, consisting of a selective optical filter and a photomultiplier tube.

01/2009:20527

## 2.5.27. OXYGEN IN GASES

Oxygen in gases is determined using a paramagnetic analyser.

The principle of the method is based on the high paramagnetic sensitivity of the oxygen molecule. Oxygen exerts a strong interaction on magnetic fields, which is measured electronically, amplified and converted to a reading of oxygen concentration. The measurement of oxygen concentration is dependent upon the pressure and temperature and, if the analyser is not automatically compensated for variations in temperature and pressure, it must be calibrated immediately prior to use. As the paramagnetic effect of oxygen is linear, the instrument must have a suitable range with a readability of 0.1 per cent or better.

*Calibration of the instrument.* Make the setting in the following manner:

- set the zero by passing *nitrogen R1* through the instrument until a constant reading is obtained;
- set the scale to 100 per cent by passing *oxygen R* through the instrument at the same flow rate as for *nitrogen R1* until a constant reading is obtained.

*Assay.* Pass the gas to be examined through the instrument at a constant flow rate until a constant reading is obtained. Record the concentration of oxygen in the gas to be examined.

01/2017:20528

## 2.5.28. WATER IN GASES

Water in gases is determined using an electrolytic hygrometer, described below.

The measuring cell consists of a thin film of diphosphorus pentoxide, between 2 coiled platinum wires which act as electrodes. The water vapour in the gas to be examined is absorbed by the diphosphorus pentoxide, which is transformed to phosphoric acid, an electrical conductor. A continuous voltage applied across the electrodes produces electrolysis of the water and the regeneration of the diphosphorus pentoxide. The resulting electric current, which is proportional to the water content in the gas to be examined, is measured. This system is self-calibrating since it obeys Faraday's law.

Take a sample of the gas to be examined. Allow the gas to stabilise at room temperature. Purge the cell continuously until a stable reading is obtained. Measure the water content in the gas to be examined, making sure that the temperature is constant throughout the device used to introduce the gas into the apparatus.

The electrolytic hygrometer achieves accurate sample flows by using a mass flow controller to deliver a constant volumetric flow rate to ensure that the water content is determined accurately. The calibration of the mass flow controller is normally performed using nitrogen. When using gases other than nitrogen for calibration, consult the manufacturer's instructions for the appropriate conversion factors and ensure that the correct cell is used for the type of gas to be examined.

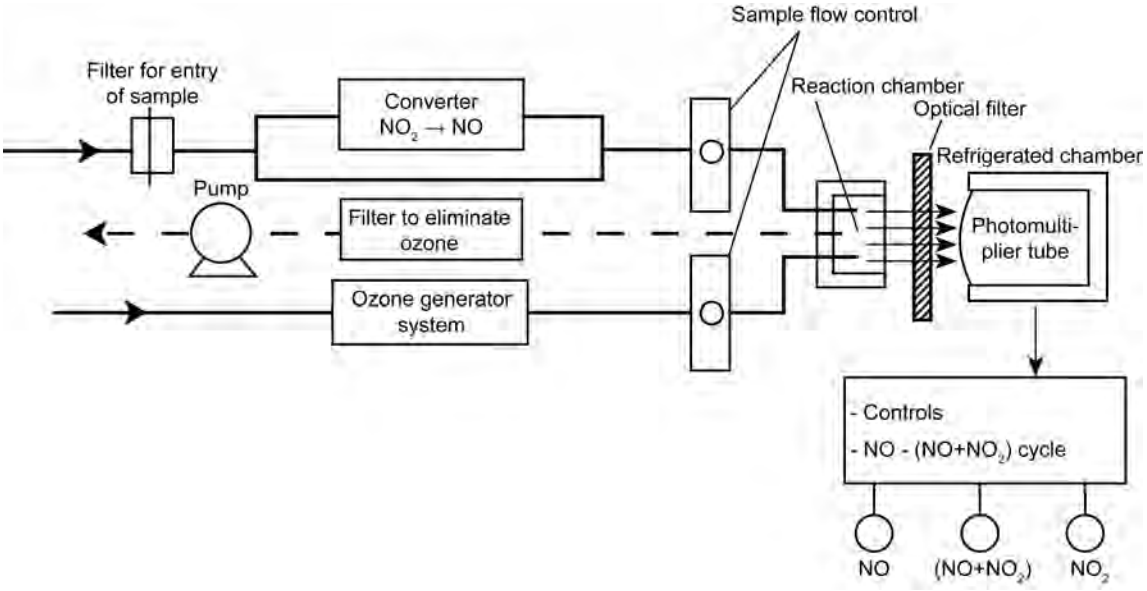

Figure 2.5.26.-1. – *Chemiluminescence analyser*

**01/2013:20529**

## 2.5.29. SULFUR DIOXIDE

Introduce 150 mL of *water R* into the flask (*A*) (see Figure 2.5.29.-1) and pass *carbon dioxide R* through the whole system for 15 min at a rate of 100 ± 5 mL/min. To 10 mL of *dilute hydrogen peroxide solution R* add 0.15 mL of a 1 g/L solution of *bromophenol blue R* in *ethanol (20 per cent V/V) R*. Add *0.1 M sodium hydroxide* until a violet-blue colour is obtained, without exceeding the end-point. Place the solution in the test-tube (*D*). Without interrupting the stream of carbon dioxide, remove the funnel (*B*) and introduce through the opening into the flask (*A*) 25.0 g (*m* g) of the substance to be examined with the aid of 100 mL of *water R*. Replace the funnel. Close the tap of the funnel and add 80 mL of *dilute hydrochloric acid R* to the funnel. Open the tap of the funnel to allow the hydrochloric acid solution to flow into the flask, making sure that no sulfur dioxide escapes into the funnel by closing the tap before the last few millilitres of hydrochloric acid solution drain out. Boil for 1 h. Open the tap of the funnel and stop the flow of carbon dioxide and also the heating and the cooling water. Transfer the contents of the test-tube with the aid of a little *water R* to a 200 mL wide-necked, conical flask. Heat on a water-bath for 15 min and allow to cool. Add 0.1 mL of a 1 g/L solution of *bromophenol blue R* in *ethanol (20 per cent V/V) R* and titrate with *0.1 M sodium hydroxide* until the colour changes from yellow to violet-blue ($V_1$ mL). Carry out a blank titration ($V_2$ mL).

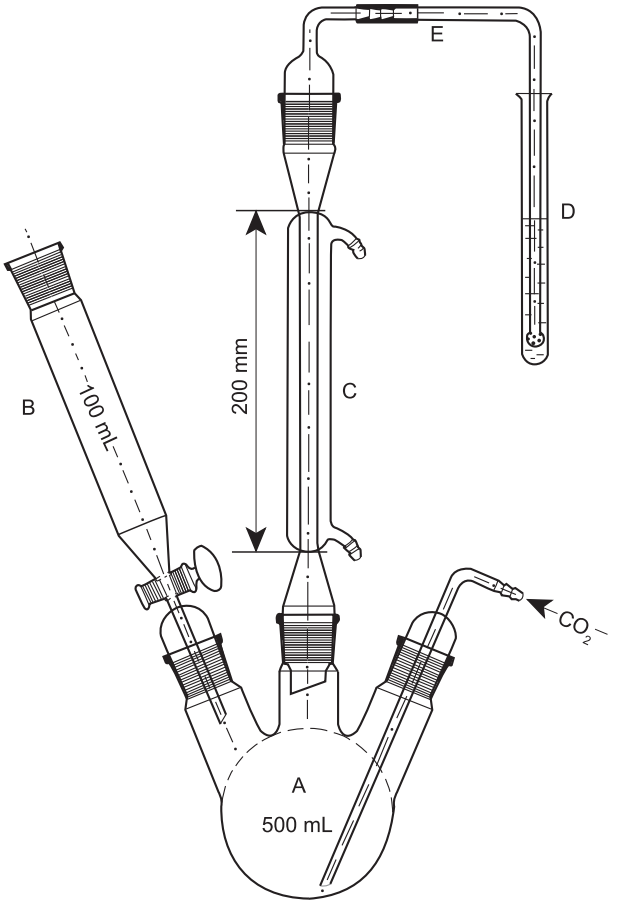

Figure 2.5.29.-1.– *Apparatus for the determination of sulfur dioxide*

Calculate the content of sulfur dioxide in parts per million using the following expression:

$$32\,030 \times (V_1 - V_2) \times \frac{n}{m}$$

$n$ = molarity of the sodium hydroxide solution used as titrant.

**01/2008:20530**

## 2.5.30. OXIDISING SUBSTANCES

Transfer 4.0 g to a glass-stoppered, 125 mL conical flask and add 50.0 mL of *water R*. Insert the stopper and swirl for 5 min. Transfer to a glass-stoppered 50 mL centrifuge tube and centrifuge. Transfer 30.0 mL of the clear supernatant to a glass-stoppered 125 mL conical flask. Add 1 mL of *glacial acetic acid R* and 0.5 g to 1.0 g of *potassium iodide R*. Insert the stopper, swirl, and allow to stand for 25 min to 30 min in the dark. Add 1 mL of *starch solution R* and titrate with *0.002 M sodium thiosulfate* until the starch-iodine colour disappears. Carry out a blank determination. Not more than 1.4 mL of *0.002 M sodium thiosulfate* is required (0.002 per cent, calculated as $H_2O_2$).

1 mL of *0.002 M sodium thiosulfate* is equivalent to 34 µg of oxidising substances, calculated as hydrogen peroxide.

**01/2008:20531**

## 2.5.31. RIBOSE IN POLYSACCHARIDE VACCINES

*Test solution.* Use a volumetric flask with a suitable volume for preparation of a solution containing about 5 mg per millilitre of dry polysaccharide. Transfer the contents of a container quantitatively to the flask and dilute to volume with *water R*. Dilute the solution so that the volumes used in the test contain 2.5 µg to 25 µg of ribose. Introduce 0.20 mL and 0.40 mL of the diluted solution into tubes in triplicate.

*Reference solutions.* Dissolve 25 mg of *ribose R* in *water R* and dilute to 100.0 mL with the same solvent (stock solution containing 0.25 g/L of ribose). Immediately before use, dilute 1 mL of the stock solution to 10.0 mL with *water R* (working dilution: 25 mg/L of ribose). Introduce 0.10 mL, 0.20 mL, 0.40 mL, 0.60 mL, 0.80 mL and 1.0 mL of the working dilution into 6 tubes.

Prepare a blank using 2 mL of *water R*.

Make up the volume in each tube to 2 mL with *water R*. Shake. Add 2 mL of a 0.5 g/L solution of *ferric chloride R* in *hydrochloric acid R* to each tube. Shake. Add 0.2 mL of a 100 g/L solution of *orcinol R* in *ethanol R*. Place the tubes in a water-bath for 20 min. Cool in iced water. Measure the absorbance (*2.2.25*) of each solution at 670 nm using the blank as the compensation liquid. Draw a calibration curve from the absorbance readings for the 6 reference solutions and the corresponding content of ribose and read from the curve the quantity of ribose in the test solution for each volume tested. Calculate the mean of the 3 values.

07/2019:20532

# 2.5.32. WATER: MICRO DETERMINATION

PRINCIPLE

The coulometric titration of water is based upon the quantitative reaction of water with sulfur dioxide and iodine in an anhydrous medium in the presence of a base with sufficient buffering capacity. In contrast to the volumetric method described in general chapter *2.5.12. Water: semi-micro determination*, iodine is produced electrochemically in the reaction cell by oxidation of iodide. The iodine produced at the anode reacts immediately with the water and the sulfur dioxide contained in the reaction cell. The quantity of water in the substance is directly proportional to the quantity of electricity (in coulombs), corresponding to electric current (in amperes) multiplied by time (in seconds), used for iodine generation up until the titration end-point. When all of the water in the reaction cell has been consumed, the end-point is reached and thus an excess of iodine appears. 1 mole of iodine corresponds to 1 mole of water, an amount of electricity of 10.71 C corresponds to 1 mg of water.

Moisture is eliminated from the reaction cell by pre-titration, i.e. the electrolyte reagent is titrated to dryness before starting the sample analysis. Individual determinations can be carried out successively in the same reagent solution, under the following conditions:

- each component of the test mixture is compatible with the other components;
- no other reactions take place;
- the volume and the water capacity of the electrolyte reagent are sufficient.

Coulometric titration is intended for the quantitative determination of small quantities of water (from 10 µg), however a working range of 100 µg to 10 mg of water is recommended for reproducibility reasons.

Accuracy and precision of the method are predominantly governed by the sample preparation and the extent to which atmospheric moisture is excluded from the system. Control of the system must be monitored by measuring the amount of baseline drift.

APPARATUS

The apparatus consists of a reaction cell, electrodes and a magnetic stirrer. The reaction cell consists of a large anode compartment and a smaller cathode compartment. Depending on the design of the electrode, both compartments can be separated by a diaphragm. Each compartment contains a platinum electrode. Liquid or solubilised samples are introduced through a septum, using a syringe. Alternatively, an evaporation technique may be used in which the sample is heated in an oven and the water is evaporated and carried into the cell by means of a stream of dry inert gas. The introduction of solid samples into the cell should in general be avoided. However, if it has to be done it is effected through a sealable port; appropriate precautions must be taken to avoid the introduction of moisture from air, such as working in a glove box in an atmosphere of dry inert gas. The analytical procedure is controlled by a suitable electronic device, which also displays the results.

Instrument qualification is carried out according to established quality system procedures, for example using a suitable certified reference material. *Sodium aminosalicylate dihydrate for equipment qualification CRS* may be used when proceeding by direct or liquid sample introduction, whereas *amoxicillin trihydrate for performance verification CRS* may be used with the evaporation technique.

METHOD

Fill the compartments of the reaction cell with *electrolyte reagent for the micro determination of water R* according to the manufacturer's instructions and perform the coulometric pre-titration to a stable end-point. Introduce the prescribed quantity of the substance to be examined into the reaction cell and titrate again to a stable end-point, stirring for at least 30 s, unless otherwise indicated in the monograph. If an oven is used, the prescribed quantity of sample is introduced into the oven and heated. After evaporation of the water from the sample into the reaction cell, the titration is started. Alternatively, the evaporated moisture is immediately titrated while heating the sample in the oven to avoid loss of evaporated water already collected in the reagent solution during prolonged heating. Read the value from the instrument's output and calculate if necessary the percentage or quantity of water that is present in the substance. When appropriate to the type of sample and the sample preparation, perform a blank titration.

VERIFICATION OF ACCURACY

At appropriate intervals, such as at least at the beginning and the end of a series of sample titrations, introduce a defined quantity of water, in the same order of magnitude as the quantity of water in the sample, using a suitable certified reference material and perform the coulometric titration. The recovery is within the range of 97.5 per cent to 102.5 per cent for an addition of 1000 µg of $H_2O$ and within the range of 90.0 per cent to 110.0 per cent for the addition of 100 µg of $H_2O$.

# 2.5.33. TOTAL PROTEIN

Many of the assay methods described in this chapter can be performed using kits from commercial sources.

METHOD 1

Protein in solution absorbs ultraviolet light at a wavelength of 280 nm, due to the presence of aromatic amino acids, mainly tyrosine and tryptophan, in the protein structure. This property can be used for assay purposes. If the buffer used to dissolve the protein has a high absorbance relative to that of water, an interfering substance is present. This interference may be obviated by using the buffer as compensation liquid but if the interfering substance produces a high absorbance, the results may nevertheless be compromised. At low concentrations, protein adsorbed onto the cell may significantly reduce the content in solution. This can be prevented by preparing samples at higher concentration or by using a non-ionic detergent in the preparation.

*Test solution.* Dissolve a suitable quantity of the substance to be examined in the prescribed buffer to obtain a solution having a protein concentration between 0.2 mg/mL and 2 mg/mL.

*Reference solution.* Prepare a solution of a suitable reference substance for the protein to be determined, in the same buffer and at the same protein concentration as the test solution.

**Procedure**. Keep the test solution, the reference solution and the compensation liquid at the same temperature during the performance of this test. Determine the absorbances (*2.2.25*) of the test solution and the reference solution in quartz cells at 280 nm, using the prescribed buffer as the compensation liquid. The response must be linear in the range of protein concentrations to be assayed to obtain accurate results.

**Light scattering**. The accuracy of the determination of protein can be diminished by the scattering of light by the test sample. If the proteins in solution exist as particles comparable in size to the wavelength of the measuring light (250 nm to 300 nm), scattering of the light beam results in an apparent increase in absorbance of the test sample. To calculate the absorbance at 280 nm due to light scattering, determine the absorbances of the test solution at wavelengths of 320 nm, 325 nm, 330 nm, 335 nm, 340 nm, 345 nm and 350 nm. Plot the logarithm of the observed absorbance against the logarithm of the wavelength and determine the standard curve best fitting the plotted points by linear regression. Extrapolate the curve to determine the logarithm of the absorbance at 280 nm. The antilogarithm of this value is the absorbance attributed to light scattering. Correct the observed values by subtracting the absorbance attributed to light scattering from the total absorbance at 280 nm to obtain the absorbance value of the protein in solution. Filtration with a 0.2 µm filter that does not adsorb protein or clarification by centrifugation may be performed to reduce the effect of light scattering, especially if the solution is noticeably turbid.

**Calculations**. Use corrected values for the calculations. Calculate the concentration of protein in the test solution ($C_U$) from the following equation:

$$C_U = C_S(A_U / A_S)$$

where $C_S$ is the concentration of protein in the reference solution and $A_U$ and $A_S$ are the corrected absorbances of the test solution and the reference solution, respectively.

METHOD 2

This method (commonly referred to as the Lowry assay) is based on the reduction by protein of the phosphomolybdotungstic mixed acid chromogen in the phosphomolybdotungstic reagent, which results in an absorbance maximum at 750 nm. The phosphomolybdotungstic reagent reacts primarily with tyrosine residues in the protein. Colour development reaches a maximum in 20 min to 30 min at room temperature, after which there is a gradual loss of colour. Because the method is sensitive to interfering substances, a procedure for precipitation of the protein from the test sample may be used. Most interfering substances cause a lower colour yield; however, some detergents cause a slight increase in colour. A high salt concentration may cause a precipitate to form. Because different protein species may give different colour response intensities, the reference substance and test protein must be the same. Where separation of interfering substances from the protein in the test sample is necessary, proceed as directed below for interfering substances prior to preparation of the test solution. The effect of interfering substances may be minimised by dilution, provided the concentration of the test protein remains sufficient for accurate measurement.

Use *distilled water R* to prepare all buffers and reagents used for this method.

*Test solution.* Dissolve a suitable quantity of the substance to be examined in the prescribed buffer to obtain a solution having a concentration within the range of the standard curve. A suitable buffer will produce a solution of pH 10.0 to 10.5.

*Reference solutions.* Dissolve the reference substance for the protein to be determined in the prescribed buffer. Dilute portions of this solution with the same buffer to obtain not fewer than five reference solutions having protein concentrations evenly spaced over a suitable range situated between 5 µg/mL and 100 µg/mL.

*Blank.* Use the buffer used to prepare the test solution and the reference solutions.

*Copper sulfate reagent.* Dissolve 100 mg of *copper sulfate pentahydrate R* and 0.2 g of *sodium tartrate R* in *distilled water R* and dilute to 50 mL with the same solvent. Dissolve 10 g of *anhydrous sodium carbonate R* in *distilled water R* and dilute to 50 mL with the same solvent. Slowly pour the sodium carbonate solution into the copper sulfate solution with mixing. Use within 24 h.

*Alkaline copper reagent.* Mix 1 volume of copper sulfate reagent, 2 volumes of a 50 g/L solution of *sodium dodecyl sulfate R* and 1 volume of a 32 g/L solution of *sodium hydroxide R*. Store at room temperature and use within 2 weeks.

*Diluted phosphomolybdotungstic reagent.* Mix 5 mL of *phosphomolybdotungstic reagent R* with 55 mL of *distilled water R*. Store in an amber bottle, at room temperature.

**Procedure**. To 1.0 mL of each reference solution, of the test solution and of the blank, add 1.0 mL of alkaline copper reagent and mix. Allow to stand for 10 min. Add 0.5 mL of the diluted phosphomolybdotungstic reagent, mix and allow to stand at room temperature for 30 min. Determine the absorbances (*2.2.25*) of the solutions at 750 nm, using the solution from the blank as compensation liquid.

**Calculations**. The relationship of absorbance to protein concentration is non-linear; however, if the range of concentrations used to prepare the standard curve is sufficiently small, the latter will approach linearity. Plot the absorbances of the reference solutions against the protein concentrations and use linear regression to establish the standard curve. From the standard curve and the absorbance of the test solution, determine the concentration of protein in the test solution.

**Interfering substances**. In the following procedure, deoxycholate-trichloroacetic acid is added to a test sample to remove interfering substances by precipitation of proteins before determination; this technique can also be used to concentrate proteins from a dilute solution.

Add 0.1 mL of a 1.5 g/L solution of *sodium deoxycholate R* to 1 mL of a solution of the substance to be examined. Mix using a vortex mixer and allow to stand at room temperature for 10 min. Add 0.1 mL of a 720 g/L solution of *trichloroacetic acid R* and mix using a vortex mixer. Centrifuge at 3000 *g* for 30 min, decant the liquid and remove any residual liquid with a pipette. Redissolve the protein pellet in 1 mL of alkaline copper reagent.

METHOD 3

This method (commonly referred to as the Bradford assay) is based on the absorption shift from 470 nm to 595 nm observed when the acid blue 90 dye binds to protein. The acid blue 90 dye binds most readily to arginine and lysine residues in the protein which can lead to variation in the response of the assay to different proteins. The protein used as reference substance must therefore be the same as the protein to be determined. There are relatively few interfering substances, but it is preferable to avoid detergents and ampholytes in the test sample. Highly alkaline samples may interfere with the acidic reagent.

Use *distilled water R* to prepare all buffers and reagents used for this method.

*Test solution.* Dissolve a suitable quantity of the substance to be examined in the prescribed buffer to obtain a solution having a concentration within the range of the standard curve.

*Reference solutions.* Dissolve the reference substance for the protein to be determined in the prescribed buffer. Dilute portions of this solution with the same buffer to obtain not fewer than five reference solutions having protein concentrations evenly spaced over a suitable range situated between 0.1 mg/mL and 1 mg/mL.

*Blank.* Use the buffer used to prepare the test solution and the reference solutions.

*Acid blue 90 reagent.* Dissolve 0.10 g of *acid blue 90 R* in 50 mL of *alcohol R*. Add 100 mL of *phosphoric acid R*, dilute to 1000 mL with *distilled water R* and mix. Filter the solution

and store in an amber bottle at room temperature. Slow precipitation of the dye occurs during storage. Filter the reagent before using.

**Procedure**. Add 5 mL of acid blue 90 reagent to 0.100 mL of each reference solution, of the test solution and of the blank. Mix by inversion. Avoid foaming, which will lead to poor reproducibility. Determine the absorbances (*2.2.25*) of the standard solutions and of the test solution at 595 nm, using the blank as compensation liquid. Do not use quartz (silica) spectrophotometer cells because the dye binds to this material.

**Calculations**. The relationship of absorbance to protein concentration is non-linear; however, if the range of concentrations used to prepare the standard curve is sufficiently small, the latter will approach linearity. Plot the absorbances of the reference solutions against protein concentrations and use linear regression to establish the standard curve. From the standard curve and the absorbance of the test solution, determine the concentration of protein in the test solution.

METHOD 4

This method (commonly referred to as the bicinchoninic acid or BCA assay) is based on reduction of the cupric ($Cu^{2+}$) ion to cuprous ($Cu^{1+}$) ion by protein. The bicinchoninic acid reagent is used to detect the cuprous ion. Few substances interfere with the reaction. When interfering substances are present their effect may be minimised by dilution, provided that the concentration of the protein to be determined remains sufficient for accurate measurement. Alternatively, the protein precipitation procedure given in Method 2 may be used to remove interfering substances. Because different protein species may give different colour response intensities, the reference protein and protein to be determined must be the same.

Use *distilled water R* to prepare all buffers and reagents used for this method.

*Test solution*. Dissolve a suitable quantity of the substance to be examined in the prescribed buffer to obtain a solution having a concentration within the range of the concentrations of the reference solutions.

*Reference solutions*. Dissolve the reference substance for the protein to be determined in the prescribed buffer. Dilute portions of this solution with the same buffer to obtain not fewer than five reference solutions having protein concentrations evenly spaced over a suitable range situated between 10 µg/mL and 1200 µg/mL.

*Blank*. Use the buffer used to prepare the test solution and the reference solutions.

*BCA reagent*. Dissolve 10 g of *disodium bicinchoninate R*, 20 g of *sodium carbonate monohydrate R*, 1.6 g of *sodium tartrate R*, 4 g of *sodium hydroxide R*, and 9.5 g of *sodium hydrogen carbonate R* in *distilled water R*. Adjust, if necessary, to pH 11.25 with a solution of *sodium hydroxide R* or a solution of *sodium hydrogen carbonate R*. Dilute to 1000 mL with *distilled water R* and mix.

*Copper-BCA reagent*. Mix 1 mL of a 40 g/L solution of *copper sulfate pentahydrate R* and 50 mL of BCA reagent.

**Procedure**. Mix 0.1 mL of each reference solution, of the test solution and of the blank with 2 mL of the copper-BCA reagent. Incubate the solutions at 37 °C for 30 min, note the time and allow the mixtures to cool to room temperature. Within 60 min of the end of incubation, determine the absorbances (*2.2.25*) of the reference solutions and of the test solution in quartz cells at 562 nm, using the blank as compensation liquid. After the solutions have cooled to room temperature, the colour intensity continues to increase gradually.

**Calculations**. The relationship of absorbance to protein concentration is non-linear; however, if the range of concentrations used to prepare the standard curve is sufficiently small, the latter will approach linearity. Plot the absorbances of the reference solutions against protein concentrations and use linear regression to establish the standard curve. From the standard curve and the absorbance of the test solution, determine the concentration of protein in the test solution.

METHOD 5

This method (commonly referred to as the biuret assay) is based on the interaction of cupric ($Cu^{2+}$) ion with protein in alkaline solution and resultant development of absorbance at 545 nm. This test shows minimal difference between equivalent IgG and albumin samples. Addition of the sodium hydroxide and the biuret reagent as a combined reagent, insufficient mixing after the addition of the sodium hydroxide, or an extended time between the addition of the sodium hydroxide solution and the addition of the biuret reagent will give IgG samples a higher response than albumin samples. The trichloroacetic acid method used to minimise the effects of interfering substances also can be used to determine the protein content in test samples at concentrations below 500 µg/mL.

Use *distilled water R* to prepare all buffers and reagents used for this method.

*Test solution*. Dissolve a suitable quantity of the substance to be examined in a 9 g/L solution of *sodium chloride R* to obtain a solution having a concentration within the range of the concentrations of the reference solutions.

*Reference solutions*. Dissolve the reference substance for the protein to be determined in a 9 g/L solution of *sodium chloride R*. Dilute portions of this solution with a 9 g/L solution of *sodium chloride R* to obtain not fewer than three reference solutions having protein concentrations evenly spaced over a suitable range situated between 0.5 mg/mL and 10 mg/mL.

*Blank*. Use a 9 g/L solution of *sodium chloride R*.

*Biuret reagent*. Dissolve 3.46 g of *copper sulfate pentahydrate R* in 10 mL of hot *distilled water R*, and allow to cool (Solution A). Dissolve 34.6 g of *sodium citrate R* and 20.0 g of *anhydrous sodium carbonate R* in 80 mL of hot *distilled water R*, and allow to cool (Solution B). Mix solutions A and B and dilute to 200 mL with *distilled water R*. Use within 6 months. Do not use the reagent if it develops turbidity or contains any precipitate.

**Procedure**. To one volume of the test solution add an equal volume of a 60 g/L solution of *sodium hydroxide R* and mix. Immediately add biuret reagent equivalent to 0.4 volumes of the test solution and mix rapidly. Allow to stand at a temperature between 15 °C and 25 °C for not less than 15 min. Within 90 min of addition of the biuret reagent, determine the absorbances (*2.2.25*) of the reference solutions and of the test solution at the maximum at 545 nm, using the blank as compensation liquid. Any solution that develops turbidity or a precipitate is not acceptable for calculation of protein concentration.

**Calculations**. The relationship of absorbance to protein concentration is approximately linear within the indicated range of protein concentrations for the reference solutions. Plot the absorbances of the reference solutions against protein concentrations and use linear regression to establish the standard curve. Calculate the correlation coefficient for the standard curve. A suitable system is one that yields a line having a correlation coefficient not less than 0.99. From the standard curve and the absorbance of the test solution, determine the concentration of protein in the test solution.

**Interfering substances**. To minimise the effect of interfering substances, the protein can be precipitated from the test sample as follows: add 0.1 volumes of a 500 g/L solution of *trichloroacetic acid R* to 1 volume of a solution of the test sample, withdraw the supernatant layer and dissolve the precipitate in a small volume of *0.5 M sodium hydroxide*. Use the solution obtained to prepare the test solution.

METHOD 6

This fluorimetric method is based on the derivatisation of the protein with *o*-phthalaldehyde, which reacts with the primary amines of the protein (*N*-terminal amino acid and the ε-amino group of lysine residues). The sensitivity of the assay can be increased by hydrolysing the protein before adding *o*-phthalaldehyde. Hydrolysis makes the α-amino group of the constituent amino acids available for reaction with the phthalaldehyde reagent. The method requires very small quantities of the protein. Primary amines, such as tris(hydroxymethyl)aminomethane and amino acid buffers, react with phthalaldehyde and must be avoided or removed. Ammonia at high concentrations reacts with phthalaldehyde. The fluorescence obtained when amine reacts with phthalaldehyde can be unstable. The use of automated procedures to standardise this procedure may improve the accuracy and precision of the test.

Use *distilled water R* to prepare all buffers and reagents used for this method.

*Test solution*. Dissolve a suitable quantity of the substance to be examined in a 9 g/L solution of *sodium chloride R* to obtain a solution having a concentration within the range of the concentrations of the reference solutions. Adjust the solution to pH 8 to 10.5 before addition of the phthalaldehyde reagent.

*Reference solutions*. Dissolve the reference substance for the protein to be determined in a 9 g/L solution of *sodium chloride R*. Dilute portions of this solution with a 9 g/L solution of *sodium chloride R* to obtain not fewer than five reference solutions having protein concentrations evenly spaced over a suitable range situated between 10 µg/mL and 200 µg/mL. Adjust the solutions to pH 8 to 10.5 before addition of the phthalaldehyde reagent.

*Blank solution*. Use a 9 g/L solution of *sodium chloride R*.

*Borate buffer solution*. Dissolve 61.83 g of *boric acid R* in *distilled water R* and adjust to pH 10.4 with a solution of *potassium hydroxide R*. Dilute to 1000 mL with *distilled water R* and mix.

*Phthalaldehyde stock solution*. Dissolve 1.20 g of *phthalaldehyde R* in 1.5 mL of *methanol R*, add 100 mL of borate buffer solution and mix. Add 0.6 mL of a 300 g/L solution of *macrogol 23 lauryl ether R* and mix. Store at room temperature and use within 3 weeks.

*Phthalaldehyde reagent*. To 5 mL of phthalaldehyde stock solution add 15 µL of *2-mercaptoethanol R*. Prepare at least 30 min before use. Use within 24 h.

**Procedure**. Mix 10 µL of the test solution and of each of the reference solutions with 0.1 mL of phthalaldehyde reagent and allow to stand at room temperature for 15 min. Add 3 mL of *0.5 M sodium hydroxide* and mix. Determine the fluorescent intensities (*2.2.21*) of solutions from the reference solutions and from the test solution at an excitation wavelength of 340 nm and an emission wavelength between 440 and 455 nm. Measure the fluorescent intensity of a given sample only once, since irradiation decreases the fluorescence intensity.

**Calculations**. The relationship of fluorescence to protein concentration is linear. Plot the fluorescent intensities of the reference solutions against protein concentrations and use linear regression to establish the standard curve. From the standard curve and the fluorescent intensity of the test solution, determine the concentration of protein in the test solution.

METHOD 7

This method is based on nitrogen analysis as a means of protein determination. Interference caused by the presence of other nitrogen-containing substances in the test sample can affect the determination of protein by this method. Nitrogen analysis techniques destroy the test sample during the analysis but are not limited to protein presentation in an aqueous environment.

**Procedure A**. Proceed as prescribed for the determination of nitrogen by sulfuric acid digestion (*2.5.9*) or use commercial instrumentation for Kjeldahl nitrogen assay.

**Procedure B**. Commercial instrumentation is available for nitrogen analysis. Most nitrogen analysis instruments use pyrolysis (i.e. combustion of the sample in oxygen at temperatures approaching 1000 °C), which produces nitric oxide (NO) and other oxides of nitrogen ($NO_x$) from the nitrogen present in the substance to be examined. Some instruments convert the nitric oxides to nitrogen gas, which is quantified using a thermal-conductivity detector. Other instruments mix nitric oxide (NO) with ozone ($O_3$) to produce excited nitrogen dioxide ($NO_2$*), which emits light when it decays and can be quantified with a chemiluminescence detector. A protein reference material that is relatively pure and is similar in composition to the test proteins is used to optimise the injection and pyrolysis parameters and to evaluate consistency in the analysis.

**Calculations**. The protein concentration is calculated by dividing the nitrogen content of the sample by the known nitrogen content of the protein. The known nitrogen content of the protein can be determined from the chemical composition of the protein or by comparison with a suitable reference substance.

**01/2008:20534**

## 2.5.34. ACETIC ACID IN SYNTHETIC PEPTIDES

Examine by liquid chromatography (*2.2.29*).

*Test solution*. Prepare as described in the monograph. The concentration of peptide in the solution may be adapted, depending on the expected amount of acetic acid in the sample.

*Reference solution*. Prepare a 0.10 g/L solution of *glacial acetic acid R* in a mixture of 5 volumes of mobile phase B and 95 volumes of mobile phase A.

The chromatographic procedure may be carried out using:

– a stainless steel column 0.25 m long and 4.6 mm in internal diameter packed with *octadecylsilyl silica gel for chromatography R* (5 µm),

– as mobile phase at a flow rate of 1.2 mL/min:

*Mobile phase A*. Dilute 0.7 mL of *phosphoric acid R* to 1000 mL with *water R*; adjust the pH to 3.0 with *strong sodium hydroxide solution R*,

*Mobile phase B*. *Methanol R2*,

| Time (min) | Mobile phase A (per cent *V/V*) | Mobile phase B (per cent *V/V*) |
|---|---|---|
| 0 - 5 | 95 | 5 |
| 5 - 10 | 95 → 50 | 5 → 50 |
| 10 - 20 | 50 | 50 |
| 20 - 22 | 50 → 95 | 50 → 5 |
| 22 - 30 | 95 | 5 |

– as detector a spectrophotometer set at 210 nm.

Inject 10 µL of the reference solution and 10 µL of the test solution. In the chromatograms obtained, the peak corresponding to acetic acid has a retention time of 3-4 min. The baseline presents a steep rise after the start of the linear gradient, which corresponds to the elution of the peptide from the column. Determine the content of acetic acid in the peptide.

01/2011:20535

## 2.5.35. NITROUS OXIDE IN GASES

Gases absorb light at one or more specific wavelengths. This property is widely used to allow highly selective measurement of their concentrations.

**Description and principle of measurement**. The concentration of nitrous oxide in other gases can be determined using an infrared analyser.

The infrared analyser generally consists of a light source emitting broadband infrared radiation, an optical device, a sample cell and a detector. The optical device may be positioned either before or after the sample cell and it consists of one or several optical filters, through which the broadband radiation is passed. The optical device in this case is selected for nitrous oxide. The measurement light beam passes through the sample cell and may also pass through a reference cell if the analyser integrates such a feature (some use an electronic system instead of a reference cell).

When nitrous oxide is present in the sample cell, absorption of energy in the measurement light beam will occur according to the Beer-Lambert law and this produces a change in the detector signal. This measurement signal is compared to a reference signal to generate an output related to the concentration of nitrous oxide. The generated signal is linearised in order to obtain the nitrous oxide concentration. To prevent the entry of particles into the sensors, which could cause stray-light phenomena, the apparatus is fitted with a suitable filter.

01/2008:20536

## 2.5.36. ANISIDINE VALUE

The anisidine value is defined as 100 times the optical density measured in a 1 cm cell of a solution containing 1 g of the substance to be examined in 100 mL of a mixture of solvents and reagents according to the following method.

*Carry out the operations as rapidly as possible, avoiding exposure to actinic light.*

*Test solution (a).* Dissolve 0.500 g of the substance to be examined in *trimethylpentane R* and dilute to 25.0 mL with the same solvent.

*Test solution (b).* To 5.0 mL of test solution (a) add 1.0 mL of a 2.5 g/L solution of *p-anisidine R* in *glacial acetic acid R*, shake and store protected from light.

*Reference solution.* To 5.0 mL of *trimethylpentane R* add 1.0 mL of a 2.5 g/L solution of *p-anisidine R* in *glacial acetic acid R*, shake and store protected from light.

Measure the absorbance (*2.2.25*) of test solution (a) at the maximum at 350 nm using *trimethylpentane R* as the compensation liquid. Measure the absorbance of test solution (b) at 350 nm exactly 10 min after its preparation, using the reference solution as the compensation liquid.

Calculate the anisidine value from the expression:

$$\frac{25 \times (1.2A_1 - A_2)}{m}$$

$A_1$ = absorbance of test solution (b) at 350 nm,

$A_2$ = absorbance of test solution (a) at 350 nm,

$m$ = mass of the substance to be examined in test solution (a), in grams.

04/2011:20537 corrected 10.0

## 2.5.37. METHYL, ETHYL AND ISOPROPYL METHANESULFONATE IN METHANESULFONIC ACID

The following method has been validated for the methyl, ethyl and isopropyl esters of methanesulfonic acid at concentrations in the range of 0.5 ppm to 100 ppm.

If it is intended to be used to determine levels of methanesulfonic acid esters outside this validated range, for example in early steps of the synthesis prior to their removal, the concentration of the test solution has to be adjusted accordingly.

Gas chromatography (*2.2.28*) coupled with mass spectrometry (*2.2.43*).

*Internal standard solution.* Dilute 7 µL of *butyl methanesulfonate CRS* (BMS) to 10.0 mL with *methylene chloride R*. Dilute 10 µL of the solution to 100.0 mL with *methylene chloride R*.

*Test solution.* Add 0.74 g of the substance to be examined to 10.0 mL of *water R* and extract with 10.0 mL of the internal standard solution. Allow to separate and transfer the organic layer to a vial containing *anhydrous sodium sulfate R*. Shake and filter.

*Reference solution (a).* Dissolve 50 mg each of *methyl methanesulfonate R* (MMS), *ethyl methanesulfonate R* (EMS) and *isopropyl methanesulfonate R* (IMS) in the internal standard solution and dilute to 50.0 mL with the same solution. Dilute 74 µL of the solution to 10.0 mL with the internal standard solution. Dilute 100 µL of this solution to 10.0 mL with the internal standard solution.

*Reference solution (b).* Dilute 3.0 mL of reference solution (a) to 10.0 mL with the internal standard solution.

*Column*:

- *material*: fused silica;
- *size*: *l* = 15 m, Ø = 0.25 mm;
- *stationary phase*: *methylpolysiloxane R* (film thickness 1 µm).

*Carrier gas*: *helium for chromatography R*.

*Flow rate*: 1 mL/min.

*Pulsed splitless*: 250 kPa, 0.25 min.

*Temperature*:

| | | Time (min) | Temperature (°C) |
|---|---|---|---|
| Column | | 0 - 1 | 55 |
| | | 1 - 9 | 55 → 135 |
| Injection port | | | 240 |
| Detector: | transfer line | | 280 |
| | source | | 230 |
| | analyser | | 150 |

*Detection*: mass spectrometer as described below; adjust the detector settings so as to comply with the system suitability criteria:

- quadrupole mass spectrometer equipped with an electron impact ionisation mode (70 eV);

– mass spectrometer parameters for the fragmentometric mode (single-ion monitoring (SIM)) set as follows:

| Substance | *m/z* | Duration of monitoring |
|---|---|---|
| Butyl methanesulfonate (BMS) | 56 | $t_R$ between 7.0 min and 9.0 min |
| Methyl methanesulfonate (MMS) | 80 | $t_R$ between 2.0 min and 3.5 min |
| Ethyl methanesulfonate (EMS) | 79 | $t_R$ between 4.0 min and 4.7 min |
| Isopropyl methanesulfonate (IMS) | 123 | $t_R$ between 4.7 min and 5.5 min |

*Injection*: 2 µL.

*Relative retention* with reference to the internal standard (BMS) (retention time = about 7.6 min): MMS = about 0.3; EMS = about 0.5; IMS = about 0.6.

*System suitability*:

– *resolution*: minimum 3.0 between the peaks due to EMS and IMS in the chromatogram obtained with reference solution (a);
– *signal-to-noise ratio*: minimum 10 for the peaks due to MMS, EMS and IMS in the chromatogram obtained with reference solution (b).

Calculate the content of MMS, EMS or IMS in parts per million using the following expression:

$$\frac{A_2 \times I_1 \times W_1 \times C \times 0.148}{A_1 \times I_2 \times W_2}$$

$A_1$ = area of the peak due to MMS, EMS or IMS in the chromatogram obtained with reference solution (a);

$A_2$ = area of the peak due to MMS, EMS or IMS in the chromatogram obtained with the test solution;

$C$ = percentage content of MMS, EMS or IMS;

$I_1$ = area of the peak due to the internal standard in the chromatogram obtained with reference solution (a);

$I_2$ = area of the peak due to the internal standard in the chromatogram obtained with the test solution;

$W_1$ = mass of MMS, EMS or IMS used to prepare reference solution (a), in milligrams;

$W_2$ = mass of the substance to be examined in the test solution, in milligrams;

0.148 = dilution factor.

**04/2016:20538 corrected 10.0**

## 2.5.38. METHYL, ETHYL AND ISOPROPYL METHANESULFONATE IN ACTIVE SUBSTANCES

The following general method has been validated for the determination of methyl, ethyl and isopropyl esters of methanesulfonic acid (in concentrations between 0.2 ppm and 5 ppm) in betahistine mesilate.

If it is intended to use the method for other active substances, particularly those that contain different concentrations of the methanesulfonic acid esters, the concentrations of the test solution and reference solutions must be adjusted accordingly and the method must be suitably validated.

METHOD

Head-space gas chromatography (*2.2.28*) coupled with mass spectrometry (*2.2.43*). *Prepare the test solution and reference solutions immediately before use.*

*Solvent mixture*: *water R*, *acetonitrile R* (20:80 *V/V*). *The use of acetonitrile of appropriate purity is essential.*

*Solution A*. Dissolve with the aid of ultrasound 30 mg of *anhydrous sodium thiosulfate R* and 60.0 g of *sodium iodide R* in *water R* and dilute to 50.0 mL with the same solvent.

*Internal standard solution.* Dilute 10 µL of *butyl methanesulfonate CRS* (BMS) to 10.0 mL with the solvent mixture. Dilute 20 µL of the solution to 100.0 mL with the solvent mixture.

*Blank solution.* Introduce 0.50 mL of solution A and 0.50 mL of the internal standard solution into a headspace vial and seal the vial immediately with a polytetrafluoroethylene-coated silicon membrane and an aluminium cap.

*Test solution.* Weigh 25.0 mg of the substance to be examined into a 20 mL headspace vial. Add 0.50 mL of solution A and 0.50 mL of the internal standard solution and seal the vial immediately with a polytetrafluoroethylene-coated silicon membrane and an aluminium cap.

*Following the derivatisation reaction, a precipitate may be observed, however this does not affect the validity of the quantification.*

*Reference solution (a).* Dissolve 25.0 mg each of *methyl methanesulfonate R* (MMS), *ethyl methanesulfonate R* (EMS) and *isopropyl methanesulfonate R* (IMS) in *toluene R* and dilute to 5.0 mL with the same solvent. Dilute 50 µL of the solution to 25.0 mL with the internal standard solution.

*Reference solution (b).* Dilute 20 µL of reference solution (a) to 20.0 mL with the internal standard solution. Introduce 0.50 mL of this solution and 0.50 mL of solution A into a 20 mL headspace vial and seal the vial immediately with a polytetrafluoroethylene-coated silicon membrane and an aluminium cap.

*Reference solution (c).* Dilute 500 µL of reference solution (a) to 20.0 mL with the internal standard solution. Introduce 0.50 mL of this solution and 0.50 mL of solution A into a 20 mL headspace vial and seal the vial immediately with a polytetrafluoroethylene-coated silicon membrane and an aluminium cap.

*Column*:

– *material*: fused silica;
– *size*: *l* = 30 m, Ø = 0.25 mm;
– *stationary phase*: *polar-deactivated macrogol R* (film thickness 1 µm).

*Carrier gas*: *helium for chromatography R.*

*The use of an inert inlet liner without glass wool significantly reduces the effect of carry-over between the injections.*

*Flow rate*: 0.5 mL/min.

*Split ratio*: 1:20.

*Static head-space conditions that may be used*:

– *equilibration temperature*: 60 °C;
– *equilibration time*: 30 min;
– *transfer-line temperature*: 120 °C.

*Temperature*:

| | | Time (min) | Temperature (°C) |
|---|---|---|---|
| Column | | 0 - 1 | 40 |
| | | 1 - 10 | 40 → 130 |
| Injection port | | | 220 |
| Detector | transfer line | | 280 |
| | source | | 250 |
| | analyser | | 200 |

At the end of analysis, the temperature of the column is raised to 240 °C and maintained at this temperature for 7 min.

*Detection*: mass spectrometer as described below; adjust the detector settings so as to comply with the system suitability criteria; alternatively a suitable electron-capture detector may be used:

- quadrupole mass spectrometer equipped with an electron impact ionisation mode (70 eV);
- mass spectrometer parameters for the fragmentometric mode (single-ion monitoring (SIM)) set as follows:

| Substance | Quantitation ion (*m*/*z*) | Qualification ion (*m*/*z*) |
|---|---|---|
| Butyl iodide (BuI)* | 184 | 127 |
| Methyl iodide (MeI)* | 142 | 127 |
| Ethyl iodide (EtI)* | 156 | 127 |
| Isopropyl iodide (iPrI)* | 170 | 127 |
| * formed from BMS, MMS, EMS and IMS in the derivatisation reaction. | | |

*Injection*: 1 mL of the gas phase of the test solution, reference solutions (b) and (c) and the blank solution.

*Relative retention* with reference to the internal standard (BuI) (retention time = about 8.5 min): MeI = about 0.51; EtI = about 0.63; iPrI = about 0.68.

*System suitability*:

- *resolution*: minimum 1.5 between the peaks due to EtI and iPrI in the chromatogram obtained with reference solution (c);
- *signal-to-noise ratio*: minimum 10 for the peak due to each alkyl iodide in the chromatogram obtained with reference solution (b).

Calculate the content in parts per million of each alkyl methanesulfonate using the following expression:

$$\frac{A_2 \times I_1 \times W_1 \times C \times 0.05}{A_1 \times I_2 \times W_2}$$

$A_1$ = area of the peak due to each alkyl iodide in the chromatogram obtained with reference solution (c);

$A_2$ = area of the peak due to each alkyl iodide in the chromatogram obtained with the test solution;

$C$ = percentage content of each ester;

$I_1$ = area of the peak due to the internal standard in the chromatogram obtained with reference solution (c);

$I_2$ = area of the peak due to the internal standard in the chromatogram obtained with the test solution;

$W_1$ = mass of each ester used to prepare reference solution (a), in milligrams;

$W_2$ = mass of the substance to be examined in the test solution, in milligrams;

0.05 = dilution factor.

**04/2013:20539 corrected 10.0**

## 2.5.39. METHANESULFONYL CHLORIDE IN METHANESULFONIC ACID

The following method has been validated for the determination of methanesulfonyl chloride in methanesulfonic acid at concentrations in the range of 0.05 ppm to 50 ppm.

Gas chromatography (*2.2.28*) coupled with mass spectrometry (*2.2.43*).

*Internal standard solution.* Dissolve 7 µL of *butyl methanesulfonate CRS* (BMS) in *methylene chloride R* and dilute to 10.0 mL with the same solvent. Dilute 5.0 mL of this solution to 50.0 mL with *methylene chloride R*.

*Test solution.* To 5 mL of *water R*, add 7.4 g of the substance to be examined and mix slowly. After cooling, add 5.0 mL of *methylene chloride R* and 100 µL of the internal standard solution and shake. Allow to separate and transfer the organic layer to a vial containing 1 g of *anhydrous sodium sulfate R*. Repeat the extraction twice with 5.0 mL of *methylene chloride R* each time, combine the organic layers and filter.

*Reference solution (a).* Dissolve 50.0 mg of *methanesulfonyl chloride R* in *methylene chloride R* and dilute to 10.0 mL with the same solvent. Dilute 1.0 mL of the solution to 10.0 mL with *methylene chloride R*. Dilute 300 µL of this solution to 10.0 mL with *methylene chloride R*.

*Reference solution (b).* Dilute 500 µL of reference solution (a) and 100 µL of the internal standard solution to 15.0 mL with *methylene chloride R*.

*Reference solution (c).* Dilute 25 µL of reference solution (a) and 100 µL of the internal standard solution to 15.0 mL with *methylene chloride R*.

*Column*:

- *material*: fused silica;
- *size*: *l* = 15 m, Ø = 0.25 mm;
- *stationary phase*: *methylpolysiloxane R* (film thickness 1 µm).

*Carrier gas*: *helium for chromatography R*.

*Flow rate*: 1 mL/min.

*Pulsed splitless*: 60 kPa, 0.1 min.

*Temperature*:

| | | Time (min) | Temperature (°C) |
|---|---|---|---|
| Column | | 0 - 4 | 40 |
| | | 4 - 8 | 40 → 200 |
| Injection port | | | 240 |
| Detector: | transfer line | | 280 |
| | source | | 230 |
| | analyser | | 150 |

At the end of analysis the temperature of the column is raised to 270 °C and maintained at this temperature for 8 min.

*Detection*: mass spectrometer as described below; adjust the detector settings so as to comply with the system suitability criteria:

- quadrupole mass spectrometer equipped with an electron impact ionisation mode (70 eV);
- mass spectrometer parameters for the fragmentometric mode (single-ion monitoring (SIM)) set as follows:

| Substance | *m*/*z* | Duration of monitoring |
|---|---|---|
| Methanesulfonyl chloride | 79 | $t_R$ between 3.3 min and 6.0 min |
| Butyl methanesulfonate (BMS) | 56 | $t_R$ between 6.0 min and 8.0 min |

*Injection*: 5 µL of the test solution, reference solutions (b) and (c), the internal standard solution and *methylene chloride R*.

*Relative retention* with reference to the internal standard (BMS) (retention time = about 7.2 min): methanesulfonyl chloride = about 0.68.

*System suitability*:

- in the chromatogram obtained with the internal standard solution, there is no peak with the same retention time as methanesulfonyl chloride;
- *resolution*: minimum 5.0 between the peaks due to methanesulfonyl chloride and BMS in the chromatogram obtained with reference solution (b);
- *signal-to-noise ratio*: minimum 10 for the peak due to methanesulfonyl chloride in the chromatogram obtained with reference solution (c).

Calculate the content of methanesulfonyl chloride in parts per million using the following expression:

$$\frac{A_2 \times I_1 \times W_1 \times C \times 1.5}{A_1 \times I_2 \times W_2}$$

$A_1$ = area of the peak due to methanesulfonyl chloride in the chromatogram obtained with reference solution (b);

$A_2$ = area of the peak due to methanesulfonyl chloride in the chromatogram obtained with the test solution;

$C$ = percentage content of methanesulfonyl chloride;

$I_1$ = area of the peak due to BMS in the chromatogram obtained with reference solution (b);

$I_2$ = area of the peak due to BMS in the chromatogram obtained with the test solution;

$W_1$ = mass of methanesulfonyl chloride used to prepare reference solution (a), in milligrams;

$W_2$ = mass of the sample in the test solution, in milligrams;

1.5 = dilution factor.

**04/2015:20540**
**corrected 10.0**

## 2.5.40. METHYL, ETHYL AND ISOPROPYL TOLUENESULFONATE IN ACTIVE SUBSTANCES

The following general method has been validated for the determination of methyl, ethyl and isopropyl esters of toluenesulfonic acid (in concentrations between 0.2 ppm and 5 ppm) in sultamicillin tosilate dihydrate.

If it is intended to use the method for other active substances, particularly those that contain different concentrations of the toluenesulfonic acid esters, the concentrations of the test solution and reference solutions must be adjusted accordingly and the method must be suitably validated.

METHOD

Head-space gas chromatography (*2.2.28*) coupled with mass spectrometry (*2.2.43*). *Prepare the test solution and reference solutions immediately before use.*

*Solvent mixture*: *water R*, *acetonitrile R* (20:80 *V/V*). *The use of acetonitrile of appropriate purity is essential.*

*Solution A*. Dissolve 30 mg of *anhydrous sodium thiosulfate R* and 60.0 g of *sodium iodide R* in *water R* using sonication and dilute to 50.0 mL with the same solvent.

*Internal standard solution*. Dilute 10 µL of *butyl methanesulfonate CRS* (BMS) to 10.0 mL with the solvent mixture. Dilute 20 µL of the solution to 100.0 mL with the solvent mixture.

*Blank solution*. Introduce 0.5 mL of solution A and 0.5 mL of the internal standard solution into a headspace vial and seal the vial immediately with a polytetrafluoroethylene-coated silicon membrane and an aluminium cap.

*Test solution*. Weigh 25.0 mg of the substance to be examined into a 20 mL headspace vial. Add 0.50 mL of solution A and 0.50 mL of the internal standard solution and seal the vial immediately with a polytetrafluoroethylene-coated silicon membrane and an aluminium cap.

*Following the derivatisation reaction, a precipitate may be observed, however this does not affect the validity of the quantification.*

*Reference solution (a)*. Dissolve 25.0 mg each of *methyl toluenesulfonate R* (MTS), *ethyl toluenesulfonate R* (ETS) and *isopropyl toluenesulfonate R* (ITS) in *toluene R* and dilute to 5.0 mL with the same solvent. Dilute 50 µL of the solution to 25.0 mL with the internal standard solution.

*Reference solution (b)*. Dilute 40 µL of reference solution (a) to 20.0 mL with the internal standard solution. Introduce 0.50 mL of this solution and 0.50 mL of solution A into a 20 mL headspace vial and seal the vial immediately with a polytetrafluoroethylene-coated silicon membrane and an aluminium cap.

*Reference solution (c)*. Dilute 500 µL of reference solution (a) to 20.0 mL with the internal standard solution. Introduce 0.50 mL of this solution and 0.50 mL of solution A into a 20 mL headspace vial and seal the vial immediately with a polytetrafluoroethylene-coated silicon membrane and an aluminium cap.

*Column*:

- *material*: fused silica;
- *size*: *l* = 30 m, Ø = 0.25 mm;
- *stationary phase*: *polar-deactivated macrogol R* (film thickness 1 µm).

*Carrier gas*: *helium for chromatography R*.

*The use of an inert inlet liner without glass wool significantly reduces the effect of carry-over between the injections.*

*Flow rate*: 0.5 mL/min.

*Split ratio*: 1:20.

*Static head-space conditions that may be used*:

- *equilibration temperature*: 60 °C;
- *equilibration time*: 30 min;
- *transfer-line temperature*: 120 °C.

*Temperature*:

| | | Time (min) | Temperature (°C) |
|---|---|---|---|
| Column | | 0 - 1 | 40 |
| | | 1 - 10 | 40 → 130 |
| Injection port | | | 220 |
| Detector | transfer line | | 280 |
| | source | | 250 |
| | analyser | | 200 |

At the end of analysis the temperature of the column is raised to 240 °C and maintained at this temperature for 7 min.

*Detection*: mass spectrometer as described below; adjust the detector settings so as to comply with the system suitability criteria:

- quadrupole mass spectrometer equipped with an electron impact ionisation mode (70 eV);
- mass spectrometer parameters for the fragmentometric mode (single-ion monitoring (SIM)) set as follows:

| Substance | Quantitation ion (*m/z*) | Qualification ion (*m/z*) |
|---|---|---|
| Butyl iodide (BuI)* | 184 | 127 |
| Methyl iodide (MeI)* | 142 | 127 |
| Ethyl iodide (EtI)* | 156 | 127 |
| Isopropyl iodide (iPrI)* | 170 | 127 |
| * formed from BMS, MTS, ETS and ITS in the derivatisation reaction. | | |

*Injection*: 1 mL of the gas phase of the test solution, reference solutions (b) and (c) and of the blank solution.

*Relative retention* with reference to the internal standard (BuI) (retention time = about 8.5 min): MeI = about 0.51; EtI = about 0.63; iPrI = about 0.68.

*System suitability*:

- *resolution*: minimum 1.5 between the peaks due to EtI and iPrI in the chromatogram obtained with reference solution (c);
- *signal-to-noise ratio*: minimum 10 for the peak due to each alkyl iodide in the chromatogram obtained with reference solution (b).

Calculate the content in parts per million of each alkyl toluenesulfonate using the following expression:

$$\frac{A_2 \times I_1 \times W_1 \times C \times 0.05}{A_1 \times I_2 \times W_2}$$

$A_1$ = area of the peak due to each alkyl iodide in the chromatogram obtained with reference solution (c);

$A_2$ = area of the peak due to each alkyl iodide in the chromatogram obtained with the test solution;

$C$ = percentage content of each ester;

$I_1$ = area of the peak due to the internal standard in the chromatogram obtained with reference solution (c);

$I_2$ = area of the peak due to the internal standard in the chromatogram obtained with the test solution;

$W_1$ = mass of each ester used to prepare reference solution (a), in milligrams;

$W_2$ = mass of the substance to be examined in the test solution, in milligrams;

0.05 = dilution factor.

**04/2016:20541 corrected 10.0**

## 2.5.41. METHYL, ETHYL AND ISOPROPYL BENZENESULFONATE IN ACTIVE SUBSTANCES

The following general method has been validated for the determination of methyl, ethyl and isopropyl esters of benzenesulfonic acid (in concentrations between 2.5 ppm and 40 ppm) in amlodipine besilate.

If it is intended to use the method for other active substances, particularly those that contain different concentrations of the benzenesulfonic acid esters, the concentrations of the test solution and reference solutions must be adjusted accordingly and the method must be suitably validated.

This method is not suitable for clopidogrel besilate as it was observed that methyl benzenesulfonate was obtained during the gas chromatographic analysis as an artefact originating from degradation.

METHOD

Head-space gas chromatography (*2.2.28*) coupled with mass spectrometry (*2.2.43*). *Prepare the test solution and reference solutions immediately before use.*

*Solvent mixture*: *water R, acetonitrile R* (20:80 *V/V*). *The use of acetonitrile of appropriate purity is essential.*

*Solution A*. Dissolve with the aid of ultrasound 30 mg of *anhydrous sodium thiosulfate R* and 60.0 g of *sodium iodide R* in *water R* and dilute to 50.0 mL with the same solvent.

*Internal standard solution.* Dilute 10 µL of *butyl methanesulfonate CRS* (BMS) to 10.0 mL with the solvent mixture. Dilute 20 µL of the solution to 100.0 mL with the solvent mixture.

*Blank solution.* Introduce 0.50 mL of solution A and 0.50 mL of the internal standard solution into a headspace vial and seal the vial immediately with a polytetrafluoroethylene-coated silicon membrane and an aluminium cap.

*Test solution.* Weigh 25.0 mg of the substance to be examined into a 20 mL headspace vial. Add 0.50 mL of solution A and 0.50 mL of the internal standard solution and seal the vial immediately with a polytetrafluoroethylene-coated silicon membrane and an aluminium cap.

*Following the derivatisation reaction, a precipitate may be observed, however this does not affect the validity of the quantification.*

*Reference solution (a).* Dissolve 25.0 mg each of *methyl benzenesulfonate R* (MBS), *ethyl benzenesulfonate R* (EBS) and *isopropyl methanesulfonate R* (IMS) in *toluene R* and dilute to 5.0 mL with the same solvent. Dilute 50 µL of the solution to 25.0 mL with the internal standard solution.

*Reference solution (b).* Dilute 40 µL of reference solution (a) to 20.0 mL with the internal standard solution. Introduce 0.50 mL of this solution and 0.50 mL of solution A into a 20 mL headspace vial and seal the vial immediately with a polytetrafluoroethylene-coated silicon membrane and an aluminium cap.

*Reference solution (c).* Dilute 500 µL of reference solution (a) to 20.0 mL with the internal standard solution. Introduce 0.50 mL of this solution and 0.50 mL of solution A into a 20 mL headspace vial and seal the vial immediately with a polytetrafluoroethylene-coated silicon membrane and an aluminium cap.

*Column*:

- *material*: fused silica;
- *size*: *l* = 30 m, Ø = 0.25 mm;
- *stationary phase*: *polar-deactivated macrogol R* (film thickness 1 µm).

*Carrier gas*: *helium for chromatography R.*

*The use of an inert inlet liner without glass wool significantly reduces the effect of carry-over between the injections.*

*Flow rate*: 0.5 mL/min.

*Split ratio*: 1:20.

*Static head-space conditions that may be used*:

- *equilibration temperature*: 60 °C;
- *equilibration time*: 30 min;
- *transfer-line temperature*: 120 °C.

*Temperature*:

| | | Time (min) | Temperature (°C) |
|---|---|---|---|
| Column | | 0 - 1 | 40 |
| | | 1 - 10 | 40 → 130 |
| Injection port | | | 220 |
| Detector | transfer line | | 280 |
| | source | | 250 |
| | analyser | | 200 |

At the end of analysis, the temperature of the column is raised to 240 °C and maintained at this temperature for 7 min.

*Detection*: mass spectrometer as described below; adjust the detector settings so as to comply with the system suitability criteria:

- quadrupole mass spectrometer equipped with an electron impact ionisation mode (70 eV);
- mass spectrometer parameters for the fragmentometric mode (single-ion monitoring (SIM)) set as follows:

| Substance | Quantitation ion (*m/z*) | Qualification ion (*m/z*) |
|---|---|---|
| Butyl iodide (BuI)* | 184 | 127 |
| Methyl iodide (MeI)* | 142 | 127 |
| Ethyl iodide (EtI)* | 156 | 127 |
| Isopropyl iodide (iPrI)* | 170 | 127 |
| * formed from BMS, MBS, EBS and IMS in the derivatisation reaction. | | |

*Injection*: 1 mL of the gas phase of the test solution, reference solutions (b) and (c) and the blank solution.

*Relative retention* with reference to the internal standard (BuI) (retention time = about 8.5 min): MeI = about 0.51; EtI = about 0.63; iPrI = about 0.68.

*System suitability*:

- *resolution*: minimum 1.5 between the peaks due to EtI and iPrI in the chromatogram obtained with reference solution (c);
- *signal-to-noise ratio*: minimum 10 for the peak due to each alkyl iodide in the chromatogram obtained with reference solution (b).

Calculate the content in parts per million of each alkyl benzenesulfonate using the following expression:

$$\frac{A_2 \times I_1 \times W_1 \times C \times 0.05}{A_1 \times I_2 \times W_2}$$

$A_1$ = area of the peak due to each alkyl iodide in the chromatogram obtained with reference solution (c);

$A_2$ = area of the peak due to each alkyl iodide in the chromatogram obtained with the test solution;

$C$ = percentage content of each ester;

$I_1$ = area of the peak due to the internal standard in the chromatogram obtained with reference solution (c);

$I_2$ = area of the peak due to the internal standard in the chromatogram obtained with the test solution;

$W_1$ = mass of each ester used to prepare reference solution (a), in milligrams;

$W_2$ = mass of the substance to be examined in the test solution, in milligrams;

0.05 = dilution factor.

# 2.6. BIOLOGICAL TESTS

**04/2011:20601**
**corrected 7.7**

## 2.6.1. STERILITY[(1)]

*The test is applied to substances, preparations or articles which, according to the Pharmacopoeia, are required to be sterile. However, a satisfactory result only indicates that no contaminating micro-organism has been found in the sample examined in the conditions of the test.*

PRECAUTIONS AGAINST MICROBIAL CONTAMINATION

The test for sterility is carried out under aseptic conditions. In order to achieve such conditions, the test environment has to be adapted to the way in which the sterility test is performed. The precautions taken to avoid contamination are such that they do not affect any micro-organisms which are to be revealed in the test. The working conditions in which the tests are performed are monitored regularly by appropriate sampling of the working area and by carrying out appropriate controls.

CULTURE MEDIA AND INCUBATION TEMPERATURES

*Media for the test may be prepared as described below, or equivalent commercial media may be used provided that they comply with the growth promotion test.*

The following culture media have been found to be suitable for the test for sterility. Fluid thioglycollate medium is primarily intended for the culture of anaerobic bacteria; however, it will also detect aerobic bacteria. Soya-bean casein digest medium is suitable for the culture of both fungi and aerobic bacteria.

**Fluid thioglycollate medium**

| | |
|---|---|
| L-Cystine | 0.5 g |
| Agar | 0.75 g |
| Sodium chloride | 2.5 g |
| Glucose monohydrate/Glucose | 5.5 g/5.0 g |
| Yeast extract (water-soluble) | 5.0 g |
| Pancreatic digest of casein | 15.0 g |
| Sodium thioglycollate or | 0.5 g |
| Thioglycollic acid | 0.3 mL |
| Resazurin sodium solution (1 g/L of resazurin sodium), freshly prepared | 1.0 mL |
| *Water R* | 1000 mL |

pH after sterilisation 7.1 ± 0.2

Mix the L-cystine, agar, sodium chloride, glucose, water-soluble yeast extract and pancreatic digest of casein with the *water R* and heat until solution is effected. Dissolve the sodium thioglycollate or thioglycollic acid in the solution and, if necessary, add *1 M sodium hydroxide* so that, after sterilisation, the solution will have a pH of 7.1 ± 0.2. If filtration is necessary, heat the solution again without boiling and filter while hot through moistened filter paper. Add the resazurin sodium solution, mix and place the medium in suitable vessels which provide a ratio of surface to depth of medium such that not more than the upper half of the medium has undergone a colour change indicative of oxygen uptake at the end of the incubation period. Sterilise using a validated process. If the medium is stored, store at a temperature between 2 °C and 25 °C in a sterile, airtight container. If more than the upper one-third of the medium has acquired a pink colour, the medium may be restored once by heating the containers in a water-bath or in free-flowing steam until the pink colour disappears and cooling quickly, taking care to prevent the introduction of non-sterile air into the container. Do not use the medium for a longer storage period than has been validated.

Fluid thioglycollate medium is to be incubated at 30-35 °C.

For products containing a mercurial preservative that cannot be tested by the membrane-filtration method, fluid thioglycollate medium incubated at 20-25 °C may be used instead of soya-bean casein digest medium provided that it has been validated as described in growth promotion test.

Where prescribed or justified and authorised, the following alternative thioglycollate medium may be used. Prepare a mixture having the same composition as that of the fluid thioglycollate medium, but omitting the agar and the resazurin sodium solution, sterilise as directed above. The pH after sterilisation is 7.1 ± 0.2. Heat in a water-bath prior to use and incubate at 30-35 °C under anaerobic conditions.

**Soya-bean casein digest medium**

| | |
|---|---|
| Pancreatic digest of casein | 17.0 g |
| Papaic digest of soya-bean meal | 3.0 g |
| Sodium chloride | 5.0 g |
| Dipotassium hydrogen phosphate | 2.5 g |
| Glucose monohydrate/Glucose | 2.5 g/2.3 g |
| *Water R* | 1000 mL |

pH after sterilisation 7.3 ± 0.2

Dissolve the solids in *water R*, warming slightly to effect solution. Cool the solution to room temperature. Add *1 M sodium hydroxide*, if necessary, so that after sterilisation the solution will have a pH of 7.3 ± 0.2. Filter, if necessary, to clarify, distribute into suitable vessels and sterilise using a validated process. Store at a temperature between 2 °C and 25 °C in a sterile well-closed container, unless it is intended for immediate use. Do not use the medium for a longer storage period than has been validated.

Soya-bean casein digest medium is to be incubated at 20-25 °C.

The media used comply with the following tests, carried out before or in parallel with the test on the product to be examined.

**Sterility**. Incubate portions of the media for 14 days. No growth of micro-organisms occurs.

**Growth promotion test of aerobes, anaerobes and fungi**. Test each batch of ready-prepared medium and each batch of medium prepared either from dehydrated medium or from ingredients. Suitable strains of micro-organisms are indicated in Table 2.6.1.-1.

Inoculate portions of fluid thioglycollate medium with a small number (not more than 100 CFU) of the following micro-organisms, using a separate portion of medium for each of the following species of micro-organism: *Clostridium sporogenes*, *Pseudomonas aeruginosa*, *Staphylococcus aureus*. Inoculate portions of soya-bean casein digest medium with a small number (not more than 100 CFU) of the following micro-organisms, using a separate portion of medium for each of the following species of micro-organism: *Aspergillus brasiliensis*, *Bacillus subtilis*, *Candida albicans*. Incubate for not more than 3 days in the case of bacteria and not more than 5 days in the case of fungi.

Seed lot culture maintenance techniques (seed-lot systems) are used so that the viable micro-organisms used for inoculation are not more than 5 passages removed from the original master seed-lot.

(1) This chapter has undergone pharmacopoeial harmonisation. See chapter *5.8. Pharmacopoeial harmonisation.*

Table 2.6.1.-1. – *Strains of the test micro-organisms suitable for use in the growth promotion test and the method suitability test*

| | |
|---|---|
| **Aerobic bacteria** | |
| *Staphylococcus aureus* | ATCC 6538, CIP 4.83, NCTC 10788, NCIMB 9518, NBRC 13276 |
| *Bacillus subtilis* | ATCC 6633, CIP 52.62, NCIMB 8054, NBRC 3134 |
| *Pseudomonas aeruginosa* | ATCC 9027, NCIMB 8626, CIP 82.118, NBRC 13275 |
| **Anaerobic bacterium** | |
| *Clostridium sporogenes* | ATCC 19404, CIP 79.3, NCTC 532, ATCC 11437, NBRC 14293 |
| **Fungi** | |
| *Candida albicans* | ATCC 10231, IP 48.72, NCPF 3179, NBRC 1594 |
| *Aspergillus brasiliensis* | ATCC 16404, IP 1431.83, IMI 149007, NBRC 9455 |

The media are suitable if a clearly visible growth of the micro-organisms occurs.

METHOD SUITABILITY TEST

Carry out a test as described below under Test for sterility of the product to be examined using exactly the same methods except for the following modifications.

**Membrane filtration**. After transferring the contents of the container or containers to be tested to the membrane add an inoculum of a small number of viable micro-organisms (not more than 100 CFU) to the final portion of sterile diluent used to rinse the filter.

**Direct inoculation**. After transferring the content of the container or containers to be tested (for catgut and other surgical sutures for veterinary use: strands) to the culture medium add an inoculum of a small number of viable micro-organisms (not more than 100 CFU) to the medium.

In both cases use the same micro-organisms as those described above under Growth promotion test of aerobes, anaerobes and fungi. Perform a growth promotion test as a positive control. Incubate all the containers containing medium for not more than 5 days.

If clearly visible growth of micro-organisms is obtained after the incubation, visually comparable to that in the control vessel without product, either the product possesses no antimicrobial activity under the conditions of the test or such activity has been satisfactorily eliminated. The test for sterility may then be carried out without further modification.

If clearly visible growth is not obtained in the presence of the product to be tested, visually comparable to that in the control vessels without product, the product possesses antimicrobial activity that has not been satisfactorily eliminated under the conditions of the test. Modify the conditions in order to eliminate the antimicrobial activity and repeat the method suitability test.

This method suitability test is performed:

a) when the test for sterility has to be carried out on a new product;

b) whenever there is a change in the experimental conditions of the test.

The method suitability test may be performed simultaneously with the test for sterility of the product to be examined.

TEST FOR STERILITY OF THE PRODUCT TO BE EXAMINED

The test may be carried out using the technique of membrane filtration or by direct inoculation of the culture media with the product to be examined. Appropriate negative controls are included. The technique of membrane filtration is used whenever the nature of the product permits, that is, for filterable aqueous preparations, for alcoholic or oily preparations and for preparations miscible with or soluble in aqueous or oily solvents provided these solvents do not have an antimicrobial effect in the conditions of the test.

**Membrane filtration**. Use membrane filters having a nominal pore size not greater than 0.45 µm whose effectiveness to retain micro-organisms has been established. Cellulose nitrate filters, for example, are used for aqueous, oily and weakly alcoholic solutions and cellulose acetate filters, for example, for strongly alcoholic solutions. Specially adapted filters may be needed for certain products, e.g. for antibiotics.

The technique described below assumes that membranes about 50 mm in diameter will be used. If filters of a different diameter are used the volumes of the dilutions and the washings should be adjusted accordingly. The filtration apparatus and membrane are sterilised by appropriate means. The apparatus is designed so that the solution to be examined can be introduced and filtered under aseptic conditions; it permits the aseptic removal of the membrane for transfer to the medium or it is suitable for carrying out the incubation after adding the medium to the apparatus itself.

*Aqueous solutions*. If appropriate, transfer a small quantity of a suitable, sterile diluent such as a 1 g/L neutral solution of meat or casein peptone pH 7.1 ± 0.2 onto the membrane in the apparatus and filter. The diluent may contain suitable neutralising substances and/or appropriate inactivating substances for example in the case of antibiotics.

Transfer the contents of the container or containers to be tested to the membrane or membranes, if necessary after diluting to the volume used in the method suitability test with the chosen sterile diluent but in any case using not less than the quantities of the product to be examined prescribed in Table 2.6.1.-2. Filter immediately. If the product has antimicrobial properties, wash the membrane not less than 3 times by filtering through it each time the volume of the chosen sterile diluent used in the method suitability test. Do not exceed a washing cycle of 5 times 100 mL per filter, even if during the method suitability test it has been demonstrated that such a cycle does not fully eliminate the antimicrobial activity. Transfer the whole membrane to the culture medium or cut it aseptically into 2 equal parts and transfer one half to each of 2 suitable media. Use the same volume of each medium as in the method suitability test. Alternatively, transfer the medium onto the membrane in the apparatus. Incubate the media for not less than 14 days.

*Soluble solids*. Use for each medium not less than the quantity prescribed in Table 2.6.1.-2 of the product dissolved in a suitable solvent such as the solvent provided with the preparation, water for injections, saline or a 1 g/L neutral solution of meat or casein peptone and proceed with the test as described above for aqueous solutions using a membrane appropriate to the chosen solvent.

*Oils and oily solutions*. Use for each medium not less than the quantity of the product prescribed in Table 2.6.1.-2. Oils and oily solutions of sufficiently low viscosity may be filtered without dilution through a dry membrane. Viscous oils may be diluted as necessary with a suitable sterile diluent such as isopropyl myristate shown not to have antimicrobial activity in the conditions of the test. Allow the oil to penetrate the membrane by its own weight then filter, applying the pressure

Table 2.6.1.-2. – *Minimum quantity to be used for each medium*

| Quantity per container | Minimum quantity to be used for each medium unless otherwise justified and authorised |
|---|---|
| *Liquids* | |
| – less than 1 mL | The whole contents of each container |
| – 1-40 mL | Half the contents of each container but not less than 1 mL |
| – greater than 40 mL and not greater than 100 mL | 20 mL |
| – greater than 100 mL | 10 per cent of the contents of the container but not less than 20 mL |
| *Antibiotic liquids* | 1 mL |
| *Insoluble preparations, creams and ointments to be suspended or emulsified* | Use the contents of each container to provide not less than 200 mg |
| *Solids* | |
| – less than 50 mg | The whole contents of each container |
| – 50 mg or more but less than 300 mg | Half the contents of each container but not less than 50 mg |
| – 300 mg to 5 g | 150 mg |
| – greater than 5 g | 500 mg |
| *Catgut and other surgical sutures for veterinary use* | 3 sections of a strand (each 30 cm long) |

or suction gradually. Wash the membrane at least 3 times by filtering through it each time about 100 mL of a suitable sterile solution such as 1 g/L neutral meat or casein peptone containing a suitable emulsifying agent at a concentration shown to be appropriate in the method suitability test, for example polysorbate 80 at a concentration of 10 g/L. Transfer the membrane or membranes to the culture medium or media or vice versa as described above for aqueous solutions, and incubate at the same temperatures and for the same times.

*Ointments and creams.* Use for each medium not less than the quantities of the product prescribed in Table 2.6.1.-2. Ointments in a fatty base and emulsions of the water-in-oil type may be diluted to 1 per cent in isopropyl myristate as described above, by heating, if necessary, to not more than 40 °C. In exceptional cases it may be necessary to heat to not more than 44 °C. Filter as rapidly as possible and proceed as described above for oils and oily solutions.

**Direct inoculation of the culture medium**. Transfer the quantity of the preparation to be examined prescribed in Table 2.6.1.-2 directly into the culture medium so that the volume of the product is not more than 10 per cent of the volume of the medium, unless otherwise prescribed.

If the product to be examined has antimicrobial activity, carry out the test after neutralising this with a suitable neutralising substance or by dilution in a sufficient quantity of culture medium. When it is necessary to use a large volume of the product it may be preferable to use a concentrated culture medium prepared in such a way that it takes account of the subsequent dilution. Where appropriate, the concentrated medium may be added directly to the product in its container.

*Oily liquids.* Use media to which have been added a suitable emulsifying agent at a concentration shown to be appropriate in the method suitability test, for example polysorbate 80 at a concentration of 10 g/L.

*Ointments and creams.* Prepare by diluting to about 1 in 10 by emulsifying with the chosen emulsifying agent in a suitable sterile diluent such as a 1 g/L neutral solution of meat or casein peptone. Transfer the diluted product to a medium not containing an emulsifying agent.

Incubate the inoculated media for not less than 14 days. Observe the cultures several times during the incubation period. Shake cultures containing oily products gently each day. However when fluid thioglycollate medium is used for the detection of anaerobic micro-organisms keep shaking or mixing to a minimum in order to maintain anaerobic conditions.

*Catgut and other surgical sutures for veterinary use.* Use for each medium not less than the quantities of the product prescribed in Table 2.6.1.-2. Open the sealed package using aseptic precautions and remove 3 sections of the strand for each culture medium. Carry out the test on 3 sections, each 30 cm long, cut off from the beginning, the centre and the end of the strand. Use whole strands from freshly opened cassette packs. Transfer each section of the strand to the selected medium. Use sufficient medium to cover adequately the material to be tested (20 mL to 150 mL).

OBSERVATION AND INTERPRETATION OF RESULTS

At intervals during the incubation period and at its conclusion, examine the media for macroscopic evidence of microbial growth. If the material being tested renders the medium turbid so that the presence or absence of microbial growth cannot be readily determined by visual examination, 14 days after the beginning of incubation transfer portions (each not less than 1 mL) of the medium to fresh vessels of the same medium and then incubate the original and transfer vessels for not less than 4 days.

If no evidence of microbial growth is found, the product to be examined complies with the test for sterility. If evidence of microbial growth is found the product to be examined does not comply with the test for sterility, unless it can be clearly demonstrated that the test was invalid for causes unrelated to the product to be examined. The test may be considered invalid only if one or more of the following conditions are fulfilled:

a) the data of the microbiological monitoring of the sterility testing facility show a fault;

b) a review of the testing procedure used during the test in question reveals a fault;

c) microbial growth is found in the negative controls;

d) after determination of the identity of the micro-organisms isolated from the test, the growth of this species or these species may be ascribed unequivocally to faults with respect to the material and/or the technique used in conducting the sterility test procedure.

If the test is declared to be invalid it is repeated with the same number of units as in the original test.

If no evidence of microbial growth is found in the repeat test the product examined complies with the test for sterility. If microbial growth is found in the repeat test the product examined does not comply with the test for sterility.

Table 2.6.1.-3. – *Minimum number of items to be tested*

| Number of items in the batch* | Minimum number of items to be tested for each medium, unless otherwise justified and authorised** |
|---|---|
| *Parenteral preparations* | |
| – Not more than 100 containers | 10 per cent or 4 containers, whichever is the greater |
| – More than 100 but not more than 500 containers | 10 containers |
| – More than 500 containers | 2 per cent or 20 containers (10 containers for large-volume parenterals) whichever is less |
| *Ophthalmic and other non-injectable preparations* | |
| – Not more than 200 containers | 5 per cent or 2 containers, whichever is the greater |
| – More than 200 containers | 10 containers |
| – If the product is presented in the form of single-dose containers, apply the scheme shown above for preparations for parenteral administration | |
| *Catgut and other surgical sutures for veterinary use* | 2 per cent or 5 packages whichever is the greater, up to a maximum total of 20 packages |
| *Bulk solid products* | |
| – Up to 4 containers | Each container |
| – More than 4 containers but not more than 50 containers | 20 per cent or 4 containers, whichever is the greater |
| – More than 50 containers | 2 per cent or 10 containers, whichever is the greater |
| * If the batch size is not known, use the maximum number of items prescribed. **If the contents of one container are enough to inoculate the 2 media, this column gives the number of containers needed for both the media together. | |

APPLICATION OF THE TEST TO PARENTERAL PREPARATIONS, OPHTHALMIC AND OTHER NON-INJECTABLE PREPARATIONS REQUIRED TO COMPLY WITH THE TEST FOR STERILITY

When using the technique of membrane filtration, use, whenever possible, the whole contents of the container, but not less than the quantities indicated in Table 2.6.1.-2, diluting where necessary to about 100 mL with a suitable sterile solution, such as 1 g/L neutral meat or casein peptone.

When using the technique of direct inoculation of media, use the quantities shown in Table 2.6.1.-2, unless otherwise justified and authorised. The tests for bacterial and fungal sterility are carried out on the same sample of the product to be examined. When the volume or the quantity in a single container is insufficient to carry out the tests, the contents of 2 or more containers are used to inoculate the different media.

MINIMUM NUMBER OF ITEMS TO BE TESTED

The minimum number of items to be tested in relation to the size of the batch is given in Table 2.6.1.-3.

*Guidelines on the test for sterility are given in general chapter 5.1.9.*

**01/2008:20602**

## 2.6.2. MYCOBACTERIA

If the sample to be examined may be contaminated by micro-organisms other than mycobacteria, treat it with a suitable decontamination solution, such as acetylcysteine-sodium hydroxide solution or sodium laurilsulfate solution.

Inoculate 0.2 mL of the sample in triplicate onto each of 2 suitable solid media (Löwenstein-Jensen medium and Middlebrook 7H10 medium are considered suitable). Inoculate 0.5 mL in triplicate into a suitable liquid medium. Incubate all media at 37 °C for 56 days.

Establish the fertility of the media in the presence of the preparation to be examined by inoculation of a suitable strain of a *Mycobacterium* sp. such as BCG and if necessary use a suitable neutralising substance.

If contaminating micro-organisms develop during the first 8 days of incubation, repeat the test and carry out at the same time a bacteriological sterility test.

If at the end of the incubation time no growth of mycobacteria occurs in any of the test media, the preparation complies with the test.

**01/2008:20607 corrected 6.1**

## 2.6.7. MYCOPLASMAS

Where the test for mycoplasmas is prescribed for a master cell bank, for a working cell bank, for a virus seed lot or for control cells, both the culture method and the indicator cell culture method are used. Where the test for mycoplasmas is prescribed for a virus harvest, for a bulk vaccine or for the final lot (batch), the culture method is used. The indicator cell culture method may also be used, where necessary, for screening of media.

Nucleic acid amplification techniques (NAT) may be used as an alternative to one or both of the other methods after suitable validation.

CULTURE METHOD

*CHOICE OF CULTURE MEDIA*

The test is carried out using a sufficient number of both solid and liquid media to ensure growth in the chosen incubation conditions of small numbers of mycoplasmas that may be present in the product to be examined. Liquid media must contain phenol red. The range of media chosen is shown to have satisfactory nutritive properties for at least the micro-organisms shown below. The nutritive properties of each new batch of medium are verified for the appropriate micro-organisms in the list. When testing for mycoplasmas in the product to be examined, at least 1 of the following species will be included as a positive control:

– *Acholeplasma laidlawii* (vaccines for human and veterinary use where an antibiotic has been used during production);

- *Mycoplasma gallisepticum* (where avian material has been used during production or where the vaccine is intended for use in poultry);
- *Mycoplasma hyorhinis* (non-avian veterinary vaccines);
- *Mycoplasma orale* (vaccines for human and veterinary use);
- *Mycoplasma pneumoniae* (vaccines for human use) or other suitable species of D-glucose fermenter such as *Mycoplasma fermentans*;
- *Mycoplasma synoviae* (where avian material has been used during production or where the vaccine is intended for use in poultry).

The test strains are field isolates having undergone a limited number of subcultures (not more than 15), and are stored frozen or freeze-dried. After cloning, the strains are identified as being of the required species by comparison with type cultures, for example:

| | | | |
|---|---|---|---|
| *A. laidlawii* | NCTC 10116 | CIP 75.27 | ATCC 23206 |
| *M. gallisepticum* | NCTC 10115 | CIP 104967 | ATCC 19610 |
| *M. fermentans* | NCTC 10117 | CIP 105680 | ATCC 19989 |
| *M. hyorhinis* | NCTC 10130 | CIP 104968 | ATCC 17981 |
| *M. orale* | NCTC 10112 | CIP 104969 | ATCC 23714 |
| *M. pneumoniae* | NCTC 10119 | CIP 103766 | ATCC 15531 |
| *M. synoviae* | NCTC 10124 | CIP 104970 | ATCC 25204 |

*Acholeplasma laidlawii BRP*, *Mycoplasma fermentans BRP*, *Mycoplasma hyorhinis BRP*, *Mycoplasma orale BRP* and *Mycoplasma synoviae BRP* are suitable for use as low-passage reference strains.

*INCUBATION CONDITIONS*

Incubate liquid media in tightly stoppered containers at 35-38 °C. Incubate solid media in microaerophilic conditions (nitrogen containing 5-10 per cent of carbon dioxide and sufficient humidity to prevent desiccation of the agar surface) at 35-38 °C.

*NUTRITIVE PROPERTIES*

*Carry out the test for nutritive properties for each new batch of medium.* Inoculate the chosen media with the appropriate test micro-organisms; use not more than 100 CFU per 60 mm diameter plate containing 9 mL of solid medium and per 100 mL container of liquid medium; use a separate plate and container for each species of micro-organism. Incubate the media and make subcultures from 0.2 mL of liquid medium to solid medium at the specified intervals (see below under Test for mycoplasmas in the product to be examined). The solid medium complies with the test if adequate growth is found for each test micro-organism (growth obtained does not differ by a factor greater than 5 from the value calculated with respect to the inoculum). The liquid medium complies with the test if growth on agar plates subcultured from the broth is found for at least 1 subculture for each test micro-organism.

*INHIBITORY SUBSTANCES*

The test for inhibitory substances is carried out once for a given product and is repeated whenever there is a change in production method that may affect the detection of mycoplasmas.

To demonstrate absence of inhibitory substances, carry out the test for nutritive properties in the presence and absence of the product to be examined. If growth of a test micro-organism occurs more than 1 subculture sooner in the absence of the product to be examined than in its presence, or if plates directly inoculated with the product to be examined have fewer than 1/5 of the number of colonies of those inoculated without the product to be examined, inhibitory substances are present and they must be neutralised or their effect otherwise countered, for example by passage in substrates not containing inhibitors or dilution in a larger volume of medium before the test. If dilution is used, larger medium volumes may be used or the inoculum volume may be divided among several 100 mL flasks. The effectiveness of the neutralisation or other process is checked by repeating the test for inhibitory substances after neutralisation.

*TEST FOR MYCOPLASMAS IN THE PRODUCT TO BE EXAMINED*

Inoculate 10 mL of the product to be examined per 100 mL of each liquid medium. If it has been found that a significant pH change occurs upon the addition of the product to be examined, the liquid medium is restored to its original pH value by the addition of a solution of either sodium hydroxide or hydrochloric acid. Inoculate 0.2 mL of the product to be examined on each plate of each solid medium. Incubate liquid media for 20-21 days. Incubate solid media for not less than 14 days, except those corresponding to the 20-21 day subculture, which are incubated for 7 days. At the same time incubate an uninoculated 100 mL portion of each liquid medium and agar plates, as a negative control. On days 2-4 after inoculation, subculture each liquid medium by inoculating 0.2 mL on at least 1 plate of each solid medium. Repeat the procedure between the 6$^{th}$ and 8$^{th}$ days, again between the 13$^{th}$ and 15$^{th}$ days and again between the 19$^{th}$ and 21$^{st}$ days of the test. Observe the liquid media every 2 or 3 days and if a colour change occurs, subculture. If a liquid medium shows bacterial or fungal contamination, the test is invalid. The test is valid if at least 1 plate per medium and per inoculation day can be read. Include in the test positive controls prepared by inoculation of not more than 100 CFU of at least 1 test micro-organism on agar medium or into broth medium. Where the test for mycoplasmas is carried out regularly and where possible, it is recommended to use the test micro-organisms in regular rotation. The test micro-organisms used are those listed under Choice of culture media.

*INTERPRETATION OF RESULTS*

At the end of the prescribed incubation period, examine all inoculated solid media microscopically for the presence of mycoplasma colonies. The product complies with the test if growth of typical mycoplasma colonies has not occurred. The product does not comply with the test if growth of typical mycoplasma colonies has occurred on any of the solid media. The test is invalid if 1 or more of the positive controls do not show growth of mycoplasmas on at least 1 subculture plate. The test is invalid if 1 or more of the negative controls show growth of mycoplasmas. If suspect colonies are observed, a suitable validated method may be used to determine whether they are due to mycoplasmas.

*The following section is published for information.*

RECOMMENDED MEDIA FOR THE CULTURE METHOD

The following media are recommended. Other media may be used, provided that their ability to sustain the growth of mycoplasmas has been demonstrated on each batch in the presence and absence of the product to be examined.

*HAYFLICK MEDIA (RECOMMENDED FOR THE GENERAL DETECTION OF MYCOPLASMAS)*

**Liquid medium**

| | |
|---|---|
| Beef heart infusion broth (1) | 90.0 mL |
| Horse serum (unheated) | 20.0 mL |
| Yeast extract (250 g/L) | 10.0 mL |
| Phenol red (0.6 g/L solution) | 5.0 mL |
| Penicillin (20 000 IU/mL) | 0.25 mL |
| Deoxyribonucleic acid (2 g/L solution) | 1.2 mL |

Adjust to pH 7.8.

**Solid medium**

Prepare as described above replacing beef heart infusion broth by beef heart infusion agar containing 15 g/L of agar.

*FREY MEDIA (RECOMMENDED FOR THE DETECTION OF M. SYNOVIAE)*

**Liquid medium**

| | |
|---|---|
| Beef heart infusion broth (1) | 90.0 mL |
| Essential vitamins (2) | 0.025 mL |
| Glucose monohydrate (500 g/L solution) | 2.0 mL |
| Swine serum (inactivated at 56 °C for 30 min) | 12.0 mL |
| β-Nicotinamide adenine dinucleotide (10 g/L solution) | 1.0 mL |
| Cysteine hydrochloride (10 g/L solution) | 1.0 mL |
| Phenol red (0.6 g/L solution) | 5.0 mL |
| Penicillin (20 000 IU/mL) | 0.25 mL |

Mix the solutions of β-nicotinamide adenine dinucleotide and cysteine hydrochloride and after 10 min add to the other ingredients. Adjust to pH 7.8.

**Solid medium**

| | |
|---|---|
| Beef heart infusion broth (1) | 90.0 mL |
| Agar, purified (3) | 1.4 g |

Adjust to pH 7.8, sterilise by autoclaving then add:

| | |
|---|---|
| Essential vitamins (2) | 0.025 mL |
| Glucose monohydrate (500 g/L solution) | 2.0 mL |
| Swine serum (unheated) | 12.0 mL |
| β-Nicotinamide adenine dinucleotide (10 g/L solution) | 1.0 mL |
| Cysteine hydrochloride (10 g/L solution) | 1.0 mL |
| Phenol red (0.6 g/L solution) | 5.0 mL |
| Penicillin (20 000 IU/mL) | 0.25 mL |

*FRIIS MEDIA (RECOMMENDED FOR THE DETECTION OF NON-AVIAN MYCOPLASMAS)*

**Liquid medium**

| | |
|---|---|
| Hanks' balanced salt solution (modified) (4) | 800 mL |
| Distilled water | 67 mL |
| Brain heart infusion (5) | 135 mL |
| PPLO Broth (6) | 248 mL |
| Yeast extract (170 g/L) | 60 mL |
| Bacitracin | 250 mg |
| Meticillin | 250 mg |
| Phenol red (5 g/L) | 4.5 mL |
| Horse serum | 165 mL |
| Swine serum | 165 mL |

Adjust to pH 7.40-7.45.

**Solid medium**

| | |
|---|---|
| Hanks' balanced salt solution (modified) (4) | 200 mL |
| DEAE-dextran | 200 mg |
| Agar, purified (3) | 15.65 g |

Mix well and sterilise by autoclaving. Cool to 100 °C. Add to 1740 mL of liquid medium as described above.

(1) *Beef heart infusion broth*

| | |
|---|---|
| Beef heart (for preparation of the infusion) | 500 g |
| Peptone | 10 g |
| Sodium chloride | 5 g |
| Distilled water | to 1000 mL |

Sterilise by autoclaving.

(2) *Essential vitamins*

| | |
|---|---|
| Biotin | 100 mg |
| Calcium pantothenate | 100 mg |
| Choline chloride | 100 mg |
| Folic acid | 100 mg |
| *i*-Inositol | 200 mg |
| Nicotinamide | 100 mg |
| Pyridoxal hydrochloride | 100 mg |
| Riboflavine | 10 mg |
| Thiamine hydrochloride | 100 mg |
| Distilled water | to 1000 mL |

(3) *Agar, purified*

A highly refined agar for use in microbiology and immunology, prepared by an ion-exchange procedure that results in a product having superior purity, clarity and gel strength. It contains about:

| | |
|---|---|
| Water | 12.2 per cent |
| Ash | 1.5 per cent |
| Acid-insoluble ash | 0.2 per cent |
| Chlorine | 0 |
| Phosphate (calculated as $P_2O_5$) | 0.3 per cent |
| Total nitrogen | 0.3 per cent |
| Copper | 8 ppm |
| Iron | 170 ppm |
| Calcium | 0.28 per cent |
| Magnesium | 0.32 per cent |

(4) *Hanks' balanced salt solution (modified)*

| | |
|---|---|
| Sodium chloride | 6.4 g |
| Potassium chloride | 0.32 g |
| Magnesium sulfate heptahydrate | 0.08 g |
| Magnesium chloride hexahydrate | 0.08 g |
| Calcium chloride, anhydrous | 0.112 g |
| Disodium hydrogen phosphate dihydrate | 0.0596 g |
| Potassium dihydrogen phosphate, anhydrous | 0.048 g |
| Distilled water | to 800 mL |

(5) *Brain heart infusion*

| | |
|---|---|
| Calf-brain infusion | 200 g |
| Beef-heart infusion | 250 g |
| Proteose peptone | 10 g |
| Glucose monohydrate | 2 g |
| Sodium chloride | 5 g |
| Disodium hydrogen phosphate, anhydrous | 2.5 g |
| Distilled water | to 1000 mL |

(6) *PPLO broth*

| | |
|---|---|
| Beef-heart infusion | 50 g |
| Peptone | 10 g |
| Sodium chloride | 5 g |
| Distilled water | to 1000 mL |

INDICATOR CELL CULTURE METHOD

Cell cultures are stained with a fluorescent dye that binds to DNA. Mycoplasmas are detected by their characteristic particulate or filamentous pattern of fluorescence on the cell surface and, if contamination is heavy, in surrounding areas. Mitochondria in the cytoplasm may be stained but are readily distinguished from mycoplasmas.

If for viral suspensions the interpretation of results is affected by marked cytopathic effects, the virus may be neutralised using a specific antiserum that has no inhibitory effects on mycoplasmas or a cell culture substrate that does not allow growth of the virus may be used. To demonstrate the absence of inhibitory effects of serum, carry out the positive control tests in the presence and absence of the antiserum.

*VERIFICATION OF THE SUBSTRATE*

Use Vero cells or another cell culture (for example, the production cell line) that is equivalent in effectiveness for detecting mycoplasmas. Test the effectiveness of the cells to be used by applying the procedure shown below and inoculating not more than 100 CFU or CFU-like micro-organisms of suitable reference strains of *M. hyorhinis* and *M. orale*. The following strains have been found to be suitable:

| | | | |
|---|---|---|---|
| *M. hyorhinis* | | | ATCC 29052 |
| *M. orale* | NCTC 10112 | CIP 104969 | ATCC 23714 |

The cells are suitable if both reference strains are detected.

The indicator cells must be subcultured without an antibiotic before use in the test.

*TEST METHOD*

1. Seed the indicator cell culture at a suitable density (for example, $2 \times 10^4$ to $2 \times 10^5$ cells/mL, $4 \times 10^3$ to $2.5 \times 10^4$ cells/cm$^2$) that will yield confluence after 3 days of growth. Inoculate 1 mL of the product to be examined into the cell culture vessel and incubate at 35-38 °C.

2. After at least 3 days of incubation, when the cells have grown to confluence, make a subculture on cover slips in suitable containers or on some other surface (for example, chambered slides) suitable for the test procedure. Seed the cells at low density so that they reach 50 per cent confluence after 3-5 days of incubation. Complete confluence impairs visualisation of mycoplasmas after staining and must be avoided.

3. Remove the medium and rinse the indicator cells with *phosphate buffered saline pH 7.4 R*, then add a suitable fixing solution (a freshly prepared mixture of 1 volume of *glacial acetic acid R* and 3 volumes of *methanol R* is suitable when *bisbenzimide R* is used for staining).

4. Remove the fixing solution and wash the cells with sterile *water R*. Dry the slides completely if they are to be stained more than 1 h later (particular care is needed for staining of slides after drying owing to artefacts that may be produced).

5. Add a suitable DNA stain and allow to stand for a suitable time (*bisbenzimide working solution R* and a standing time of 10 min are suitable).

6. Remove the stain and rinse the monolayer with *water R*.

7. Mount each coverslip, where applicable (a mixture of equal volumes of *glycerol R* and *phosphate-citrate buffer solution pH 5.5 R* is suitable for mounting). Examine by fluorescence (for bisbenzimide stain a 330 nm/380 nm excitation filter and an LP 440 nm barrier filter are suitable) at 400 × magnification or greater.

8. Compare the microscopic appearance of the test cultures with that of the negative and positive controls, examining for extranuclear fluorescence. Mycoplasmas produce pinpoints or filaments over the indicator cell cytoplasm. They may also produce pinpoints and filaments in the intercellular spaces. Multiple microscopic fields are examined according to the protocol established during validation.

*INTERPRETATION OF RESULTS*

The product to be examined complies with the test if fluorescence typical of mycoplasmas is not present. The test is invalid if the positive controls do not show fluorescence typical of mycoplasmas. The test is invalid if the negative controls show fluorescence typical of mycoplasmas.

NUCLEIC ACID AMPLIFICATION TECHNIQUES (NAT)

NAT (*2.6.21*) may be used for detection of mycoplasmas by amplification of nucleic acids extracted from a test sample with specific primers that reveal the presence of the target nucleic acid. NAT indicate the presence of a particular nucleic acid sequence and not necessarily the presence of viable mycoplasmas. A number of different techniques are available. This general chapter does not prescribe a particular method for the test. The procedure applied must be validated as described, taking account of the guidelines presented at the end of this section. Where a commercial kit is used, certain elements of the validation may be carried out by the manufacturer and information provided to the user but it must be remembered that full information on the primers may not be available and that production of the kit may be modified or discontinued.

NAT are applied where prescribed in a monograph. They may also be used instead of the culture method and the indicator cell culture method after suitable validation.

*Direct NAT* can be applied in the presence of cytotoxic material and where a rapid method is needed.

*Cell-culture enrichment followed by NAT*: the test sample and a suitable cell substrate (as described under the indicator cell-culture method) are cultured together for a suitable period; the nucleic acids are then extracted from cells and supernatant and used for detection by NAT.

*VALIDATION*

Reference standards are required at various stages during validation and for use as controls during routine application of the test. The reference standards may be mycoplasmas or nucleic acids.

For validation of the limit of detection, the following species represent an optimal selection in terms of the frequency of occurrence as contaminants and phylogenetic relationships:

- *A. laidlawii*;
- *M. fermentans*;
- *M. hyorhinis* (where cell-culture enrichment is used, a fastidious strain such as ATCC 29052 is included);
- *M. orale*;
- *M. pneumoniae* or *M. gallisepticum*;
- *M. synoviae* (where there is use of or exposure to avian material during production);
- *Mycoplasma arginini;*
- *Spiroplasma citri* (where there is use of or exposure to insect or plant material during production).

Demonstration of specificity requires the use of a suitable range of bacterial species other than mycoplasmas. Bacterial genera with close phylogenetic relation to mycoplasmas are most appropriate for this validation; these include *Clostridium, Lactobacillus* and *Streptococcus*.

*Comparability studies for use of NAT as an alternative method.* For each mycoplasma test species:

- as an alternative to the culture method: the NAT test system must be shown to detect 10 CFU/mL;
- as an alternative to the indicator cell culture method: the NAT test system must be shown to detect 100 CFU/mL;

*or* an equivalent limit of detection in terms of the number of copies of mycoplasma nucleic acid in the test sample (using suitable reference standards of mycoplasma nucleic acid).

*CONTROLS*

**Internal controls**. Internal controls are necessary for routine verification of absence of inhibition. The internal control may contain the primer binding-site, or some other suitable sequence may be used. It is preferably added to the test material before isolating the nucleic acid and therefore acts as an overall control (extraction, reverse transcription, amplification, detection).

**External controls**. The external positive control contains a defined number of target-sequence copies or CFUs from 1 or more suitable species of mycoplasma chosen from those used during validation of the test conditions. 1 of the positive controls is set close to the positive cut-off point to demonstrate that the expected sensitivity is achieved. The external negative control contains no target sequence but does not necessarily represent the same matrix as the test article.

*INTERPRETATION OF RESULTS*

The primers used may also amplify non-mycoplasmal bacterial nucleic acid, leading to false positive results. Procedures are established at the time of validation for dealing with confirmation of positive results, where necessary.

*The following section is published for information.*

## Validation of nucleic acid amplification techniques (NAT) for the detection of mycoplasmas: guidelines

1. *SCOPE*

Nucleic acid amplification techniques (NAT) are either qualitative or quantitative tests for the presence of nucleic acid. For the detection of mycoplasma contamination of various samples such as vaccines and cell substrates, qualitative tests are adequate and may be considered to be limit tests. These guidelines describe methods to validate qualitative nucleic acid amplification analytical procedures for assessing mycoplasma contamination. They may also be applicable for real-time NAT used as limit tests for the control of contaminants.

The 2 characteristics regarded as the most important for validation of the analytical procedure are the specificity and the detection limit. In addition, the robustness of the analytical procedure should be evaluated.

For the purpose of this document, an analytical procedure is defined as the complete procedure from extraction of nucleic acid to detection of the amplified products.

Where commercial kits are used for part or all of the analytical procedure, documented validation points already covered by the kit manufacturer can replace validation by the user. Nevertheless, the performance of the kit with respect to its intended use has to be demonstrated by the user (e.g. detection limit, robustness, cross-detection of other classes of bacteria).

NAT may be used as:

- a complementary test (for example, for cytotoxic viral suspensions) or for in-process control purposes;
- an alternative method to replace an official method (indicator cell culture method or culture method).

These guidelines will thus separate these 2 objectives by presenting first a guideline for the validation of the NAT themselves, and second, a guideline for a comparability study between NAT and official methods.

2. *GUIDELINE FOR MYCOPLASMA NAT VALIDATION*

3 parameters should be evaluated: specificity, detection limit and robustness.

2-1. **Specificity**. Specificity is the ability to unequivocally assess target nucleic acid in the presence of components that may be expected to be present.

The specificity of NAT is dependent on the choice of primers, the choice of probe (for analysis of the final product) and the stringency of the test conditions (for both the amplification and detection steps).

The ability of the NAT to detect a large panel of mycoplasma species will depend on the choice of primers, probes and method parameters. This ability should be demonstrated using characterised reference panels (e.g. reference strains provided by the EDQM). Since NAT systems are usually based on a mix of primers, the theoretical analysis of primers and probes by comparison with databases is not recommended, because interpretation of the results may be quite complex and may not reflect the experimental results.

Moreover, as it is likely that the primers will detect other bacterial species, the potential cross-detection should be documented in the validation study. Bacterial genera such as gram-positive bacteria with close phylogenetic relation to mycoplasmas are most appropriate for this validation; these include *Clostridium*, *Lactobacillus* and *Streptococcus*. However, this is not an exhaustive list and species to be tested will depend on the theoretical ability (based on primers/probes sequences) of the NAT system to detect such other species.

Based on the results from this validation of the specificity, if a gap in the specificity of the method is identified (such as detection of non-mycoplasmal bacterial nucleic acid), an appropriate strategy must be proposed in the validation study to allow interpretation of positive results on a routine basis. For example, a second test may be performed using an alternative method without this specificity gap or using an official method.

2-2. **Detection limit**. The detection limit of an individual analytical procedure is the lowest amount of target nucleic acid in a sample that can be detected but not necessarily quantitated as an exact value.

For establishment of the detection limit, a positive cut-off point should be determined for the nucleic acid amplification analytical procedure. The positive cut-off point (as defined in general chapter *2.6.21*) is the minimum number of target sequence copies per volume of sample that can be detected in 95 per cent of test runs. This positive cut-off point is influenced by the distribution of mycoplasmal genomes in the individual samples being tested and by factors such as enzyme efficiency, and can result in different 95 per cent cut-off values for individual analytical test runs.

To determine the positive cut-off point, a dilution series of characterised and calibrated (either in CFUs or nucleic acid copies) in-house working strains or EDQM standards should be tested on different days to examine variation between test runs.

For validation of the limit of detection, the following species represent an optimal selection in terms of the frequency of occurrence as contaminants and phylogenetic relationships:

- *A. laidlawii*;
- *M. fermentans*;
- *M. hyorhinis*;
- *M. orale*;
- *M. pneumoniae* or *M. gallisepticum*;
- *M. synoviae* (where there is use of or exposure to avian material during production);
- *M. arginini*;
- *S. citri* (where there is use of or exposure to insect or plant material during production).

For each strain, at least 3 independent 10-fold dilution series should be tested, with a sufficient number of replicates at each dilution to give a total number of 24 test results for each dilution, to enable a statistical analysis of the results.

For example, a laboratory may test 3 dilution series on different days with 8 replicates for each dilution, 4 dilution series on different days with 6 replicates for each dilution, or 6 dilution series on different days with 4 replicates for each dilution. In order to keep the number of dilutions at a

manageable level, a preliminary test should be performed to obtain a preliminary value for the positive cut-off point (i.e. the highest dilution giving a positive signal). The range of dilutions can then be chosen around the predetermined preliminary cut-off point. The concentration of mycoplasmas (CFUs or copies) that can be detected in 95 per cent of test runs can then be calculated using an appropriate statistical evaluation.

These results may also serve to evaluate the variability of the analytical procedure.

2-3. **Robustness**. The robustness of an analytical procedure is a measure of its capacity to remain unaffected by small but deliberate variations in method parameters, and provides an indication of its reliability during normal usage.

The evaluation of robustness should be considered during the development phase. It should show the reliability of the analytical procedure with respect to deliberate variations in method parameters. For NAT, small variations in the method parameters can be crucial. However, the robustness of the method can be demonstrated during its development when small variations in the concentrations of reagents (e.g. $MgCl_2$, primers or deoxyribonucleotides) are tested. Modifications of extraction kits or extraction procedures as well as different thermal cycler types may also be evaluated.

Finally, robustness of the method can be evaluated through collaborative studies.

3. *GUIDELINE FOR COMPARABILITY STUDY*

NAT may be used instead of official methods (indicator cell culture method and/or culture method). In this case a comparability study should be carried out. This comparability study should include mainly a comparison of the respective detection limits of the alternative method and official methods. However, specificity (mycoplasma panel detected, putative false positive results) should also be considered. For the detection limit, acceptability criteria are defined as follows:

- if the alternative method is proposed to replace the culture method, the NAT system must be shown to detect 10 CFU/mL for each mycoplasma test species described in paragraph 2-2;
- if the alternative method is proposed to replace the indicator cell culture method, the NAT system must be shown to detect 100 CFU/mL for each mycoplasma test species described in paragraph 2-2.

For both cases, suitable standards calibrated for the number of nucleic acid copies and the number of CFUs may be used for establishing that these acceptability criteria are reached. The relation between CFUs and nucleic acid copies for the reference preparations should be previously established to compare the performance of the alternative NAT method with the performance of the official methods.

1 of the following 2 strategies can be used to perform this comparability study:

- perform the NAT alternative method in parallel with the official method(s) to evaluate simultaneously the detection limit of both methods using the same samples of calibrated strains;
- compare the performance of the NAT alternative method using previously obtained data from official method validation. In this case, calibration of standards used for both validations as well as their stabilities should be documented carefully.

Comparability study reports should describe all the validation elements described in section 2 (specificity, limit of detection and variability, as well as robustness) in order to assess all the advantages and/or disadvantages of the alternative NAT method compared to official methods.

**01/2020:20608**

# 2.6.8. PYROGENS

The test consists of measuring the rise in body temperature evoked in rabbits by the intravenous injection of a sterile solution of the substance to be examined.

**Selection of animals**. Use healthy, adult rabbits of either sex weighing not less than 1.5 kg, fed a complete and balanced diet not containing antibiotics, and not showing loss of body mass during the week preceding the test. A rabbit is not to be used in a pyrogen test if:

a) it has been used in a negative pyrogen test in the preceding 3 days; or

b) it has been used in the preceding 3 weeks in a pyrogen test in which the substance under examination failed to pass the test.

**Animals' quarters**. Keep the rabbits individually in a quiet area with a uniform appropriate temperature. Withhold food from the rabbits overnight and until the test is completed; withhold water during the test. Carry out the test in a quiet room where there is no risk of disturbance exciting the animals and in which the room temperature is within 3 °C of that of the rabbits' living quarters, or in which the rabbits have been kept for at least 18 h before the test.

**Materials**. Thoroughly wash all glassware, syringes and needles with water for injections and heat in a hot-air oven at 250 °C for 30 min or at 200 °C for 1 h.

**Retaining boxes**. The retaining boxes for rabbits whose temperature is being measured by an electrical device are made in such a way that the animals are retained only by loosely fitting neck-stocks; the rest of the body remains relatively free so that the rabbits may sit in a normal position. They are not restrained by straps or other similar methods that may harm the animal. The animals are put into the boxes not less than 1 h before the 1st recording of the temperature and remain in them throughout the test.

**Thermometers**. Use a thermometer or electrical device that indicates the temperature with a resolution of 0.1 °C and insert into the rectum of the rabbit to a depth of about 5 cm. The depth of insertion is constant for any 1 rabbit in any 1 test. When an electrical device is used it may be left in position throughout the test.

**Preliminary test**. After selection of the animals, 1-3 days before testing the product to be examined, treat those animals that have not been used during the previous 2 weeks by intravenous injection of 10 mL per kilogram of body mass of a pyrogen-free 9 g/L solution of *sodium chloride R* warmed to about 38.0 °C. Record the temperatures of the animals, beginning at least 90 min before injection and continuing for 3 h after the injection of the solution. Any animal showing a temperature variation greater than 0.6 °C is not used in the main test.

**Main test**. Carry out the test using a group of 3 rabbits.

*Preparation and injection of the product*. Warm the liquid to be examined to approximately 38.0 °C before the injection. The product to be examined may be dissolved in, or diluted with, a pyrogen-free 9 g/L solution of *sodium chloride R* or another prescribed liquid. Inject the solution slowly into the marginal vein of the ear of each rabbit over a period not exceeding 4 min, unless otherwise prescribed in the monograph. The amount of the product to be injected varies according to the product to be examined and is prescribed in the monograph. The volume injected is not less than 0.5 mL per kilogram and not more than 10 mL per kilogram of body mass.

*Determination of the initial and maximum temperatures.* The 'initial temperature' of each rabbit is the mean of 2 temperature readings recorded for that rabbit at an interval of 30 min in the 40 min immediately preceding the injection of the product to be examined. The 'maximum temperature' of each rabbit is the highest temperature recorded for that rabbit in the 3 h after the injection. Record the temperature of each rabbit at intervals of not more than 30 min, beginning at least 90 min before the injection of the product to be examined and continuing 3 h after the injection. The difference between the maximum temperature and the initial temperature of each rabbit is taken to be its response. When this difference is negative, the result is counted as a zero response.

Rabbits showing a temperature variation greater than 0.2 °C between 2 successive readings in the determination of the initial temperature are withdrawn from the test. In any 1 test, only rabbits having initial temperatures that do not differ from one another by more than 1 °C are used. All rabbits having an initial temperature higher than 39.8 °C or less than 38.0 °C are withdrawn from the test.

**Interpretation of results**. Having carried out the test 1st on a group of 3 rabbits, repeat if necessary on further groups of 3 rabbits to a total of 4 groups, depending on the results obtained. If the summed response of the 1st group does not exceed the figure given in the 2nd column of Table 2.6.8.-1, the substance passes the test. If the summed response exceeds the figure given in the 2nd column of the table but does not exceed the figure given in the 3rd column of the table, repeat the test as indicated above. If the summed response exceeds the figure given in the 3rd column of the table, the product fails the test.

Table 2.6.8.-1

| Number of rabbits | Product passes if summed response does not exceed | Product fails if summed response exceeds |
|---|---|---|
| 3 | 1.15 °C | 2.65 °C |
| 6 | 2.80 °C | 4.30 °C |
| 9 | 4.45 °C | 5.95 °C |
| 12 | 6.60 °C | 6.60 °C |

Rabbits used in a test for pyrogens where the mean rise in the rabbits' temperature has exceeded 1.2 °C are permanently excluded.

In accordance with the provisions of the European Convention for the Protection of Vertebrate Animals used for Experimental and Other Scientific Purposes, tests must be carried out in such a way as to use the minimum number of animals and to cause the least pain, suffering, distress or lasting harm. Wherever possible and after product-specific validation, the pyrogen test is replaced by the monocyte-activation test (*2.6.30*).

**01/2008:20610**

## 2.6.10. HISTAMINE

Euthanise a guinea-pig weighing 250 g to 350 g that has been deprived of food for the preceding 24 h. Remove a portion of the distal small intestine 2 cm in length and empty the isolated part by rinsing carefully with solution B described below using a syringe. Attach a fine thread to each end and make a small transverse incision in the middle of the piece of intestine. Place it in an organ bath with a capacity of 10 mL to 20 mL, containing solution B maintained at a constant temperature (34 °C to 36 °C) and pass through the solution a current of a mixture of 95 parts of oxygen and 5 parts of carbon dioxide. Attach one of the threads near to the bottom of the organ bath. Attach the other thread to an isotonic myograph and record the contractions of the organ on a kymograph or other suitable means of giving a permanent record. If a lever is used, its length is such that the movements of the organ are amplified about 20 times. The tension on the intestine should be about 9.8 mN (1 g) and it should be adjusted to the sensitivity of the organ. Flush out the organ bath with solution B. Allow it to stand for 10 min. Flush 2 or 3 times more with solution B. Stimulate a series of contractions by the addition of measured volumes between 0.2 mL and 0.5 mL of a solution of *histamine dihydrochloride R* having a strength which produces reproducible submaximal responses. This dose is termed the "high dose". Flush the organ bath (preferably by overflow without emptying the bath) 3 times with solution B before each addition of histamine. The successive additions should be made at regular intervals allowing a complete relaxation between additions (about 2 min). Add equal volumes of a weaker dilution of *histamine dihydrochloride R* which produces reproducible responses approximately half as great as the "high dose". This dose is termed the "low dose". Continue the regular additions of "high" and "low" doses of histamine solution as indicated above, and alternate each addition with an equal volume of a dilution of the solution to be examined, adjusting the dilution so that the contraction of the intestine, if any, is smaller than that due to the "high dose" of histamine. Determine whether the contraction, if any, is reproducible and that the responses to the "high" and "low" doses of histamine are unchanged. Calculate the activity of the substance to be examined in terms of its equivalent in micrograms of histamine base from the dilution determined as above.

The quantity so determined does not exceed the quantity prescribed in the monograph.

If the solution to be examined does not produce a contraction, prepare a fresh solution adding a quantity of histamine corresponding to the maximum tolerated in the monograph and note whether the contractions produced by the preparation with the added histamine correspond to the amount of histamine added. If this is not the case, or if the contractions caused by the substance to be examined are not reproducible or if subsequent responses to "high" and "low" doses of histamine are diminished, the results of the tests are invalid and the test for depressor substances (*2.6.11*) must be carried out.

**Solution A**

| | |
|---|---|
| Sodium chloride | 160.0 g |
| Potassium chloride | 4.0 g |
| Calcium chloride, anhydrous | 2.0 g |
| Magnesium chloride, anhydrous | 1.0 g |
| Disodium hydrogen phosphate dodecahydrate | 0.10 g |
| *Water for injections R* | to 1000 mL |

**Solution B**

| | |
|---|---|
| Solution A | 50.0 mL |
| Atropine sulfate | 0.5 mg |
| Sodium hydrogen carbonate | 1.0 g |
| Glucose monohydrate | 0.5 g |
| *Water for injections R* | to 1000 mL |

Solution B should be freshly prepared and used within 24 h.

**01/2008:20611**

## 2.6.11. DEPRESSOR SUBSTANCES

Carry out the test on a cat weighing not less than 2 kg and anaesthetised with chloralose or with a barbiturate that allows the maintenance of uniform blood pressure. Protect

the animal from loss of body heat and maintain it so that the rectal temperature remains within physiological limits. Introduce a cannula into the trachea. Insert a cannula filled with a heparinised 9 g/L solution of sodium chloride into the common carotid artery and connect it to a device capable of giving a continuous record of the blood pressure. Insert into the femoral vein another cannula, filled with a heparinised 9 g/L solution of sodium chloride, through which can be injected the solutions of histamine and of the substance to be examined. Determine the sensitivity of the animal to histamine by injecting intravenously at regular intervals, doses of *histamine solution R* corresponding to 0.1 µg and 0.15 µg of histamine base per kilogram of body mass. Repeat the lower dose at least 3 times. Administer the second and subsequent injections not less than 1 min after the blood pressure has returned to the level it was at immediately before the previous injection. The animal is used for the test only if a readily discernible decrease in blood pressure that is constant for the lower dose is obtained and if the higher dose causes greater responses. Dissolve the substance to be examined in sufficient of a 9 g/L solution of sodium chloride or other prescribed solvent, to give the prescribed concentration. Inject intravenously per kilogram of body mass 1.0 mL of *histamine solution R*, followed by 2 successive injections of the prescribed amount of the solution to be examined and, finally, 1.0 mL of *histamine solution R*. The second, third and fourth injections are given not less than 1 min after the blood pressure has returned to the level it was at immediately before the preceding injection. Repeat this series of injections twice and conclude the test by giving 1.5 mL of *histamine solution R* per kilogram of body mass.

If the response to 1.5 mL of *histamine solution R* per kilogram of body mass is not greater than that to 1.0 mL the test is invalid. The substance to be examined fails the test if the mean of the series of responses to the substance is greater than the mean of the responses to 1.0 mL of *histamine solution R* per kilogram of body mass or if any one dose of the substance causes a greater depressor response than the concluding dose of the histamine solution. The test animal must not be used in another test for depressor substances if the second criterion applies or if the response to the high dose of histamine given after the administration of the substance to be examined is less than the mean response to the low doses of histamine previously injected.

**07/2010:20612**

# 2.6.12. MICROBIOLOGICAL EXAMINATION OF NON-STERILE PRODUCTS: MICROBIAL ENUMERATION TESTS(2)

## 1. INTRODUCTION

The tests described hereafter will allow quantitative enumeration of mesophilic bacteria and fungi that may grow under aerobic conditions.

The tests are designed primarily to determine whether a substance or preparation complies with an established specification for microbiological quality. When used for such purposes follow the instructions given below, including the number of samples to be taken, and interpret the results as stated below.

The methods are not applicable to products containing viable micro-organisms as active ingredients.

Alternative microbiological procedures, including automated methods, may be used, provided that their equivalence to the Pharmacopoeia method has been demonstrated.

## 2. GENERAL PROCEDURES

Carry out the determination under conditions designed to avoid extrinsic microbial contamination of the product to be examined. The precautions taken to avoid contamination must be such that they do not affect any micro-organisms that are to be revealed in the test.

If the product to be examined has antimicrobial activity, this is insofar as possible removed or neutralised. If inactivators are used for this purpose, their efficacy and their absence of toxicity for micro-organisms must be demonstrated.

If surface-active substances are used for sample preparation, their absence of toxicity for micro-organisms and their compatibility with inactivators used must be demonstrated.

## 3. ENUMERATION METHODS

Use the membrane filtration method or the plate-count methods, as prescribed. The most-probable-number (MPN) method is generally the least accurate method for microbial counts, however, for certain product groups with a very low bioburden, it may be the most appropriate method.

The choice of method is based on factors such as the nature of the product and the required limit of micro-organisms. The chosen method must allow testing of a sufficient sample size to judge compliance with the specification. The suitability of the method chosen must be established.

## 4. GROWTH PROMOTION TEST, SUITABILITY OF THE COUNTING METHOD AND NEGATIVE CONTROLS

### 4-1. *GENERAL CONSIDERATIONS*

The ability of the test to detect micro-organisms in the presence of product to be tested must be established.

Suitability must be confirmed if a change in testing performance, or the product, which may affect the outcome of the test is introduced.

### 4-2. *PREPARATION OF TEST STRAINS*

Use standardised stable suspensions of test strains or prepare them as stated below. Seed lot culture maintenance techniques (seed-lot systems) are used so that the viable micro-organisms used for inoculation are not more than 5 passages removed from the original master seed-lot. Grow each of the bacterial and fungal test strains separately as described in Table 2.6.12.-1.

Use buffered sodium chloride-peptone solution pH 7.0 or phosphate buffer solution pH 7.2 to make test suspensions; to suspend *A. brasiliensis* spores, 0.05 per cent of polysorbate 80 may be added to the buffer. Use the suspensions within 2 h or within 24 h if stored at 2-8 °C. As an alternative to preparing and then diluting a fresh suspension of vegetative cells of *A. brasiliensis* or *B. subtilis*, a stable spore suspension is prepared and then an appropriate volume of the spore suspension is used for test inoculation. The stable spore suspension may be maintained at 2-8 °C for a validated period of time.

### 4-3. *NEGATIVE CONTROL*

To verify testing conditions, a negative control is performed using the chosen diluent in place of the test preparation. There must be no growth of micro-organisms. A negative control is also performed when testing the products as described in section 5. A failed negative control requires an investigation.

### 4-4. *GROWTH PROMOTION OF THE MEDIA*

Test each batch of ready-prepared medium and each batch of medium, prepared either from dehydrated medium or from the ingredients described.

(2) This chapter has undergone pharmacopoeial harmonisation. See chapter *5.8. Pharmacopoeial harmonisation.*

Table 2.6.12.-1. – *Preparation and use of test micro-organisms*

| Micro-organism | Preparation of test strain | Growth promotion | | Suitability of counting method in the presence of the product | |

| *Candida albicans*<br>such as:<br>ATCC 10231<br>NCPF 3179<br>IP 48.72<br>NBRC 1594 | Sabouraud-dextrose agar or Sabouraud-dextrose broth<br>20-25 °C<br>2-3 days | Casein soya bean digest agar<br>≤ 100 CFU<br>30-35 °C<br>≤ 5 days | Sabouraud-dextrose agar<br>≤ 100 CFU<br>20-25 °C<br>≤ 5 days | Casein soya bean digest agar<br>≤ 100 CFU<br>30-35 °C<br>≤ 5 days<br>MPN: not applicable | Sabouraud-dextrose agar<br>≤ 100 CFU<br>20-25 °C<br>≤ 5 days |
| *Aspergillus brasiliensis*<br>such as:<br>ATCC 16404<br>IMI 149007<br>IP 1431.83<br>NBRC 9455 | Sabouraud-dextrose agar or potato-dextrose agar<br>20-25 °C<br>5-7 days, or until good sporulation is achieved | Casein soya bean digest agar<br>≤ 100 CFU<br>30-35 °C<br>≤ 5 days | Sabouraud-dextrose agar<br>≤ 100 CFU<br>20-25 °C<br>≤ 5 days | Casein soya bean digest agar<br>≤ 100 CFU<br>30-35 °C<br>≤ 5 days<br>MPN: not applicable | Sabouraud-dextrose agar<br>≤ 100 CFU<br>20-25 °C<br>≤ 5 days |

Inoculate portions/plates of casein soya bean digest broth and casein soya bean digest agar with a small number (not more than 100 CFU) of the micro-organisms indicated in Table 2.6.12.-1, using a separate portion/plate of medium for each. Inoculate plates of Sabouraud-dextrose agar with a small number (not more than 100 CFU) of the micro-organisms indicated in Table 2.6.12.-1, using a separate plate of medium for each. Incubate in the conditions described in Table 2.6.12.-1.

For solid media, growth obtained must not differ by a factor greater than 2 from the calculated value for a standardised inoculum. For a freshly prepared inoculum, growth of the micro-organisms comparable to that previously obtained with a previously tested and approved batch of medium occurs. Liquid media are suitable if clearly visible growth of the micro-organisms comparable to that previously obtained with a previously tested and approved batch of medium occurs.

4-5. *SUITABILITY OF THE COUNTING METHOD IN THE PRESENCE OF PRODUCT*

4-5-1. **Preparation of the sample**. The method for sample preparation depends upon the physical characteristics of the product to be tested. If none of the procedures described below can be demonstrated to be satisfactory, an alternative procedure must be developed.

*Water-soluble products.* Dissolve or dilute (usually a 1 in 10 dilution is prepared) the product to be examined in buffered sodium chloride-peptone solution pH 7.0, phosphate buffer solution pH 7.2 or casein soya bean digest broth. If necessary, adjust to pH 6-8. Further dilutions, where necessary, are prepared with the same diluent.

*Non-fatty products insoluble in water.* Suspend the product to be examined (usually a 1 in 10 dilution is prepared) in buffered sodium chloride-peptone solution pH 7.0, phosphate buffer solution pH 7.2 or casein soya bean digest broth. A surface-active agent such as 1 g/L of polysorbate 80 may be added to assist the suspension of poorly wettable substances. If necessary, adjust to pH 6-8. Further dilutions, where necessary, are prepared with the same diluent.

*Fatty products.* Dissolve in isopropyl myristate, sterilised by filtration or mix the product to be examined with the minimum necessary quantity of sterile polysorbate 80 or another non-inhibitory sterile surface-active agent, heated if necessary to not more than 40 °C, or in exceptional cases to not more than 45 °C. Mix carefully and if necessary maintain the temperature in a water-bath. Add sufficient of the pre-warmed chosen diluent to make a 1 in 10 dilution of the original product. Mix carefully whilst maintaining the temperature for the shortest time necessary for the formation of an emulsion. Further serial tenfold dilutions may be prepared using the chosen diluent containing a suitable concentration of sterile polysorbate 80 or another non-inhibitory sterile surface-active agent.

*Fluids or solids in aerosol form.* Aseptically transfer the product into a membrane filter apparatus or a sterile container for further sampling. Use either the total contents or a defined number of metered doses from each of the containers tested.

*Transdermal patches.* Remove the protective cover sheets ('release liners') of the transdermal patches and place them, adhesive side upwards, on sterile glass or plastic trays. Cover the adhesive surface with a sterile porous material, for example sterile gauze, to prevent the patches from sticking together, and transfer the patches to a suitable volume of the chosen diluent containing inactivators such as polysorbate 80 and/or lecithin. Shake the preparation vigorously for at least 30 min.

4-5-2. **Inoculation and dilution**. Add to the sample prepared as described above (4-5-1) and to a control (with no test material included) a sufficient volume of the microbial

suspension to obtain an inoculum of not more than 100 CFU. The volume of the suspension of the inoculum should not exceed 1 per cent of the volume of diluted product.

To demonstrate acceptable microbial recovery from the product, the lowest possible dilution factor of the prepared sample must be used for the test. Where this is not possible due to antimicrobial activity or poor solubility, further appropriate protocols must be developed. If inhibition of growth by the sample cannot otherwise be avoided, the aliquot of the microbial suspension may be added after neutralisation, dilution or filtration.

4-5-3. **Neutralisation/removal of antimicrobial activity**. The number of micro-organisms recovered from the prepared sample diluted as described in 4-5-2 and incubated following the procedure described in 4-5-4, is compared to the number of micro-organisms recovered from the control preparation.

If growth is inhibited (reduction by a factor greater than 2), then modify the procedure for the particular enumeration test to ensure the validity of the results. Modification of the procedure may include, for example, (1) an increase in the volume of the diluent or culture medium, (2) incorporation of specific or general neutralising agents into the diluent, (3) membrane filtration, or (4) a combination of the above measures.

*Neutralising agents*. Neutralising agents may be used to neutralise the activity of antimicrobial agents (Table 2.6.12.-2). They may be added to the chosen diluent or the medium preferably before sterilisation. If used, their efficacy and their absence of toxicity for micro-organisms must be demonstrated by carrying out a blank with neutraliser and without product.

If no suitable neutralising method can be found, it can be assumed that the failure to isolate the inoculated organism is attributable to the microbicidal activity of the product. This information serves to indicate that the product is not likely to be contaminated with the given species of the micro-organism. However, it is possible that the product only inhibits some of the micro-organisms specified herein, but does not inhibit others not included amongst the test strains or for which the latter are not representative. Then, perform the test with the highest dilution factor compatible with microbial growth and the specific acceptance criterion.

Table 2.6.12.-2. – *Common neutralising agents for interfering substances*

| Interfering substance | Potential neutralising method |
|---|---|
| Glutaraldehyde, mercurials | Sodium hydrogensulfite (sodium bisulfite) |
| Phenolics, alcohol, aldehydes, sorbate | Dilution |
| Aldehydes | Glycine |
| Quaternary Ammonium Compounds (QACs), parahydroxybenzoates (parabens), bis-biguanides | Lecithin |
| QACs, iodine, parabens | Polysorbate |
| Mercurials | Thioglycollate |
| Mercurials, halogens, aldehydes | Thiosulfate |
| EDTA (edetate) | $Mg^{2+}$ or $Ca^{2+}$ ions |

4-5-4. **Recovery of micro-organism in the presence of product**. For each of the micro-organisms listed, separate tests are performed. Only micro-organisms of the added test strain are counted.

4-5-4-1. *Membrane filtration*. Use membrane filters having a nominal pore size not greater than 0.45 µm. The type of filter material is chosen such that the bacteria-retaining efficiency is not affected by the components of the sample to be investigated. For each of the micro-organisms listed, one membrane filter is used.

Transfer a suitable amount of the sample prepared as described under 4-5-1 to 4-5-3 (preferably representing 1 g of the product, or less if large numbers of CFU are expected) to the membrane filter, filter immediately and rinse the membrane filter with an appropriate volume of diluent.

For the determination of total aerobic microbial count (TAMC), transfer the membrane filter to the surface of casein soya bean digest agar. For the determination of total combined yeasts/moulds count (TYMC), transfer the membrane to the surface of Sabouraud-dextrose agar. Incubate the plates as indicated in Table 2.6.12.-1. Perform the counting.

4-5-4-2. *Plate-count methods*. Perform plate-count methods at least in duplicate for each medium and use the mean count of the result.

4-5-4-2-1. Pour-plate method

For Petri dishes 9 cm in diameter, add to the dish 1 mL of the sample prepared as described under 4-5-1 to 4-5-3 and 15-20 mL of casein soya bean digest agar or Sabouraud-dextrose agar, both media being at not more than 45 °C. If larger Petri dishes are used, the amount of agar medium is increased accordingly. For each of the micro-organisms listed in Table 2.6.12.-1, at least 2 Petri dishes are used. Incubate the plates as indicated in Table 2.6.12.-1. Take the arithmetic mean of the counts per medium and calculate the number of CFU in the original inoculum.

4-5-4-2-2. Surface-spread method

For Petri dishes 9 cm in diameter, add 15-20 mL of casein soya bean digest agar or Sabouraud-dextrose agar at about 45 °C to each Petri dish and allow to solidify. If larger Petri dishes are used, the volume of the agar is increased accordingly. Dry the plates, for example in a laminar-air-flow cabinet or an incubator. For each of the micro-organisms listed in Table 2.6.12.-1, at least 2 Petri dishes are used. Spread a measured volume of not less than 0.1 mL of the sample prepared as described under 4-5-1 to 4-5-3 over the surface of the medium. Incubate and count as prescribed under 4-5-4-2-1.

4-5-4-3. *Most-probable-number (MPN) method*. The precision and accuracy of the MPN method is less than that of the membrane filtration method or the plate-count method. Unreliable results are obtained particularly for the enumeration of moulds. For these reasons the MPN method is reserved for the enumeration of TAMC in situations where no other method is available. If the use of the method is justified, proceed as follows.

Prepare a series of at least 3 serial tenfold dilutions of the product as described under 4-5-1 to 4-5-3. From each level of dilution, 3 aliquots of 1 g or 1 mL are used to inoculate 3 tubes with 9-10 mL of casein soya bean digest broth. If necessary, a surface-active agent such as polysorbate 80 or an inactivator of antimicrobial agents may be added to the medium. Thus, if 3 levels of dilution are prepared, 9 tubes are inoculated.

Incubate all tubes at 30-35 °C for not more than 3 days. If reading of the results is difficult or uncertain owing to the nature of the product to be examined, subculture in the same broth, or in casein soya bean digest agar, for 1-2 days at the same temperature and use these results. Determine the most probable number of micro-organisms per gram or millilitre of the product to be examined from Table 2.6.12.-3.

4-6. *RESULTS AND INTERPRETATION*

When verifying the suitability of the membrane filtration method or the plate-count method, a mean count of any of the test organisms not differing by a factor greater than 2 from the value of the control defined in 4-5-2 in the absence of the product must be obtained. When verifying the suitability of the MPN method the calculated value from the inoculum must be within 95 per cent confidence limits of the results obtained with the control.

If the above criteria cannot be met for one or more of the organisms tested with any of the described methods, the method and test conditions that come closest to the criteria are used to test the product.

## 5. TESTING OF PRODUCTS

### 5-1. *AMOUNT USED FOR THE TEST*

Unless otherwise prescribed, use 10 g or 10 mL of the product to be examined taken with the precautions referred to above. For fluids or solids in aerosol form, sample 10 containers. For transdermal patches, sample 10 patches.

The amount to be tested may be reduced for active substances that will be formulated in the following conditions: the amount per dosage unit (e.g. tablet, capsule, injection) is less than or equal to 1 mg or the amount per gram or millilitre (for preparations not presented in dose units) is less than 1 mg. In these cases, the amount to be tested is not less than the amount present in 10 dosage units or 10 g or 10 mL of the product.

Table 2.6.12.-3. – *Most-probable-number values of micro-organisms*

| Observed combinations of numbers of tubes showing growth in each set | | | MPN per gram or per millilitre of product | 95 per cent confidence limits |
|---|---|---|---|---|
| Number of grams or millilitres of product per tube | | | | |
| 0.1 | 0.01 | 0.001 | | |
| 0 | 0 | 0 | < 3 | 0-9.4 |
| 0 | 0 | 1 | 3 | 0.1-9.5 |
| 0 | 1 | 0 | 3 | 0.1-10 |
| 0 | 1 | 1 | 6.1 | 1.2-17 |
| 0 | 2 | 0 | 6.2 | 1.2-17 |
| 0 | 3 | 0 | 9.4 | 3.5-35 |
| 1 | 0 | 0 | 3.6 | 0.2-17 |
| 1 | 0 | 1 | 7.2 | 1.2-17 |
| 1 | 0 | 2 | 11 | 4-35 |
| 1 | 1 | 0 | 7.4 | 1.3-20 |
| 1 | 1 | 1 | 11 | 4-35 |
| 1 | 2 | 0 | 11 | 4-35 |
| 1 | 2 | 1 | 15 | 5-38 |

| 3 | 2 | 2 | 210 | 30-400 |
| 3 | 2 | 3 | 290 | 90-990 |
| 3 | 3 | 0 | 240 | 40-990 |
| 3 | 3 | 1 | 460 | 90-1980 |
| 3 | 3 | 2 | 1100 | 200-4000 |
| 3 | 3 | 3 | > 1100 | |

For materials used as active substances where sample quantity is limited or batch size is extremely small (i.e. less than 1000 mL or 1000 g), the amount tested shall be 1 per cent of the batch unless a lesser amount is prescribed or justified and authorised.

For products where the total number of entities in a batch is less than 200 (e.g. samples used in clinical trials), the sample size may be reduced to 2 units, or 1 unit if the size is less than 100.

Select the sample(s) at random from the bulk material or from the available containers of the preparation. To obtain the required quantity, mix the contents of a sufficient number of containers to provide the sample.

### 5-2. *EXAMINATION OF THE PRODUCT*

#### 5-2-1. **Membrane filtration**

Use a filtration apparatus designed to allow the transfer of the filter to the medium. Prepare the sample using a method that has been shown suitable as described in section 4 and transfer the appropriate amount to each of 2 membrane filters and filter immediately. Wash each filter following the procedure shown to be suitable.

For the determination of TAMC, transfer one of the membrane filters to the surface of casein soya bean digest agar. For the determination of TYMC, transfer the other membrane to the surface of Sabouraud-dextrose agar. Incubate the plate of casein soya bean digest agar at 30-35 °C for 3-5 days and the plate of Sabouraud-dextrose agar at 20-25 °C for 5-7 days. Calculate the number of CFU per gram or per millilitre of product.

When examining transdermal patches, filter 10 per cent of the volume of the preparation described under 4-5-1 separately through each of 2 sterile filter membranes. Transfer one membrane to casein soya bean digest agar for TAMC and the other membrane to Sabouraud-dextrose agar for TYMC.

#### 5-2-2. **Plate-count methods**

##### 5-2-2-1. Pour-plate method

Prepare the sample using a method that has been shown to be suitable as described in section 4. Prepare for each medium at least 2 Petri dishes for each level of dilution. Incubate the plates of casein soya bean digest agar at 30-35 °C for 3-5 days and the plates of Sabouraud-dextrose agar at 20-25 °C for 5-7 days. Select the plates corresponding to a given dilution and showing the highest number of colonies less than 250 for TAMC and 50 for TYMC. Take the arithmetic mean per culture medium of the counts and calculate the number of CFU per gram or per millilitre of product.

5-2-2-2. Surface-spread method

Prepare the sample using a method that has been shown to be suitable as described in section 4. Prepare at least 2 Petri dishes for each medium and each level of dilution. For incubation and calculation of the number of CFU proceed as described for the pour-plate method.

5-2-3. **Most-probable-number method**

Prepare and dilute the sample using a method that has been shown to be suitable as described in section 4. Incubate all tubes at 30-35 °C for 3-5 days. Subculture if necessary, using the procedure shown to be suitable. Record for each level of dilution the number of tubes showing microbial growth. Determine the most probable number of micro-organisms per gram or millilitre of the product to be examined from Table 2.6.12.-3.

5-3. *INTERPRETATION OF THE RESULTS*

The total aerobic microbial count (TAMC) is considered to be equal to the number of CFU found using casein soya bean digest agar; if colonies of fungi are detected on this medium, they are counted as part of the TAMC. The total combined yeasts/mould count (TYMC) is considered to be equal to the number of CFU found using Sabouraud-dextrose agar; if colonies of bacteria are detected on this medium, they are counted as part of the TYMC. When the TYMC is expected to exceed the acceptance criterion due to the bacterial growth, Sabouraud-dextrose agar containing antibiotics may be used. If the count is carried out by the MPN method the calculated value is the TAMC.

When an acceptance criterion for microbiological quality is prescribed it is interpreted as follows:

- $10^1$ CFU: maximum acceptable count = 20;
- $10^2$ CFU: maximum acceptable count = 200;
- $10^3$ CFU: maximum acceptable count = 2000, and so forth.

The recommended solutions and media are described in general chapter *2.6.13*.

**04/2010:20613**

# 2.6.13. MICROBIOLOGICAL EXAMINATION OF NON-STERILE PRODUCTS: TEST FOR SPECIFIED MICRO-ORGANISMS(3)

1. INTRODUCTION

The tests described hereafter will allow determination of the absence or limited occurrence of specified micro-organisms that may be detected under the conditions described.

The tests are designed primarily to determine whether a substance or preparation complies with an established specification for microbiological quality. When used for such purposes, follow the instructions given below, including the number of samples to be taken, and interpret the results as stated below.

Alternative microbiological procedures, including automated methods, may be used, provided that their equivalence to the Pharmacopoeia method has been demonstrated.

2. GENERAL PROCEDURES

The preparation of samples is carried out as described in general chapter *2.6.12*.

If the product to be examined has antimicrobial activity, this is insofar as possible removed or neutralised as described in general chapter *2.6.12*.

If surface-active substances are used for sample preparation, their absence of toxicity for micro-organisms and their compatibility with inactivators used must be demonstrated as described in general chapter *2.6.12*.

3. GROWTH-PROMOTING AND INHIBITORY PROPERTIES OF THE MEDIA, SUITABILITY OF THE TEST AND NEGATIVE CONTROLS

The ability of the test to detect micro-organisms in the presence of the product to be tested must be established. Suitability must be confirmed if a change in testing performance, or the product, which may affect the outcome of the test is introduced.

3-1. *PREPARATION OF TEST STRAINS*

Use standardised stable suspensions of test strains or prepare them as stated below. Seed lot culture maintenance techniques (seed-lot systems) are used so that the viable micro-organisms used for inoculation are not more than 5 passages removed from the original master seed-lot.

3-1-1. **Aerobic micro-organisms**. Grow each of the bacterial test strains separately in casein soya bean digest broth or on casein soya bean digest agar at 30-35 °C for 18-24 h. Grow the test strain for *Candida albicans* separately on Sabouraud-dextrose agar or in Sabouraud-dextrose broth at 20-25 °C for 2-3 days.

- *Staphylococcus aureus* such as ATCC 6538, NCIMB 9518, CIP 4.83 or NBRC 13276;
- *Pseudomonas aeruginosa* such as ATCC 9027, NCIMB 8626, CIP 82.118 or NBRC 13275;
- *Escherichia coli* such as ATCC 8739, NCIMB 8545, CIP 53.126 or NBRC 3972;
- *Salmonella enterica* subsp. *enterica* serovar Typhimurium, such as ATCC 14028 or, as an alternative, *Salmonella enterica* subsp. *enterica* serovar Abony such as NBRC 100797, NCTC 6017 or CIP 80.39;
- *Candida albicans* such as ATCC 10231, NCPF 3179, IP 48.72 or NBRC 1594.

Use buffered sodium chloride-peptone solution pH 7.0 or phosphate buffer solution pH 7.2 to make test suspensions. Use the suspensions within 2 h or within 24 h if stored at 2-8 °C.

3-1-2. **Clostridia**. Use *Clostridium sporogenes* such as ATCC 11437 (NBRC 14293, NCIMB 12343, CIP 100651) or ATCC 19404 (NCTC 532 or CIP 79.03) or NBRC 14293. Grow the clostridial test strain under anaerobic conditions in reinforced medium for clostridia at 30-35 °C for 24-48 h. As an alternative to preparing and then diluting down a fresh suspension of vegetative cells of *Cl. sporogenes*, a stable spore suspension is used for test inoculation. The stable spore suspension may be maintained at 2-8 °C for a validated period.

3-2. *NEGATIVE CONTROL*

To verify testing conditions, a negative control is performed using the chosen diluent in place of the test preparation. There must be no growth of micro-organisms. A negative control is also performed when testing the products as described in section 4. A failed negative control requires an investigation.

3-3. *GROWTH PROMOTION AND INHIBITORY PROPERTIES OF THE MEDIA*

Test each batch of ready-prepared medium and each batch of medium prepared either from dehydrated medium or from ingredients.

Verify suitable properties of relevant media as described in Table 2.6.13.-1.

*Test for growth promoting properties, liquid media*: inoculate a portion of the appropriate medium with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for not more than the

(3) This chapter has undergone pharmacopoeial harmonisation. See chapter *5.8. Pharmacopoeial harmonisation.*

Table 2.6.13.-1 – *Growth promoting, inhibitory and indicative properties of media*

| | Medium | Property | Test strains |
|---|---|---|---|
| Test for bile-tolerant gram-negative bacteria | Enterobacteria enrichment broth-Mossel | Growth promoting | *E. coli*<br>*P. aeruginosa* |
| | | Inhibitory | *S. aureus* |
| | Violet red bile glucose agar | Growth promoting + indicative | *E. coli*<br>*P. aeruginosa* |
| Test for *Escherichia coli* | MacConkey broth | Growth promoting | *E. coli* |
| | | Inhibitory | *S. aureus* |
| | MacConkey agar | Growth promoting + indicative | *E. coli* |
| Test for *Salmonella* | Rappaport Vassiliadis *Salmonella* enrichment broth | Growth promoting | *Salmonella enterica* subsp. *enterica* serovar Typhimurium or *Salmonella enterica* subsp. *enterica* serovar Abony |
| | | Inhibitory | *S. aureus* |
| | Xylose, lysine, deoxycholate agar | Growth promoting + indicative | *Salmonella enterica* subsp. *enterica* serovar Typhimurium or *Salmonella enterica* subsp. *enterica* serovar Abony |
| Test for *Pseudomonas aeruginosa* | Cetrimide agar | Growth promoting | *P. aeruginosa* |
| | | Inhibitory | *E. coli* |
| Test for *Staphylococcus aureus* | Mannitol salt agar | Growth promoting + indicative | *S. aureus* |
| | | Inhibitory | *E. coli* |
| Test for clostridia | Reinforced medium for clostridia | Growth promoting | *Cl. sporogenes* |
| | Columbia agar | Growth promoting | *Cl. sporogenes* |
| Test for *Candida albicans* | Sabouraud dextrose broth | Growth promoting | *C. albicans* |
| | Sabouraud dextrose agar | Growth promoting + indicative | *C. albicans* |

shortest period of time specified in the test. Clearly visible growth of the micro-organism comparable to that previously obtained with a previously tested and approved batch of medium occurs.

*Test for growth promoting properties, solid media*: perform the surface-spread method, inoculating each plate with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for not more than the shortest period of time specified in the test. Growth of the micro-organism comparable to that previously obtained with a previously tested and approved batch of medium occurs.

*Test for inhibitory properties, liquid or solid media*: inoculate the appropriate medium with at least 100 CFU of the appropriate micro-organism. Incubate at the specified temperature for not less than the longest period of time specified in the test. No growth of the test micro-organism occurs.

*Test for indicative properties*: perform the surface-spread method, inoculating each plate with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for a period of time within the range specified in the test. Colonies are comparable in appearance and indication reactions to those previously obtained with a previously tested and approved batch of medium.

3-4. *SUITABILITY OF THE TEST METHOD*

For each product to be tested, perform the sample preparation as described in the relevant paragraph in section 4. Add each test strain at the time of mixing, in the prescribed growth medium. Inoculate the test strains individually. Use a number of micro-organisms equivalent to not more than 100 CFU in the inoculated test preparation.

Perform the test as described in the relevant paragraph in section 4 using the shortest incubation period prescribed.

The specified micro-organisms must be detected with the indication reactions as described in section 4.

Any antimicrobial activity of the product necessitates a modification of the test procedure (see 4-5-3 of general chapter *2.6.12*).

If for a given product the antimicrobial activity with respect to a micro-organism for which testing is prescribed cannot be neutralised, then it is to be assumed that the inhibited micro-organism will not be present in the product.

4. TESTING OF PRODUCTS

4-1. *BILE-TOLERANT GRAM-NEGATIVE BACTERIA*

4-1-1. **Sample preparation and pre-incubation**. Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in general chapter *2.6.12*, but using casein soya bean digest broth as the chosen diluent, mix and incubate at 20-25 °C for a time sufficient to resuscitate the bacteria but not sufficient to encourage multiplication of the organisms (usually 2 h but not more than 5 h).

4-1-2. **Test for absence**. Unless otherwise prescribed, use the volume corresponding to 1 g of the product, as prepared in 4-1-1, to inoculate enterobacteria enrichment broth-Mossel. Incubate at 30-35 °C for 24-48 h. Subculture on plates of violet red bile glucose agar. Incubate at 30-35 °C for 18-24 h.

The product complies with the test if there is no growth of colonies.

4-1-3. **Quantitative test**

4-1-3-1. *Selection and subculture.* Inoculate suitable quantities of enterobacteria enrichment broth-Mossel with the preparation as described under 4-1-1 and/or dilutions of it containing respectively 0.1 g, 0.01 g and 0.001 g (or 0.1 mL, 0.01 mL and 0.001 mL) of the product to be examined. Incubate at 30-35 °C for 24-48 h. Subculture each of the cultures on a plate of violet red bile glucose agar. Incubate at 30-35 °C for 18-24 h.

4-1-3-2. *Interpretation.* Growth of colonies constitutes a positive result. Note the smallest quantity of the product that gives a positive result and the largest quantity that gives a negative result. Determine from Table 2.6.13.-2 the probable number of bacteria.

Table 2.6.13.-2 – *Interpretation of results*

| Results for each quantity of product | | | Probable number of bacteria per gram or millilitre of product |
|---|---|---|---|
| 0.1 g or 0.1 mL | 0.01 g or 0.01 mL | 0.001 g or 0.001 mL | |
| + | + | + | $> 10^3$ |
| + | + | − | $< 10^3$ and $> 10^2$ |
| + | − | − | $< 10^2$ and $> 10$ |
| − | − | − | $< 10$ |

4-2. *ESCHERICHIA COLI*

4-2-1. **Sample preparation and pre-incubation**. Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in general chapter *2.6.12*, and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as described under 3-4) of casein soya bean digest broth, mix and incubate at 30-35 °C for 18-24 h.

4-2-2. **Selection and subculture**. Shake the container, transfer 1 mL of casein soya bean digest broth to 100 mL of MacConkey broth and incubate at 42-44 °C for 24-48 h. Subculture on a plate of MacConkey agar at 30-35 °C for 18-72 h.

4-2-3. **Interpretation**. Growth of colonies indicates the possible presence of *E. coli*. This is confirmed by identification tests.

The product complies with the test if no colonies are present or if the identification tests are negative.

4-3. *SALMONELLA*

4-3-1. **Sample preparation and pre-incubation**. Prepare the product to be examined as described in general chapter *2.6.12*, and use the quantity corresponding to not less than 10 g or 10 mL to inoculate a suitable amount (determined as described under 3-4) of casein soya bean digest broth, mix and incubate at 30-35 °C for 18-24 h.

4-3-2. **Selection and subculture**. Transfer 0.1 mL of casein soya bean digest broth to 10 mL of Rappaport Vassiliadis *Salmonella* enrichment broth and incubate at 30-35 °C for 18-24 h. Subculture on plates of xylose, lysine, deoxycholate agar. Incubate at 30-35 °C for 18-48 h.

4-3-3. **Interpretation**. The possible presence of *Salmonella* is indicated by the growth of well-developed, red colonies, with or without black centres. This is confirmed by identification tests.

The product complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

4-4. *PSEUDOMONAS AERUGINOSA*

4-4-1. **Sample preparation and pre-incubation**. Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in general chapter *2.6.12*, and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as described under 3-4) of casein soya bean digest broth and mix. When testing transdermal patches, filter the volume of sample corresponding to 1 patch of the preparation described under 4-5-1 in general chapter *2.6.12* through a sterile filter membrane and place in 100 mL of casein soya bean digest broth. Incubate at 30-35 °C for 18-24 h.

4-4-2. **Selection and subculture**. Subculture on a plate of cetrimide agar and incubate at 30-35 °C for 18-72 h.

4-4-3. **Interpretation**. Growth of colonies indicates the possible presence of *P. aeruginosa*. This is confirmed by identification tests.

The product complies with the test if colonies are not present or if the confirmatory identification tests are negative.

4-5. *STAPHYLOCOCCUS AUREUS*

4-5-1. **Sample preparation and pre-incubation**. Prepare a sample using a 1 in 10 dilution of not less than 1 g of the product to be examined as described in general chapter *2.6.12*, and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as described under 3-4) of casein soya bean digest broth and mix. When testing transdermal patches, filter the volume of sample corresponding to 1 patch of the preparation described under 4-5-1 in general chapter *2.6.12* through a sterile filter membrane and place in 100 mL of casein soya bean digest broth. Incubate at 30-35 °C for 18-24 h.

4-5-2. **Selection and subculture**. Subculture on a plate of mannitol salt agar and incubate at 30-35 °C for 18-72 h.

4-5-3. **Interpretation**. The possible presence of *S. aureus* is indicated by the growth of yellow/white colonies surrounded by a yellow zone. This is confirmed by identification tests.

The product complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

4-6. *CLOSTRIDIA*

4-6-1. **Sample preparation and heat treatment**. Prepare a sample using a 1 in 10 dilution (with a minimum total volume of 20 mL) of not less than 2 g or 2 mL of the product to be examined as described in general chapter *2.6.12*. Divide the sample into 2 portions of at least 10 mL. Heat 1 portion at 80 °C for 10 min and cool rapidly. Do not heat the other portion.

4-6-2. **Selection and subculture**. Use 10 mL or the quantity corresponding to 1 g or 1 mL of the product to be examined of both portions to inoculate suitable amounts (determined as described under 3-4) of reinforced medium for clostridia. Incubate under anaerobic conditions at 30-35 °C for 48 h. After incubation, make subcultures from each container on Columbia agar and incubate under anaerobic conditions at 30-35 °C for 48-72 h.

4-6-3. **Interpretation**. The occurrence of anaerobic growth of rods (with or without endospores) giving a negative catalase reaction indicates the presence of clostridia. This is confirmed by identification tests.

The product complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

4-7. *CANDIDA ALBICANS*

4-7-1. **Sample preparation and pre-incubation**. Prepare the product to be examined as described in general chapter *2.6.12*, and use 10 mL or the quantity corresponding to not less than 1 g or 1 mL to inoculate 100 mL of Sabouraud-dextrose broth and mix. Incubate at 30-35 °C for 3-5 days.

4-7-2. **Selection and subculture**. Subculture on a plate of Sabouraud-dextrose agar and incubate at 30-35 °C for 24-48 h.

4-7-3. **Interpretation**. Growth of white colonies may indicate the presence of *C. albicans*. This is confirmed by identification tests.

The product complies with the test if such colonies are not present or if the confirmatory identification tests are negative.

*The following section is given for information.*

## 5. RECOMMENDED SOLUTIONS AND CULTURE MEDIA

The following solutions and culture media have been found to be satisfactory for the purposes for which they are prescribed in the test for microbial contamination in the Pharmacopoeia. Other media may be used provided that their suitability can be demonstrated.

*Stock buffer solution.* Place 34 g of potassium dihydrogen phosphate in a 1000 mL volumetric flask, dissolve in 500 mL of purified water, adjust to pH 7.2 ± 0.2 with sodium hydroxide, dilute to 1000.0 mL with purified water and mix. Dispense into containers and sterilise. Store at 2-8 °C.

*Phosphate buffer solution pH 7.2.* Prepare a mixture of stock buffer solution and purified water (1:800 *V/V*) and sterilise.

**Buffered sodium chloride-peptone solution pH 7.0**

| | |
|---|---|
| Potassium dihydrogen phosphate | 3.6 g |
| Disodium hydrogen phosphate dihydrate | 7.2 g, equivalent to 0.067 M phosphate |
| Sodium chloride | 4.3 g |
| Peptone (meat or casein) | 1.0 g |
| Purified water | 1000 mL |

Sterilise in an autoclave using a validated cycle.

**Casein soya bean digest broth**

| | |
|---|---|
| Pancreatic digest of casein | 17.0 g |
| Papaic digest of soya bean | 3.0 g |
| Sodium chloride | 5.0 g |
| Dipotassium hydrogen phosphate | 2.5 g |
| Glucose monohydrate | 2.5 g |
| Purified water | 1000 mL |

Adjust the pH so that after sterilisation it is 7.3 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

**Casein soya bean digest agar**

| | |
|---|---|
| Pancreatic digest of casein | 15.0 g |
| Papaic digest of soya bean | 5.0 g |
| Sodium chloride | 5.0 g |
| Agar | 15.0 g |
| Purified water | 1000 mL |

Adjust the pH so that after sterilisation it is 7.3 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

**Sabouraud-dextrose agar**

| | |
|---|---|
| Dextrose | 40.0 g |
| Mixture of peptic digest of animal tissue and pancreatic digest of casein (1:1) | 10.0 g |
| Agar | 15.0 g |
| Purified water | 1000 mL |

Adjust the pH so that after sterilisation it is 5.6 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

**Potato dextrose agar**

| | |
|---|---|
| Infusion from potatoes | 200 g |
| Dextrose | 20.0 g |
| Agar | 15.0 g |
| Purified water | 1000 mL |

Adjust the pH so that after sterilisation it is 5.6 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

**Sabouraud-dextrose broth**

| | |
|---|---|
| Dextrose | 20.0 g |
| Mixture of peptic digest of animal tissue and pancreatic digest of casein (1:1) | 10.0 g |
| Purified water | 1000 mL |

Adjust the pH so that after sterilisation it is 5.6 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

**Enterobacteria enrichment broth-Mossel**

| | |
|---|---|
| Pancreatic digest of gelatin | 10.0 g |
| Glucose monohydrate | 5.0 g |
| Dehydrated ox bile | 20.0 g |
| Potassium dihydrogen phosphate | 2.0 g |
| Disodium hydrogen phosphate dihydrate | 8.0 g |
| Brilliant green | 15 mg |
| Purified water | 1000 mL |

Adjust the pH so that after heating it is 7.2 ± 0.2 at 25 °C. Heat at 100 °C for 30 min and cool immediately.

**Violet red bile glucose agar**

| | |
|---|---|
| Yeast extract | 3.0 g |
| Pancreatic digest of gelatin | 7.0 g |
| Bile salts | 1.5 g |
| Sodium chloride | 5.0 g |
| Glucose monohydrate | 10.0 g |
| Agar | 15.0 g |
| Neutral red | 30 mg |
| Crystal violet | 2 mg |
| Purified water | 1000 mL |

Adjust the pH so that after heating it is 7.4 ± 0.2 at 25 °C. Heat to boiling; do not heat in an autoclave.

**MacConkey broth**

| | |
|---|---|
| Pancreatic digest of gelatin | 20.0 g |
| Lactose monohydrate | 10.0 g |
| Dehydrated ox bile | 5.0 g |
| Bromocresol purple | 10 mg |
| Purified water | 1000 mL |

Adjust the pH so that after sterilisation it is 7.3 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

**MacConkey agar**

| | |
|---|---|
| Pancreatic digest of gelatin | 17.0 g |
| Peptones (meat and casein) | 3.0 g |
| Lactose monohydrate | 10.0 g |
| Sodium chloride | 5.0 g |
| Bile salts | 1.5 g |
| Agar | 13.5 g |
| Neutral red | 30.0 mg |
| Crystal violet | 1 mg |
| Purified water | 1000 mL |

Adjust the pH so that after sterilisation it is 7.1 ± 0.2 at 25 °C. Boil for 1 min with constant shaking then sterilise in an autoclave using a validated cycle.

**Rappaport Vassiliadis *Salmonella* enrichment broth**

| | |
|---|---|
| Soya peptone | 4.5 g |
| Magnesium chloride hexahydrate | 29.0 g |
| Sodium chloride | 8.0 g |
| Dipotassium phosphate | 0.4 g |
| Potassium dihydrogen phosphate | 0.6 g |
| Malachite green | 0.036 g |
| Purified water | 1000 mL |

Dissolve, warming gently. Sterilise in an autoclave using a validated cycle, at a temperature not exceeding 115 °C. The pH is to be 5.2 ± 0.2 at 25 °C after heating and autoclaving.

**Xylose, lysine, deoxycholate agar**

| | |
|---|---|
| Xylose | 3.5 g |
| L-Lysine | 5.0 g |
| Lactose monohydrate | 7.5 g |
| Sucrose | 7.5 g |
| Sodium chloride | 5.0 g |
| Yeast extract | 3.0 g |
| Phenol red | 80 mg |
| Agar | 13.5 g |
| Sodium deoxycholate | 2.5 g |
| Sodium thiosulfate | 6.8 g |
| Ferric ammonium citrate | 0.8 g |
| Purified water | 1000 mL |

Adjust the pH so that after heating it is 7.4 ± 0.2 at 25 °C. Heat to boiling, cool to 50 °C and pour into Petri dishes. Do not heat in an autoclave.

**Cetrimide agar**

| | |
|---|---|
| Pancreatic digest of gelatin | 20.0 g |
| Magnesium chloride | 1.4 g |
| Dipotassium sulfate | 10.0 g |
| Cetrimide | 0.3 g |
| Agar | 13.6 g |
| Purified water | 1000 mL |
| Glycerol | 10.0 mL |

Heat to boiling for 1 min with shaking. Adjust the pH so that after sterilisation it is 7.2 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

**Mannitol salt agar**

| | |
|---|---|
| Pancreatic digest of casein | 5.0 g |
| Peptic digest of animal tissue | 5.0 g |
| Beef extract | 1.0 g |
| D-Mannitol | 10.0 g |
| Sodium chloride | 75.0 g |
| Agar | 15.0 g |
| Phenol red | 0.025 g |
| Purified water | 1000 mL |

Heat to boiling for 1 min with shaking. Adjust the pH so that after sterilisation it is 7.4 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

**Reinforced medium for clostridia**

| | |
|---|---|
| Beef extract | 10.0 g |
| Peptone | 10.0 g |
| Yeast extract | 3.0 g |
| Soluble starch | 1.0 g |
| Glucose monohydrate | 5.0 g |
| Cysteine hydrochloride | 0.5 g |
| Sodium chloride | 5.0 g |
| Sodium acetate | 3.0 g |
| Agar | 0.5 g |
| Purified water | 1000 mL |

Hydrate the agar, dissolve by heating to boiling with continuous stirring. If necessary, adjust the pH so that after sterilisation it is 6.8 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

**Columbia agar**

| | |
|---|---|
| Pancreatic digest of casein | 10.0 g |
| Meat peptic digest | 5.0 g |
| Heart pancreatic digest | 3.0 g |
| Yeast extract | 5.0 g |
| Maize starch | 1.0 g |
| Sodium chloride | 5.0 g |
| Agar, according to gelling power | 10.0-15.0 g |
| Purified water | 1000 mL |

Hydrate the agar, dissolve by heating to boiling with continuous stirring. If necessary, adjust the pH so that after sterilisation it is 7.3 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle. Allow to cool to 45-50 °C; add, where necessary, gentamicin sulfate corresponding to 20 mg of gentamicin base and pour into Petri dishes.

**01/2018:20614**

## 2.6.14. BACTERIAL ENDOTOXINS[4]

The test for bacterial endotoxins (BET) is used to detect or quantify endotoxins from gram-negative bacteria using amoebocyte lysate from the horseshoe crab (*Limulus polyphemus* or *Tachypleus tridentatus*). There are 3 techniques for this test: the gel-clot technique, which is based on gel formation; the turbidimetric technique, based on the development of turbidity after cleavage of an endogenous substrate; and the chromogenic technique, based on the development of colour after cleavage of a synthetic peptide-chromogen complex.

The following 6 methods are described in the present chapter:

Method A. Gel-clot method: limit test

Method B. Gel-clot method: quantitative test

Method C. Turbidimetric kinetic method

Method D. Chromogenic kinetic method

Method E. Chromogenic end-point method

Method F. Turbidimetric end-point method

Proceed by any of the 6 methods for the test. In the event of doubt or dispute, the final decision is made based upon method A unless otherwise indicated in the monograph.

The test is carried out in a manner that avoids endotoxin contamination.

1. APPARATUS

Depyrogenate all glassware and other heat-stable apparatus in a hot-air oven using a validated process. A commonly used minimum time and temperature is 30 min at 250 °C. If employing plastic apparatus, such as microtitre plates and pipette tips for automatic pipetters, use apparatus shown to be free of detectable endotoxin and which does not interfere in the test.

(4) This chapter has undergone pharmacopoeial harmonisation. See chapter *5.8. Pharmacopoeial harmonisation.*

*NOTE: in this chapter, the term 'tube' includes all types of receptacles, for example microtitre plate wells.*

2. REAGENTS, TEST SOLUTIONS

**(1) Amoebocyte lysate**

Amoebocyte lysate is a lyophilised product obtained from amoebocyte lysate from the horseshoe crab (*Limulus polyphemus* or *Tachypleus tridentatus*). This reagent refers only to a product manufactured in accordance with the regulations of the competent authority.

*NOTE: amoebocyte lysate reacts with some β-glucans in addition to endotoxins. Amoebocyte lysate preparations which do not react with glucans are available; they are prepared by removing from amoebocyte lysate the G factor, which reacts with glucans, or by inhibiting the G factor reacting system of amoebocyte lysate. These preparations may be used for endotoxin testing in the presence of glucans.*

**(2) Lysate solution**

Dissolve amoebocyte lysate in water for BET or in a buffer, as recommended by the lysate manufacturer, by gentle stirring. Store the reconstituted lysate, refrigerated or frozen, as indicated by the manufacturer.

**(3) Water for BET (water for bacterial endotoxins test)**

*Water for injections R* or water produced by other procedures that shows no reaction with the lysate employed at the detection limit of the reagent.

3. PREPARATION OF THE STANDARD ENDOTOXIN STOCK SOLUTION

The standard endotoxin stock solution is prepared from an endotoxin reference standard that has been calibrated against the International Standard, for example *endotoxin standard BRP*.

Endotoxin is expressed in International Units (IU). The equivalence in IU of the International Standard is stated by the World Health Organization.

*NOTE: one International Unit (IU) of endotoxin is equal to one Endotoxin Unit (E.U.).*

Follow the specifications in the package leaflet and on the label for preparation and storage of the standard endotoxin stock solution.

4. PREPARATION OF THE STANDARD ENDOTOXIN SOLUTIONS

After vigorously mixing the standard endotoxin stock solution, prepare appropriate serial dilutions of this solution using water for BET.

Use the solutions as soon as possible to avoid loss of activity by adsorption.

5. PREPARATION OF THE TEST SOLUTIONS

Prepare the test solutions by dissolving or diluting active substances or medicinal products using water for BET. Some substances or preparations may be more appropriately dissolved or diluted in other aqueous solutions. If necessary, adjust the pH of the test solution (or dilution thereof) so that the pH of the mixture of the lysate and test solution falls within the pH range specified by the lysate manufacturer, usually 6.0 to 8.0. The pH may be adjusted by the use of acid, base or a suitable buffer, as recommended by the lysate manufacturer. Acids and bases may be prepared from concentrates or solids with water for BET in containers free of detectable endotoxin. Buffers must be validated to be free of detectable endotoxin and interfering factors.

6. DETERMINATION OF THE MAXIMUM VALID DILUTION

The Maximum Valid Dilution (MVD) is the maximum allowable dilution of a sample at which the endotoxin limit can be determined. Determine the MVD using the following formulae:

$$\mathrm{MVD} = \frac{\text{endotoxin limit} \times \text{concentration of test solution}}{\lambda}$$

*Endotoxin limit*: the endotoxin limit for active substances administered parenterally, defined on the basis of dose, is equal to:

$$\frac{K}{M}$$

$K$ = threshold pyrogenic dose of endotoxin per kilogram of body mass,

$M$ = maximum recommended bolus dose of product per kilogram of body mass.

When the product is to be injected at frequent intervals or infused continuously, $M$ is the maximum total dose administered in a single hour period.

The endotoxin limit for active substances administered parenterally is specified in units such as IU/mL, IU/mg, IU/Unit of biological activity, etc., in monographs.

*Concentration of test solution*:

- mg/mL if the endotoxin limit is specified by mass (IU/mg),
- Units/mL if the endotoxin limit is specified by unit of biological activity (IU/Unit),
- mL/mL if the endotoxin limit is specified by volume (IU/mL).

λ = the labelled lysate sensitivity in the gel-clot technique (IU/mL) or the lowest concentration used in the standard curve of the turbidimetric or chromogenic techniques.

7. GEL-CLOT TECHNIQUE (METHODS A AND B)

The gel-clot technique allows detection or quantification of endotoxins and is based on clotting of the lysate in the presence of endotoxins. The minimum concentration of endotoxins required to cause the lysate to clot under standard conditions is the labelled lysate sensitivity. To ensure both the precision and validity of the test, confirm the labelled lysate sensitivity and perform the test for interfering factors as described under 1. Preparatory testing.

*1. PREPARATORY TESTING*

**(i) Confirmation of the labelled lysate sensitivity**

Confirm in 4 replicates the labelled sensitivity λ, expressed in IU/mL, of the lysate solution prior to use in the test. Confirmation of the lysate sensitivity is carried out when a new lot of lysate is used or when there is any change in the test conditions which may affect the outcome of the test.

Prepare standard solutions of at least 4 concentrations equivalent to 2λ, λ, 0.5λ and 0.25λ by diluting the standard endotoxin stock solution with water for BET.

Mix a volume of the lysate solution with an equal volume of 1 of the standard solutions (such as 0.1 mL aliquots) in each tube. When single test vials or ampoules containing lyophilised lysate are employed, add solutions of standards directly to the vial or ampoule. Incubate the reaction mixture for a constant period according to the recommendations of the lysate manufacturer (usually at 37 ± 1 °C for 60 ± 2 min), avoiding vibration. Test the integrity of the gel: for tubes, take each tube in turn directly from the incubator and invert it through approximately 180° in one smooth motion. If a firm gel has formed that remains in place upon inversion, record the result as positive. A result is negative if an intact gel is not formed.

The test is considered valid when the lowest concentration of the standard solutions shows a negative result in all replicate tests.

The end-point is the lowest concentration in the series of decreasing concentrations of standard endotoxin that clots the lysate. Determine the geometric mean end-point

concentration by calculting the mean of the logarithms of the end-point concentrations of the 4 dilution series, take the antilogarithm of this value, as indicated by the following expression:

$$\text{Geometric mean end-point concentration} = \text{antilog}\frac{\sum e}{f}$$

$\sum e$ = sum of the $\log_{10}$ end-point concentrations of the dilution series used,

$f$ = number of replicates.

The geometric mean end-point concentration is the measured sensitivity of the lysate solution (IU/mL). If this is not less than 0.5λ and not more than 2λ, the labelled sensitivity is confirmed and is used in the tests performed with this lysate.

**(ii) Test for interfering factors**

Prepare solutions A, B, C and D as shown in Table 2.6.14.-1, and use the test solutions at a dilution less than the MVD, not containing any detectable endotoxins, operating as described under 1. Preparatory testing, (i) Confirmation of the labelled lysate sensitivity.

The geometric mean end-point concentrations of solutions B and C are determined using the expression described in 1. Preparatory testing, (i) Confirmation of the labelled lysate sensitivity.

The test for interfering factors must be repeated when any changes are made to the experimental conditions that are likely to influence the result of the test.

The test is considered valid when all replicates of solutions A and D show no reaction and the result of solution C confirms the labelled lysate sensitivity.

If the sensitivity of the lysate determined with solution B is not less than 0.5λ and not greater than 2λ, the test solution does not contain interfering factors under the experimental conditions used. Otherwise, the test solution interferes with the test.

If the preparation being examined interferes with the test at a dilution less than the MVD, repeat the test for interfering factors using a greater dilution, not exceeding the MVD. The use of a more sensitive lysate permits a greater dilution of the preparation being examined and this may contribute to the elimination of interference.

Interference may be overcome by suitable validated treatment, such as filtration, neutralisation, dialysis or heat treatment. To establish that the treatment chosen effectively eliminates interference without loss of endotoxins, repeat the test for interfering factors using the preparation being examined to which the standard endotoxin has been added and which has then been submitted to the chosen treatment.

*2. LIMIT TEST (METHOD A)*

**(i) Procedure**

Prepare solutions A, B, C and D as shown in Table 2.6.14.-2, and perform the test on these solutions following the procedure described under 1. Preparatory testing, (i) Confirmation of the labelled lysate sensitivity.

Table 2.6.14.-2

| Solution | Endotoxin concentration/Solution to which endotoxin is added | Number of replicates |
|---|---|---|
| A | None/Diluted test solution | 2 |
| B | 2λ/Diluted test solution | 2 |
| C | 2λ/Water for BET | 2 |
| D | None/Water for BET | 2 |

Prepare solution A and solution B (positive product control) using a dilution not greater than the MVD and treatments as described in 1. Preparatory testing, (ii) Test for interfering factors. Solutions B and C (positive controls) contain the standard endotoxin at a concentration corresponding to twice the labelled lysate sensitivity. Solution D (negative control) consists of water for BET.

**(ii) Interpretation**

The test is considered valid when both replicates of solution B and C are positive and those of solution D are negative.

When a negative result is found for both replicates of solution A, the preparation being examined complies with the test.

When a positive result is found for both replicates of solution A, the preparation being examined does not comply with the test.

When a positive result is found for one replicate of solution A and a negative result is found for the other, repeat the test. In the repeat test, the preparation being examined complies with the test if a negative result is found for both replicates of solution A. The preparation does not comply with the test if a positive result is found for one or both replicates of solution A.

However, if the preparation does not comply with the test at a dilution less than the MVD, the test may be repeated using a greater dilution, not exceeding the MVD.

*3. QUANTITATIVE TEST (METHOD B)*

**(i) Procedure**

The test quantifies bacterial endotoxins in the test solution by titration to an end-point. Prepare solutions A, B, C and D as shown in Table 2.6.14.-3, and test these solutions according to the procedure described under 1. Preparatory testing, (i) Confirmation of the labelled lysate sensitivity.

Table 2.6.14.-1

| Solution | Endotoxin concentration/Solution to which endotoxin is added | Diluent | Dilution factor | Endotoxin concentration | Number of replicates |
|---|---|---|---|---|---|
| A | None/Test solution | - | - | - | 4 |
| B | 2λ/Test solution | Test solution | 1 | 2λ | 4 |
| | | | 2 | 1λ | 4 |
| | | | 4 | 0.5λ | 4 |
| | | | 8 | 0.25λ | 4 |
| C | 2λ/Water for BET | Water for BET | 1 | 2λ | 2 |
| | | | 2 | 1λ | 2 |
| | | | 4 | 0.5λ | 2 |
| | | | 8 | 0.25λ | 2 |
| D | None/Water for BET | - | - | - | 2 |

Solution A = solution of the preparation being examined that is free of detectable endotoxins.
Solution B = test for interference.
Solution C = control of the labelled lysate sensitivity.
Solution D = negative control (water for BET).

**(ii) Calculation and interpretation**

The test is considered valid when the following 3 conditions are met:

(a) both replicates of solution D (negative control) are negative,

(b) both replicates of solution B (positive product control) are positive,

(c) the geometric mean end-point concentration of solution C is in the range of 0.5λ to 2λ.

To determine the endotoxin concentration of solution A, calculate the end-point concentration for each replicate, by multiplying each end-point dilution factor by λ.

The endotoxin concentration in the test solution is the end-point concentration of the replicates. If the test is conducted with a diluted test solution, calculate the concentration of endotoxin in the original solution by multiplying the result by the dilution factor.

If none of the dilutions of the test solution is positive in a valid test, report the endotoxin concentration as less than λ (or, if a diluted sample was tested, report as less than the lowest dilution factor of the sample × λ). If all dilutions are positive, the endotoxin concentration is reported as equal to or greater than the largest dilution factor multiplied by λ (e.g. in Table 2.6.14.-3, the initial dilution factor × 8 × λ).

The preparation being examined meets the requirements of the test if the endotoxin concentration in both replicates is less than that specified in the monograph.

Table 2.6.14.-3

| Solution | Endotoxin concentration/Solution to which endotoxin is added | Diluent | Dilution factor | Endotoxin concentration | Number of replicates |
|---|---|---|---|---|---|
| A | None/Test solution | Water for BET | 1 | - | 2 |
| | | | 2 | - | 2 |
| | | | 4 | - | 2 |
| | | | 8 | - | 2 |
| B | 2λ/Test solution | | 1 | 2λ | 2 |
| C | 2λ/Water for BET | Water for BET | 1 | 2λ | 2 |
| | | | 2 | 1λ | 2 |
| | | | 4 | 0.5λ | 2 |
| | | | 8 | 0.25λ | 2 |
| D | None/Water for BET | - | - | - | 2 |

Solution A = test solution at the dilution, not exceeding the MVD, with which the test for interfering factors was carried out. Subsequent dilution of the test solution must not exceed the MVD. Use water for BET to make a dilution series of 4 tubes containing the test solution at concentrations of 1, 1/2, 1/4 and 1/8, relative to the dilution used in the test for interfering factors. Other dilutions up to the MVD may be used as appropriate.

Solution B = solution A containing standard endotoxin at a concentration of 2λ (positive product control).

Solution C = a dilution series of 4 tubes of water for BET containing the standard endotoxin at concentrations of 2λ, λ, 0.5λ and 0.25λ.

Solution D = water for BET (negative control).

8. PHOTOMETRIC QUANTITATIVE TECHNIQUES (METHODS C, D, E AND F)

*1. TURBIDIMETRIC TECHNIQUE (METHODS C AND F)*

This technique is a photometric test to measure the increase in turbidity. Based on the test principle employed, this technique may be classified as being either the end-point-turbidimetric test or the kinetic-turbidimetric test.

The end-point-turbidimetric test (Method F) is based on the quantitative relationship between the endotoxin concentration and the turbidity (absorbance or transmission) of the reaction mixture at the end of an incubation period.

The kinetic-turbidimetric test (Method C) is a method to measure either the time (onset time) needed for the reaction mixture to reach a predetermined absorbance or transmission, or the rate of turbidity development.

The test is carried out at the incubation temperature recommended by the lysate manufacturer (usually 37 ± 1 °C).

*2. CHROMOGENIC TECHNIQUE (METHODS D AND E)*

This technique is used to measure the chromophore released from a suitable chromogenic peptide by the reaction of endotoxins with the lysate. Depending on the test principle employed, this technique may be classified as being either the end-point-chromogenic test or the kinetic-chromogenic test.

The end-point-chromogenic test (Method E) is based on the quantitative relationship between the endotoxin concentration and the quantity of chromophore released at the end of an incubation period.

The kinetic-chromogenic test (Method D) measures either the time (onset time) needed for the reaction mixture to reach a predetermined absorbance, or the rate of colour development.

The test is carried out at the incubation temperature recommended by the lysate manufacturer (usually 37 ± 1 °C).

*3. PREPARATORY TESTING*

To assure the precision or validity of the turbidimetric and chromogenic techniques, preparatory tests are conducted to show that the criteria for the standard curve are satisfied and that the test solution does not interfere with the test.

Validation of the test method is required when any changes are made to the experimental conditions that are likely to influence the result of the test.

**(i) Assurance of criteria for the standard curve**

The test must be carried out for each lot of lysate reagent.

Using the standard endotoxin solution, prepare at least 3 endotoxin concentrations within the range indicated by the lysate manufacturer to generate the standard curve. Perform the test using at least 3 replicates of each standard endotoxin solution as recommended by the lysate manufacturer (volume ratios, incubation time, temperature, pH, etc.).

If the desired range is greater than 2 $\log_{10}$ in the kinetic methods, additional standards must be included to bracket each $\log_{10}$ increase in the range of the standard curve.

The absolute value of the correlation coefficient, $|r|$, must be greater than or equal to 0.980, for the range of endotoxin concentrations set up.

**(ii) Test for interfering factors**

Select an endotoxin concentration at or near the middle of the endotoxin standard curve.

Prepare solutions A, B, C and D as shown in Table 2.6.14.-4. Perform the test on at least 2 replicates of these solutions as recommended by the lysate manufacturer (volume of test solution and lysate solution, volume ratio of test solution to lysate solution, incubation time, etc.).

Table 2.6.14.-4

| Solution | Endotoxin concentration | Solution to which endotoxin is added | Number of replicates |
|---|---|---|---|
| A | None | Test solution | Not less than 2 |
| B | Middle concentration of the standard curve | Test solution | Not less than 2 |
| C | At least 3 concentrations (lowest concentration is designated λ) | Water for BET | Each concentration not less than 2 |
| D | None | Water for BET | Not less than 2 |

Solution A = test solution, that may be diluted not to exceed the MVD.

Solution B = preparation to be examined at the same dilution as solution A, containing added endotoxin at a concentration equal to or near the middle of the standard curve.

Solution C = standard endotoxin solution at the concentrations used in the validation of the method as described under 3. Preparatory testing, (i) Assurance of criteria for the standard curve (positive controls).

Solution D = water for BET (negative control).

The test is considered valid when the following conditions are met:

- the absolute value of the correlation coefficient of the standard curve generated using solution C is greater than or equal to 0.980;
- the result with solution D does not exceed the limit of the blank value required in the description of the lysate reagent employed, or it is less than the endotoxin detection limit of the lysate reagent employed.

Calculate the mean recovery of the added endotoxin by subtracting the mean endotoxin concentration in the solution (if any) (solution A, Table 2.6.14.-4) from that in the solution containing the added endotoxin (solution B, Table 2.6.14.-4).

The test solution is considered free of interfering factors if under the conditions of the test, the measured concentration of the endotoxin added to the test solution is within 50-200 per cent of the known added endotoxin concentration, after subtraction of any endotoxin detected in the solution without added endotoxin.

When the endotoxin recovery is out of the specified range, the test solution is considered to contain interfering factors. Repeat the test using a greater dilution, not exceeding the MVD. Furthermore, interference of the test solution or diluted test solution not to exceed the MVD may be eliminated by suitable validated treatment, such as filtration, neutralisation, dialysis or heat treatment. To establish that the treatment chosen effectively eliminates interference without loss of endotoxins, repeat the test for interfering factors using the preparation being examined to which the standard endotoxin has been added and which has then been submitted to the chosen treatment.

*4. TEST*

**(i) Procedure**

Follow the procedure described in 3. Preparatory testing, (ii) Test for interfering factors.

**(ii) Calculation**

Calculate the endotoxin concentration of each replicate of solution A using the standard curve generated by the positive control solution C.

The test is considered valid when the following 3 requirements are met:

(1) the results obtained with solution C comply with the requirements for validation defined under 3. Preparatory testing, (i) Assurance of criteria for the standard curve,

(2) the endotoxin recovery, calculated from the endotoxin concentration found in solution B after subtracting the endotoxin concentration found in solution A, is within the range of 50-200 per cent,

(3) the result obtained with solution D (negative control) does not exceed the limit of the blank value required in the description of the lysate employed, or it is less than the endotoxin detection limit of the lysate reagent employed.

**(iii) Interpretation**

The preparation being examined complies with the test if the mean endotoxin concentration of the replicates of solution A, after correction for dilution and concentration, is less than the endotoxin limit for the product.

*Guidelines on the test for bacterial endotoxins are given in general chapter 5.1.10.*

**04/2016:20615**

# 2.6.15. PREKALLIKREIN ACTIVATOR

Prekallikrein activator (PKA) activates prekallikrein to kallikrein and may be assayed by its ability to cleave a chromophore from a synthetic peptide substrate so that the rate of cleavage can be measured spectrophotometrically and the concentration of PKA calculated by comparison with a reference preparation calibrated in International Units.

The International Unit is the activity of a stated amount of the International Standard, which consists of freeze-dried prekallikrein activator. The equivalence in International Units of the International Standard is stated by the World Health Organization.

REAGENTS

*Prekallikrein activator in albumin BRP* is calibrated in International Units by comparison with the International Standard.

*Buffer A*. Dissolve 6.055 g of *tris(hydroxymethyl)aminomethane R*, 1.17 g of *sodium chloride R*, 50 mg of *hexadimethrine bromide R* and 0.100 g of *sodium azide R* in *water R*. Adjust to pH 8.0 with *2 M hydrochloric acid R* and dilute to 1000 mL with *water R*.

*Buffer B*. Dissolve 6.055 g of *tris(hydroxymethyl)aminomethane R* and 8.77 g of *sodium chloride R* in *water R*. Adjust to pH 8.0 with *2 M hydrochloric acid R* and dilute to 1000 mL with *water R*.

PREPARATION OF PREKALLIKREIN SUBSTRATE

*To avoid coagulation activation, blood or plasma used for the preparation of prekallikrein must come into contact only with plastics or silicone-treated glass surfaces.*

Draw 9 volumes of human blood into 1 volume of anticoagulant solution (ACD, CPD or a 38 g/L solution of *sodium citrate R*) to which 1 mg/mL of *hexadimethrine bromide R* has been added. Centrifuge the mixture at 3600 *g* for 5 min. Separate the plasma and centrifuge again at 6000 *g* for 20 min to sediment platelets. Separate the platelet-poor plasma and dialyse against 10 volumes of buffer A for 20 h. Apply the dialysed plasma to a chromatography column containing *agarose-DEAE for ion-exchange chromatography R* that has been equilibrated in buffer A and is equal to twice the volume of the plasma. Elute from the column with buffer A at 20 mL/cm$^2$/h. Collect the eluate in fractions and record the absorbance at 280 nm (*2.2.25*). Pool the fractions containing the 1$^{st}$ protein peak so that the volume of the pool is about 1.2 times the volume of the platelet-poor plasma.

Test the substrate pool for absence of kallikrein activity by mixing 1 part with 20 parts of the pre-warmed chromogenic substrate solution to be used in the assay and incubate at 37 °C for 2 min. The substrate is suitable if the increase in absorbance is less than 0.001 per minute. Add to the pooled solution 7 g/L of *sodium chloride R* and filter through a membrane filter (nominal pore size 0.45 µm). Freeze the filtrate in portions and store at – 25 °C; the substrate may be freeze-dried before storage.

Carry out all procedures from the beginning of the chromatography to freezing in portions during a single working day.

METHOD

The assay may be carried out using an automated enzyme analyser or a suitable microtitre plate system allowing kinetic measurements, with appropriate software for calculation of results. Standards, samples and prekallikrein substrate may be diluted as necessary using buffer B.

Incubate diluted standards or samples with prekallikrein substrate for 10 min such that the volume of the undiluted sample does not exceed 1/10 of the total volume of the incubation mixture to avoid errors caused by variation in ionic strength and pH in the incubation mixture. Incubate the mixture or a part thereof with at least an equal volume of a solution of a suitable synthetic chromogenic substrate, known to be specific for kallikrein (for example, *N-benzoyl-L-prolyl-L-phenylalanyl-L-arginine 4-nitroanilide acetate R* or *D-prolyl-L-phenylalanyl-L-arginine 4-nitroanilide dihydrochloride R*), dissolved in buffer B. Record the rate of change in absorbance per minute for 2-10 min at the wavelength specific for the substrate used. Prepare a blank for each mixture of sample or standard using buffer B instead of prekallikrein substrate.

Depending on the method used, $\Delta A$/min has to be corrected by subtracting the value obtained for the corresponding blank without the prekallikrein substrate. The results may be calculated using a standard curve, a parallel-line or a slope ratio assay or any other suitable statistical method. Plot a calibration curve using the values thus obtained for the reference preparation and the respective concentrations; use the curve to determine the PKA activity of the preparation to be examined. During method validation, the spiking experiments must show that the sample matrix has no influence on the results. High blank values may impact assay validity and should be appropriately investigated.

# 2.6.16. TESTS FOR EXTRANEOUS AGENTS IN VIRAL VACCINES FOR HUMAN USE

INTRODUCTION

A strategy for testing extraneous agents in viral vaccines must be developed based on a risk assessment following the principles of viral contamination risk detailed in general chapter *5.1.7. Viral safety*. This strategy includes a full package of suitable tests that are able to detect different families of extraneous agents that may infect the source of virus strains including cell substrates and raw material of animal or plant origin. It also takes into account the capacity of the manufacturing process to remove or inactivate viruses. The list of tests summarised in Table 2.6.16.-1 must be adapted depending on the extraneous agents that have the potential to contaminate the product: for *in vitro* tests, the risk assessment may allow, with the agreement of the competent authority, the use of other permissive cell lines or molecular biology methods depending on the manufacturing process and the incubation temperature for the growth of particular viruses. If *in vivo* tests are more relevant than *in vitro* tests for the detection of some adventitious viruses (e.g. suckling mice for the vesicular stomatitis virus and fertilised SPF eggs for the influenza virus) the decision to maintain or to introduce such *in vivo* assays in a testing strategy must be justified by the risk assessment.

New, sensitive molecular methods with broad detection capabilities are available. These new approaches include high-throughput sequencing (HTS) methods, nucleic acid amplification techniques (NAT) (e.g. polymerase chain reaction (PCR), reverse transcriptase PCR (RT-PCR), product-enhanced reverse transcriptase (PERT) assays) for whole virus families or random-priming methods (associated or not with sequencing), hybridisation to oligonucleotide arrays, and mass spectrometry with broad-spectrum PCR. These methods may be used either as an alternative to *in vivo* tests and specific NAT or as a supplement/alternative to *in vitro* culture tests based on the risk assessment and with the agreement of the competent authority.

In tests that require prior neutralisation of the virus, use specific antibodies of non-human, non-simian origin; if the virus has been propagated in avian tissues, the antibodies must also be of non-avian origin. To prepare antiserum, use an immunising antigen produced in cell cultures from a species different from that used for the production of the vaccine and free from extraneous agents. Where the use of SPF eggs is prescribed, the eggs are obtained from a flock free from specified pathogens (*5.2.2*).

TEST METHODS

Relevant tests for extraneous agents to be carried out at various production stages are indicated in Table 2.6.16.-1 using the methods described below, based on the risk assessment.

Take samples at the time of harvesting, and if not tested immediately, keep at a temperature below – 40 °C.

Table 2.6.16.-1. – *Relevant tests for extraneous agents at various production stages*

| | Virus seed lots | Virus harvests | Production of culture substrates | |
|---|---|---|---|---|
| | | | Control cells | Control eggs |
| Bacterial and fungal contamination | + | + | - | - |
| Mycoplasmas | + | + | - | - |
| Spiroplasmas[1] | + | - | - | - |
| Mycobacteria | + | + | - | - |
| Test in suckling mice[2] | + | - | - | - |
| Avian viruses[3] | + | + | - | - |
| Test for extraneous agents in cell cultures[4] | + | + | + | + |
| Insect viruses[5] | + | + | - | - |
| Test on control cells (microscopic examination) | - | - | + | - |
| Haemadsorbing viruses | - | - | + | - |
| Test on control eggs (haemagglutinating agents) | - | - | - | + |
| Avian leucosis viruses[6] | - | - | + | + |

| | | | | |
|---|---|---|---|---|
| Test for specific viruses by NAT[7] | + | + | - | - |
| Test for viruses using broad molecular methods[8] | + | + | - | - |

(1) If insect cells or raw materials of plant origin are used.

(2) If the risk assessment indicates that this test provides a risk mitigation taking into account the overall testing package.

(3) If the virus is propagated in avian or primary avian tissues. If the risk assessment indicates that this test provides a risk mitigation taking into account the overall testing package.

(4) Test performed in suitable permissive cell cultures. Based on a risk assessment.

(5) If the virus is propagated in insect cells.

(6) If the virus is propagated in primary avian tissues or in eggs.

(7) Based on a risk assessment.

(8) These methods may be used either as an alternative to *in vivo* tests and specific NAT or as a supplement/alternative to *in vitro* culture tests based on the risk assessment and in agreement with the competent authority.

**Bacterial and fungal contamination**. Each virus seed lot and virus harvest complies with the test for sterility (*2.6.1*).

**Mycoplasmas** (*2.6.7*). Each virus seed lot and virus harvest complies with the test for mycoplasmas.

**Spiroplasmas**. Spiroplasmas may be introduced into virus seed lots through contamination of raw materials of plant origin or when insect cell lines are used for virus propagation. When appropriate, virus seed lots are demonstrated to be free of spiroplasmas using a validated method approved by the competent authority. NAT methods for detection of mycoplasmas (*2.6.7*) may be used to detect spiroplasmas after validation and agreement from the competent authority.

**Mycobacteria** (*2.6.2*). A 2.7 mL sample of each virus seed lot and each virus harvest is tested for the presence of *Mycobacterium* spp. by culture methods known to be sensitive for the detection of these organisms. NAT (*2.6.21*) may be used as an alternative, provided such an assay is validated and shown to be comparable to the culture method.

**Suckling mice**. Each virus seed lot is tested in suckling mice if the risk assessment indicates that this test provides a risk mitigation taking into account the overall testing package. Inoculate no fewer than 20 suckling mice, each less than 24 h old, intracerebrally with 0.01 mL and intraperitoneally with at least 0.1 mL of the virus seed lot. Observe the suckling mice daily for at least 4 weeks. Carry out an autopsy of all suckling mice that die after the first 24 h of the test or that show signs of illness, and examine for evidence of viral infection by direct macroscopical observation. The virus seed lot passes the test if no suckling mice show evidence of infection attributable to the seed lot. The test is not valid unless at least 80 per cent of the original inoculated suckling mice survive the observation period.

**Avian viruses**. Each virus seed lot propagated in avian tissues and each virus harvest propagated in primary avian tissues is tested for avian viruses if the risk assessment indicates that this test provides a risk mitigation taking into account the overall testing package. Neutralise a sample equivalent to 100 human doses of vaccine or 10 mL, whichever is the greater. Using 0.5 mL per egg, inoculate a group of fertilised SPF eggs, 9-11 days old, by the allantoic route and a second group, 5-7 days old, into the yolk sac. Incubate for 7 days. The virus seed lot or harvest complies with the test if the allantoic and yolk sac fluids show no sign of the presence of any haemagglutinating agent and if all embryos and chorio-allantoic membranes examined for gross pathology, are normal. The test is not valid unless at least 80 per cent of the inoculated eggs survive for 7 days.

**Test for extraneous agents in cell cultures**. For each virus seed lot, each virus harvest and each production cell culture (control cells or control eggs), tests for other extraneous agents must be carried out based on a risk assessment. The origin of the cell substrate and virus strain, as well as the potential extraneous agents that may be inadvertently introduced during production processes or through the use of animal-or plant-derived raw materials, must be taken into account when choosing suitable permissive cells.

For each virus seed lot and virus harvest, neutralised samples, equivalent (unless otherwise prescribed) to 500 human doses of vaccine or 50 mL, whichever is the greater, are tested for the presence of extraneous agents by inoculation into continuous simian and human cell cultures. If the virus is grown in simian or human cells, the neutralised virus harvest is tested on a separate culture of these cells. If the virus is grown in a mammalian cell system other than simian or human, or in avian cells, cells of that species, but from a separate batch, are also inoculated. The cells are incubated at 36 ± 1 °C and observed for a period of 14 days. If the production cell culture is maintained at a temperature other than 36 ± 1 °C, a supplementary test for extraneous agents is carried out at the production temperature using the same type of cells used for growth of the virus. A subculture of 14 days is carried out followed by a haemadsorbing test. The virus seed lot or harvest passes the tests if none of the cell cultures show evidence of the presence of any extraneous agents after 14 and 28 days of incubation, and no evidence of any haemadsorbing viruses after 28 days. The test is not valid unless at least 80 per cent of the cell cultures remain viable.

**Insect viruses**. Each virus seed lot and virus harvest propagated in insect cells is tested for insect viruses. Neutralised samples, equivalent (unless otherwise prescribed) to 500 human doses of vaccine or 50 mL, whichever is the greater, are tested for the presence of extraneous agents by inoculation into at least 1 cell culture different from that used in production and permissible to insect viruses, and that also allows detection of human arboviruses (e.g. BHK-21). The choice of cells is approved by the competent authority and takes into account the origin of the production cells and the likely contaminants that may be detected by the chosen cells. The cells are incubated at an appropriate temperature and observed for a period of 14 days. A subculture of 14 days is carried out followed by a haemadsorbing test. The virus seed lot or harvest passes the tests if none of the cell cultures show evidence of the presence of any extraneous agents after 14 and 28 days of incubation, and no evidence of any haemadsorbing virus after 28 days. The test is not valid unless at least 80 per cent of the cell cultures remain viable.

**Tests on control cells**. Where cell cultures are used for virus production, examine the control cells microscopically for the absence of any virus causing cytopathic degeneration throughout the incubation time of the inoculated production cell cultures or for no less than 14 days beyond the time of inoculation of the production vessels, whichever is the longer. The test is not valid unless at least 80 per cent of the control cell cultures survive to the end of the observation period.

At 14 days or at the time of the last virus harvest, whichever is the longer, pool the supernatant fluids from the control cells and examine for the presence of extraneous agents over a period of 14 days as described above for the virus seed lot and the virus harvest by inoculation of relevant cell cultures depending on the type of cells used for virus growth.

**Haemadsorbing viruses**. Where cell cultures are used for virus production, a microscopic examination of the control cells is carried out as described above for the test for extraneous agents in cell cultures. At 14 days or at the time of the last virus harvest, whichever is the longer, examine no fewer than 25 per cent of the control cultures for the presence of haemadsorbing viruses by the addition of guinea-pig red blood cells. If the test for haemadsorbing viruses is not feasible, carry out a test for haemagglutinating viruses. If the guinea-pig red blood cells have been stored, they shall have been stored at 5 ± 3 °C for not more than 7 days. Read half

of the cultures after incubation at 5 ± 3 °C for 30 min and the other half after incubation at 20-25 °C for 30 min. No evidence of haemadsorbing agents is found.

**Tests on control eggs**. Where eggs are used for virus production, examine 0.25 mL of the allantoic fluid from each control egg for haemagglutinating agents by mixing directly with chicken red blood cells and after a passage in SPF eggs carried out as follows: inoculate a 5 mL sample of the pooled amniotic fluids from the control eggs in 0.5 mL volumes into the allantoic cavity and into the amniotic cavity of SPF eggs. The control eggs comply with the test if no evidence of the presence of haemagglutinating agents is found in either test.

In addition, inoculate 5 mL samples of the pooled amniotic fluids from the control eggs into suitable permissive cells including human, simian and avian cells. Observe the cell cultures for 14 days at a suitable incubation temperature. The control eggs comply with the test if no evidence of the presence of extraneous agents is found. The test is not valid unless 80 per cent of the inoculated cultures survive to the end of the observation period.

**Avian leucosis viruses**. For each virus propagated in primary avian cell tissues or in eggs, the production cell culture (control cells or control eggs) is tested for avian leucosis viruses in accordance with general chapter *2.6.24*. When cell cultures are used for virus production, a microscopic examination of the control cells is carried out as described above for the test for extraneous agents prior to the test for avian leucosis viruses. At 14 days or at the time of the last virus harvest, whichever is the longer, carry out the test for avian leucosis viruses on DF1 cells or leucosis-free chick-embryo cell cultures with amplification through 5 passages using at least 5 mL of the supernatant fluid from the control cells or at least 10 mL of a sample of the pooled amniotic fluids from the control eggs. PERT assay end-point can be used after DF1 amplification for detection of exogenous avian retroviruses (including avian leucosis virus). For specific detection of avian leucosis virus, several end-points can be used such as immunostaining, enzyme-linked immunosorbent assay (ELISA) or complement fixation for avian leucosis (COFAL). Control cells or control eggs comply with the test if there is no evidence of the presence of any avian leucosis virus.

**Tests for specific viruses by NAT**. Based on a risk assessment related to the manufacturing process, each virus seed lot and each virus harvest may be tested by NAT (*2.6.21*) for specific viruses that are not detected by conventional *in vivo* or cell culture assays.

**Test for viruses using broad molecular methods**. With the agreement of the competent authority, broad molecular methods (e.g. high-throughput sequencing) may be used either as an alternative to *in vivo* tests and specific NAT, or as a supplement/alternative to *in vitro* culture tests based on the risk assessment.

Both NAT (*2.6.21*) and broad molecular methods are carried out with or without prior amplification in suitable permissive cells. In cases of positive results with either broad molecular methods or NAT, a follow-up investigation must be conducted to determine whether detected nucleic acids are due to the presence of infectious extraneous agents and/or are known to constitute a risk to human health.

01/2018:20617

# 2.6.17. TEST FOR ANTICOMPLEMENTARY ACTIVITY OF IMMUNOGLOBULIN

For the measurement of anticomplementary activity (ACA) of immunoglobulin, a defined amount of test material (10 mg of immunoglobulin) is incubated with a defined amount of guinea-pig complement (20 $CH_{50}$) and the remaining complement is titrated; the anticomplementary activity is expressed as the percentage consumption of complement relative to the complement control considered as 100 per cent.

The haemolytic unit of complement activity ($CH_{50}$) is the amount of complement that, in the given reaction conditions, will produce the lysis of $2.5 \times 10^8$ out of a total of $5 \times 10^8$ optimally sensitised red blood cells.

*Magnesium and calcium stock solution*. Dissolve 1.103 g of *calcium chloride R* and 5.083 g of *magnesium chloride R* in *water R* and dilute to 25 mL with the same solvent.

*Barbital buffer stock solution*. Dissolve 207.5 g of *sodium chloride R* and 25.48 g of *barbital sodium R* in 4000 mL of *water R* and adjust to pH 7.3 using *1 M hydrochloric acid*. Add 12.5 mL of magnesium and calcium stock solution and dilute to 5000 mL with *water R*. Filter through a membrane filter (nominal pore size 0.22 µm). Store at 4 °C in glass containers.

*Gelatin solution*. Dissolve 12.5 g of *gelatin R* in about 800 mL of *water R* and heat to boiling in a water-bath. Cool to 20 °C and dilute to 10 L with *water R*. Filter through a membrane filter (nominal pore size 0.22 µm). Store at 4 °C. Use clear solutions only.

*Citrate solution*. Dissolve 8.0 g of *sodium citrate R*, 4.2 g of *sodium chloride R* and 20.5 g of *glucose R* in 750 mL of *water R*. Adjust to pH 6.1 using a 100 g/L solution of *citric acid monohydrate R* and dilute to 1000 mL with *water R*.

*Gelatin barbital buffer solution*. Add 4 volumes of gelatin solution to 1 volume of barbital buffer stock solution and mix. Adjust to pH 7.3, if necessary, using *1 M sodium hydroxide* or *1 M hydrochloric acid*. Maintain at 4 °C. Prepare fresh solutions daily.

*Stabilised sheep blood*. Collect 1 volume of sheep blood into 1 volume of citrate solution and mix. Store at 4 °C for not less than 7 days and not more than 28 days. (Stabilised sheep blood and sheep red blood cells are available from a number of commercial sources.)

*Haemolysin*. Antiserum against sheep red blood cells prepared in rabbits. (Such antisera are available from a number of commercial sources.)

*Guinea-pig complement*. Prepare a pool of serum from the blood of not fewer than 10 guinea-pigs. Separate the serum from the clotted blood by centrifugation at about 4 °C. Store the serum in small amounts below – 70 °C.

METHOD

**Preparation of standardised 5 per cent sheep red blood cell suspension**. Separate sheep red blood cells by centrifuging an appropriate volume of stabilised sheep blood and wash the cells at least 3 times with gelatin barbital buffer solution and prepare a 5 per cent *V/V* suspension in the same solution. Measure the cell density of the suspension as follows: add 0.2 mL to 2.8 mL of *water R* and centrifuge the lysed solution for 5 min at 1000 *g*; the cell density is suitable if the absorbance (*2.2.25*) of the supernatant at 541 nm is 0.62 ± 0.01. Correct the cell density by adding gelatin barbital buffer solution according to the following equation:

$$V_f = \frac{V_i \times A}{0.62}$$

$V_f$ = final adjusted volume;

$V_i$ = the initial volume;

$A$ = absorbance of the original suspension at 541 nm.

The adjusted suspension contains about $1 \times 10^9$ cells/mL.

**Haemolysin titration**. Prepare haemolysin dilutions as shown in Table 2.6.17.-1.

Table 2.6.17.-1

| Required dilution of haemolysin | Prepared using | | |
|---|---|---|---|
| | Gelatin barbital buffer solution | | Haemolysin |
| | Volume (mL) | Dilution (1/...) | Volume (mL) |
| 7.5 | 0.65 | undiluted | 0.1 |
| 10 | 0.90 | undiluted | 0.1 |
| 75 | 1.80 | 7.5 | 0.2 |
| 100 | 1.80 | 10 | 0.2 |
| 150 | 1.00 | 75 | 1.0 |
| 200 | 1.00 | 100 | 1.0 |
| 300 | 1.00 | 150 | 1.0 |
| 400 | 1.00 | 200 | 1.0 |
| 600 | 1.00 | 300 | 1.0 |
| 800 | 1.00 | 400 | 1.0 |
| 1200 | 1.00 | 600 | 1.0 |
| 1600 | 1.00 | 800 | 1.0 |
| 2400 | 1.00 | 1200 | 1.0 |
| 3200* | 1.00 | 1600 | 1.0 |
| 4800* | 1.00 | 2400 | 1.0 |

* discard 1.0 mL of the mixture.

Add 1.0 mL of 5 per cent sheep red blood cell suspension to each tube of the haemolysin dilution series, starting at the 1/75 dilution, and mix. Incubate at 37 °C for 30 min.

Transfer 0.2 mL of each of these incubated mixtures to new tubes and add 1.10 mL of gelatin barbital buffer solution and 0.2 mL of diluted guinea-pig complement (for example, 1/150). Perform this in duplicate.

As the unhaemolysed cell control, prepare 3 tubes with 1.4 mL of gelatin barbital buffer solution and 0.1 mL of 5 per cent sheep red blood cell suspension.

As the fully haemolysed control, prepare 3 tubes with 1.4 mL of *water R* and 0.1 mL of 5 per cent sheep red cell suspension.

Incubate all tubes at 37 °C for 60 min and centrifuge at 1000 *g* for 5 min. Measure the absorbance (*2.2.25*) of the supernatants at 541 nm and calculate the percentage degree of haemolysis in each tube using the following expression:

$$\frac{A_a - A_1}{A_b - A_1} \times 100$$

$A_a$ = absorbance of tubes with haemolysin dilution;

$A_b$ = mean absorbance of the 3 tubes with full haemolysis;

$A_1$ = mean absorbance of the 3 tubes with no haemolysis.

Plot the percentage degree of haemolysis as the ordinate against the corresponding reciprocal value of the haemolysin dilution as the abscissa on linear graph paper. Determine the optimal dilution of the haemolysin from the graph by inspection. Select a dilution such that further increase in the amount of haemolysin does not cause appreciable change in the degree of haemolysis. This dilution is defined as 1 minimal haemolytic unit (1 MHU) in 1.0 mL. The optimal haemolytic haemolysin dilution for preparation of sensitised sheep red blood cells contains 2 MHU/mL.

The haemolysin titration is not valid unless the maximum degree of haemolysis is 50 per cent to 70 per cent. If the maximum degree of haemolysis is not in this range, repeat the titration with more or less diluted complement solution.

**Preparation of optimised sensitised sheep red blood cells (haemolytic system)**. Prepare an appropriate volume of diluted haemolysin containing 2 MHU/mL and an equal volume of standardised 5 per cent sheep red blood cell suspension. Add the haemolysin dilution to the standardised cell suspension and mix. Incubate at 37 °C for 15 min, store at 2 °C to 8 °C and use within 6 h.

**Titration of complement**. Prepare an appropriate dilution of complement (for example 1/250) with gelatin barbital buffer solution and perform the titration in duplicate as shown in Table 2.6.17.-2.

Table 2.6.17.-2

| Tube number | Volume of diluted complement (for example 1/250) (mL) | Volume of gelatin barbital buffer solution (mL) |
|---|---|---|
| 1 | 0.1 | 1.2 |
| 2 | 0.2 | 1.1 |
| 3 | 0.3 | 1.0 |
| 4 | 0.4 | 0.9 |
| 5 | 0.5 | 0.8 |
| 6 | 0.6 | 0.7 |
| 7 | 0.7 | 0.6 |
| 8 | 0.8 | 0.5 |
| 9 | 0.9 | 0.4 |
| 10 | 1.0 | 0.3 |
| 11 | 1.1 | 0.2 |
| 12 | 1.2 | 0.1 |
| 3 tubes as cell control at 0 per cent haemolysis | – | 1.3 |
| 3 tubes at 100 per cent haemolysis | – | 1.3 mL of water |

Add 0.2 mL of sensitised sheep red blood cells to each tube, mix well and incubate at 37 °C for 60 min. Cool the tubes in an ice-bath and centrifuge at 1000 *g* for 5 min. Measure the absorbance of the supernatant at 541 nm and calculate the degree of haemolysis ($Y$) using the following expression:

$$\frac{A_c - A_1}{A_b - A_1}$$

$A_c$ = absorbance of tubes 1 to 12;

$A_b$ = mean absorbance of tubes with 100 per cent haemolysis;

$A_1$ = mean absorbance of cell controls with 0 per cent haemolysis.

Plot $Y/(1- Y)$ as the abscissa against the amount of diluted complement in millilitres as the ordinate on log–log graph paper. Fit the best line to the points and determine the

ordinate for the 50 per cent haemolytic complement dose where $Y/(1-Y) = 1.0$. Calculate the activity in haemolytic units ($CH_{50}$/mL) using the following expression:

$$\frac{C_d}{C_a \times 5}$$

$C_d$ = reciprocal value of the complement dilution;

$C_a$ = volume of diluted complement resulting in 50 per cent haemolysis, in millilitres;

5 = scaling factor to take account of the number of red blood cells.

The test is not valid unless the plot is a straight line between 15 per cent and 85 per cent haemolysis and the slope is 0.15 to 0.40, and preferably 0.18 to 0.30.

**Test for anticomplementary activity**. Prepare a complement dilution having 100 $CH_{50}$/mL by diluting titrated guinea-pig complement with gelatin barbital buffer solution. Depending on the immunoglobulin to be examined and based on validation data, a pH adjustment to 7 may be necessary. Prepare incubation mixtures as follows for an immunoglobulin containing 50 mg/mL:

Table 2.6.17.-3

| | Immunoglobulin to be examined | Complement control (in duplicate) |
|---|---|---|
| Immunoglobulin (50 mg/mL) | 0.2 mL | – |
| Gelatin barbital buffer | 0.6 mL | 0.8 mL |
| Complement | 0.2 mL | 0.2 mL |

Carry out the test on the immunoglobulin to be examined and prepare ACA negative and positive controls using *human immunoglobulin for anticomplementary activity BRP*, as indicated in the leaflet accompanying the reference preparation. Higher or lower volumes of sample and of gelatin barbital buffer solution are added if the immunoglobulin concentration varies from 50 mg/mL; for example, 0.47 mL of gelatin barbital buffer solution is added to 0.33 mL of immunoglobulin containing 30 mg/mL to give 0.8 mL. Close the tubes and incubate at 37 °C for 60 min. Add 0.2 mL of each incubation mixture to 9.8 mL of gelatin barbital buffer solution to dilute the complement. Perform complement titrations on each tube as described above to determine the remaining complement activity (Table 2.6.17.-2). Calculate the anticomplementary activity of the preparation to be examined relative to the complement control considered as 100 per cent, using the following expression:

$$\frac{a-b}{a} \times 100$$

$a$ = mean complement activity ($CH_{50}$/mL) of complement control;

$b$ = complement activity ($CH_{50}$/mL) of tested sample.

The test is not valid unless:

- the anticomplementary activities found for ACA negative control and ACA positive control are within the limits stated in the leaflet accompanying the reference preparation;
- the mean complement activity of complement control ($a$) is in the range 80 $CH_{50}$/mL to 120 $CH_{50}$/mL.

**01/2008:20618**

## 2.6.18. TEST FOR NEUROVIRULENCE OF LIVE VIRUS VACCINES

For each test, use not fewer than ten monkeys that are seronegative for the virus to be tested. For each monkey, inject not more than 0.5 mL of the material to be examined into the thalamic region of each hemisphere, unless otherwise prescribed. The total amount of virus inoculated in each monkey must be not less than the amount contained in the recommended single human dose of the vaccine. As a check against the introduction of wild neurovirulent virus, keep a group of not fewer than four control monkeys as cage-mates or in the immediate vicinity of the inoculated monkeys. Observe the inoculated monkeys for 17 to 21 days for symptoms of paralysis and other evidence of neurological involvement; observe the control monkeys for the same period plus 10 days. Animals that die within 48 h of injection are considered to have died from non-specific causes and may be replaced. The test is not valid if: more than 20 per cent of the inoculated monkeys die from nonspecific causes; serum samples taken from the control monkeys at the time of inoculation of the test animals and 10 days after the latter are euthanised show evidence of infection by wild virus of the type to be tested or by measles virus. At the end of the observation period, carry out autopsy and histopathological examinations of appropriate areas of the brain for evidence of central nervous system involvement. The material complies with the test if there is no unexpected clinical or histopathological evidence of involvement of the central nervous system attributable to the inoculated virus.

**07/2019:20620**

## 2.6.20. ANTI-A AND ANTI-B HAEMAGGLUTININS

METHOD A: INDIRECT METHOD

Prepare in duplicate serial dilutions of the preparation to be examined in a 9 g/L solution of *sodium chloride R*. To each dilution of 1 series add an equal volume of a 5 per cent *V/V* suspension of group $A_1$ red blood cells previously washed 3 times with the sodium chloride solution. To each dilution of the other series add an equal volume of a 5 per cent *V/V* suspension of group B red blood cells previously washed 3 times with the sodium chloride solution. Incubate the suspensions at 37 °C for 30 min then wash the cells 3 times with the sodium chloride solution. Leave the cells in contact with a polyvalent anti-human globulin reagent for 30 min. Without centrifuging, examine each suspension for agglutination under a microscope.

METHOD B: DIRECT METHOD

*MATERIALS*

*Phosphate-buffered saline (PBS)*. Dissolve 8.0 g of *sodium chloride R*, 0.76 g of *anhydrous disodium hydrogen phosphate R*, 0.2 g of *potassium chloride R* and 0.2 g of *potassium dihydrogen phosphate R* in *water R* and dilute to 1000 mL with the same solvent. If the solution has to be kept for several days, 0.2 g of *sodium azide R* may be added in order to avoid microbial contamination.

*PBS-BSA solution*. PBS containing 2 g/L of *bovine albumin R* (Cohn Fraction V, for ELISA). Store the solution at 2-8 °C but allow it to reach 19-25 °C before use.

*Papain solution*. Use serological-grade papain from a commercial source, the activity of which has been validated.

*Red blood cells*. Use pooled D-negative $A_1$ ($A_1$rr), D-negative B (Brr) and D-negative O (Orr) red blood cells from preferably 3 donors. When *Immunoglobulin for anti-A and anti-B antibodies limit test BRP* is used, 3 donors are to be used. $A_2$ red blood cells are not recommended as they give weaker reactions.

Wash the cells 4 times with PBS or until the supernatant is clear. Each wash consists of suspending the cells in a minimum of 2 volumes of PBS, centrifuging the cells at 1800 *g* for 5 min to pack, and discarding the supernatant. Treat the packed cells with papain solution according to the manufacturer's instructions and wash the cells 4 times with PBS.

Red blood cells may be stored for not more than 1 week in a preservative solution at 2-8 °C. A preparation of the following composition is appropriate:

| | |
|---|---|
| Trisodium citrate | 8 g/L |
| D-glucose | 20 g/L |
| Citric acid | 0.5 g/L |
| Sodium chloride | 4.2 g/L |
| Inosine | 0.938 g/L |
| Adenosine triphosphate (ATP) | 0.4 g/L |
| Chloramphenicol | 0.34 g/L |
| Neomycin sulfate | 0.1 g/L |

If using stored cells, wash the cells at least twice in PBS or until the supernatant is clear before proceeding.

*Microtitre plates*. Use V-bottomed rigid microtitre plates.

*Reference standards*. *Immunoglobulin (anti-A, anti-B antibodies test positive control) BRP* and *Immunoglobulin (anti-A, anti-B antibodies test negative control) BRP* are suitable for use as the positive control and negative control, respectively, and should be used as guides for operators establishing and performing the direct method for anti-A and anti-B haemagglutinins.

*Immunoglobulin for anti-A and anti-B antibodies limit test BRP* defines the recommended maximum limits permissible for batches of human immunoglobulin and must be used only for comparison with batches of human immunoglobulin that have higher titres than the positive control.

*METHOD*

The test described in this chapter is performed at room temperature on the positive control solutions, the negative control solutions and the test solutions at the same time and under identical conditions. Whenever necessary, a further test is performed with *Immunoglobulin for anti-A and anti-B antibodies limit test BRP*.

*Reference solutions*. Reconstitute the positive control and the negative control according to the instructions. The immunoglobulin G (IgG) concentration is 50 g/L in each of the reconstituted preparations. Make a 2-fold dilution of each reconstituted preparation with PBS-BSA solution to obtain solutions containing IgG at 25 g/L. Prepare 7 further serial 2-fold dilutions of each preparation using PBS-BSA solution to extend the dilution range to 1/256 (0.195 g/L IgG). Add 20 µL of each dilution of each preparation in triplicate to the microtitre plate.

*Test solutions*. Dilute the preparation to be examined with PBS-BSA solution to obtain a starting IgG concentration of 25 g/L. For 50 g/L preparations, this is a 2-fold dilution; adjust the dilution factor accordingly for preparations with an IgG concentration other than 50 g/L to obtain a starting concentration of 25 g/L for testing. This 25 g/L solution is assigned a nominal 2-fold dilution factor for comparison with the reference solutions, even if this does not reflect the true dilution factor used to achieve 25 g/L. Prepare 7 further serial 2-fold dilutions of the preparation using PBS-BSA solution to extend the nominal dilution range to 1/256 (0.195 g/L IgG) for comparison with the reference preparations over the same IgG concentration range. Add 20 µL of each dilution in triplicate to the microtitre plate.

For preparations with an IgG concentration lower than 25 g/L, dilute to a starting concentration corresponding to the nearest lower concentration of the reference solutions. This solution is assigned the same nominal dilution factor as the corresponding reference solution having the same IgG concentration. Proceed with the preparation of the appropriate 2-fold dilution series as described above.

Prepare 3 per cent *V/V* suspensions of papain-treated D-negative $A_1$, B and O red blood cells in PBS/BSA solution. Add 20 µL of D-negative $A_1$, B and O red blood cells respectively to the 1st, the 2nd and the 3rd dilution series of each of the preparation to be examined, the positive control and the negative control. Mix by shaking the plate on a shaker for 10 s (or until the cells are resuspended).

Centrifuge the plate at 80 *g* at room temperature for 1 min to pack the cells. Place the plate at an angle of approximately 70°. Read after 4-5 min or when the negative controls (D-negative O red blood cells and negative control solution) have streamed. A cell button at the bottom of the well indicates a positive result. A stream of cells represents a negative result.

Record the endpoint titre as the reciprocal of the highest dilution that gives rise to a positive result.

The positive control has nominal anti-A and anti-B titres of 32 (range 32-64 for anti-A; range 16-32 for anti-B) and the negative controls (D-negative O red blood cells and negative control solution) must not show agglutination at the starting dilution of 1 in 2. Users must validate their own test conditions, and investigate their assay conditions and reagents in the event of results being significantly different from those expected. Failure to obtain negative reactions with the negative controls may indicate that, for example, insufficient time has elapsed for the cells to stream, or that reagents have been used directly from cold storage.

If the nominal anti-A or anti-B titre of the preparation to be examined is greater than the titre of the positive control, the test preparation is to be compared with *Immunoglobulin for anti-A and anti-B antibodies limit test BRP*.

The maximum allowable titre is 64.

# 2.6.21. NUCLEIC ACID AMPLIFICATION TECHNIQUES

1. INTRODUCTION

Nucleic acid amplification techniques are based on 2 different approaches:

1. amplification of a target nucleic acid sequence using, for example, polymerase chain reaction (PCR), ligase chain reaction (LCR), or isothermal ribonucleic acid (RNA) amplification;
2. amplification of a hybridisation signal using, for example, for deoxyribonucleic acid (DNA), the branched DNA (bDNA) method; in this case signal amplification is achieved without subjecting the nucleic acid to repetitive cycles of amplification.

In this general chapter, the PCR method is described as the reference technique. Alternative methods may be used, if they comply with the quality requirements described below.

2. SCOPE

This section establishes the requirements for sample preparation, *in vitro* amplification of DNA sequences and detection of the specific PCR product. With the aid of PCR, defined DNA sequences can be detected. RNA sequences can also be detected following reverse transcription of the RNA to complementary DNA (cDNA) and subsequent amplification.

3. PRINCIPLE OF THE METHOD

PCR is a procedure that allows specific *in vitro* amplification of segments of DNA or of RNA after reverse transcription into cDNA.

Following denaturation of double-stranded DNA into single-stranded DNA, 2 synthetic oligonucleotide primers of opposite polarity anneal to their respective complementary sequences in the DNA to be amplified. The short double-stranded regions that form as a result of specific base pairing between the primers and the complementary DNA sequence border the DNA segment to be amplified, and serve as starting positions for *in vitro* DNA synthesis by means of a heat-stable DNA polymerase.

Amplification of the DNA occurs in cycles consisting of:

- heat denaturation of the nucleic acid (target sequence) into 2 single strands;
- specific annealing of the primers to the target sequence under suitable reaction conditions;
- extension of the primers, which are bound to both single strands, by DNA polymerase at a suitable temperature (DNA synthesis).

Repeated cycles of heat denaturation, primer annealing and DNA synthesis results in an exponential amplification of the DNA segment limited by the primers.

The specific PCR product known as an amplicon can be detected by a variety of methods of appropriate specificity and sensitivity.

Multiplex PCR assays use several primer pairs designed for simultaneous amplification of different targets in one reaction.

4. TEST MATERIAL

Because of the high sensitivity of PCR, the samples must be protected against external contamination with target sequences. Sampling, storage and transport of the test material are performed under conditions that minimise degradation of the target sequence. In the case of RNA target sequences, special precautions are necessary since RNA is highly sensitive to degradation by ribonucleases. Care must be taken since some added reagents, such as anticoagulants or preservatives, may interfere with the test procedure.

5. TEST METHOD

**5.1. Prevention of contamination**

The risk of contamination requires a strict segregation of the areas depending on the material handled and the technology used. Points to consider include movement of personnel, gowning, material flow and air supply and decontamination procedures.

The system should be sub-divided into compartments such as:

- master-mix area (area where exclusively template-free material is handled, e.g. primers, buffers, etc.);
- pre-PCR (area where reagents, samples and controls are handled);
- PCR amplification (amplified material is handled in a closed system);
- post-PCR detection (the only area where the amplified material is handled in an open system).

If closed systems are used, the strict segregation of areas is not required.

**5.2. Sample preparation**

When preparing samples, the target sequence to be amplified needs to be efficiently extracted or liberated from the test material in a reproducible manner and in such a way that amplification under the selected reaction conditions is possible. A variety of physico-chemical extraction procedures and/or enrichment procedures may be employed.

Additives present in test material may interfere with PCR. The procedures described under 7.3.2. must be used as a control for the presence of inhibitors originating from the test material.

In the case of RNA-templates, care must be taken to avoid ribonuclease activity.

**5.3. Amplification**

PCR amplification of the target sequence is conducted under defined cycling conditions (temperature profile for denaturation of double-stranded DNA, annealing and extension of primers; incubation times at selected temperatures; ramp rates). These depend on various parameters such as:

- the length and base composition of primer and target sequences;
- the type of DNA polymerase, buffer composition and reaction volume used for the amplification;
- the type of thermocycler used and the thermal conductivity rate between the apparatus, reaction tube and reaction fluid.

**5.4. Detection**

The amplicon generated by PCR may be identified by size, sequence, chemical modification or a combination of these parameters. Detection and characterisation by size may be achieved by gel electrophoresis (using agarose or polyacrylamide slab gels or capillary electrophoresis) or column chromatography (for example, liquid chromatography). Detection and characterisation by sequence composition may be achieved by the specific hybridisation of probes having a sequence complementary to the target sequence or by cleavage of the amplified material reflecting target-specific restriction-enzyme sites. Detection and characterisation by chemical modification may be achieved by, for example, incorporation of a fluorophore into the amplicons and subsequent detection of fluorescence following excitation.

Detection of amplicons may also be achieved by using probes labelled to permit a subsequent chemiluminescent, radioisotopic or immuno-enzyme-coupled detection.

6. EVALUATION AND INTERPRETATION OF RESULTS

A valid result is obtained within a test only if the positive control(s) is unambiguously positive and the negative control(s) is unambiguously negative. Due to the very high sensitivity of the PCR method and the inherent risk of contamination, it is necessary to confirm positive results by repeating the complete test procedure in duplicate, where possible on a new aliquot of the sample. The sample is considered positive if at least one of the repeat tests gives a positive result. As soon as a measurable target threshold is defined, a quantitative test system is required.

7. QUALITY ASSURANCE

**7.1. Validation of the PCR assay system**

The validation programme must include validation of instrumentation and the PCR method employed. Reference should be made to the ICH guideline Q2(R1) Validation of Analytical Procedures: Text and Methodology.

Appropriate official working reference preparations or in-house reference preparations calibrated against International Standards for the target sequences are used for validation of a PCR test, when available.

*7.1.1. Determination of the positive cut-off point*

During validation of qualitative tests, the positive cut-off point must be determined. The positive cut-off point is defined as the minimum number of target sequences per volume sample that can be detected in 95 per cent of test runs. The positive cut-off point depends on interrelated factors such as the volume of the sample extracted and the efficacy of the extraction methodology, the transcription of the target RNA into cDNA, the amplification process and the detection.

To define the detection limit of the assay system, reference must be made to the positive cut-off point for each target sequence and the test performance above and below the positive cut-off point.

*7.1.2. Quantitative assay systems*

For a quantitative assay, the following parameters are determined during validation: accuracy, precision, specificity, quantitation limit, linearity, range and robustness.

**7.2. Quality control of reagents**

All reagents crucial for the methodology used have to be controlled prior to use in routine applications. Their acceptance/withdrawal is based on pre-defined quality criteria.

Primers are a crucial component of the PCR assay and as such their design, their purity and the validation of their use in a PCR assay require careful attention. Primers may be modified (for example, by conjugation with a fluorophore or antigen) in order to permit a specific method of detection of the amplicon, provided such modifications do not inhibit accurate and efficient amplification of the target sequence.

**7.3. Run controls**

*7.3.1. External controls*

In order to minimise the risk of contamination and to ensure adequate sensitivity, the following external controls are included in each PCR assay:

- positive control: this contains a defined number of target-sequence copies, the number being close to the positive cut-off value, and determined individually for each assay system and indicated as a multiple of the positive cut-off value of the assay system;
- negative control: a sample of a suitable matrix already proven to be free of the target sequences.

*7.3.2. Internal control*

Internal controls are defined nucleic acid sequences containing, unless otherwise prescribed, the primer binding sites. Internal controls must be amplified with defined efficacy, and the amplicons must be clearly discernible. Internal controls must be of the same type of nucleic acid (DNA/RNA) as the material to be tested. The internal control is preferably added to the test material before isolating the nucleic acid and therefore acts as an overall control (extraction, reverse transcription, amplification, detection).

*7.3.3. Threshold control*

The threshold control for quantitative assays is a test sample with the analyte at a concentration that is defined as the threshold not to be exceeded. It contains the analyte suitably calibrated in International Units and is analysed in parallel in each run of a quantitative assay.

**7.4. External quality assessment**

Participation in external quality assessment programmes is an important PCR quality assurance procedure for each laboratory and each operator.

*The following sections are published for information.*

## Validation of nucleic acid amplification techniques (NAT) for the detection of hepatitis C virus (HCV) RNA in plasma pools: guidelines

1. SCOPE

The majority of nucleic acid amplification analytical procedures are qualitative (quantal) tests for the presence of nucleic acid with some quantitative tests (either in-house or commercial) being available. For the detection of HCV RNA contamination of plasma pools, qualitative tests are adequate and may be considered to be a limit test for the control of impurities as described in the *Pharmeuropa* Technical Guide for the elaboration of monographs, December 1999, Chapter III 'Validation of analytical procedures'. These guidelines describe methods to validate only qualitative nucleic acid amplification analytical procedures for assessing HCV RNA contamination of plasma pools. Therefore, the 2 characteristics regarded as the most important for validation of the analytical procedure are the specificity and the detection limit. In addition, the robustness of the analytical procedure should be evaluated.

However, this document may also be used as a basis for the validation of nucleic acid amplification in general.

For the purpose of this document, an analytical procedure is defined as the complete procedure from extraction of nucleic acid to detection of the amplified products.

Where commercial kits are used for part or all of the analytical procedure, documented validation points already covered by the kit manufacturer can substitute for the validation by the user. Nevertheless, the performance of the kit with respect to its intended use has to be demonstrated by the user (e.g. detection limit, robustness, cross-contamination).

2. SPECIFICITY

Specificity is the ability to assess unequivocally nucleic acid in the presence of components that may be expected to be present.

The specificity of nucleic acid amplification analytical procedures is dependent on the choice of primers, the choice of probe (for analysis of the final product) and the stringency of the test conditions (for both the amplification and the detection steps).

When designing primers and probes, the specificity of the primers and probes to detect only HCV RNA should be investigated by comparing the chosen sequences with sequences in published data banks. For HCV, primers (and probes) will normally be chosen from areas of the 5' non-coding region of the HCV genome which are highly conserved for all genotypes.

The amplified product should be unequivocally identified by using one of a number of methods such as amplification with nested primers, restriction enzyme analysis, sequencing, or hybridisation with a specific probe.

In order to validate the specificity of the analytical procedure, at least 100 HCV RNA-negative plasma pools should be tested and shown to be non-reactive. Suitable samples of non-reactive pools are available from the European Directorate for the Quality of Medicines & HealthCare (EDQM).

The ability of the analytical procedure to detect all HCV genotypes will again depend on the choice of primers, probes and method parameters. This ability should be demonstrated using characterised reference panels. However, in view of the difficulty in obtaining samples of some genotypes (e.g. genotype 6), the most prevalent genotypes (e.g. genotypes 1 and 3 in Europe) should be detected at a suitable level.

3. DETECTION LIMIT

The detection limit of an individual analytical procedure is the lowest amount of nucleic acid in a sample that can be detected but not necessarily quantitated as an exact value.

The nucleic acid amplification analytical procedure used for the detection of HCV RNA in plasma pools usually yields qualitative results. The number of possible results is limited to 2: either positive or negative. Although the determination of the detection limit is recommended, for practical purposes, a positive cut-off point should be determined for the nucleic acid amplification analytical procedure. The positive cut-off point (as defined in the general chapter *2.6.21*) is the minimum number of target sequences per volume sample that can be detected in 95 per cent of test runs. This positive cut-off point is influenced by the distribution of viral genomes in the individual samples being tested and by factors such as enzyme efficiency, and can result in different 95 per cent cut-off values for individual analytical test runs.

In order to determine the positive cut-off point, a dilution series of a working reagent or of the *hepatitis C virus BRP*, which has been calibrated against the WHO HCV International Standard, should be tested on different days to examine variation between test runs. At least 3 independent dilution series should be tested with a sufficient number of replicates at each dilution to give a total number of 24 test results for each dilution, to enable a statistical analysis of the results.

For example, a laboratory could test 3 dilution series on different days with 8 replicates for each dilution, 4 dilution series on different days with 6 replicates for each dilution, or 6 dilution series on different days with 4 replicates for each dilution. In order to keep the number of dilutions at a manageable level, a preliminary test (using, for example, $\log_{10}$ dilutions of the plasma pool sample) should be carried out in order to obtain a preliminary value for the positive cut-off point (i.e. the highest dilution giving a positive signal). The range of dilutions can then be chosen around the predetermined preliminary cut-off point (using, for example, a dilution factor of 0.5 $\log_{10}$ or less and a negative plasma pool for the dilution matrix). The concentration of HCV RNA that can be detected in 95 per cent of test runs can then be calculated using an appropriate statistical evaluation.

These results may also serve to demonstrate the intra-assay variation and the day-to-day variation of the analytical procedure.

4. ROBUSTNESS

The robustness of an analytical procedure is a measure of its capacity to remain unaffected by small but deliberate variations in method parameters and provides an indication of its reliability during normal usage.

The evaluation of robustness should be considered during the development phase. It should show the reliability of the analytical procedure with respect to deliberate variations in method parameters. For NAT, small variations in the method parameters can be crucial. However, the robustness of the method can be demonstrated during its development when small variations in the concentrations of reagents (e.g. $MgCl_2$, primers or dNTP) are tested. To demonstrate robustness, at least 20 HCV RNA negative plasma pools (selected at random) spiked with HCV RNA to a final concentration of 3 times the previously determined 95 per cent cut-off value should be tested and found positive.

Problems with robustness may also arise with methods that use an initial ultracentrifugation step prior to extraction of the viral RNA. Therefore, to test the robustness of such methods, at least 20 plasma pools containing varying levels of HCV RNA, but lacking HCV-specific antibodies, should be tested and found positive.

Cross-contamination prevention should be demonstrated by the accurate detection of a panel of at least 20 samples consisting of alternate samples of negative plasma pools and negative plasma pools spiked with high concentrations of HCV (at least $10^2$ times the 95 per cent cut-off value or at least $10^4$ IU/mL).

5. QUALITY ASSURANCE

For biological tests such as NAT, specific problems may arise that influence both the validation and the interpretation of results. The test procedures must be described precisely in the form of standard operating procedures (SOPs). These should cover:

- the mode of sampling (type of container, etc.);
- the preparation of mini-pools (where appropriate);
- the conditions of storage before analysis;
- the exact description of the test conditions, including precautions taken to prevent cross-contamination or destruction of the viral RNA, reagents and reference preparations used;
- the exact description of the apparatus used;
- the detailed formulae for calculation of results, including statistical evaluation.

The use of a suitable run control (for example, an appropriate dilution of *hepatitis C virus BRP* or plasma spiked with an HCV sample calibrated against the WHO HCV International Standard) can be considered a satisfactory system-suitability check and ensures that the reliability of the analytical procedure is maintained whenever used.

*Technical qualification*. An appropriate installation and operation qualification programme should be implemented for each critical piece of the equipment used. For confirmation of analytical procedure performance after a change of critical equipment (e.g. thermocyclers), the change should be documented by conducting a parallel test on 8 samples of a plasma pool that is spiked with HCV RNA to a final concentration of 3 times the previously determined 95 per cent cut-off value. All results should be positive.

*Operator qualification*. An appropriate qualification programme should be implemented for each operator involved in the testing.

## Validation of nucleic acid amplification techniques (NAT) for the quantification of B19 virus (B19V) DNA in plasma pools: guidelines

1. SCOPE

The European Pharmacopoeia requires that plasma pools used for manufacture of certain products are tested for the presence of B19 virus (B19V) DNA with a threshold concentration that must not be exceeded. In order to comply with these requirements, quantitative NAT tests are preferred. The characteristics regarded as the most important for validation of the quantitative NAT procedure are accuracy, precision, specificity, quantitation limit, linearity and range. In addition, the robustness of the analytical procedure should be evaluated.

This guideline describes methods to validate NAT analytical procedures for assessing B19V DNA contamination of plasma pools based on the ICH guidelines. However, this document may also be used as a basis for the validation of quantitative NAT in general.

For the purpose of this document, an analytical procedure is defined as the complete procedure from extraction of nucleic acid to detection of the amplified products.

Where commercial kits are used for part or all of the analytical procedure, documented validation points already covered by the kit manufacturer can substitute for the validation by the user. Nevertheless, the performance of the kit with respect to its intended use has to be demonstrated by the user (e.g. precision, accuracy, range, robustness).

2. ACCURACY

Accuracy expresses the closeness of agreement between the value that is accepted as either a conventional true value or an accepted reference value and the value found. The accuracy of an assay is dependent on the calibration of the assay and on the variance of the different assay steps. Though it is recommended to establish the accuracy across the specified range of the analytical procedure, the most important assessment of accuracy is in the range of the threshold concentration. In the case of B19V NAT assays for investigation of plasma pools it is recommended to assess the accuracy of the calibrated assay by assaying at least 5 concentrations (dilution factor of 0.5 $\log_{10}$) of *B19 virus DNA for NAT testing BRP* or another material, suitably calibrated in International Units against the actual WHO B19 DNA International Standard, covering the range of the currently recommended threshold concentration of 10.0 IU/µL B19V DNA (e.g. $10^5$ IU/mL, $10^{4.5}$ IU/mL, $10^4$ IU/mL, $10^{3.5}$ IU/mL and $10^3$ IU/mL), with at least 3 replicates for each dilution. Accuracy should be reported for the different concentrations in terms of percentage determined compared with the known amount of B19V DNA. It should reflect the level of technology of the respective assays, which should also be defined, for example in collaborative studies.

3. PRECISION

Precision expresses the closeness of agreement between a series of measurements, obtained from multiple sampling of the same homogenous sample. The precision is defined at 3 levels:

- repeatability expresses the precision under the same operating conditions over a short interval of time (intra-assay precision); it is assessed by using 1 assay and testing 3 replicates of appropriate dilutions of a B19V DNA-positive sample suitably calibrated in International Units and covering the whole quantitative range of the assay; the coefficient of variation for the individual samples is calculated (intra-assay variability);
- intermediate precision expresses the intra-laboratory variations (inter-assay precision); it is established by assaying replicates (as routinely used for the assay) of appropriate dilutions of a B19V DNA-positive sample suitably calibrated in International Units covering the whole quantitative range of the assay under different circumstances (e.g. different days, different analysts, different equipment, different reagents); the coefficient of variation for the individual samples is calculated;
- reproducibility expresses the precision between different laboratories (inter-laboratory precision); it is assessed by participation in quantitative collaborative studies on B19V DNA-NAT assays, e.g. under the Proficiency Testing Scheme (PTS), including the comparative analysis of the obtained quantitative results, where appropriate.

4. SPECIFICITY

Specificity expresses the ability to assess unequivocally nucleic acid in the presence of components that may be expected to be present. The specificity of NAT analytical procedures is dependent on the choice of primers, the choice of probe (for analysis of the final product) and the stringency of the test conditions (for both the amplification and the detection steps).

When designing primers and probes, the specificity of the primers and probes to detect only human B19V DNA should be investigated by comparing the chosen sequences with sequences in published data banks. There should be no major homology found with sequences unrelated to B19V.

The amplified product should be unequivocally identified by using one of a number of methods such as amplification with nested primers, restriction enzyme analysis, sequencing, or hybridisation with a specific probe.

In order to examine the specificity of the analytical procedure, at least 20 B19V DNA-negative plasma pools should be tested and shown to be non-reactive.

*Parvovirus B19 genotypes.* The International Committee on Taxonomy of Viruses (ICTV) has classified representatives of the 3 genotypes as strains of human parvovirus B19. Genotype 1 represents prototype B19V, genotype 2 represents viral sequences like A6, and genotype 3 represents V9-like sequences. By performing sequence alignment with respective B19V genotype sequences available from nucleic acid sequence databases, primers and probes should be designed to detect and quantify consistently the different human parvovirus B19 genotypes. Reference materials should be used to check the approach chosen. Since biological reference preparations reflecting some genotypes might be difficult to obtain, respective plasmid preparations or synthetic nucleic acids may also serve as a characterised target sequence source. However, those cannot be used to validate the extraction procedure.

5. QUANTITATION LIMIT

The quantitation limit is the lowest amount of nucleic acid in a sample that can be determined quantitatively with suitable precision and accuracy. The quantitation limit of the B19V NAT assay is assessed during the repeatability and intermediate-precision studies by limiting dilution analysis. The lowest concentration of target nucleic acids that is quantitated with suitable precision and accuracy is defined.

6. LINEARITY

The linearity of an assay is its ability to obtain test results that are directly proportional to the concentration of the nucleic acid. The linearity of the B19V NAT assay is assessed during the repeatability and intermediate-precision studies by testing replicates of diluted samples with the concentrations covering the whole quantitative range. The interval between the upper and the lower concentration of the target nucleic acid where test results are directly proportional to the concentrations is defined.

7. RANGE

The range of an assay is the interval between the upper and the lower concentration of nucleic acid in the sample for which it has been demonstrated that the procedure has a suitable level of precision, accuracy and linearity. The range of the B19V NAT assay is assessed during the repeatability and intermediate-precision studies by testing replicates of diluted samples. The interval between the upper and the lower concentration that can be expressed with an acceptable degree of accuracy and precision is defined.

8. ROBUSTNESS

The robustness of an analytical procedure is a measure of its capacity to remain unaffected by small but deliberate variations in method parameters and provides an indication of its reliability during normal usage. The evaluation of robustness should be considered during the development phase. It should show the reliability of the analytical procedure with respect to deliberate variations in method parameters. For NAT, small variations in the method parameters can be crucial. Nonetheless, the robustness of NAT can be demonstrated during the development of the method when small variations in the concentrations of reagents, for example $MgCl_2$, primers or dNTP, are tested. To demonstrate robustness, at least 20 B19V DNA-negative plasma pool samples spiked with B19V DNA at the threshold concentration should be tested and found to have acceptable quantitative values.

Cross-contamination prevention should be demonstrated by the accurate detection of a panel of at least 20 samples consisting of alternate samples of plasma pools without B19V DNA or with levels below the threshold concentration

(10 samples) and plasma pools spiked with high concentrations of B19V DNA (at least $10^2$ times the threshold level, 10 samples).

9. QUALITY ASSURANCE

For biological tests such as NAT, specific problems may arise that may influence both the validation and the interpretation of results. The test procedures must be described precisely in the form of standard operating procedures (SOPs). These should cover:

- the mode of sampling (type of container, etc.);
- the preparation of mini-pools by manufacturers (where appropriate);
- the conditions of storage before analysis;
- the exact description of the test conditions including precautions taken to prevent cross-contamination or destruction of the viral nucleic acids, reagents and reference preparations used;
- the exact description of the apparatus used;
- the detailed formulae for calculation of results, including statistical evaluation.

The inclusion of an appropriate threshold control (for example, plasma spiked with a B19V DNA sample suitably calibrated in International Units, such as *B19 virus DNA for NAT testing BRP*) is considered to be a satisfactory system-suitability check and ensures that the reliability of the analytical procedure is maintained whenever used.

*Technical qualification.* An appropriate installation and operation qualification programme should be implemented for each critical piece of the equipment used. For confirmation of analytical procedure performance after a change of critical equipment (e.g. thermocyclers), the change should be documented by conducting a parallel test on 8 samples of a plasma pool that is spiked with a concentration of B19V DNA around the threshold concentration. All results should be acceptable and reflect the features of the assay as determined during the validation phase.

*Operator qualification.* An appropriate qualification programme should be implemented for each operator involved in the testing.

## 2.6.22. ACTIVATED COAGULATION FACTORS

Where applicable, determine the amount of heparin present (*2.7.12*) and neutralise the heparin, for example by addition of *protamine sulfate R* (10 µg of protamine sulfate neutralises 1 IU of heparin). Prepare 1 to 10 and 1 to 100 dilutions of the preparation to be examined using *tris(hydroxymethyl)aminomethane buffer solution pH 7.5 R*. Place a series of polystyrene tubes in a water-bath at 37 °C and add to each tube 0.1 mL of *platelet-poor plasma R* and 0.1 mL of a suitable dilution of a phospholipid preparation to act as a platelet substitute. Allow to stand for 60 s. Add to each tube either 0.1 mL of 1 of the dilutions or 0.1 mL of the buffer solution (control tube). To each tube add immediately 0.1 mL of a 3.7 g/L solution of *calcium chloride R* previously heated to 37 °C, and measure, within 30 min of preparing the original dilution, the time that elapses between addition of the calcium chloride solution and the formation of a clot. The test is not valid unless the coagulation time measured for the control tube is 200 s to 350 s.

**04/2014:20624**

## 2.6.24. AVIAN VIRAL VACCINES: TESTS FOR EXTRANEOUS AGENTS IN SEED LOTS

GENERAL PROVISIONS

a) In the following tests, chickens and/or chicken material such as eggs and cell cultures shall be derived from chicken flocks free from specified pathogens (SPF) (*5.2.2*).

b) Cell cultures for the testing of extraneous agents comply with the requirements for the master cell seed of general chapter *5.2.4. Cell cultures for the production of veterinary vaccines*, with the exception of the karyotype test and the tumorigenicity test, which do not have to be carried out.

c) In tests using cell cultures, precise specifications are given for the number of replicates, monolayer surface areas and minimum survival rate of the cultures. Alternative numbers of replicates and cell surface areas are possible as well, provided that a minimum of 2 replicates are used, the total surface area and the total volume of test substance applied are not less than that prescribed here and the survival rate requirements are adapted accordingly.

d) For a freeze-dried preparation, reconstitute using a suitable liquid. Unless otherwise stated or justified, the test substance must contain a quantity of virus equivalent to at least 10 doses of vaccine in 0.1 mL of inoculum.

e) If the virus of the seed lot would interfere with the conduct and sensitivity of the test, neutralise the virus in the preparation with a monospecific antiserum.

f) Monospecific antiserum and serum of avian origin used for cell culture or any other purpose, in any of these tests, shall be free from antibodies against and free from inhibitory effects on the organisms listed hereafter under 7. Antibody specifications for sera used in extraneous agents testing.

g) Where specified in a monograph or otherwise justified, if neutralisation of the virus of the seed lot is required but difficult to achieve, the tests described below are adapted, as required, to provide the necessary guarantees of freedom from contamination with an extraneous agent.

h) Other types of tests than those indicated may be used, provided they are at least as sensitive as those indicated and of appropriate specificity. Nucleic acid amplification techniques (*2.6.21*) give specific detection for many agents and can be used after validation for sensitivity and specificity.

1. TEST FOR EXTRANEOUS AGENTS USING EMBRYONATED HENS' EGGS

Use a test substance, diluted if necessary, containing a quantity of neutralised virus equivalent to at least 10 doses of vaccine in 0.2 mL of inoculum. Suitable antibiotics may be added. Inoculate the test substance into 3 groups of 10 embryonated hens' eggs as follows:

- group 1: 0.2 mL into the allantoic cavity of each 9- to 11-day-old embryonated egg;
- group 2: 0.2 mL onto the chorio-allantoic membrane of each 9- to 11-day-old embryonated egg;
- group 3: 0.2 mL into the yolk sac of each 5- to 6-day-old embryonated egg.

Candle the eggs in groups 1 and 2 daily for 7 days and the eggs in group 3 daily for 12 days. Discard embryos that die during the first 24 h as non-specific deaths; the test is not valid unless at least 6 embryos in each group survive beyond the first 24 h after inoculation. Examine macroscopically for abnormalities all embryos that die more than 24 h after inoculation, or that survive the incubation period. Examine

also the chorio-allantoic membranes of these eggs for any abnormality and test the allantoic fluids for the presence of haemagglutinating agents.

Carry out a further embryo passage. Pool separately material from live and from the dead and abnormal embryos. Inoculate each pool into 10 eggs for each route as described above, chorio-allantoic membrane material being inoculated onto chorio-allantoic membranes, allantoic fluids into the allantoic cavity and embryo material into the yolk sac. For eggs inoculated by the allantoic and chorio-allantoic routes, candle the eggs daily for 7 days, proceeding and examining the material as described above. For eggs inoculated by the yolk sac route, candle the eggs daily for 12 days, proceeding and examining the material as described above.

The seed lot complies with the test if no test embryo shows macroscopic abnormalities or dies from causes attributable to the seed lot and if examination of the chorio-allantoic membranes and testing of the allantoic fluids show no evidence of the presence of any extraneous agent.

2. TEST IN CHICKEN KIDNEY CELLS

Prepare 7 monolayers of chicken kidney cells, each monolayer having an area of about 25 $cm^2$. Maintain 2 monolayers as negative controls and treat these in the same way as the 5 monolayers inoculated with the test substance, as described below. Remove the culture medium when the cells reach confluence. Inoculate 0.1 mL of the test substance onto each of the 5 monolayers. Allow adsorption for 1 h, add culture medium and incubate the cultures for a total of at least 21 days, subculturing at 4- to 7-day intervals. Each passage is made with pooled cells and fluids from all 5 monolayers after carrying out a freeze-thaw cycle. Inoculate 0.1 mL of pooled material onto each of 5 recently prepared monolayers of about 25 $cm^2$ each, at each passage. For the last passage, grow the cells also on a suitable substrate so as to obtain an area of about 10 $cm^2$ of cells from each of the monolayers for test A. The test is not valid if less than 80 per cent of the monolayers survive after any passage.

Examine microscopically all the cell cultures frequently throughout the entire incubation period for any signs of cytopathic effect or other evidence of the presence of contaminating agents in the test substance. At the end of the total incubation period, carry out the following procedures.

A. Fix and stain (with Giemsa or haematoxylin and eosin) about 10 $cm^2$ of confluent cells from each of the 5 monolayers. Examine the cells microscopically for any cytopathic effect, inclusion bodies, syncytial formation, or other evidence of the presence of contaminating agents from the test substance.

B. Drain and wash about 25 $cm^2$ of cells from each of the 5 monolayers. Cover these cells with a 0.5 per cent suspension of washed chicken erythrocytes (using at least 1 mL of suspension for each 5 $cm^2$ of cells). Incubate the cells at 4 °C for 20 min and then wash gently in phosphate buffered saline pH 7.4. Examine the cells microscopically for haemadsorption attributable to the presence of a haemadsorbing agent in the test substance.

C. Test individual samples of the fluids from each cell culture using chicken erythrocytes for haemagglutination attributable to the presence of a haemagglutinating agent in the test substance.

The test is not valid if there are any signs of extraneous agents in the negative control cultures. The seed lot complies with the test if there is no evidence of the presence of any extraneous agent.

3. TEST FOR AVIAN LEUCOSIS VIRUSES

Prepare at least 13 replicate monolayers of either DF-1 cells or primary or secondary chick embryo fibroblasts from the tissues of 9- to 11-day-old embryos that are known to be genetically susceptible to subgroups A, B and J of avian leucosis viruses and that support the growth of exogenous but not endogenous avian leucosis viruses (cells from C/E strain chickens are suitable). Each replicate shall have an area of about 50 $cm^2$.

Remove the culture medium when the cells reach confluence. Inoculate 0.1 mL of the test substance onto each of 5 of the replicate monolayers. Allow adsorption for 1 h, and add culture medium. Inoculate 2 of the replicate monolayers with subgroup A avian leucosis virus (not more than 10 $CCID_{50}$ in 0.1 mL), 2 with subgroup B avian leucosis virus (not more than 10 $CCID_{50}$ in 0.1 mL) and 2 with subgroup J avian leucosis virus (not more than 10 $CCID_{50}$ in 0.1 mL) as positive controls. Maintain not fewer than 2 non-inoculated replicate monolayers as negative controls.

Incubate the cells for a total of at least 9 days, subculturing at 3- to 4-day intervals. Retain cells from each passage level and harvest the cells at the end of the total incubation period. Wash cells from each passage level from each replicate and resuspend the cells at $10^7$ cells per millilitre in barbital-buffered saline for subsequent testing by a Complement Fixation for Avian Leucosis (COFAL) test or in phosphate buffered saline for testing by Enzyme-Linked Immunosorbent Assay (ELISA). Then, carry out 3 cycles of freezing and thawing to release any group-specific antigen and perform a COFAL test or an ELISA test on each extract to detect group-specific avian leucosis antigen if present.

The test is not valid if group-specific antigen is detected in fewer than 5 of the 6 positive control replicate monolayers or if a positive result is obtained in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive. If the results for more than 1 of the test replicate monolayers are inconclusive, then further subcultures of reserved portions of the fibroblast monolayers shall be made and tested until an unequivocal result is obtained. If a positive result is obtained for any of the test monolayers, then the presence of avian leucosis virus in the test substance has been detected.

The seed lot complies with the test if there is no evidence of the presence of any avian leucosis virus.

4. TEST FOR AVIAN RETICULOENDOTHELIOSIS VIRUS

Prepare 11 monolayers of primary or secondary chick embryo fibroblasts from the tissues of 9- to 11-day old chick embryos or duck embryo fibroblasts from the tissues of 13- to 14-day-old embryos, each monolayer having an area of about 25 $cm^2$.

Remove the culture medium when the cells reach confluence. Inoculate 0.1 mL of the test substance onto each of 5 of the monolayers. Allow adsorption for 1 h, and add culture medium. Inoculate 4 of the monolayers with avian reticuloendotheliosis virus as positive controls (not more than 10 $CCID_{50}$ in 0.1 mL). Maintain 2 non-inoculated monolayers as negative controls.

Incubate the cells for a total of at least 10 days, subculturing twice at 3- to 4-day intervals. The test is not valid if fewer than 3 of the 4 positive controls or fewer than 4 of the 5 test monolayers or neither of the 2 negative controls survive after any passage.

For the last subculture, grow the fibroblasts on a suitable substrate so as to obtain an area of about 10 $cm^2$ of confluent fibroblasts from each of the original 11 monolayers for the subsequent test: test about 10 $cm^2$ of confluent fibroblasts derived from each of the original 11 monolayers by immunostaining for the presence of avian reticuloendotheliosis virus. The test is not valid if avian reticuloendotheliosis virus is detected in fewer than 3 of the 4 positive control monolayers or in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive. If the results for more than 1 of the test monolayers are inconclusive then further subcultures of reserved portions of the fibroblast monolayers shall be made and tested until an unequivocal result is obtained.

The seed lot complies with the test if there is no evidence of the presence of avian reticuloendotheliosis virus.

5. TEST FOR CHICKEN ANAEMIA VIRUS

Prepare eleven 20 mL suspensions of the MDCC-MSBI cell line or another cell line of equivalent sensitivity in 25 $cm^2$ cell culture flasks containing about $5 \times 10^5$ cells/mL. Inoculate 0.1 mL of the test substance into each of 5 flasks. Inoculate 4 of the suspensions with 10 $CCID_{50}$ chicken anaemia virus as positive controls. Maintain not fewer than 2 non-inoculated suspensions. Maintain all the cell cultures for a total of at least 24 days, subculturing 8 times at 3- to 4-day intervals. During the subculturing the presence of chicken anaemia virus may be indicated by a metabolic colour change in the infected cultures, the culture fluids becoming red in comparison with the control cultures. Examine the cells microscopically for cytopathic effect. At this time or at the end of the incubation period, centrifuge the cells from each flask at low speed and resuspend at about $10^6$ cells/mL and place 25 µL in each of 10 wells of a multi-well slide. Examine the cells by immunostaining.

The test is not valid if chicken anaemia virus is detected in fewer than 3 of the 4 positive controls or in any of the non-inoculated controls. If the results for more than 1 of the test suspensions are inconclusive, then further subcultures of reserved portions of the test suspensions shall be made and tested until an unequivocal result is obtained.

The seed lot complies with the test if there is no evidence of the presence of chicken anaemia virus.

6. TEST FOR EXTRANEOUS AGENTS USING CHICKS

Inoculate each of at least 10 chicks with the equivalent of 100 doses of vaccine by the intramuscular route and with the equivalent of 10 doses by eye-drop. Chicks that are 2 weeks of age are used in the test except that if the seed virus is pathogenic for birds of this age, older birds may be used, if required and justified. In exceptional cases, for inactivated vaccines, the virus may be neutralised by specific antiserum if the seed virus is pathogenic for birds at the age of administration. Repeat these inoculations 2 weeks later. Observe the chicks for a period of 5 weeks from the day of the first inoculation. No antimicrobial agents shall be administered to the chicks during the test period. The test is not valid if fewer than 80 per cent of the chicks survive to the end of the test period.

Collect serum from each chick at the end of the test period. Test each serum sample for antibodies against each of the agents listed below (with the exception of the virus type of the seed lot) using one of the methods indicated for testing for the agent.

Clinical signs of disease in the chicks during the test period (other than signs attributable to the virus of the seed lot) and the detection of antibodies in the chicks after inoculation (with the exception of antibodies to the virus of the seed lot), are classed as evidence of the presence of an extraneous agent in the seed lot.

It is recommended that sera from these birds is retained so that additional testing may be carried out if requirements change.

**A. Standard tests**

| Agent | Type of test |
|---|---|
| Avian adenoviruses, group 1 | SN, EIA, AGP |
| Avian encephalomyelitis virus | AGP, EIA |
| Avian infectious bronchitis virus | EIA, HI |
| Avian infectious laryngotracheitis virus | SN, EIA, IS |
| Avian leucosis viruses | SN, EIA |
| Avian nephritis virus | IS |
| Avian orthoreoviruses | IS, EIA |
| Avian reticuloendotheliosis virus | AGP, IS, EIA |
| Chicken anaemia virus | IS, EIA, SN |
| Egg drop syndrome virus | HI, EIA |
| Avian infectious bursal disease virus | Serotype 1: AGP, EIA, SN<br>Serotype 2: SN |
| Influenza A virus | AGP, EIA, HI |
| Marek's disease virus | AGP |
| Newcastle disease virus | HI, EIA |
| Turkey rhinotracheitis virus | EIA |
| *Salmonella pullorum* | Agg |

Agg: agglutination
AGP: agar gel precipitation
EIA: enzyme immunoassay (e.g. ELISA)
HI: haemagglutination inhibition
IS: immunostaining (e.g. fluorescent antibody)
SN: serum neutralisation

**B. Additional tests for turkey extraneous agents**

If the seed virus is of turkey origin or was propagated in turkey substrates, tests for antibodies against the following agents are also carried out.

| Agent | Type of test |
|---|---|
| *Chlamydia* spp. | EIA |
| Avian infectious haemorrhagic enteritis virus | AGP |
| Avian paramyxovirus 3 | HI |
| Avian infectious bursal disease virus type 2 | SN |

A test for freedom from turkey lympho-proliferative disease virus is carried out by intraperitoneal inoculation of twenty 4-week-old turkey poults. Observe the poults for 40 days. The test is not valid if more than 20 per cent of the poults die from non-specific causes. The seed lot complies with the test if sections of spleen and thymus taken from 10 poults 2 weeks after inoculation show no macroscopic or microscopic lesions (other than those attributable to the seed lot virus) and no poult dies from causes attributable to the seed lot.

**C. Additional tests for duck extraneous agents**

If the seed virus is of duck origin or was propagated in duck substrates, tests for antibodies against the following agents are also carried out.

| Agent | Type of test |
|---|---|
| *Chlamydia* spp. | EIA |
| Duck and goose parvoviruses | SN, EIA |
| Duck enteritis virus | SN |
| Duck hepatitis virus type I | SN |

The seed lot complies with the test if there is no evidence of the presence of any extraneous agent.

**D. Additional tests for goose extraneous agents**

If the seed virus is of goose origin or was prepared in goose substrates, tests for the following agents are also carried out.

| Agent | Type of test |
|---|---|
| Duck and goose parvovirus | SN, EIA |
| Duck enteritis virus | SN |
| Goose haemorrhagic polyomavirus | test in goslings shown below or another suitable test |

Inoculate subcutaneously the equivalent of at least 10 doses to each of ten 1-day-old susceptible goslings. Observe the goslings for 28 days. The test is not valid if more than

20 per cent of the goslings die from non-specific causes. The seed virus complies with the test if no gosling dies from causes attributable to the seed lot.

7. ANTIBODY SPECIFICATIONS FOR SERA USED IN EXTRANEOUS AGENTS TESTING

All batches of serum to be used in extraneous agents testing, either to neutralise the vaccine virus (seed lot or batch of finished product) or as a supplement for cell culture media, shall be shown by suitably sensitive tests to be free from antibodies against and free from inhibitory effects on the following micro-organisms - except for one type, namely, antibodies against the virus that they are supposed to neutralise.

Avian adenoviruses

Avian encephalomyelitis virus

Avian infectious bronchitis viruses

Avian infectious bursal disease virus types 1 and 2

Avian infectious haemorrhagic enteritis virus

Avian infectious laryngotracheitis virus

Avian leucosis viruses

Avian nephritis virus

Avian paramyxoviruses 1 to 9

Avian orthoreoviruses

Avian reticuloendotheliosis virus

Chicken anaemia virus

Duck enteritis virus

Duck hepatitis virus type I

Egg drop syndrome virus

Fowl pox virus

Influenza viruses

Marek's disease virus

Turkey herpesvirus

Turkey rhinotracheitis virus

Non-immune serum for addition to culture media can be assumed to be free from antibodies against any of these viruses if the agent is known not to infect the species of origin of the serum and it is not necessary to test the serum for such antibodies. Monospecific antisera for virus neutralisation can be assumed to be free from the antibodies against any of these viruses if it can be shown that the immunising antigen could not have been contaminated with antigens derived from that virus and if the virus is known not to infect the species of origin of the serum; it is not necessary to test the serum for such antibodies. It is not necessary to retest sera obtained from birds from SPF chicken flocks (*5.2.2*).

Batches of sera prepared for neutralising the vaccine virus must not be prepared from any passage level derived from the virus isolate used to prepare the master seed lot or from an isolate cultured in the same cell line.

**04/2015:20625**

## 2.6.25. AVIAN LIVE VIRUS VACCINES: TESTS FOR EXTRANEOUS AGENTS IN BATCHES OF FINISHED PRODUCT

GENERAL PROVISIONS

a) In the following tests, chickens and/or chicken material such as eggs and cell cultures shall be derived from chicken flocks free from specified pathogens (SPF) (*5.2.2*).

b) Cell cultures for the testing of extraneous agents comply with the requirements for the master cell seed of general chapter *5.2.4. Cell cultures for the production of veterinary vaccines*, with the exception of the karyotype test and the tumorigenicity test, which do not have to be carried out.

c) In tests using cell cultures, precise specifications are given for the number of replicates, monolayer surface areas and minimum survival rate of the cultures. Alternative numbers of replicates and cell surface areas are possible as well, provided that a minimum of 2 replicates are used, the total surface area and the total volume of vaccine test applied are not less than that prescribed here and the survival rate requirements are adapted accordingly.

d) In these tests, use the liquid vaccine or reconstitute a quantity of the freeze-dried preparation to be tested with the liquid stated on the label or another suitable diluent such as water for injections. Unless otherwise stated or justified, the test substance contains the equivalent of 10 doses in 0.1 mL of inoculum.

e) If the vaccine virus would interfere with the conduct and sensitivity of the test, neutralise the virus in the preparation with a monospecific antiserum.

f) Monospecific antiserum and serum of avian origin used for cell culture and any other purpose, in any of these tests, shall be free of antibodies against and free from inhibitory effects on the organisms listed under 7. Antibody specifications for sera used in extraneous agents testing (*2.6.24*).

g) Where specified in a monograph or otherwise justified, if neutralisation of the vaccine virus is required but difficult to achieve, the tests described below are adapted, as required, to provide the necessary guarantees of freedom from contamination with an extraneous agent.

If the vaccine virus cannot be completely neutralised – using monospecific antiserum – for the yolk sac inoculation test, the following tests may be performed:

- for enveloped viruses such as Newcastle disease virus: perform the test for extraneous agents using embryonated hens' eggs by the yolk sac route with prior inactivation of enveloped vaccine viruses with lipid solvents,
- for avian encephalomyelitis virus and avian nephritis viruses: perform appropriate tests to detect these viruses. For avian nephritis virus, the test in chicken kidney cells described in section 2 of general chapter *2.6.24. Avian viral vaccines: tests for extraneous agents in seed lots* may be used.

If the vaccine virus cannot be completely neutralised – using monospecific antiserum – for the other tests below, alternatively or in addition to *in vitro* tests conducted on the batch, a test for extraneous agents may be conducted on chick sera obtained from testing the batch of vaccine, as described under 6. Test for extraneous agents using chicks in general chapter *2.6.24. Avian viral vaccines: tests for extraneous agents in seed lots.*

h) Other types of tests than those indicated may be used, provided they are at least as sensitive as those indicated and of appropriate specificity. Nucleic acid amplification techniques (*2.6.21*) give specific detection for many agents and can be used after validation for sensitivity and specificity.

1. TEST FOR EXTRANEOUS AGENTS USING EMBRYONATED HENS' EGGS

Prepare the test vaccine, diluted if necessary, to contain neutralised virus equivalent to 10 doses of vaccine in 0.2 mL of inoculum. Suitable antibiotics may be added. Inoculate the test vaccine into 3 groups of 10 embryonated hens' eggs as follows:

- group 1: 0.2 mL into the allantoic cavity of each 9- to 11-day-old embryonated egg,

– group 2: 0.2 mL onto the chorio-allantoic membrane of each 9- to 11-day-old embryonated egg,
– group 3: 0.2 mL into the yolk sac of each 5- to 6-day-old embryonated egg.

Candle the eggs in groups 1 and 2 daily for 7 days and the eggs in group 3 for 12 days. Discard embryos that die during the first 24 h as non-specific deaths; the test is not valid unless at least 6 embryos in each group survive beyond the first 24 h after inoculation. Examine macroscopically for abnormalities all embryos which die more than 24 h after inoculation, or which survive the incubation period. Examine also the chorio-allantoic membranes of these eggs for any abnormality and test the allantoic fluids for the presence of haemagglutinating agents.

Carry out a further embryo passage. Pool separately material from live and from the dead and abnormal embryos. Inoculate each pool into 10 eggs for each route as described above, chorio-allantoic membrane material being inoculated onto chorio-allantoic membranes, allantoic fluids into the allantoic cavity and embryo material into the yolk sac. For eggs inoculated by the allantoic and chorio-allantoic routes, candle the eggs daily for 7 days, proceeding and examining the material as described above. For eggs inoculated by the yolk sac route, candle the eggs daily for 12 days, proceeding and examining the material as described above.

The batch of vaccine complies with the test if no test embryo shows macroscopic abnormalities or dies from causes attributable to the vaccine and if examination of the chorio-allantoic membranes and testing of the allantoic fluids show no evidence of the presence of extraneous agents.

As previously mentioned under General provisions (paragraph g), if neutralisation of the virus is not possible and as a consequence the yolk sac inoculation cannot be evaluated, suitable tests other than those indicated may be carried out to provide the necessary guarantees of freedom from contamination with an extraneous agent; in particular other tests to detect avian encephalomyelitis and avian nephritis viruses may be carried out. In this case, justification to use other tests must be provided, and the vaccine complies if there is no evidence of the presence of avian encephalomyelitis virus or avian nephritis virus.

2. TEST IN CHICKEN EMBRYO FIBROBLAST CELLS

Prepare 7 monolayers of primary or secondary chicken embryo fibroblasts, from the tissues of 9- to 11-day-old embryos, each monolayer having an area of about 25 $cm^2$. Maintain 2 monolayers as negative controls and treat these in the same way as the 5 monolayers inoculated with the test vaccine, as described below. Remove the culture medium when the cells reach confluence. Inoculate 0.1 mL of test vaccine onto each of 5 of the monolayers. Allow adsorption for 1 h and add culture medium. Incubate the cultures for a total of at least 21 days, subculturing at 4- to 5-day intervals. Each passage is made with pooled cells and fluids from all 5 monolayers after carrying out a freeze-thaw cycle. Inoculate 0.1 mL of pooled material onto each of 5 recently prepared monolayers of chicken embryo fibroblast cells, each monolayer having an area of about 25 $cm^2$ each as before. For the last passage, grow the cells also on a suitable substrate so as to obtain an area of about 10 $cm^2$ of cells from each of the monolayers, for test A. The test is not valid if less than 80 per cent of the test monolayers, or neither of the 2 negative control monolayers survive after any passage.

Examine microscopically all the cell cultures frequently throughout the entire incubation period for any signs of cytopathic effect or other evidence of the presence of contaminating agents in the test vaccine. At the end of the total incubation period, carry out the following procedures.

A. Fix and stain (with Giemsa or haematoxylin and eosin) about 10 $cm^2$ of confluent cells from each of the 5 original monolayers. Examine the cells microscopically for any cytopathic effect, inclusion bodies, syncytial formation, or any other evidence of the presence of a contaminating agent from the test vaccine.
B. Drain and wash about 25 $cm^2$ of cells from each of the 5 monolayers. Cover these cells with a 0.5 per cent suspension of washed chicken red blood cells (using at least 1 mL of suspension for each 5 $cm^2$ of cells). Incubate the cells at 4 °C for 20 min and then wash gently in phosphate buffered saline pH 7.4. Examine the cells microscopically for haemadsorption attributable to the presence of a haemadsorbing agent in the test vaccine.
C. Test individually samples of the fluid from each cell culture using chicken red blood cells for haemagglutination attributable to the presence of a haemagglutinating agent in the test vaccine.

The test is not valid if there are any signs of extraneous agents in the negative control cultures. The batch of vaccine complies with the test if there is no evidence of the presence of any extraneous agent.

3. TEST FOR EGG DROP SYNDROME VIRUS

Prepare 11 monolayers of chicken embryo liver cells, from the tissues of 14- to 16-day-old embryos, each monolayer having an area of about 25 $cm^2$. Remove the culture medium when the cells reach confluence. Inoculate 0.1 mL of test vaccine onto each of 5 of the monolayers (test monolayers). Allow adsorption for 1 h, add culture medium. Inoculate 4 of the monolayers with a suitable strain of egg drop syndrome virus (not more than 10 $CCID_{50}$ in 0.1 mL) to serve as positive control monolayers. Maintain 2 non-inoculated monolayers as negative control monolayers.

Incubate the cells for a total of at least 21 days, subculturing every 4-5 days. Each passage is made as follows: carry out a freeze-thaw cycle; prepare separate pools of the cells plus fluid from the test monolayers, from the positive control monolayers and from the negative control monolayers; inoculate 0.1 mL of the pooled material onto each of 5, 4 and 2 recently prepared monolayers of chicken embryo liver cells, each monolayer having an area of about 25 $cm^2$ as before. The test is not valid if fewer than 4 of the 5 test monolayers or fewer than 3 of the 4 positive controls or neither of the 2 negative control monolayers survive after any passage.

Examine microscopically all the cell cultures at frequent intervals throughout the entire incubation period for any signs of cytopathic effect or other evidence of the presence of a contaminating agent in the test vaccine. At the end of the total incubation period, carry out the following procedure: test separately, cell culture fluid from the test monolayers, positive control monolayers and negative control monolayers, using chicken red blood cells, for haemagglutination attributable to the presence of haemagglutinating agents.

The test is not valid if egg drop syndrome virus is detected in fewer than 3 of the 4 positive control monolayers or in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive. If the results for more than 1 of the test monolayers are inconclusive then further subcultures of reserved portions of the monolayers shall be made and tested until an unequivocal result is obtained.

The batch of vaccine complies with the test if there is no evidence of the presence of egg drop syndrome virus or any other extraneous agent.

4. TEST FOR MAREK'S DISEASE VIRUS

Prepare 11 monolayers of primary or secondary chick embryo fibroblasts from the tissues of 9- to 11-day-old embryos, each monolayer having an area of about 25 $cm^2$. Remove the culture medium when the cells reach confluence. Inoculate 0.1 mL of test vaccine onto each of 5 of the monolayers (test monolayers). Allow adsorption for 1 h, and add culture medium. Inoculate 4 of the monolayers with a suitable strain

of Marek's disease virus (not more than 10 $CCID_{50}$ in 0.1 mL) to serve as positive controls. Maintain 2 non-inoculated monolayers as negative controls.

Incubate the cultures for a total of at least 21 days, subculturing at 4- to 5-day intervals. Each passage is made as follows: trypsinise the cells, prepare separate pools of the cells from the test monolayers, from the positive control monolayers and from the negative control monolayers. Mix an appropriate quantity of each with a suspension of freshly prepared primary or secondary chick embryo fibroblasts and prepare 5, 4 and 2 monolayers, as before. The test is not valid if fewer than 4 of the 5 test monolayers or fewer than 3 of the 4 positive controls or neither of the 2 negative control monolayers survive after any passage.

Examine microscopically all the cell cultures frequently throughout the entire incubation period for any signs of cytopathic effect or other evidence of the presence of a contaminating agent in the test vaccine.

For the last subculture, grow the cells on a suitable substrate so as to obtain an area of about 10 $cm^2$ of confluent cells from each of the original 11 monolayers for the subsequent test: test about 10 $cm^2$ of confluent cells derived from each of the original 11 monolayers by immunostaining for the presence of Marek's disease virus. The test is not valid if Marek's disease virus is detected in fewer than 3 of the 4 positive control monolayers or in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive.

The batch of vaccine complies with the test if there is no evidence of the presence of Marek's disease virus or any other extraneous agent.

5. TESTS FOR TURKEY RHINOTRACHEITIS VIRUS

A. In chicken embryo fibroblasts

*NOTE: this test can be combined with Test 2 by using the same test monolayers and negative controls, for all stages up to the final specific test for turkey rhinotracheitis virus on cells prepared from the last subculture.*

Prepare 11 monolayers of primary or secondary chick embryo fibroblasts from the tissues of 9- to 11-day-old embryos, each monolayer having an area of about 25 $cm^2$. Remove the culture medium when the cells reach confluence. Inoculate 0.1 mL of test vaccine onto each of 5 of the monolayers (test monolayers). Allow adsorption for 1 h, and add culture medium. Inoculate 4 of the monolayers with a suitable strain of turkey rhinotracheitis virus as positive controls (not more than 10 $CCID_{50}$ in 0.1 mL). Maintain 2 non-inoculated monolayers as negative controls.

Incubate the cultures for a total of at least 21 days, subculturing at 4- to 5-day intervals. Each passage is made as follows: carry out a freeze-thaw cycle; prepare separate pools of the cells plus fluid from the test monolayers, from the positive control monolayers and from the negative control monolayers; inoculate 0.1 mL of the pooled material onto each of 5, 4 and 2 recently prepared monolayers of chicken embryo fibroblasts cells, each monolayer having an area of about 25 $cm^2$ as before. The test is not valid if fewer than 4 of the 5 test monolayers or fewer than 3 of the 4 positive controls or neither of the 2 negative control monolayers survive after any passage.

For the last subculture, grow the cells on a suitable substrate so as to obtain an area of about 10 $cm^2$ of confluent cells from each of the original 11 monolayers for the subsequent test: test about 10 $cm^2$ of confluent cells derived from each of the original 11 monolayers by immunostaining for the presence of turkey rhinotracheitis virus. The test is not valid if turkey rhinotracheitis virus is detected in fewer than 3 of the 4 positive control monolayers or in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive. If the results for both of the 2 test monolayers are inconclusive then further subcultures of reserved portions of the fibroblasts shall be made and tested until an unequivocal result is obtained.

The batch of vaccine complies with the test if there is no evidence of the presence of turkey rhinotracheitis virus or any other extraneous agent.

B. In Vero cells

Prepare 11 monolayers of Vero cells, each monolayer having an area of about 25 $cm^2$. Remove the culture medium when the cells reach confluence. Inoculate 0.1 mL of test vaccine onto each of 5 of the monolayers (test monolayers). Allow adsorption for 1 h, and add culture medium. Inoculate 4 of the monolayers with a suitable strain of turkey rhinotracheitis virus (not more than 10 $CCID_{50}$ in 0.1 mL) to serve as positive controls. Maintain 2 non-inoculated monolayers as negative controls.

Incubate the cultures for a total of at least 21 days, subculturing at 4- to 5-day intervals. Each passage is made as follows: carry out a freeze-thaw cycle. Prepare separate pools of the cells plus fluid from the test monolayers, from the positive control monolayers and from the negative control monolayers. Inoculate 0.1 mL of the pooled material onto each of 5, 4 and 2 recently prepared monolayers of Vero cells, each monolayer having an area of about 25 $cm^2$ as before. The test is not valid if fewer than 4 of the 5 test monolayers or fewer than 3 of the 4 positive controls or neither of the 2 negative controls survive after any passage.

For the last subculture, grow the cells on a suitable substrate so as to obtain an area of about 10 $cm^2$ of confluent cells from each of the original 11 monolayers for the subsequent test: test about 10 $cm^2$ of confluent cells derived from each of the original 11 monolayers by immunostaining for the presence of turkey rhinotracheitis virus. The test is not valid if turkey rhinotracheitis virus is detected in fewer than 3 of the 4 positive control monolayers or in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive. If the results for more than 1 of the test monolayers are inconclusive then further subcultures of reserved portions of the monolayers shall be made and tested until an unequivocal result is obtained.

The batch of vaccine complies with the test if there is no evidence of the presence of turkey rhinotracheitis virus or any other extraneous agent.

6. TEST FOR CHICKEN ANAEMIA VIRUS

Prepare eleven 20 mL suspensions of the MDCC-MSBI cell line or another cell line of equivalent sensitivity in 25 $cm^2$ flasks containing about $5 \times 10^5$ cells/mL. Inoculate 0.1 mL of test vaccine into each of 5 of these flasks. Inoculate 4 other suspensions with 10 $CCID_{50}$ chicken anaemia virus as positive controls. Maintain not fewer than 2 non-inoculated suspensions. Maintain all the cell cultures for a total of at least 24 days, subculturing 8 times at 3- to 4-day intervals. During the subculturing the presence of chicken anaemia virus may be indicated by a metabolic colour change in the infected cultures, the culture fluids becoming red in comparison with the control cultures. Examine the cells microscopically for cytopathic effect. At this time or at the end of the incubation period, centrifuge the cells from each flask at low speed, resuspend at about $10^6$ cells per millilitre and place 25 µL in each of 10 wells of a multi-well slide. Examine the cells by immunostaining.

The test is not valid if chicken anaemia virus is detected in fewer than 3 of the 4 positive controls or in any of the non-inoculated controls. If the results for more than 1 of the test suspensions are inconclusive then further subcultures of reserved portions of the test suspensions shall be made and tested until an unequivocal result is obtained.

The batch of vaccine complies with the test if there is no evidence of the presence of chicken anaemia virus.

7. TEST FOR DUCK ENTERITIS VIRUS

This test is carried out for vaccines prepared on duck or goose substrates.

Prepare 11 monolayers of primary or secondary Muscovy duck embryo liver cells, from the tissues of 21- or 22-day-old embryos, each monolayer having an area of about 25 $cm^2$. Remove the culture medium when the cells reach confluence. Inoculate 0.1 mL of test vaccine onto each of 5 of the monolayers (test monolayers). Allow adsorption for 1 h and add culture medium. Inoculate 4 of the monolayers with a suitable strain of duck enteritis virus (not more than 10 $CCID_{50}$ in 0.1 mL) to serve as positive controls. Maintain 2 non-inoculated monolayers as negative controls.

Incubate the cultures for a total of at least 21 days, subculturing at 4- to 5-day intervals. Each passage is made as follows: trypsinise the cells and prepare separate pools of the cells from the test monolayers, from the positive control monolayers and from the negative control monolayers. Mix a portion of each with a suspension of freshly prepared primary or secondary Muscovy duck embryo liver cells to prepare 5, 4 and 2 monolayers, as before. The test is not valid if fewer than 4 of the 5 test monolayers or fewer than 3 of the 4 positive controls or neither of the 2 negative controls survive after any passage.

For the last subculture, grow the cells on a suitable substrate so as to obtain an area of about 10 $cm^2$ of confluent cells from each of the original 11 monolayers for the subsequent test: test about 10 $cm^2$ of confluent cells derived from each of the original 11 monolayers by immunostaining for the presence of duck enteritis virus. The test is not valid if duck enteritis virus is detected in fewer than 3 of the 4 positive control monolayers or in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive. If the results for more than 1 of the test monolayers are inconclusive then further subcultures of reserved portions of the monolayers shall be made and tested until an unequivocal result is obtained.

The batch of vaccine complies with the test if there is no evidence of the presence of duck enteritis virus or any other extraneous agent.

8. TEST FOR DUCK AND GOOSE PARVOVIRUSES

This test is carried out for vaccines prepared on duck or goose substrates.

Prepare a suspension of sufficient primary or secondary Muscovy duck embryo fibroblasts from the tissues of 16- to 18-day-old embryos, to obtain not fewer than 11 monolayers, each having an area of about 25 $cm^2$. Inoculate 0.5 mL of test vaccine into an aliquot of cells for 5 monolayers and seed into 5 replicate containers to form 5 test monolayers. Inoculate 0.4 mL of a suitable strain of duck parvovirus (not more than 10 $CCID_{50}$ in 0.1 mL) into an aliquot of cells for 4 monolayers and seed into 4 replicate containers to form 4 positive control monolayers. Prepare 2 non-inoculated monolayers as negative controls.

Incubate the cultures for a total of at least 21 days, subculturing at 4- to 5-day intervals. Each passage is made as follows: carry out a freeze-thaw cycle. Prepare separate pools of the cells plus fluid from the test monolayers, from the positive control monolayers and from the negative control monolayers. Inoculate 0.5 mL, 0.4 mL and 0.2 mL of the pooled materials into aliquots of a fresh suspension of sufficient primary or secondary Muscovy duck embryo fibroblast cells to prepare 5, 4 and 2 monolayers, as before. The test is not valid if fewer than 4 of the 5 test monolayers or fewer than 3 of the 4 positive controls or neither of the 2 negative controls survive after any passage.

For the last subculture, grow the cells on a suitable substrate so as to obtain an area of about 10 $cm^2$ of confluent cells from each of the original 11 monolayers for the subsequent test: test about 10 $cm^2$ of confluent cells derived from each of the original 11 monolayers by immunostaining for the presence of duck or goose parvovirus. The test is not valid if duck parvovirus is detected in fewer than 3 of the 4 positive control monolayers or in any of the negative control monolayers, or if the results for both of the 2 negative control monolayers are inconclusive.

The batch of vaccine complies with the test if there is no evidence of the presence of duck (or goose) parvovirus or any other extraneous agent.

# 2.6.26. TEST FOR ANTI-D ANTIBODIES IN HUMAN IMMUNOGLOBULIN

MATERIALS

*Phosphate-buffered saline (PBS).* Dissolve 8.0 g of *sodium chloride R*, 0.76 g of *anhydrous disodium hydrogen phosphate R*, 0.2 g of *potassium chloride R* and 0.2 g of *potassium dihydrogen phosphate R* in *water R* and dilute to 1000 mL with the same solvent. If the solution has to be kept for several days, 0.2 g of *sodium azide R* may be added in order to avoid microbial contamination.

*PBS-BSA solution.* PBS containing 2 g/L of *bovine albumin R* (Cohn Fraction V, for ELISA). Store the solution at 2-8 °C but allow it to reach 19-25 °C before use.

*Papain solution.* Use serological-grade papain from a commercial source, the activity of which has been validated.

*Red blood cells.* Use pooled D-positive red blood cells from not fewer than 3 donors, preferably of group $OR_2R_2$. D-positive red blood cells may also be obtained from $OR_1R_1$ or $OR_1R_2$ donors. Mixing phenotypes has not been tested and is therefore not recommended.

Use pooled D-negative red blood cells, preferably from 3 donors of group Orr. When only 1 donor of group Orr is available, D-negative red blood cells from only 1 donor may be used.

Wash the cells 4 times with PBS or until the supernatant is clear. Each wash consists of suspending the cells in a minimum of 2 volumes of PBS, centrifuging the cells at 1800 *g* for 5 min to pack, and discarding the supernatant. Treat the packed cells with papain solution according to the manufacturer's instructions and wash the cells 4 times with PBS.

Red blood cells may be stored for not more than 1 week in a preservative solution at 2-8 °C. A preparation of the following composition is appropriate:

| | |
|---|---|
| Trisodium citrate | 8 g/L |
| D-glucose | 20 g/L |
| Citric acid | 0.5 g/L |
| Sodium chloride | 4.2 g/L |
| Inosine | 0.938 g/L |
| Adenosine triphosphate (ATP) | 0.4 g/L |
| Chloramphenicol | 0.34 g/L |
| Neomycin sulfate | 0.1 g/L |

If using stored cells, wash the cells at least twice in PBS or until the supernatant is clear before proceeding.

*Microtitre plates.* Use V-bottomed rigid microtitre plates.

*Reference standards. Immunoglobulin (anti-D antibodies test) BRP* and *Immunoglobulin (anti-D antibodies test negative control) BRP* are suitable for use as the positive control and negative control, respectively.

METHOD

The test described in this chapter is performed at room temperature on the positive control solutions, the negative control solutions and the test solutions at the same time and under identical conditions.

*Reference solutions.* Reconstitute the positive control and the negative control according to the instructions. The immunoglobulin G (IgG) concentration is 50 g/L in each of the reconstituted preparations. Make a 2-fold dilution of each reconstituted preparation with PBS-BSA solution to obtain solutions containing IgG at 25 g/L. Prepare 7 further serial 2-fold dilutions of each preparation using PBS-BSA solution to extend the dilution range to 1/256 (0.195 g/L IgG). Add 20 µL of each dilution of each preparation in duplicate to the microtitre plate.

*Test solutions.* Dilute the preparation to be examined with PBS-BSA solution to obtain a starting IgG concentration of 25 g/L. For 50 g/L preparations, this is a 2-fold dilution; adjust the dilution factor accordingly for preparations with an IgG concentration other than 50 g/L to obtain a starting concentration of 25 g/L for testing. This 25 g/L solution is assigned a nominal 2-fold dilution factor for comparison with the reference solutions, even if this does not reflect the true dilution factor used to achieve 25 g/L. Prepare 7 further serial 2-fold dilutions of the preparation using PBS-BSA solution to extend the nominal dilution range to 1/256 (0.195 g/L IgG) for comparison with the reference preparations over the same IgG concentration range. Add 20 µL of each dilution in duplicate to the microtitre plate.

Prepare 3 per cent *V/V* suspensions of papain-treated D-positive (preferably $OR_2R_2$, but $OR_1R_1$ or $OR_1R_2$ may also be used) and D-negative (Orr) red blood cells in PBS-BSA solution. Add 20 µL of D-positive red blood cells to 1 dilution series of each of the preparation to be examined, the positive control and the negative control, and 20 µL of D-negative red blood cells to the other dilution series. Mix by shaking the plate on a shaker for 10 s (or until the cells are resuspended).

Centrifuge the plate at 80 *g* at room temperature for 1 min to pack the cells. Place the plate at an angle of approximately 70°. Read after 4-5 min or when the negative controls (D-negative red blood cells and negative control solution) have streamed. A cell button at the bottom of the well indicates a positive result. A stream of cells represents a negative result.

Record the endpoint titre as the reciprocal of the highest dilution that gives rise to a positive result.

The positive control has a nominal titre of 8 and the negative controls (D-negative red blood cells and negative control solution) must not show agglutination at the starting dilution of 1 in 2. Users must validate their own test conditions, and investigate their assay conditions and reagents in the event of results being significantly different from those expected. Failure to obtain negative reactions with the negative controls may indicate that, for example, insufficient time has elapsed for the cells to stream, or that reagents have been used directly from cold storage.

The titre of the preparation to be examined must not be greater than the titre of the positive control when both preparations are titrated from 25 g/L.

**07/2017:20627**

# 2.6.27. MICROBIOLOGICAL EXAMINATION OF CELL-BASED PREPARATIONS

*This chapter does not concern the examination of human blood or blood components, which is covered by Directive 2002/98/EC of the European Parliament and of the Council of 27 January 2003 and Commission Directive 2004/33/EC of 22 March 2004 implementing Directive 2002/98/EC.*

## 1. INTRODUCTION

The approaches to microbiological examination of cell-based preparations outlined in this general chapter take into account the characteristics and limitations of these preparations, in particular their shelf-life, which may not always allow for completion of conventional microbiological examination tests before administration to the patient, as well as the amounts available for testing and sampling-related issues. These approaches may be applied when the test for sterility, described in general chapter *2.6.1. Sterility*, is required but cannot be performed for technical reasons or due to the characteristics of the specific cell-based preparation.

### 1-1. *SHELF-LIFE*

The shelf-life of cell-based preparations is dependent on the cell characteristics and on the preservation conditions. For non-cryopreserved cell-based preparations, the shelf-life usually does not exceed 3-4 days and sometimes not more than a few hours. In such cases the microbiological status of the final preparation cannot be determined, according to general chapter *2.6.1*, before the time of administration.

### 1-2. *SAMPLE COMPOSITION*

Microbial contaminants may be found either inside or on the surface of cells or other components of the cell-based preparation and may not be detected if only supernatants, such as culture or transport media, are analysed. The sample tested must be representative of all of the components of the cell-based preparation, unless otherwise justified.

### 1-3. *SAMPLE SIZE*

Due to constraints surrounding the use of a single donor or manufacturing-related capacities, the sample volume available for testing at the end of the production process may be limited. Nevertheless, with regard to the sampling error, which may lead to microbial contamination not being detected, the sample size must be sufficient to ensure suitable sensitivity and specificity of the chosen test method.

### 1-4. *RATIONALE FOR METHOD SELECTION*

Method selection must be based on the characteristics of the final preparation and the manufacturing process. To ensure safety for the intended use, the choice of method or combination of methods could be supported by a risk analysis of the potential exposure to microbiological contaminants, and the characteristics and intended use of the cell-based preparation. The media and incubation times used in these methods must be chosen taking into account the properties of the source material and the conditions during the manufacturing process that may support growth of specific micro-organisms (e.g. psychrophilic, thermophilic or fastidious bacteria or fungi). The composition of the cell-based preparation may impede certain test methods for physical reasons such as initial turbidity of the culture media after addition of the test sample.

The following approaches to microbiological examination may be applied:

– automated growth-based methods;

– a combination of preculturing and detection by alternative methods (*5.1.6*);
– direct detection by alternative methods (*5.1.6*);
– methods based on the sterility test prescribed in general chapter *2.6.1*.

## 2. GENERAL CONSIDERATIONS

### 2-1. *GENERAL PRECAUTIONS*

The test is carried out under aseptic conditions according to current regulations for potentially infective material. The precautions taken to avoid contamination are such that they do not affect any micro-organisms that are to be revealed in the test. The test is performed under working conditions that are monitored regularly by appropriate sampling of the working area and by carrying out appropriate controls. Testing shall take account of the potential for the presence of inhibitory substances in the sample that may affect the outcome of the test.

### 2-2. *HANDLING CONSTRAINTS*

#### 2-2-1. **Shelf-life**

'Negative-to-date' is understood as an intermediate reading of a test method (*2.6.1* or an automated growth-based method) that has not yet been completed. Where cell-based preparations have limiting shelf-lives, 'negative-to-date' results may be used as the readout, where justified. Based on the risk analysis of the characteristics and intended use of the cell-based preparation, results from additional microbiological in-process control may be needed at the time of use.

#### 2-2-2. **Sampling**

The test sample must be representative of all of the components of the cell-based preparation and be taken from the final preparation. Where this is not possible, surrogate testing may be performed, for example on the liquids last in contact with the cells being processed.

## 3. METHODS FOR MICROBIOLOGICAL EXAMINATION OF CELL-BASED PREPARATIONS

### 3-1. *AUTOMATED GROWTH-BASED METHOD*

#### 3-1-1. **Growth promotion test**

This section outlines the conditions for confirming the suitability of the culture media used for microbiological examination.

At least 2 suitable culture media intended for detection of fungi and aerobic and anaerobic bacteria are used. Each batch of sterile medium is tested for its growth-promoting capacities by inoculating duplicate test containers of each medium with not more than 100 CFU of each of the strains listed in Table 2.6.27.-1, and incubating for a maximum of 7 days for detection of microbial growth at the temperature defined for testing (see Table 2.6.27.-3). The test media are satisfactory if there is clear evidence of growth in all inoculated media containers within this incubation period.

Table 2.6.27.-1. – *Micro-organisms used for growth promotion test*

| **Aerobic medium** | |
|---|---|
| *Staphylococcus aureus* | for example, ATCC 6538, CIP 4.83, NCTC 10788, NCIMB 9518 |
| *Bacillus subtilis* | for example, ATCC 6633, CIP 52.62, NCIMB 8054 |
| *Pseudomonas aeruginosa* | for example, ATCC 9027, NCIMB 8626, CIP 82.118 |
| *Candida albicans* | for example, ATCC 10231, IP 48.72, NCPF 3179 |
| *Aspergillus brasiliensis* | for example, ATCC 16404, IP 1431.83, IMI 149007 |
| **Anaerobic medium** | |
| *Clostridium sporogenes* | for example, ATCC 11437, CIP 79.3, NCTC 532 or ATCC 19404 |
| *Bacteroides fragilis* | for example, ATCC 25285, CIP 77.16, NCTC 9343 |

#### 3-1-2. **Method suitability**

The test system is validated with respect to specificity (absence of false positive results), sensitivity, reproducibility and robustness. Regardless of the type of cell-based preparation, the manufacturing process, the sample volume analysed or the type of test system, the suitability of the method is to be confirmed in the presence of the specific sample composition. During the confirmation of the suitability of the method, particularly to determine sensitivity, the test is carried out using the micro-organisms listed in Table 2.6.27.-2. Sensitivity is meant as the capacity to detect 100 CFU or less. Not more than 100 CFU of the chosen micro-organisms are inoculated into the medium in the presence of the preparation to be tested, using at least 3 replicates. The microbial count in the micro-organism suspensions used for inoculation is determined by streaking an appropriate sample on agar plates. If between 1 and 100 CFU are detected for each strain within the duration of the assay, the method is valid for the intended sample composition.

It may be necessary to modify the list of micro-organisms in Table 2.6.27.-2 depending on the origin of the cells and any micro-organisms previously found or associated with the particular type of cells.

Table 2.6.27.-2. – *Micro-organisms used for method suitability*

| **Aerobic medium** | |
|---|---|
| *Aspergillus brasiliensis* | for example, ATCC 16404, IP 1431.83, IMI 149007 |
| *Bacillus subtilis* | for example, ATCC 6633, CIP 52.62, NCIMB 8054 |
| *Candida albicans* | for example, ATCC 10231, IP 48.72, NCPF 3179 |
| *Pseudomonas aeruginosa* | for example, ATCC 9027, NCIMB 8626, CIP 82.118 |
| *Staphylococcus aureus* | for example, ATCC 6538, CIP 4.83, NCTC 10788, NCIMB 9518 |
| *Streptococcus pyogenes* | for example, ATCC 19615, CIP 1042.26, NCIMB 13285 |
| *Micrococcus* sp. | for example, ATCC 700405, NCTC 7567 |
| **Anaerobic medium** | |
| *Clostridium sporogenes* | for example, ATCC 11437, CIP 79.3, NCTC 532 or ATCC 19404 |
| *Propionibacterium acnes* | for example, ATCC 11827 |

In some cases, the cell-based preparation itself can inactivate contaminating micro-organisms. Appropriate measures must be taken to ensure the suitability of any additional microbial strains used for method validation.

#### 3-1-3. **Testing of the preparation to be examined**

*Sample*. A sample that is representative of the characteristics of the cell-based preparation is tested. The sample is added to the culture medium as soon as possible. If it is necessary to store samples, the impact of the storage on potential contaminants is evaluated.

For cell-based preparations where the total volume (*V*) of the batch is between 1 mL and 1 L in a single container, the following table indicates the inoculation volume to be used.

| Total cell-based preparation volume (mL) | Total inoculum volume (divided between aerobic and anaerobic bottles) |
|---|---|
| 10 ≤ V ≤ 1000 | 1 per cent of total volume of preparation to be tested |
| 1 ≤ V < 10 | 100 µL |
| V < 1 | Not applicable |

For other volumes or multiple containers, alternative approaches should be used and have to be justified (see section 2-2-2). Enlargement of the total volume by means of dilution may be envisaged to assure complete inoculation of sample volumes of 100 µL. For preparation volumes less than 1 mL, where final sampling is not possible, surrogate testing, in-process testing or other appropriate testing should be used and has to be justified.

*Analysis.* Samples are inoculated into containers of culture medium as soon as possible and incubated for not less than 7 days. Depending on the results obtained during method suitability testing and considering relevant micro-organisms, the incubation period may be extended up to 14 days. Selection of incubation temperatures should enable detection of a broad range of micro-organisms. This is typically in the range of 30-37 °C; however, for cell-based preparations with a very short shelf-life, a growth-accelerating temperature of not less than 35 °C may be more appropriate to obtain a relevant 'negative-to-date' readout of the test. In addition, for preparations where there is a significant risk of contamination from the environment, 2 temperature ranges of, for example, 20-25 °C (for aerobic) and 30-37 °C (for anaerobic) are used, in order to cover both environmental and clinical micro-organisms.

Table 2.6.27.-3 lists possible alternative approaches for the choice of incubation temperatures. The temperature and time for incubation are based on the results of the suitability study for the specific cell-based preparation.

Table 2.6.27.-3. – *Possible temperature settings in automated culturing systems used alone or in combination with manual testing*

| | Aerobic incubation | Anaerobic incubation |
|---|---|---|
| Option 1 | 20-25 °C (automated system), if necessary 30-35 °C (automated system) | 30-35 °C (automated system) |
| Option 2 | 35-37 °C (automated system); where relevant, additional incubation at a lower temperature (manual method)* | 35-37 °C (automated system) |
| Option 3 | 30-32 °C (automated system) | 30-32 °C (automated system) |
| Option 4 | 30-32 °C (automated system) | 35-37 °C (automated system) |

* Where relevant, incubate in addition at a temperature between 20 °C and 30 °C. Incubation can be performed using commercially available microbiological media, either aerobic bottles intended for automated systems or casein soya bean digest broth.

3-1-4. **Observation and interpretation of results**

Media are examined, visually or with automated systems, at least daily and at the end of the observation period for evidence of microbial growth. If no growth is observed during or at the end of the observation period, the product is 'culture negative'. If growth is observed in a valid test, the product is 'culture positive'.

If the inoculated bottles are stored for more than 12 h before being placed into the automated culturing system, a subculture of each incubated bottle is performed to check for false negatives. This addresses cases in which, where a micro-organism is fast-growing and the conditions are optimal, micro-organisms may start to proliferate during storage. As a consequence, there may not be a significant increase in the relevant parameters at the time of testing and microbial contaminants may not be recognised by the system (false negative result).

3-2. *ALTERNATIVE METHODS*

3-2-1. **Combination of preculturing and detection by alternative methods**

The samples to be tested are incubated in both aerobic and anaerobic liquid cultivation media or equivalent solid media for a short period of time (e.g. 12-24 h depending on the sensitivity of the alternative approach used). An alternative method suitable for rapid detection of micro-organisms is then performed (e.g. nucleic acid amplification techniques (*2.6.21*), flow cytometry (*2.7.24*), bioluminescence (*5.1.6*)).

3-2-2. **Direct detection by alternative methods** (*5.1.6*)

Where a cell-based preparation has a very short shelf-life (e.g. a few hours) or where standard methods do not provide satisfactory detection of micro-organisms, non-growth-based, direct detection methods may be carried out for microbiological examination (e.g. nucleic acid amplification techniques (*2.6.21*), flow cytometry (*2.7.24*), bioluminescence (*5.1.6*)).

This approach enables a result to be obtained within a very short time, although at the expense of lower sensitivity, in comparison to growth-based methods. Depending on the approach used, both viable and non-viable micro-organisms may be detected.

3-2-3. **Method validation**

Validation is carried out according to the general recommendations of general chapter *5.1.6* and according to the recommendations specific to cell-based preparations in section 3-1-2 for automated growth-based methods. The sensitivity of these approaches must be validated considering the doubling times of potentially contaminating micro-organisms during pre-incubation.

**07/2017:20630**

# 2.6.30. MONOCYTE-ACTIVATION TEST

1. INTRODUCTION

The monocyte-activation test (MAT) is used to detect or quantify substances that activate human monocytes or monocytic cells to release endogenous mediators such as pro-inflammatory cytokines, for example tumour necrosis factor alpha (TNFα), interleukin-1 beta (IL-1β) and interleukin-6 (IL-6). These cytokines have a role in fever pathogenesis. Consequently, the MAT will detect the presence of pyrogens in the test sample. The MAT is suitable, after a product-specific validation, as a replacement for the rabbit pyrogen test.

Pharmaceutical products that contain non-endotoxin pyrogenic or pro-inflammatory contaminants often show very steep or non-linear dose-response curves in comparison with endotoxin dose-response curves. Preparations that contain or may contain non-endotoxin contaminants have to be tested at a range of dilutions that includes minimum dilution.

The following 3 methods are described in the present chapter.

Method A. Quantitative test

Method B. Semi-quantitative test

Method C. Reference lot comparison test

In addition, further useful information on practical aspects of the tests can be found in the 'Guidance notes' section at the end of this general chapter.

The test is carried out in a manner that avoids pyrogen contamination.

## 2. DEFINITIONS

The maximum valid dilution (MVD) is the maximum allowable dilution of a sample at which the contaminant limit can be determined. The calculation of the MVD is based on the endotoxin reference standard. Determine the MVD using the following expression:

$$\frac{CLC \times C}{LOD}$$

*CLC* = contaminant limit concentration;

*C* = concentration of test solution;

*LOD* = limit of detection.

As the LOD is not always available in advance, an estimated LOD based on historical data can be used to calculate the MVD.

The acceptance criterion for a pass/fail decision is the contaminant limit concentration (CLC), which is expressed in endotoxin equivalents per milligram or millilitre or per units of biological activity of the preparation being examined.

The CLC is calculated using the following expression:

$$\frac{K}{M}$$

*K* = threshold pyrogenic dose per kilogram of body mass;

*M* = maximum recommended bolus dose of product per kilogram of body mass.

When the product is to be injected at frequent intervals or infused continuously, *M* is the maximum total dose administered in a single hour period.

Where an endotoxin limit concentration (ELC) has been specified for a product, the CLC is the same as the ELC, unless otherwise prescribed. In this case, the concentration of test solution is expressed in mg/mL if the endotoxin limit is specified by mass (IU/mg), in Units/mL if the endotoxin limit is specified by unit of biological activity (IU/Unit), in mL/mL if the endotoxin limit is specified by volume (IU/mL).

Endotoxin equivalents are values for the contaminant concentration read off the standard endotoxin dose-response curve (Method A) or estimated by comparison with responses to standard endotoxin solutions (Method B). The standard endotoxin stock solution is prepared from an endotoxin reference standard that has been calibrated against the International Standard, for example *endotoxin standard BRP*.

The LOD is determined using the endotoxin standard curve. It is the concentration of endotoxin corresponding to the cut-off value. For the purpose of the test, the LOD is expressed as endotoxin equivalents per millilitre. The cut-off value is expressed in units appropriate to the read-out (e.g. for an enzyme-linked immunosorbent assay (ELISA), use the optical density).

The cut-off value may be calculated using the following expression:

$$\bar{x} + 3s$$

$\bar{x}$ = mean of the 4 replicates for the responses to the blank ($R_0$);

$s$ = standard deviation of the 4 replicates of the responses to the blank ($R_0$).

## 3. GENERAL PROCEDURE

A solution of the preparation being examined is incubated with a source of human monocytes or human monocytic cells, e.g. from human heparinised peripheral blood that is preferably not more than 4 h old, or a monocyte-containing fraction of that blood, such as human peripheral blood mononuclear cells (PBMC) isolated, e.g. by density-gradient centrifugation, or a human monocytic cell line. Human heparinised peripheral blood is usually diluted with culture medium or saline e.g. to 2-50 per cent *V/V* (final concentration). PBMC or monocytic cell lines, in culture medium and with either the donor's own plasma or AB serum, are typically used at a final cell density of 0.1-1.0 × $10^6$ cells per well, tube or other receptacle. For monocytic cell lines, heat-inactivated foetal bovine serum may be substituted for AB serum. The cell culture is carried out at 37 ± 1 °C, in an atmosphere appropriate for the culture medium, e.g. 5 per cent $CO_2$ in humidified air. The duration of the culture is sufficient to allow accumulation of the chosen read-out. The responses of the chosen read-out, e.g. a pro-inflammatory or pyrogenic cytokine, to a solution of the preparation being examined are compared with responses to standard endotoxin or to a reference lot of the preparation being examined.

## 4. APPARATUS

Depyrogenate all glassware and other heat-stable apparatus in a hot-air oven using a validated process. A commonly used minimum time and temperature is 30 min at 250 °C. If employing plastic apparatus, such as microtitre plates and pipette tips for automatic pipetters, use apparatus shown to be free of detectable pyrogens and which do not interfere with the test.

## 5. CELL SOURCES AND QUALIFICATION

### 5-1. *WHOLE BLOOD*

Whole blood is obtained from single donors or from pooled whole blood which are qualified according to the requirements described under sections 5-3, 5-4, 5-5 and where applicable, section 6-3.

### 5-2. *PERIPHERAL BLOOD MONONUCLEAR CELLS (PBMC)*

PBMC are isolated from blood obtained from single donors or from pooled whole blood which are qualified according to the requirements described under sections 5-3, 5-4, 5-5 and where applicable, section 6-3.

### 5-3. *QUALIFICATION OF BLOOD DONORS*

Blood donors are to satisfy the following qualification criteria, together with other requirements in force that relate to consent, health and safety and ethical considerations. Blood donors are to describe themselves as being in good health, as not to be suffering from any bacterial or viral infections and to have been free from the symptoms of any such infection for a period of at least 1 week prior to the donation of blood. Blood donors are not to have taken non-steroidal anti-inflammatory drugs during the 48 h prior to donating blood and steroidal anti-inflammatory drugs during the 7 days prior to donating blood. Individuals who have been prescribed immunosuppressant or other drugs known to influence the production of the chosen readout are not to serve as blood donors. Blood donations are to be tested for infection markers according to national requirements for transfusion medicine.

### 5-4. *QUALIFICATION OF CELLS POOLED FROM A NUMBER OF DONORS*

Pools (of whole blood or blood fractions, e.g. PBMC), must consist of donations from a minimum of 4 individual donors but preferably 8 or more donors, where practicable, taking from each donation an approximately equal volume of blood, or cells from an approximately equal volume of blood. For the qualification of pooled cells proceed as follows: within 4 h of collection of blood, generate dose-response curves from the pool using standard endotoxin with at least 4 geometrically diluted endotoxin concentrations, e.g. in the

range of 0.01 IU/mL to 4 IU/mL. The dose-response curves are to meet the 2 criteria for the endotoxin standard curve described under section 6-1. If the pool is to be used for the detection of non-endotoxin contaminants, pools are to be qualified as described in section 6-3. Where cells are pooled, the averaging effect is to be considered when setting the pass/fail specification for a given product.

5-5. *QUALIFICATION OF CRYO-PRESERVED CELLS*

The cell source intended for use in a MAT, e.g. human whole blood, blood fractions, such as PBMC or monocytic cell lines, may be cryo-preserved. Pools of cryo-preserved cells are obtained by pooling before freezing, or by pooling single cryo-preserved donations immediately after thawing. Qualification of cryo-preserved blood or cells is performed immediately after thawing (and pooling if necessary). Dose-response curves for the cryo-preserved blood or cells are to comply with the 2 criteria for the endotoxin standard curve described under section 6-1. Qualification of the cryo-preserved blood or cells is to be performed according to section 6-3 if the intended use is for the detection of non-endotoxin contaminants.

5-6. *MONOCYTIC CONTINUOUS CELL LINES*

Monocytic cell lines are appropriate for the detection of bacterial endotoxins, but have limited use for the detection of non-endotoxin pyrogens.

A human monocytic cell line is cultured in order to ensure a sufficient supply for the MAT. To optimise the method, clones derived from the cell line can be used.

Cells must be maintained under aseptic conditions and regularly tested for the presence of mycoplasma contamination. Additionally, cells must be regularly checked for identity (e.g. doubling time, morphology, and function) and stability. The functional stability of a cell line is assessed by monitoring its performance in relation to the number of passages during routine testing. Criteria for functional stability are to be established and may include growth criteria, maximum signal obtained in the test, background noise and receptor expression. The receptor expression may be tested with specific ligands e.g. lipopolysaccharide (LPS) for toll-like receptor 4 (TLR4), lipoteichoic acid (LTA) for toll-like receptor 2 (TLR2), synthetic bacterial lipoprotein for TLR2-TLR1, synthetic bacterial lipoprotein for TLR2-TLR6 or flagellin.

The dose-response curves are to meet the 2 criteria for the endotoxin standard curve described under section 6-1. If the cells are to be used for the detection of non-endotoxin contaminants, they are to be qualified as described in section 6-3.

## 6. PREPARATORY TESTING

To ensure both the precision and validity of the test, preparatory tests are conducted, to assure that the criteria for the endotoxin standard curve are satisfied, that the solution does not interfere with the test, that the test detects endotoxins and non-endotoxins contaminants and that the solution does not interfere in the detection system.

A test for interfering factors is required when any changes are made to the experimental conditions that are likely to influence the result of the test.

6-1. *ASSURANCE OF CRITERIA FOR THE ENDOTOXIN STANDARD CURVE*

Using the standard endotoxin solution, prepare at least 4 endotoxin concentrations to generate the standard curve. Perform the test using at least 4 replicates of each concentration of standard endotoxin.

The basal release of the chosen read-out (blank) in the absence of added standard endotoxin is optimised to be as low as possible (e.g. an optical density below 0.1 when using an ELISA).

There are 2 acceptance criteria for the standard curve:

- the regression of responses (appropriately transformed if necessary) on $\log_{10}$ dose shall be statistically significant ($p < 0.01$);
- the regression of responses on $\log_{10}$ dose must not deviate significantly from linearity ($p > 0.05$) (see chapter *5.3. Statistical analysis*).

6-2. *TEST FOR INTERFERING FACTORS*

To assure the validity of the test, preparatory tests are conducted to ensure that the preparation being examined does not interfere with the test. Using an appropriate diluent, dilute the preparation being examined in geometric steps, with all dilutions not exceeding the MVD. Make the same dilutions of the preparation being examined and add endotoxin at a justified concentration. Alternatively, use a diluent containing added endotoxin at a justified concentration. In both cases, this concentration is usually equal to or near the estimated middle of the endotoxin standard curve (Method A) or twice the estimated LOD (Method B). Test these dilution series in parallel in the same experiment. Use the endotoxin standard curve to calculate the concentration of endotoxin-equivalents in each solution. Calculate the mean recovery of the added endotoxin by subtracting the mean concentration of endotoxin equivalents in the solution (if any) from that in the solution containing the added endotoxin. The test solution is considered free of interfering factors if, under the conditions of the test, the measured endotoxin equivalents in the test solution to which endotoxin is added is within 50-200 per cent of the added concentration, after subtraction of any endotoxin equivalents detected in the solution without added endotoxin. When this criterion is not met, Method C is to be preferred over Methods A and B.

In Method C, the dilutions of the test and reference lots depend on the type of analysis used to make the comparison between the two. The type of analysis is to be justified and validated for each product, and is to include assay validity criteria. In an example, a solution of the preparation being examined is tested at 3 dilutions: the highest concentration (lowest dilution) that stimulates the greatest release of the chosen read-out and the 2-fold dilutions immediately below and above the chosen dilution. Since the concentration that stimulates the greatest release of the chosen read-out may be donor-dependent as well as batch-dependent, the product-specific validation is to be performed in at least 3 independent tests, each using cells from different donors. The highest concentration (lowest dilution) that stimulates the greatest release of the chosen read-out in the majority of donors, and the 2-fold dilutions immediately below and above that dilution are deemed to be validated for further testing. If undiluted test solution stimulates the greatest release of the chosen read-out, subsequent testing is to be performed using undiluted test solution and also test solution diluted in the ratios 1:2 and 1:4 before its addition to the monocytic cells. The dilution factors for these 3 solutions are designated $f_1$, $f_2$ and $f_3$.

If the pyrogen content of the product is inherently high, it may be more appropriate to carry out, for example, a parallel-line analysis on the dose-response curves for the test and reference lots. In this situation, solutions of the preparations are tested at 3 or more geometric dilutions which cover the range of the dose-response curve used for the validated analysis (see chapter *5.3. Statistical analysis*).

6-3. *METHOD VALIDATION FOR NON-ENDOTOXIN MONOCYTE-ACTIVATING CONTAMINANTS*

The preparatory testing is also to show that the chosen test system detects, in addition to bacterial endotoxins, non-endotoxin pro-inflammatory or pyrogenic contaminants. The suitability of the method for the particular product has to be verified. This can be achieved using historic batches found to be contaminated with non-endotoxin contaminants that caused positive responses in the rabbit pyrogens test or

adverse drug reactions in man. Where such batches are not available, the preparatory testing is to include validation of the test system using at least 2 non-endotoxin ligands for toll-like receptors, e.g. peptidoglycans, lipoteichoic acids, synthetic bacterial lipoproteins, flagellin and crude bacterial whole cell extract, at least 1 of which is to be spiked into the preparation being examined. The choice of non-endotoxin pyrogens used should reflect the most likely contaminant(s) of the preparation being examined.

6-4. *INTERFERENCE IN THE DETECTION SYSTEM*

Once the optimum dilution of the solution of the preparation being examined for further testing has been identified, this dilution is tested for interference in the detection system (e.g. ELISA) for the chosen read-out. The agreement between a dilution series of the standard for the chosen read-out, in the presence and absence of the preparation being examined, is to be within, for example ± 20 per cent of the optical density.

## 7. METHODS

### 7-1. *METHOD A: QUANTITATIVE TEST*

Method A involves a comparison of the preparation being examined with a standard endotoxin dose-response curve. The contaminant concentration of the preparation being examined is to be less than the CLC to pass the test.

#### 7-1-1. **Test procedure**

Using the validated test method, prepare the solutions shown in Table 2.6.30.-1 and culture 4 replicates of each solution with the qualified cells.

Table 2.6.30.-1

| Solution | Solution | Added endotoxin (IU/mL) | Number of replicates |
|---|---|---|---|
| A | Test solution/*f* | None | 4 |
| B | Test solution/2 × *f* | None | 4 |
| C | Test solution/4 × *f* | None | 4 |
| AS | Test solution/*f* | Middle dose from endotoxin standard curve ($R_3$) | 4 |
| BS | Test solution/2 × *f* | Middle dose from endotoxin standard curve ($R_3$) | 4 |
| CS | Test solution/4 × *f* | Middle dose from endotoxin standard curve ($R_3$) | 4 |
| $R_0$ | Pyrogen-free saline or test diluent | None (negative control) | 4 |
| $R_1$-$R_4$ | Pyrogen-free saline or test diluent | 4 concentrations of standard endotoxin | 4 of each concentration |

Solution A = solution of the preparation being examined at the dilution, here designated *f*, at which the test for interfering factors was carried out, i.e. the highest concentration (lowest dilution) for which the endotoxin recovery is within 50-200 per cent.

Solution B = 2-fold dilution of solution A, not exceeding the MVD.

Solution C = 2-fold dilution of solution B, not exceeding the MVD.

Solution AS = solution A spiked with standard endotoxin at a concentration equal to the middle dose from the endotoxin standard curve ($R_3$).

Solution BS = solution B spiked with standard endotoxin at a concentration equal to the middle dose from the endotoxin standard curve ($R_3$).

Solution CS = solution C spiked with standard endotoxin at a concentration equal to the middle dose from the endotoxin standard curve ($R_3$).

Solution $R_0$ = negative control.

Solutions $R_1$-$R_4$ = solutions of standard endotoxin at the concentrations used in the test for interfering factors.

#### 7-1-2. **Calculation and interpretation**

All data to be included in the data analysis are to relate to cells for which the 2 criteria for the endotoxin standard curve are satisfied. For each different cell source, e.g. individual donation, donor pool, or cell line, use the endotoxin standard curve $R_1$-$R_4$ to calculate the concentration of endotoxin equivalents in each of the replicates of solutions A, B and C and solutions AS, BS and CS. The recovery of endotoxin equivalents calculated from the endotoxin equivalents concentration found in solutions AS, BS and CS after subtracting the endotoxin equivalents concentration found in solutions A, B and C is within the range of 50-200 per cent. Dilutions not fulfilling the spike recovery argument are not valid and are therefore excluded from further evaluation. The preparation being examined complies with the requirements of the test for a given cell source if the mean concentrations of endotoxin equivalents measured in the replicates of solutions A, B and C, after correction for dilution and concentration, are all less than the CLC specified for the preparation being examined. One valid dilution is the minimum required for a valid test.

#### 7-1-3. **Pass/fail criteria of the preparation**

When cells from individual donors are used, the preparation being examined is required to comply with the test with the cells from each of 4 different donors. If the preparation being examined passes the test with cells from 3 of the 4 donors, the test is continued with cells from a further 4 donors, none of whom provided cells for the 1st test, and the preparation being examined is required to pass the test with cells from 7 of the 8 different donors (i.e. a maximum of 1 positive reaction in 8 donors is allowed). When the source of monocytes consists of cells pooled from a number of individual donors, the preparation being examined is required to pass the test with 1 pool of cells. Where a human monocytic cell line is used for the test, the preparation being examined is required to pass the test with 1 qualified passage of cells.

### 7-2. *METHOD B. SEMI-QUANTITATIVE TEST*

Method B involves a comparison of the preparation being examined with standard endotoxin. The contaminant concentration of the preparation being examined is to be less than the CLC to pass the test. Solution A must be chosen for the pass decision, unless otherwise justified and authorised.

#### 7-2-1. **Test procedure**

Using the validated test method, prepare the solutions shown in Table 2.6.30.-2 and culture 4 replicates of each solution with the qualified cells.

Table 2.6.30.-2

| Solution | Solution | Added endotoxin (IU/mL) | Number of replicates |
|---|---|---|---|
| A | Test solution/*f* | None | 4 |
| B | Test solution/$f_1$ | None | 4 |
| C | Test solution/$f_2$ | None | 4 |
| AS | Test solution/*f* | Standard endotoxin at 2 × estimated LOD for the test system | 4 |
| BS | Test solution/$f_1$ | Standard endotoxin at 2 × estimated LOD for the test system | 4 |

| Solution | Solution | Added endotoxin (IU/mL) | Number of replicates |
|---|---|---|---|
| CS | Test solution/$f_2$ | Standard endotoxin at 2 × estimated LOD for the test system | 4 |
| $R_0$ | Pyrogen-free saline or test diluent | None (negative control) | 4 |
| $R_1$ | Pyrogen-free saline or test diluent | Standard endotoxin at 0.5 × estimated LOD for the test system | 4 |
| $R_2$ | Pyrogen-free saline or test diluent | Standard endotoxin at 1 × estimated LOD for the test system | 4 |
| $R_3$ | Pyrogen-free saline or test diluent | Standard endotoxin at 2 × estimated LOD for the test system | 4 |
| $R_4$ | Pyrogen-free saline or test diluent | Standard endotoxin at 4 × estimated LOD for the test system | 4 |

Solution A = solution of the preparation being examined at the dilution, here designated *f*, at which the test for interfering factors was completed.

Solution B = solution of the preparation being examined at a dilution, here designated $f_1$, not exceeding the MVD, chosen after a review of data from the product-specific validation, e.g. 1:2 × MVD (i.e. 2 times less diluted than the MVD).

Solution C = solution of the preparation being examined at a dilution, here designated $f_2$, not exceeding the MVD, chosen after a review of data from the product-specific validation, e.g. MVD.

Solution AS = solution A spiked with standard endotoxin at 2 × estimated LOD for the test system (as determined in preparatory testing).

Solution BS = solution B spiked with standard endotoxin at 2 × estimated LOD for the test system.

Solution CS = solution C spiked with standard endotoxin at 2 × estimated LOD for the test system.

Solution $R_0$ = negative control.

Solution $R_1$ = standard endotoxin at 0.5 × estimated LOD for the test system.

Solution $R_2$ = standard endotoxin at 1 × estimated LOD for the test system.

Solution $R_3$ = standard endotoxin at 2 × estimated LOD for the test system.

Solution $R_4$ = standard endotoxin at 4 × estimated LOD for the test system.

7-2-2. **Calculation and interpretation**

All data to be included in the data analysis are to relate to cells for which mean responses to solutions $R_0$-$R_4$ increase progressively. The mean response to $R_0$ may be equal to the mean response to $R_1$. For each different cell source, the mean response to solution $R_2$ is to be greater than a positive cut-off value. Data below this cut-off value are considered negative. If the mean response to $R_1$ or $R_2$ exceeds the cut-off value, the response to the solution chosen for the pass/fail decision must be negative (= pass). For each negative solution of the preparation being examined (A, B and C), the mean response to the corresponding spiked solution (AS, BS or CS respectively) is compared with the mean response to $R_3$ to determine the percentage spike recovery. The contaminant concentration of the preparation being examined is less than the CLC for a given cell source if the solution of the preparation being examined designated for the pass/fail-decision and the dilutions below all give negative results and the endotoxin spike recovery is within the range of 50-200 per cent.

7-2-3. **Pass/fail criteria of the preparation**

The criteria are the same as for method A (see 7-1-3).

7-3. *METHOD C: REFERENCE LOT COMPARISON TEST*

Method C involves a comparison of the preparation being examined with a validated reference lot of that preparation. The type of analysis selected to compare the two is to be justified and validated for each product and is to include assay validity criteria. The reference lot is also selected according to criteria that have been justified and authorised. The test is intended to be performed in cases where a preparation being examined shows marked interference but cannot be diluted within the MVD to overcome the interference or because it contains or is believed to contain non-endotoxin contaminants. Responses to non-endotoxin contaminants may dilute out more rapidly than responses to endotoxin, which makes it necessary to perform the test at a range of dilutions that include minimum dilution. The test procedure is described below and includes an example of a type of analysis used for the comparison of a test lot and reference lot.

7-3-1. **Test procedure**

Using the validated test method, prepare the solutions shown in Table 2.6.30.-3 and culture 4 replicates of each solution with the qualified cells.

Table 2.6.30.-3

| Solution | Solution/dilution factor | Number of replicates |
|---|---|---|
| A | Solution of reference lot/$f_1$ | 4 |
| B | Solution of reference lot/$f_2$ | 4 |
| C | Solution of reference lot/$f_3$ | 4 |
| D | Solution of preparation being examined/$f_1$ | 4 |
| E | Solution of preparation being examined/$f_2$ | 4 |
| F | Solution of preparation being examined/$f_3$ | 4 |
| G | Positive control (standard endotoxin) | 4 |
| $R_0$ | Diluent (negative control) | 4 |

Solutions A, B and C are solutions of the reference lot diluted by the dilution factors, $f_1$, $f_2$ and $f_3$, determined in the test for interfering factors.

Solutions D, E and F are solutions of the preparation being examined diluted by the dilution factors, $f_1$, $f_2$ and $f_3$, determined for the reference lot in the test for interfering factors.

Solution G is the positive test control for the viability of the cells and is a standard endotoxin concentration that gives a clear positive response.

Solution $R_0$ is the diluent used to dilute the preparation being examined and serves as the test blank.

7-3-2. **Calculation and interpretation**

All data to be included in the data analysis are to relate to cells for which solution G and at least one of solutions A, B and C give a response that is greater than the basal release of the read-out (Solution $R_0$). For each different cell source, e.g. individual donation, donor pool, or cell line, use the standard

curve for the read-out (a calibration curve in duplicate with a blank and at least 4 geometrically diluted concentrations of the standard for the chosen read-out) and calculate the mean responses of the replicates of solutions A-F. Sum the mean responses to solutions A, B and C and sum the mean responses to solutions D, E and F. Divide the sum of the mean responses to solutions D, E and F by the sum of the mean responses to solutions A, B and C. The preparation being examined complies with the test for a given cell source if the resulting value complies with a defined acceptance criterion not exceeding a justified value, e.g. 2.5.

7-3-3. **Pass/fail criteria of the preparation**

The criteria are the same as for method A (see 7-1-3).

To quantify more closely the level of contamination, Methods A, B and C may be performed using other dilutions of the solution of the preparation being examined not exceeding the MVD.

*The following section is published for information only.*

## Guidance notes

1. INTRODUCTION

The monocyte-activation test (MAT) is primarily intended to be used as a replacement for the rabbit pyrogen test. The MAT detects pyrogenic and pro-inflammatory contaminants, including endotoxins from gram-negative bacteria and 'non-endotoxin' contaminants, including pathogen-associated molecular patterns (PAMPs), derived from gram-positive and gram-negative bacteria, viruses and fungi, and product-related and process-related biological or chemical entities.

Since non-endotoxin contaminants are a physico-chemically diverse class of molecules, and usually the nature of the contaminant in a preparation being examined is unknown, the level of contamination is expressed either in endotoxin-equivalent units, derived by comparison with responses to standard endotoxin, or by comparison with a reference lot of the preparation being examined.

In the MAT, responses to standard endotoxin usually dilute out over approximatively 1 $\log_{10}$ and responses to products contaminated with non-endotoxin contaminants (alone or in combination with endotoxins) often show very steep dose-response curves, usually over only 1 or 2 dilution steps when tested for their capability to stimulate monocytes. Frequently, the largest response to such contaminated products is obtained with undiluted solutions of preparations being examined or small dilutions of the preparations being examined. For this reason test solutions of preparations being examined that contain or may contain non-endotoxin contaminants have to be tested at a range of dilutions that includes minimum dilution.

2. METHODS

2-1. *INFORMATION REGARDING THE CHOICE OF METHODS*

Methods A, B and C, are not normally applied where a preparation being examined has the intrinsic activity of stimulating the release of the chosen read-out or where the preparation being examined is contaminated with the chosen read-out. In both cases, this fact is to be addressed by modifying and validating the chosen method accordingly. The product-specific validation of the chosen method would be expected to identify the frequency of non-responders to a particular product/contaminant(s) combination and to identify steps to address this, e.g. screening of donors, increasing the number of donors per test, and setting pass/fail criteria of appropriate stringency to maximise the likelihood of detecting contaminated batches. Method A is not appropriate if the results of different dilutions (endotoxin equivalents per millilitre) show that the dose response curve is not parallel to the standard endotoxin curve. Method B is a semi-quantitative test that can be applied when responses to dilutions of a preparation being examined are not parallel to responses to dilutions of standard endotoxin.

Method C, the reference lot comparison test, was developed to address extreme donor variability in responses to certain product/contaminant(s) combinations. In this regard, it should be noted that, while monocytes from most donors respond in a broadly similar manner to bacterial endotoxin, responses of monocytes from different donors to non-endotoxin contaminants can differ markedly, so that it is possible to identify non-responders along with low and high responders to certain product/contaminant(s) combinations.

2-2. *CALCULATION OF CONTAMINANT LIMIT CONCENTRATION*

The acceptance criterion for a pass/fail decision is the contaminant limit concentration (CLC), which is expressed in endotoxin equivalents per milligram or millilitre or in units of biological activity of the preparation being examined. Where an endotoxin limit concentration (ELC) has been specified for a product, the CLC is the same as the ELC, unless otherwise prescribed. The CLC is expressed in terms of endotoxin equivalents. The CLC is calculated using the following expression:

$$\frac{K}{M}$$

$K$ = threshold pyrogenic dose per kilogram of body mass;

$M$ = maximum recommended bolus dose of product per kilogram of body mass.

When the product is to be injected at frequent intervals or infused continuously, $M$ is the maximum total dose administered in a single hour period.

The CLC depends on the product and its route of administration and is stated in some monographs.

Values for $K$ are suggested in Table 2.6.30.-4.

Table 2.6.30.-4

| Route of administration | *K* |
|---|---|
| Intravenous | 5.0 IU of endotoxin per kilogram of body mass |
| Intravenous, for radiopharmaceuticals | 2.5 IU of endotoxin per kilogram of body mass |
| Intrathecal | 0.2 IU of endotoxin per kilogram of body mass |
| Parenteral formulations administered per square metre of body surface | 100 IU/m$^2$ |

2-3. *INFORMATION REGARDING CRYO-PROTECTANTS*

The influence of cryo-protectants, e.g. dimethyl sulfoxide (DMSO), and their residues in thawed cells, is to be considered: DMSO is toxic to cells in culture and, even when cells have been washed thoroughly, cryo-preservation may have altered cell properties, e.g. cell membrane permeability.

2-4. *INTERFERENCE TESTING*

Where practicable, interference testing is performed on at least 3 different lots of the preparation being examined. Preparations being examined that show marked batch-to-batch variation, that effectively renders each batch unique for the purposes of interference testing, are to be subjected to interference testing within each individual test, i.e. concomitant validation.

Interference testing is preferably performed on batches of the preparation being examined that are free of endotoxins and other pyrogenic/pro-inflammatory contaminants and, where this is not practicable, none of the batches are to be heavily contaminated. If only 1 batch is available the validation has to be performed on that batch in 3 independent tests. Precision parameters for reproducibility, e.g. ± 50 per cent, are to be fulfilled.

2-5. *CROSS-VALIDATION*

General chapter *5.1.10. Guidelines for using the test for bacterial endotoxins*, states that an MAT should be performed on products where the presence of non-endotoxin pyrogenic substances cannot be ruled out. It is therefore recommended to perform cross-validation experiments with the MAT together with the validation experiments for the test for bacterial endotoxins (BET) using the same 3 batches. Cross-validation should be repeated on 3 batches if important process parameters have changed, as potential contamination by non-endotoxin pyrogens cannot be ruled out.

The rabbit pyrogen test (see general chapter *2.6.8. Pyrogens*) must only be performed for cross validation if none of the MAT methods (A, B or C) can be validated for a certain product.

3. REPLACEMENT OF THE RABBIT PYROGEN TEST BY THE MONOCYTE ACTIVATION TEST

As noted above, MAT is primarily intended to be used as a replacement for the rabbit pyrogen test. Monographs on pharmaceutical products intended for parenteral administration that may contain pyrogenic contaminants require either a test for bacterial endotoxins or a monocyte activation test.

As a general policy:

- in any individual monograph, when a test is required, only 1 test is included, either that for bacterial endotoxins or the MAT. Before including the MAT in a monograph, evidence is required that 1 of the 3 methods described in the MAT chapter can be applied satisfactorily to the product in question;
- the necessary information is sought from manufacturers. Companies are invited to provide any validation data that they have concerning the applicability of the MAT to the substances and formulations of interest. Such data include details of sample preparation and of any procedures necessary to eliminate interfering factors. In addition, any available parallel data for rabbit pyrogen testing that would contribute to an assurance that the replacement of a rabbit pyrogen test by the MAT is appropriate, is to be provided.

4. VALIDATION OF ALTERNATIVE METHODS

Replacement of a rabbit pyrogen test, or replacement of a method for detecting pro-inflammatory/pyrogenic contaminants by another method, is to be regarded as the use of an alternative method in the replacement of a pharmacopoeial test, as described in the General Notices.

The following procedures are suggested for validating a method for the MAT other than the one indicated in the monograph:

- the procedure and the materials and reagents used in the method should be validated as described for the test concerned;
- the presence of interfering factors (and, if needed, the procedure for removing them) should be tested on samples of at least 3 production batches.

MAT should be applied to all new products intended for parenteral administration that have to be tested for the presence of non-endotoxin pyrogens according to the requirements of the European Pharmacopoeia.

**01/2014:20631**

# 2.6.31. MICROBIOLOGICAL EXAMINATION OF HERBAL MEDICINAL PRODUCTS FOR ORAL USE AND EXTRACTS USED IN THEIR PREPARATION

1. MICROBIAL ENUMERATION TESTS

**Total aerobic microbial count (TAMC)**. Perform as described in general chapter *2.6.12*.

**Total combined yeasts/moulds count (TYMC)**. Perform as described in general chapter *2.6.12*. Due to the natural high bioburden in the products covered by general chapter *5.1.8*, use of Sabouraud-dextrose agar containing antibiotics is suitable.

2. TEST FOR SPECIFIED MICRO-ORGANISMS

2-1. *INTRODUCTION*

The tests described hereafter will allow determination of the absence or limited occurrence of specified micro-organisms that may be detected under the conditions described.
The tests are designed primarily to determine whether a product, substance or preparation (hereinafter referred to as 'the product') complies with an established specification for microbiological quality. When used for such purposes, follow the instructions given below, including the number of samples to be taken, and interpret the results as stated below.

Alternative microbiological procedures, including automated methods, may be used, provided that their equivalence to the Pharmacopoeia method has been demonstrated.

2-2. *GENERAL PROCEDURES*

The preparation of samples is carried out as described in general chapter *2.6.12*.
If the product to be examined has antimicrobial activity, this is as far as possible removed or neutralised as described in general chapter *2.6.12*.

If surface-active substances are used for sample preparation, their absence of toxicity for micro-organisms and their compatibility with inactivators used must be demonstrated as described in general chapter *2.6.12*.

2-3. *GROWTH-PROMOTING AND INHIBITORY PROPERTIES OF THE MEDIA, SUITABILITY OF THE TEST AND NEGATIVE CONTROLS*

The ability of the test to detect micro-organisms in the presence of the product to be examined must be established. Suitability must be confirmed if a change in testing performance, or the product, which may affect the outcome of the test is introduced.

2-3-1. **PREPARATION OF TEST STRAINS**

Use standardised stable suspensions of test strains or prepare them as stated below. Seed lot culture maintenance techniques (seed-lot systems) are used so that the viable micro-organisms used for inoculation are not more than 5 passages removed from the original master seed lot.

2-3-1-1. **Aerobic micro-organisms**. Grow each of the bacterial test strains separately in casein soya bean digest broth or on casein soya bean digest agar at 30-35 °C for 18-24 h.

- *Staphylococcus aureus* such as ATCC 6538, NCIMB 9518, CIP 4.83 or NBRC 13276;
- *Pseudomonas aeruginosa* such as ATCC 9027, NCIMB 8626, CIP 82.118 or NBRC 13275;
- *Escherichia coli* such as ATCC 8739, NCIMB 8545, CIP 53.126 or NBRC 3972;

– *Salmonella enterica* subsp. *enterica* serovar Typhimurium such as ATCC 14028 or, as an alternative, *S. enterica* subsp. *enterica* serovar Abony such as NBRC 100797, NCTC 6017 or CIP 80.39;

– *Bacillus subtilis* such as ATCC 6633, NCIMB 8054, CIP 52.62 or NBRC 3134.

Use buffered sodium chloride-peptone solution pH 7.0 or phosphate buffer solution pH 7.2 to make test suspensions. Use the suspensions within 2 h, or within 24 h if stored at 2-8 °C. As an alternative to preparing and then diluting a fresh suspension of vegetative cells of *B. subtilis*, a stable spore suspension is prepared and then an appropriate volume is used for test inoculation. The stable spore suspension may be maintained at 2-8 °C for a validated period of time.

2-3-2. **NEGATIVE CONTROL**

To verify testing conditions, a negative control is performed using the chosen diluent in place of the test preparation. There must be no growth of micro-organisms. A negative control is also performed when testing the products as described in section 2-4. A failed negative control requires an investigation.

2-3-3. **GROWTH-PROMOTING AND INHIBITORY PROPERTIES OF THE MEDIA**

Test each batch of ready-prepared medium and each batch of medium prepared either from dehydrated medium or from the ingredients described.

Verify suitable properties of relevant media as described in Table 2.6.31.-1.

Table 2.6.31.-1. – *Growth-promoting, inhibitory and indicative properties of media*

| | Medium | Property | Test strains |
|---|---|---|---|
| Test for bile-tolerant gram-negative bacteria | Casein soya bean digest broth | Growth promoting | *S. aureus*<br>*P. aeruginosa*<br>*B. subtilis* |
| | Enterobacteria enrichment broth-Mossel | Growth promoting | *E. coli*<br>*P. aeruginosa* |
| | | Inhibitory | *S. aureus* |
| | Violet red bile glucose agar | Growth promoting + indicative | *E. coli*<br>*P. aeruginosa* |
| Test for *Escherichia coli* | Casein soya bean digest broth | Growth promoting | *S. aureus*<br>*P. aeruginosa*<br>*B. subtilis* |
| | MacConkey broth | Growth promoting | *E. coli* |
| | | Inhibitory | *S. aureus* |
| | MacConkey agar | Growth promoting + indicative | *E. coli* |
| Test for *Salmonella* | Buffered peptone medium | Growth promoting | *S. enterica* subsp. *enterica* serovar Typhimurium or *S. enterica* subsp. *enterica* serovar Abony |
| | Rappaport Vassiliadis *Salmonella* enrichment broth | Growth promoting | *S. enterica* subsp. *enterica* serovar Typhimurium or *S. enterica* subsp. *enterica* serovar Abony |
| | | Inhibitory | *S. aureus* |
| | Xylose, lysine, deoxycholate agar | Growth promoting + indicative | *S. enterica* subsp. *enterica* serovar Typhimurium or *S. enterica* subsp. *enterica* serovar Abony |

**Test for growth-promoting properties, liquid media**: inoculate a portion of the appropriate medium with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for not more than the shortest period of time specified in the test. Incubate the casein soya bean digest broth at 30-35 °C for not more than 3 days. Clearly visible growth of the micro-organism comparable to that obtained with a previously tested and approved batch of medium occurs.

**Test for growth-promoting properties, solid media**: perform the surface-spread method, inoculating each plate with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for not more than the shortest period of time specified in the test. Growth of the micro-organism comparable to that obtained with a previously tested and approved batch of medium occurs.

**Test for inhibitory properties, liquid or solid media**: inoculate the appropriate medium with at least 100 CFU of the appropriate micro-organism. Incubate at the specified temperature for not less than the longest period of time specified in the test. No growth of the test micro-organism occurs.

**Test for indicative properties**: perform the surface-spread method, inoculating each plate with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for a period of time within the range specified in the test. Colonies are comparable in appearance and indication reactions to those obtained with a previously tested and approved batch of medium.

2-3-4. **SUITABILITY OF THE TEST METHOD**

For each product to be examined, perform the sample preparation as described in the relevant paragraph in section 2-4. Add each test strain at the time of mixing, in the prescribed growth medium (casein soya bean digest broth or buffered peptone medium). For the enumeration method for bile-tolerant gram-negative bacteria, inoculate *E. coli* and *P. aeruginosa* individually. For the tests for *E. coli* and *Salmonella*, inoculate the specified micro-organism individually.

Any antimicrobial activity of the product necessitates a modification of the test procedure (see section 4-5-3 of general chapter *2.6.12*).

If for a given product the antimicrobial activity with respect to a micro-organism for which testing is prescribed cannot be neutralised, then it is to be assumed that the inhibited micro-organism will not be present in the product.

2-3-4-1. **Test for absence**. Use a number of micro-organisms equivalent to not more than 100 CFU in the inoculated test preparation. Perform the test as described in the relevant paragraph in section 2-4 using the shortest incubation period prescribed. The specified micro-organisms must be detected with the indication reactions as described in section 2-4.

2-3-4-2. **Enumeration test**. Semi-quantitative test (probable-number method).

Use a number of micro-organisms equivalent to not more than 100 CFU per gram or millilitre of product. Perform the test as described in the relevant paragraph in section 2-4 using the shortest incubation period prescribed. The dilution corresponding to 0.1 g or 0.1 mL of product must be positive.

2-4. *TESTING OF PRODUCTS*

2-4-1. **BILE-TOLERANT GRAM-NEGATIVE BACTERIA**

2-4-1-1. **Enumeration test**. Semi-quantitative test (probable-number method).

2-4-1-1-1. *Sample preparation and pre-incubation*. Prepare a sample using a 10-fold dilution of not less than 1 g of the product to be examined as described in general chapter *2.6.12*, but using casein soya bean digest broth as the chosen diluent, mix and incubate at 20-25 °C for a time sufficient to resuscitate

the bacteria but not sufficient to encourage multiplication of the organisms (2-3 h).

2-4-1-1-2. *Selection and subculture.* Inoculate suitable quantities of enterobacteria enrichment broth-Mossel with the preparation as described above and/or, depending on the limit applied for the particular product, with 3 of the 4 dilutions of the preparation, which contain respectively 0.1 g, 0.01 g, 0.001 g and 0.0001 g (or 0.1 mL, 0.01 mL, 0.001 mL and 0.0001 mL) of the product to be examined. Incubate at 30-35 °C for 24-48 h. Subculture each of the cultures on a plate of violet red bile glucose agar. Incubate at 30-35 °C for 18-24 h.

2-4-1-1-3. *Interpretation.* Growth of colonies constitutes a positive result. Note the smallest quantity of the product that gives a positive result and the largest quantity that gives a negative result.

Determine from Table 2.6.31.-2 the probable number of bacteria.

Table 2.6.31.-2. – *Interpretation of results*

| Results for each quantity of product | | | | Probable number of bacteria per gram or millilitre of product |
|---|---|---|---|---|
| 0.1 g or 0.1 mL | 0.01 g or 0.01 mL | 0.001 g or 0.001 mL | 0.0001 g or 0.0001 mL | |
| + | + | + | + | $> 10^4$ |
| + | + | + | - | $< 10^4$ and $> 10^3$ |
| + | + | - | - | $< 10^3$ and $> 10^2$ |
| + | - | - | - | $< 10^2$ and $> 10$ |
| - | - | - | - | $< 10$ |

2-4-2. **ESCHERICHIA COLI**

2-4-2-1. **Test for absence**

2-4-2-1-1. *Sample preparation and pre-incubation.* Prepare a sample using a 10-fold dilution of not less than 1 g of the product to be examined as described in general chapter *2.6.12*, and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as described in section 2-3-4) of casein soya bean digest broth, mix and incubate at 30-35 °C for 18-24 h.

2-4-2-1-2. *Selection and subculture.* Shake the container, transfer 1 mL of casein soya bean digest broth to 100 mL of MacConkey broth and incubate at 42-44 °C for 24-48 h. Subculture on a plate of MacConkey agar at 30-35 °C for 18-72 h.

2-4-2-1-3. *Interpretation.* Growth of colonies indicates the possible presence of *E. coli*. This is confirmed by identification tests.

The product complies with the test if no colonies are present or if the identification tests are negative.

2-4-2-2. **Enumeration test**. Semi-quantitative test (probable-number method).

2-4-2-2-1. *Sample preparation and pre-incubation.* Prepare a sample using a 10-fold dilution of not less than 1 g of the product to be examined as described in general chapter *2.6.12*, and use the quantities corresponding respectively to 0.1 g, 0.01 g and 0.001 g (or 0.1 mL, 0.01 mL and 0.001 mL) to inoculate a suitable amount (determined as described in section 2-3-4) of casein soya bean digest broth, mix and incubate at 30-35 °C for 18-24 h.

2-4-2-2-2. *Selection and subculture.* Shake the container, transfer 1 mL of casein soya bean digest broth to 100 mL of MacConkey broth and incubate at 42-44 °C for 24-48 h. Subculture on a plate of MacConkey agar at 30-35 °C for 18-72 h.

2-4-2-2-3. *Interpretation.* Growth of colonies indicates the possible presence of *E. coli*. This is confirmed by identification tests.

Note the smallest quantity of the product that gives a positive result and the largest quantity that gives a negative result.

Determine from Table 2.6.31.-3 the probable number of bacteria.

Table 2.6.31.-3. – *Interpretation of results*

| Results for each quantity of product | | | Probable number of bacteria per gram or millilitre of product |
|---|---|---|---|
| 0.1 g or 0.1 mL | 0.01 g or 0.01 mL | 0.001 g or 0.001 mL | |
| + | + | + | $> 10^3$ |
| + | + | - | $< 10^3$ and $> 10^2$ |
| + | - | - | $< 10^2$ and $> 10$ |
| - | - | - | $< 10$ |

2-4-3. **SALMONELLA**

2-4-3-1. **Test for absence**

2-4-3-1-1. *Sample preparation and pre-incubation.* Use 25 g or 25 mL of the product to be examined to inoculate 225 mL of buffered peptone medium and mix (e.g. homogenise in a filter bag by using a blender). Incubate at 30-35 °C for 18-24 h.

2-4-3-1-2. *Selection and subculture.* Transfer 0.1 mL of buffered peptone medium to 10 mL of Rappaport Vassiliadis *Salmonella* enrichment broth and incubate at 30-35 °C for 18-24 h. Subculture on plates of xylose, lysine and deoxycholate agar. Incubate at 30-35 °C for 18-48 h.

2-4-3-1-3. *Interpretation.* The possible presence of *Salmonella* is indicated by the growth of well-developed, red colonies, with or without black centres. This is confirmed by identification tests.

The product complies with the test if colonies of the types described are not present or if the identification tests are negative.

*The following section is given for information.*

*RECOMMENDED SOLUTIONS AND CULTURE MEDIA*

The solutions and culture media mentioned in this chapter and described in general chapter *2.6.13* and the following buffered peptone medium have been found to be satisfactory for the purposes for which they are prescribed in this chapter. Other media may be used provided that their suitability can be demonstrated.

**Buffered peptone medium**

| | |
|---|---|
| Potassium dihydrogen phosphate | 1.5 g |
| Disodium hydrogen phosphate dodecahydrate | 9.0 g |
| Sodium chloride | 5.0 g |
| Peptone | 10.0 g |
| Purified water | 1000 mL |

Adjust the pH so that after sterilisation it is 7.0 ± 0.2 at 25 °C. Sterilise in an autoclave using a validated cycle.

**01/2020:20633**

# 2.6.33. RESIDUAL PERTUSSIS TOXIN

The test for residual pertussis toxin is performed *in vitro*, using a Chinese Hamster Ovary (CHO) cell-based assay, and is intended for the assay of non-adsorbed purified pertussis components.

*Pertussis toxin BRP* is suitable as a reference pertussis toxin preparation.

The CHO cell-clustering assay (CHO assay) is based on the induction of clusters in non-confluent CHO cell cultures by active pertussis toxin. The cultures are then examined under a microscope and any clusters present are counted. The assay may be used as a quantitative test or as a limit test with the sensitivity determined within each assay using dilutions of a reference pertussis toxin preparation.

The sensitivity of the CHO assay to pertussis toxin is verified with *pertussis toxin BRP* or a suitable reference preparation calibrated in International Units using a suitable CHO assay. The assay sensitivity is defined as the lowest concentration in the reference preparation dilution series to produce a positive response, i.e. at least 10 CHO cell clusters. A suitable assay has a sensitivity of at least 5 mIU/mL.

*The following method is given as an example.*

**Reagents and equipment**

- *Pertussis toxin BRP.*
- *CHO-K1 cell line* (ATCC No. CCL-61 or ECACC No. 85051005).
- *Kaighn's modified Ham's F-12K medium.*

  Media that have a slightly different composition from that in Table 2.6.33.-1 may also be used. Proline is an essential component of the medium. Adjust to pH 7.2 ± 0.2 if necessary.

Table 2.6.33.-1. – *Kaighn's modified Ham's F-12K medium*

| | |
|---|---|
| **Amino acids** | |
| L-Alanine | 18.0 mg |
| L-Arginine hydrochloride | 0.4220 g |
| L-Asparagine monohydrate | 30.0 mg |
| L-Aspartic acid | 26.6 mg |
| L-Cysteine hydrochloride monohydrate | 70.0 mg |
| L-Glutamic acid | 29.0 mg |
| L-Glutamine | 0.2920 g |
| Glycine | 15.0 mg |
| L-Histidine hydrochloride monohydrate | 45.8 mg |
| L-Isoleucine | 7.88 mg |
| L-Leucine | 26.2 mg |
| L-Lysine hydrochloride | 73.0 mg |
| L-Methionine | 8.96 mg |
| L-Phenylalanine | 9.92 mg |
| L-Proline | 69.0 mg |
| L-Serine | 21.0 mg |
| L-Threonine | 23.0 mg |
| L-Tryptophan | 4.1 mg |
| L-Tyrosine disodium salt dihydrate | 13.5 mg |
| L-Valine | 23.0 mg |
| **Vitamins** | |
| Biotin | 70 µg |
| D-Calcium pantothenate | 0.5 mg |
| Choline chloride | 14.0 mg |
| Folic acid | 1.3 mg |
| *myo*-Inositol | 18.0 mg |
| Nicotinamide | 37 µg |
| Pyridoxine hydrochloride | 60 µg |
| Riboflavin | 40 µg |
| Thiamine hydrochloride | 0.3 mg |
| Vitamin B12 | 1.4 mg |
| **Inorganic salts** | |
| Calcium chloride, anhydrous | 0.1020 g |
| Cupric sulfate pentahydrate | 2 µg |
| Disodium hydrogen phosphate, anhydrous | 0.1155 g |
| Ferric sulfate heptahydrate | 0.8 mg |
| Magnesium chloride, anhydrous | 49.7 mg |
| Magnesium sulfate, anhydrous | 0.1920 g |
| Potassium chloride | 0.2850 g |
| Sodium bicarbonate | 2.5000 g |
| Sodium chloride | 7.5300 g |
| Zinc sulfate heptahydrate | 0.144 mg |
| **Other components** | |
| D-Glucose | 1.2600 g |
| Hypoxanthine sodium salt | 4.0 mg |
| Lipoic acid | 0.21 mg |
| Phenol red | 3.0 mg |
| Putrescine dihydrochloride | 0.32 mg |
| Sodium pyruvate | 0.2200 g |
| Thymidine | 0.7 mg |
| Water | to 1000 mL |

- *CHO cell culture medium.* Supplement Kaighn's modified Ham's F-12K medium with foetal bovine serum to obtain a final concentration of 10 per cent *V/V*. Add a sufficient quantity of 0.2 M L-glutamine solution to obtain a final concentration of 1 per cent *V/V*. An antibiotic/antimycotic solution may be added if required. Adjust to pH 7.2 ± 0.2 if necessary. Store at 5 ± 3 °C for a maximum of 3 weeks, protected from light.
- *Trypsin-EDTA solution* (trypsin 0.25 per cent).
- *Phosphate-buffered saline pH 7.4 (PBS)*, without calcium or magnesium. Dissolve 9.0 g of *sodium chloride R*, 0.144 g of *potassium dihydrogen phosphate R* and 0.795 g of *disodium hydrogen phosphate heptahydrate R* in *water R*, and dilute to 1000.0 mL with the same solvent. Adjust the pH if necessary.
- *24-well flat-bottomed assay plates with lid.*
- *75 $cm^2$ tissue culture flasks.*
- *Low protein binding polypropylene microtubes.*

**CHO cell culture**. The cells are obtained from a cell bank and used between defined passage levels. CHO cells are cultured in tissue culture flasks containing 20 mL of CHO cell culture medium in a humidified incubator set at 37 °C and 5 per cent $CO_2$. The cells are passaged at a ratio of 1:5 to 1:20 as they approach confluence.

Before use, allow all reagents to reach room temperature or warm to 37 °C.

To passage the cells, remove the CHO cell culture medium. Wash the cell layer gently by rinsing briefly 2-3 times with PBS. Remove the PBS and add 2 mL of trypsin-EDTA solution to the flask, allowing it to cover the monolayer for 20 s. Remove the trypsin-EDTA solution by aspiration. Immediately observe the culture using phase-contrast microscopy. When the cells begin to contract, tap the side of the culture flask firmly to dislodge the cells. When the majority of cells are free-floating, add 10 mL of CHO cell culture medium to stop the trypsin digestion. Trypsinisation used for cell detachment must be carefully controlled to avoid over-digestion which causes cleavage of either pertussis toxin receptors or cell adherence proteins, or both.

Determine the cell concentration and viability using trypan blue exclusion or another appropriate method. The cell viability must be greater than 95 per cent to continue. Transfer a sufficient volume of the cell suspension to a fresh flask for a 1:5 to 1:20 passage ratio and add CHO cell culture medium to bring the volume to 20 mL. Incubate the cells in a humidified incubator set at 37 °C and 5 per cent $CO_2$ for at least 48 h prior to use in the CHO assay.

**Seeding density for CHO assay**. Prepare a suspension of CHO cells using the trypsinisation procedure described above. Count and dilute the cell suspension to between $4 \times 10^4$ and $8 \times 10^4$ CHO cells/mL in CHO cell culture medium. The cell concentration selected must allow clusters to be identified at the end of the stimulation period. Transfer 250 µL of the cell suspension into each well of the 24-well plates. Store the seeded plates in a humidified incubator set at 37 °C and 5 per cent $CO_2$ while the reference preparation and test sample are prepared.

**Preparation of pertussis toxin reference**. Reconstitute *pertussis toxin BRP* as stated in the leaflet accompanying the reference preparation. Prepare 7 two-fold serial dilutions in CHO cell culture medium, in such a way that the assay end-point occurs in the middle of the dilution series. The dilutions are prepared in low protein binding polypropylene microtubes. One dilution series for the reference preparation is included in each assay plate.

**Preparation of non-adsorbed purified pertussis component samples**. Dilute the test sample in CHO cell culture medium to obtain the highest concentration of the test sample which does not significantly dilute the nutrients of the medium, in order to maximise the sensitivity of the assay. Prepare a dilution series as described for the reference preparation.

**Stimulation of CHO cells**. Transfer 250 µL from each tube of the reference preparation dilution series into the assigned wells of the assay plates seeded with CHO cells. Similarly, transfer 250 µL of each dilution of the test sample into the assigned well(s). Transfer 250 µL of CHO cell culture medium into the negative control wells. Return the assay plates to a humidified incubator set at 37 °C and 5 per cent $CO_2$ for 48 h.

**Scoring and interpretation of results**. Observe the cell cultures using phase contrast microscopy at a magnification of 4× or 10×. In all wells the cell cultures must not be confluent and must have sufficient growth space to allow any clusters present to be counted. Assign a positive score when 10 or more CHO cell cluster formations are clearly evident within a single well. Assign a negative score to wells containing fewer than 10 clusters. The end-point concentration is the lowest concentration at which there is a positive score.

**Assay validity**

The test is not valid unless:

- the negative control wells show no evidence of clustering.
- wells containing the reference toxin preparation at a concentration greater than or equal to 5 mIU/mL exhibit a positive response (i.e. 10 or more CHO cell clusters).
- a clear end-point dilution is observed for the reference preparation.
- replicate values for the end-point of the reference preparation do not differ by more than one 2-fold dilution within one assay.

**Calculation**

Calculate the residual pertussis toxin activity in the test sample in International Units per millilitre, relative to the reference preparation, using the following expression:

$$\frac{GM(end-point)_S}{GM(end-point)_R} \times A_R$$

$GM(end\text{-}point)_S$ = geometric mean of the reciprocal of the end-point dilutions (last dilution at which there is a positive score) for the test sample;

$GM(end\text{-}point)_R$ = geometric mean of the reciprocal of the end-point dilutions (last dilution at which there is a positive score) for the reference preparation;

$A_R$ = activity of the reference preparation (stock solution), in International Units per millilitre.

*Example*

Series of 7 two-fold dilutions were prepared for the reference preparation and test sample. In this example, the reference stock solution has an activity of 1000 IU/mL. The scores observed at each dilution of the reference preparation and test sample, the reciprocal end-point dilutions and the geometric means of reciprocal end-point dilutions are shown in Tables 2.6.33.-2 and 2.6.33.-3.

Table 2.6.33.-2 – *Reference preparation dilutions and scores*

| **Reference preparation dilution** | **Score** | |
|---|---|---|
| | Rep. 1 | Rep. 2 |
| 1:100 000 | + | + |
| 1:200 000 | + | + |
| 1:400 000 | + | + |
| 1:800 000 | + | - |
| 1:1 600 000 | - | - |
| 1:3 200 000 | - | - |
| 1:6 400 000 | - | - |
| **End-point dilutions** | 1:800 000 | 1:400 000 |
| Reciprocal of end-point dilutions | 800 000 | 400 000 |
| ***GM(end-point)*$_R$** | 565 685 | |

Table 2.6.33.-3 – *Test sample dilutions and scores*

| Test sample dilution | Score | |
|---|---|---|
| | Rep. 1 | Rep. 2 |
| 1:100 | + | + |
| 1:200 | + | + |
| 1:400 | + | + |
| 1:800 | + | + |
| 1:1600 | + | - |
| 1:3200 | - | - |
| 1:6400 | - | - |
| **End-point dilutions** | 1:1600 | 1:800 |
| Reciprocal of end-point dilutions | 1600 | 800 |
| $GM(end\text{-}point)_s$ | 1131 | |

The residual pertussis toxin activity in the test sample can be determined as follows: (1131/565685) × 1000 = 2 IU/mL.

**04/2017:20634**

# 2.6.34. HOST-CELL PROTEIN ASSAYS

*This general chapter provides guidance for the development and validation of host-cell protein (HCP) assays used to test products obtained by recombinant DNA technology. It does not exclude the use of alternative approaches that are acceptable to the competent authority.*

INTRODUCTION

Host-cell proteins (HCPs) are process-related impurities derived from the host organism used for the production of a medicinal product by recombinant DNA technology. In order to mitigate their potential adverse effects (e.g. immunogenicity), HCP content is expected to be reduced to the lowest possible level.

HCP clearance during the purification process must be assessed and the HCP content determined using an HCP assay that has been evaluated and validated for a given product.

The HCP acceptance limit, typically expressed in nanograms of HCP per milligram of active substance (ppm), must be justified with regard to the HCP clearance capacity of the purification process and with regard to the potential impact of residual HCP on patients, taking into account the worst-case quantity of HCP that could be administered with the product.

HCPs are generally measured using an immuno-based assay containing, as reagents, the HCP antigen preparation (hereinafter 'the HCP antigens') or HCP reference standard and the corresponding polyclonal antibodies (antisera). Antisera must cover a broad spectrum of HCPs representative of the product concerned.

Sandwich-type enzyme-linked immunosorbent assays (ELISA) are the most commonly employed assays to assess quantitatively the level of HCPs. It should be noted that HCP content measured by ELISA does not represent absolute HCP mass content. The sensitivity is the result of the observed cumulative responses of many individual HCPs in comparison to the response of an HCP reference standard. The use of orthogonal analytical methods (e.g. electrophoresis, HPLC, Western blot, mass spectrometry) to characterise the various HCPs in the product is recommended to support the development and selection of the assay.

ASSAY SELECTION

Several types of assay are available, with selection taking into account several factors, including the stage of development of the product, the nature of the host cell and the protein immunogenicity, the expression mode, the manufacturing process, and prior knowledge. When selecting and developing the assay, its life cycle (e.g. reagent supply, consistency, assay validation, process change) must also be considered.

*TYPES OF ASSAY*

**Process-specific assays**

Process-specific HCP assays (also called product-specific HCP assays) are developed and validated taking into account the specificity of the production process, and using the same host organism expressing the recombinant product.

The HCP antigens are derived from a mock run of the active substance manufacturing process (or a process representative of it) up to a step capable of generating a broad spectrum of HCPs in sufficient quantities.

The antisera raised must cover a broad range of HCPs, in order to detect as many different HCPs as possible and also to accommodate process variations.

**Platform assays**

Platform assays are developed by individual manufacturers and customised for the processes and host organism used by the manufacturer for production. The same sets of reference standards and reagents may be used to monitor HCPs in several products manufactured in the same host organism, provided that upstream processes (and downstream, if relevant) are sufficiently similar for these products. The suitability of the antiserum should be evaluated as described above for process-specific assays.

**Generic assays**

Commercially available HCP test kits are commonly referred to as generic HCP assays. They are intended to work broadly across similar expression hosts. Detailed information on the preparation of the reagents may not be disclosed by the vendor. For instance, the HCP antigens may be derived from a combination of strains of an expression host species, and the process(es) used may not mimic the process applied for the product of interest. The suitability of the antiserum should be evaluated as described above for process-specific assays.

*CRITERIA FOR ASSAY SELECTION*

In view of the potential safety issues associated with residual HCPs in the active substance, a risk assessment is performed to support the choice between a generic, a platform or a process-specific strategy, taking into account the stage of development of the product.

For early development a generic assay or a platform assay may be used. For later development phases, process-specific assays must be considered, as they are generally regarded as superior, especially when compared to generic assays. This is because process-specific assays are more likely to show immunoreactivity against representative HCPs.

Platform or generic assays may be used, provided that the assay is appropriately characterised and validated against process-specific HCPs.

PRODUCTION AND TESTING OF THE HCP ANTIGEN PREPARATION

The HCP reagents (HCP antigens and anti-HCP antibodies) are produced in such a way as to facilitate replication of the production when a replenishment for the HCP assay is needed.

The HCP antigens are used to generate the polyclonal antibody reagent for the HCP immunoassay by immunising one or more suitable animal species. In addition, they serve as the HCP reference standard in the HCP immunoassay.

As far as possible, the HCP antigens must cover the relevant HCP population expected to be derived from the manufacturing process of the protein of interest.

The HCP population must also be broad enough to cover worst-case purification scenarios and to provide robustness against potential manufacturing process changes during the life cycle of the product.

*PROCESS-SPECIFIC ASSAYS*

**Null cell line**

Development of a process-specific assay involves the selection of a null cell line that does not contain the expression gene for the product of interest and is derived from the same cell line that has been used to establish the production cell line. This null cell line may be non-transfected or mock-transfected. A mock-transfected cell line is created by transfecting the parental cell line with a blank plasmid, i.e. the plasmid used to create the production cell line, but missing the gene coding for the protein of interest.

**Mock production process**

*Upstream*

The antigens produced for process-specific assays are obtained by a mock production process that mimics the intended manufacturing process, using the null cell line and, as far as possible, the same operating conditions.

As for any mock production, the process used represents an approximation of the intended manufacturing process and leads to differences (e.g. different scale, operating parameters, product interaction). However, the impact of those differences needs to be considered carefully because they may affect the composition of the HCP population.

For example, a mock fermentation of an inclusion body manufacturing process may not deliver the desired inclusion bodies if the product is not present. Therefore, depending on the null cell line used (e.g. mock-transfected or not), the antigens may need to be isolated differently compared to the intended manufacturing process.

In some situations, operating parameters for the mock production may be adjusted to cover worst-case scenarios (e.g. to deliver antigens covering a broad spectrum of different HCP species). For example, the antigen-containing cell culture supernatant may be harvested beyond the minimum level of cell viability in order to include more cytosolic proteins, which are released by additional cell lysis.

*Downstream*

The HCP antigens derived from the upstream process are usually only minimally processed (filtration, concentration), in order to obtain a representative spectrum of HCPs. Further purification is generally not recommended as there will be a risk of losing HCP species.

However, in cases where the antigens are not representative (e.g. resulting in low coverage), mixing of mock materials from different processing steps can be considered. Enrichment may also be achieved by pooling materials from mock fermentation or purification runs using different operating conditions, or from selective purification steps (e.g. to reduce large amounts of the few immunodominant HCPs).

**Cross-contamination with the protein of interest**

The HCP antigens must be produced in a manner that avoids contamination with even minute traces of the product in order to avoid cross-reactivity with the polyclonal antibodies.

To achieve this goal, dedicated or single-use equipment is used as much as possible. Where multi-purpose equipment is used, it must be cleaned appropriately. In addition, the risk of contamination when filling or handling the antigens in the laboratory environment must also be considered.

**Characterisation and testing**

Before using the HCP antigens for immunisation, the protein content is assessed (total protein assay) and the absence of the protein of interest verified.

Comparison of the HCP population with the mock and the intended production process is performed, typically by SDS-PAGE and/or two-dimensional (2D) electrophoresis with a high sensitivity stain. The aim of this comparison is to show that the HCP antigens resulting from the mock production process contain most of the representative HCP species of the intended manufacturing process. Where necessary, complementary information may be gathered by orthogonal methods, e.g. mass spectrometry.

*PLATFORM ASSAYS*

**Null cell line**

Development of a platform assay involves a null cell line that does not contain the expression gene for the product of interest, and uses the same host species. This null cell line may be non-transfected or mock-transfected, and may be used for the production of HCP antigens for products from a given company's manufacturing platform.

**Mock production process**

*Upstream*

The HCP antigens produced for platform assays are obtained by a mock production process that mimics the platform upstream process that is used for several products, and typically uses the same media components. As for any mock production, the process used represents an approximation of the intended manufacturing process, which may impact the composition of the HCP population (see process-specific assays).

*Downstream*

As for other assays, the HCP antigens derived from the upstream process are, in general, only minimally processed (e.g. no or limited number of purification steps) to obtain a broad spectrum of HCPs, although mixing and pooling strategies may also be used to widen the spectrum of HCP species.

**Characterisation and testing**

As for process-specific assays, both the protein content and the absence of the protein of interest are tested. Comparison of the HCP population with the mock and the intended production process is performed.

*GENERIC ASSAYS*

Generic assays are commercially available and are developed by the vendor.

Detailed information on the preparation of the reagents may not be disclosed by the vendor. For instance, the null cell line may be derived from a combination of strains of an expression host species, and the process(es) used may not mimic the process applied for the product of interest.

Nevertheless, the generic assay must be selected with consideration given to the intended manufacturing process (e.g. appropriate host cell line), and be appropriately validated for the product of interest and phase of development. As a consequence, if generic assays are used in later stages of development or during commercial manufacturing, it is recommended to validate the assay and control lot-to-lot reagent consistency using either appropriate upstream fractions from the production process or a mock preparation generated using a null cell line.

PRODUCTION AND CHARACTERISATION OF THE ANTI-HCP ANTIBODY REAGENT

*PROCESS-SPECIFIC AND PLATFORM ASSAYS*

**Immunisation**

One of the challenges of the immunisation step is to generate polyclonal antibodies that are highly specific and sensitive for each of the antigenic proteins in the complex mixture of HCPs used as an immunogen. An animal's immune response must be stimulated against both the stronger and the weaker antigens.

An animal host that yields a sufficient quantity and diversity of HCP-specific immunoglobulin G (IgG) is selected.

Where both the polyclonal capture and the polyclonal detection antibodies are from the same source, it can be assumed that they recognise different epitopes on the same HCP in the assay. Alternatively, polyclonal anti-HCP antibodies from different animal species may be used. Using several animals for a given species may reduce the impact of individual variations in immune competence and provide additional response diversity, resulting in maximised antibody coverage against the HCP antigens.

An immune response to a limited number of HCP antigens may be obtained rapidly, particularly when adjuvants are used to boost the immune response. However, in complex mixtures, differential enhancement of the immune response towards weaker antigens or those at lower concentrations may be necessary.

It usually takes several immunisations to reach a maximum immunological response and, depending on the frequency of immunisation, the process can take 3-6 months to complete.

The immune response against the HCPs for a given immunisation scheme has to be monitored by determining the antibody titre using, for example, an ELISA, and by comparing the results of 1D or 2D electrophoresis after protein staining and a Western blot, where the polyclonal anti-HCP antibodies are used as primary antibody. In practice, some minor proteins that elicit a strong immune response may not be visible in the protein-stained gel, and some poorly antigenic proteins that are detectable by protein staining may not elicit a detectable immune response. To achieve sample-dilution linearity in complex multi-analyte immunoassays, it is essential that the immune reagent simultaneously and specifically recognises as many individual analytes as possible in an assay sample and that it is present in stoichiometric excess. For this purpose, a series of sample dilutions from different process steps may be tested by ELISA using purified anti-HCP antibodies from bleedings that have shown suitable coverage by Western blot.

Finally, based on the results of the tests described above, antisera from different animals are pooled, retested and purified.

**Purification and preparation**

The HCP antibodies must be purified before an assay can be developed.

Typically, this is achieved by protein A- or protein G-chromatography and/or HCP antigen affinity chromatography. In the case of HCP antigen affinity chromatography, the antigens used for immunisation are immobilised on column chromatography media and the specific antibodies are captured by applying the antisera onto the column.

Additional purification to remove potential aggregates might be required by gel permeation chromatography.

For the ELISA, a part of the purified anti-HCP antibodies is conjugated to a detection label (e.g. biotin or horseradish peroxidase).

The purified anti-HCP antibodies and the sera must be stored at a temperature that ensures their stability.

**Characterisation and testing**

The suitability of the derived HCP assay reagent is assessed by demonstrating the coverage of the HCPs representative of the manufacturing process by the anti-HCP antibodies.

For this purpose, 2D electrophoresis of the HCP antigens is performed. The protein pattern of the immunostain is compared with the protein pattern of the total stain. The anti-HCP antibodies must recognise a broad range of HCPs over the full range of charge and molecular size. Other methods using native conditions may be considered.

*GENERIC ASSAYS*

Immunisation, purification and preparation of the anti-HCP antibody reagent are carried out by the vendor and details may not be available.

Characterisation and testing of anti-HCP antibodies are performed as for other assay types. Typically, there is limited control over lot-to-lot reagent consistency. Appropriate comparative lot testing is therefore required.

VALIDATION OF THE HCP ASSAY

The HCP ELISA is developed to detect and quantify a heterogeneous mixture of antigens at varying concentrations, and with a reagent containing antibodies that are not represented at a one-to-one ratio. The section below is intended to target the specifics in development and validation of this type of ELISA.

HCP assays such as ELISA are validated with regard to accuracy, specificity, precision, quantitation and detection limits, linearity, range and robustness.

During the life cycle of the product, a full or partial revalidation of the assay may be required, for example when implementing a manufacturing process change that may impact the suitability of the HCP reagent.

**Accuracy**

Accuracy is demonstrated by spike/recovery analysis of the HCP reference standard in a relevant background matrix (e.g. the active substance or a sample from a relevant purification step).

**Specificity**

Specificity is demonstrated by the absence of interference from the matrix background (including the active substance). For instance, data from the accuracy study can be used to assess specificity.

**Precision**

As for any other quantitative assay, repeatability, intermediate precision and reproducibility are appropriately demonstrated.

**Quantitation and detection limits**

Sensitivity is usually in the ppm range and is normally described through the quantitation limit (QL). QL is typically determined by HCP spike recovery studies in the active substance or an appropriate sample matrix, and is calculated from the minimal spike providing a response with predefined accuracy and precision from replicate analyses.

Detection limit (DL) is often not determined (optional validation parameter).

**Linearity**

The linearity of the HCP assay is demonstrated using dilution series of the HCP standard and spike/recovery experiments (accuracy study).

Additionally, due to the nature of HCP assays, the multiple HCP analytes and polyclonal anti-HCP antibodies, sample-dilution non-linearity may be observed, i.e. back-calculated results increase with increasing dilutions of samples, which in most cases is related to the excess of one or more individual HCPs in the sample when compared to the available antibodies in the HCP immunoassay. As a consequence, dilution linearity must be properly assessed for the relevant process steps by comparison of target versus measured HCP concentrations at varying sample dilutions. Dilution linearity is demonstrated if the acceptance criteria for assay variation are met for different sample dilutions. Studies demonstrating dilution linearity can be carried out either during method development or at the latest during method validation.

If a sample shows dilution non-linearity, multiple sample dilutions are prepared beyond the range where non-linear behaviour is observed.

The final HCP value is typically reported as the average HCP concentration obtained for a minimum of 2 dilutions within the linear dilution range. If justified, 1 dilution may be sufficient.

**Range**

The range of the assay is typically defined by the HCP concentrations for which a suitable level of precision, accuracy and linearity has been demonstrated.

**Robustness**

The evaluation of robustness is considered during the development phase.

CHANGE OF HCP ASSAY AND/OR REAGENT

The quantities of antigens and antibodies must be large enough to supply the HCP assay for several years. Therefore, the supply, quality and consistency of reagents must be appropriately managed throughout the life cycle of the assay.

For generic HCP assays, in order to ensure the consistency and quality of the reagents, recharacterisation or revalidation of the assay may be required for each new batch of reagent, as their quality may change from one batch to another.

For process-specific and for platform assays, there are generally 2 situations where new HCP assay reagents may be required:

- the HCP reference standard and/or antibody are depleted; antibody may then be purified from a frozen serum stock or a new immunisation is required;
- a manufacturing process change can impact the HCP composition for the purification intermediates or the final product; the assay reagent may not be properly suited to detect and quantify the modified HCPs; a manufacturing process change can therefore render the reagents unsuitable for assay use.

Newly prepared reagents must be thoroughly characterised (e.g. by 2D-SDS-PAGE/Western blot for coverage, 2D-SDS-PAGE/differential gel electrophoresis (DIGE)/identification by MS). Afterwards, the validation status of the assay using the new reagents must be assessed. It is recommended to perform these experiments side-by-side with the currently used reagents.

Table 2.6.34.-1 outlines a recommendation for reagent characterisation and assessment of immunoassay validation, as a consequence of a depletion of assay reagents or a process change.

Table 2.6.34.-1

| | Depleted reagents | | Process change |
|---|---|---|---|
| | **HCP reference standard** | **Anti-HCP antibody** | |
| Reagent characterisation | The protein concentration of the new reference standard is determined preferably using the same method as for the current reference standard to ensure that the protein concentrations are comparable.<br>Using suitable methods (e.g. 1D-/2D-PAGE, 2D-DIGE), the similarity in protein composition between the new and current HCP reference standards is assessed. | Total protein concentration of the new antibody is determined. The final assay concentration must be titrated for the new lot in order to achieve a similar standard curve as for the current lot.<br>For detection antibodies, the detection label: protein stoichiometry is controlled and ensured to be similar to the current antibody lot.<br>Immunoreactivity of the new antibody is compared qualitatively (by visual comparison) or semi-quantitatively (coverage determination) against the current lot by suitable methods (e.g. 1D or 2D Western blot). Due to the variability of the method, it is particularly advisable to perform this characterisation side-by-side with the current antibody lot. | The effects of process changes that have the potential to impact the HCP composition are analysed by suitable methods (e.g. 1D-/2D-PAGE, Western blot, HCP assay).<br>If the process change does not lead to a relevant change in HCP composition, the current HCP reagents are also suitable for the new process.<br>If the process change does lead to a relevant change in HCP composition, but the suitability of the current HCP reagents was demonstrated, the current HCP reagents are also suitable for the new process.<br>If the process change does lead to a relevant change in HCP composition, but the current HCP reagents were shown to be unsuitable for the new process, a new assay must to be developed including a mock fermentation according to the new process and a new immunisation. |
| Testing of reagents in HCP assays | The new HCP reference standard is quantitatively tested against the current reference standard for spike recovery at different concentrations covering the validated assay range.<br>Standard curves obtained with the new versus the current reference standard are assessed for similarity. | Standard curves obtained when using new versus current antibody lots are compared.<br>A bridging study is performed with testing of relevant process samples (e.g. purification steps from harvest to the final active substance). In a side-by-side experiment, new antibodies must detect HCP levels at different process steps equally or with an improved quantitation limit. | A mock run harvest from the new process is tested for spike recovery using the current HCP assay.<br>Relevant process samples (e.g. purification steps from harvest to the final active substance) from the new and the previous process are tested side-by-side. |

| | Depleted reagents | | Process change |
|---|---|---|---|
| | HCP reference standard | Anti-HCP antibody | |
| Assessment of validation status | If reagent characterisation and ELISA testing demonstrate suitability of the new HCP reference standard, the current reference standard can be replaced. No revalidation of the test method is required.<br>If the new HCP reference standard differs significantly in protein composition and/or assay performance from the current reference standard, revalidation is required. | If reagent characterisation and ELISA testing demonstrate that the new antibody is suitable, the current antibody can be replaced. No revalidation of the test method is required.<br>If the new antibody differs significantly in Western blot immunoreactivity or immunoassay sensitivity and/or assay performance compared to the current antibody, revalidation is required. | If, for the new process, the antibody shows similar or higher immunoreactivity compared to the previous process, and the HCP assay shows adequate recovery from the mock harvest of the new process and also similar or higher sensitivity for samples from the relevant process steps, then the current assay and reagents are considered suitable for the new process. No revalidation of the test method is required.<br>If reagents appear suitable to detect HCP from the new process, but the ELISA indicates significant differences in spike recovery of the mock sample or of HCP levels at relevant process steps, then revalidation is required. The process change might also impact dilution linearity of test samples from certain process steps; if these steps are essential for the HCP control strategy, revalidation or even generation of new antibody reagents might be required.<br>In case of a major change in HCP composition with the new process that leads to either a mismatch in protein composition compared to the current assay standard, reduced immunoreactivity of the antibody, or significantly decreased immunoassay sensitivity, then new assay reagents are prepared and the HCP assay is validated with the new reagents. |

# 2.6.35. QUANTIFICATION AND CHARACTERISATION OF RESIDUAL HOST-CELL DNA

*This general chapter describes analytical methods that may be used to measure the content and to characterise the size of residual host-cell DNA in biological products produced in cell substrates. It does not exclude the use of alternative approaches that are acceptable to the competent authority.*

## INTRODUCTION

Several sensitive analytical methods exist for the quantification of residual host-cell DNA, including real-time quantitative PCR (qPCR) (Method A) and an immunoenzymatic method (Method B).

qPCR may also be used to assess the residual host-cell DNA size distribution, as a characterisation test depending on the nature of the cell substrate (e.g. continuous cell lines) and on the amount of residual host-cell DNA.

A suitable method is selected depending on the nature of the biological product to be tested and taking into account the characteristics and limitations of each method as summarised in Table 2.6.35.-1.

Table 2.6.35.-1 - *Comparison of the characteristics of qPCR and immunoenzymatic methods*

| Characteristics | qPCR (Method A) | Immunoenzymatic method (Method B) |
|---|---|---|
| Can be used to assess DNA size distribution | Yes | No |
| Limit of quantification (*may vary depending on the matrix, method and interfering substances*) | 0.01-10 pg/mL | 2-10 pg/mL |
| Specificity (total DNA versus specific DNA) | Specific DNA | Total DNA |
| Interfering substances | Proteins | Detergents/proteins/solvents/RNA |
| Limitations | Fragments smaller than the PCR product can not be detected and quantified. | Not applicable for DNA-based products.<br>The DNA content is underestimated for fragments below 1000 base pairs (bp).<br>Detectability depends on DNA size.<br>Undetectable short DNA fragments (below 80 nucleotides) can interfere with the assay through reagent consumption.<br>Products must be free of bacterial DNA.<br>Narrow quantification range: 5-150 pg/well. |

SAMPLE PREPARATION

The concentration of residual host-cell DNA may vary depending on the type of biological product and the DNA clearance capacity of the manufacturing process.

Depending on the sample matrix, pretreatment of the sample may be necessary to ensure appropriate recovery of the residual host-cell DNA.

When analysing highly purified protein samples such as recombinant proteins or monoclonal antibodies, simple digestion with proteinase or affinity chromatography may be sufficient to recover the residual host-cell DNA. For more complex matrices such as viral vaccines and viral vectors, an additional virus lysis step may be required to release the residual host-cell DNA from the viral particles.

The immunoenzymatic method is especially sensitive to interference from proteins. This can be avoided by performing an initial pretreatment step, which may include digestion with proteinase K and sodium dodecyl sulfate (SDS). This step may suffice to recover the residual host-cell DNA. However, in other cases, the residual host-cell DNA may be bound to the sample components, and/or soluble interfering substances may be present, in which case it may be necessary to extract the residual host-cell DNA from the sample.

The DNA can be extracted using protocols which have demonstrated a satisfactory recovery rate during spiking experiments. Several suitable methods exist, including DNA precipitation or DNA-specific binding to a matrix (e.g. magnetic beads or silica columns). Commercial kits can be used to extract residual host-cell DNA samples. Some of these kits use a chaotrope (sodium iodide) and a detergent (sodium lauroylsarcosinate) to disrupt the association between the residual host-cell DNA and the sample components. The residual host-cell DNA in the sample is then recovered by co-precipitation with a carrier molecule such as glycogen in the presence of ethanol or 2-propanol. Several independent extraction procedures may be required, depending on the reproducibility of the spike recovery. Negative controls must be included in each extraction procedure. In some cases, dilution of the samples may be recommended to reduce the matrix effect. A correction factor may also be applied to take into account the recovery rate of the spike.

METHOD A – REAL-TIME QUANTITATIVE PCR (qPCR)

This method can be used to quantify a cellular DNA target sequence from a variety of samples. For the quantification of residual host-cell DNA, qPCR targeting either a stable sequence within a highly conserved host-cell region or targeting repetitive elements to enhance the sensitivity of the test can be used. When repetitive elements are targeted, it may be difficult to eliminate potential background noise due to environmental DNA (e.g. when using Alu human sequences). The specificity of the qPCR method must be established during the validation studies by demonstrating the absence of cross-reactivity with unrelated sequences.

Alternatively, digital PCR methods may be used.

**qPCR amplification**

The detection and quantification of residual host-cell DNA by qPCR may involve the use of either a non-specific fluorescent dye that intercalates with any double-stranded DNA, or sequence-specific DNA probes. The qPCR principle described in general chapter *2.6.21. Nucleic acid amplification techniques* applies.

The number of cycles required for the fluorescent measurement to exceed a threshold value (Ct or Cp) correlates to the starting amount of residual host-cell DNA in the sample.

If several extractions are performed, the resulting samples must be analysed at an appropriate dilution.

PCR negative controls are used.

A standard curve is plotted using serial dilutions of host-cell genomic DNA in order to allow residual host-cell DNA levels in biological products to be determined based on their Ct or Cp values. The use of carefully characterised representative genomic DNA extracted from the cells used for the production of the biological product is recommended for the preparation of the standard.

The same methodology is applied for residual host-cell DNA size evaluation. At least 2 sets of primers can be designed to amplify overlapping fragments of different sizes in the target sequence.

**Suitability criteria**

*Control samples*. In order to control the risk of contamination and to ensure adequate sensitivity, each PCR assay includes the following controls:

- *a negative control for qPCR* and *a negative control for extraction*, composed of a sample of a suitable matrix already proven to be free of the target sequence(s);
- *a positive control for qPCR*, which contains a defined number of target sequence copies or a defined DNA concentration which is determined individually for each assay system;
- *a control for extraction*, typically an internal control added to the test material as a defined concentration or number of target-sequence copies. In this case, the amplicons must be clearly discernible and may be detected in a separate qPCR. Alternatively, an external control consisting of test sample spiked with a well-characterised level of genomic DNA may be used.

Extraction recovery must fall within predetermined values based on the performance of the assay as demonstrated during assay validation.

*Genomic DNA standard curve*. The standard curve is linear over the chosen range.

The coefficient of determination $R^2$ associated with the standard curve must be greater or equal to 0.98. The PCR efficiency falls within pre-established limits.

The coefficient of variation for the different extracts or replicates is not higher than a predefined criterion.

**Calculation**

If several extractions are performed, each extracted sample is analysed individually. The residual host-cell DNA content is calculated from the genomic standard curve by averaging the values obtained for the different extractions or replicates. A correction factor may also be applied to take into account the recovery rate for total DNA quantification in the samples.

For the characterisation of residual host-cell DNA size, the distribution of the overlapping fragments of different sizes is calculated as the ratio of the number of copies for each amplicon size to the number of copies of the smallest amplicon size.

METHOD B – IMMUNOENZYMATIC METHOD

The immunoenzymatic method is a non-specific technique for the quantification of residual host-cell DNA (regardless of its origin). It is therefore also a total DNA assay, and consequently, it is not only critical to avoid contamination through environmental DNA, but all materials and reagents used must be DNA-free. The samples to be tested must be free of microbial contamination and all samples, controls and standards must be processed under controlled conditions until the denaturation step.

By design, the method detects single-stranded DNA.

**Principle**

This total DNA assay consists of 4 steps:

- *denaturation and formation of complexes*, where the DNA is denatured into single-stranded DNA by heating the sample. The denatured DNA is mixed with a single reagent that contains a single-stranded DNA-binding protein

conjugated to streptavidin and a monoclonal anti-DNA antibody conjugated to urease. The DNA-binding protein and the monoclonal antibody are specific for single-stranded DNA but are not sequence-specific. The liquid phase, in the presence of streptavidin, facilitates the formation of a complex with the single-stranded DNA from the sample.

– *filtration*, where the complex is filtered through a biotinylated nitrocellulose membrane. The biotin in the membrane captures the complexes by binding to streptavidin. The membrane is washed to remove any unbound reagents. Non-specific binding is avoided by the use of an albumin-coated nitrocellulose membrane.

– *detection*, where the membrane is placed in a reader, which contains a urea solution that reacts with the urease in the DNA complex and produces ammonia. The associated change in pH is measured by a potentiometric sensor in µV/s and is directly proportional to the amount of DNA in the sample.

– *analysis*, where the raw data from the sample and from the standard curve are analysed using appropriate software to determine the residual host-cell DNA content in the sample.

All samples and negative controls are tested spiked and unspiked. The spike solution (1000 pg/mL) is prepared by dilution of a concentrated standard (calf thymus DNA) at 5000 pg/mL.

**Suitability criteria**

*Control samples*

– the amount of DNA in the positive control falls within the range indicated on the batch certificate provided by the supplier;

– spike recovery in the negative control is between 80 per cent and 120 per cent.

*Samples*

– when several replicates are analysed, the coefficient of variation for the different replicates is not higher than a predefined criterion;

– spike recovery is between 80 per cent and 120 per cent.

**Calculation**

The content of residual host-cell DNA is calculated in picograms per millilitre using the following expression:

$$\frac{ID \times (C - A)}{V}$$

*ID* = ratio for dilution and sampling;

*C* = raw mean value (in picograms per tube) for the test tubes containing the diluted sample;

*A* = raw mean value (in picograms per tube) for the test tubes containing the negative control;

*V* = volume in the test tube, in millilitres (usually 0.5 mL per tube).

Where necessary, this result may be corrected by the extraction recovery (e.g. mean recovery for a given product).

# 2.6.36. MICROBIOLOGICAL EXAMINATION OF LIVE BIOTHERAPEUTIC PRODUCTS: TESTS FOR ENUMERATION OF MICROBIAL CONTAMINANTS

## 1. INTRODUCTION

The tests described hereafter will allow enumeration of live biotherapeutic product (LBP) contaminants: mesophilic bacteria and yeasts/moulds that may grow under aerobic conditions.

The tests are designed primarily to determine whether an LBP substance or preparation complies with the established specifications for microbial contamination.

Alternative microbiological procedures (*5.1.6*), including automated methods, may be used, provided that their equivalence to the Pharmacopoeia method has been demonstrated.

## 2. GENERAL PROCEDURES

Carry out the determination under conditions designed to avoid extrinsic microbial contamination of the LBP to be tested. The precautions taken to avoid contamination must be such that they do not affect any contaminant micro-organisms that are to be revealed in the test.

If the LBP to be tested prevents the enumeration of contaminant micro-organisms, apply the decision tree shown in Figure 2.6.36.-1.

If components other than the active substance (i.e. the micro-organism) of the LBP to be tested have inhibitory activity, this is insofar as possible removed or neutralised as described in general chapter *2.6.12*. If inactivators are used for this purpose, their efficacy and their absence of toxicity for the target contaminant micro-organisms must be demonstrated.

If surface-active substances are used for sample preparation, their absence of toxicity for the target contaminant micro-organisms and their compatibility with inactivators used must be demonstrated.

## 3. ENUMERATION METHODS

Use the plate-count or the most-probable-number (MPN) method. The MPN method is generally the least accurate method for microbial counts.

The choice of method is based on factors such as the nature of the LBP and the required limit of microbial contamination. The chosen method must allow testing of a sufficient sample size to judge compliance with the specification. The suitability of the method chosen must be established.

## 4. GROWTH PROMOTION TEST, SUITABILITY OF THE COUNTING METHOD AND NEGATIVE CONTROLS

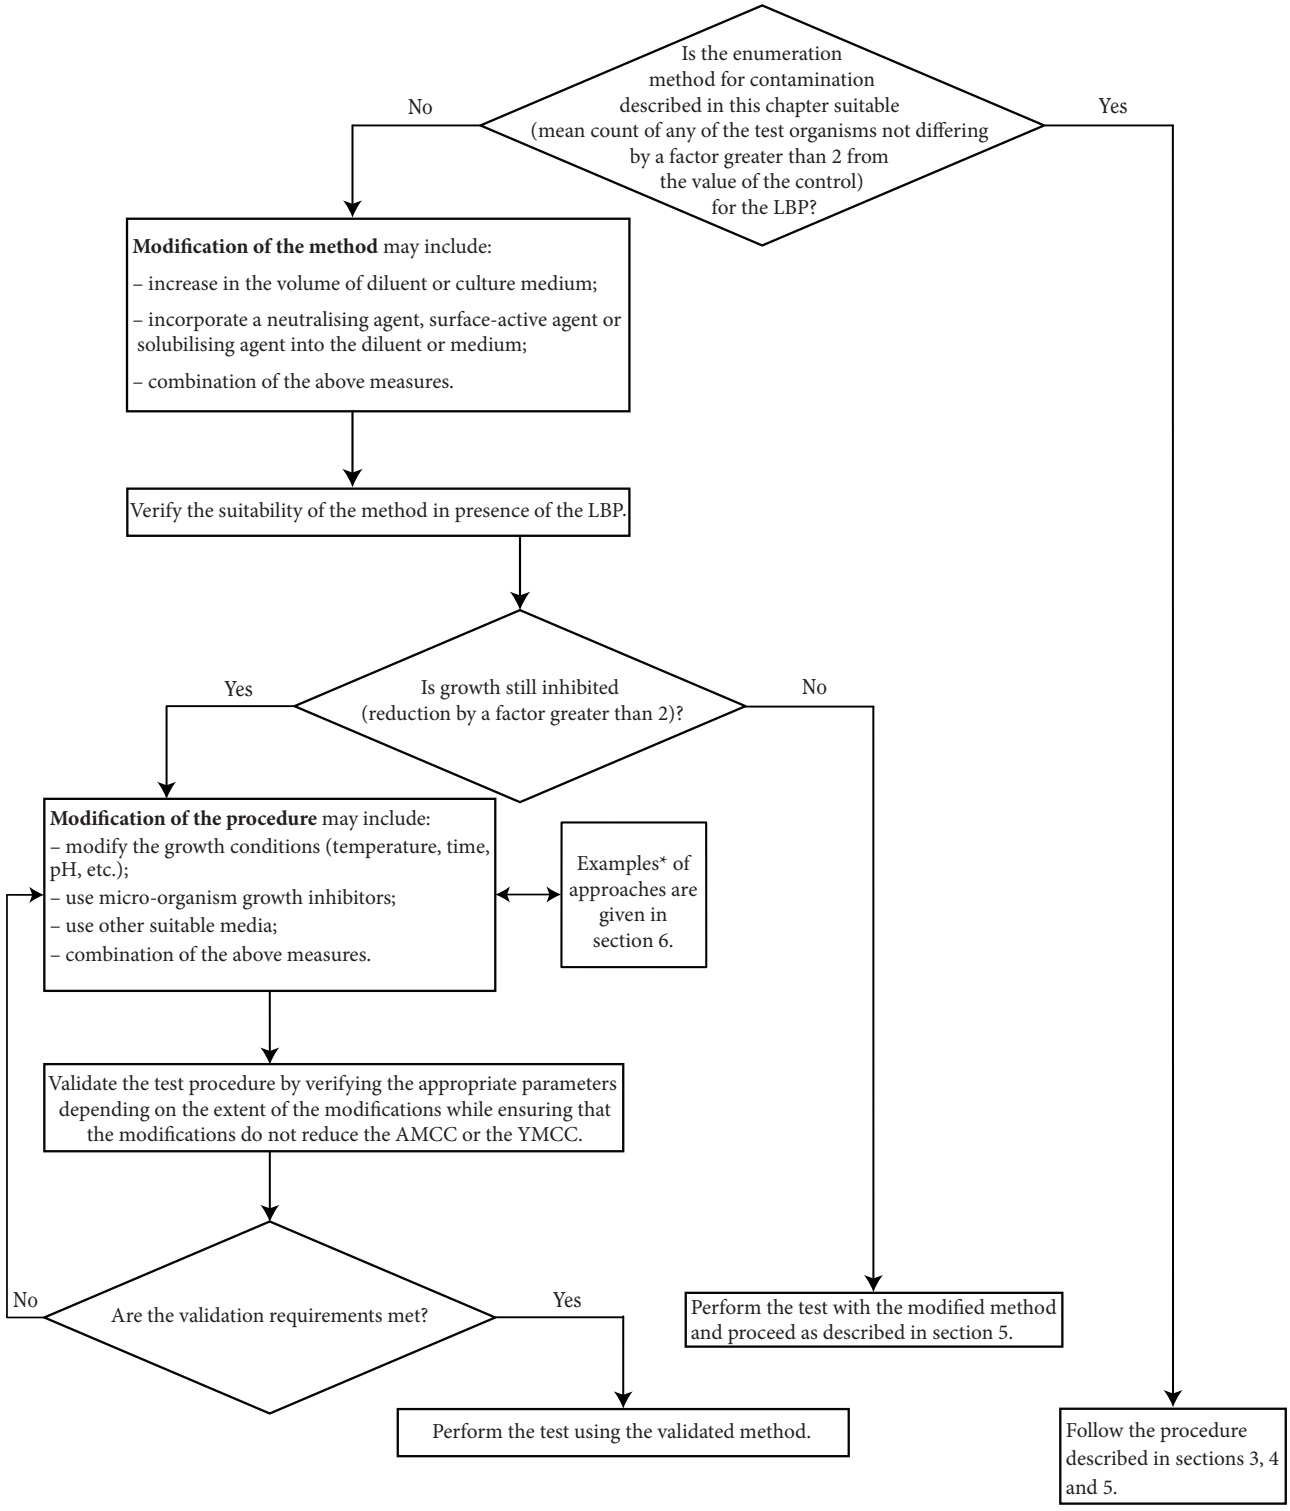
### *4-1. GENERAL CONSIDERATIONS*

The ability of the test to detect microbial contamination in the presence of the LBP to be tested must be established.

Suitability must be confirmed if a change in testing performance, or in the LBP, which may affect the outcome of the test is introduced.

### *4-2. PREPARATION OF TEST STRAINS*

Use standardised stable suspensions of test strains or prepare them as stated below. Seed lot culture maintenance techniques (seed-lot systems) are used so that the viable



* This section should be understood as informative suggestion. Other procedures are possible as far as they are justified.

Figure 2.6.36.-1. – *Decision tree for the microbial contamination enumeration methods*

micro-organisms used for inoculation are not more than 5 passages removed from the original master seed-lot. Grow each of the bacterial and fungal test strains separately as described in Table 2.6.36.-1.

Use buffered sodium chloride-peptone solution pH 7.0 or phosphate buffer solution pH 7.2 to make test suspensions; to suspend *A. brasiliensis* spores, 0.05 per cent of polysorbate 80 may be added to the buffer. Use the suspensions within 2 h or within 24 h if stored at 2-8 °C. As an alternative to preparing and then diluting a fresh suspension of vegetative cells of *A. brasiliensis* or *B. subtilis*, a stable spore suspension is prepared and then an appropriate volume of the spore suspension is used for test inoculation. The stable spore suspension may be maintained at 2-8 °C for a validated period of time.

*4-3. NEGATIVE CONTROL*

To verify testing conditions, a negative control is performed using the chosen diluent in place of the test preparation. There must be no growth of micro-organisms. A negative control is also performed when testing the LBP as described in section 5. A failed negative control requires an investigation.

*4-4. GROWTH PROMOTION OF THE MEDIA*

Test each batch of ready-prepared medium and each batch of medium, prepared either from dehydrated medium or from the ingredients described.

Inoculate portions/plates of casein soya bean digest broth and casein soya bean digest agar with a small number (not more than 100 CFU) of the micro-organisms indicated in Table 2.6.36.-1, using a separate portion/plate of medium for each. Inoculate plates of Sabouraud-dextrose agar with a small number (not more than 100 CFU) of the micro-organisms indicated in Table 2.6.36.-1, using a separate plate of medium for each. Incubate in the conditions described in Table 2.6.36.-1.

For solid media, growth obtained must not differ by a factor greater than 2 from the calculated value for a standardised inoculum. For a freshly prepared inoculum, growth of the micro-organisms comparable to that previously obtained with a previously tested and approved batch of medium occurs.

Liquid media are suitable if clearly visible growth of the micro-organisms comparable to that previously obtained with a previously tested and approved batch of medium occurs.

*4-5. SUITABILITY OF THE COUNTING METHOD IN THE PRESENCE OF THE LBP TO BE TESTED*

**4-5-1. Preparation of the sample**. The method for sample preparation depends upon the physical characteristics of the LBP to be tested. If none of the procedures described below can be demonstrated to be satisfactory, an alternative procedure must be developed.

Prepare a homogenous suspension of the LBP to be tested (usually a 1 in 10 dilution is prepared) in buffered sodium chloride-peptone solution pH 7.0, phosphate buffer solution pH 7.2 or casein soya bean digest broth. A surface-active agent such as a 1 g/L solution of polysorbate 80 may be added to assist the suspension of poorly wettable substances. If necessary, adjust to pH 6-8. Further dilutions, where necessary, are prepared with the same diluent.

Table 2.6.36.-1. – *Preparation and use of test micro-organisms*

| Micro-organism | Preparation of test strain | Growth promotion | | Suitability of counting method in the presence of the LBP | |
|---|---|---|---|---|---|
| | | Aerobic microbial contamination count (AMCC) | Yeasts and moulds contamination count (YMCC) | Aerobic microbial contamination count (AMCC) | Yeasts and moulds contamination count (YMCC) |
| *Staphylococcus aureus* such as: ATCC 6538 NCIMB 9518 CIP 4.83 NBRC 13276 | Casein soya bean digest agar or casein soya bean digest broth 30-35 °C 18-24 h | Casein soya bean digest agar and casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days | - | Casein soya bean digest agar/MPN: casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days | - |
| *Pseudomonas aeruginosa* such as: ATCC 9027 NCIMB 8626 CIP 82.118 NBRC 13275 | Casein soya bean digest agar or casein soya bean digest broth 30-35 °C 18-24 h | Casein soya bean digest agar and casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days | - | Casein soya bean digest agar/MPN: casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days | - |
| *Bacillus subtilis* such as: ATCC 6633 NCIMB 8054 CIP 52.62 NBRC 3134 | Casein soya bean digest agar or casein soya bean digest broth 30-35 °C 18-24 h | Casein soya bean digest agar and casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days | - | Casein soya bean digest agar/MPN: casein soya bean digest broth ≤ 100 CFU 30-35 °C ≤ 3 days | - |
| *Candida albicans* such as: ATCC 10231 NCPF 3179 IP 48.72 NBRC 1594 | Sabouraud- dextrose agar or Sabouraud-dextrose broth 20-25 °C 2-3 days | Casein soya bean digest agar ≤ 100 CFU 30-35 °C ≤ 5 days | Sabouraud- dextrose agar ≤ 100 CFU 20-25 °C ≤ 5 days | Casein soya bean digest agar ≤ 100 CFU 30-35 °C ≤ 5 days MPN: not applicable | Sabouraud- dextrose agar ≤ 100 CFU 20-25 °C ≤ 5 days |
| *Aspergillus brasiliensis* such as: ATCC 16404 IMI 149007 IP 1431.83 NBRC 9455 | Sabouraud- dextrose agar or potato-dextrose agar 20-25 °C 5-7 days, or until good sporulation is achieved | Casein soya bean digest agar ≤ 100 CFU 30-35 °C ≤ 5 days | Sabouraud- dextrose agar ≤ 100 CFU 20-25 °C ≤ 5 days | Casein soya bean digest agar ≤ 100 CFU 30-35 °C ≤ 5 days MPN: not applicable | Sabouraud- dextrose agar ≤ 100 CFU 20-25 °C ≤ 5 days |

**4-5-2. Inoculation and dilution**. Add to the sample prepared as described above (4-5-1) and to a control (with no test material included) a sufficient volume of the microbial suspension to obtain an inoculum of not more than 100 CFU. The volume of the suspension of the inoculum should not exceed 1 per cent of the volume of diluted LBP.

To demonstrate acceptable recovery of the test micro-organisms from the LBP, the lowest possible dilution factor of the prepared sample must be used for the test. Where this is not possible due to inhibitory activity of the LBP, further appropriate protocols must be developed (see decision tree shown in Figure 2.6.36.-1). If inhibition of growth by the sample cannot otherwise be avoided, the aliquot of the test micro-organisms may be added after neutralisation or dilution.

*Inhibitory activity*. The number of micro-organisms recovered from the prepared sample diluted as described in 4-5-2 and incubated following the procedure described in 4-5-3, is compared to the number of micro-organisms recovered from the control preparation.

If growth is inhibited (reduction by a factor greater than 2), follow the decision tree shown in Figure 2.6.36.-1 and modify the procedure for the particular enumeration test to ensure the validity of the results. Modification of the procedure may include, for example, (1) an increase in the volume of the

diluent or culture medium, (2) incorporation of specific or general neutralising agents into the diluent, (3) membrane filtration, or (4) a combination of the above measures.

If growth is still inhibited (reduction by a factor greater than 2) continue to follow the decision tree shown in Figure 2.6.36.-1.

A new approach needs to be validated using the appropriate parameters depending on the extent of modification, while ensuring that the modifications do not reduce the AMCC or the YMCC.

**4-5-3. Recovery of the test micro-organisms in the presence of an LBP**. For each of the test micro-organisms listed, separate tests are performed. Only micro-organisms of the added test strain are counted.

*4-5-3-1. Plate-count methods.* Perform plate-count methods at least in duplicate for each medium and use the mean count of the result.

4-5-3-1-1. Pour-plate method

For Petri dishes 9 cm in diameter, add to the dish 1 mL of the sample prepared as described under 4-5-1 and 4-5-2, and 15-20 mL of casein soya bean digest agar or Sabouraud-dextrose agar, both media being at not more than 45 °C. If larger Petri dishes are used, the amount of agar medium is increased accordingly. For each of the micro-organisms listed in Table 2.6.36.-1, at least 2 Petri dishes are used. Incubate the plates as indicated in Table 2.6.36.-1. Take the arithmetic mean of the counts per medium and calculate the number of CFU in the original inoculum.

4-5-3-1-2. Surface-spread method

For Petri dishes 9 cm in diameter, add 15-20 mL of casein soya bean digest agar or Sabouraud-dextrose agar at about 45 °C to each Petri dish and allow to solidify. If larger Petri dishes are used, the volume of the agar is increased accordingly. Dry the plates, for example in a laminar-air-flow cabinet or an incubator. For each of the micro-organisms listed in Table 2.6.36.-1, at least 2 Petri dishes are used. Spread a measured volume of not less than 0.1 mL of the sample prepared as described under 4-5-1 and 4-5-2 over the surface of the medium. Incubate and count as prescribed under 4-5-3-1-1.

*4-5-3-2. Most-probable-number (MPN) method.* The precision and accuracy of the MPN method is less than the plate-count method. Unreliable results are obtained particularly for the enumeration of moulds. For these reasons the MPN method is reserved for the enumeration of AMCC in situations where no other method is available. If the use of the method is justified, proceed as follows.

Prepare a series of at least 3 serial tenfold dilutions of the LBP as described under 4-5-1 and 4-5-2. From each level of dilution, 3 aliquots of 1 g or 1 mL are used to inoculate 3 tubes with 9-10 mL of casein soya bean digest broth. If necessary, a surface-active agent such as polysorbate 80 may be added to the medium. Thus, if 3 levels of dilution are prepared, 9 tubes are inoculated.

Incubate all tubes at 30-35 °C for not more than 3 days. If reading of the results is difficult or uncertain owing to the nature of the LBP to be tested, subculture in the same broth, or in casein soya bean digest agar, for 1-2 days at the same temperature and use these results. Determine the most probable number of micro-organisms per gram or millilitre of the LBP to be tested from Table 2.6.36.-2.

*4-6. RESULTS AND INTERPRETATION*

When verifying the suitability of the plate-count method, a mean count of any of the test organisms not differing by a factor greater than 2 from the value of the control defined in 4-5-2 in the absence of the LBP must be obtained. When verifying the suitability of the MPN method the calculated value from the inoculum must be within 95 per cent confidence limits of the results obtained with the control.

If the above criteria cannot be met, follow the decision tree shown in Figure 2.6.36.-1 and modify the procedure for the particular enumeration test to ensure the validity of the results.

5. TESTING OF LIVE BIOTHERAPEUTIC PRODUCTS

*5-1. AMOUNT USED FOR THE TEST*

Unless otherwise prescribed, use 10 g or 10 mL of the LBP to be tested taken with the precautions referred to above.

For LBP where the total number of entities in a batch is less than 200 (e.g. samples used in clinical trials), the sample size may be reduced to 2 units, or 1 unit if the size is less than 100.

Select the sample(s) at random from the bulk material or from the available containers of the preparation. To obtain the required quantity, mix the contents of a sufficient number of containers to provide the sample.

Table 2.6.36.-2. – *Most-probable-number values of micro-organisms*

| Observed combinations of numbers of tubes showing growth in each set | | | MPN per gram or per millilitre of LBP | 95 per cent confidence limits |
|---|---|---|---|---|
| Number of grams or millilitres of LBP per tube | | | | |

| 3 | 3 | 3 | > 1100 | |

*5-2. EXAMINATION OF THE LBP*

**5-2-1. Plate-count methods**

*5-2-1-1. Pour-plate method.* Prepare the sample using a method that has been shown to be suitable as described in section 4. Prepare for each medium at least 2 Petri dishes for each level of dilution. Incubate the plates of casein soya bean digest agar at 30-35 °C for 3-5 days and the plates of Sabouraud-dextrose agar at 20-25 °C for 5-7 days. Select the plates corresponding to a given dilution and showing the highest number of contaminating colonies less than 250 for AMCC and 50 for YMCC. Take the arithmetic mean per culture medium of the counts and calculate the number of CFU per gram or per millilitre of LBP.

*5-2-1-2. Surface-spread method.* Prepare the sample using a method that has been shown to be suitable as described in section 4. Prepare at least 2 Petri dishes for each medium and each level of dilution. For incubation and calculation of the number of contaminant CFU proceed as described for the pour-plate method.

**5-2-2. Most-probable-number method**. Prepare and dilute the sample using a method that has been shown to be suitable as described in section 4. Incubate all tubes at 30-35 °C for 3-5 days. Subculture if necessary, using the procedure shown to be suitable. Record for each level of dilution the number of tubes showing microbial growth. Determine the most probable number of contaminant micro-organisms per gram or millilitre of the LBP to be tested from Table 2.6.36.-2.

*5-3. INTERPRETATION OF THE RESULTS*

The aerobic microbial contamination count (AMCC) is considered to be equal to the number of contaminating CFU found using casein soya bean digest agar; if colonies of contaminating yeasts/moulds are detected on this medium, they are counted as part of the AMCC. The combined yeasts/moulds contaminants count (YMCC) is considered to be equal to the number of CFU found using Sabouraud-dextrose agar; if colonies of contaminating bacteria are detected on this medium, they may be excluded from the YMCC. When the YMCC is expected to exceed the acceptance criterion due to bacterial growth, Sabouraud-dextrose agar containing antibiotics can be used (see decision tree shown in Figure 2.6.36.-1). If the count is carried out by the MPN method the calculated value is the AMCC.

When an acceptance criterion for microbial contamination is prescribed it is interpreted as follows:

- $10^1$ CFU: maximum acceptable count = 20;
- $10^2$ CFU: maximum acceptable count = 200;
- $10^3$ CFU: maximum acceptable count = 2000.

The recommended solutions and media are described in general chapter *2.6.13*.

6. APPROACHES FOR ENUMERATION OF MICROBIAL CONTAMINANTS IN THE PRESENCE OF INHIBITION DUE TO THE LBP

This section should be understood as informative suggestion. Other procedures are possible as far as they are justified. Examples of approaches for enumeration of microbial contaminants for LBP inhibiting the microbial contamination enumeration are indicated below.

Each approach needs to be validated using the appropriate parameters depending on the extent of modification, while ensuring that the modifications do not reduce the AMCC or the YMCC.

The test strains indicated in Table 2.6.36.-1 are used. Preparation of test strains is performed as described in 4-2. Negative control is performed as described in 4-3. Growth promotion and suitability of new culture media chosen is carried out by inoculating each batch of the medium with a small number (not more than 100 CFU) of the micro-organisms. Growth obtained does not differ by a factor greater than 2 from the calculated value for a standardised inoculum counted on casein soya bean digest agar (AMCC) or Sabouraud-dextrose agar (YMCC).

*6-1. ENUMERATION OF AEROBIC MICROBIAL CONTAMINANTS*

LBP containing lactic acid bacteria may be tested for aerobic microbial contamination on sugar-free agar plates incubated aerobically at 30-35 °C for 72 h. Lactic acid bacteria grow slowly as pinpoint colonies, while contaminants can easily be detected as larger colonies and are fast growing.

Alternatively, the aerobic microbial contamination may be tested on casein soya bean digest agar plates supplemented with 5 per cent of sheep blood at 30-35 °C for 44-48 h. The addition of blood enhances growth of contaminants and formation of distinctive colony morphology that are better discriminated in the presence of lactic acid bacteria.

For LBP containing *Bacillus clausii* spores, the aerobic microbial contamination may be enumerated on sporulating agar. The medium, by promoting the sporulation of *Bacillus clausii*, inhibits the vegetative growth of the LBP micro-organism, making the detection of contaminants possible. Plates are incubated at 33-37 °C for 48 h.

LBP containing *Saccharomyces cerevisiae*, var. *boulardii* may be tested for aerobic microbial contamination on casein soya bean digest agar containing cycloheximide, a suitable inhibitor of *Saccharomyces*. Plates are incubated at 30-35 °C for 3-5 days.

For LBP for which suitable media and growth conditions to enumerate aerobic microbial contamination are not available, not only the absence of specific contaminants (*Escherichia coli*, *Staphylococcus aureus*, *Pseudomonas aeruginosa*, *Salmonella* spp. and bile-tolerant Gram-negative bacteria) is verified using the method described in general chapter *2.6.38*, and tests for other contaminating micro-organisms are carried out based on a risk assessment (e.g. specific environmental contaminants).

*6-2. ENUMERATION OF YEAST AND MOULD CONTAMINANTS*

For LBP containing bacteria, the test may be carried out with Sabouraud-dextrose agar containing antimicrobials (e.g. chloramphenicol) incubated at 20-25 °C for 5-7 days.

For LBP containing *Saccharomyces cerevisae*, var. *boulardii*, yeasts and moulds may be determined using several media (Sabouraud-dextrose agar supplemented with chloramphenicol and cycloheximide, Czapek-Dox agar, potato dextrose agar).

04/2019:20638

# 2.6.38. MICROBIOLOGICAL EXAMINATION OF LIVE BIOTHERAPEUTIC PRODUCTS: TESTS FOR SPECIFIED MICRO-ORGANISMS

## 1. INTRODUCTION

The tests described hereafter are intended for determination of the absence or limited occurrence of specified micro-organisms that may be detected under the conditions described. The tests are designed primarily to determine whether a live biotherapeutic product (LBP) complies with the established specification for microbiological quality.

Alternative microbiological procedures, including automated methods, may be used, provided that their equivalence to the Pharmacopoeia method has been demonstrated.

## 2. GENERAL PROCEDURES

The preparation of samples is carried out as described in general chapter *2.6.36*.

If the LBP to be tested prevents the detection of specified micro-organisms apply the decision tree shown in Figure 2.6.38.-1.

If components other than the active substance (i.e. the micro-organism) of the LBP to be tested have inhibitory activity against the target contaminant micro-organisms, this is insofar as possible removed or neutralised as described in general chapter *2.6.36*.

If surface-active agents are used for sample preparation, their absence of toxicity for the target contaminant micro-organisms and their compatibility with inactivators used must be demonstrated as described in general chapter *2.6.36*.

## 3. GROWTH-PROMOTING AND INHIBITORY PROPERTIES OF THE MEDIA, SUITABILITY OF THE TEST AND NEGATIVE CONTROLS

The ability of the test to detect the target micro-organisms in the presence of the LBP to be tested must be established. Suitability must be confirmed if a change is introduced in the testing procedure or the LBP, which may affect the outcome of the test.

### *3-1. PREPARATION OF TEST STRAINS*

Use standardised stable suspensions of test strains or prepare them as stated below. Seed lot culture maintenance techniques (seed-lot systems) are used so that the viable micro-organisms used for inoculation are not more than 5 passages removed from the original master seed-lot.

**3-1-1. Aerobic micro-organisms**. Grow each of the bacterial test strains separately in casein soya bean digest broth or on casein soya bean digest agar at 30-35 °C for 18-24 h. Grow the test strain for *Candida albicans* separately on Sabouraud-dextrose agar or in Sabouraud-dextrose broth at 20-25 °C for 2-3 days.

- *Staphylococcus aureus* such as ATCC 6538, NCIMB 9518, CIP 4.83 or NBRC 13276;
- *Pseudomonas aeruginosa* such as ATCC 9027, NCIMB 8626, CIP 82.118 or NBRC 13275;
- *Escherichia coli* such as ATCC 8739, NCIMB 8545, CIP 53.126 or NBRC 3972;
- *Salmonella enterica* subsp. *enterica* serovar Typhimurium, such as ATCC 14028 or, as an alternative, *Salmonella enterica* subsp. *enterica* serovar Abony such as NBRC 100797, NCTC 6017 or CIP 80.39;
- *Candida albicans* such as ATCC 10231, NCPF 3179, IP 48.72 or NBRC 1594.

Use buffered sodium chloride-peptone solution pH 7.0 or phosphate buffer solution pH 7.2 to make test suspensions. Use the suspensions within 2 h or within 24 h if stored at 2-8 °C.

**3-1-2. Anaerobic micro-organisms**

**Clostridia**. Use a *Clostridium sporogenes* strain such as ATCC 11437 (NBRC 14293, NCIMB 12343, CIP 100651) or ATCC 19404 (NCTC 532 or CIP 79.03) or NBRC 14293. Grow the clostridial test strain under anaerobic conditions in reinforced medium for Clostridia at 30-35 °C for 24-48 h. As an alternative to preparing and then diluting down a fresh suspension of vegetative cells of *C. sporogenes*, a stable spore suspension is used for test inoculation. The stable spore suspension may be maintained at 2-8 °C for a validated period.

### *3-2. NEGATIVE CONTROL*

To verify testing conditions, a negative control is performed using the chosen diluent in place of the test preparation. There must be no growth of micro-organisms. A negative control is also performed when testing the LBP as described in section 4. A failed negative control requires an investigation.

### *3-3. GROWTH PROMOTION AND INHIBITORY PROPERTIES OF THE MEDIA*

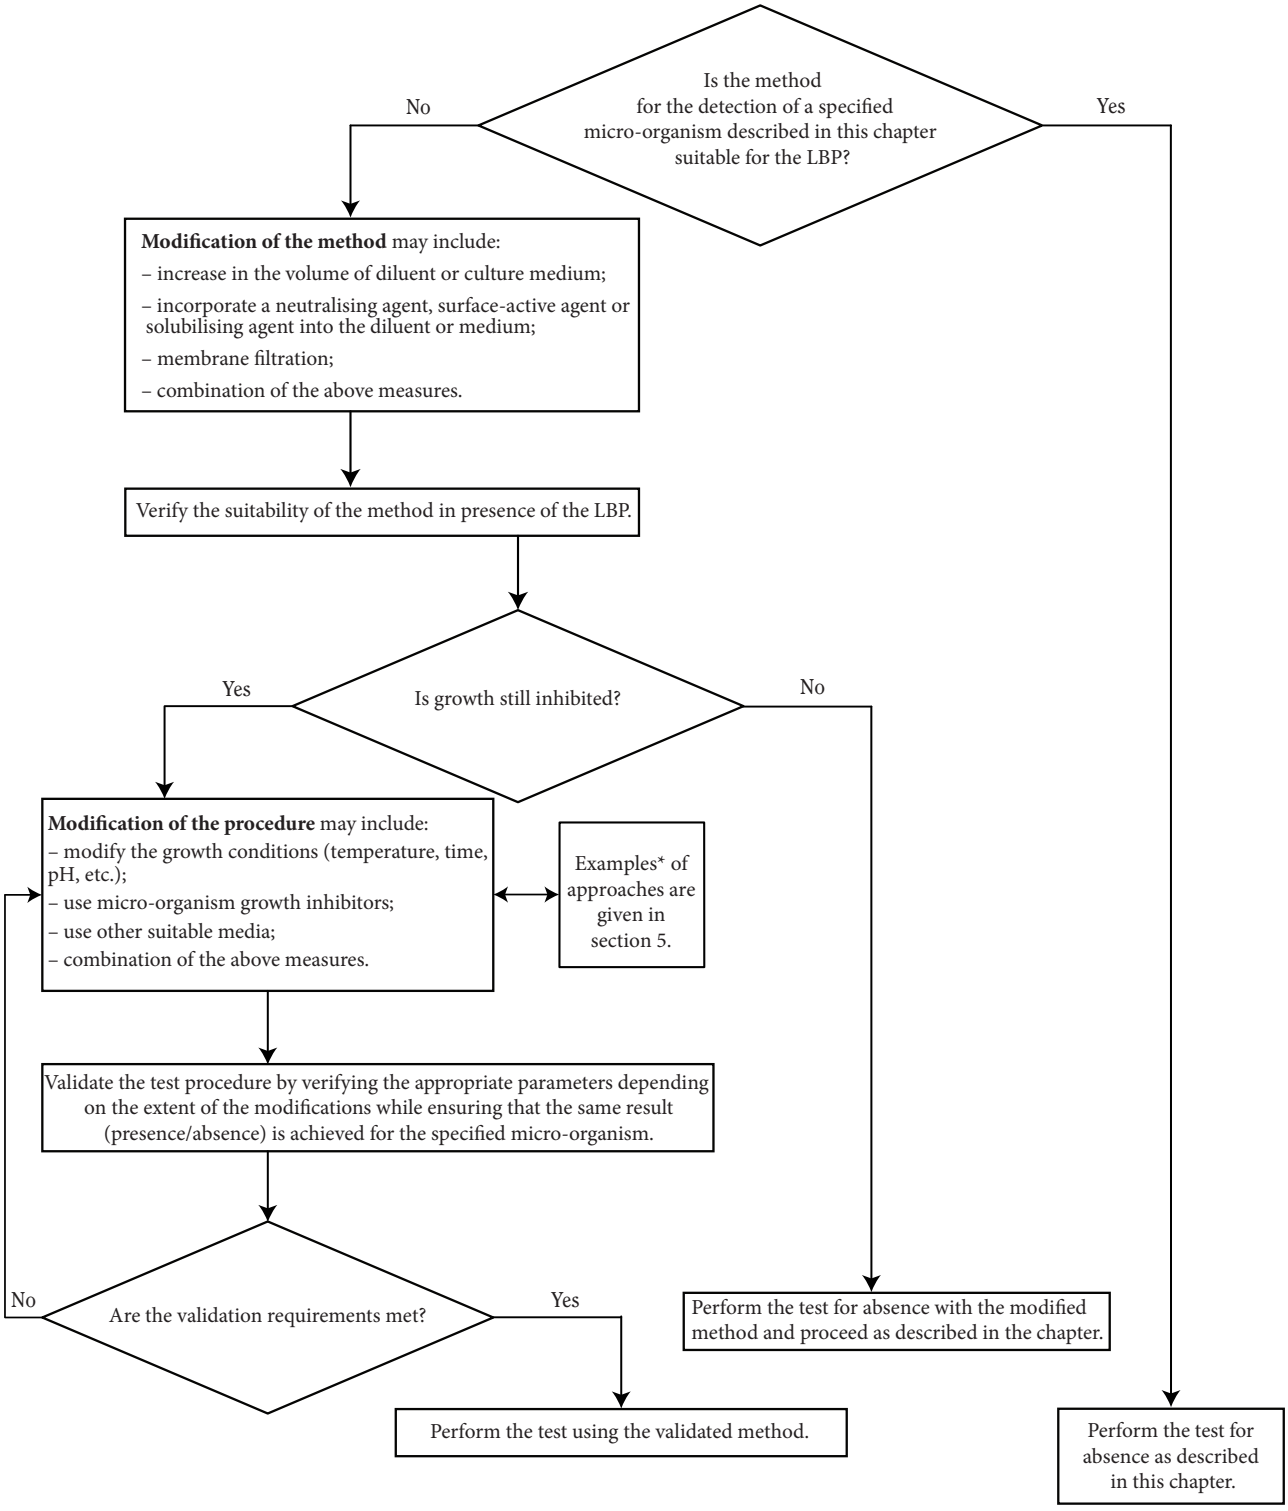
Test each batch of ready-prepared medium and each batch of medium prepared either from dehydrated medium or from ingredients.

Verify suitable properties of relevant media as described in Table 2.6.38.-1.

**3-3-1. Test for growth promoting properties, liquid media**. Inoculate a portion of the appropriate medium of the same volume to be used in the test (see sections 3-4 and 4) with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for not more than the shortest period of time specified in the test. Clearly visible growth of the micro-organism comparable to that previously obtained with a previously tested and approved batch of medium occurs.

**3-3-2. Test for growth promoting properties, solid media**. Perform the surface-spread method, inoculating each plate with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for not more than the shortest period of time specified in the test. Growth of the micro-organism is comparable to that previously obtained with a previously tested and approved batch of medium and does not differ by a factor greater than 2.

**3-3-3. Test for inhibitory properties, liquid or solid media**. Inoculate the appropriate medium with at least 100 CFU of the appropriate micro-organism. Incubate at the specified



* This section should be understood as informative suggestion. Other procedures are possible as far as they are justified.

Figure 2.6.38.-1. – *Decision tree for the test for specified micro-organisms*

temperature for not less than the longest period of time specified in the test. No growth of the test micro-organism occurs.

Table 2.6.38.-1. – *Growth promoting, inhibitory and indicative properties of media*

| | Medium | Property | Test strains |
|---|---|---|---|
| Test for bile-tolerant Gram-negative bacteria | Enterobacteria enrichment broth-Mossel | Growth promoting | *E. coli*<br>*P. aeruginosa* |
| | | Inhibitory | *S. aureus* |
| | Violet red bile glucose agar | Growth promoting + indicative | *E. coli*<br>*P. aeruginosa* |
| Test for *Escherichia coli* | MacConkey broth | Growth promoting | *E. coli* |
| | | Inhibitory | *S. aureus* |
| | MacConkey agar | Growth promoting + indicative | *E. coli* |
| Test for *Salmonella* | Rappaport Vassiliadis *Salmonella* enrichment broth | Growth promoting | *Salmonella enterica* subsp. *enterica* serovar Typhimurium or *Salmonella enterica* subsp. *enterica* serovar Abony |
| | | Inhibitory | *S. aureus* |
| | Xylose, lysine, deoxycholate agar | Growth promoting + indicative | *Salmonella enterica* subsp. *enterica* serovar Typhimurium or *Salmonella enterica* subsp. *enterica* serovar Abony |
| Test for *Pseudomonas aeruginosa* | Cetrimide agar | Growth promoting | *P. aeruginosa* |
| | | Inhibitory | *E. coli* |
| Test for *Staphylococcus aureus* | Mannitol salt agar | Growth promoting + indicative | *S. aureus* |
| | | Inhibitory | *E. coli* |
| Test for Clostridia | Reinforced medium for Clostridia | Growth promoting | *C. sporogenes* |
| | Columbia agar | Growth promoting | *C. sporogenes* |
| Test for *Candida albicans* | Sabouraud-dextrose broth | Growth promoting | *C. albicans* |
| | Sabouraud-dextrose agar | Growth promoting + indicative | *C. albicans* |

**3-3-4. Test for indicative properties**. Perform the surface-spread method, inoculating each plate with a small number (not more than 100 CFU) of the appropriate micro-organism. Incubate at the specified temperature for not more than the shortest validated period of time specified in the test. Colonies are comparable in appearance and indication reactions to those previously obtained with a previously tested and approved batch of medium.

*3-4. SUITABILITY OF THE TEST METHOD*

For each LBP to be tested, perform the sample preparation as described in the relevant paragraph in section 4. Inoculate the test strains individually. Add each test strain at the time of mixing, in the prescribed growth medium. Use a number of micro-organisms equivalent to not more than 100 CFU in the inoculated test preparation. The inoculum should not exceed 1 per cent of the volume of the growth medium. Perform the test as described in the relevant paragraph in section 4 using for each step of the test the shortest incubation time to be used in the test.

The specified micro-organisms must be detected with the appearance and indication reactions described in section 4. If non-characteristic colonies and reactions are obtained, the method may still be suitable provided that all colony types are identified when performing the test.

Any inhibitory activity of the LBP against the target micro-organisms necessitates a modification of the test procedure (see decision tree shown in Figure 2.6.38.-1) and then the suitability for the LBP must be confirmed.

## 4. TESTING OF LIVE BIOTHERAPEUTIC PRODUCTS

*4-1. BILE-TOLERANT GRAM-NEGATIVE BACTERIA*

**4-1-1. Sample preparation and pre-incubation**. Prepare a sample using a 1 in 10 dilution of not less than 1 g or 1 mL of the LBP to be tested as described in general chapter *2.6.36*, but using casein soya bean digest broth as the chosen diluent, mix and incubate at 20-25 °C for a time sufficient to resuscitate the bacteria but not sufficient to encourage multiplication of the micro-organisms (usually 2 h but not more than 5 h).

**4-1-2. Test for absence**. Unless otherwise prescribed, use the volume corresponding to 1 g of the LBP, as prepared in 4-1-1, to inoculate enterobacteria enrichment broth-Mossel. Incubate at 30-35 °C for 24-48 h. Subculture on violet red bile glucose agar. Incubate at 30-35 °C for 18-24 h.

The LBP complies with the test if there is no growth of colonies.

*4-2. ESCHERICHIA COLI*

**4-2-1. Sample preparation and pre-enrichment**. Prepare a sample using a 1 in 10 dilution of not less than 1 g or 1 mL of the LBP to be tested as described in general chapter *2.6.36* and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as described under 3-4) of casein soya bean digest broth, mix and incubate at 30-35 °C for 18-24 h.

**4-2-2. Selection and subculture**. Shake the container, transfer 1 mL of the casein soya bean digest broth to 100 mL of MacConkey broth and incubate at 42-44 °C for 24-48 h. Subculture on MacConkey agar at 30-35 °C for 18-72 h.

**4-2-3. Interpretation**. Growth of colonies indicates the possible presence of *E. coli*. This is confirmed by identification tests.

The LBP complies with the test if colonies are not present or if the confirmatory identification tests are negative.

*4-3. SALMONELLA*

**4-3-1. Sample preparation and pre-enrichment**. Prepare the LBP to be tested as described in general chapter *2.6.36* and use the quantity corresponding to not less than 10 g or 10 mL to inoculate a suitable amount (determined as described under 3-4) of casein soya bean digest broth, mix and incubate at 30-35 °C for 18-24 h.

**4-3-2. Selection and subculture**. Transfer 0.1 mL of the casein soya bean digest broth to 10 mL of Rappaport Vassiliadis *Salmonella* enrichment broth and incubate at 30-35 °C for 18-24 h. Subculture on xylose, lysine, deoxycholate agar. Incubate at 30-35 °C for 18-48 h.

**4-3-3. Interpretation**. Growth of well-developed, red colonies, with or without black centres indicates the possible presence of *Salmonella*. This is confirmed by identification tests.

The LBP complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

*4-4. PSEUDOMONAS AERUGINOSA*

**4-4-1. Sample preparation and pre-enrichment**. Prepare a sample using a 1 in 10 dilution of not less than 1 g or 1 mL of the LBP to be tested as described in general chapter *2.6.36* and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as described under 3-4) of casein soya bean digest broth and mix. Incubate at 30-35 °C for 18-24 h.

**4-4-2. Selection and subculture**. Subculture on cetrimide agar and incubate at 30-35 °C for 18-72 h.

**4-4-3. Interpretation**. Growth of colonies indicates the possible presence of *P. aeruginosa*. This is confirmed by identification tests.

The LBP complies with the test if colonies are not present or if the confirmatory identification tests are negative.

*4-5. STAPHYLOCOCCUS AUREUS*

**4-5-1. Sample preparation and pre-enrichment**. Prepare a sample using a 1 in 10 dilution of not less than 1 g or 1 mL of the LBP to be tested as described in general chapter *2.6.36* and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount (determined as described under 3-4) of casein soya bean digest broth and mix. Incubate at 30-35 °C for 18-24 h.

**4-5-2. Selection and subculture**. Subculture on mannitol salt agar and incubate at 30-35 °C for 18-72 h.

**4-5-3. Interpretation**. Growth of yellow/white colonies surrounded by a yellow zone indicates the possible presence of *S. aureus*. This is confirmed by identification tests.

The LBP complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

*4-6. CLOSTRIDIA*

**4-6-1. Sample preparation and heat treatment**. Prepare a sample using a 1 in 10 dilution (with a minimum total volume of 20 mL) of not less than 2 g or 2 mL of the LBP to be tested as described in general chapter *2.6.36*. Divide the sample into 2 portions of at least 10 mL. Heat 1 portion at 80 °C for 10 min and cool rapidly. Do not heat the other portion.

**4-6-2. Selection and subculture**. Use 10 mL or the quantity corresponding to 1 g or 1 mL of the LBP to be tested of both portions to inoculate suitable amounts (determined as described under 3-4) of reinforced medium for Clostridia. Incubate under anaerobic conditions at 30-35 °C for 48 h. After incubation, make subcultures from each container on Columbia agar and incubate under anaerobic conditions at 30-35 °C for 48-72 h.

**4-6-3. Interpretation**. The occurrence of anaerobic growth of rods (with or without endospores) giving a negative catalase reaction may indicate the presence of Clostridia. This is confirmed by identification tests.

The LBP complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

*4-7. CANDIDA ALBICANS*

**4-7-1. Sample preparation and pre-enrichment**. Prepare the LBP to be tested as described in general chapter *2.6.36* and use 10 mL or the quantity corresponding to not less than 1 g or 1 mL to inoculate 100 mL of Sabouraud-dextrose broth and mix. Incubate at 30-35 °C for 3-5 days.

**4-7-2. Selection and subculture**. Subculture on Sabouraud-dextrose agar and incubate at 30-35 °C for 24-48 h.

**4-7-3. Interpretation**. Growth of white colonies may indicate the presence of *C. albicans*. This is confirmed by identification tests.

The LBP complies with the test if colonies of the types described are not present or if the confirmatory identification tests are negative.

## 5. APPROACHES FOR TESTING SPECIFIED MICRO-ORGANISMS AND ADDITIONAL TESTING

This section should be understood as informative suggestion. Other procedures are possible as far as they are justified.

If the detection of the specified micro-organism is inhibited by the LBP, its detection is carried out under conditions that neutralise the inhibition or limit the growth of the LBP micro-organisms. The modified test for specified micro-organisms is validated using the appropriate validation parameters depending on the extent of the modifications while ensuring that the same result (presence/absence) is achieved for the specified micro-organism.

A suitable combination of antibiotics may be used to inhibit the LBP and detect the specified micro-organism. For example, for LBP samples containing *S. cerevisiae*, var. *boulardii*, pre-enrichment and selective media (Sabouraud-dextrose broth and agar) can be supplemented with chloramphenicol and cycloheximide to detect contaminant *C. albicans*.

Alternative pre-enrichment media (e.g. buffered peptone medium for *Salmonella* — see general chapter *2.6.31*), media and test/growth conditions may be used to support growth of the target micro-organisms while limiting growth of the micro-organisms of the LBP.

LBP containing *Bacillus clausii* spores are tested for contaminating *Bacillus cereus* on chromogenic selective agar media plates. Incubation time and temperature depends on the specific medium.

A proposed approach to detect *Bacillus cereus* is described below.

Prepare a sample using a 1 in 10 dilution of not less than 1 g or 1 mL of the LBP to be tested and use 10 mL or the quantity corresponding to 1 g or 1 mL to inoculate a suitable amount of casein soya bean digest broth, mix and incubate at 35-37 °C for 18-24 h. Subculture on selective media (e.g. *B. cereus* Mossel agar). For each LBP to be tested, validate incubation time and temperature. The appearance of *B. cereus* colonies depends on the medium used. The LBP complies with the test if no *B. cereus* colonies are present.

For LBP containing *E. coli*, use *Enterococcus faecalis* and *Enterococcus faecium* as microbial indicators of faecal contamination to replace the test for absence of *E. coli*. Use selective or differential chromogenic media and, for each LBP to be tested, validate incubation time and temperature. The LBP complies with the test when there is no growth of *Enterococcus* spp.

A search for pathogenic *E. coli* strains may be carried out by suitable methods (e.g. molecular methods for the detection of gene *stx* or *eae*) based on risk-assessment.

## 6. RECOMMENDED SOLUTIONS AND CULTURE MEDIA

The solutions and culture media mentioned in this chapter and described in chapter *2.6.13* have been found satisfactory for bile-tolerant Gram-negative bacteria, *E. coli*, *P. aeruginosa*, *S. aureus*, Clostridia, *Salmonella* and *C. albicans*. Other media may be used provided that their suitability can be demonstrated and the analytical method where they are used is validated with the appropriate validation parameters.

## 2.7.1. IMMUNOCHEMICAL METHODS

Immunochemical methods are based on the selective, reversible and non-covalent binding of antigens by antibodies. These methods are employed to detect or quantify either antigens or antibodies. The formation of an antigen-antibody complex may be detected, and the amount of complex formed may be measured by a variety of techniques. The provisions of this general method apply to immunochemical methods using labelled or unlabelled reagents, as appropriate.

The results of immunochemical methods depend on the experimental conditions and the nature and quality of the reagents used. It is essential to standardise the components of an immunoassay and to use, wherever available, international reference preparations for immunoassays.

The reagents necessary for many immunochemical methods are available as commercial assay kits, that is, a set including reagents (particularly the antigen or the antibody) and materials intended for the *in vitro* estimation of a specified substance as well as instructions for their proper use. The kits are used in accordance with the manufacturers' instructions; it is important to ascertain that the kits are suitable for the analysis of the substance to be examined, with particular reference to selectivity and sensitivity. Guidance concerning immunoassay kits is provided by the World Health Organization, Technical Report Series 658 (1981).

METHODS IN WHICH A LABELLED ANTIGEN OR A LABELLED ANTIBODY IS USED

Methods using labelled substances may employ suitable labels such as enzymes, fluorophores, luminophores and radioisotopes. Where the label is a radioisotope, the method is described as a "radio-immunoassay". The recommendations for the measurement of radioactivity given in the monograph on *Radiopharmaceutical Preparations (0125)* are applicable to immunoassays involving radioisotopes. All work with radioactive materials must be carried out in conformity with national legislation and internationally accepted codes of practice for protection against radiation hazards.

METHODS IN WHICH AN UNLABELLED ANTIGEN OR ANTIBODY IS USED

**Immunoprecipitation methods**

Immunoprecipitation methods include flocculation and precipitation reactions. When a solution of an antigen is mixed with its corresponding antibody under suitable conditions, the reactants form flocculating or precipitating aggregates. The ratio of the reactants which gives the shortest flocculation time or the most marked precipitation is called the optimal ratio, and is usually produced by equivalent amounts of antigen and antibody. Immunoprecipitation can be assessed visually or by light-scattering techniques (nephelometric or turbidimetric assay). An increase in sensitivity can be obtained by using antigen- or antibody-coated particles (e.g. latex) as reactants.

In flocculation methods, stepwise dilutions of one of the reactants is usually used whereas, in immunodiffusion (ID) methods, the dilution is obtained by diffusion in a gel medium: concentration gradients of one or both of the reactants are obtained, thus creating zones in the gel medium where the ratio of the reactants favours precipitation. While flocculation methods are performed in tubes, immunodiffusion methods may be performed using different supports such as tubes, plates, slides, cells or chambers.

Where the immunoprecipitating system consists of one antigen combining with its corresponding antibody, the system is referred to as *simple*; when it involves related but not serologically identical reactants, the system is *complex* and where several serologically unrelated reactants are involved, the system is *multiple*.

In *simple diffusion methods*, a concentration gradient is established for only one of the reactants diffusing from an external source into the gel medium containing the corresponding reactant at a comparatively low concentration.

*Single radial immunodiffusion* (SRID) is a simple quantitative immunodiffusion technique. When the equilibrium between the external and the internal reactant has been established, the circular precipitation area, originating from the site of the external reactant, is directly proportional to the amount of the antigen applied and inversely proportional to the concentration of the antibody in the gel.

In *double diffusion methods*, concentration gradients are established for both reactants. Both antigen and antibody diffuse from separate sites into an initially immunologically neutral gel.

*Comparative double diffusion methods* are used for qualitatively comparing various antigens versus a suitable antibody or vice versa. The comparison is based on the presence or absence of interaction between the precipitation patterns. Reactions of identity, non-identity or partial identity of antigens/antibodies can be distinguished.

**Immunoelectrophoretic methods**

Immunoelectrophoresis (IE) is a qualitative technique combining 2 methods: gel electrophoresis followed by immunodiffusion.

*Crossed immunoelectrophoresis* is a modification of the IE method. It is suitable both for qualitative and quantitative analysis. The first part of the procedure is an ordinary gel electrophoresis, after which a longitudinal gel strip, containing the separated fractions to be determined, is cut out and transferred to another plate. The electrophoresis in the second direction is carried out perpendicular to the previous electrophoretic run in a gel containing a comparatively low concentration of antibodies corresponding to the antigens. For a given antibody concentration and gel thickness, the relationship between the area of the respective precipitation peaks and the amount of the corresponding antigen is linear.

*Electroimmunoassay*, often referred to as *rocket immuno-electrophoresis* is a rapid quantitative method for determining antigens with a charge differing from that of the antibodies or vice versa. The electrophoresis of the antigen to be determined is carried out in a gel containing a comparatively lower concentration of the corresponding antibody. The test material and dilutions of a standard antigen used for calibration are introduced into different wells in the gel. During electrophoresis, migrating peak-shaped precipitation zones originating from the wells are developed. The front of the precipitate becomes stationary when the antigen is no longer in excess. For a given antibody concentration, the relationship between the distance travelled by the precipitate and the amount of antigen applied is linear.

*Counter-immunoelectrophoresis* is a rapid quantitative method allowing concentration gradients of external antigen and external antibody to be established in an electric field depending on the different charges. Dilutions of a standard for calibration and dilutions of the test material are introduced into a row of wells in a gel and a fixed amount of the corresponding reactant is introduced into an opposite row of wells. The titre of the test material may be determined as the highest dilution showing a precipitation line.

A number of modifications of crossed immunoelectrophoresis and electroimmunoassay methods exist.

Other techniques combine separation of antigens by molecular size and serological properties.

**Visualisation and characterisation of immunoprecipitation lines**

These may be performed by selective or non-selective stains, by fluorescence, by enzyme or isotope labelling or other relevant techniques. Selective staining methods are usually performed for characterisation of non-protein substances in the precipitates.

In translucent gels such as agar or agarose, the precipitation line becomes clearly visible in the gel, provided that the concentration of each of the reactants is appropriate.

VALIDATION OF THE METHOD

**Validation criteria**

A quantitative immunochemical method is not valid unless:

1) The antibody or antigen does not significantly discriminate between the test and standard. For a labelled reactant, the corresponding reactant does not significantly discriminate between the labelled and unlabelled compound,

2) The method is not affected by the assay matrix, that is, any component of the test sample or its excipients, which can vary between samples. These may include high concentrations of other proteins, salts, preservatives or contaminating proteolytic activity,

3) The limit of quantitation is below the acceptance criteria stated in the individual monograph,

4) The precision of the assay is such that the variance of the results meets the requirements stated in the individual monographs,

5) The order in which the assay is performed does not give rise to systematic errors.

**Validation methods**

In order to verify these criteria, the validation design includes the following elements:

1) The assay is performed at least in triplicate,

2) The assay includes at least 3 different dilutions of the standard preparation and 3 dilutions of sample preparations of presumed activity similar to the standard preparation,

3) The assay layout is randomised,

4) If the test sample is presented in serum or formulated with other components, the standard is likewise prepared,

5) The test includes the measurement of non-specific binding of the labelled reactant,

6) For displacement immunoassay:

(a) maximum binding (zero displacement) is determined,

(b) dilutions cover the complete response range from values close to non-specific binding to maximum binding, preferably for both standard and test preparations.

STATISTICAL CALCULATION

To analyse the results, response curves for test and standard may be analysed by the methods described in *5.3. Statistical Analysis of Results of Biological Assays and Tests*.

Significant non-parallelism indicates that the antibody or antigen discriminates between test and standard, and the results are not valid.

In displacement immunoassays, the values for non-specific binding and maximum displacement at high test or standard concentration must not be significantly different. Differences may indicate effects due to the matrix, either inhibition of binding or degradation of tracer.

01/2020:20702

# 2.7.2. MICROBIOLOGICAL ASSAY OF ANTIBIOTICS

The potency of an antibiotic is estimated by comparing the inhibition of growth of sensitive micro-organisms produced by known concentrations of the antibiotic to be examined and a reference substance.

The reference substances used in the assays are substances whose activity has been precisely determined with reference to the corresponding international standard or international reference preparation.

The assay must be designed in a way that will permit examination of the validity of the mathematical model on which the potency equation is based. If a parallel-line model is chosen, the 2 log dose-response (or transformed response) lines of the preparation to be examined and the reference preparation must be parallel; they must be linear over the range of doses used in the calculation. These conditions must be verified by validity tests for a given probability, usually $P = 0.05$. Other mathematical models, such as the slope ratio model, may be used provided that proof of validity is demonstrated.

Unless otherwise stated in the monograph, the confidence limits ($P = 0.95$) of the assay for potency are not less than 95 per cent and not more than 105 per cent of the estimated potency.

Carry out the assay by method A or method B.

A. DIFFUSION METHOD

Liquefy a medium suitable for the conditions of the assay and inoculate it at a suitable temperature, for example 48 °C to 50 °C for vegetative forms, with a known quantity of a suspension of micro-organisms sensitive to the antibiotic to be examined, such that clearly defined zones of inhibition of suitable diameter are produced with the concentrations of the antibiotic used for the assay. Immediately pour into Petri dishes or large rectangular dishes a quantity of the inoculated medium to form a uniform layer 2-5 mm thick. Alternatively, the medium may consist of 2 layers, only the upper layer being inoculated.

Store the dishes so that no appreciable growth or death of the micro-organisms occurs before the dishes are used and so that the surface of the medium is dry at the time of use.

Using the solvent and the buffer solution indicated in Table 2.7.2.-1, prepare solutions of the reference substance and of the antibiotic to be examined having known concentrations and presumed to be of equal activity. Apply the solutions to the surface of the medium, for example, in sterile cylinders of porcelain, stainless steel or other suitable material, or in cavities prepared in the agar. The same volume of solution must be added to each cylinder or cavity. Alternatively, use sterile absorbent paper discs of suitable quality; impregnate the discs with the solutions of the reference substance or the solutions of the antibiotic to be examined and place on the surface of the agar.

In order to assess the validity of the assay, use not fewer than 3 doses of the reference substance and 3 doses of the antibiotic to be examined having the same presumed activity as the doses of the reference substance. It is preferable to use a series of doses in geometric progression. In routine assays when the linearity of the system has been demonstrated over an adequate number of experiments using a three-point assay, a two-point assay may be sufficient, subject to agreement by the competent authority. However, in all cases of dispute, a three-point assay as described above must be applied.

Arrange the solutions on each Petri dish or on each rectangular dish according to a statistically suitable design, except for small Petri dishes that cannot accommodate more than 6 solutions, arrange the solutions of the antibiotic to be examined and the solutions of the reference substance in an alternate manner to avoid interaction of the more concentrated solutions.

Incubate at a suitable temperature for about 18 h. A period of diffusion prior to incubation, usually 1-4 h, at room temperature or at about 4 °C, as appropriate, may be used to minimise the effects of the variation in time between the application of the solutions and to improve the regression slope.

Measure the diameters to the nearest 0.1 mm or the areas of the circular inhibition zones to the nearest 0.01 $mm^2$ and calculate the potency using appropriate statistical methods.

Use in each assay the number of replications per dose sufficient to ensure the required accuracy and precision. The assay may be repeated and the results combined statistically to obtain the required accuracy and precision and to ascertain whether the potency of the antibiotic to be examined is not less than the minimum required.

B. TURBIDIMETRIC METHOD

Inoculate a suitable medium with a suspension of the chosen micro-organism having a sensitivity to the antibiotic to be examined such that a sufficiently large inhibition of microbial growth occurs in the conditions of the test. Use a known quantity of the suspension chosen so as to obtain a readily measurable opacity after an incubation period of about 4 h.

Use the inoculated medium immediately after its preparation.

Using the solvent and the buffer solution indicated in Table 2.7.2.-2 prepare solutions of the reference substance and of the antibiotic to be examined having known concentrations presumed to be of equal activity.

In order that the validity of the assay may be assessed, use not fewer than 3 doses of the reference substance and 3 doses of the antibiotic to be examined having the same presumed activity as the doses of the reference substance. It is preferable to use a series of doses in geometric progression. In order to obtain the required linearity, it may be necessary to select from a large number 3 consecutive doses, using corresponding doses for the reference substance and the antibiotic to be examined.

Distribute an equal volume of each of the solutions into identical test-tubes and add to each tube an equal volume of inoculated medium (for example, 1 mL of the solution and 9 mL of the medium). For the assay of tyrothricin add 0.1 mL of the solution to 9.9 mL of inoculated medium.

Prepare at the same time 2 control tubes without antibiotic, both containing the inoculated medium and to one of which is added immediately 0.5 mL of *formaldehyde R*. These tubes are used to set the optical apparatus used to measure the growth.

Place all the tubes, randomly distributed or in a Latin square or randomised block arrangement, in a water-bath or other suitable apparatus fitted with a means of bringing all the tubes rapidly to the appropriate incubation temperature and maintain them at that temperature for 3-4 h, taking precautions to ensure uniformity of temperature and identical incubation time.

After incubation, stop the growth of the micro-organisms by adding 0.5 mL of *formaldehyde R* to each tube or by heat treatment and measure the opacity to 3 significant figures using suitable optical apparatus. Alternatively use a method which allows the opacity of each tube to be measured after exactly the same period of incubation.

Calculate the potency using appropriate statistical methods.

Linearity of the dose-response relationship, transformed or untransformed, is often obtained only over a very limited range. It is this range which must be used in calculating the activity and it must include at least 3 consecutive doses in order to permit linearity to be verified. In routine assays when the linearity of the system has been demonstrated over an adequate number of experiments using a three-point assay, a two-point assay may be sufficient, subject to agreement by the competent authority. However, in all cases of dispute, a three-point assay must be applied.

Use in each assay the number of replications per dose sufficient to ensure the required accuracy and precision. The assay may be repeated and the results combined statistically to obtain the required accuracy and precision and to ascertain whether the potency of the antibiotic to be examined is not less than the minimum required.

*The following section is published for information.*

## Recommended micro-organisms

The following text details the recommended micro-organisms and the conditions of use. Other micro-organisms may be used provided that they are shown to be sensitive to the antibiotic to be examined and are used in appropriate media and appropriate conditions of temperature and pH. The concentrations of the solutions used should be chosen so as to ensure that a linear relationship exists between the logarithm of the dose and the response in the conditions of the test.

**Preparation of inocula**. *Bacillus cereus* var. *mycoides*; *Bacillus subtilis*; *Bacillus pumilus*. Spore suspensions of the organisms to be used as inocula are prepared as follows.

Grow the organism at 35-37 °C for 7 days on the surface of a suitable medium to which has been added 0.001 g/L of *manganese sulfate R*. Using sterile *water R*, wash off the growth, which consists mainly of spores. Heat the suspension at 70 °C for 30 min and dilute to give an appropriate concentration of spores, usually $10 \times 10^6$ to $100 \times 10^6$ per millilitre. The spore suspensions may be stored for long periods at a temperature not exceeding 4 °C.

Alternatively, spore suspensions may be prepared by cultivating the organisms in medium C at 26 °C for 4-6 days, then adding, aseptically, sufficient *manganese sulfate R* to give a concentration of 0.001 g/L and incubating for a further 48 h. Examine the suspension microscopically to ensure that adequate spore formation has taken place (about 80 per cent) and centrifuge. Re-suspend the sediment in sterile *water R* to give a concentration of $10 \times 10^6$ to $100 \times 10^6$ spores per millilitre, and then heat to 70 °C for 30 min. Store the suspension at a temperature not exceeding 4 °C.

*Bordetella bronchiseptica*. Grow the test organism on medium B at 35-37 °C for 16-18 h. Wash off the bacterial growth with sterile *water R* and dilute to a suitable opacity.

*Staphylococcus aureus*; *Klebsiella pneumoniae*; *Escherichia coli*; *Micrococcus luteus*; *Staphylococcus epidermidis*. Prepare as described above for *B. bronchiseptica* but using medium A and adjusting the opacity to one which has been shown to produce a satisfactory dose-response relationship in the turbidimetric assay, or to produce clearly defined zones of inhibition of convenient diameter in the diffusion assay, as appropriate.

*Saccharomyces cerevisiae*; *Candida tropicalis*. Grow the test organism on medium F at 30-37 °C for 24 h. Wash off the growth with a sterile 9 g/L solution of *sodium chloride R*. Dilute to a suitable opacity with the same solution.

**Buffer solutions**. Buffer solutions having a pH between 5.8 and 8.0 are prepared by mixing 50.0 mL of *0.2 M potassium dihydrogen phosphate R* with the quantity of *0.2 M sodium hydroxide* indicated in Table 2.7.2.-3. Dilute with freshly prepared *distilled water R* to produce 200.0 mL.

Table 2.7.2.-3

| pH | *0.2 M Sodium hydroxide* (mL) |
|---|---|
| 5.8 | 3.72 |
| 6.0 | 5.70 |
| 6.2 | 8.60 |
| 6.4 | 12.60 |
| 6.6 | 17.80 |
| 6.8 | 23.65 |
| 7.0 | 29.63 |
| 7.2 | 35.00 |
| 7.4 | 39.50 |
| 7.6 | 42.80 |
| 7.8 | 45.20 |
| 8.0 | 46.80 |

These buffer solutions are used for all microbiological assays shown in Table 2.7.2.-1 with the exception of bleomycin sulfate and amphotericin B.

For bleomycin sulfate, prepare the buffer solution pH 6.8 as follows: dissolve 6.4 g of *potassium dihydrogen phosphate R* and 18.9 g of *disodium hydrogen phosphate dodecahydrate R* in *water R* and dilute to 1000 mL with *water R*.

For amphotericin B, prepare the 0.2 M phosphate buffer solution pH 10.5 as follows: dissolve 35 g of *dipotassium hydrogen phosphate R* in 900 mL of *water R*, add 20 mL of *1 M sodium hydroxide* and dilute to 1000.0 mL with *water R*.

**Culture media**. The following media or equivalent media may be used.

Medium A

| | |
|---|---|
| Peptone | 6 g |
| Pancreatic digest of casein | 4 g |
| Beef extract | 1.5 g |
| Yeast extract | 3 g |
| Glucose monohydrate | 1 g |
| Agar | 15 g |
| Water | to 1000 mL |

Medium B

| | |
|---|---|
| Pancreatic digest of casein | 17 g |
| Papaic digest of soya bean | 3 g |
| Sodium chloride | 5 g |
| Dipotassium hydrogen phosphate | 2.5 g |
| Glucose monohydrate | 2.5 g |
| Agar | 15 g |
| Polysorbate 80 | 10 g |
| Water | to 1000 mL |

The polysorbate 80 is added to the hot solution of the other ingredients after boiling, and immediately before adjusting to volume.

Medium C

| | |
|---|---|
| Peptone | 6 g |
| Beef extract | 1.5 g |
| Yeast extract | 3 g |
| Sodium chloride | 3.5 g |
| Glucose monohydrate | 1 g |
| Dipotassium hydrogen phosphate | 3.68 g |
| Potassium dihydrogen phosphate | 1.32 g |
| Water | to 1000 mL |

Medium D

| | |
|---|---|
| Heart extract | 1.5 g |
| Yeast extract | 1.5 g |
| Peptone-casein | 5 g |
| Glucose monohydrate | 1 g |
| Sodium chloride | 3.5 g |
| Dipotassium hydrogen phosphate | 3.68 g |
| Potassium dihydrogen phosphate | 1.32 g |
| Potassium nitrate | 2 g |
| Water | to 1000 mL |

Medium E

| | |
|---|---|
| Peptone | 5 g |
| Meat extract | 3 g |
| Disodium hydrogen phosphate,12$H_2O$ | 26.9 g |
| Agar | 10 g |
| Water | to 1000 mL |

The disodium hydrogen phosphate is added as a sterile solution after sterilisation of the medium.

Medium F

| | |
|---|---|
| Peptone | 9.4 g |
| Yeast extract | 4.7 g |
| Beef extract | 2.4 g |
| Sodium chloride | 10.0 g |
| Glucose monohydrate | 10.0 g |
| Agar | 23.5 g |
| Water | to 1000 mL |

Medium G

| | |
|---|---|
| Glycerol | 10 g |
| Peptone | 10 g |
| Meat extract | 10 g |
| Sodium chloride | 3 g |
| Agar | 15 g |
| Water | to 1000 mL |

pH 7.0 ± 0.1 after sterilisation.

Medium H

| | |
|---|---|
| Peptone | 5.0 g |
| Agar | 15.0 g |
| Beef extract powder | 3.0 g |
| Water | to 1000 mL |

pH 7.8 - 8.0 adjusted with *0.1 M sodium hydroxide*.

07/2014:20704

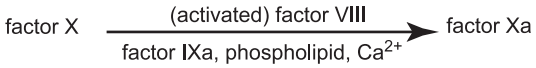
# 2.7.4. ASSAY OF HUMAN COAGULATION FACTOR VIII

Human coagulation factor VIII is assayed by its biological activity as a cofactor in the activation of factor X by activated factor IX (factor IXa) in the presence of calcium ions and phospholipid. Factor VIII activity may be measured in plasma preparations and therapeutic concentrates (plasma-derived and recombinant). The potency of a factor VIII preparation is estimated by comparing the quantity necessary to achieve a certain rate of factor Xa formation in a test mixture containing the substances that take part in the activation of factor X, and the quantity of the International Standard, or of a reference preparation calibrated in International Units, required to produce the same rate of factor Xa formation.

Quantification of factor VIII activity in plasma preparations is expressed in International Units defined by the International Standard for blood coagulation factor VIII in plasma, and *coagulation factors V, VIII, XI and XIII plasma BRP* is suitable for use as a reference preparation. Quantification of factor VIII activity in therapeutic concentrates is expressed in International Units defined by the International Standard for blood coagulation factor VIII concentrate, and *human coagulation factor VIII concentrate BRP* is suitable for use as a reference preparation.

The chromogenic assay method consists of 2 consecutive steps: the factor VIII-dependent activation of factor X in a coagulation-factor reagent composed of purified components, and the enzymatic cleavage of a chromogenic factor Xa substrate to yield a chromophore that can be quantified spectrophotometrically. Under appropriate assay conditions, there is a linear relation between the rate of factor Xa formation and the factor VIII concentration. The assay is summarised by the following scheme.

**Step 1**



**Step 2**

Both steps employ reagents that may be obtained commercially from a variety of sources. Although the composition of individual reagents may be subject to some variation, their essential features are described in the following specification. Deviations from this description may be permissible provided that it has been shown, using the appropriate International Standard for blood coagulation factor VIII as the standard, that the results obtained do not differ significantly.

It is important to demonstrate by validation the suitability of the kit used, notably by checking the time course of factor Xa generation in order to determine the time taken to reach 50 per cent of the maximal factor Xa generation.

## REAGENTS

The coagulation factor reagent comprises purified proteins derived from human or bovine sources. These include factor X, factor IXa, and a factor VIII activator, usually thrombin. These proteins are partly purified, preferably to at least 50 per cent, and do not contain impurities that interfere with the activation of factor VIII or factor X. Thrombin may be present in its precursor form prothrombin, provided that its activation in the reagent is sufficiently rapid to give almost instantaneous activation of factor VIII in the assay.

Phospholipid may be obtained from natural sources or be synthetically prepared, and must, to a substantial extent, consist of the species phosphatidylserine. The components of the complete reagent are usually divided into at least 2 separate reagents, each lacking the ability to generate factor Xa on its own. One of the reagents contains calcium ions. After reconstitution, the reagents may be combined provided that no substantial amounts of factor Xa are generated in the absence of factor VIII. In the final incubation mixture, factor VIII must be the only rate-limiting component.

The 2nd step comprises the quantification of the formed factor Xa, employing a chromogenic substrate that is specific for factor Xa. Generally this consists of a derivatised short peptide of between 3 and 5 amino acids, joined to a chromophore group. On cleavage of this group from the peptide substrate, its chromophoric properties shift to a wavelength allowing its spectrophotometric quantification. The substrate must also contain appropriate inhibitors to stop further factor Xa generation, e.g. chelating agents, and to suppress thrombin activity.

## ASSAY PROCEDURE

For the assay of therapeutic concentrates, add sufficient prediluent to the reference and test preparations to produce solutions containing 0.5-2.0 IU/mL. The prediluent consists of haemophilia A plasma, or of an artificially prepared reagent that contains sufficient von Willebrand factor and that gives results that do not differ significantly from those obtained employing haemophilia plasma. The prediluted materials must be stable beyond the time required for the assay. Pre-dilution in haemophilia A plasma is not required for the assay of factor VIII in plasma preparations.

Prepare dilutions of the pre-diluted reference and test concentrate preparations (or the reference and test plasma preparations) using a non-chelating, appropriately buffered solution, for example, tris(hydroxymethyl)aminomethane or imidazole, containing 1 per cent of human or bovine albumin. Prepare at least 2 dilution series of at least 3 further dilutions for each material. Prepare the dilutions such that the final factor VIII concentration in the reaction mixture is preferably below 0.01 IU/mL, during the step of factor Xa generation.

Prepare a control solution that includes all components except factor VIII.

Prepare all dilutions in plastic tubes and use immediately.

**Step 1**. Mix prewarmed dilutions of the factor VIII reference preparation and of the preparation to be examined with an appropriate volume of the prewarmed coagulation factor reagent or a combination of its separate constituents, and incubate the mixture in plastic tubes or microplate wells at 37 °C. Allow the activation of factor X to proceed for a suitable time, terminating the reaction (step 2) when the factor Xa concentration has reached approximately 50 per cent of the maximal (plateau) level. Appropriate activation times are usually between 2 min and 5 min.

**Step 2**. Terminate the activation by addition of a prewarmed reagent containing a chromogenic substrate. Quantify the rate of substrate cleavage, which must be linear with the concentration of factor Xa formed, by measuring the absorbance change at an appropriate wavelength using a spectrophotometer, either monitoring the absorbance continuously, thus allowing the initial rate of substrate cleavage to be calculated, or terminating the hydrolysis reaction after a suitable interval by lowering the pH by addition of a suitable reagent, such as a 50 per cent *V/V* solution of acetic acid, or a 1 M pH 3 citrate buffer solution. Adjust the hydrolysis time to achieve a linear development of chromophore over time. Appropriate hydrolysis times are usually between 3 min and 15 min, but deviations are permissible if better linearity of the dose-response relationship is thus obtained.

Calculate the potency of the test preparation by the usual statistical methods (for example, *5.3*).

**04/2017:20705**

# 2.7.5. ASSAY OF HEPARIN

The anticoagulant activity of heparin is determined *in vitro* by its ability to accelerate the inhibition of thrombin, factor IIa (anti-IIa assay), by antithrombin. The International Unit is the activity contained in a stated amount of the International Standard for unfractionated heparin. *Heparin sodium BRP*, calibrated in International Units by comparison with the International Standard using the 2 assays given below, is used as the reference preparation.

The assay of anti-factor Xa activity is carried out to determine the ratio of anti-factor Xa activity to anti-factor IIa activity.

For anti-IIa and anti-Xa assays, carry out the assay by determining the absorbance (end-point method) or the change of absorbance per minute (kinetic method).

ANTI-FACTOR IIa ACTIVITY

**Reference and test solutions**

Prepare 4 independent series of 4 dilutions each of the substance to be examined and of *heparin sodium BRP* in *tris(hydroxymethyl)aminomethane-EDTA buffer solution pH 8.4 R1*; a concentration range within 0.005 IU and 0.03 IU per millilitre is suitable. The dilutions chosen must give a linear response when results are plotted as absorbance against log concentration.

**Procedure**

Label 16 tubes for the dilutions of the substance to be examined and 16 tubes for the dilutions of the reference preparation: $T_1$, $T_2$, $T_3$, $T_4$ for each of the 4 series of dilutions of the substance to be examined and $S_1$, $S_2$, $S_3$, $S_4$ for each of the 4 series of dilutions of the reference preparation. To each of the 32 tubes add 100 µL of *antithrombin III solution R5* and 50 µL of the appropriate dilution of the substance to be examined or the reference preparation. After each addition, mix but do not allow bubbles to form. Treating the tubes in 2 subsequent series in the order $S_1$, $S_2$, $S_3$, $S_4$, $T_1$, $T_2$, $T_3$, $T_4$, $T_1$, $T_2$, $T_3$, $T_4$, $S_1$, $S_2$, $S_3$, $S_4$, allow to equilibrate at 37 °C (water-bath or heating block) for at least 1 min and add to each tube 25 µL of *human thrombin solution R2*. Incubate for exactly 1 min and add 50 µL of a chromogenic substrate specific to factor IIa at a concentration suitable for the assay (for example, D-phenylalanyl-L-pipecolyl-L-arginine-4-nitroanilide dihydrochloride dissolved in *water R* to give a 1.25 mM solution).

For the kinetic method, transfer the mixtures to semi-micro cuvettes and measure the change in absorbance per minute (*2.2.25*) at 405 nm using a suitable reading device.

For the end-point method, stop the reaction after exactly 4 min by adding 50 µL of a 20 per cent *V/V* solution of *glacial acetic acid R*. Assess whether exactly 4 min of incubation with the chromogenic substrate yields the optimal absorbance reading and, if necessary, adjust the incubation time to give the best dose-response curve. Then, transfer the mixtures to semi-micro cuvettes and measure the absorbance (*2.2.25*) at 405 nm using a suitable reading device.

Determine the blank amidolytic activity at the beginning and at the end of the procedure in a similar manner, using *tris(hydroxymethyl)aminomethane-EDTA buffer solution pH 8.4 R1* instead of the reference and test solutions; the 2 blank values do not differ significantly.

Calculate the regression of the absorbance on log concentrations of the solutions of the substance to be examined and of *heparin sodium BRP*, and calculate the potency of the substance to be examined in International Units per millilitre using the usual statistical methods for parallel-line assays (*5.3*).

ANTI-FACTOR Xa ACTIVITY

**Reference and test solutions**

Prepare 4 independent series of 4 dilutions each of the substance to be examined and of *heparin sodium BRP* in *tris(hydroxymethyl)aminomethane-EDTA buffer solution pH 8.4 R1*; a concentration range within 0.03 IU and 0.375 IU per millilitre is suitable. The dilutions chosen must give a linear response when results are plotted as absorbance against log concentration.

**Procedure**

Label 16 tubes for the dilutions of the substance to be examined and 16 tubes for the dilutions of the reference preparation: $T_1$, $T_2$, $T_3$, $T_4$ for each of the 4 series of dilutions of the substance to be examined and $S_1$, $S_2$, $S_3$, $S_4$ for each of the 4 series of dilutions of the reference preparation. To each of the 32 tubes add 50 µL of *antithrombin III solution R6* and 50 µL of the appropriate dilution of the substance to be examined or the reference preparation. After each addition, mix but do not allow bubbles to form. Treating the tubes in 2 subsequent series in the order $S_1$, $S_2$, $S_3$, $S_4$, $T_1$, $T_2$, $T_3$, $T_4$, $T_1$, $T_2$, $T_3$, $T_4$, $S_1$, $S_2$, $S_3$, $S_4$, allow to equilibrate at 37 °C (water-bath or heating block) for 1 min and add to each tube 100 µL of *bovine factor Xa solution R2*. Incubate for exactly 2 min and add 100 µL of a chromogenic substrate specific to factor Xa at a concentration suitable for the assay (for example, *N*-α-benzyloxycarbonyl-D-arginyl-L-glycyl-L-arginine-4-nitroanilide dihydrochloride dissolved in *water R* to give a 1 mM solution).

For the kinetic method, transfer the mixtures to semi-micro cuvettes and measure the change in absorbance per minute (*2.2.25*) at 405 nm using a suitable reading device.

For the end-point method, stop the reaction after exactly 4 min by adding 50 µL of a 20 per cent *V/V* solution of *glacial acetic acid R*. Assess whether exactly 4 min of incubation with the chromogenic substrate yields the optimal absorbance reading and, if necessary, adjust the incubation time to give the best dose-response curve. Then, transfer the mixtures to semi-micro cuvettes and measure the absorbance (*2.2.25*) at 405 nm using a suitable reading device.

Determine the blank amidolytic activity at the beginning and at the end of the procedure in a similar manner, using *tris(hydroxymethyl)aminomethane-EDTA buffer solution pH 8.4 R1* instead of the reference and test solutions; the 2 blank values do not differ significantly.

Calculate the regression of the absorbance on log concentrations of the solutions of the substance to be examined and of *heparin sodium BRP*, and calculate the potency of the substance to be examined in International Units per millilitre using the usual statistical methods for parallel-line assays (*5.3*).

**corrected 6.0**

# 2.7.6. ASSAY OF DIPHTHERIA VACCINE (ADSORBED)

The potency of diphtheria vaccine is determined by administration of the vaccine to guinea-pigs followed either by challenge with diphtheria toxin (method A or B) or by determination of the titre of antibodies against diphtheria toxin or toxoid in the serum of guinea-pigs (method C). In both cases, the potency of the vaccine is calculated by comparison with a reference preparation, calibrated in International Units.

The International Unit is the activity contained in a stated amount of the International Standard, which consists of a quantity of diphtheria toxoid adsorbed on aluminium hydroxide. The equivalence in International Units of the International Standard is stated by the World Health Organization (WHO).

*Diphtheria vaccine (adsorbed) BRP* is suitable for use as a reference preparation.

The method chosen for the assay of diphtheria vaccine (adsorbed) depends on the intended purpose. Method A or B is used:

1. during development of a vaccine, to assay batches produced to validate the production;
2. wherever revalidation is needed following a significant change in the manufacturing process.

Method A or B may also be used for the routine assay of batches of vaccine, but in the interests of animal welfare, method C is used wherever possible.

Method C may be used, except as specified under 1 and 2 above, after verification of the suitability of the method for the product. For this purpose, a suitable number of batches (usually 3) are assayed by method C and method A or B. Where different vaccines (monovalent or combinations) are prepared from diphtheria toxoid of the same origin, and with comparable levels (expressed in Lf/mL) of the same diphtheria toxoid, suitability demonstrated for the combination with the highest number of components can be assumed to be valid for combinations with fewer components and for monovalent vaccines. Any combinations containing a whole-cell pertussis component or containing haemophilus type b conjugate vaccine with diphtheria toxoid or CRM 197 diphtheria protein as carrier in the same vial must always be assessed separately.

For combinations containing diphtheria and tetanus components, the serological assay (method C) can be performed with the same group of animals used for the serological assay of the tetanus vaccine (adsorbed) (*2.7.8*) when the common immunisation conditions for the diphtheria and the tetanus components (for example, doses, duration) have been demonstrated to be valid for the combined vaccine.

The design of the assays described below uses multiple dilutions for the test and reference preparations. Once the analyst has sufficient experience with this method for a given vaccine, it is possible to apply a simplified model such as a single dilution for both test and reference preparations. Such a model enables the analyst to determine whether the potency of the test preparation is significantly higher than the minimum required, but does not give information on linearity, parallelism and the dose-response curve. The simplified model allows for a considerable reduction in the number of animals required and must be considered by each analyst in accordance with the provisions of the European Convention for the Protection of Vertebrate Animals Used for Experimental and Other Scientific Purposes.

Where a single-dilution assay is used, production and test consistency over time are monitored via suitable indicators and by carrying out a full multiple-dilution assay periodically, for example every 2 years. For serological assays, suitable indicators to monitor test consistency are:

- the mean and standard deviation of relative antitoxin titres or scores of the serum samples obtained after administration of a fixed dose of the vaccine reference preparation;
- the antitoxin titres or scores of run controls (positive and negative serum samples);
- the ratio of antitoxin titres or scores for the positive serum control to the serum samples corresponding to the reference vaccine.

METHOD A: INTRADERMAL CHALLENGE TEST IN GUINEA-PIGS

*SELECTION AND DISTRIBUTION OF THE TEST ANIMALS*

Use in the test healthy, white guinea-pigs from the same stock and of a size suitable for the prescribed number of challenge sites, the difference in body mass between the heaviest and the lightest animal being not greater than 100 g. Use guinea-pigs of the same sex or with males and females equally distributed between the groups. Distribute the guinea-pigs in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay prescribed below. If the challenge toxin to be used has not been shown to be stable or has not been adequately standardised, include 5 guinea-pigs as unvaccinated controls.

*SELECTION OF THE CHALLENGE TOXIN*

Select a preparation of diphtheria toxin containing 67 to 133 lr/100 in 1 Lf and 25 000 to 50 000 minimal reacting doses for guinea-pig skin in 1 Lf. If the challenge toxin preparation has been shown to be stable, it is not necessary to verify the activity for every assay.

*PREPARATION OF THE CHALLENGE TOXIN SOLUTION*

Immediately before use, dilute the challenge toxin with a suitable diluent to obtain a challenge toxin solution containing about 0.0512 Lf in 0.2 mL. Prepare from this a further series of 5 four-fold dilutions containing about 0.0128, 0.0032, 0.0008, 0.0002 and 0.00005 Lf in 0.2 mL.

*DILUTION OF THE TEST AND REFERENCE PREPARATIONS*

Using a 9 g/L solution of *sodium chloride R*, prepare dilutions of the vaccine to be examined and of the reference preparation, such that for each, the dilutions form a series differing by not more than 2.5-fold steps and in which the intermediate dilutions, when injected subcutaneously at a dose of 1.0 mL per guinea-pig, will result in an intradermal score of approximately 3 when the animals are challenged.

*IMMUNISATION AND CHALLENGE*

Allocate the dilutions, 1 to each of the groups of guinea-pigs, and inject subcutaneously 1.0 mL of each dilution into each guinea-pig in the group to which that dilution is allocated. After 28 days, shave both flanks of each guinea-pig and inject 0.2 mL of each of the 6 toxin dilutions intradermally into 6 separate sites on each of the vaccinated guinea-pigs in such a way as to minimise interference between adjacent sites.

*DETERMINATION OF THE ACTIVITY OF THE CHALLENGE TOXIN*

If necessary, inject the unvaccinated control animals with dilutions containing 80, 40, 20, 10 and $5 \times 10^{-6}$ Lf of the challenge toxin.

*READING AND INTERPRETATION OF RESULTS*

Examine all injection sites 48 h after injection of the challenge toxin and record the incidence of specific diphtheria erythema. Record also the number of sites free from such reactions as the intra-dermal challenge score. Tabulate the intradermal challenge scores for all the animals receiving the same dilution of vaccine and use those data with a suitable transformation, such as $(\text{score})^2$ or $\arcsin((\text{score}/6)^2)$, to obtain an estimate of the relative potency for each of the test preparations by parallel-line quantitative analysis.

*REQUIREMENTS FOR A VALID ASSAY*

The test is not valid unless:

- for both the vaccine to be examined and the reference preparation, the mean score obtained at the lowest dose level is less than 3 and the mean score at the highest dose level is more than 3;
- where applicable, the toxin dilution that contains $40 \times 10^{-6}$ Lf gives a positive erythema in at least 80 per cent of the control guinea-pigs and the dilution containing

$20 \times 10^{-6}$ Lf gives a positive erythema in less than 80 per cent of the guinea-pigs (if these criteria are not met a different toxin has to be selected);

– the confidence limits ($P = 0.95$) are not less than 50 per cent and not more than 200 per cent of the estimated potency;

– the statistical analysis shows no deviation from linearity and parallelism.

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

METHOD B: LETHAL CHALLENGE TEST IN GUINEA-PIGS

*SELECTION AND DISTRIBUTION OF THE TEST ANIMALS*

Use in the test healthy guinea-pigs from the same stock, each weighing 250-350 g. Use guinea-pigs of the same sex or with males and females equally distributed between the groups. Distribute the guinea-pigs in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay prescribed below. If the challenge toxin to be used has not been shown to be stable or has not been adequately standardised, include 4 further groups of 5 guinea-pigs as unvaccinated controls.

*SELECTION OF THE CHALLENGE TOXIN*

Select a preparation of diphtheria toxin containing not less than 100 $LD_{50}$ per millilitre. If the challenge toxin preparation has been shown to be stable, it is not necessary to verify the lethal dose for every assay.

*PREPARATION OF THE CHALLENGE TOXIN SOLUTION*

Immediately before use, dilute the challenge toxin with a suitable diluent to obtain a challenge toxin solution containing approximately 100 $LD_{50}$ per millilitre. If necessary, use portions of the challenge toxin solution diluted 1 to 32, 1 to 100 and 1 to 320 with the same diluent.

*DILUTION OF THE TEST AND REFERENCE PREPARATIONS*

Using a 9 g/L solution of *sodium chloride R*, prepare dilutions of the vaccine to be examined and of the reference preparation, such that for each, the dilutions form a series differing by not more than 2.5-fold steps and in which the intermediate dilutions, when injected subcutaneously at a dose of 1.0 mL per guinea-pig, protect approximately 50 per cent of the animals from the lethal effects of the subcutaneous injection of the quantity of diphtheria toxin prescribed for this test.

*IMMUNISATION AND CHALLENGE*

Allocate the dilutions, 1 to each of the groups of guinea-pigs, and inject subcutaneously 1.0 mL of each dilution into each guinea-pig in the group to which that dilution is allocated. After 28 days, inject subcutaneously into each animal 1.0 mL of the challenge toxin solution (100 $LD_{50}$).

*DETERMINATION OF THE ACTIVITY OF THE CHALLENGE TOXIN*

If necessary, allocate the challenge toxin solution and the 3 dilutions made from it, 1 to each of the 4 groups of 5 guinea-pigs, and inject subcutaneously 1.0 mL of each solution into each guinea-pig in the group to which that solution is allocated.

*READING AND INTERPRETATION OF RESULTS*

Count the number of surviving guinea-pigs 4 days after injection of the challenge toxin. Calculate the potency of the vaccine to be examined relative to the potency of the reference preparation on the basis of the proportion of animals surviving in each of the groups of vaccinated guinea-pigs, using the usual statistical methods (for example, *5.3*).

*REQUIREMENTS FOR A VALID ASSAY*

The test is not valid unless:

– for both the vaccine to be examined and the reference preparation, the 50 per cent protective dose lies between the largest and smallest doses of the preparations given to the guinea-pigs;

– where applicable, the number of animals that die in the 4 groups of 5 injected with the challenge toxin solution and its 3 dilutions indicates that the challenge dose was approximately 100 $LD_{50}$;

– the confidence limits ($P = 0.95$) are not less than 50 per cent and not more than 200 per cent of the estimated potency;

– the statistical analysis shows no deviation from linearity and parallelism.

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

METHOD C. DETERMINATION OF ANTIBODIES IN GUINEA-PIGS

*SELECTION AND DISTRIBUTION OF THE TEST ANIMALS*

Use in the test healthy guinea-pigs from the same stock, each weighing 250-350 g. Use guinea-pigs of the same sex or with males and females equally distributed between the groups. Distribute the guinea-pigs in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay prescribed below. Use a further group of non-vaccinated guinea-pigs of the same origin to provide a negative serum control. If test consistency has been demonstrated, a reference negative serum control may be used.

*REFERENCE PREPARATION*

Use a suitable reference preparation such as *diphtheria vaccine (adsorbed) BRP* or a batch of vaccine shown to be effective in clinical studies, or a batch representative thereof, and which has been calibrated in International Units with reference to *diphtheria vaccine (adsorbed) BRP* or the International Standard for diphtheria toxoid (adsorbed).

*DILUTION OF THE TEST AND REFERENCE PREPARATIONS*

Using a 9 g/L solution of *sodium chloride R* as diluent, prepare serial dilutions of the vaccine to be examined and the reference preparation; series differing by 2.5- to 5-fold steps have been found to be suitable. Use not fewer than 3 dilutions within the range of, for example, 0.5-16 IU/mL for the reference vaccine and within the range of, for example, 1:2 to 1:125 for the vaccine to be examined. Use the dilutions for immunisation preferably within 1 h of preparation. Allocate 1 dilution to each group of guinea-pigs.

*IMMUNISATION*

Inject subcutaneously to each guinea-pig 1.0 mL of the dilution allocated to its group.

*BLOOD SAMPLING*

35-42 days after immunisation, take a blood sample from each vaccinated and control guinea-pig using a suitable method.

*PREPARATION OF SERUM SAMPLES*

Avoid frequent freezing and thawing of serum samples. To avoid microbial contamination, it is preferable to carry out manipulations in a laminar-flow cabinet.

*DETERMINATION OF ANTIBODY TITRE*

Determine the relative antibody titre or score of each serum sample by a suitable immunochemical method (*2.7.1*). The methods shown below (enzyme-linked immunosorbent assay (ELISA) and Vero cell assay) have been found to be suitable.

*CALCULATION OF POTENCY*

Calculate the potency of the vaccine to be examined in International Units relative to the reference preparation, using the usual statistical methods (for example, *5.3*).

*REQUIREMENTS FOR A VALID ASSAY*

The test is not valid unless:

- the confidence limits ($P = 0.95$) are not less than 50 per cent and not more than 200 per cent of the estimated potency;
- the statistical analysis shows a significant slope and no deviation from linearity and parallelism of the dose-response curves (chapter *5.3* describes possible alternatives if significant deviations are observed).

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

*The following section is published for information.*

## Assay of diphtheria vaccine (adsorbed): guidelines

METHOD C. DETERMINATION OF ANTIBODIES IN GUINEA-PIGS

*PREPARATION OF SERUM SAMPLES*

For the preparation of serum samples, the following technique has been found to be suitable. Invert the tubes containing blood samples 6 times and allow to stand at 37 °C for 2 h, then at 4 °C for 2 h. Centrifuge at room temperature at 800 *g* for 20 min. Transfer the serum to sterile tubes and store at a temperature below − 20 °C. At least a 40 per cent yield of serum is obtained by this procedure.

*DETERMINATION OF ANTIBODY TITRE*

The ELISA and Vero cell assays shown below are given as examples of immunochemical methods that have been found to be suitable for the determination of antibody titre.

**Determination of antibody titre in guinea-pig serum by enzyme-linked immunosorbent assay (ELISA)**. Dilutions of test and reference sera are made on ELISA plates coated with diphtheria toxoid. A positive guinea-pig serum control and a negative guinea-pig serum control are included on each plate to monitor the assay performance. Peroxidase-conjugated rabbit or goat antibody directed against guinea-pig-IgG is added, followed by a peroxidase substrate. Optical density is measured and the relative antibody titre is calculated using the usual statistical methods (for example, *5.3*).

*Reagents and equipment*

- *ELISA plates*: 96 wells, columns 1-12, rows A-H.
- *Diphtheria guinea-pig antiserum (for vaccines-human use)* (positive control serum), obtained by immunisation of guinea-pigs using *diphtheria vaccine (adsorbed) BRP*.
- *Peroxidase conjugate*. Peroxidase-conjugated rabbit or goat antibody directed against guinea-pig IgG.
- *Diphtheria toxoid*.
- *Carbonate coating buffer pH 9.6*. Dissolve 1.59 g of *anhydrous sodium carbonate R* and 2.93 g of *sodium hydrogen carbonate R* in 1000 mL of *water R*. Distribute into 150 mL bottles and sterilise by autoclaving at 121 °C for 15 min.
- *Phosphate-buffered saline pH 7.4 (PBS)*. Dissolve with stirring 80.0 g of *sodium chloride R*, 2.0 g of *potassium dihydrogen phosphate R*, 14.3 g of *disodium hydrogen phosphate dihydrate R* and 2.0 g of *potassium chloride R* in 1000 mL of *water R*. Store at room temperature to prevent crystallisation. Dilute to 10 times its volume with *water R* before use.
- *Citric acid solution*. Dissolve 10.51 g of *citric acid monohydrate R* in 1000 mL of *water R* and adjust the solution to pH 4.0 with a 400 g/L solution of *sodium hydroxide R*.
- *Washing buffer*. PBS containing 0.5 g/L of *polysorbate 20 R*.
- *Diluent blocking buffer*. PBS containing 0.5 g/L of *polysorbate 20 R* and 25 g/L of dried skimmed milk.
- *Peroxidase substrate*. Shortly before use, dissolve 10 mg of *diammonium 2,2′-azinobis(3-ethylbenzothiazoline-6-sulfonate) R* (ABTS) in 20 mL of citric acid solution. Immediately before use add 5 µL of *strong hydrogen peroxide solution R*.

*Method*

The description below is given as an example of a suitable plate layout but others may be used. Wells 1A-H are for negative control serum and wells 2A-H and 12A-H are for positive control serum for assay monitoring. Wells 3-11A-H are for test samples.

Coat each well of the ELISA plates with 100 µL of diphtheria toxoid solution (0.5 Lf/mL in carbonate coating buffer pH 9.6). Allow to stand overnight at 4 °C in a humid atmosphere. To avoid temperature gradient effects, do not stack more than 4 plates high. On the following day, wash the plates thoroughly with washing buffer. Block the plates by addition of 100 µL of diluent block buffer to each well. Incubate in a humid atmosphere at 37 °C for 1 h. Wash the plates thoroughly with washing buffer. Place 100 µL of diluent block buffer in each well of the plates, except those of row A. Prepare suitable dilutions of negative control serum, positive control serum (from about 0.01 IU/mL) and test sera. Allocate the negative control serum to column 1, positive control serum to columns 2 and 12 and test sera to columns 3-11 and add 100 µL of each serum to the first 2 wells of the column to which it is allocated. Using a multichannel micropipette, make twofold serial dilutions from row B, down the plate to row H, by transferring 100 µL from one well to the next well. Discard 100 µL from the last row so that all wells contain 100 µL. Incubate at 37 °C for 2 h. Wash thoroughly with washing buffer. Prepare a suitable dilution (a 2000-fold dilution has been found to be suitable) of peroxidase conjugate in diluent block buffer and add 100 µL to each well. Incubate at 37 °C in a humid atmosphere for 1 h. Wash the plates thoroughly with washing buffer. Add 100 µL of peroxidase substrate to each well. Allow to stand at room temperature, protected from light, for 30 min. Read the plates at 405 nm in the same order as addition of substrate was made.

**Determination of antibody titre in guinea-pig serum by Vero cell assay**. The method used relies either on metabolic inhibition (method 1) or on cytotoxicity (method 2) as the end point, and on either microscopic (cell morphology) or visual (colour) inspection of the cells.

The limit of detection is specific for each antitoxin and is usually between 0.015 IU/mL (method 1) and 0.05 IU/mL (method 2).

The endpoint is taken as the highest serum dilution protecting cells from the diphtheria toxin effect. The antitoxin activity is calculated with respect to guinea-pig or WHO reference standard, and expressed in International Units per millilitre.

*Reagents and equipment*

- *Flat-bottomed tissue culture plates*: 96 wells, columns 1-12, rows A-H.
- *75 $cm^2$ tissue culture flasks*.
- *Diphtheria toxin*.
- *Diphtheria guinea-pig antiserum (for vaccines-human use)* (positive control serum), obtained by immunisation of guinea-pigs with *diphtheria vaccine (adsorbed) BRP*.
- *Vero cells* (African Green Monkey kidney cells). Cell passages from P2 to P15 are suitable for use.

*Method 1*. The diphtheria toxin causes a cytopathogenic effect on Vero cells leading to cellular lysis. Antibodies directed against diphtheria toxin may inhibit this cytopathogenic effect. Consequently, the potency of a diphtheria vaccine may be indirectly determined with the help of this cell culture system if different serum dilutions from immunised animals are cultured with a constant toxin concentration. In the Vero

cell assay, yellow colour indicates viable cells, red colour dead cells. When only part of the cells are dead, the colour may be orange.

*Reagents and equipment*

- *Modified MEM*. Minimum Essential Medium (MEM) with Earle's Salts, without L-glutamine and sodium bicarbonate.
- *Modified medium 199*. Medium 199, with Hanks' Solution and L-glutamine, without sodium bicarbonate.
- *Foetal bovine serum*.
- *Sodium bicarbonate 7.5 per cent solution*.
- *Trypsin solution*: trypsin 2.5 per cent solution.
- *EDTA solution*: EDTA 0.02 per cent (Versene 1:5000) solution.
- *Modified D-PBS*. Dulbecco's phosphate buffered saline (D-PBS), without calcium, or magnesium.
- *L-glutamine 200mM solution*.
- *Penicillin/streptomycin solution*.
- *Primary culture medium*. To 50 mL of modified MEM add 440 mL of *water R*, 5 mL of L-glutamine 200 mM solution, and 10 mL of sodium bicarbonate 7.5 per cent solution. To 25 mL of this medium add 1.25 mL of foetal bovine serum.
- *Maintenance culture medium*. Similar to the primary culture medium except that 0.5 mL instead of 1.25 mL of foetal bovine serum is added to 20 mL of the enriched MEM medium.
- *Medium A*. To 50.0 mL of modified medium 199 add 440.0 mL of *water R*, 5.0 mL of L-glutamine 200 mM solution and 10.0 mL of sodium bicarbonate 7.5 per cent solution.
- *Medium B*. To 150.0 mL of medium A add 3.0 mL of foetal bovine serum and 0.3 mL of penicillin/streptomycin solution.
- *Medium C*. To 22.0 mL of medium A add 0.44 mL of foetal bovine serum and 0.44 mL of penicillin/streptomycin solution.

Vero cells are cultured in tissue culture flasks (for example 75 $cm^2$/250 mL) in an incubator at 36 ± 1 °C, 5 per cent $CO_2$ and 90 per cent relative humidity. Vero cells are first grown in the primary culture medium. After 2-3 days of growth, the primary culture medium is replaced by the maintenance culture medium. When a confluent monolayer is obtained, the culture supernatant is discarded and the cell layer washed gently with modified D-PBS. Add a mixture of 1 volume of trypsin solution and 1 volume of EDTA solution to the flask. Swirl the flask gently and incubate in the $CO_2$ incubator for about 3 min until the cells start to break from the monolayer. Vigorously tap the side of the flask to make the cells fall. Resuspend the cells in 5-6 mL of fresh medium C to obtain a homogeneous suspension. Prepare a cell suspension in medium C containing approximately $1 \times 10^5$ cells/mL.

Place 25 µL of medium B in each well except those of column 1. Place 25 µL of the diphtheria guinea-pig antiserum (for vaccines-human use) (positive control serum, working dilution in medium B of 0.40 IU/mL) in wells A1, A2 and A11. Place 25 µL of guinea-pig serum samples in wells B-G of columns 1, 2 and 11. Place 25 µL of negative control serum in row H of columns 1, 2 and 11. Using a multichannel micropipette, make twofold serial dilutions across the plate (from column 2 up to column 10 for rows A-G and up to column 8 for row H). Discard 25 µL from the wells in column 10 in rows A-G, and from well H8.

Reconstitute the diphtheria toxin with saline solution to give a solution of 50 IU/mL. Prepare a 50-fold dilution of this diphtheria toxin dilution in medium B to obtain a working solution of 1.0 IU/mL. Add 25 µL of this working solution to wells A12 and B12 (toxin control). Make twofold serial dilutions by tranferring 25 µL from one well to the next, from well B12 down to H12. Change the tip between each dilution. Discard 25 µL from well H12. Add 25 µL of medium B to wells B12-H12. Then, place 25 µL of the working dilution of the diphtheria toxin (1.0 IU/mL) in each well of rows A-H, from column 1-10, except in wells H9 and H10 (cells only, without serum and without toxin).

Cover the plates with lids or sealer and shake gently. Incubate the plates for at least 2 h in a humid container in a $CO_2$ incubator at 37 °C. Add 200 µL of cell suspension containing $1 \times 10^5$ cells/mL to all the wells. Cover the plates with sealer. Incubate at 37 °C for 5 days. Check for microbial contamination by microscopic examination.

Yellow wells are recorded as negative and red wells indicate dead cells and are recorded as positive. A colour between yellow and red indicates a mixture of viable and dead cells and is recorded as positive/negative. The results based on the change in colour can be confirmed by reading viable and dead cells under the microscope.

The potency of the guinea-pig antiserum samples is obtained by comparing the last well of the standard preparation showing complete neutralisation of the toxin, with the last well of the sample demonstrating the same effect. For calculations of potency, it must be remembered that the endpoint may be between a negative well and a positive/negative well.

*Method 2*: Thiazolyl blue MTT is reduced to a blue/black formazan product by the mitochondrial dehydrogenase of viable cells, and thus serves as a quantitative measure of living cells present, indicating when the toxin has been neutralised by the antitoxin. White or colourless wells indicate absence of viable cells due to insufficient antitoxin to neutralise the toxin.

*Reagents and equipment*

- *MEM* (Minimal Essential Media).
- *Newborn calf serum*.
- *Antibiotic solution* (containing 10 000 units of penicillin, 10 mg of streptomycin and 25 µg of amphotericin B per millilitre).
- *L-glutamine 200mM solution*.
- *Trypsin-EDTA*.
- *Thiazolyl blue MTT* [3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide].
- *1 M HEPES buffer pH 8.1*. Dissolve 18.75 g of HEPES in 82.5 mL of *water R* and 30.0 mL of *2 M sodium hydroxide R*.
- *Glucose solution (10 per cent)*.
- *Complete culture medium*. Mix 200 mL of MEM with 10 mL of newborn calf serum, 3.0 mL of 1 M HEPES buffer pH 8.1, 2.0 mL of glucose solution (10 per cent), 2.0 mL of antibiotic solution and 2.0 mL of L-glutamine 200mM solution.
- *Phosphate-buffered saline pH 7.4 (PBS)*. Dissolve 10.0 g of *sodium chloride R*, 0.75 g of *potassium chloride R*, 1.44 g of *disodium hydrogen phosphate dodecahydrate R*, and 0.125 g of *potassium dihydrogen phosphate R* in *water R*, and dilute to 1000.0 mL with the same solvent. Adjust the pH if necessary. Autoclave at 120 °C for 15 min.
- *Thiazolyl blue MTT solution*. Dissolve 0.1 g of thiazolyl blue MTT in 20 mL of PBS. Sterilise by filtration (0.2 µm) and store in dark bottle.
- *pH adjuster solution*. Mix 40 mL of *acetic acid R* with 1.25 mL of *1 M hydrochloric acid* and 8.75 mL of *water R*.
- *Extraction buffer pH 4.7*. Dissolve 10 g of *sodium laurilsulfate R* in *water R* and add 50 mL of *dimethylformamide R*, and dilute to 100 mL with *water R*. Adjust the pH with an appropriate volume of pH adjuster solution.

Vero cells are cultured in tissue culture flasks (for example 75 $cm^2$/250 mL) in an incubator at 36 ± 1 °C, 5 per cent $CO_2$ and 90 per cent relative humidity. Vero cells are grown in the complete culture medium. After 6-7 days of growth, a confluent monolayer is obtained, the culture supernatant is discarded and the cell layer is washed 3 times with trypsin-EDTA: gently pipette out the medium, add 0.5-1 mL

of trypsin-EDTA, swirl the flask and tip the trypsin out. Do this twice, and the 3rd time, place the flask in the incubator for 5 min until the cells start to break from the monolayer. Vigorously tap the side of the flask to make the cells fall. Resuspend the cells in 6-25 mL of fresh complete culture medium to obtain a homogeneous suspension. Prepare a cell suspension in complete culture medium containing approximately $4 \times 10^5$ cells/mL.

Place 50 µL of complete culture medium in each well except those of column 1. Place 100 µL of diphtheria guinea pig antiserum (for vaccines-human use) (positive control serum, working dilution in complete culture medium of 0.12 IU/mL) in well A1 and 50 µL in well A11. Place 100 µL of guinea pig test serum samples, diluted if necessary, in wells B1-G1. Add 50 µL of the same sample to wells B11-G11 in the corresponding row. Place 100 µL of negative control serum in well H1 and 50 µL in well H11. Using a multi-channel micropipette, make twofold serial dilutions by transferring 50 µL from one well to the next working across the plate (from column 1-10 for rows A-G and from column 1-8 for row H).

Diphtheria toxin of known activity and Lf content is diluted to a suitable working stock containing at least 4 minimum cytopathic doses in complete culture medium. Add 50 µL of the diluted toxin to each well except H9 and H10 (cell control), A11-H11 (serum control) and A12-H12 (toxin control). Add 100 µL of diluted toxin to well A12 and make twofold serial dilutions by transferring 50 µL from one well to the next working down the plate (from well A12-H12). Discard 50 µL from well H12. Add 50 µL of complete medium to wells H9 and H10.

Cover the plates with a lid or sealer and leave for 1 h at room temperature to allow toxin neutralisation to occur. 50 µL of cell suspension containing approximately $4 \times 10^5$ cells/mL is added to each well. The plates are sealed and incubated at 37 °C for 6 days. Check for microbial contamination by microscopic examination. 10 µL of thyazolyl blue MTT solution is added to each well. The plates are incubated at 37 °C for a further 2-4 h. Then, the medium is removed and 100 µL of extraction buffer pH 4.7 is added to each well. The plates are incubated at 37 °C and left overnight to aid the extraction process. Once extraction and solubilisation is complete, plates are visually examined or read at 570 nm.

Blue/black wells are recorded as negative (all the cells are alive, toxin neutralisation by antitoxin) and white or colourless wells indicate dead cells (no toxin neutralisation) and are recorded as positive.

The potency of the test antitoxin is obtained by comparing the last well of the reference antitoxin preparation showing neutralisation of the toxin, with the last well of the antitoxin preparation demonstrating the same effect. The neutralising antibody titre of the sample being examined can be calculated by multiplication of the dilution factor with total number of International Units per millilitre of the reference preparation at the end point. The test is valid if all the cells in the toxin control are dead and reference antitoxin gives a neutralisation in at least the first 2 dilutions tested.

**07/2011:20707**

## 2.7.7. ASSAY OF PERTUSSIS VACCINE (WHOLE CELL)

The potency of pertussis vaccine (whole cell) is determined by comparing the dose necessary to protect mice against the effects of a lethal dose of *Bordetella pertussis*, administered intracerebrally, with the quantity of a reference preparation, calibrated in International Units, needed to give the same protection.

The International Unit is the activity contained in a stated amount of the International Standard which consists of a quantity of dried pertussis vaccine. The equivalence in International Units of the International Standard is stated by the World Health Organization.

**Selection and distribution of the test animals**. Use in the test healthy mice less than 5 weeks old of a suitable strain from the same stock, the difference in mass between the heaviest and the lightest being not greater than 5 g. Distribute the mice in 6 groups of not fewer than 16 and 4 groups of 10. The mice must all be of the same sex or the males and females distributed equally between the groups.

**Selection of the challenge strain and preparation of the challenge suspension**. Select a suitable strain of *B. pertussis* capable of causing the death of mice within 14 days of intracerebral injection. If more than 20 per cent of the mice die within 48 h of the injection the strain is not suitable. Make one subculture from the strain and suspend the harvested *B. pertussis* in a solution containing 10 g/L of *casein R* hydrolysate and 6 g/L of *sodium chloride R* and having a pH of 7.0 to 7.2 or in another suitable solution. Determine the opacity of the suspension. Prepare a series of dilutions in the same solution and allocate each dilution to a group of 10 mice. Inject intracerebrally into each mouse a dose (0.02 mL or 0.03 mL) of the dilution allocated to its group. After 14 days, count the number of mice surviving in each group. From the results, calculate the expected opacity of a suspension containing 100 $LD_{50}$ in each challenge dose. For the test of the vaccine to be examined make a fresh subculture from the same strain of *B. pertussis* and prepare a suspension of the harvested organisms with an opacity corresponding to about 100 $LD_{50}$ in each challenge dose. Prepare 3 dilutions of the challenge suspension.

**Determination of potency**. Prepare 3 serial dilutions of the vaccine to be examined and 3 similar dilutions of the reference preparation such that in each the intermediate dilution may be expected to protect about 50 per cent of the mice from the lethal effects of the challenge dose of *B. pertussis*. Suggested doses are 1/8, 1/40 and 1/200 of the human dose of the vaccine to be examined and 0.5 IU, 0.1 IU and 0.02 IU of the reference preparation, each dose being contained in a volume not exceeding 0.5 mL. Allocate the 6 dilutions, one to each of the groups of not fewer than 16 mice, and inject intraperitoneally into each mouse one dose of the dilution allocated to its group. After 14 - 17 days inject intracerebrally into each animal in the groups of not fewer than 16, one dose of the challenge suspension. Allocate the challenge suspension and the 3 dilutions made from it, one to each of the groups of 10 mice, and inject intracerebrally one dose of each suspension into each mouse in the group to which that suspension is allocated. Exclude from consideration any mice that die within 48 h of challenge. Count the number of mice surviving in each of the groups after 14 days. Calculate the potency of the vaccine to be examined relative to the potency of the reference preparation on the basis of the numbers of animals surviving in each of the groups of not fewer than 16.

The test is not valid unless:

- for both the vaccine to be examined and the reference preparation, the 50 per cent protective dose lies between the largest and the smallest doses given to the mice;
- the number of animals that die in the 4 groups of 10 injected with the challenge suspension and its dilutions indicates that the challenge dose is approximately 100 $LD_{50}$; and
- the statistical analysis shows no deviation from linearity or parallelism.

The test may be repeated but when more than one test is performed the results of all valid tests must be combined.

# 2.7.8. ASSAY OF TETANUS VACCINE (ADSORBED)

The potency of tetanus vaccine is determined by administration of the vaccine to animals (guinea-pigs or mice) followed either by challenge with tetanus toxin (method A or B) or by determination of the titre of antibodies against tetanus toxoid in the serum of the guinea-pigs (method C). In both cases, the potency of the vaccine is calculated by comparison with a reference vaccine, calibrated in International Units. For methods A and B, in countries where the paralysis method is not obligatory, the $LD_{50}$ method may be used. For the $LD_{50}$ method, the number of animals and the procedure are identical to those described for the paralysis method, but the end-point is the death of the animal rather than paralysis.

The International Unit is the activity contained in a stated amount of the International Standard for tetanus toxoid (adsorbed). The equivalence in International Units of the International Standard is stated by the World Health Organization.

*Tetanus vaccine (adsorbed) BRP* is calibrated in International Units with reference to the International Standard.

The method chosen for the assay of tetanus vaccine (adsorbed) depends on the intended purpose. Method A or B is used:

1. during development of a vaccine, to assay batches produced to validate the production;
2. wherever revalidation is needed following a significant change in the manufacturing process.

Method A or B may also be used for the routine assay of batches of vaccine, but in the interests of animal welfare, method C is used wherever possible.

Method C may be used, except as specified under 1 and 2 above, after verification of the suitability of the method for the product. For this purpose, a suitable number of batches (usually 3) are assayed by method C and method A or B. Where different vaccines (monovalent or combinations) are prepared from tetanus toxoid of the same origin and with comparable levels (expressed in Lf/mL) of the same tetanus toxoid, suitability demonstrated for the combination with the highest number of components can be assumed to be valid for combinations with fewer components and for monovalent vaccines. Any combinations containing a whole-cell pertussis component or containing haemophilus type b conjugate vaccine with tetanus toxoid in the same vial must always be assessed separately.

For combinations containing diphtheria and tetanus components, the serological assay (method C) can be performed with the same group of animals used for the serological assay of the diphtheria vaccine (adsorbed) (*2.7.6*) when the common immunisation conditions for the tetanus and the diphtheria components (for example, doses, duration) have been demonstrated to be valid for the combined vaccine.

The design of the assays described below uses multiple dilutions for the test and reference preparations. Based on the potency data obtained in multiple-dilution assays, it may be possible to reduce the number of animals needed to obtain a statistically significant result by applying a simplified model such as a single dilution for both test and reference preparations. Such a model enables the analyst to determine whether the potency of the test preparation is significantly higher than the minimum required, but does not give information on the dose-response curves and their linearity, parallelism and significant slope. The simplified model allows for a considerable reduction in the number of animals required and must be considered by each analyst in accordance with the provisions of the European Convention for the Protection of Vertebrate Animals Used for Experimental and Other Scientific Purposes.

Where a single-dilution assay is used, production and test consistency over time are monitored via suitable indicators and by carrying out a full multiple-dilution assay periodically, for example every 2 years. For serological assays, suitable indicators to monitor test consistency are:

- the mean and standard deviation of relative antitoxin titres or scores of the serum samples obtained after administration of a fixed dose of the vaccine reference preparation;
- the antitoxin titres or scores of run controls (positive and negative serum samples);
- the ratio of antitoxin titres or scores for the positive serum control to the serum samples corresponding to the reference vaccine.

## METHOD A. CHALLENGE TEST IN GUINEA-PIGS

### *SELECTION AND DISTRIBUTION OF THE TEST ANIMALS*

Use in the test healthy guinea-pigs from the same stock, each weighing 250-350 g. Use guinea-pigs of the same sex or with males and females equally distributed between the groups. Distribute the guinea-pigs in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay prescribed below. If the activity of the challenge toxin has to be determined, include 3 further groups of 5 guinea-pigs as unvaccinated controls.

### *SELECTION OF THE CHALLENGE TOXIN*

Select a preparation of tetanus toxin containing not less than 50 times the 50 per cent paralytic dose per millilitre. If the challenge toxin preparation has been shown to be stable, it is not necessary to verify the paralytic dose for every assay.

### *PREPARATION OF THE CHALLENGE TOXIN SOLUTION*

Immediately before use, dilute the challenge toxin with a suitable diluent (for example, peptone buffered saline solution pH 7.4) to obtain a stable challenge toxin solution containing approximately 50 times the 50 per cent paralytic dose per millilitre. If necessary, use portions of the challenge toxin solution diluted 1 to 16, 1 to 50 and 1 to 160 with the same diluent to determine the activity of the toxin.

### *DILUTION OF THE TEST AND REFERENCE PREPARATIONS*

Using a 9 g/L solution of *sodium chloride R*, prepare dilutions of the vaccine to be examined and of the reference preparation, such that for each, the dilutions form a series differing by not more than 2.5-fold steps and in which the intermediate dilutions, when injected subcutaneously at a dose of 1.0 mL per guinea-pig, protect approximately 50 per cent of the animals from the paralytic effects of the subcutaneous injection of the quantity of tetanus toxin prescribed for this test.

### *IMMUNISATION AND CHALLENGE*

Allocate the dilutions, 1 to each of the groups of guinea-pigs, and inject subcutaneously 1.0 mL of each dilution into each guinea-pig in the group to which that dilution is allocated. After 28 days, inject subcutaneously into each animal 1.0 mL of the challenge toxin solution (containing 50 times the 50 per cent paralytic dose).

### *DETERMINATION OF THE ACTIVITY OF THE CHALLENGE TOXIN*

If necessary, allocate the 3 dilutions made from the challenge toxin solution, 1 to each of the 3 groups of 5 guinea-pigs, and inject subcutaneously 1.0 mL of each solution into each guinea-pig in the group to which that solution is allocated. The activity and stability of the challenge toxin are determined by carrying out a suitable number of determinations of the 50 per cent paralytic dose. It is then not necessary to repeat the determination for each assay.

*READING AND INTERPRETATION OF RESULTS*

Examine the guinea-pigs twice daily. Remove and euthanise all animals showing definite signs of tetanus paralysis. Count the number of guinea-pigs without paralysis 5 days after injection of the challenge toxin. Calculate the potency of the vaccine to be examined relative to the potency of the reference preparation on the basis of the proportion of challenged animals without paralysis in each group of vaccinated guinea-pigs, using the usual statistical methods (for example, *5.3*).

*REQUIREMENTS FOR A VALID ASSAY*

The test is not valid unless:

- for both the vaccine to be examined and the reference preparation, the 50 per cent protective dose lies between the largest and smallest doses of the preparations given to the guinea-pigs;
- where applicable, the number of paralysed animals in the 3 groups of 5 injected with the dilutions of the challenge toxin solution indicates that the challenge was approximately 50 times the 50 per cent paralytic dose;
- the confidence limits ($P = 0.95$) are not less than 50 per cent and not more than 200 per cent of the estimated potency;
- the statistical analysis shows a significant slope and no deviation from linearity and parallelism of the dose-response curves (chapter *5.3* describes possible alternatives if significant deviations are observed).

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

METHOD B. CHALLENGE TEST IN MICE

*SELECTION AND DISTRIBUTION OF THE TEST ANIMALS*

Use in the test healthy mice from the same stock, about 5 weeks old and from a strain shown to be suitable. Use mice of the same sex or with males and females equally distributed between the groups. Distribute the mice in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay prescribed below. If the challenge toxin to be used has not been shown to be stable or has not been adequately standardised, include 3 further groups of not fewer than 5 mice to serve as unvaccinated controls.

*SELECTION OF THE CHALLENGE TOXIN*

Select a preparation of tetanus toxin containing not less than 100 times the 50 per cent paralytic dose per millilitre. If the challenge toxin preparation has been shown to be stable, it is not necessary to verify the paralytic dose for every assay.

*PREPARATION OF THE CHALLENGE TOXIN SOLUTION*

Immediately before use, dilute the challenge toxin with a suitable diluent (for example, peptone buffered saline solution pH 7.4) to obtain a stable challenge toxin solution containing approximately 50 times the 50 per cent paralytic dose in 0.5 mL. If necessary, use portions of the challenge toxin solution diluted 1 to 16, 1 to 50 and 1 to 160 with the same diluent to determine the activity of the toxin.

*DILUTION OF THE TEST AND REFERENCE PREPARATIONS*

Using a 9 g/L solution of *sodium chloride R*, prepare dilutions of the vaccine to be examined and of the reference preparation, such that for each, the dilutions form a series differing by not more than 2.5-fold steps and in which the intermediate dilutions, when injected subcutaneously at a dose of 0.5 mL per mouse, protect approximately 50 per cent of the animals from the paralytic effects of the subcutaneous injection of the quantity of tetanus toxin prescribed for this test.

*IMMUNISATION AND CHALLENGE*

Allocate the dilutions, 1 to each of the groups of mice, and inject subcutaneously 0.5 mL of each dilution into each mouse in the group to which that dilution is allocated. After 28 days, inject subcutaneously into each animal 0.5 mL of the challenge toxin solution (containing 50 times the 50 per cent paralytic dose).

*DETERMINATION OF THE ACTIVITY OF THE CHALLENGE TOXIN*

If necessary, allocate the 3 dilutions made from the challenge toxin solution, 1 to each of the 3 groups of not fewer than 5 mice, and inject subcutaneously 0.5 mL of each solution into each mouse in the group to which that solution is allocated.

*READING AND INTERPRETATION OF RESULTS*

Examine the mice twice daily. Remove and euthanise all animals showing definite signs of tetanus paralysis. Count the number of mice without paralysis 4 days after injection of the challenge toxin. Calculate the potency of the vaccine to be examined relative to the potency of the reference preparation on the basis of the proportion of challenged animals without paralysis in each group of vaccinated mice, using the usual statistical methods (for example, *5.3*).

*REQUIREMENTS FOR A VALID ASSAY*

The test is not valid unless:

- for both the vaccine to be examined and the reference preparation, the 50 per cent protective dose lies between the largest and smallest doses of the preparations given to the mice;
- where applicable, the number of paralysed animals in the 3 groups of not fewer than 5 injected with the dilutions of the challenge toxin solution, indicates that the challenge dose was approximately 50 times the 50 per cent paralytic dose;
- the confidence limits ($P = 0.95$) are not less than 50 per cent and not more than 200 per cent of the estimated potency;
- the statistical analysis shows a significant slope and no deviation from linearity and parallelism of the dose-response curves (chapter *5.3* describes possible alternatives if significant deviations are observed).

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

METHOD C. DETERMINATION OF ANTIBODIES IN GUINEA-PIGS

*SELECTION AND DISTRIBUTION OF THE TEST ANIMALS*

Use in the test healthy guinea-pigs from the same stock, each weighing 250-350 g. Use guinea-pigs of the same sex or with males and females equally distributed between the groups. Distribute the guinea-pigs in not fewer than 6 equal groups; use groups containing a number of animals sufficient to obtain results that fulfil the requirements for a valid assay prescribed below. Use a further group of non-vaccinated guinea-pigs of the same origin to provide a negative serum control. If test consistency has been demonstrated, a reference negative serum control may be used.

*REFERENCE PREPARATION*

Use a suitable reference preparation such as *tetanus vaccine (adsorbed) BRP* or a batch of vaccine shown to be effective in clinical studies, or a batch representative thereof, and which has been calibrated in International Units with reference to *tetanus vaccine (adsorbed) BRP* or the International Standard for tetanus toxoid (adsorbed).

*DILUTION OF THE TEST AND REFERENCE PREPARATIONS*

Using a 9 g/L solution of *sodium chloride R* as diluent, prepare serial dilutions of the vaccine to be examined and the reference preparation; series differing by 2.5- to 5-fold steps have been found to be suitable. Use not fewer than 3 dilutions within the range of, for example, 0.5-16 IU/mL for each series. Use the dilutions for immunisation preferably within 1 h of preparation. Allocate 1 dilution to each group of guinea-pigs.

*IMMUNISATION*

Inject subcutaneously to each guinea-pig 1.0 mL of the dilution allocated to its group.

*BLOOD SAMPLING*

35-42 days after immunisation, take a blood sample from each vaccinated and control guinea-pig using a suitable method.

*PREPARATION OF SERUM SAMPLES*

Avoid frequent freezing and thawing of serum samples. To avoid microbial contamination, it is preferable to carry out manipulations in a laminar-flow cabinet.

*DETERMINATION OF ANTIBODY TITRE*

Determine the relative antibody titre or score of each serum sample by a suitable immunochemical method (*2.7.1*). The methods shown below (enzyme-linked immunosorbent assay (ELISA) and toxin-binding inhibition (ToBI)) have been found to be suitable.

*CALCULATION OF POTENCY*

Calculate the potency of the vaccine to be examined in International Units relative to the reference preparation, using the usual statistical methods (for example, *5.3*).

*REQUIREMENTS FOR A VALID ASSAY*

The test is not valid unless:

- the confidence limits ($P = 0.95$) are not less than 50 per cent and not more than 200 per cent of the estimated potency;
- the statistical analysis shows a significant slope and no deviation from linearity and parallelism of the dose-response curves (chapter *5.3* describes possible alternatives if significant deviations are observed).

The test may be repeated but when more than 1 test is performed the results of all valid tests must be combined in the estimate of potency.

*The following section is published for information.*

## Assay of tetanus vaccine (adsorbed): guidelines

METHOD A. CHALLENGE TEST IN GUINEA-PIGS

*READING AND INTERPRETATION OF RESULTS*

In order to minimise suffering in the test animals, it is recommended to note the degree of paralysis on a scale such as that shown below. The scale gives typical signs when subcutaneous injection of the challenge toxin is made mid-ventrally, directly behind the sternum with the needle pointing towards the neck of the guinea-pig. Grade T3 is taken as the end-point, but with experience grade T2 can be used instead. Tetanus toxin produces in at least 1 of the forelimbs paralysis that can be recognised at an early stage. The tetanus grades in guinea-pigs are characterised by the following signs:

- T1: slight stiffness of 1 forelimb, but difficult to observe;
- T2: paresis of 1 forelimb which still can function;
- T3: paralysis of 1 forelimb. The animal moves reluctantly, the body is often slightly banana-shaped owing to scoliosis;
- T4: the forelimb is completely stiff and the toes are immovable. The muscular contraction of the forelimb is very pronounced and usually scoliosis is observed;
- T5: tetanus seizures, continuous tonic spasm of muscles;
- D: death.

METHOD B. CHALLENGE TEST IN MICE

*READING AND INTERPRETATION OF RESULTS*

In order to minimise suffering in the test animals, it is recommended to note the degree of paralysis on a scale such as that shown below. The scale gives typical signs when injection of the challenge toxin is made in the dorsal region, close to one of the hind legs. Grade T3 is taken as the end-point, but with experience grade T2 can be used instead. Tetanus toxin produces in the toxin-injected hind leg paresis followed by paralysis that can be recognised at an early stage. The tetanus grades in mice are characterised by the following signs:

- T1: slight stiffness of toxin-injected hind leg, only observed when the mouse is lifted by the tail;
- T2: paresis of the toxin-injected hind leg, which still can function for walking;
- T3: paralysis of the toxin-injected hind leg, which does not function for walking;
- T4: the toxin-injected hind leg is completely stiff with immovable toes;
- T5: tetanus seizures, continuous tonic spasm of muscles;
- D: death.

METHOD C. DETERMINATION OF ANTIBODIES IN GUINEA-PIGS

*PREPARATION OF SERUM SAMPLES*

For the preparation of serum samples, the following technique has been found to be suitable. Invert the tubes containing blood samples 6 times and allow to stand at 37 °C for 2 h, then at 4 °C for 2 h. Centrifuge at room temperature at 800 *g* for 20 min. Transfer the serum to sterile tubes and store at a temperature below − 20 °C. At least a 40 per cent yield of serum is obtained by this procedure.

*DETERMINATION OF ANTIBODY TITRE*

The ELISA and ToBI tests shown below are given as examples of immunochemical methods that have been found to be suitable for the determination of antibody titre.

**Determination of antibody titre in guinea-pig serum by enzyme-linked immunosorbent assay (ELISA)**. Dilutions of test and reference sera are made on ELISA plates coated with tetanus toxoid. A positive guinea-pig serum control and a negative guinea-pig serum control are included on each plate to monitor the assay performance. Peroxidase-conjugated rabbit or goat antibody directed against guinea-pig-IgG is added, followed by a peroxidase substrate. Optical density is measured and the relative antibody titre is calculated using the usual statistical methods (for example, *5.3*).

*Reagents and equipment*

- *ELISA plates*: 96 wells, columns 1-12, rows A-H.
- *Clostridium tetani guinea-pig antiserum (for vaccines-human use) BRP* (positive control serum).
- *Peroxidase conjugate*. Peroxidase-conjugated rabbit or goat antibody directed against guinea-pig IgG.
- *Tetanus toxoid*.
- *Carbonate coating buffer pH 9.6*. Dissolve 1.59 g of *anhydrous sodium carbonate R* and 2.93 g of *sodium hydrogen carbonate R* in 1000 mL of *water R*. Distribute into 150 mL bottles and sterilise by autoclaving at 121 °C for 15 min.
- *Phosphate-buffered saline pH 7.4 (PBS)*. Dissolve with stirring 80.0 g of *sodium chloride R*, 2.0 g of *potassium dihydrogen phosphate R*, 14.3 g of *disodium hydrogen phosphate dihydrate R* and 2.0 g of *potassium chloride R* in 1000 mL of *water R*. Store at room temperature to prevent crystallisation. Dilute to 10 times its volume with *water R* before use.
- *Citric acid solution*. Dissolve 10.51 g of *citric acid monohydrate R* in 1000 mL of *water R* and adjust the solution to pH 4.0 with a 400 g/L solution of *sodium hydroxide R*.
- *Washing buffer*. PBS containing 0.5 g/L of *polysorbate 20 R*.
- *Diluent block buffer*. PBS containing 0.5 g/L of *polysorbate 20 R* and 25 g/L of dried skimmed milk.

– *Peroxidase substrate*. Shortly before use, dissolve 10 mg of *diammonium 2,2'-azinobis(3-ethylbenzothiazoline-6-sulfonate) R* (ABTS) in 20 mL of citric acid solution. Immediately before use add 5 µL of *strong hydrogen peroxide solution R*.

*Method*

The description below is given as an example of a suitable plate layout but others may be used. Wells 1A-H are for negative control serum and wells 2A-H and 12A-H are for positive control serum for assay monitoring. Wells 3-11A-H are for test samples.

Coat each well of the ELISA plates with 100 µL of tetanus toxoid solution (0.5 Lf/mL in carbonate coating buffer pH 9.6). Allow to stand overnight at 4 °C in a humid atmosphere. To avoid temperature gradient effects, do not stack more than 4 plates high. On the following day, wash the plates thoroughly with washing buffer. Block the plates by addition of 100 µL of diluent block buffer to each well. Incubate in a humid atmosphere at 37 °C for 1 h. Wash the plates thoroughly with washing buffer. Place 100 µL of diluent block buffer in each well of the plates, except those of row A. Prepare suitable dilutions of negative control serum, positive control serum (from about 0.01 IU/mL) and test sera. Allocate the negative control serum to column 1, positive control serum to columns 2 and 12 and test sera to columns 3-11 and add 100 µL of each serum to the first 2 wells of the column to which it is allocated. Using a multichannel micropipette, make twofold serial dilutions from row B down the plate to row H, by transferring 100 µL from one well to the next. Discard 100 µL from the last row so that all wells contain 100 µL. Incubate at 37 °C for 2 h. Wash thoroughly with washing buffer. Prepare a suitable dilution (a 2000-fold dilution has been found to be suitable) of peroxidase conjugate in diluent block buffer and add 100 µL to each well. Incubate at 37 °C in a humid atmosphere for 1 h. Wash the plates thoroughly with washing buffer. Add 100 µL of peroxidase substrate to each well. Allow to stand at room temperature, protected from light, for 30 min. Read the plates at 405 nm in the same order as addition of substrate was made.

**Determination of antibody titre in guinea-pig serum by toxin- or toxoid-binding inhibition (ToBI)**. Tetanus toxin or toxoid is added to serial dilutions of test and reference sera; the serum/antigen mixtures are incubated overnight. To determine unbound toxin or toxoid, the mixtures are transferred to an ELISA plate coated with tetanus antitoxin. Peroxidase-conjugated equine anti-tetanus IgG is added followed by a peroxidase substrate. Optical density is measured and the antibody titre is calculated using the usual statistical methods (for example, *5.3*). A positive control serum and a negative control serum are included on each plate to monitor assay performance.

*Reagents and equipment*

– *Round-bottomed, rigid polystyrene microtitre plates*.

– *Flat-bottomed ELISA plates*.

– *Tetanus toxin or tetanus toxoid*.

– *Clostridium tetani guinea-pig antiserum (for vaccines-human use) BRP* (positive control serum).

– *Equine anti-tetanus IgG*.

– *Peroxidase-conjugated equine anti-tetanus IgG*.

– *Carbonate buffer pH 9.6*. Dissolve 1.5 g of *anhydrous sodium carbonate R*, 2.39 g of *sodium hydrogen carbonate R* and 0.2 g of *sodium azide R* in 1000 mL of *water R*, adjust to pH 9.6 and autoclave at 121 °C for 20 min.

– *Sodium acetate buffer pH 5.5*. Dissolve 90.2 g of *anhydrous sodium acetate R* in 900 mL of *water R*, adjust to pH 5.5 using a saturated solution of *citric acid monohydrate R* and dilute to 1000 mL with *water R*.

– *Phosphate-buffered saline pH 7.2 (PBS)*. Dissolve 135.0 g of *sodium chloride R*, 20.55 g of *disodium hydrogen phosphate dihydrate R* and 4.80 g of *sodium dihydrogen phosphate monohydrate R* in *water R* and dilute to 15 L with the same solvent. Autoclave at 100 °C for 60 min.

– *Diluent buffer*. PBS containing 5 g/L of *bovine albumin R* and 0.5 g/L of *polysorbate 80 R*.

– *Block buffer*. PBS containing 5 g/L of *bovine albumin R*.

– *Tetramethylbenzidine solution*. 6 g/L solution of *tetramethylbenzidine R* in *ethanol (96 per cent) R*. The substance dissolves within 30-40 min at room temperature.

– *Peroxidase substrate*. Mix 90 mL of *water R*, 10 mL of sodium acetate buffer pH 5.5, 1.67 mL of tetramethylbenzidine solution and 20 µL of *strong hydrogen peroxide solution R*.

– *Washing solution*. Tap water containing 0.5 g/L of *polysorbate 80 R*.

*Method*

Block the microtitre plates by placing in each well 150 µL of block buffer. Cover the plates with a lid or sealer. Incubate in a humid atmosphere at 37 °C for 1 h. Wash the plates thoroughly with washing solution. Place 100 µL of PBS in each well. Place 100 µL of reference guinea-pig tetanus antitoxin in the first well of a row. Place 100 µL of undiluted test sera in the first well of the required number of rows. Using a multichannel micropipette, make twofold serial dilutions across the plate (up to column 10), by transferring 100 µL from one well to the next. Discard 100 µL from the last column so that all wells contain 100 µL. Prepare a 0.1 Lf/mL solution of tetanus toxin or toxoid using PBS as diluent. Add 40 µL of this solution to each well except those of column 12. The wells of column 11 are a positive control. Add 40 µL of PBS to the wells of column 12 (negative control). Shake the plates gently and cover them with lids. Coat the ELISA plates: immediately before use make a suitable dilution of equine anti-tetanus IgG in carbonate buffer pH 9.6 and add 100 µL to each well. Incubate the 2 series of plates overnight in a humid atmosphere at 37 °C. To avoid temperature gradient effects, do not stack more than 4 plates high. Cover the plates with lids. On the following day, wash the ELISA plates thoroughly with washing solution. Block the plates by placing in each well 125 µL of block buffer. Incubate at 37 °C in a humid atmosphere for 1 h. Wash the plates thoroughly with washing solution. Transfer 100 µL of the pre-incubation mixture from the polystyrene plates to the corresponding wells of the ELISA plates, starting with column 12 and then continuing from 1 to 11. Cover the plates with a lid. Incubate at 37 °C in a humid atmosphere for 2 h. Wash the ELISA plates thoroughly with washing solution. Make a suitable dilution (a 4000-fold dilution has been found to be suitable) of the peroxidase-conjugated equine anti-tetanus IgG in diluent buffer. Add 100 µL of the dilution to each well and cover the plates with a lid. Incubate at 37 °C in a humid atmosphere for 1.5 h. Wash the ELISA plates thoroughly with washing solution. Add 100 µL of peroxidase substrate to each well. A blue colour develops. Incubate the plates at room temperature. Stop the reaction at a given time (within 10 min) by the addition of 100 µL of a 2 M solution of sulfuric acid prepared from *sulfuric acid R* to each well in the same order as the addition of substrate. The colour changes from blue to yellow. Measure the absorbance at 450 nm immediately after addition of the sulfuric acid or maintain the plates in the dark until reading.

01/2018:20709

# 2.7.9. TEST FOR Fc FUNCTION OF IMMUNOGLOBULIN

*The test for Fc function of immunoglobulin is carried out using method A or B. Method B is an adaptation of the procedure of method A for the use of microtitre plates for the measurement of complement-mediated haemolysis. Differences in the test procedures between methods A and B are addressed in the test.*

REAGENTS

*Stabilised human blood*. Collect group O human blood into ACD anticoagulant solution. Store the stabilised blood at 4 °C for not more than 3 weeks.

*Phosphate-buffered saline pH 7.2*. Dissolve 1.022 g of *anhydrous disodium hydrogen phosphate R*, 0.336 g of *anhydrous sodium dihydrogen phosphate R* and 8.766 g of *sodium chloride R* in 800 mL of *water R* and dilute to 1000 mL with the same solvent.

*Magnesium and calcium stock solution*. Dissolve 1.103 g of *calcium chloride R* and 5.083 g of *magnesium chloride R* in *water R* and dilute to 25 mL with the same solvent.

*Barbital buffer stock solution*. Dissolve 207.5 g of *sodium chloride R* and 25.48 g of *barbital sodium R* in 4000 mL of *water R* and adjust to pH 7.3 using *1 M hydrochloric acid*. Add 12.5 mL of magnesium and calcium stock solution and dilute to 5000 mL with *water R*. Store at 4 °C in transparent containers.

*Albumin barbital buffer solution*. Dissolve 0.150 g of *bovine albumin R* in 20 mL of barbital buffer stock solution and dilute to 100 mL with *water R*. Prepare immediately before use.

*Tannic acid solution*. Dissolve 10 mg of *tannic acid R* in 100 mL of phosphate-buffered saline pH 7.2. Prepare immediately before use.

*Guinea-pig complement*. Prepare a pool of serum from the blood of not fewer than 10 guinea-pigs. Separate the serum from the clotted blood by centrifugation at about 4 °C. Store the serum in small amounts below – 70 °C. Immediately before starting complement-initiated haemolysis, dilute to 125-200 $CH_{50}$ per millilitre with albumin barbital buffer solution and store in an ice-bath during the test.

*Rubella antigen*. Suitable rubella antigen for haemagglutination-inhibition titre (HIT). Titre > 256 HA units.

**Preparation of tanned human red blood cells**. Separate human red blood cells by centrifuging an appropriate volume of stabilised human blood, wash the cells at least 3 times with phosphate-buffered saline pH 7.2 and suspend at 2 per cent *V/V* in phosphate-buffered saline pH 7.2. Add 0.2 mL of tannic acid solution to 14.8 mL of phosphate-buffered saline pH 7.2. Mix 1 volume of the freshly prepared dilution with 1 volume of the human red blood cell suspension and incubate at 37 °C for 10 min. Collect the cells by centrifugation (800 *g* for 10 min), discard the supernatant and wash the cells once with phosphate-buffered saline pH 7.2. Resuspend the tanned cells at 1 per cent *V/V* in phosphate-buffered saline pH 7.2.

**Antigen coating of tanned human red blood cells**. Take a suitable volume ($V_s$) of tanned cells, add 0.2 mL of rubella antigen per 1.0 mL of tanned cells and incubate at 37 °C for 30 min. Collect the cells by centrifugation (800 *g* for 10 min) and discard the supernatant. Add a volume of albumin barbital buffer solution equivalent to the discarded supernatant, resuspend and collect the cells as described and repeat the washing procedure. Resuspend with albumin barbital buffer solution using a volume equivalent to 3/4 of $V_s$, thereby obtaining the initial volume ($V_i$). Mix 900 µL of albumin barbital buffer solution with 100 µL of $V_i$, which is thereby reduced to the residual volume ($V_r$), and determine the initial absorbance at 541 nm ($A$). Dilute $V_r$ by a factor equal to $A$ using albumin barbital buffer solution, thereby obtaining the final adjusted volume $V_f = V_r \times A$ of sensitised human red blood cells and adjusting $A$ to 1.0 ± 0.1 for a tenfold dilution.

**Antibody binding of antigen-coated tanned human red blood cells**. Prepare the following solutions in succession and in duplicate, using for each solution a separate half-micro cuvette (for example, disposable type) or test-tube.

(1) *Test solutions*. If necessary, adjust the immunoglobulin to be examined to pH 7.

Where method A is performed, dilute volumes of the preparation to be examined with albumin barbital buffer to obtain 30 mg and 40 mg of immunoglobulin and adjust the volume to 900 µL with albumin barbital buffer.

Where method B is performed, dilute volumes of the preparation to be examined with albumin barbital buffer to obtain 15 mg and 30 mg of immunoglobulin and adjust the volume to 1200 µL with albumin barbital buffer.

(2) *Reference solutions*. Prepare as for the test solutions using *human immunoglobulin for Fc function BRP*.

(3) *Complement control*. Albumin barbital buffer solution.

Where method A is performed, add to each cuvette/test-tube 100 µL of sensitised human red blood cells and mix well. Allow to stand for 15 min, add 1000 µL of albumin barbital buffer solution, collect the cells by centrifugation (1000 *g* for 10 min) of the cuvette/test-tube and remove 1900 µL of the supernatant. Replace the 1900 µL with albumin barbital buffer solution and repeat the whole of the washing procedure, finally leaving a volume of 200 µL. Test samples may be stored in sealed cuvettes/test-tubes at 4 °C for not longer than 24 h.

Where method B is performed, add to each test-tube 300 µL of sensitised human red blood cells and mix well (the final immunoglobulin concentration is in the range of 10-20 mg/mL). Allow to stand for 15 min, add 1500 µL of albumin barbital buffer solution and stir gently until homogeneous. Collect the cells by centrifugation (1000 *g* for 10 min) of the test-tube, remove the supernatant and add approximately 3 mL of albumin barbital buffer solution. Repeat this operation up to 4 times in total, leaving a final volume of 300 µL. Test samples may be stored in sealed test-tubes at 4 °C for not longer than 24 h.

**Complement-initiated haemolysis**.

To measure haemolysis where method A is performed, add 600 µL of albumin barbital buffer solution warmed to 37 °C to the test sample, resuspend the cells carefully by repeated pipetting (not fewer than 5 times) and place the cuvette in the thermostatted cuvette holder of a spectrophotometer. After 2 min, add 200 µL of diluted guinea-pig complement (125-200 $CH_{50}$/mL), mix thoroughly by pipetting twice and start immediately after the second pipetting the time-dependent recording of absorbance at 541 nm, using albumin barbital buffer solution as the compensation liquid. Stop the measurement if absorbance as a function of time has clearly passed the inflexion point.

To measure haemolysis where method B is performed, add 900 µL of albumin barbital buffer solution warmed to 37 °C to each test-tube and resuspend the cells carefully by repeated pipetting (not fewer than 5 times). The microtitre plate must be prewarmed to 37 °C before starting the test. Transfer 240 µL of each solution into 4 microtitre plate wells then incubate the microplate at 37 °C for 6 min, stirring gently every 10 s. To each microtitre plate well add 60 µL of diluted guinea-pig complement (150 $CH_{50}$/mL). Mix for 10 s and immediately start recording the absorbance at 541 nm at 37 °C, measuring every 20 s. Stop the measurement if the absorbance as a function of time has clearly passed the inflexion point.

**Evaluation**. For each cuvette/test-tube/well, determine the slope ($S$) of the haemolysis curve at the approximate inflexion point by segmenting the steepest section in suitable time

intervals (for example, $\Delta t$ = 1 min), and calculate $S$ between adjacent intersection points, expressed as $\Delta A$ per minute. The largest value for $S$ serves as $S_{exp}$. In addition, determine the absorbance at the start of measurement ($A_s$) by extrapolating the curve, which is almost linear and parallel to the time axis within the first few minutes. Correct $S_{exp}$ using the expression:

$$S' = \frac{S_{exp}}{A_s}$$

Calculate the arithmetic mean of the values of $S'$ for each preparation (test and reference solution). Calculate the index of Fc function ($I_{Fc}$) from the expression:

$$I_{Fc} = \frac{100 \times (\overline{S'} - \overline{S'}_c)}{\overline{S'}_s - \overline{S'}_c}$$

$\overline{S'}$ = arithmetic mean of the corrected slope for the preparation to be examined;

$\overline{S'}_s$ = arithmetic mean of the corrected slope for the reference preparation;

$\overline{S'}_c$ = arithmetic mean of the corrected slope for the complement control.

Calculate the index of Fc function for the preparation to be examined: the value is not less than that stated in the leaflet accompanying the reference preparation.

**01/2008:20710**

# 2.7.10. ASSAY OF HUMAN COAGULATION FACTOR VII

Human coagulation factor VII is assayed by its biological activity as a factor VIIa-tissue factor complex in the activation of factor X in the presence of calcium ions and phospholipids. The potency of a factor VII preparation is estimated by comparing the quantity necessary to achieve a certain rate of factor Xa formation in a test mixture containing the substances that take part in the activation of factor X, and the quantity of the International Standard, or of a reference preparation calibrated in International Units, required to produce the same rate of factor Xa formation.

The International Unit is the factor VII activity of a stated amount of the International Standard, which consists of freeze-dried plasma. The equivalence in International Units of the International Standard is stated by the World Health Organization.

*Human coagulation factor VII concentrate BRP* is calibrated in International Units by comparison with the International Standard.

The chromogenic assay method consists of 2 consecutive steps: the factor VII-dependent activation of factor X reagent mixture containing tissue factor, phospholipids and calcium ions, followed by enzymatic cleavage of a chromogenic factor Xa substrate into a chromophore that can be quantified spectrophotometrically. Under appropriate assay conditions, there is a linear relation between the rate of factor Xa formation and the factor VII concentration. The assay is summarised in the following scheme.

**Step 1**

a) factor VII —(tissue factor, $Ca^{2+}$)→ factor VIIa

b) factor X —(factor VIIa, $Ca^{2+}$; tissue factor/phospholipid)→ factor Xa

**Step 2**

chromogenic substrate —(factor Xa)→ peptide + chromophore

Both steps employ reagents that may be obtained commercially from a variety of sources. Although the composition of individual reagents may be subject to some variation, their essential features are described in the following specification.

REAGENTS

The coagulation factor reagent comprises purified proteins derived from human or bovine sources. These include factor X and thromboplastin tissue factor/phospholipid as factor VII activator. These proteins are partly purified and do not contain impurities that interfere with the activation of factor VII or factor X. Factor X is present in amounts giving a final concentration during the first step of the assay of 10-350 nmol/L, preferably 14-70 nmol/L. Thromboplastin from natural sources (bovine or rabbit brain) or synthetic preparations may be used as the tissue factor/phospholipid component. Thromboplastin suitable for use in prothrombin time determination is diluted 1:5 to 1:50 in buffer such that the final concentration of $Ca^{2+}$ is 15-25 mmol/L. The final factor Xa generation is performed in a solution containing human or bovine albumin at a concentration such that adsorption losses do not occur and which is appropriately buffered at pH 7.3-8.0. In the final incubation mixture, factor VII must be the only rate-limiting component and each reagent component must lack the ability to generate factor Xa on its own.

The second step comprises the quantification of the formed factor Xa employing a chromogenic substrate that is specific for factor Xa. Generally this consists of a short peptide of between three and five amino acids, bound to a chromophore group. On cleavage of this group from the peptide substrate, its absorption maximum shifts to a wavelength allowing its spectrophotometric quantification. The substrate is usually dissolved in *water R* and used at a final concentration of 0.2-2 mmol/L. The substrate may also contain appropriate inhibitors to stop further factor Xa generation (addition of edetate).

ASSAY PROCEDURE

Reconstitute the entire contents of one ampoule of the reference preparation and the preparation to be examined by adding the appropriate quantity of *water R*; use within 1 h. Add sufficient prediluent to the reconstituted preparations to produce solutions containing between 0.5 IU and 2.0 IU of factor VII per millilitre.

Prepare further dilutions of reference and test preparations using an isotonic non-chelating buffer containing 1 per cent of bovine or human albumin, buffered preferably between pH 7.3 and 8.0. Prepare at least three separate, independent dilutions for each material, preferably in duplicate. Prepare the dilutions such that the final factor VII concentration is below 0.005 IU/mL.

Prepare a control solution that includes all components except factor VII.

*Prepare all dilutions in plastic tubes and use within 1 h.*

**Step 1**. Mix dilutions of the factor VII reference preparation and the preparation to be examined with an appropriate volume of the prewarmed coagulation factor reagent or a combination of its separate constituents, and incubate the mixture in plastic tubes or microplate wells at 37 °C. The

concentrations of the various components during the factor Xa generation must be as specified above under the description of the reagents.

Allow the activation of factor X to proceed for a suitable time, usually terminating the reaction before the factor Xa concentration has reached its maximal level in order to obtain a satisfactory linear dose-response relationship. The activation time is also chosen to achieve linear production of factor Xa in time. Appropriate activation times are usually between 2 min and 5 min, but deviations are permissible if acceptable linearity of the dose-response relationship is thus obtained.

**Step 2**. Terminate the activation by the addition of a prewarmed reagent containing a chromogenic substrate. Quantify the rate of substrate cleavage, which must be linear with the concentration of factor Xa formed, by measuring the absorbance change at an appropriate wavelength using a spectrophotometer, either monitoring the absorbance continuously, thus allowing the initial rate of substrate cleavage to be calculated, or terminating the hydrolysis reaction after a suitable interval by lowering the pH by the addition of a suitable reagent, such as acetic acid (500 g/L $C_2H_4O_2$) or a citrate solution (1 mol/L) at pH 3. Adjust the hydrolysis time to achieve a linear development of chromophore with time. Appropriate hydrolysis times are usually between 3 min and 15 min, but deviations are permissible if better linearity of the dose-response relationship is thus obtained.

Check the validity of the assay and calculate the potency of the test preparation by the usual statistical methods (for example, *5.3*).

**01/2008:20711**

## 2.7.11. ASSAY OF HUMAN COAGULATION FACTOR IX

The principle of the assay is to measure the ability of a factor IX preparation to reduce the prolonged coagulation time of factor IX-deficient plasma. The reaction is accelerated by addition of a reagent containing phospholipid and a contact activator, e.g. kaolin, silica or ellagic acid. The potency is assessed by comparing the dose-response curve of the preparation to be examined to that of a reference preparation, calibrated in International Units.

The International Unit is the factor IX activity of a stated amount of the International Standard, which consists of a freeze-dried concentrate of human coagulation factor IX. The equivalence in International Units of the International Standard is stated by the World Health Organization.

*Human coagulation factor IX concentrate BRP* is calibrated in International Units by comparison with the International Standard.

Reconstitute separately the preparation to be examined and the reference preparation as stated on the label and use immediately. Where applicable, determine the amount of heparin present (*2.7.12*) and neutralise the heparin, for example by addition of *protamine sulfate R* (10 µg of protamine sulfate neutralises 1 IU of heparin). Predilute the preparation to be examined and the reference preparation in factor IX-deficient plasma (for example *plasma substrate R2*) to produce solutions containing 0.5-2.0 IU/mL. Prepare at least 3 dilutions for each material, preferably in duplicate, using a suitable buffer solution (for example *imidazole buffer solution pH 7.3 R*) containing 10 g/L of bovine or human albumin. Use these dilutions immediately.

Use an apparatus suitable for measurement of coagulation times or carry out the assay with incubation tubes maintained in a water-bath at 37 °C. Place in each tube 0.1 mL of factor IX-deficient plasma (for example *plasma substrate R2*) and 0.1 mL of one of the dilutions of the reference preparation or of the preparation to be examined. Add to each tube 0.1 mL of a suitable Activated Partial Thromboplastin Time (APTT) reagent containing phospholipid and contact activator and incubate the mixture for a recommended time at 37 °C. To each tube, add 0.1 mL of a 3.7 g/L solution of *calcium chloride R* previously heated to 37 °C. Using a timer, measure the coagulation time, i.e. the interval between the moment of the addition of the calcium chloride and the first indication of the formation of fibrin. The volumes given above may be adapted to the APTT reagent and apparatus used. Calculate the potency using the usual statistical methods (for example, *5.3*).

**01/2008:20712**

## 2.7.12. ASSAY OF HEPARIN IN COAGULATION FACTORS

Heparin is assayed as a complex with antithrombin III (AT) via its inhibition of coagulation factor Xa (anti-Xa activity). An excess of AT is maintained in the reaction mixture to ensure a constant concentration of the heparin-AT complex. Factor Xa is neutralised by the heparin-AT complex and the residual factor Xa hydrolyses a specific chromogenic peptide substrate to release a chromophore. The quantity of chromophore is inversely proportional to the activity of the heparin.

*Factor Xa chromogenic substrate*. Specific chromogenic substrate for factor Xa such as: *N*-benzoyl-L-isoleucyl-L-glutamyl-glycyl-L-arginine-4-nitroanilide hydrochloride. Reconstitute according to the manufacturer's instructions.

*Dilution buffer*. 6.05 g/L solution of *tris(hydroxymethyl)aminomethane R*. Adjust to pH 8.4 if necessary using *hydrochloric acid R*.

*Test solution*. Dilute the preparation to be examined with dilution buffer to obtain a solution expected to contain 0.1 IU of heparin per millilitre.

*Reference solution*. Dilute the heparin reference preparation with dilution buffer to obtain a solution containing 0.1 IU of heparin per millilitre.

The following working conditions apply to microtitre plates. If the assay is carried out in tubes, the volumes are adjusted while maintaining the proportions in the mixture.

Warm all solutions to 37 °C in a water-bath shortly before the test.

Distribute in a series of wells, 20 µL of normal human plasma and 20 µL of *antithrombin III solution R1*. Add to the wells a series of volumes (20 µL, 60 µL, 100 µL and 140 µL) of the test solution or the reference solution and make up the volume in each well to 200 µL using dilution buffer (0.02-0.08 IU of heparin per millilitre in the final reaction mixture).

*End-point method*. Transfer 40 µL from each well to a second series of wells, add 20 µL of *bovine factor Xa solution R* and incubate at 37 °C for 30 s. Add 40 µL of a 1 mmol/L solution of factor Xa chromogenic substrate and incubate at 37 °C for 3 min. Terminate the reaction by lowering the pH by the addition of a suitable reagent, such as a 20 per cent *V/V* solution of *glacial acetic acid R* and measure the absorbance at 405 nm (*2.2.25*). Appropriate reaction times are usually between 3 min and 15 min, but deviations are permissible if better linearity of the dose-response relationship is thus obtained.

*Kinetic method*. Transfer 40 µL from each well to a second series of wells, add 20 µL of *bovine factor Xa solution R* and incubate at 37 °C for 30 s. Add 40 µL of a 2 mmol/L solution of factor Xa chromogenic substrate, incubate at 37 °C and measure the rate of substrate cleavage by continuous measurement of the absorbance change at 405 nm (*2.2.25*),

thus allowing the initial rate of substrate cleavage to be calculated. This rate must be linear with the concentration of residual factor Xa.

Check the validity of the assay and calculate the heparin activity of the test preparation by the usual statistical methods for a slope-ratio assay (for example, *5.3*).

**01/2008:20713**
**corrected 7.5**

## 2.7.13. ASSAY OF HUMAN ANTI-D IMMUNOGLOBULIN

METHOD A

The potency of human anti-D immunoglobulin is determined by comparing the quantity necessary to produce agglutination of D-positive red blood cells with the quantity of a reference preparation, calibrated in International Units, required to produce the same effect.

The International Unit is the activity contained in a stated amount of the International Reference Preparation. The equivalence in International Units of the International Reference Preparation is stated by the World Health Organization.

*Human anti-D immunoglobulin BRP* is calibrated in International Units by comparison with the International Standard and intended for use in the assay of human anti-D immunoglobulin.

Use pooled D-positive red blood cells, collected not more than 7 days earlier and suitably stored, obtained from not fewer than 4 group O $R_1R_1$ donors. To a suitable volume of the cells, previously washed 3 times with a 9 g/L solution of *sodium chloride R*, add an equal volume of *bromelains solution R*, allow to stand at 37 °C for 10 min, centrifuge, remove the supernatant and wash 3 times with a 9 g/L solution of *sodium chloride R*. Suspend 20 volumes of the red blood cells in a mixture of 15 volumes of inert serum, 20 volumes of a 300 g/L solution of *bovine albumin R* and 45 volumes of a 9 g/L solution of *sodium chloride R*. Stand the resulting suspension in iced water, stirring continuously.

Using a calibrated automated dilutor, prepare suitable dilutions of the preparation to be examined and of the reference preparation using as diluent a solution containing 5 g/L of *bovine albumin R* and 9 g/L of *sodium chloride R*.

Use a suitable apparatus for automatic continuous analysis. The following protocol is usually suitable: maintain the temperature in the manifold, except for the incubation coils, at 15.0 °C. Pump into the manifold of the apparatus the red blood cell suspension at a rate of 0.1 mL/min and a 3 g/L solution of *methylcellulose 450 R* at a rate of 0.05 mL/min. Introduce the dilutions of the preparation to be examined and the reference preparation at a rate of 0.1 mL/min for 2 min, followed by the diluent solution at a rate of 0.1 mL/min for 4 min before the next dilution is introduced.

Introduce air at a rate of 0.6 mL/min. Incubate at 37 °C for 18 min and then disperse the rouleaux by introducing at a rate of 1.6 mL/min a 9 g/L solution of *sodium chloride R* containing a suitable wetting agent (for example, *polysorbate 20 R* at a final concentration of 0.2 g/L) to prevent disruption of the bubble pattern. Allow the agglutinates to settle and decant twice, first at 0.4 mL/min and then at 0.6 mL/min. Lyse the unagglutinated red blood cells with a solution containing 5 g/L of *octoxinol 10 R*, 0.2 g/L of *potassium ferricyanide R*, 1 g/L of *sodium hydrogen carbonate R* and 0.05 g/L of *potassium cyanide R* at a rate of 2.5 mL/min. A 10-minute delay coil is introduced to allow for conversion of the haemoglobin. Continuously record the absorbance (*2.2.25*) of the haemolysate at a wavelength between 540 nm and 550 nm. Determine the range of antibody concentrations over which there is a linear relationship between the concentration and the resultant change in absorbance ($\Delta A$). From the results, prepare a standard curve and use the linear portion of the curve to determine the activity of the preparation to be examined.

Calculate the potency of the preparation to be examined using the usual statistical methods (*5.3*).

METHOD B

The potency of human anti-D immunoglobulin is determined by competitive enzyme-linked immunoassay on erythrocyte-coated microtitre plates. The method is based on the competitive binding between a polyclonal anti-D immunoglobulin preparation and a biotinylated monoclonal anti-D antibody directed against a D-antigen-specific epitope. The activity of the preparation to be examined is compared with a reference preparation calibrated in International Units.

The International Unit is the activity of a stated amount of International Reference Preparation. The equivalence in International Units of the International Reference Preparation is stated by the World Health Organization.

*Human anti-D immunoglobulin BRP* is calibrated in International Units by comparison with the International Standard and intended for use in the assay of human anti-D immunoglobulin.

*MATERIALS*

Reagents not specified are of analytical grade.

*PBS (Phosphate-buffered saline).* Dissolve 8.0 g of *sodium chloride R*, 0.76 g of *anhydrous disodium hydrogen phosphate R*, 0.2 g of *potassium chloride R*, 0.2 g of *potassium dihydrogen phosphate R* and 0.2 g of *sodium azide R* in *water R* and dilute to 1000 mL with the same solvent.

*TBS (Tris-buffered saline).* Dissolve 8.0 g of *sodium chloride R* and 0.6 g of *tris(hydroxymethyl)aminomethane R* in *water R*. Adjust to pH 7.2 with *1 M hydrochloric acid* and dilute to 1000 mL with *water R*.

*Papain solution.* Prepare a solution by stirring 1 g of *papain R* at 37 °C for 30 min in 10 mL of *0.067 M phosphate buffer solution pH 5.4 R*, centrifuge at 10 000 *g* for 5 min and filter through a membrane filter (nominal pore size 0.22 µm). To activate, combine 1 mL of the filtrate with 1 mL of a 48.44 g/L solution of *L-cysteine R* and 1 mL of a 3.72 g/L solution of *sodium edetate R* and dilute to 10 mL with *0.067 M phosphate buffer solution pH 5.4 R*. Freeze in aliquots at − 20 °C or below.

*Red blood cells.* Use pooled D-positive red blood cells obtained from not fewer than 3 group O $R_2R_2$ donors. Wash the cells 4 times with PBS. Centrifuge the cells at 1800 *g* for 5 min, mix a suitable volume of prewarmed packed cells with a suitable volume of prewarmed papain solution (2 volumes to 1 volume has been found suitable) and incubate at 37 °C for 10 min. Wash the cells 4 times with PBS. Store at 4 °C in an appropriate stabiliser for up to 1 week.

*Biotinylated Brad-5.* Use according to instructions.

*Alkaline phosphatase-conjugated avidin/streptavidin reagent.* Preferably modified to combine high specific activity with low non-specific binding. Use according to instructions.

*Substrate solution.* Use *para*-nitrophenyl phosphate according to instructions.

*Cell fixation buffer.* Dissolve 18.02 g of *glucose R*, 4.09 g of *sodium chloride R*, 1.24 g of *boric acid R*, 10.29 g of *sodium citrate R* and 0.74 g of *sodium edetate R* in *water R*. Adjust to pH 7.2-7.3 using *1 M sodium hydroxide* or *1 M hydrochloric acid*, and dilute to 1000 mL with *water R*. Use directly from storage at 4 °C.

*Glutaraldehyde solution.* Immediately before use, add 750 µL of a 250 g/L solution of *glutaraldehyde R* to 50 mL of cold PBS.

*Microtitre plates.* Plates to be coated with red blood cells are flat-bottomed polystyrene plates with surface properties optimised for enzyme immunoassay and high protein-binding capacity. Plates used to prepare immunoglobulin dilutions are U- or V-bottomed polystyrene or poly(vinyl chloride) plates.

*METHOD*

Prepare a 0.1 per cent *V/V* suspension of papain-treated red blood cells in cold cell-fixation buffer. Pipette 50 µL into each well of the flat-bottomed microtitre plate.

Centrifuge the plate at 350 *g* for 3 min, preferably at 4 °C. Without removing the supernatant, gently add 100 µL of glutaraldehyde solution to each well and leave for 10 min.

Drain the wells by quickly inverting the plate and wash 3 times with 250-300 µL of PBS. This may be done manually or using a suitable automated plate washer. Either carry out the assay as described below, or store the plate at 4 °C after draining off the PBS and adding 100 µL of cell-fixation buffer per well and sealing with plastic film. Plates can be stored at 4 °C for up to 1 month.

*Test solutions.* For freeze-dried preparations, reconstitute as stated on the label. Prepare 4 independent replicates of 5 serial 2-fold dilutions starting with 30 IU/mL in PBS containing 10 g/L of *bovine albumin R*. If necessary, adjust the starting dilution to obtain responses falling in the linear portion of the dose-response curve.

*Reference solutions.* Reconstitute the reference preparation according to instructions. Prepare 4 independent replicates of 5 serial 2-fold dilutions starting with 30 IU/mL in PBS containing 10 g/L of *bovine albumin R*.

Using U- or V-bottomed microtitre plates, add 35 µL of each of the dilutions of the test solution or reference solution to each of a series of wells. To each well add 35 µL of biotinylated Brad-5 at 250 ng/mL.

Empty the wells of the red cell-coated plate by inverting and draining on a paper towel. Add 250 µL of PBS containing 20 g/L of *bovine albumin R* and leave at room temperature for 30 min.

Empty the wells of the red cell-coated plate by inverting and draining on a paper towel and transfer 50 µL from each of the dilutions of the test solution or reference solution containing biotinylated Brad-5 into the wells. Use 50 µL of PBS containing 10 g/L of *bovine albumin R* as negative control. Seal the plate with plastic film and incubate at room temperature for 1 h.

Remove the liquid from the wells of the red cell-coated plate and wash 3 times with 250-300 µL of TBS.

Dilute the alkaline phosphatase-conjugated avidin/streptavidin reagent in TBS containing 10 g/L of *bovine albumin R* and add 50 µL to each well. Incubate for 30 min at room temperature.

Remove the liquid from the wells of the red cell-coated plate and wash 3 times with 250-300 µL of TBS.

Add 100 µL of substrate solution to each of the wells and incubate at room temperature for 10 min in the dark. To stop the reaction, add 50 µL of *3 M sodium hydroxide* to each of the wells.

Measure the absorbances at 405 nm and substract the negative control reading. Use the absorbance values in the linear range of the titration curve to estimate the potency of the preparation to be examined by the usual statistical methods (*5.3*).

METHOD C

The potency of human anti-D immunoglobulin is determined by flow cytometry in a microtitre plate format. The method is based on the specific binding between anti-D immunoglobulin and D-positive red blood cells. The activity of the preparation to be examined is compared with a reference preparation calibrated in International Units.

The International Unit is the activity of a stated amount of International Reference Preparation. The equivalence in International Units of the International Reference preparation is stated by the World Health Organization.

*Human anti-D immunoglobulin BRP* is calibrated in International Units by comparison with the International Standard and intended for use in the assay of human anti-D immunoglobulin.

*MATERIALS*

Reagents not specified are of analytical grade.

*PBS.* Dissolve 8.0 g of *sodium chloride R*, 0.76 g of *disodium hydrogen phosphate dodecahydrate R*, 0.2 g of *potassium chloride R* and 0.2 g of *potassium dihydrogen phosphate R* in *water R* and dilute to 1000 mL with the same solvent.

*PBS-BSA solution.* PBS containing 10.0 g/L of *bovine albumin R*.

*Red blood cells.* Use D-positive red blood cells obtained from a group O $R_1R_1$ donor within 2 weeks of collection. Store if necessary in an appropriate stabiliser at 4 °C. Wash the cells at least twice with PBS-BSA solution and prepare a suspension containing $1 \times 10^4$ cells per microlitre but not more than $5 \times 10^4$ cells per microlitre in PBS-BSA solution.

Use D-negative red blood cells obtained from a group O rr donor and prepared similarly.

*Secondary antibody.* Use a suitable fluorescent dye-conjugated anti-IgG antibody fragment specific for human IgG or parts of it. Store and use according to the manufacturer's instructions.

*Microtitres plates.* Use flat-bottomed plates without surface treatment for enzyme immunoassays.

*METHOD*

*Test solutions.* For freeze-dried preparations, reconstitute as stated on the label. Prepare at least 3 independent replicates of at least 3 serial 1.5- or 2-fold dilutions starting with a concentration in the range of 1.2-0.15 IU/mL using PBS/BSA solution as diluent. If necessary, adjust the starting dilution to obtain responses falling in the linear portion of the dose-response curve.

*Reference solutions.* Reconstitute the reference preparation according to instructions. Prepare at least 3 independent replicates of at least 3 serial 1.5- or 2-fold dilutions starting with a concentration in the range of 1.2-0.15 IU/mL using PBS-BSA solution as diluent. If necessary, adjust the starting dilution to obtain responses falling in the linear portion of the dose-response curve.

Distribute 50 µL of the D-positive red blood cells into each well of a microtitre plate. Add 50 µL of each of the dilutions of the test solution or reference solution to each of a series of wells. Use 50 µL of PBS-BSA solution as negative control. Distribute 50 µL of the D-negative red blood cells into 4 wells of the same microtitre plate and add 50 µL of the lowest dilution of the test preparation. To monitor spurious reactions, distribute 50 µL of the D-positive red blood cells into 4 wells of the same microtitre plate and add 50 µL of PBS-BSA solution. Seal with plastic film and incubate at 37 °C for 40 min.

Centrifuge the plates at 50 *g* for 3 min, discard the supernatant and wash the cells with 200-250 µL of PBS-BSA solution. Repeat this at least once.

Centrifuge the plates at 50 *g* for 3 min, discard the supernatant and add 50 µL of the secondary antibody diluted with PBS-BSA solution to a suitable protein concentration. Seal with plastic film and incubate, protected from light, at room temperature for 20 min.

Centrifuge the plates at 50 *g* for 3 min, discard the supernatant and wash the cells with 200-250 µL of PBS-BSA solution. Repeat this at least once.

Centrifuge the plates at 50 *g* for 3 min, resuspend the cells into 200-250 µL of PBS. Transfer the cell suspension into a tube suitable for the flow-cytometry equipment available and further dilute by adding PBS to allow a suitable flow rate.

Proceed immediately with measurement of the median fluorescence intensity in a flow cytometer. Record at least 10 000 events without gating but excluding debris.

Use the median fluorescence intensity in the linear range of the dose-response curve to estimate the potency of the preparation to be examined by the usual statistical methods (*5.3*).

# 2.7.14. ASSAY OF HEPATITIS A VACCINE

The assay of hepatitis A vaccine is carried out either *in vitro*, by an immunochemical determination of antigen content (method A), or *in vivo*, by comparing under given conditions its capacity to induce specific antibodies in mice with the same capacity of a reference preparation (method B).

METHOD A. *IN VITRO* ASSAY

The hepatitis A antigen content is determined by a suitable immunochemical method (*2.7.1*) such as enzyme-linked immunosorbent assay (ELISA).

*Hepatitis A vaccine (inactivated, non-adsorbed) BRP* may be used as a reference preparation.

The following method is given as an example of an immunochemical method that has been found to be suitable. Perform an ELISA assay for the determination of hepatitis A antigen content using monoclonal antibodies specific for the detection of a hepatitis A epitope that induces neutralising antibodies.

**Materials**

*ELISA microtitre plates*: 96 wells.

*Hepatitis A virus coating reagent for ELISA BRR.*

*Hepatitis A vaccine ELISA detection antibodies set BRR*, composed of *anti-hepatitis A virus primary detection antibody BRR* and *conjugated secondary detection antibody BRR.*

*Hepatitis A vaccine (inactivated, non-adsorbed) BRP.*

*Carbonate-bicarbonate coating buffer (0.05 M) pH 9.6.* Solution 1: dissolve 2.1 g of *sodium hydrogen carbonate R* in 500 mL of *water for injections R*. Solution 2: dissolve 7.16 g of *sodium carbonate R* in 500 mL of *water for injections R*. Mix 70 mL of solution 1 and about 30 mL of solution 2, adjusting the pH with solution 2 if necessary. Filter through a membrane filter (nominal pore size 0.22 µm) and prepare appropriate aliquots in sterile tubes. Store at 2-8 °C for up to 5 months.

*Blocking buffer.* Solution 1: dissolve 4.2 g of *sodium hydrogen carbonate R* in 1000 mL of *water for injections R*. Solution 2: dissolve 5.3 g of *sodium carbonate R* in 1000 mL of *water for injections R*. Mix 630 mL of solution 1 and 270 mL of solution 2, add 50 g of *sucrose R* and stir until dissolution is complete. Add 3 g of *bovine albumin R* (pour small quantities to avoid lumps) and stir until dissolution is complete, avoiding foaming. Adjust to pH 9.6 carefully with solution 2. Prepare appropriate aliquots in sterile tubes. Store at − 20 °C for up to 5 months.

*PBS buffer pH 7.5 ± 0.3.* Dissolve 0.2 g of *potassium dihydrogen phosphate R*, 0.2 g of *potassium chloride R*, 8.0 g of *sodium chloride R* and 1.15 g of *disodium hydrogen phosphate dodecahydrate R* in 1000 mL of *water for injections R*. Store at 2-8 °C for up to 1 month.

*Polysorbate 20 solution.* Dilute 5 mL of *polysorbate 20 R* to 100 mL with *water for injections R*. Store at 2-8 °C for up to 1 month.

*PBS-T buffer.* Immediately before use, add 1 mL of the polysorbate 20 solution to 1000 mL of the PBS buffer pH 7.5 ± 0.3.

*PBS-B-T buffer.* Dissolve 2.5 g of *bovine albumin R* in 400 mL of the PBS-T buffer (pour small quantities of bovine albumin to avoid lumps) and stir until dissolution is complete, avoiding foaming. Adjust to pH 7.25 with *4 M sodium hydroxide R* and dilute to 500 mL with the PBS-T buffer. Prepare appropriate aliquots in sterile tubes. Store at − 20 °C for up to 5 months.

*Chromogenic substrate.* Immediately before use, dissolve at room temperature *diammonium 2,2′-azinobis(3-ethylbenzothiazoline-6-sulfonate) R* (ABTS) according to the manufacturer's instructions.

*Stop solution.* Dissolve 1 g of *sodium dodecyl sulfate R* in *water for injections R* and dilute to 100 mL with the same solvent. Store at room temperature for up to 1 month, protected from light.

**Method**. Dilute an appropriate volume of *hepatitis A virus coating reagent for ELISA BRR* in an appropriate volume of the carbonate-bicarbonate coating buffer (0.05 M) pH 9.6. Transfer 100 µL of the solution to each well of the microtitre plates. Seal the plates and incubate for 3 h ± 5 min at 37 ± 2 °C in a humidified atmosphere. Store at 5 ± 3 °C overnight in a humidified atmosphere. On the following day, empty the plates by inverting them on absorbent paper and add 200 µL of the blocking buffer to each well. Incubate for 45 ± 5 min at 37 ± 2 °C in a humidified atmosphere. Empty the plates by inverting them on absorbent paper. Seal the plates and store at − 20 °C for up to 1 month.

For adsorbed vaccines, a pre-treatment or desorption step is necessary before dilution. The treatment step is considered as a pre-dilution. Prepare 2 independent dilution series in the PBS-B-T buffer for each test sample and for the reference preparation. A 2-fold serial dilution has been found suitable. Thaw an appropriate number of coated plates for the assay. Wash the plates 3 times with the PBS-T buffer. Tap the plates gently on absorbent paper to drain off the washing buffer. For the test samples and the reference preparation, transfer 100 µL of each sample (pre-dilution and serial dilutions) to separate wells of the plate following the appropriate plate layout. For blanks, transfer 100 µL of the PBS-B-T buffer per well. Seal the plates and incubate at 37 ± 2 °C in a humidified atmosphere for 1.5 h ± 5 min. Discard the incubation mix and wash the plates 3 times with the PBS-T buffer. Tap the plates gently on absorbent paper to drain off the washing buffer.

Immediately before use, dilute an appropriate volume of *anti-hepatitis A virus primary detection antibody BRR* in an appropriate volume of the PBS-B-T buffer. Transfer 100 µL of the solution to each well. Seal the plates and incubate at 37 ± 2 °C in a humidified atmosphere for 1 h ± 3 min. Discard the incubation mix and wash the plates 3 times with the PBS-T buffer. Tap the plates gently on absorbent paper to drain off the washing buffer.

Immediately before use, dilute an appropriate volume of *conjugated secondary detection antibody BRR* in an appropriate volume of the PBS-B-T buffer. Transfer 100 µL of the solution to each well. Seal the plates and incubate at 37 ± 2 °C in a humidified atmosphere for 1 h ± 3 min. Discard the incubation mix and wash the plates 3 times with the PBS-T buffer. Tap the plates gently on absorbent paper to drain off the washing buffer.

Add 100 µL of the chromogenic substrate to each well. Seal the plates and incubate at 37 ± 2 °C in a humidified atmosphere for 30 ± 2 min. Stop the reaction by adding 50 µL of the stop solution to each well. Read the absorbance immediately at 405 nm.

**Calculation**. Calculate the potency of the vaccine to be examined relative to *hepatitis A vaccine (inactivated, non-adsorbed) BRP*, using the usual statistical methods (*5.3*).

**Validity conditions**. The test is not valid unless:

- the statistical analysis shows a significant slope and no deviation from linearity and parallelism of the dose-response curves;
- the confidence limits ($P = 0.95$) are not less than 80 per cent and not more than 125 per cent of the estimated potency.

METHOD B. *IN VIVO* ASSAY

The test in mice shown below is given as an example of a method that has been found suitable for a given vaccine; other validated methods may also be used.

**Selection and distribution of the test animals**. Use in the test healthy mice from the same stock, about 5 weeks old and from a strain shown to be suitable. Use animals of the same sex. Distribute the animals in at least 7 equal groups of a number suitable for the requirements of the assay.

**Determination of potency of the vaccine to be examined**. Using a 9 g/L solution of *sodium chloride R* containing the aluminium adjuvant used for the vaccine, prepare at least 3 dilutions of the vaccine to be examined and matching dilutions of the reference preparation. Allocate the dilutions one to each of the groups of animals and inject subcutaneously not more than 1.0 mL of each dilution into each animal in the group to which that dilution is allocated. Maintain a group of unvaccinated controls, injected subcutaneously with the same volume of diluent. After 28-32 days, anaesthetise and bleed all animals, keeping the individual sera separate. Assay the individual sera for specific antibodies against hepatitis A virus by a suitable immunochemical method (*2.7.1*).

**Calculations**. Carry out the calculations by the usual statistical methods for an assay with a quantal response (*5.3*).

From the distribution of reaction levels measured on all the sera in the unvaccinated group, determine the maximum reaction level that can be expected to occur in an unvaccinated animal for that particular assay. Any response in vaccinated animals that exceeds this level is by definition a seroconversion.

Make a suitable transformation of the percentage of animals showing seroconversion in each group (for example, a probit transformation) and analyse the data according to a parallel-line log dose-response model. Determine the potency of the test preparation relative to the reference preparation.

**Validity conditions**. The test is not valid unless:

- for both the test and the reference vaccine, the $ED_{50}$ lies between the smallest and the largest doses given to the animals;
- the statistical analysis shows no significant deviation from linearity or parallelism;
- the confidence limits ($P = 0.95$) are not less than 33 per cent and not more than 300 per cent of the estimated potency.

**Potency requirement**. The upper confidence limit ($P = 0.95$) of the estimated relative potency is not less than 1.0.

*IN VIVO* ASSAY

**Selection and distribution of the test animals**. Use in the test healthy mice from the same stock, about 5 weeks old. The strain of mice used for this test must give a significant slope for the dose-response curve to the antigen; mice with haplotype H-$2^q$ or H-$2^d$ are suitable. Healthy guinea-pigs weighing 300 g to 350 g (about 7 weeks old) from the same stock are also suitable. Use animals of the same sex. Distribute the animals in at least 7 equal groups of a number appropriate to the requirements of the assay.

**Determination of potency of the vaccine to be examined**. Using a 9 g/L solution of *sodium chloride R* containing the aluminium adjuvant used for the vaccine or another appropriate diluent, prepare at least 3 dilutions of the vaccine to be examined and matching dilutions of the reference preparation. Allocate the dilutions, 1 to each of the groups of animals, and inject intraperitoneally not more than 1.0 mL of each dilution into each animal in the group to which that dilution is allocated. One group of animals remains unvaccinated and is injected intraperitoneally with the same volume of diluent. After an appropriate time interval (for example, 4-6 weeks), anaesthetise and bleed the animals, keeping the individual sera separate. Assay the individual sera for specific antibodies against HBsAg by a suitable immunochemical method (*2.7.1*).

**Calculations**. Calculations are carried out by the usual statistical methods for an assay with a quantal response (*5.3*).

From the distribution of reaction levels measured on all the sera in the unvaccinated group, the maximum reaction level that can be expected to occur in an unvaccinated animal for that particular assay is determined. Any response in vaccinated animals that exceeds this level is by definition a seroconversion.

Make a suitable transformation of the percentage of animals showing seroconversion in each group (for example, a probit transformation) and analyse the data according to a parallel-line log dose-response model. Determine the potency of the test preparation relative to the reference preparation.

**Validity conditions**. The test is not valid unless:

- for both the test and the reference vaccine, the $ED_{50}$ lies between the smallest and the largest doses given to the animals;
- the statistical analysis shows no significant deviation from linearity or parallelism;
- the confidence limits ($P = 0.95$) are not less than 33 per cent and not more than 300 per cent of the estimated potency.

**Potency requirement**. The upper confidence limit ($P = 0.95$) of the estimated relative potency is not less than 1.0.

*IN VITRO* ASSAY

Carry out an immunochemical determination (*2.7.1*) of antigen content with acceptance criteria validated against the *in vivo* test.

Enzyme-linked immunosorbent assay (ELISA) and radio-immunoassay (RIA) using monoclonal antibodies specific for protection-inducing epitopes of HBsAg have been shown to be suitable. Suitable numbers of dilutions of the vaccine to be examined and the reference preparation are used and a parallel-line model is used to analyse the data, which may be suitably transformed. Kits for measuring HBsAg *in vitro* are commercially available and it is possible to adapt their test procedures for use as an *in vitro* potency assay.

The acceptance criteria are approved for a given reference preparation by the competent authority in light of the validation data.

**01/2012:20715**

## 2.7.15. ASSAY OF HEPATITIS B VACCINE (rDNA)

The assay of hepatitis B vaccine (rDNA) is carried out either *in vivo*, by comparing in given conditions its capacity to induce specific antibodies against hepatitis B surface antigen (HBsAg) in mice or guinea-pigs with the same capacity of a reference preparation, or *in vitro*, by an immunochemical determination of the antigen content.

07/2019:20716

# 2.7.16. ASSAY OF PERTUSSIS VACCINE (ACELLULAR)

The assay of acellular pertussis vaccine measures the capacity of the vaccine to induce the formation of specific antibodies in mice or guinea-pigs. Antibody titres for each antigen are determined using a suitable immunochemical method (*2.7.1*) such as enzyme-linked immunosorbent assay (ELISA).

The assay results can be expressed:

- either as a ratio of the geometric mean titre (GMT) of antibodies produced following administration of the test vaccine to the GMT of antibodies produced following administration of a reference vaccine examined in parallel (relative potency assay);
- or directly as a GMT of antibodies induced by the test vaccine (geometric mean unit assay or GMU assay).

For combinations containing pertussis components together with diphtheria and tetanus components, the serological assay in guinea-pigs can be performed with the same group of animals used for the serological assay of diphtheria vaccine (adsorbed) (*2.7.6*) and of tetanus vaccine (adsorbed) (*2.7.8*) when the common immunisation conditions for all components (for example, doses, duration) have been demonstrated to be valid for the combined vaccine. The guinea-pig model allows for a further reduction in the number of animals required and must be considered by each analyst in accordance with the provisions of the European Convention for the Protection of Vertebrate Animals Used for Experimental and Other Scientific Purposes.

Methods A and B described below are developed by testing multiple dilutions of the test vaccine and the reference vaccine or internal control (see Glossary), to determine which dilutions are suitable. Once the suitable dilutions have been confirmed for a given vaccine, it is recommended, in accordance with 3R principles (Replacement, Reduction, Refinement), to apply a simplified model such as a single dilution for both the test vaccine and the reference vaccine or internal control. Such a model enables the analyst to determine whether the immunogenicity of the test vaccine is satisfactory.

Suitable indicators to monitor the performance of the serological assay (single or multiple dilutions) are:

- the geometric mean and geometric standard deviation of antibody titres in the serum samples obtained after administration of a fixed dose of the reference vaccine or internal control;
- the antibody titres of run controls (positive control and negative serum samples).

It may be necessary to reconfirm the suitability of the selected dilution with a multiple-dilution assay, e.g. after major process changes or for investigational purposes.

## METHOD A. SEROLOGY IN MICE

*The following test model is given as an example of a multiple-dilution assay which may form the basis for the establishment of a single-dilution assay.*

**Selection and distribution of the test animals**. Use healthy mice (for example, CD1 strain from the same stock and more than 5 weeks old). Distribute the animals into not fewer than 6 equal groups; use groups containing a number of animals sufficient to meet the pre-defined criteria for variability of the antibody responses prescribed under Calculations and validity criteria. Use serial dilutions of the test vaccine and the reference vaccine or internal control and allocate each dilution to a group of mice. During validation studies a further group of mice may be used as a negative control by injecting the animals with diluent alone.

**Immunisation**. Inject intraperitoneally or subcutaneously into each mouse 0.5 mL of the dilution allocated to its group.

**Collection of serum samples**. 4-5 weeks after vaccination, bleed the mice individually under anaesthesia. Store the sera at − 20 °C until used for antibody determination. Avoid frequent freezing and thawing of serum samples.

**Reference antiserum**. A reference antiserum of assigned activity serves as the basis for calculation of the antibody titres in the test sera. *Bordetella pertussis mouse antiserum BRP* is suitable for use as a reference antiserum.

**Antibody determination**. Assay the individual sera for content of specific antibodies against each acellular pertussis antigen using a validated method such as the ELISA test shown below.

**ELISA test**. Microtitre plates (poly(vinyl chloride) or polystyrene as appropriate for the specific antigen) are coated with the purified antigen at a concentration of 100 ng per well. After washing, unreacted sites are blocked by incubating the plates with a solution of bovine serum albumin and then washed. 2-fold dilutions of sera from individual mice immunised with the test vaccine or either the reference vaccine or the internal control are prepared on the plates. Reference antiserum is included on each plate. After incubation at 22-25 °C for 1 h, the plates are washed. A suitable solution of enzyme-conjugated anti-mouse IgG antibody is added to each well and incubated at 22-25 °C for 1 h. After washing, a chromogenic substrate is added from which the bound enzyme conjugate liberates a chromophore that can be quantified by measurement of absorbance (*2.2.25*).

## METHOD B. SEROLOGY IN GUINEA-PIGS

*The following test model is given as an example of a multiple-dilution assay which may form the basis for the establishment of a single-dilution assay.*

**Selection and distribution of the test animals**. Use healthy guinea-pigs from the same stock, each weighing 250-350 g. Use guinea-pigs of the same sex or with males and females equally distributed between the groups. Distribute the guinea-pigs into not fewer than 6 equal groups; use groups containing a number of animals sufficient to meet the pre-defined criteria for variability of the antibody responses prescribed under Calculations and validity criteria. During validation studies a further group of guinea-pigs may be used as a negative control by injecting the animals with diluent alone.

**Dilution of the test and reference preparations**. Using a 9 g/L solution of *sodium chloride R* as diluent, prepare serial dilutions of the test vaccine and the reference vaccine or internal control; series differing by 2.5- to 5-fold steps have been found to be suitable. Use not fewer than 3 dilutions within the range found to be suitable for all the components in the test vaccine. Use the dilutions for immunisation preferably within 1 h of preparation. Allocate 1 dilution to each group of guinea-pigs.

**Immunisation**. Inject subcutaneously into each guinea-pig 1.0 mL of the dilution allocated to its group.

**Collection of serum samples**. 5-6 weeks after immunisation, take a blood sample from each vaccinated and negative control guinea-pig using a suitable method. Store the sera at − 20 °C until used for antibody determination. Avoid frequent freezing and thawing of serum samples.

**Reference antiserum**. An in-house guinea-pig reference antiserum of assigned activity serves as the basis for calculation of the antibody titres in the test sera.

**Antibody determination**. Assay the individual sera for content of specific antibodies against each acellular pertussis antigen using a validated method such as the ELISA test shown below.

**ELISA test**. Suitable 96-well microtitre plates are coated with the purified antigens (e.g. pertussis toxin (PT), pertactin (PRN), filamentous haemagglutinin (FHA) and/or fimbrial agglutinogens (Fim 2/3)) representing components in the combined vaccine at a concentration of 200-400 ng per well. After washing, unreacted sites are blocked by incubating the plates with a suitable blocking buffer and then washed. 2-fold dilutions of sera from individual guinea-pigs immunised with the test vaccine or either the reference vaccine or the internal control are prepared on the plates. Reference antiserum is included on each plate. After incubation at 37 °C for 1 h, the plates are washed. A suitable solution of enzyme-conjugated anti-guinea-pig IgG antibody is added to each well and incubated at 37 °C for 1 h. After washing, a chromogenic substrate is added from which the bound enzyme conjugate liberates a chromophore that can be quantified by measurement of absorbance (*2.2.25*).

CALCULATIONS AND VALIDITY CRITERIA

**Relative potency assay**. The antibody titres in the sera of mice or guinea-pigs immunised with the test and reference vaccines are determined for each acellular pertussis antigen using the reference antiserum. From the values obtained, the GMT ratio of the test vaccine in relation to the reference vaccine is calculated for each antigen.

The relative potency assay is not valid unless:

- the number of responder animals for the test and reference vaccines meets the pre-defined criteria;
- the GMT for the reference vaccine is within the limits of the control chart;
- the variability of the antibody responses meets the pre-defined criteria.

**GMU assay**. The antibody titres in the sera of mice or guinea-pigs immunised with the internal control and test vaccine are determined for each acellular pertussis antigen using the reference antiserum, and the GMTs are calculated for each antigen.

The GMU assay is not valid unless:

- the number of responder animals for the test vaccine and internal control meets the pre-defined criteria;
- the GMT for the internal control is within the limits of the control chart;
- the variability of the antibody responses meets the pre-defined criteria.

GLOSSARY

**Internal control for GMU assay**. A batch of vaccine shown to be representative of the current manufacturing process and whose response in mice or guinea pigs has been appropriately measured. The stability of the internal control shall be monitored and documented.

**Reference vaccine for relative potency assay**. A batch of vaccine shown to be effective in clinical trials or a batch representative thereof. The stability of the reference vaccine shall be monitored and documented.

**Responder animals**. Immunised animals producing antibodies at a titre greater than a threshold defined during the development and validation of the method.

*The following section is published for information.*

## Assay of pertussis vaccine (acellular): guidelines

METHOD B. DETERMINATION OF ANTIBODIES IN GUINEA-PIGS

The ELISA shown below is given as an example of an immunochemical method that has been found to be suitable.

**Determination of antibody titre by ELISA method for pertussis toxin (PT), filamentous haemagglutinin (FHA), fimbrial agglutinogens (Fim 2/3) and pertactin (PRN)**. 2-fold dilutions of sera from test and reference vaccine or internal control are made on ELISA plates coated with acellular pertussis antigens (PRN, PT, FHA or Fim 2/3). A guinea-pig reference antiserum and a negative guinea-pig serum are included on each plate. Peroxidase-conjugated rabbit or goat antibody directed against guinea-pig IgG is added, followed by a peroxidase substrate.

**Reagents and equipment:**

- *ELISA plates*: 96 wells, columns 1-12, rows A-H.
- *Reference antiserum* (guinea-pig).
- *Peroxidase conjugate*. Peroxidase-conjugated rabbit or goat antibody directed against guinea-pig IgG.
- *Bordetella pertussis antigens* (PRN, PT, FHA or Fim 2/3).
- *Carbonate coating buffer pH 9.6*. Dissolve 1.59 g of *anhydrous sodium carbonate R* and 2.93 g of *sodium hydrogen carbonate R* in 1000 mL of *water R*. Distribute into 150 mL bottles and sterilise by autoclaving at 121 °C for 15 min.
- *Phosphate-buffered saline pH 7.4 (PBS)*. Dissolve with stirring 80.0 g of *sodium chloride R*, 2.0 g of *potassium dihydrogen phosphate R*, 14.3 g of *disodium hydrogen phosphate dihydrate R* and 2.0 g of *potassium chloride R* in 1000 mL of *water R*. Store at room temperature to prevent crystallisation. Dilute 10-fold with *water R* before use.
- *Citric acid solution*. Dissolve 10.51 g of *citric acid monohydrate R* in 1000 mL of *water R* and adjust to pH 4.0 with a 400 g/L solution of *sodium hydroxide R*.
- *Washing buffer*. PBS containing 0.5 g/L of *polysorbate 20 R*.
- *Diluent block buffer*. PBS containing 0.5 g/L of *polysorbate 20 R* and 25 g/L of dried skimmed milk.
- *Peroxidase substrate*. Shortly before use, dissolve 10 mg of *diammonium 2,2′-azinobis(3-ethylbenzothiazoline-6-sulfonate) R* (ABTS) in 20 mL of the citric acid solution. Immediately before use add 5 µL of *strong hydrogen peroxide solution R*.

**Method**. The description below is given as an example of a suitable plate layout but others may be used. Wells 1A-H are used for negative control serum. Wells 2-12 A-H are used for guinea-pig reference antiserum (usually in 2 positions) and individual sera from guinea-pigs immunised with the test vaccine, or either the reference vaccine or the internal control.

Coat each well of the ELISA plates with 100 µL of the appropriate antigen solution (PT, FHA and Fim 2/3 at 2 µg/mL and PRT at 4 µg/mL, in carbonate coating buffer pH 9.6). Allow to stand overnight at 4 °C in a humid atmosphere. To avoid temperature gradient effects, do not stack more than 4 plates high. On the following day, wash the plates thoroughly with the washing buffer. Block the plates by addition of 150 µL of the diluent block buffer to each well. Incubate in a humid atmosphere at 37 °C for 1 h. Wash the plates thoroughly with the washing buffer. Place 100 µL of the diluent block buffer in each well of the plates, except those of row A. Prepare suitable dilutions of individual test and reference vaccine or internal control serum samples, reference antiserum and negative control serum samples. Allocate the negative control serum to column 1, the reference antiserum to at least 2 other columns and individual test and reference vaccine or internal control

sera to the remaining columns and add 100 µL of each serum to the first 2 wells of the column to which it is allocated. Using a multichannel micropipette, make 2-fold serial dilutions from row B down the plate to row H, by transferring 100 µL from one well to the next. Discard 100 µL from the last row so that all wells contain 100 µL. Incubate at 37 °C for 2 h. Wash thoroughly with the washing buffer. Prepare a suitable dilution of the peroxidase conjugate in the diluent block buffer and add 100 µL to each well. Incubate at 37 °C in a humid atmosphere for 1 h. Wash the plates thoroughly with the washing buffer. Add 100 µL of the peroxidase substrate to each well. Allow to stand at room temperature, protected from light, for 30 min. Read the plates at 405 nm in the same order as the addition of substrate was made.

**01/2008:20717**

## 2.7.17. ASSAY OF HUMAN ANTITHROMBIN III

The antithrombin III content of the preparation to be examined is determined by comparing its ability to inactivate thrombin in the presence of an excess of heparin with the same ability of a reference preparation of human antithrombin III concentrate calibrated in International Units. Varying quantities of the preparation to be examined are mixed with a given quantity of thrombin and the remaining thrombin activity is determined using a suitable chromogenic substrate.

The International Unit is the activity of a stated amount of the International Standard for human antithrombin III concentrate. The equivalence in International Units of the International Standard is stated by the World Health Organization.

*Method.* Prepare 2 independent series of 3 or 4 dilutions in the range 1/75 to 1/200 from 1 IU/mL, for both the preparation to be examined and the reference preparation, using *tris-EDTA BSA buffer solution pH 8.4 R* containing 15 IU of heparin per millilitre.

Warm 200 µL of each dilution at 37 °C for 1-2 min. Add to each dilution 200 µL of a solution of *bovine thrombin R* containing 2 IU/mL in *tris-EDTA BSA buffer solution pH 8.4 R*. Mix and maintain at 37 °C for exactly 1 min. Add 500 µL of a suitable chromogenic substrate (for example, D-phenylalanyl-L-pipecolyl-L-arginine-4-nitroanilide, reconstituted in *water R* to give a solution containing 4 mmol/L and further diluted to a concentration suitable for the assay using *tris-EDTA BSA buffer solution pH 8.4 R* without albumin). Immediately start measurement of the change in absorbance at 405 nm (*2.2.25*), continuing the measurement for at least 30 s. Calculate the rate of change of absorbance ($\Delta A$/min). (Alternatively, an end-point assay may be used by stopping the reaction with acetic acid and measuring the absorbance at 405 nm.)

The rate of change of absorbance ($\Delta A$/min) is inversely proportional to antithrombin III activity.

Check the validity of the assay and calculate the potency of the test preparation by the usual statistical methods (*5.3*).

**07/2015:20718**

## 2.7.18. ASSAY OF HUMAN COAGULATION FACTOR II

Human coagulation factor II is assayed following specific activation to form factor IIa. Factor IIa is estimated by comparing its activity in cleaving a specific chromogenic peptide substrate with the same activity of the International Standard or of a reference preparation calibrated in International Units.

The International Unit is the factor II activity of a stated amount of the International Standard which consists of a freeze-dried concentrate of human blood coagulation factor II. The equivalence in International Units of the International Standard is stated by the World Health Organization.

The chromogenic assay method consists of 2 steps: snake venom-dependent activation of factor II, followed by enzymatic cleavage of a chromogenic factor IIa substrate to form a chromophore that can be quantified spectrophotometrically. Under appropriate assay conditions, there is a linear relation between factor IIa activity and the cleavage of the chromogenic substrate.

*REAGENTS*

*Viper venom specific factor II activator* (ecarin). A protein derived from the venom of the saw-scaled viper (*Echis carinatus*) which specifically activates factor II. Reconstitute according to the manufacturer's instructions. Store the reconstituted preparation at 4 °C and use within 1 month.

*Factor IIa chromogenic substrate.* Specific chromogenic substrate for factor IIa such as: *H*-D-phenylalanyl-L-pipecolyl-L-arginine-4-nitroanilide dihydrochloride, 4-toluenesulfonyl-glycyl-prolyl-L-arginine-4-nitroanilide, *H*-D-cyclohexylglycyl-α-aminobutyryl-L-arginine-4-nitroanilide, D-cyclohexylglycyl-L-alanyl-L-arginine-4-nitroanilide diacetate. Reconstitute according to the manufacturer's instructions.

*Dilution buffer.* Solution containing 6.06 g/L of *tris(hydroxymethyl)aminomethane R*, 17.53 g/L of *sodium chloride R* and 1 g/L of *bovine albumin R* or *human albumin R*. Adjust to pH 8.4 if necessary, using *hydrochloric acid R*.

*METHOD*

*Test solution.* Dilute the preparation to be examined with dilution buffer to obtain a solution containing 0.015 IU of factor II per millilitre. Prepare at least 3 further dilutions in dilution buffer.

*Reference solution.* Dilute the reference preparation to be examined with dilution buffer to obtain a solution containing 0.015 IU of factor II per millilitre. Prepare at least 3 further dilutions in dilution buffer.

Warm all solutions to 37 °C in a water-bath shortly before the test.

The following working conditions apply to microtitre plates. If the assay is carried out in tubes, the volumes are adjusted while maintaining the proportions in the mixture.

Using a microtitre plate maintained at 37 °C, add 25 µL of each dilution of the test solution or the reference solution to each of a series of wells. To each well add 125 µL of dilution buffer, then 25 µL of ecarin and incubate for exactly 2 min. To each well add 25 µL of factor IIa chromogenic substrate.

Read the rate of change of absorbance (*2.2.25*) at 405 nm continuously over a period of 3 min and obtain the mean rate of change of absorbance ($\Delta A$/min). If continuous monitoring is not possible, read the absorbance at 405 nm at suitable consecutive intervals, for instance 40 s, plot the absorbances against time on a linear graph and calculate $\Delta A$/min as the slope of the line. From the $\Delta A$/min values of each individual

dilution of standard and test preparations, calculate the potency of the preparation to be examined and check the validity of the assay by the usual statistical methods (*5.3*).

**01/2008:20719**

## 2.7.19. ASSAY OF HUMAN COAGULATION FACTOR X

Human coagulation factor X is assayed following specific activation to form factor Xa. Factor Xa is estimated by comparing its activity in cleaving a specific chromogenic peptide substrate with the same activity of the International Standard or of a reference preparation calibrated in International Units.

The International Unit is the factor X activity of a stated amount of the International Standard which consists of a freeze-dried concentrate of human coagulation factor X. The equivalence in International Units of the International Standard is stated by the World Health Organization.

The chromogenic assay method consists of 2 steps: snake venom-dependent activation of factor X, followed by enzymatic cleavage of a chromogenic factor Xa substrate to form a chromophore that can be quantified spectrophotometrically. Under appropriate assay conditions, there is a linear relation between factor Xa activity and the cleavage of the chromogenic substrate.

REAGENTS

*Russell's viper venom specific factor X activator* (RVV). A protein derived from the venom of Russell's viper (*Vipera russelli*) which specifically activates factor X. Reconstitute according to the manufacturer's instructions. Store the reconstituted preparation at 4 °C and use within 1 month.

*Factor Xa chromogenic substrate*. Specific chromogenic substrate for factor Xa such as: *N*-α-benzyloxycarbonyl-D-arginyl-L-glycyl-L-arginine-4-nitroanilide dihydrochloride, *N*-benzoyl-L-isoleucyl-L-glutamyl-glycyl-L-arginine-4-nitroanilide hydrochloride, methanesulfonyl-D-leucyl-glycyl-L-arginine-4-nitroanilide, methoxycarbonyl-D-cyclohexylalanyl-glycyl-L-arginine-4-nitroanilide acetate. Reconstitute according to the manufacturer's instructions.

*Dilution buffer*. Solution containing 3.7 g/L of *tris(hydroxymethyl)aminomethane R*, 18.0 g/L of *sodium chloride R*, 2.1 g/L of *imidazole R*, 0.02 g/L of *hexadimethrine bromide R* and 1 g/L of *bovine albumin R* or *human albumin R*. Adjust to pH 8.4 if necessary using *hydrochloric acid R*.

METHOD

*Test solution*. Dilute the preparation to be examined with dilution buffer to obtain a solution containing 0.18 IU of factor X per millilitre. Prepare at least 3 further dilutions in dilution buffer.

*Reference solution*. Dilute the reference preparation to be examined with dilution buffer to obtain a solution containing 0.18 IU of factor X per millilitre. Prepare at least 3 further dilutions in dilution buffer.

Warm all solutions to 37 °C in a water-bath shortly before the test.

The following working conditions apply to microtitre plates. If the assay is carried out in tubes, the volumes are adjusted while maintaining the proportions in the mixture.

Using a microtitre plate maintained at 37 °C, add 12.5 µL of each dilution of the test solution or the reference solution to each of a series of wells. To each well add 25 µL of RVV and incubate for exactly 90 s. To each well add 150 µL of factor Xa chromogenic substrate, diluted 1 in 6 in dilution buffer. Read the rate of change of absorbance (*2.2.25*) (at 405 nm continuously over a period of 3 min and obtain the mean rate of change of absorbance (Δ*A*/min). If continuous monitoring is not possible, read the absorbance at 405 nm at suitable consecutive intervals, for instance 40 s, plot the absorbances against time on a linear graph and calculate Δ*A*/min as the slope of the line. From the Δ*A*/min values of each individual dilution of standard and test preparations, calculate the potency of the preparation to be examined and check the validity of the assay by the usual statistical methods (*5.3*).

**01/2008:20720**

## 2.7.20. *IN VIVO* ASSAY OF POLIOMYELITIS VACCINE (INACTIVATED)

The capacity of the vaccine to induce the formation of neutralising antibodies is determined *in vivo* by one of the following methods.

TEST IN CHICKS OR GUINEA-PIGS

Prepare a suitable series of not fewer than 3 dilutions of the vaccine to be examined using a suitable buffered saline solution. Distribute either guinea-pigs weighing 250-350 g or 3-week-old chicks into groups of 10, and allocate a group to each dilution of the vaccine. Inject intramuscularly into each animal 0.5 mL of the dilution intended for its group. Bleed the animals after 5-6 days and separate the sera. Examine the sera for the presence of neutralising antibodies, at a dilution of 1 in 4, to each of the human poliovirus types 1, 2 and 3. Mix 100 $CCID_{50}$ of virus with the dilution of serum and incubate at 37 °C for 4.5-6 h. Keep at 5 ± 3 °C for 12-18 h where necessary for consistency of results. Inoculate the mixtures into cell cultures for the detection of unneutralised virus and read the results up to 7 days after inoculation. For each group of animals, note the number of sera that have neutralising antibodies and calculate the dilution of the vaccine that gives an antibody response in 50 per cent of the animals. Carry out in parallel a control test using a suitable reference preparation. The vaccine complies with the test if a dilution of 1 to 100 or more produces an antibody response for each of the 3 types of virus in 50 per cent of the animals.

TEST IN RATS

A suitable *in vivo* assay method consists of intramuscular injection into the hind limb(s) of not fewer than 3 dilutions of the vaccine to be examined and a reference vaccine, using for each dilution a group of 10 specific pathogen-free rats of a suitable strain. Use of 4 dilutions is often necessary to obtain valid results for all 3 serotypes. The number of animals per group must be sufficient to obtain results that meet the validity criteria; groups of 10 rats are usually sufficient, although valid results may be obtained with fewer animals per group. If animals of different sex are used, males and females are evenly distributed between all groups. A weight range of 175-250 g has been found to be suitable. An inoculum of 0.5 mL per rat is used. The dose range is chosen such that a dose response to all 3 poliovirus types is obtained. Bleed the animals after 20-22 days. Neutralising titres against all 3 poliovirus types are measured separately using 100 $CCID_{50}$ of the Sabin strains as challenge viruses, Vero or Hep2 as indicator cells, and neutralisation conditions of 3 h at 35-37 °C followed by 18 h at 2-8 °C where necessary for consistency of results. Results are read following fixation and staining after 7 days of incubation at 35 °C. For a valid antibody assay, the titre of each challenge virus must be shown to be within the range 10 $CCID_{50}$ to 1000 $CCID_{50}$ and the neutralising antibody titre of a control serum must be within 2 twofold dilutions of the

geometric mean titre of the serum. The potency is calculated by comparison of the proportion of responders for the vaccine to be examined and the reference vaccine by the probit method or, after validation, using a parallel-line model. For the probit method it is necessary to establish a cut-off neutralising antibody titre for each poliovirus type to define a responder. Due to interlaboratory variation, it is not possible to define cut-off values that could be applied by all laboratories. Rather, the cut-off values are determined for each laboratory based on a minimum series of 3 tests with the reference vaccine. The mid-point on a $\log_2$ scale of the minimum and maximum geometric mean titres of the series of 3 or more tests is used as the cut-off value. For each of the 3 poliovirus types, the potency of the vaccine is not significantly less than that of the reference preparation. The test is not valid unless:

- for both the vaccine to be examined and the reference vaccine, the $ED_{50}$ lies between the smallest and the largest doses given to the animals;
- the statistical analysis shows no significant deviation from linearity or parallelism;
- the confidence limits ($P = 0.95$) are not less than 25 per cent and not more than 400 per cent of the estimated potency.

*The following section is published for information.*

## Guideline on waiving of the *in vivo* assay of poliomyelitis vaccine (inactivated) and its combinations

*This guideline applies to vaccines derived from wild strains of poliovirus. The validation described should be carried out for each product before waiving of the in vivo assay, and should be repeated wherever there is a substantial change to the manufacturing process that may affect the in vitro or in vivo assays.*

The European convention on the protection of vertebrate animals used for experimental and other scientific purposes requires that tests in animals shall not be carried out if a scientifically satisfactory alternative is reasonably and practically available. The aim of this guideline is therefore to promote waiving of the *in vivo* assay wherever it can be shown for a given product that the *in vitro* assay (D-antigen determination) gives sufficient assurance of satisfactory potency for routine batch control.

For the *in vivo* assay, the test in rats is considered to be the method of choice. For vaccines that are assayed using chicks or guinea-pigs and that have an established record of production history, the *in vivo* assay may be waived if the rat assay is also applied to the batches included in the validation study described below. For vaccines not yet approved, the results of the rat assay on all final bulks should be included in all data generated for demonstration of consistency of production before waiving of the *in vivo* assay.

Once the *in vivo* assay has been waived, batches of vaccine will be released on the basis of the *in vitro* assay, and the *in vivo* assay should not be used as an alternative for the release of a batch that fails the *in vitro* assay. Repetition of the *in vitro* assay may be performed according to an authorised procedure.

PROCEDURE

The following conditions should be met before performance of the validation study:

- appropriate experience of the rat assay;
- full validation of the D-antigen assay (linearity, repeatability, intermediate precision, accuracy and limits of quantification);
- establishment of acceptance criteria for the D-antigen assay based on a suitable number of consecutive final lots;
- establishment of production consistency on recent final bulks using the currently approved *in vivo* assay; the final bulks should correspond to the final lots used to establish the acceptance criteria for the D-antigen assay and should represent different inactivated harvests of each of the 3 types of poliovirus.

The validation study should be performed on:

- a final bulk/lot that is representative of the current production method;
- 2 sub-potent batches prepared, for example, by heating normal vaccine or mixing it with heat-treated vaccine; the sub-potent batches should have expected titres of about half that of the representative final bulk/lot.

These batches are assayed using as reference standard a homologous production batch:

- by the currently approved *in vivo* assay for the vaccine;
- by the rat assay where this is not the currently approved *in vivo* assay;
- by the D-antigen assay.

Waiving of the *in vivo* assay is acceptable if the representative final bulk/lot complies with the *in vivo* and *in vitro* assays and the sub-potent batches fail to comply. If a sub-potent batch fails to comply with the D-antigen assay but complies with the *in vivo* assay, the latter may be repeated.

**01/2008:20721**

# 2.7.21. ASSAY OF HUMAN VON WILLEBRAND FACTOR

The biological functions of human von Willebrand factor are numerous. At present, its ristocetin cofactor activity and its collagen binding activity can be utilised for assays. The potency of human von Willebrand factor is determined by comparing, in given conditions, its activity with the same activity of a reference preparation calibrated against the International Standard, in International Units where applicable.

The International Unit is the activity of a stated amount of the International Standard, which consists of a freeze-dried human von Willebrand factor concentrate. The equivalence in International Units of the International Standard is stated by the World Health Organization (WHO).

RISTOCETIN COFACTOR ASSAY

The ristocetin cofactor activity of von Willebrand factor is determined by measuring agglutination of a suspension of platelets in the presence of ristocetin A. The assay can be carried out for quantitative determinations by using automated instruments, or for semi-quantitative determinations by visually assessing the endpoint of agglutination in a dilution series. Quantitative assays are preferred.

*REAGENTS*

*Suspension of platelets.* Use standardised and, for example, formaldehyde- or paraformaldehyde-fixed preparations of freshly isolated and washed human platelets. The suspension may also be freeze-dried. An appropriate amount of ristocetin A is added if necessary. Some platelet reagents may already contain ristocetin A.

*Reference preparation.* The reference preparation for von Willebrand factor is the WHO International Standard for von Willebrand factor concentrate.

*METHOD*

*Semi-quantitative assay.* Prepare suitable dilutions of the preparation to be examined and of the reference preparation, using as diluent a solution containing 9 g/L of *sodium chloride R* and 10-50 g/L of *human albumin R*. Add to each

dilution an appropriate amount of the suspension of platelets and, if necessary, of ristocetin A. Mix on a glass slide by moving it gently in circles for 1 min. Allow to stand for a further 1 min and read the result against a dark background with side lighting. The last dilution which clearly shows visible agglutination indicates the ristocetin cofactor titre of the sample. Use diluent as a negative control.

*Quantitative Assay*. Reconstitute the entire contents of 1 ampoule of the reference preparation and the preparation to be examined by adding the appropriate quantity of the recommended diluent (for example *water R*); use immediately. Add sufficient prediluent to the reconstituted preparations to produce solutions containing 0.5-2.0 IU/mL. The prediluent consists of an isotonic non-chelating buffer containing, for example, 1-5 per cent of human or bovine albumin, and tris(hydroxymethyl)aminomethane or imidazole, appropriately buffered.

The test is performed in accordance with the manufacturer's instructions with at least 2 dilution series with as many dilutions as are needed to obtain a total of at least 3 different concentrations in the linear range of the assay.

Check the validity of the assay and calculate the potency of the test preparation using the usual statistical methods (for example, *5.3*).

COLLAGEN-BINDING ASSAY

Collagen-binding is determined by an enzyme-linked immunosorbent assay on collagen-coated microtitre plates. The method is based on the specific binding of von Willebrand factor to collagen fibrils and the subsequent binding of polyclonal anti-von Willebrand factor antibody conjugated to an enzyme, which on addition of a chromogenic substrate yields a product that can be quantitated spectrophotometrically. Under appropriate conditions, there is a linear relationship between von Willebrand factor collagen-binding and absorbance.

*REAGENTS*

*Collagen*. Use native equine or human fibrils of collagen type I or III. For ease of handling, collagen solutions may be used.

*Collagen diluent*. Dissolve 50 g of *glucose R* in *water R*, adjust to pH 2.7-2.9 with *1 M hydrochloric acid* and dilute to 1000 mL with *water R*.

*Phosphate-buffered saline (PBS)*. Dissolve 8.0 g of *sodium chloride R*, 1.05 g of *disodium hydrogen phosphate dihydrate R*, 0.2 g of *sodium dihydrogen phosphate R* and 0.2 g of *potassium chloride R* in *water R*. Adjust to pH 7.2 using *1 M sodium hydroxide* or *1 M hydrochloric acid* and dilute to 1000 mL with *water R*.

*Washing buffer*. PBS containing 1 g/L of *polysorbate 20 R*.

*Blocking reagent*. PBS containing 1 g/L of *polysorbate 20 R* and 10 g/L of *bovine albumin R*.

*Dilution buffer*. PBS containing 1 g/L of *polysorbate 20 R* and 50 g/L of *bovine albumin R*.

*Conjugate*. Rabbit anti-human von Willebrand factor serum horseradish peroxidase conjugate. Use according to the manufacturer's instructions.

*Substrate solution*. Immediately before use, dissolve a tablet of *o*-phenylenediamine dihydrochloride and a tablet of urea hydrogen peroxide in 20 mL of *water R* or use a suitable volume of hydrogen peroxide. Protect from light.

*Microtitre plates*. Flat-bottomed polystyrene plates with surface properties optimised for enzyme immunoassay and high protein-binding capacity.

*METHOD*

*Test solutions*. Reconstitute the preparation to be examined as stated on the label. Dilute with dilution buffer to produce a solution containing approximately 1 IU of von Willebrand factor. Prepare 2 series of at least 3 further dilutions using dilution buffer.

*Reference solutions*. Reconstitute the reference preparation as directed. Dilute with dilution buffer to produce a solution containing approximately 1 IU of von Willebrand factor. Prepare 2 series of at least 3 further dilutions using dilution buffer.

Allow the solution of collagen to warm to room temperature. Dilute with collagen diluent to obtain a solution containing 30-75 µg/mL of collagen, mix gently to produce a uniform suspension of collagen fibrils. Pipette 100 µL into each well of the microtitre plate. Cover the plate with plastic film and incubate at 37 °C overnight. Empty the wells of the collagen-coated plate by inverting and draining on a paper towel. Add 250 µL of washing buffer. Empty the wells of the plate by inverting and draining on a paper towel. Repeat this operation 3 times. Add 250 µL of blocking reagent to each well, cover the plate with plastic film and incubate at 37 °C for 1 h. Empty the wells of the plate by inverting and draining on a paper towel. Add 250 µL of washing buffer. Empty the wells of the plate by inverting and draining on a paper towel. Repeat this operation 3 times.

Add 100 µL each of the test solutions or reference solutions to the wells. Add 100 µL of dilution buffer to a series of wells to serve as negative control. Cover the plate with plastic film and incubate at 37 °C for 2 h. Empty the wells of the plate by inverting and draining on a paper towel. Add 250 µL of washing buffer. Empty the wells of the plate by inverting and draining on a paper towel. Repeat this operation 3 times.

Prepare a suitable dilution of the conjugate (for example, a dilution factor of 1 to 4000) with PBS containing 5 g/L of *bovine albumin R* and add 100 µL to each well. Cover the plate with plastic film and incubate at 37 °C for 2 h. Empty the wells of the plate by inverting and draining on a paper towel. Add 250 µL of washing buffer. Empty the wells of the plate by inverting and draining on a paper towel. Repeat this operation 3 times.

Add 100 µL of substrate solution to each of the wells and incubate at room temperature for 20 min in the dark. Add 100 µL of *1 M hydrochloric acid* to each of the wells.

Measure the absorbance at 492 nm. Use the absorbance values to estimate the potency of the preparation to be examined using the usual statistical methods (*5.3*).

The assay is invalid if the absorbances measured for the negative controls are greater than 0.05.

**07/2014:20722**

## 2.7.22. ASSAY OF HUMAN COAGULATION FACTOR XI

The principle of the assay is to measure the ability of a factor XI preparation to reduce the prolonged coagulation time of factor XI-deficient plasma. The reaction is accelerated by addition of a reagent containing phospholipid and a contact activator, e.g. kaolin, silica or ellagic acid. The potency is assessed by comparing the dose-response curve of the preparation to be examined to that of a reference plasma calibrated against the International Standard for blood coagulation factor XI in plasma.

Reconstitute separately the preparation to be examined and the reference preparation as stated on the label and use immediately. *Coagulation factors V, VIII, XI and XIII plasma BRP* is suitable for use as a reference preparation. Where applicable, determine the amount of heparin present (*2.7.12*) and neutralise the heparin, for example by addition of *protamine sulfate R* (10 µg of protamine sulfate neutralises 1 IU of heparin). Predilute the preparation to be examined and the reference preparation in factor XI-deficient plasma (for example *plasma substrate R3*) to produce solutions

containing 0.5-2.0 units/mL. Prepare at least 3 appropriate dilutions for each material, preferably in duplicate, using a suitable buffer solution (for example *imidazole buffer solution pH 7.3 R*) containing 10 g/L of bovine or human albumin. Use these dilutions immediately.

Use an apparatus suitable for measurement of coagulation times or perform the assay with incubation tubes maintained in a water bath at 37 °C. Place in each tube 0.1 mL of factor XI-deficient plasma (for example *plasma substrate R3*) and 0.1 mL of one of the dilutions of the reference preparation or of the preparation to be examined. Add to each tube 0.1 mL of a suitable Activated Partial Thromboplastin Time (APTT) reagent containing phospholipid and contact activator and incubate the mixture for a recommended time at 37 °C. To each tube, add 0.1 mL of a 3.7 g/L solution of *calcium chloride R* previously heated to 37 °C. Using a timer, measure the coagulation time, i.e. the interval between the moment of the addition of the calcium chloride and the first indication of the formation of fibrin. The volumes given above may be adapted to the APTT reagent and apparatus used. Calculate the potency using the usual statistical methods (for example, *5.3*).

**01/2020:20723**

# 2.7.23. NUMERATION OF CD34/CD45+ CELLS IN HAEMATOPOIETIC PRODUCTS

This chapter describes immunolabelling and analysis by flow cytometry (*2.7.24*) to determine the number of CD34/CD45+ cells contained in haematopoietic products. The determination is carried out by a single platform method using calibrated fluorospheres, after lysis of the sample red blood cells if necessary.

This method applies to all types of preparations and whole blood. However, the characteristics of this method make it particularly suitable for preparations containing very low percentages of CD34/CD45+ cells.

**Graft quality assessment by CD34/CD45+ cell enumeration**

A variety of studies have established that the 1-3 per cent of cells in the bone marrow that express the CD34 cell surface antigen are capable of reconstituting long-term, multilineage haematopoiesis after myeloablative therapy. CD34/CD45+ cells are also found in the peripheral circulation of normal individuals but are extremely rare (0.01-0.1 per cent). However, CD34/CD45+ cells may also be mobilised from marrow to the peripheral circulation in greater numbers by haematopoietic cytokines such as granulocyte colony-stimulating factor and/or chemotherapy.

The technique used for enumeration of CD34/CD45+ cells must meet the following requirements:

- high sensitivity, since haematopoietic stem cells are rare events;
- accuracy, to provide clinically relevant results;
- reproducibility, to provide clinically reliable results;
- speed, to provide real-time analysis.

**Selection of parameters**

The flow cytometry assay uses commercially available, directly conjugated fluorochrome-labelled monoclonal antibodies, routine staining and whole blood lysing procedures, and a gating strategy using light scatter and immunofluorescence analysis using a pan-CD45/CD34 monoclonal antibody combination.

It is possible to determine CD34/CD45+ cell viability by appropriate nucleic acid staining with a stain that does not cross the intact cell membrane (for example, with 7-aminoactinomycin D).

**Selection of monoclonal antibodies**

*CD34 antibodies.* Use class III CD34 antibodies that detect all glycosylation variants of the molecule (for example, clone 8G12 or 581). To detect rare events, use an antibody conjugated to the brightest fluorochrome excitable using an argon laser-based flow cytometer, for example phycoerythrin (PE).

*CD45 antibodies.* Pan-CD45 antibodies that detect all isoforms and all glycoforms of this structure are required. A CD45 antibody conjugated to fluorescein isothiocyanate (FITC) fluorochrome is generally used (for example, J33, HLe1, 2D1).

*Isotypic or isoclonic controls.* A negative control is analysed to detect any non-specific signal in the PE fluorescence region. If using an isotypic control (a monoclonal antibody to an irrelevant antigen of the same isotype as the CD34 antibody employed), the PE-conjugated isotype is combined with CD45-FITC (or PerCP). If using an isoclonic control, the unconjugated (in excess) and PE-conjugated CD34 identical monoclonal antibody is combined with conjugated CD45. Alternative combinations may be used.

**Absolute count of CD34/CD45+**

*Calibrated fluorospheres.* Depending on the technique used, the internal standard either consists of calibrated beads in suspension or is directly introduced into the associated tubes by the manufacturer.

The absolute count of the CD34/CD45+ cells per microlitre is calculated using the following expression:

$$\frac{A}{B} \times C$$

$A$ = number of CD34/CD45+ cells counted;

$B$ = number of fluorosphere singlets counted;

$C$ = known fluorosphere concentration.

**Gating strategies**

The purpose of sequential gating is to select the population of interest and simultaneously minimise interference from debris and mature cells to which antibodies can bind non-specifically. If using a commercial kit, apply the gating recommended by the manufacturer. If using an in-house assay, it is preferable to apply a currently recommended strategy. A gating strategy that uses light scattering parameters and CD34/CD45 fluorescence will aid in the accurate identification and enumeration of CD34/CD45+ cells.

**Number of events analysed**

A sufficient number of events are analysed to maintain acceptable accuracy and precision, for example not fewer than 100 CD34+ events and not fewer than 60 000 CD45+ events; the total number of cells counted may be greater if the percentage of CD34 is 0.1 per cent or less.

**Specimen collection**

Acid citrate dextrose (ACD) formula A is the anticoagulant used in apheresis procedures. This anticoagulant allows both an automated leucocyte count and flow cytometry evaluation to be performed on the same specimen. Edetic acid (EDTA) is the anticoagulant of choice for peripheral blood sampling.

**Specimen transport**

Transport conditions guarantee the physical and thermal safety of samples.

**Specimen integrity and storage**

Fresh (less than 24 h old) apheresis products, whole blood samples, umbilical cord blood specimens or bone marrow samples can be processed. Old specimens (more than 24 h old) and specimens that have been frozen and thawed are

stained with a viability dye. On receipt, the temperature within the package is verified.

TECHNIQUE

**Sample preparation**

Ensure that the concentration of leucocytes is suitable prior to staining with monoclonal antibodies. If necessary, dilute the sample with medium that is compatible with the product to be tested and the lysing system. Record the dilution factor. It is recommended to perform the test with a negative control.

**Flow cytometry analysis**

*Autostandardisation*

For analysis of cells labelled with a commercially available kit, manufacturers have developed some quality tools for setting the flow cytometer. These settings are then automatically transferred on protocol analysis of samples. Specific fluorospheres are used to set the photomultiplier tube (PMT) on target values, compensation is set and the system is checked using a control preparation.

*System settings*

- *Discriminator/threshold*: the forward angle light scatter threshold is set to exclude debris (low forward scatter) but not small lymphocytes from the light-scatter plot.
- *PMT high voltage settings*: these must be consistent with cell-surface marker analysis and established within each laboratory so that negative and positive cell populations of moderate antigen density can be distinguished; PMT voltages are reviewed and adjusted periodically according to standardised laboratory procedures.
- *Compensation*: this must be acceptable for the colour spectra overlap (for example, FITC/PE) encountered in cell-surface marker analysis; colour compensation is analysed and adjusted according to standardised laboratory procedures.
- *Flow rate*: this must be consistent with routine cell-surface marker analysis.
- *Gating regions*: the gating regions established for the CD34/CD45 samples are maintained unaltered for the analysis of the negative region.

**Calculation of absolute number of CD34/CD45+ cells**

The absolute number of CD34/CD45+ cells is calculated using the following expression:

$$n \times D \times V$$

$n$ = total number of CD34/CD45+ cells per microlitre;

$D$ = dilution factor;

$V$ = volume of the product to be tested, in microlitres.

Results are reported as both the percentage of CD34/CD45+ cells and the absolute number per microlitre. They may also be reported as the absolute number per kilogram of recipient body mass, where this is possible.

**01/2008:20724**

# 2.7.24. FLOW CYTOMETRY

Flow cytometry consists of a multiparametric analysis of optical properties of individual particles in a fluidic system.

Cells or particles in suspension are individually distributed into a linear array (stream), which flows through a detection device. Solid tissues have to be reduced to a single-cell suspension to be analysed.

The spectrum of parameters measurable by flow cytometry includes volume and morphological complexity of cells or cell-like structures, cell pigments, DNA content, RNA content, proteins, cell surface markers, intracellular markers, enzymatic activity, pH, membrane and fluidity.

It is possible to collect 2 morphological parameters plus 1 or more fluorescence signals per single cell. The multiparametric analysis allows the definition of cell populations by their phenotype.

APPARATUS

Focusing, magnifying, and choice of light source are optimised to allow the automatic detection and measurement of morphological differences and staining patterns. Flow cytofluorimetric analysis meets the following criteria:

- choice of light source depending on the parameters to be analysed;
- adjustment of instrument settings depending on the cell type to be analysed (for example, cell cultures, leucocytes, platelets, bacteria, spermatozoa, yeast) and the analysis to be performed (for example, phenotyping, cell cycle, apoptosis, cytokines, membrane fluidity, fluorescent protein).

Flow cytometry is characterised by the automated quantification of set parameters for a high number of single cells during each analysis session. For example, 100 000 particles or more (practically unlimited) are analysed one after the other, typically in about 1 min. The detection limit is as low as 100 fluorescent molecules per cell.

A flow cytometer apparatus has 5 main components:

- a fluidic system and a flow cell;
- a light source;
- a detection and Analogue to Digital Conversion (ADC) system;
- an amplification system;
- a computer provided with software for analysis of the signals.

*FLUIDIC SYSTEM AND FLOW CELL*

The single cell is exposed to the light source and detected in the flow cell. The fluidic system carries the suspended cells individually from the sample tube to the laser intercept point. To achieve this, the sample stream is drawn out to a very thin fluid thread by a sheath fluid in the flow cell (hydrodynamic focusing). The light beam is focused in an elliptical shape, by 2 confocal lenses, into the flow cell channel through which the cells pass. The flow rate must be constant during routine cell surface marker analysis and must ensure a suitable distance between the cells to allow counting.

*LIGHT SOURCES*

Commonly used light sources are:

- lamps (mercury, xenon);
- high power water-cooled lasers (argon, krypton, dye laser);
- low power air-cooled lasers (argon (488 nm), red helium-neon (633 nm), green helium-neon, helium-cadmium (UV));
- diode lasers (blue, green, red, violet).

*SIGNAL DETECTION*

When a particle passes across the light beam, it scatters some of the light in all directions. Fluorescent dyes, when added to the particle, give off their own light (fluorescence), which is also radiated in all directions. 2 types of signals may thereby be generated:

- scatter of light;
- fluorescence emission.

The instrument's light detectors collect some of this scattered and fluorescent light and produce electronic signals proportional to the amount of light collected.

**Scatter**. 2 parameters of light scattering are measured:
- the amount scattered mainly forward (forward scatter (FS))
- the amount scattered at 90° from the direction of the light beam (side scatter (SS)).

Forward scatter correlates with the cell volume while side scatter is influenced by parameters such as the shape of the nucleus, the amount and type of cytoplasmic granules or the membrane roughness, and correlates with the morphological complexity of the cell, so that the higher the SS intensity, the higher the cell complexity. As a function of the morphological characteristics of cells, scatter signals will always be generated during a flow analysis; they are defined as intrinsic parameters.

**Fluorescence**. Depending on the type and number of light sources, when a cell passes through the sensing area, it will emit fluorescent light. Fluorescence signals are generated from fluorescent dyes naturally present in the cells (for example, co-enzymes, chlorophyll, seaweed pigments) and/or from fluorescent probes taken up by the cells when stained for the analysis of specific characteristics (for example, fluorescent antibodies, nucleic acid dyes, pH probes, calcium probes, fluorescent proteins). Nowadays, there is a large number and a wide range of different types of fluorescent probes available. The optical filters must be adapted to the fluorochromes used and changed if necessary. Each fluorescent probe is characterised by its excitation spectrum and its emission spectrum. They are chosen depending on the nature of the excitation source and the detection system, and according to the specific purpose of the analysis.

*SIGNAL MANAGEMENT AND ANALOGUE TO DIGITAL CONVERSION*

Scatter and fluorescence signals emitted by cells when passing across the laser beam are sorted and addressed to their detectors using optical filters. The detectors are transducers (photomultiplier tubes (PMTs)) that convert light signals radiated from the cells into voltage pulses.

The process of counting each pulse in the appropriate channel is known as Analogue to Digital Conversion (ADC). The process is finally shown as a frequency histogram.

**Amplification**. Voltage pulses need to be amplified for optimal visualisation. The amplification process accentuates the differences between cell signals, and consequently increases the resolution among cell populations of different characteristics (for example, the differentiation of viable from non-viable cells, or non-specific fluorescence from antigen-specific fluorescence after staining with a fluorescent monoclonal antibody).

There are 2 methods of amplification: linear or logarithmic; the choice between the 2 types is made for every single signal according to the morphological characteristics of the cells and the staining reagents used (for example, fluorescent monoclonal antibodies, nucleic acid dyes).

*Linear amplification*, which enhances the differences among strong pulses, is used with those parameters that generate high intensity signals, for example:
- cell scatters;
- fluorescence from nucleic acid dyes for cell cycle studies.

*Logarithmic amplification*, in contrast, is for weak pulses and parameters or analysis conditions that may generate both weak and strong pulses, for example:
- cell antigens;
- scatter from platelets, bacteria, yeast;
- fluorescence from nucleic acid dyes for apoptosis studies.

**Compensation of fluorescence signals**. Each fluorescent dye has an absorption wavelength spectrum and a higher emission wavelength spectrum. When using 2 or more fluorescent probes simultaneously for staining cells (for example, 4-antigen immunophenotyping), the fluorochromes emission spectra may overlap. As a consequence, each fluorescence detector will sense its own specific fluorescent light and a variable quantity of light emitted by the other fluorescent probes. This results in signal over-evaluation and poor separation of the cell populations.

The solution is in the use of an electronic matrix that allows the selective subtraction of the interfering signals from each fluorescence signal after detector sensing (fluorescence compensation).

Fluorescence compensation requires the use of fluorescence calibrators, preferably positive cell samples stained with the fluorochromes of interest, combined in a manner equivalent to that for the antibody used for the analysis.

*SIGNAL PLOTTING AND DISPLAY*

After amplification and compensation, the signals are plotted in 2 or 3 dimensions. Histograms show the signal intensities versus the cell counts for a given parameter. Cytograms, in which each dot represents a cell, result from the combination of 2 signal intensities (dual-parameter dot plots). The type and number of plots and signal combinations are chosen on the basis of the specimens and dyes used. When analysing acquired data, the flow cytometry software can also generate other kinds of graphs (such as overlays, surface plots, tomograms, contour plots, density plots, overlay plots). Statistical data such as mean fluorescent intensities (and their shifts in time or their dependence on cell function) can also be used.

*DATA ANALYSIS*

Different kinds of cell populations may be present inside the cell suspensions to be analysed, some of which are unwanted (such as dead cells, debris or macro-aggregates), or simply not relevant for the analysis (for example, granulocytes when studying lymphocytes). This depends on the cell sample type (whole blood, bone marrow, cell cultures, biological fluids, cell suspensions from solid tissues) and on the handling procedures (for example, staining methods, lysis, fixation, cryopreservation, thawing, paraffin-embedded tissue preparation).

As a consequence, not all the signals generated during a flow cytometry analysis belong to the cells to be studied. 2 strategies are adopted to exclude unwanted and irrelevant cell signals.

The 1st is used during data acquisition. It is a noise threshold, applied to 1 (or more) significant parameter(s), set to acquire only the cells with signal intensities higher than the pre-defined discrimination value for that parameter. Due to its characteristics of a strong signal with a low grade of interference, forward scatter is the parameter most often used as discriminator.

The 2nd, applied during data analysis, consists of the use of gating regions to restrict the analysis only to signals from those populations that satisfy given morphological and expression profile characteristics. 2 types of logical gating are commonly used. The 1st is the morphological gate. The cell populations are identified using their morphological signals (FS and SS). A region gate is drawn around the population of interest (for example, lymphocytes, viable cells) then the fluorescence plots are gated into the selected region. The 2nd is the fluorescence-based gate. The cell population of interest is identified on the basis of the expression intensity of an antigen or a dye, then a gate region is drawn around it. Afterwards the fluorescence plots are gated into the selected region.

The analysis software allows the creation of multiple gate regions, using a sequential logic order. This feature is especially useful when studying rare cell populations or for sorting purposes.

*CONTROLS*

**Internal control**. The system's optical alignment must be validated before analysis using adapted fluorospheres and the optimum fluidic stability is checked. The data obtained are reported and allow the periodical review of control values against the mean performance value. A positive control is highly desirable to prove that the test antibody is functional

and to allow the proper setting of the flow cytometer. The positive control must include samples known to be positive for the marker of interest.

**External control**. To ensure reliability in the data obtained or to check inter-laboratory reproducibility, participation in a proficiency testing study is recommended.

## 2.7.25. ASSAY OF HUMAN PLASMIN INHIBITOR

Human plasmin inhibitor, also called human $\alpha_2$-antiplasmin, is a plasma protein that inhibits the plasmin (a serine protease) pathway of fibrinolysis by rapidly forming a complex with free plasmin. Furthermore, upon blood coagulation, human plasmin inhibitor is cross-linked to fibrin strands by factor XIII, and interferes with binding of the proenzyme plasminogen to fibrin.

The potency of human plasmin inhibitor is estimated by comparing the ability of the preparation to be examined to inhibit the cleavage of a specific chromogenic substrate by plasmin with the same ability of a reference standard of human plasmin inhibitor. Plasmin cleavage of the chromogenic substrate yields a chromophore that can be quantified spectrophotometrically.

The individual reagents for the assay may be obtained separately or in commercial kits. Both end-point and kinetic methods are available. Procedures and reagents may vary between different kits and the manufacturer's instructions are followed. The essential features of the procedure are described in the following example of a microtitre-plate kinetic method.

REAGENTS

*Dilution buffer pH 7.5*. According to the manufacturer's instructions, a suitable buffer is used. Adjust the pH if necessary.

*Plasmin*. A preparation of human plasmin that does not contain significant amounts of other proteases is preferably used. Reconstitute and store according to the manufacturer's instructions.

*Plasmin chromogenic substrate*. A suitable specific chromogenic substrate for plasmin is used: H-D-cyclohexylalanyl-norvalyl-lysyl-*p*-nitroaniline hydrochloride (H-D-CHA-Nva-Lys-*p*NA.HCl) or L-pyroglutamyl-L-phenylalanyl-L-lysyl-*p*-nitroaniline hydrochloride (Glp-Phe-Lys-*p*NA.HCl). Reconstitute in *water R* to give a suitable concentration according to the manufacturer's instructions.

METHOD

Varying quantities of the preparation to be examined are mixed with a given quantity of plasmin and the remaining plasmin activity is determined using a suitable chromogenic substrate.

Reconstitute or thaw the preparation to be examined according to the manufacturer's instructions. Dilute with dilution buffer pH 7.5 and prepare at least 2 independent series of 3 or 4 dilutions for both the preparation to be examined and the reference standard.

Mix 0.020 mL of each dilution with 0.020 mL of dilution buffer pH 7.5 and warm to 37 °C. Add 0.040 mL of a plasmin solution (test concentration in the range of 0.2 nkat/mL to 1.6 nkat/mL) previously heated to 37 °C and leave at 37 °C for 1 min. Add 0.020 mL of the chromogenic substrate solution, previously heated to 37 °C, to each mixture. Immediately start measurement of the change in absorbance at 405 nm (*2.2.25*) using a microtitre plate reader. Calculate the rate of change of absorbance (ΔA/min). Alternatively, an end-point assay might be used by stopping the reaction with acetic acid and measuring the absorbance at 405 nm.

In both cases the duration of the cleavage of the chromogenic substrate should be chosen to produce a linear increase in absorbance at 405 nm, before substrate depletion becomes significant. If the assay is performed in test tubes or cuvettes using a spectrophotometric method, the volumes of reagent solutions are changed proportionally.

Substract the optical density of the blank (prepared with dilution buffer pH 7.5) from the optical density of the preparation to be examined. Check the validity of the assay and calculate the potency of the preparation to be examined by the usual statistical methods (*5.3*).

## 2.7.27. FLOCCULATION VALUE (Lf) OF DIPHTHERIA AND TETANUS TOXINS AND TOXOIDS (RAMON ASSAY)

The content of toxin or toxoid in a sample can be expressed as a flocculation value (Lf) using the Ramon assay. In this assay, antitoxin is added in increasing concentrations to a series of tubes containing a constant amount of toxin or toxoid. At the equivalence point of toxin/toxoid and antitoxin, flocculation occurs in 1 or more tubes. The first tube in which flocculation occurs is used to determine the Lf value of the sample.

The Lf value of a toxin or toxoid is determined by the number of units of antitoxin that, when mixed with the sample, produces an optimally flocculating mixture (Ramon assay).

Practical experience has shown that the results of the calibration of antitoxins in International Units (IU), for example by comparison to international antitoxin standards, depends on the immunochemical method used. For this reason, antitoxins used for the Ramon assay must be directly calibrated against the *international biological reference reagents for diphtheria or tetanus toxoid for flocculation tests*, using the principles described below. The concentration thus determined may be indicated in Lf-equivalents per millilitre (Lf-eq./mL).

By definition, 1 Lf is the quantity of toxin or toxoid that flocculates in the shortest time with 1 Lf-eq. of specific antitoxin.

A range of volumes of the reference standard of antitoxin adjusted to a concentration of 100 Lf-eq./mL is dispensed into a series of, for example, 7 cm × 1 cm flocculation tubes. A sufficient quantity of a 9 g/L solution of *sodium chloride R* is added to each tube to give a constant total volume of, for example, 1 mL. The test sample is diluted to give an expected concentration of approximately 50 Lf/mL, and, for example, 1 mL aliquots of this dilution are dispensed into each of the tubes containing antitoxin. The tubes are properly mixed by shaking, then placed in a water-bath at a constant temperature between 30 °C and 52 °C, and observed at regular intervals for the first appearance of floccules. This may require the use of a magnifying lens and strong illumination.

The first and the second mixtures to flocculate are recorded as well as the time taken for the first flocculation to appear. 2 tubes may flocculate simultaneously.

The first tube to flocculate is the one that contains the amount of antitoxin closest in equivalence to the amount of antigen in the sample. The antitoxin content of this tube can be used to calculate the Lf value of the sample. If 2 tubes flocculate at the same time, the mean from the tubes are given as the result.

The time taken for the first tube to flocculate (Kf) is a useful indicator of the quality of the antigen. If at a given temperature and concentration of toxoid and antitoxin the Kf value is increased compared with normal, this indicates that the antigen has been damaged. The Kf value may also change with the quality of the antitoxin used.

*Example*

| Tube | A | B | C | D | E | F |
|---|---|---|---|---|---|---|
| Antitoxin added (Lf-eq.) | 40 | 45 | 50 | 55 | 60 | 65 |
| Antitoxin added (mL) | 0.40 | 0.45 | 0.50 | 0.55 | 0.60 | 0.65 |
| Saline added (mL) | 0.60 | 0.55 | 0.50 | 0.45 | 0.40 | 0.35 |
| Diluted sample added | 1.0 | 1.0 | 1.0 | 1.0 | 1.0 | 1.0 |

If in this example the first tube to flocculate is tube C then the Lf value of the diluted sample is 50 Lf/mL. However, if the first tube to flocculate is tube A or tube F this does not indicate equivalence at that level. It would be necessary to perform a repeat test using either a different dilution of test sample or selecting a different range of doses of reference antitoxin.

More precision can be obtained by making allowance for the sequence of flocculation after the first tube. Thus, in the example quoted, if the second tube to flocculate had been tube D, the final value for the diluted sample would be 52, whereas if the second tube to flocculate was tube B, the final value would be 48. The test may be performed in duplicate with slightly different dilutions of the test sample.

If there is no indication of the expected Lf value of the sample available, it is advisable to obtain a rough estimate by use of a wider range of antitoxin content in the tubes before proceeding to the final test.

*Example*

| Tube | A | B | C | D | E | F |
|---|---|---|---|---|---|---|
| Antitoxin content (Lf-eq.) | 20 | 30 | 45 | 70 | 100 | 150 |

The level of toxin or toxoid and antitoxin concentration in the test may be varied, but this will markedly affect the flocculation time, so that at very low levels the test will take too long, whilst at a high concentration the onset of flocculation may be so rapid as to make it difficult to distinguish the first and second tubes to flocculate.

**Assay of low concentrations by blend flocculation**

For very low concentrations, it is preferable to measure toxin or toxoid by the method of blend flocculation. This involves comparison of the Lf value of a known toxin or toxoid and that of a mixture of the sample with that toxin or toxoid.

When a toxin or toxoid with a known Lf value and a toxin or toxoid with an unknown Lf value are flocculated together, the mixture will flocculate as the sum of their values if they are homogeneous. If non-homogenous toxins or toxoids are mixed they will produce an aberrant pattern with 2 flocculation maxima.

**01/2008:20728**

# 2.7.28. COLONY-FORMING CELL ASSAY FOR HUMAN HAEMATOPOIETIC PROGENITOR CELLS

The haematopoietic system represents a continuum of cells whose phenotype and properties change as they progress from stem cells to differentiated cells.

Haematopoietic progenitor cells (HPCs) are capable of forming colonies or 'cell clusters' in cultures grown in semi-solid media and are said to be 'clonogenic'. The determination of the number of colony-forming cells (CFCs) in a cellular product is an indicator of the functional capacity of the progenitor cells and is a predictor of haematopoietic reconstitution. The measured number of CFCs correlates with the minimum number of progenitors present in the sample.

CELL-SURFACE MARKERS

The capacity of colony-forming cells to give rise to haematopoietic colonies *in vitro* and/or to reconstitute the haematopoietic system has been correlated with the expression of specific cell-surface antigens. The expression of the membrane antigen CD34 is an accepted marker for most of the haematopoietic progenitors and stem cells.

COLONY ASSAY SPECIFICITY

Colony-forming cells are identified with a nomenclature based on the lineages of mature cells present in the colony (for example, CFU-Mix, CFU-GEMM, CFU-GM, CFU-G, CFU-M, BFU-E, CFU-E, CFU-Meg) and are a population of progenitors able to give rise to colonies containing one or more lineages of haematopoietic cells. No or low capacity for self-renewal has been ascribed to this population of human HPCs compared with the most immature stem cells.

The amount and type of growth factors supplied during the culture modulate the type and size of colonies that will be formed.

Greater specificity on the general class of HPCs and on their relative proliferative potential is provided by the time required to differentiate *in vitro* into mature cells. The time required by post-natal colony-forming cells to give rise to a colony formed of mature cells *in vitro* is 10-14 days.

QUALITY ASSURANCE FOR A CFC ASSAY

It is paramount for the overall quality of the colony-forming cell assay to apply a strictly standardised approach.
It is therefore recommended to carry out intra- and inter-laboratory validations. The source of the materials, including reagents, growth factors and disposables, is identified.

The main factors affecting variability in the CFC assay are the number of cells plated and the identification of colonies. Up to 15 per cent intra-laboratory variability may be observed for the same test. If it is necessary to evaluate the number of colony-forming cells in a purified cell population, it is possible to use a limiting dilution approach where the number of wells positive for cell proliferation is measured with an automated system.

The other main source of variability stems from the use of undefined materials (for example, foetal bovine serum or bovine serum albumin) in the CFC assay. These products derive from pools of source materials and provide a non-specific stimulation of cellular proliferation. However, it is not uncommon to have batches with particular characteristics that selectively stimulate the proliferation of specific haematopoietic lineages.

Finally, a low level of endotoxins (less than 0.01 IU/mL or less than 0.01 IU/mg) in all the materials used for the clonogenic assay is advisable, as higher levels result first in a progressive skewing of the haematopoietic lineages expression in the cultures, and afterwards in a more general inhibition of cell proliferation and clonogenesis.

CFC CLONOGENIC ASSAY

The CFC assay is based on the capacity of progenitor cells to form a colony when plated in a semi-solid medium or in a gel in the presence of specific growth factors. Different types of semi-solid media may be used (for example, methylcellulose, collagen, agar and plasma-clot) depending on the desired readout. Commercially available media usually give more reproducible results.

*MATERIALS*

A validation is performed at least for the following critical materials.

**Growth factors**. Both multilineage (such as Kit-ligand or stem cell factor (SCF), interleukin-3, granulocyte-macrophage colony-stimulating factor (GM-CSF)) and lineage-specific (erythropoietin, granulocyte colony-stimulating factor (G-CSF)) growth factors are required to obtain the highest number of colonies from a cell suspension containing a mixed population of HPCs.

**Other media components**. Media may be supplemented by serum (notably by foetal bovine serum) and/or albumin.

*CELL CULTURE*

**Cells**. The sample placed in culture must be representative of the cellular product injected. Cell suspensions are required for this assay. In the case of bone marrow aspirates, such suspensions can be obtained by forcing the bone marrow through a sieve or through progressively smaller calibre needles. Repeated passages through a 21-gauge needle are usually sufficient to disperse cell clusters into a cell suspension.

*PLATING AND SCORING*

The cells diluted in the culture medium are mixed in the semi-solid medium. It is common to plate 1 mL of the mixture in an untreated sterile Petri dish (Ø 35 mm).

Because of the viscosity of the medium, the solution cannot be plated with air displacement pipettes and the use of syringes equipped with large bore (≤ 18-gauge) needles is required.

The number of cells to be plated depends on the HPC concentration in the sample to be tested. So that no colony is derived from 2 different HPCs, the number of cells plated must allow between 40 and 80 colonies per plate (Ø 35 mm) to be counted. The 'target' number of colonies per plate may be obtained either from the percentage of CD34+ (or concentration of CD34+ cells/mL) determined by flow cytometry (*2.7.24*) or from different dilutions of the cell suspension (usually 2 concentrations are tested).

The plates are incubated in aerobic conditions with a carbon dioxide concentration of 5 per cent, at 37 °C in a humid (saturated) atmosphere for 10-14 days, and the number of colonies is then scored under an inverted microscope. Care must be taken when manipulating the dishes containing the colonies as the methylcellulose-based medium is viscous but not jellified. An inclined plate will result in mixed and 'comet'-shaped colonies making the scoring likely to be incorrect.

*IDENTIFICATION OF THE COLONIES*

The size and structure of the colonies depend on the type of mature cells that are their constituents. 50 cells per colony is usually considered a minimum. The presence of haemoglobinised cells identifies progenitors of the erythroid lineage. As the amount of mature cells for each lineage largely depends on the growth factors added to the cultures, performing differentiated counts is not recommended unless otherwise prescribed.

*EXPRESSION OF THE RESULTS*

The results of CFC culture are usually expressed as the arithmetic mean of the number of colonies counted in at least 3 plates in the test. The mean number of colonies is then related to $10^4$ or $10^5$ viable nucleated cells placed in culture.

**01/2008:20729**

# 2.7.29. NUCLEATED CELL COUNT AND VIABILITY

The determination of the quality of cell suspensions requires accurate measurements of both cell concentration and percentage of viable cells. These data are essential to the decision-making process for preparing cellular products and for maintaining optimum culture conditions. The cell count may be expressed as the number of cells per volume of cell suspension and the cell viability as the number of viable cells per volume of cell suspension. The cell-count procedure may be performed manually (haemocytometer) or with an automated apparatus (for example, particle counter, flow cytometer). Other methods than that described below may be used.

CELL NUMBER

*MANUAL COUNTING*

*Description of the apparatus and test principle.* The following materials are required:

- a haemocytometer: a specialised microscope counting chamber available in different designs. It consists of a thick slide and a coverslip mounted to delimit a chamber with a specific volume for each design. The thick slide of the various haemocytometers consists of counting chambers separated by deep grooves to avoid cross-filling. The counting chamber is etched in the glass and contains a grid which is specific for each model;
- a light microscope - low power 10× to 40× magnification;
- pipettes of a suitable volume range.

The haemocytometer is used to quantify the number of cells in a given solution by calculation of the cell concentration per millilitre ($C$) using the following expression:

$$a \times 10^n \times d$$

$a$ = number of cells counted;

$d$ = dilution factor (where applicable);

$n$ = factor varying with the volume of the haemocytometer chamber.

It is possible to distinguish between mixed cell populations provided they differ in size or pigmentation (for example, leukocytes and erythrocytes).

*Preparation of the counting chamber and analysis.* Mount the coverslip (slightly moistened on the edges) on the slide. Move the coverslip back and forth over the slide, pressing slightly on the sides. Prepare a suitable dilution of the cell suspension in isotonic buffer or in haemolysis buffer.

Add an appropriate volume of the dilution to the counting chamber. The liquid is added to the border of the coverslip and is drained inside the chamber by capillarity. Carefully place the haemocytometer under the microscope and focus. Count the cells in a zone of the grid. Calculate the cell concentration in the diluted and original samples.

To increase the accuracy of the measurement, it is important to respect the following basic precautions:

- use only suitably thickened coverslips;
- wherever possible, count more than 100 cells (if necessary, count more areas);

– where cell clustering is detected (i.e. the cell suspension is not monocellular), resuspend the cells before sampling and count again;
– avoid underfilling or overflowing the chamber, otherwise the volume will no longer be accurate.

*AUTOMATED COUNTING METHODS*

*Particle counters based on conductivity variation.* Electronic particle counting devices measure the size and number of particles in a solution.

Particle counters are calibrated before use with a solution of particles of known concentration and size. To allow the counting of larger particles, tubes fitted with differently calibrated orifices are available. These apparatuses do not allow the discrimination between dead and live cells. As cell debris may also generate pulses that may cause errors, counters are also fitted with a threshold control allowing only larger particles to be counted.

The apparatus must be qualified for the counting of cellular products (in terms of linearity, accuracy, etc.).

*Particle counters based on flow cytometry* (*2.7.24*). The flow cytometer is calibrated with reference particles of known concentration and size to give an absolute cell number per volume. However, a calibrating solution is no longer necessary in instruments using 2 electrodes inserted in the sampling chamber where the fixed size of the sampling chamber and distance between the 2 electrodes allow the measurement of the content of a fixed volume. This type of instrument rarely needs to be calibrated after the initial setting.

VIABILITY

This section applies to cell staining by viability dyes and manual or automated analysis, under a light microscope or by flow cytometry, of a cell suspension in order to determine the percentage of viable cells.

Depending on the type of cells and the method used, the results may differ.

*MANUAL DYE-EXCLUSION METHOD*

*Test principle.* This test is based on the exclusion of the dye from viable cells whereas dead or damaged cells absorb the dye and are coloured. It provides information on the cytoplasmic membrane integrity but its results do not necessarily reflect cell functionality. Recently trypsinised or thawed viable cells may have leaky membranes, causing them to absorb the dye.

*Dye.* Trypan blue is the stain most commonly used to distinguish between viable and non-viable cells, but other suitable dyes such as erythrosin B or nigrosin may also be used. It is an acid dye ($M_r$ 961), an anion with 4 sulfonate groups that can easily bind to proteins; therefore the protein concentration of the preparation to be tested must be as low as possible.

*Test conditions.* Dye fixation is strongly influenced by pH, within a range of 6.6 to 7.6. Fixation is optimal at pH 7.5. The other conditions, such as the dye concentration and the staining time are validated.

*Storage conditions of the dye*: Generally a 0.4 or 0.5 per cent trypan blue solution in sterile phosphate-buffered saline is used. Store protected from light and air.

*Test preparation and analysis.* Stain the cell suspension at the required dilution (usually in phosphate-buffered saline) with, for example, a trypan blue solution having a final concentration of 0.1 to 0.2 per cent. Mix gently. Incubate for not more than 2-4 min at room temperature. Mix gently and place a suitable volume in a counting chamber. Count without delay.

Determine the percentage of viable cells from the ratio of the number of unstained cells to the total number of cells under a light microscope, considering all stained cells as dead cells. Viability (*V*) is calculated as a percentage using the following expression:

$$\frac{n}{N} \times 100$$

*n* = number of unstained (viable) cells;

*N* = total number of cells (stained and unstained).

It is essential that the incubation time be not more than 4 min as the number of stained cells may increase significantly afterwards. For a new determination, it may therefore be necessary to prepare a new test.

*AUTOMATED METHODS*

**Flow cytometry**

*Test principle.* The test is based on the ability of certain dyes to cross damaged membranes and bind to DNA by intercalating between bases so that dead cells may fluoresce and be detected by flow cytometry (*2.7.24*). Non-viable cells are evaluated and discriminated by focusing on positive staining whereas viable cells remain unstained. This analysis is generally performed with 7-aminoactinomycin D (7-AAD) or propidium iodide (PI) but other suitable dyes may also be used.

*Dye.* 7-AAD and PI are given as examples of membrane-impermeants that may be used as viability dyes.

7-AAD is an analogue of actinomycin D that contains a substituted amino group at position 7 of the chromophore. It intercalates between cytosine and guanine DNA bases. The spectral properties of 7-AAD make this molecule particularly suitable for flow-cytometry analysis. The maximum absorption of the 7-AAD/DNA complex is situated in the green spectral region and is thus suitable for an argon laser-equipped cytometer (excitation wavelength of 488 nm). The deep red fluorescence emission of the 7-AAD viability dye (635 nm to 675 nm) eases the use of the probe in combination with fluorescein isothiocyanate (FITC) and phycoerythrin (PE)-conjugated antibodies, because in contrast to PI, the 7-AAD/DNA complex shows minimal overlap with FITC and PE.

PI binds to double-stranded DNA by intercalating between bases with little or no sequence preference and with a stoichiometry of 1 dye molecule per 4-5 DNA base pairs. Once the dye is bound to nucleic acids, its fluorescence is enhanced 20- to 30-fold, the fluorescence excitation maximum is shifted around 30-40 nm towards the red and the fluorescence emission maximum (615 nm) is shifted around 15 nm towards the blue. Although its absorptivity is quite low, PI exhibits a sufficiently large Stokes shift to allow simultaneous detection of nucleic acids and fluorescein-labelled antibodies, provided that the suitable optical filters are used.

*Storage conditions of nucleic acid dye solution*: 5 ± 3 °C.

*Test preparation and analysis.* In the case of haematopoietic cells, the dye may be added after CD45 labelling to obtain a better separation of cells from debris and platelets with a side scatter (SS)/CD45+ gating region. The incubation conditions of the cell suspension with the dye are validated previously.

Incubation is performed at room temperature protected from light. Where necessary, lysis of red blood cells is performed using, for example, ammonium chloride. If not, add buffer alone.

Percentages of viable cells are directly given by the flow cytometer and deduced from the analysis of positive cells (dead cells) in the SS/7-AAD or SS/PI cytogram (dot plots).

Positive controls may consist of stabilised cells (dead cells) mixed with fresh viable cells at a target value.

**Digital imaging of stained cells**. Digital imaging allows the automation of dye-exclusion methods. The cell suspension and viability-dye solution are directly mixed by a machine. The system, which allows sample aspiration, reagent handling, and subsequent instrument cleaning is fully automated. Once the cellular suspension has been aspirated and mixed with the dye solution, it is pumped to the flow cell for imaging. The

stained cell suspension is aspirated through a chamber where stroboscopic light allows a camera to photograph the flowing cells. The images are digitalised and the number of dead or live cells counted by the software.

# 2.7.30. ASSAY OF HUMAN PROTEIN C

## 1. CHROMOGENIC ASSAY

Human protein C is a vitamin K-dependent plasma protein that, upon activation to activated protein C (APC), can inhibit blood coagulation through the proteolytic cleavage of factors Va and VIIIa. Human protein C activity is estimated using a two-step method: in the 1st step, human protein C in the preparation is activated by a specific activator from snake venom; in the 2nd step, APC cleaves a specific chromogenic substrate to form a chromophore that can be quantified spectrophotometrically.

**Step 1**

**Step 2**

The potency of human protein C is estimated by comparing the ability of the preparation to be examined to cleave a chromogenic substrate with the same ability of a reference standard of human protein C calibrated in International Units. The International Unit is the activity of a stated amount of the International Standard for human protein C. The equivalence in International Units of the International Standard is stated by the World Health Organization.

Individual reagents may be obtained separately or in commercial kits. Both end-point and kinetic methods are available. Procedures and reagents may vary between different kits and the manufacturer's instructions are followed. The essential features of the procedure are described in the following example of a microtitre plate end-point method.

### REAGENTS

*Dilution buffer pH 8.4.* Dissolve 6.055 g of *tris(hydroxymethyl)aminomethane R* and 16.84 g of *caesium chloride R* in *water R* and adjust the pH if necessary. Dilute to 1000.0 mL with *water R*.

*Human protein C activator.* Protein isolated from the venom of the viper *Agkistrodon contortrix contortrix* that specifically activates human protein C. Reconstitute and store according to the manufacturer's instructions. Dilute to 0.25 U/mL with *water R* before use in the assay.

*Activated protein C chromogenic substrate.* Specific chromogenic substrate for APC, for example L-pyroglutamyl-L-prolyl-L-arginyl-*p*-nitroaniline hydrochloride (pyroGlu-Pro-Arg-pNA.HCl). Reconstitute with *water R* to give a concentration of 4.5 mmol/L. Further dilute to 1.1 mmol/L with dilution buffer pH 8.4 before use in the assay.

### METHOD

Reconstitute or thaw the preparation to be examined according to the manufacturer's instructions. Dilute with *water R* to produce at least 3 separate dilutions for each preparation in the range 0.050-0.200 IU/mL, preferably in duplicate.

**Step 1**. Mix 0.025 mL of each dilution with 0.050 mL of the human protein C activator, both previously heated to 37 °C, and leave at 37 °C for exactly 10 min. For each dilution, prepare a blank in the same manner, using *water R* instead of the human protein C activator.

**Step 2**. Add 0.150 mL of diluted chromogenic substrate, previously heated to 37 °C, to each mixture and leave at 37 °C for exactly 10 min. The incubation time must be adjusted, if necessary, to ensure a linear development of chromophore with time. Terminate the reaction by adding 0.050 mL of a 50 per cent *V/V* solution of *glacial acetic acid R*.

Cleavage of the chromogenic substrate by APC causes release of the chromophore pNA, in proportion to the concentration of human protein C in the preparation. Measure the optical density at a wavelength of 405 nm. Subtract the optical density of the blank from the optical density of the test sample. Check the validity of the assay and calculate the potency of the preparation to be examined using the usual statistical methods (*5.3*).

## 2. CLOTTING ASSAY

Human protein C activity is estimated following cleavage to APC by a specific activator extracted from the venom of the viper *Agkistrodon contortrix contortrix*. The resulting APC inactivates factors Va and VIIIa, and thus prolongs the APTT (Activated Partial Thromboplastin Time) of a system in which all the coagulation factors are present, constant and in excess, except for human protein C, which is derived from the preparation being tested. Prolongation of the clotting time is proportional to the concentration of human protein C in the preparation.

The potency of human protein C is estimated by comparing the ability of the preparation to be examined to prolong the clotting time with the same ability of a reference standard of human protein C calibrated in International Units. The International Unit is the activity of a stated amount of the International Standard for human protein C. The equivalence in International Units of the International Standard is stated by the World Health Organization.

Individual reagents may be obtained separately or in commercial kits. Procedures and reagents may vary between different kits and the manufacturer's instructions are followed. The essential features of the procedure are described in the following example.

### REAGENTS

*Dilution buffer pH 7.4.* Isotonic non-chelating buffer.

*Human protein C-deficient plasma.* Citrated human plasma with no measurable human protein C content. Reconstitute and store according to the manufacturer's instructions.

*Human protein C activator.* Protein isolated from the venom of the viper *Agkistrodon contortrix contortrix* that specifically activates human protein C. Reconstitute and store according to the manufacturer's instructions.

*Coagulation activator.* A suitable APTT reagent containing phospholipids and a contact activator may be used. It may be combined with the human protein C activator.

### METHOD

Reconstitute or thaw the preparation to be examined according to the manufacturer's instructions. Dilute with dilution buffer pH 7.4 to produce at least 3 separate dilutions for each preparation in the range 0.010-0.150 IU/mL, preferably in duplicate.

Mix 1 volume of each dilution with 1 volume of human protein C-deficient plasma and 1 volume of the human protein C activator (combined with the APTT reagent where appropriate), all previously heated to 37 °C. Add 1 volume of *0.025 M calcium chloride solution R* previously heated to 37 °C, and record the clotting time.

The clotting time is proportional to the concentration of human protein C in each dilution. Check the validity of the assay and calculate the potency of the preparation to be examined using the usual statistical methods (*5.3*).

**07/2008:20731**

## 2.7.31. ASSAY OF HUMAN PROTEIN S

Human protein S is a vitamin K-dependent plasma protein that acts as a cofactor for the anticoagulant functions of activated protein C (APC). Human protein S activity may be determined by the clotting assay described below, which is sensitive to the ability of human protein S to accelerate the inactivation of factor Va by APC. In practice, the assay involves the addition of human protein S to a reagent mixture containing APC, factor Va and human protein S-deficient plasma. Prolongation of the clotting time is proportional to the concentration of human protein S in the preparation. Methods in which APC is added directly as a reagent are preferred to those in which APC is generated during the assay by the addition of a specific human protein C activator purified from snake venom. Activation of coagulation is initiated by the addition of an activating reagent such as thromboplastin or activated factor X, together with phospholipids and calcium chloride. During the assay, factor Va is generated from factor V in the human protein S-deficient plasma following the activation of coagulation. The assay procedure must ensure that human protein S is the only limiting factor.

The potency of human protein S is estimated by comparing the ability of the preparation to be examined to prolong the clotting time with the same ability of a reference standard of human protein S calibrated in International Units. The International Unit is the activity of a stated amount of the International Standard for human protein S. The equivalence in International Units of the International Standard is stated by the World Health Organization.

Individual reagents may be obtained separately or in commercial kits. Procedures and reagents may vary between different kits and the manufacturer's instructions are followed. The essential features of the procedure are described in the following example.

REAGENTS

*Dilution buffer pH 7.4.* Isotonic non-chelating buffer prepared as follows: dissolve 6.08 g of *tris(hydroxymethyl)aminomethane R* and 8.77 g of *sodium chloride R* in *water R* and adjust the pH if necessary; add 10 g of *bovine albumin R* or *human albumin R* and dilute to 1000.0 mL with *water R*.

*Human protein S-deficient plasma.* Citrated human plasma with no measurable human protein S content and, preferably, also free of C4b-binding protein.

*Coagulation activator.* This reagent is used to initiate coagulation in the human protein S-deficient plasma, and thereby also provides a source of activated factor V. The activator may consist of tissue factor, activated factor X, or an agent capable of directly activating factor X that may be purified from the venom of Russell's viper (*Vipera russelli*). The reagent also contains APC, phospholipids and *calcium chloride R*, or, alternatively, calcium chloride may be added separately after a timed activation period.

METHOD

Reconstitute or thaw the preparation to be examined according to the manufacturer's instructions. Dilute with dilution buffer pH 7.4 to produce at least 3 separate dilutions for each preparation in the range 0.020-0.100 IU/mL, preferably in duplicate.

Mix 1 volume of each dilution with 1 volume of human protein S-deficient plasma, both previously heated to 37 °C. Add 2 volumes of the coagulation activator, previously heated to 37 °C, and record the clotting time.

Alternative procedures may use a coagulation activator without calcium chloride, and require a precisely timed activation period before the addition of calcium chloride and the measurement of clotting time.

The clotting time is proportional to the concentration of human protein S in each dilution. Check the validity of the assay and calculate the potency of the preparation to be examined using the usual statistical methods (*5.3*).

**07/2008:20732**

## 2.7.32. ASSAY OF HUMAN α-1-PROTEINASE INHIBITOR

Human α-1-proteinase inhibitor (also known as α-1-antitrypsin or α-1-antiproteinase) content is determined by comparing the ability of the preparation to be examined to inactivate the serine protease elastase (porcine pancreatic elastase or human neutrophil elastase) with the same ability of a reference standard of human α-1-proteinase inhibitor calibrated in milligrams of active (functional) α-1-proteinase inhibitor. Varying quantities of the preparation to be examined are mixed with a given quantity of elastase and the remaining elastase activity is determined using a suitable chromogenic substrate. The method described below is given as an example.

REAGENTS

*Tris-albumin buffer solution.* Dissolve 24.23 g of *trometamol R* in *water R*, adjust to pH 8.0 ± 0.3 using *hydrochloric acid R1* and dilute to 1000 mL with *water R*. To 100 mL of this solution add 0.5 mL of a 20 per cent solution of *human albumin R* or *bovine albumin R*.

Buffer solution containing human or bovine albumin must be prepared fresh on the day of its use; otherwise, it can be conserved by sterile filtration (0.2 µm) and stored at 2-8 °C for up to 2 weeks.

METHOD

Prepare 2 series of 4 or 5 dilutions in an appropriate human α-1-proteinase inhibitor concentration range, for both the preparation to be examined and the reference standard, using the tris-albumin buffer solution.

Transfer 50 µL of the reference solution dilutions into the wells of a microtitre plate and to each well, add 150 µL of a porcine pancreatic elastase solution diluted to an appropriate concentration with the tris-albumin buffer solution. Incubate for a defined period of time, 3-10 min, at room temperature. Since the activity of the solutions of the different porcine pancreatic elastases may vary, the concentration of elastase can be adjusted by evaluation of blank values containing elastase but no human α-1-proteinase inhibitor, to exhibit a suitable change of absorbance at 405 nm under the actual assay conditions.

Add to each well 100 µL of a solution of chromogenic substrate *N*-succinyl-tri-L-alanyl 4-p-nitroanilide (Suc-Ala-Ala-Ala-pNA), reconstituted in *dimethyl sulfoxide R* to give a solution containing 4.5 mg/mL, then further diluted with the tris-albumin buffer solution to a concentration of 0.45 mg/mL. Immediately start measurement of the change in absorbance (*2.2.25*) at 405 nm using a microtitre plate reader, continuing the measurement for at least 5 min. Calculate the rate of change of absorbance (ΔA/min). Alternatively, an end-point assay may be used by stopping the reaction with acetic acid and measuring the absorbance at 405 nm. If the

assay is performed in test tubes using spectrophotometers for monitoring the change in absorbance at 405 nm, the volumes of reagent solutions are changed proportionally.

The rate of change of absorbance (ΔA/min) is inversely proportional to human α-1-proteinase inhibitor activity.

Check the validity of the assay and calculate the potency of the test preparation by the usual statistical methods (*5.3*).

**04/2016:20734**

## 2.7.34. ASSAY OF HUMAN C1-ESTERASE INHIBITOR

The human C1-esterase inhibitor content of the preparation to be examined is determined by comparing its ability to inhibit C1-esterase with that of a reference preparation calibrated in International Units. The International Unit is the activity of a stated amount of the International Standard for human plasma-derived C1-esterase inhibitor concentrate. The equivalence in International Units of the International Standard is stated by the World Health Organization. Varying quantities of the preparation to be examined are mixed with an excess of C1-esterase and the remaining C1-esterase activity is determined using a suitable chromogenic substrate.

Individual reagents may be obtained separately or in commercial kits. Procedures and reagents may vary between different kits and the manufacturer's instructions are followed. The essential features of the procedure are described in the following example of a microtitre-plate kinetic method.

Reconstitute the preparation as stated on the label. Prepare an appropriate series of at least 3 dilutions, from 1 IU/mL of C1-esterase inhibitor, for both the preparation to be examined and the reference preparation, using a suitable pH 7.4 buffer solution containing 9 g/L of *sodium chloride R* and either 10 g/L of *human albumin R* or 10 g/L of *bovine albumin R*. Warm all solutions to 37 °C. Place a suitable quantity of 1 of the dilutions of the reference preparation or of the preparation to be examined in microtitre plate wells and incubate at 37 °C. To each well add a suitable quantity of C1-esterase solution and incubate at 37 °C for 5 min. Add an appropriate quantity of a suitable specific chromogenic substrate such as methoxycarbonyl-L-lysyl(ε-benzyloxycarbonyl)-glycyl-L-arginine-4-nitroanilide. Read the rate of increase of absorbance (Δ*A*/min) at 405 nm. A positive control, using the pH 7.4 buffer solution instead of the C1-esterase inhibitor, is included. For preparations that may exhibit proteolytic activity, a test is carried out on a suitable blank composed of the preparation to be examined, the pH 7.4 buffer solution and the chromogenic substrate.

Calculate the C1-esterase inhibitor content using the usual statistical methods, for example slope ratio (*5.3*).

**01/2020:20735**

## 2.7.35. IMMUNONEPHELOMETRY FOR VACCINE COMPONENT ASSAY

GENERAL PRINCIPLE

The general principle of nephelometry is described in general chapter *2.2.1. Clarity and degree of opalescence of liquids*. Immunonephelometry measures turbidity that is mainly due to immune complexes formed by the antigen-antibody reaction. Although immunonephelometry is applicable for the quantification of both antibodies and antigens, this general chapter describes the quantification of antigens as vaccine components.

APPARATUS

The nephelometer used is described in general chapter *2.2.1. Clarity and degree of opalescence of liquids*. However the measurement may be made at a non-zero angle different from 90°.

METHODS

In general, the progress of the reaction measured by light scattering can be described in 3 steps.

Initially, a baseline level of light scattering due to the reaction medium is detected. After the 1st reagent (antigen) is added, an increase in the signal is observed followed by a plateau. When the 2nd reagent (antibody) is added, a 2nd increase of the signal is observed with a 2nd plateau followed by a final increase in the intensity of the signal, which continues until a 3rd plateau is reached. The measurement zone starts from the addition of the 2nd reagent until the higher intensity of light scattering (the 3rd plateau) is reached depending on the concentrations of the component to be assayed.

The following methods can be used to quantify the immune complexes formed during this type of reaction.

*END-POINT NEPHELOMETRY*

The light scattering is measured after the immune complex has formed, i.e. after about 60 min. The value of the end-point is in this case directly proportional to the content of the component to be assayed when an excess of antibodies is used. A blank is necessary in order to subtract the value of nonspecific scattering due to the reaction mixture and to the reaction/measurement cell.

*RATE NEPHELOMETRY*

Rate nephelometry is based on the rate of immune complex formation (rate of increase in light scattering), which is proportional to the concentration of the component to be assayed.

There are 2 types of rate nephelometry.

**Fixed-time rate nephelometry**. A 1st measurement of light scattering is carried out a few seconds after the last reagent has been added. A 2nd measurement is carried out after a fixed time interval established during development of the method. The difference between the 2 values is proportional to the quantity of the component to be assayed.

**Rate nephelometry using the peak of the first derivative**. The formation of the immune complex is described by the curve of the first derivative of the variation in light scattering with time ($d\Theta_D/dt$). Two successive peaks are observed due to the addition of the 1st and then the 2nd reagent.

The height of the 3rd peak of the first derivative is proportional to the quantity of component to be assayed in the reaction medium. Successive measurements are carried out a few seconds after the 2nd reagent has been added.

In this case, the light scattered by the reaction medium, the component and the reagent does not affect the initial value of the derived signal.

OPERATING CONDITIONS

*REAGENTS AND REFERENCE STANDARDS*

The reagents, diluents and samples to be examined must be clear and free from any suspended particles. To this end, a preliminary filtration or centrifugation step may be considered.

The antisera or antibodies are selected based on their specificity, their precipitating capacity and their avidity for the antigen. Indeed, high avidity results in clearly detectable signals being generated rapidly, which thus improves the quality of the results.

In addition, it is important to define the range of antigen concentrations to be assayed with an excess of antibodies and to verify the absence of a zone effect in this range.

It is recommended to ensure that the profiles of response will be similar to that of an appropriate reference standard.

*PRE-TREATMENT OF THE SAMPLES TO BE EXAMINED*

An appropriate pre-treatment could be envisaged to eliminate an adjuvant or another interfering substance.

*ASSAY*

Ensure that all the reagents are at a suitable temperature to optimise the reaction.

To the samples diluted with a suitable medium in the reaction measurement cell, add a fixed quantity of antibodies. Carry out several determinations of the dilution being examined.

In some cases, the progress of the reaction may be improved by introducing additional substances into the reaction medium (e.g. polyethylene glycol).

The reference standards and samples must be treated in the same manner.

*PERFORMANCE OF A BLANK TEST*

To ensure that the assays are specific, only the scattering due to immune complexes must be measured. Other particles, the matrix of the sample, the reagents or the reaction measurement cell may interfere. In this case and if the end-point method is used, it is necessary to carry out a blank test to avoid taking non-specific scattering into account.

*CALIBRATION*

The calibration curve is obtained by preparing a set of dilutions of a reference standard. The concentrations are chosen in order to encompass the working range.

*METHODS OF CALCULATION*

The parallel line method (see general chapter *5.3*) or a calibration curve is used for the calculations.

VALIDITY OF THE TESTS

*VALIDITY OF THE CALIBRATION CURVES*

Only calibration curves that comply with the defined validity criteria may be used.

The following parameters are examples to be used to define validity criteria:

- minimum of light scattering units (LSU) obtained for the lowest concentration point of the calibration curve;
- coefficient of variation for the LSU measured for each point on the curve;
- coefficients of regression or of correlation of the calibration curve;
- slope and intercept of the calibration curve.

*VALIDITY OF THE RESULTS*

The following criteria are examples of validity criteria of the samples to be assayed:

- coefficient of variation or the range of values for the determinations carried out on the sample;
- assay of an in-house reference standard with trend monitoring or a control chart.

# 2.8. METHODS IN PHARMACOGNOSY

01/2008:20801

## 2.8.1. ASH INSOLUBLE IN HYDROCHLORIC ACID

Ash insoluble in hydrochloric acid is the residue obtained after extracting the sulfated or total ash with hydrochloric acid, calculated with reference to 100 g of drug.

To the crucible containing the residue from the determination of sulfated or total ash, add 15 mL of *water R* and 10 mL of *hydrochloric acid R*, cover with a watch-glass, boil the mixture gently for 10 min and allow to cool. Filter through an ashless filter, wash the residue with hot *water R* until the filtrate is neutral, dry, ignite to dull redness, allow to cool in a desiccator and weigh. Reheat until the difference between 2 consecutive weighings is not more than 1 mg.

04/2014:20802

## 2.8.2. FOREIGN MATTER

Herbal drugs should be free from moulds, insects and other animal contamination.

Foreign matter is material consisting of any or all of the following:

1) *foreign organs*: matter coming from the source plant but not defined as the herbal drug;

2) *foreign elements*: matter not coming from the source plant and of either vegetable or mineral origin.

DRIED PLANTS

**Sampling and sample preparation**. Apply general chapter *2.8.20. Herbal drugs: sampling and sample preparation*.

**Determination of foreign matter**. Weigh 100-500 g of the sample, or the minimum quantity prescribed in the individual monograph, and spread it out in a thin layer. Examine for foreign matter by inspection with the unaided eye or by use of a lens (6 ×). Separate foreign matter, weigh it and calculate the percentage present.

FRESH PLANTS

Where general chapter *2.8.20. Herbal drugs: sampling and sample preparation* cannot be applied, use one of the following methods, as appropriate: use method A when the test can be carried out on the whole batch; use method B when the test cannot be carried on the whole batch.

*METHOD A*

**Sampling and sample preparation**. Carry out the test on the whole batch.

**Determination of foreign matter**. Spread the batch out in a thin layer and examine for foreign matter by inspection with the unaided eye or by use of a lens (6 ×). Separate foreign matter, weigh it and calculate the percentage present.

*METHOD B*

**Sampling and sample preparation**. If it is not possible to inspect the whole batch, proceed as follows.

*Bulk sample*. Prepare the bulk sample as described in general chapter *2.8.20. Herbal drugs: sampling and sample preparation*.

*Test sample*. Use the bulk sample or, where the bulk sample is greater than 1 kg, reduce it to a mass of 500-1000 g by a suitable method which retains the representative nature of the bulk sample.

**Determination of foreign matter**. Use the sample, or the minimum quantity prescribed in the individual monograph, and spread it out in a thin layer. Examine for foreign matter by inspection with the unaided eye or by use of a lens (6 ×). Separate foreign matter, weigh it and calculate the percentage present.

01/2008:20803

## 2.8.3. STOMATA AND STOMATAL INDEX

STOMATA

There are several types of stomata (see Figure 2.8.3.-1), distinguished by the form and arrangement of the surrounding cells:

(1) The *anomocytic* (irregular-celled) type: the stoma is surrounded by a varying number of cells in no way differing from those of the epidermis generally,

(2) The *anisocytic* (unequal-celled) type: the stoma is usually surrounded by 3 subsidiary cells, of which one is markedly smaller than the others,

(3) The *diacytic* (cross-celled) type: the stoma is accompanied by 2 subsidiary cells, whose common wall is at right angles to the guard cells,

(4) The *paracytic* (parallel-celled) type: the stoma has on each side one or more subsidiary cells parallel to the long axis of the pore and guard cells.

STOMATAL INDEX

$$\text{Stomatal Index} = \frac{100 \times S}{E + S}$$

S = the number of stomata in a given area of leaf,

E = the number of epidermal cells (including trichomes) in the same area of leaf.

For each sample of leaf, make not fewer than 10 determinations and calculate the mean.

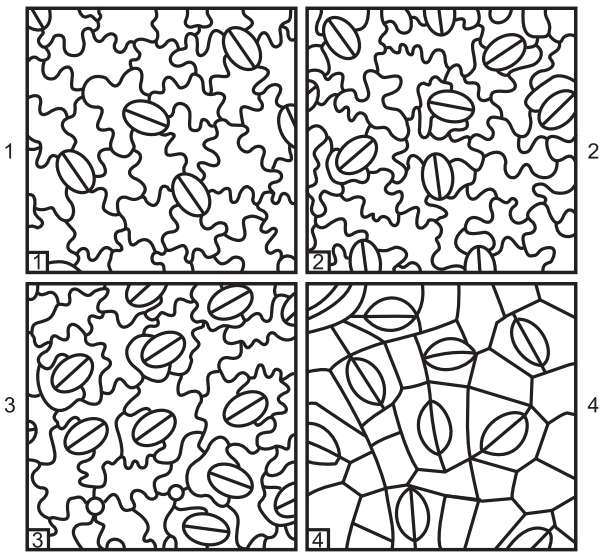

Figure 2.8.3.-1

01/2008:20804

## 2.8.4. SWELLING INDEX

The swelling index is the volume in millilitres occupied by 1 gram of a drug, including any adhering mucilage, after it has swollen in an aqueous liquid for 4 h.

In a 25 mL ground-glass stoppered cylinder graduated over a height of 125 ± 5 mm in 0.5 mL divisions, place 1.0 g of the drug, whole or of the degree of comminution prescribed in the monograph. Unless otherwise prescribed, moisten the drug with 1.0 mL of *alcohol R*, add 25 mL of *water R* and close the cylinder. Shake vigorously every 10 min for 1 h. Allow to stand for 3 h. At 90 min after the beginning of the test, release any large volumes of liquid retained in the layer of the drug and any particles of the drug floating at the surface of the liquid by rotating the cylinder about a vertical axis. Measure the volume occupied by the drug, including any adhering mucilage. Carry out 3 tests at the same time.

The swelling index is given by the mean of the 3 tests.

01/2008:20805

## 2.8.5. WATER IN ESSENTIAL OILS

Mix 10 drops of the essential oil with 1 mL of *carbon disulfide R*. The solution remains clear on standing.

01/2008:20806

## 2.8.6. FOREIGN ESTERS IN ESSENTIAL OILS

Heat 1 mL of the essential oil for 2 min on a water-bath with 3.0 mL of a freshly prepared 100 g/L solution of *potassium hydroxide R* in *alcohol R*. No crystals are formed within 30 min, even after cooling.

01/2008:20807

## 2.8.7. FATTY OILS AND RESINIFIED ESSENTIAL OILS IN ESSENTIAL OILS

Allow 1 drop of the essential oil to fall onto filter paper. The drop evaporates completely within 24 h without leaving any translucent or greasy spot.

01/2008:20808

## 2.8.8. ODOUR AND TASTE OF ESSENTIAL OILS

Mix 3 drops of the essential oil with 5 mL of *alcohol (90 per cent V/V) R* and stir in 10 g of powdered *sucrose R*. The odour and taste are similar to that of the plant or parts of the plant from which the essential oil has been obtained.

01/2008:20809
corrected 10.0

## 2.8.9. RESIDUE ON EVAPORATION OF ESSENTIAL OILS

The residue on evaporation of an essential oil is the percentage by mass of the oil which remains after evaporation on a water-bath under the conditions specified below.

*Apparatus.* The apparatus (see Figure 2.8.9.-1) consists of:
- water-bath with a cover having holes of 70 mm diameter;
- evaporating dish of heat-resistant glass which is inert to the contents;
- desiccator.

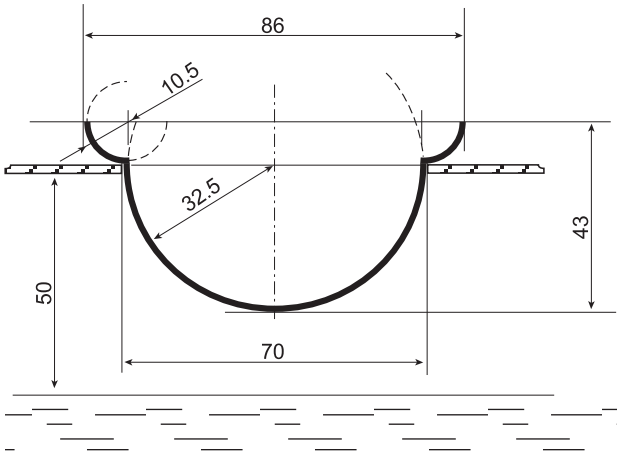

Figure 2.8.9.-1
*Dimensions in millimetres*

*Method.* Weigh the evaporating dish after having heated it on the water-bath for 1 h and cooled it in the desiccator. Weigh into the evaporating dish 5.00 g of the essential oil, unless otherwise prescribed. Evaporate the oil by heating on a water-bath in a draught-free atmosphere for the prescribed time. Allow to cool in the desiccator and weigh.

During the test, the level of water in the bath is maintained about 50 mm beneath the level of the cover.

01/2008:20810

## 2.8.10. SOLUBILITY IN ALCOHOL OF ESSENTIAL OILS

Place 1.0 mL of the essential oil in a 25 mL or 30 mL glass-stoppered cylinder. Place in a constant temperature device, maintained at a temperature of 20 ± 0.2 °C. Using a burette of at least 20 mL capacity, add the alcohol of the strength prescribed in the monograph by increments of 0.1 mL until solution is complete and then continue adding by increments of 0.5 mL to a total of 20 mL, shaking frequently and vigorously. Record the volume of alcohol added when a clear solution has been obtained and, if the solution becomes cloudy or opalescent before 20 mL of alcohol has been added, record the volume added when the cloudiness or opalescence appears and, where applicable, the volume added when the cloudiness or opalescence disappears.

If a clear solution has not been obtained when 20 mL of alcohol of the prescribed strength has been added, repeat the test using the next highest concentration of alcohol.

An essential oil is said to be "soluble in *n* volumes and more of alcohol of given strength *t*" when the clear solution in *n* volumes remains clear when compared with the undiluted oil after further addition of alcohol of the same strength up to a total of 20 volumes of alcohol.

An essential oil is said to be "soluble in *n* volumes of alcohol of given strength *t*, becoming cloudy when diluted" when the clear solution in *n* volumes becomes cloudy in $n_1$ volumes ($n_1$ less than 20) and stays so after further gradual addition of alcohol of the same strength up to a total of 20 volumes of alcohol.

An essential oil is said to be "soluble in *n* volumes of alcohol of given strength *t* with cloudiness between $n_1$ and $n_2$ volumes" when the clear solution in *n* volumes becomes cloudy in $n_1$ volumes ($n_1$ less than 20) and stays so after further gradual addition of alcohol of the same strength up to a total of $n_2$ volumes of alcohol and then becomes clear ($n_2$ less than 20).

An essential oil is said to be "soluble with opalescence" when the alcoholic solution shows a bluish tinge, similar to that of a standard of opalescence freshly prepared as follows: mix 0.5 mL of *silver nitrate solution R2* and 0.05 mL of *nitric acid R*; add 50 mL of a 12 mg/L solution of *sodium chloride R*; mix and allow to stand protected from light for 5 min.

**01/2008:20811**

## 2.8.11. ASSAY OF 1,8-CINEOLE IN ESSENTIAL OILS

Weigh 3.00 g of the oil, recently dried with *anhydrous sodium sulfate R*, into a dry test-tube and add 2.10 g of melted *cresol R*. Place the tube in the apparatus for the determination of freezing point (*2.2.18*) and allow to cool, stirring continuously. When crystallisation takes place there is a small rise in temperature. Note the highest temperature reached ($t_1$).

Remelt the mixture on a water-bath at a temperature that does not exceed $t_1$ by more than 5 °C and place the tube in the apparatus, maintained at a temperature 5 °C below $t_1$. When crystallisation takes place, or when the temperature of the mixture has fallen 3 °C below $t_1$, stir continuously. Note the highest temperature at which the mixture crystallises ($t_2$). Repeat the operation until 2 highest values obtained for $t_2$ do not differ by more than 0.2 °C. If supercooling occurs, induce crystallisation by adding a small crystal of the complex consisting of 3.00 g of *cineole R* and 2.10 g of melted *cresol R*. If $t_2$ is below 27.4 °C, repeat the determination after the addition of 5.10 g of the complex.

The content of cineole corresponding to the highest temperature observed ($t_2$) is given in Table 2.8.11.-1. If 5.10 g of the complex has been added, calculate the cineole content per cent *m/m* from the expression:

$$2(A - 50)$$

where $A$ is the value found in Table 2.8.11.-1.

The content of cineole, corresponding to the highest temperature observed ($t_2$), is obtained, where necessary, by interpolation.

Table 2.8.11.-1

| $t_2$ °C | cineole per cent *m/m* | $t_2$ °C | cineole per cent *m/m* | $t_2$ °C | cineole per cent *m/m* | $t_2$ °C | cineole per cent *m/m* |
|---|---|---|---|---|---|---|---|
| 24 | 45.5 | 32 | 56.0 | 40 | 67.0 | 48 | 82.0 |
| 25 | 47.0 | 33 | 57.0 | 41 | 68.5 | 49 | 84.0 |
| 26 | 48.5 | 34 | 58.5 | 42 | 70.0 | 50 | 86.0 |
| 27 | 49.5 | 35 | 60.0 | 43 | 72.5 | 51 | 88.5 |

| 29 | 52.0 | 37 | 62.5 | 45 | 76.0 | 53 | 93.5 |
| 30 | 53.5 | 38 | 63.5 | 46 | 78.0 | 54 | 96.0 |
| 31 | 54.5 | 39 | 65.0 | 47 | 80.0 | 55 | 99.0 |

**07/2019:20812**

## 2.8.12. ESSENTIAL OILS IN HERBAL DRUGS

PRINCIPLE

The determination of essential oils in herbal drugs is carried out by steam distillation in a special apparatus under the conditions described below. The distillate is collected in the graduated tube using the solvent prescribed in the monograph (usually *xylene R*, *trimethylpentane R* or *1,2,4-trimethylbenzene R*) to take up the essential oil; the aqueous phase is automatically returned to the distillation flask.

EQUIPMENT

The equipment typically consists of:

- a suitable round-bottomed flask with a short, ground-glass neck that has an internal diameter of about 29 mm at the wide end;
- a condenser assembly (see Figure 2.8.12.-1) that closely fits the flask, the different parts being fused into 1 piece and made of glass with a low coefficient of thermal expansion:
  - a vented stopper (*K'*) with an opening about 1 mm in diameter, and a tube (*K*), the wide end of which is made of ground-glass and has an internal diameter of 10 mm;
  - a pear-shaped swelling (*J*) with a capacity of 3 mL;
  - a tube (*JL*) graduated in 0.01 mL;
  - a bulb-shaped swelling (*L*) with a capacity of about 2 mL;
  - a 3-way tap (*M*);
  - a junction (*B*) situated at a level 20 mm higher than the uppermost graduation of tube *JL*;
- a suitable heating device, allowing fine temperature control;
- a vertical support with a horizontal ring covered with insulating material.

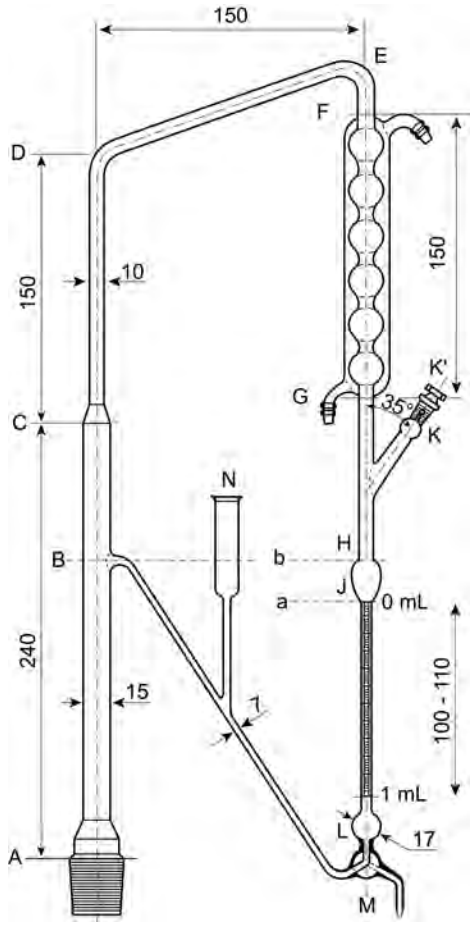

Figure 2.8.12.-1. – *Apparatus for the determination of essential oils in herbal drugs*

*Dimensions in millimetres*

PROCEDURE

Use a thoroughly cleaned apparatus. Carry out the determination according to the nature of the herbal drug to be examined. Place the prescribed volume of distillation liquid in the flask, add a few pieces of porous porcelain and attach the condenser assembly. Introduce *water R* through the filling funnel (*N*) until it reaches level *B*. Remove the stopper (*K'*) and introduce the prescribed quantity of the solvent indicated in the monograph using a pipette with its tip placed at the bottom of tube *K*. Re-insert the stopper (*K'*) and ensure that the vent is unobstructed. Heat the liquid in the flask to boiling and adjust the distillation rate to 2-3 mL/min, unless otherwise prescribed.

**Determination of the rate of distillation**. During distillation, determine the rate of distillation by lowering the level of the water by means of tap *M* until the meniscus reaches the level of the lower mark (*a*) (see Figure 2.8.12.-2). Close tap *M* and measure the time taken for the liquid to reach the upper mark (*b*). Modify the heat to obtain the target distillation rate. If the distillation rate is still not within the prescribed range, repeat the operation. If the distillation conditions are not changed, it is sufficient to determine the distillation rate at regular intervals rather than before each test.

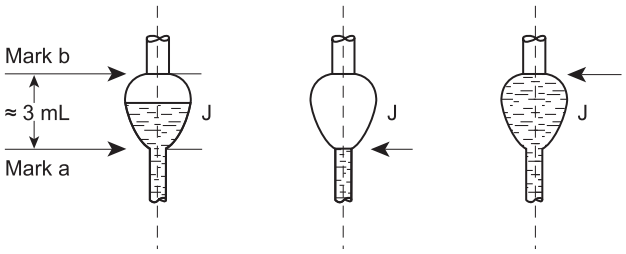

Figure 2.8.12.-2

**Determination of the solvent volume after blank distillation**. If using *xylene R* or *trimethylpentane R*, distil for 30 min. Ensure that tubes *BM* and *JM* are connected via tap *M* during distillation. Stop heating and wait at least 10 min before reading the volume of solvent in the graduated tube.

If using *1,2,4-trimethylbenzene R*, the 30 min blank distillation step is not necessary. Stop heating after adjusting the distillation rate and wait at least 10 min before reading the volume of solvent in the graduated tube.

**Determination of the essential oil in the herbal drug**. Introduce the prescribed quantity of the herbal drug into the flask and continue distillation as described above for the time and at the rate prescribed. Stop heating, read the volume of liquid collected in the graduated tube after 10 min and subtract the volume of the solvent previously noted. The difference represents the quantity of essential oil in the sample. Calculate the result in millilitres per kilogram of herbal drug.

**Recovery of the mixture of solvent and essential oil**. When the essential oil is to be used for other analytical purposes, the water-free mixture of solvent and essential oil may be recovered as follows: remove the stopper (*K'*) and introduce 0.1 mL of a 1 g/L solution of *sodium fluoresceinate R* and 0.5 mL of *water R*. Run the mixture of solvent and essential oil into the bulb-shaped swelling (*L*) by opening tap *M*, allow to stand for 5 min and lower the level of the mixture slowly until it just reaches the level of tap *M*. Open tap *M* clockwise so that the water flows out of the connecting tube (*BM*). Wash the tube with *acetone R* introduced through the filling funnel (*N*). Turn tap *M* anti-clockwise in order to recover the mixture of solvent and essential oil in an appropriate flask.

**01/2019:20813**

# 2.8.13. PESTICIDE RESIDUES

**Definition**. For the purposes of the Pharmacopoeia, a pesticide is any substance or mixture of substances intended for preventing, destroying or controlling any pest, unwanted species of plants or animals causing harm during or otherwise interfering with the production, processing, storage, transport or marketing of herbal drugs. The item includes substances intended for use as growth-regulators, defoliants or desiccants and any substance applied to crops, either before or after harvest, to protect the commodity from deterioration during storage and transport. Pesticide residues can be present and are controlled in herbal drugs and herbal drug preparations.

**Limits**. Unless otherwise indicated in the monograph, the herbal drug to be examined at least complies with the limits indicated in Table 2.8.13.-1. The limits applying to pesticides that are not listed in Table 2.8.13.-1 and whose presence is suspected for any reason comply with the limits (levels) cross-referred to by Regulation (EC) No. 396/2005, including

annexes and successive updates. Limits for pesticides that are not listed in Table 2.8.13.-1 or in European Union texts are calculated using the following expression:

$$\frac{ADI \times M}{MDD_{HD} \times 100}$$

*ADI* = acceptable daily intake, as published by FAO-WHO, in milligrams per kilogram of body mass;

*M* = body mass in kilograms (60 kg);

$MDD_{HD}$ = daily dose of the herbal drug, in kilograms.

The limits for pesticides in herbal drug preparations are calculated using the following expressions:

If *DER* ≤ 10: $MRL_{HD} \times DER$

If *DER* > 10: $\frac{ADI \times M}{MDD_{HP} \times 100}$

$MRL_{HD}$ = maximum residue limit of the pesticide in the herbal drug as given in Table 2.8.13.-1 or in EU texts or calculated using the expression mentioned above;

*DER* = drug/extract ratio, i.e. the ratio between the quantity of herbal drug used in the manufacture of a herbal drug preparation and the quantity of herbal drug preparation obtained;

$MDD_{HP}$ = daily dose of the herbal drug preparation, in kilograms.

The competent authority may grant total or partial exemption from the test when the complete history (nature and quantity of the pesticides used, date of each treatment during cultivation and after the harvest) of the treatment of the batch is known and can be checked precisely according to good agricultural and collection practice (GACP).

Table 2.8.13.-1

| Substance | Limit (mg/kg) |
|---|---|
| Acephate | 0.1 |
| Alachlor | 0.05 |
| Aldrin and dieldrin (sum of) | 0.05 |
| Azinphos-ethyl | 0.1 |
| Azinphos-methyl | 1 |
| Bromophos-ethyl | 0.05 |
| Bromophos-methyl | 0.05 |
| Brompropylate | 3 |
| Chlordane (sum of *cis*-, *trans* - and oxychlordane) | 0.05 |
| Chlorfenvinphos | 0.5 |
| Chlorpyriphos-ethyl | 0.2 |
| Chlorpyriphos-methyl | 0.1 |
| Chlorthal-dimethyl | 0.01 |
| Cyfluthrin (sum of) | 0.1 |
| λ-Cyhalothrin | 1 |
| Cypermethrin and isomers (sum of) | 1 |
| DDT (sum of *o,p′*-DDE, *p,p′*-DDE, *o,p′*-DDT, *p,p′*-DDT, *o,p′*-TDE and *p,p′*-TDE) | 1 |
| Deltamethrin | 0.5 |
| Diazinon | 0.5 |
| Dichlofluanid | 0.1 |
| Dichlorvos | 1 |
| Dicofol | 0.5 |
| Dimethoate and omethoate (sum of) | 0.1 |
| Dithiocarbamates (expressed as CS2) | 2 |
| Endosulfan (sum of isomers and endosulfan sulfate) | 3 |
| Endrin | 0.05 |
| Ethion | 2 |
| Etrimphos | 0.05 |
| Fenchlorophos (sum of fenchlorophos and fenchlorophos-oxon) | 0.1 |
| Fenitrothion | 0.5 |
| Fenpropathrin | 0.03 |
| Fensulfothion (sum of fensulfothion, fensulfothion-oxon, fensulfothion-oxonsulfon and fensulfothion-sulfon) | 0.05 |
| Fenthion (sum of fenthion, fenthion-oxon, fenthion-oxon-sulfon, fenthion-oxon-sulfoxid, fenthion-sulfon and fenthion-sulfoxid) | 0.05 |
| Fenvalerate | 1.5 |
| Flucytrinate | 0.05 |
| τ-Fluvalinate | 0.05 |
| Fonophos | 0.05 |
| Heptachlor (sum of heptachlor, *cis*-heptachlorepoxide and *trans*-heptachlorepoxide) | 0.05 |
| Hexachlorbenzene | 0.1 |
| Hexachlorocyclohexane (sum of isomers α-, β-, δ- and ε) | 0.3 |
| Lindan (γ-hexachlorocyclohexane) | 0.6 |
| Malathion and malaoxon (sum of) | 1 |
| Mecarbam | 0.05 |
| Methacriphos | 0.05 |
| Methamidophos | 0.05 |
| Methidathion | 0.2 |
| Methoxychlor | 0.05 |
| Mirex | 0.01 |
| Monocrotophos | 0.1 |
| Parathion-ethyl and paraoxon-ethyl (sum of) | 0.5 |
| Parathion-methyl and paraoxon-methyl (sum of) | 0.2 |
| Pendimethalin | 0.5 |
| Pentachloranisol | 0.01 |
| Permethrin and isomers (sum of) | 1 |
| Phosalone | 0.1 |
| Phosmet | 0.05 |
| Piperonyl butoxide | 3 |
| Pirimiphos-ethyl | 0.05 |
| Pirimiphos-methyl (sum of pirimiphos-methyl and *N*-desethyl-pirimiphos-methyl) | 4 |
| Procymidone | 0.1 |
| Profenophos | 0.1 |
| Prothiophos | 0.05 |

| Substance | Limit (mg/kg) |
|---|---|
| Pyrethrum (sum of cinerin I, cinerin II, jasmolin I, jasmolin II, pyrethrin I and pyrethrin II) | 3 |
| Quinalphos | 0.05 |
| Quintozene (sum of quintozene, pentachloraniline and methyl penthachlorphenyl sulfide) | 1 |
| S-421 | 0.02 |
| Tecnazene | 0.05 |
| Tetradifon | 0.3 |
| Vinclozolin | 0.4 |

**Sampling of herbal drugs**. Sampling is done according to general chapter *2.8.20. Herbal drugs: sampling and sample preparation*.

**Qualitative and quantitative analysis of pesticide residues**. The analytical procedures used are validated (e.g. according to Document No. SANCO/10232/2006 or any subsequent revisions of this document). In particular, they satisfy the following criteria:

- the chosen method, especially the purification steps, is suitable for the combination pesticide residue/substance to be examined, and not susceptible to interference from co-extractives;
- natural occurrence of some constituents is considered in the interpretation of results (e.g. disulfide from crucifers);
- the concentration of test and reference solutions and the setting of the apparatus are such that the responses used for quantification of the pesticide residues are within the dynamic range of the detector; test solutions containing pesticide residues at a level outside the dynamic range, may be diluted within the calibration range, provided that the concentration of the matrix in the solution is adjusted in the case where the calibration solutions must be matrix-matched;
- between 70 per cent to 110 per cent of each pesticide is recovered;
- repeatability of the method: RSD is not greater than the values indicated in Table 2.8.13.-2;
- reproducibility of the method: RSD is not greater than the values indicated in Table 2.8.13.-2.

Table 2.8.13.-2

| Concentration range of the pesticide (mg/kg) | Repeatability (RSD) (per cent) | Reproducibility (RSD) (per cent) |
|---|---|---|
| 0.001 - 0.01 | 30 | 60 |
| > 0.01 - 0.1 | 20 | 40 |
| > 0.1 - 1 | 15 | 30 |
| > 1 | 10 | 20 |

**01/2008:20814**

## 2.8.14. TANNINS IN HERBAL DRUGS

*Carry out all the extraction and dilution operations protected from light.*

In the case of a herbal drug or a dry extract, to the stated amount of the powdered drug (180) (*2.9.12*) or the extract in a 250 mL round-bottomed flask add 150 mL of *water R*. Heat on a water-bath for 30 min. Cool under running water and transfer quantitatively to a 250 mL volumetric flask. Rinse the round-bottomed flask and collect the washings in the volumetric flask, then dilute to 250.0 mL with *water R*. Allow the solids to settle and filter the liquid through a filter paper 125 mm in diameter. Discard the first 50 mL of the filtrate.

In the case of a liquid extract or a tincture, dilute the stated amount of the liquid extract or tincture to 250.0 mL with *water R*. Filter the mixture through a filter paper 125 mm in diameter. Discard the first 50 mL of the filtrate.

*Total polyphenols*. Dilute 5.0 mL of the filtrate to 25.0 mL with *water R*. Mix 2.0 mL of this solution with 1.0 mL of *phosphomolybdotungstic reagent R* and 10.0 mL of *water R* and dilute to 25.0 mL with a 290 g/L solution of *sodium carbonate R*. After 30 min measure the absorbance (*2.2.25*) at 760 nm ($A_1$), using *water R* as the compensation liquid.

*Polyphenols not adsorbed by hide powder*. To 10.0 mL of the filtrate, add 0.10 g of *hide powder CRS* and shake vigorously for 60 min. Filter and dilute 5.0 mL of the filtrate to 25.0 mL with *water R*. Mix 2.0 mL of this solution with 1.0 mL of *phosphomolybdotungstic reagent R* and 10.0 mL of *water R* and dilute to 25.0 mL with a 290 g/L solution of *sodium carbonate R*. After 30 min measure the absorbance (*2.2.25*) at 760 nm ($A_2$), using *water R* as the compensation liquid.

*Standard*. Dissolve immediately before use 50.0 mg of *pyrogallol R* in *water R* and dilute to 100.0 mL with the same solvent. Dilute 5.0 mL of the solution to 100.0 mL with *water R*. Mix 2.0 mL of this solution with 1.0 mL of *phosphomolybdotungstic reagent R* and 10.0 mL of *water R* and dilute to 25.0 mL with a 290 g/L solution of *sodium carbonate R*. After 30 min measure the absorbance (*2.2.25*) at 760 nm ($A_3$), using *water R* as the compensation liquid.

Calculate the percentage content of tannins expressed as pyrogallol from the expression:

$$\frac{62.5(A_1 - A_2)m_2}{A_3 \times m_1}$$

$m_1$ = mass of the sample to be examined, in grams;

$m_2$ = mass of pyrogallol, in grams.

**01/2008:20815**

## 2.8.15. BITTERNESS VALUE

The bitterness value is the reciprocal of the dilution of a compound, a liquid or an extract that still has a bitter taste. It is determined by comparison with quinine hydrochloride, the bitterness value of which is set at 200 000.

*Determination of the correction factor*

A taste panel comprising at least 6 persons is recommended. The mouth must be rinsed with *water R* before tasting.

To correct for individual differences in tasting bitterness amongst the panel members it is necessary to determine a correction factor for each panel member.

*Stock solution*. Dissolve 0.100 g of *quinine hydrochloride R* in *water R* and dilute to 100.0 mL with the same solvent. Dilute 1.0 mL of this solution to 100.0 mL with *water R*.

*Reference solutions*. Prepare a series of dilutions by placing in a first tube 3.6 mL of the stock solution and increasing the volume by 0.2 mL in each subsequent tube to a total of 5.8 mL; dilute the contents of each tube to 10.0 mL with *water R*.

Determine as follows the dilution with the lowest concentration that still has a bitter taste. Take 10.0 mL of the weakest solution into the mouth and pass it from side to side over the back of the tongue for 30 s. If the solution is not found to be bitter, spit it out and wait for 1 min. Rinse the mouth with *water R*. After 10 min, use the next dilution in order of increasing concentration.

Calculate the correction factor *k* for each panel member from the expression:

$$k = \frac{n}{5.00}$$

*n* = number of millilitres of the stock solution in the dilution of lowest concentration that is judged to be bitter.

Persons who are unable to taste any bitterness when using the reference solution prepared from 5.8 mL of stock solution have to be excluded from the panel.

*Sample preparation*

If necessary, reduce the sample to a powder (710) (*2.9.12*). To 1.0 g of sample add 100 mL of boiling *water R*. Heat on a water-bath for 30 min, stirring continuously. Allow to cool and dilute to 100 mL with *water R*. Shake vigorously and filter, discarding the first 2 mL of the filtrate. The filtrate is labelled C-1 and has a dilution factor (DF) of 100.

If liquids have to be examined, 1 mL of the liquid is diluted with a suitable solvent to 100 mL and designated C-1.

*Determination of the bitterness value*

Test solutions:

10.0 mL of C-1 is diluted with *water R* to 100 mL: C-2 (DF = 1000)

10.0 mL of C-2 is diluted with *water R* to 100 mL: C-3 (DF = 10 000)

20.0 mL of C-3 is diluted with *water R* to 100 mL: C-3A (DF = 50 000)

10.0 mL of C-3 is diluted with *water R* to 100 mL: C-4 (DF = 100 000)

Starting with dilution C-4 each panel member determines the dilution which still has a bitter taste. This solution is designated D. Note the DF of solution D is Y.

Starting with solution D prepare the following sequence of dilutions:

| Solution D (mL) | 1.2 | 1.5 | 2.0 | 3.0 | 6.0 | 8.0 |
|---|---|---|---|---|---|---|
| *water R* (mL) | 8.8 | 8.5 | 8.0 | 7.0 | 4.0 | 2.0 |

Determine the number of millilitres of solution D which, when diluted to 10.0 mL with *water R*, still has a bitter taste (X).

Calculate the bitterness value for each panel member from the expression:

$$\left(\frac{Y \times k}{X \times 0.1}\right)$$

Calculate the bitterness value of the sample to be examined as the average value for all panel members.

**01/2008:20816**

## 2.8.16. DRY RESIDUE OF EXTRACTS

In a flat-bottomed dish about 50 mm in diameter and about 30 mm in height, introduce rapidly 2.00 g or 2.0 mL of the extract to be examined. Evaporate to dryness on a water-bath and dry in an oven at 100-105 °C for 3 h. Allow to cool in a desiccator over *diphosphorus pentoxide R* or *anhydrous silica gel R* and weigh. Calculate the result as a mass percentage or in grams per litre.

**01/2008:20817**

## 2.8.17. LOSS ON DRYING OF EXTRACTS

In a flat-bottomed dish about 50 mm in diameter and about 30 mm in height, weigh rapidly 0.50 g of the extract to be examined, finely powdered. Dry in an oven at 100-105 °C for 3 h. Allow to cool in a desiccator over *diphosphorus pentoxide R* or *anhydrous silica gel R* and weigh. Calculate the result as a mass percentage.

**01/2008:20818**

## 2.8.18. DETERMINATION OF AFLATOXIN $B_1$ IN HERBAL DRUGS

*CAUTION: aflatoxins are very toxic and carcinogenic. Perform manipulations in a fume cupboard whenever possible. Take particular precautions, such as use of a glove box, when toxins are in dry form because of their electrostatic properties and the tendency to disperse through the working areas. Decontamination procedures for laboratory wastes of aflatoxins were developed by the International Agency for Research on Cancer (IARC).*

Aflatoxins are naturally occurring mycotoxins produced mainly by *Aspergillus flavus* and *Aspergillus parasiticus*. These fungi are common and widespread in nature and are most often found when certain grains are grown under conditions of stress such as drought. The mould occurs in soil, decaying vegetation, hay, and grains undergoing microbial spoilage, and invades all types of organic substrates whenever and wherever the conditions are favourable for its growth. Favourable conditions include high moisture content and high temperature. At least 13 different types of aflatoxin are produced in nature and most of these are known to be highly toxic and carcinogenic. Aflatoxin $B_1$ is considered the most toxic. Herbal drugs that are subject to contamination by aflatoxins are tested by a validated method.

Unless otherwise indicated in the monograph, herbal drugs contain not more than 2 µg/kg of aflatoxin $B_1$. The competent authority may also require compliance with a limit of 4 µg/kg for the sum of aflatoxins $B_1$, $B_2$, $G_1$ and $G_2$.

The method described below is cited as an example of a method that has been shown to be suitable for devil's claw root, ginger and senna pods. Its suitability for other herbal drugs must be demonstrated or another validated method used.

METHOD

Liquid chromatography (*2.2.29*).

*Aflatoxins are subject to light degradation. Carry out the determination protected from daylight by using UV-absorbing foil on windows in combination with subdued light, or curtains or blinds in combination with artificial light (fluorescent tubes are acceptable). Protect aflatoxin-containing solutions from daylight.*

Rinse glassware before use with a 10 per cent *V/V* solution of *sulfuric acid R* and then rinse carefully with *distilled water R* until no more acid is present.

*Test solution.* Use an immunoaffinity column containing antibodies against aflatoxin $B_1$ with a capacity of not less than 100 ng of aflatoxin $B_1$ and which gives a recovery of not less than 80 per cent when a solution of 5 ng of aflatoxin $B_1$ in a mixture of 12.5 mL of *methanol R* and 87.5 mL of *water R* is passed through. Allow the immunoaffinity column to reach

room temperature. To 5.00 g of the powdered drug (500) (*2.9.12*) add 100 mL of a mixture of 30 volumes of *water R* and 70 volumes of *methanol R* and extract by sonication for 30 min. Filter through folded filter paper. Pipette 10.0 mL of the clear filtrate into a 150 mL conical flask. Add 70 mL of *water R*. Pass 40 mL through the immunoaffinity column at a flow rate of 3 mL/min (not exceeding 5 mL/min). Wash the column with 2 volumes, each of 10 mL, of *water R* at a flow rate not exceeding 5 mL/min and dry by applying a slight vacuum for 5-10 s or by passing air through the immunoaffinity column by means of a syringe for 10 s. Apply 0.5 mL of *methanol R* to the column and allow to pass through by gravity. Collect the eluate in a 5 mL volumetric flask. After 1 min, apply a 2nd portion of 0.5 mL of *methanol R*. After a further 1 min, apply a 3rd portion of 0.5 mL of *methanol R*. Collect most of the applied elution solvent by pressing air through or applying vacuum to the column. Dilute to 5 mL with *water R* and shake well. If the solution is clear it can be used directly for analysis. Otherwise, pass it through a disposable filter unit prior to injection. Use a disposable filter unit (e.g. 0.45 µm pore size polytetrafluoroethylene filter) that has been shown not to cause loss of aflatoxin by retention.

*Aflatoxin $B_1$ primary stock solution.* Dissolve *aflatoxin $B_1$ R* in a mixture of 2 volumes of *acetonitrile R* and 98 volumes of *toluene R* to give a 10 µg/mL solution. To determine the exact concentration of aflatoxin $B_1$ in the stock solution, record the absorption curve (*2.2.25*) between 330 nm and 370 nm in quartz cells.

Calculate the aflatoxin $B_1$ mass concentration, in micrograms per millilitre, using the following expression:

$$\frac{A \times M \times 100}{\varepsilon \times l}$$

$A$ = absorbance determined at the maximum of the absorption curve;

$M$ = molar mass of aflatoxin $B_1$ (312 g/mol);

$\varepsilon$ = molar absorptivity of aflatoxin $B_1$ in the toluene-acetonitrile mixture (1930 $m^2$/mol);

$l$ = optical path length of the cell (1 cm).

*Aflatoxin $B_1$ secondary stock solution.* Prepare a secondary stock solution containing 100 ng/mL aflatoxin $B_1$ by diluting aflatoxin $B_1$ primary stock solution with a mixture of 2 volumes of *acetonitrile R* and 98 volumes of *toluene R*. Wrap the flask tightly in aluminium foil and store it below 4 °C. Before use, do not remove the aluminium foil until the contents have reached room temperature. If the solution has to be stored for a long period (for example, 1 month), weigh the flask and record the mass before and after each use of the solution.

*Aflatoxin $B_1$ standard solutions.* Place the volumes of aflatoxin secondary stock solution indicated in Table 2.8.18.-1 in separate 250 mL volumetric flasks. Pass a stream of nitrogen through at room temperature until the solvent has just evaporated. To each flask, add 75 mL of *methanol R*, allow the aflatoxin $B_1$ to dissolve and dilute to 250 mL with *water R*.

Table 2.8.18.-1. – *Aflatoxin $B_1$ standard solutions*

| Standard solution | Volume of secondary stock solution (µL) | Final concentration of standard solution (ng/mL) |
|---|---|---|
| 1 | 125 | 0.05 |
| 2 | 250 | 0.1 |
| 3 | 500 | 0.2 |
| 4 | 750 | 0.3 |
| 5 | 1000 | 0.4 |

*Calibration curve.* Prepare the calibration curve using aflatoxin $B_1$ standard solutions 1 to 5, which cover a range equivalent to 1-8 µg/kg of aflatoxin $B_1$ in the herbal drug. Check the plot for linearity. If the content of aflatoxin $B_1$ in the sample to be examined is outside of the calibration range, the test solution must be diluted to an aflatoxin content that is appropriate for the established calibration curve.

*Column*:

- *size*: $l$ = 0.25 m, Ø = 4.6 mm;
- *stationary phase*: *octadecylsilyl silica gel for chromatography R* (5 µm).

*Mobile phase*:

- *mobile phase A* (for post-column derivatisation with photochemical reactor or pyridinium bromide): *acetonitrile R*, *methanol R*, *water R* (2:3:6 *V/V/V*);
- *mobile phase B* (for post-column derivatisation with electrochemically derived bromine): add 0.12 g of *potassium bromide R* and 350 µL of *dilute nitric acid R1* per litre of mobile phase A.

*Flow rate*: 1 mL/min.

*Detection*: fluorescence detector with a 360 nm excitation filter and a 420 nm cut-off emission filter, or equivalent. Recommended settings for adjustable detectors are 365 nm (excitation wavelength) and 435 nm (emission wavelength).

*Injection*: 500 µL.

*Post-column derivatisation with pyridinium hydrobromide perbromide (PBPB)*:

- pulseless pump;
- T-piece with zero dead volume;
- polytetrafluoroethylene reaction tube, $l$ = 0.45 m, Ø = 0.5 mm;
- mobile phase A;
- post-column derivatisation reagent: dissolve 50 mg of *pyridinium hydrobromide perbromide R* in 1000 mL of *water R* (store protected from light and use within 4 days);
- flow rate of the derivatisation reagent: 0.4 mL/min.

*Post-column derivatisation with photochemical reactor (PHRED)*

- reactor unit with one 254 nm low pressure mercury UV bulb (minimum 8 W);
- polished support plate;
- knitted reactor coil: polytetrafluoroethylene tubing knitted tightly around the UV bulb, $l$ = 25 m, Ø = 0.25 mm, nominal void volume 1.25 mL;
- exposure time: 2 min;
- mobile phase A.

*Post-column derivatisation with electrochemically generated bromine (KOBRA)*:

- KOBRA-cell: electrochemical cell that generates a reactive form of bromine for derivatisation of aflatoxins, resulting in enhanced fluorescence; available from various commercial suppliers;
- Derivation direct-current supply in series with the KOBRA-cell, providing a constant current of about 100 µA;
- polytetrafluoroethylene reaction tube, $l$ = 0.12 m, Ø = 0.25 mm;
- mobile phase B.

*Elution order*: aflatoxin $G_2$, aflatoxin $G_1$, aflatoxin $B_2$, aflatoxin $B_1$.

*Calculation*: calculate the calibration curve $y = ax + b$, with aflatoxin $B_1$ concentration (ng/mL) on the $x$-axis and the signal ($S$) on the $y$-axis. The aflatoxin $B_1$ concentration ($C$) in a measured solution is equal to $\frac{S-b}{a}$.

Calculate the aflatoxin $B_1$ content of the herbal drug, in nanograms per gram, using the following expression:

$$\frac{V_1 \times V_2 \times C}{m \times V_i}$$

$m$ = mass of the herbal drug taken for analysis, in grams;

$V_1$ = volume of the solvent used for extraction, in millilitres;

$V_i$ = aliquot taken for immunoaffinity clean-up, in millilitres;

$V_2$ = final volume of solution after elution from the immunoaffinity column and dilution, in millilitres;

$C$ = measured aflatoxin $B_1$ concentration of the test solution, in nanograms per millilitre.

The presence of aflatoxin $B_1$ may be confirmed by recording the chromatogram without post-column derivatisation, which leads to a large decrease (greater than 10-fold) in the response due to aflatoxin $B_1$.

01/2008:20820

# 2.8.20. HERBAL DRUGS: SAMPLING AND SAMPLE PREPARATION

In order to reduce the effect of sampling in qualitative and quantitative analysis, it is necessary to ensure that the composition of the sample used is representative of the batch of material being examined. The following procedures are the minimum considered applicable for herbal drugs. *NOTE: other procedures may be used if they can be demonstrated to produce representative batch samples.*

## BULK SAMPLE

Where external examination of containers, markings and labels of a batch indicate that it can be considered to be homogeneous, sample the number of randomly selected containers indicated below. Where a batch cannot be considered to be homogeneous, divide it into sub-batches that are as homogeneous as possible, then sample each sub-batch as a homogeneous batch using, as a minimum, the number of randomly selected containers indicated below.

| Number of containers in batch (*N*) | Number of containers to be sampled (*n*) |
|---|---|
| 1 - 3 | all |
| > 3 | $n^* = \sqrt{N} + 1$ |

* round *n* up to the next integer

Take one sample from each container to be sampled. The sample is taken from the upper, middle or lower section of the container, such that the samples taken are representative of different parts of the containers. In the case of large bales or bags, samples must be taken from a depth of at least 10 cm. The mass of the material taken from each container is such that the total mass of the bulk sample complies with the following values.

| Mass of herbal drug in the batch (kg) | Minimum mass of samples as a percentage of the mass of the batch of herbal drug |
|---|---|
| < 50 | 1.00* |
| 50 - 100 | 0.50 |
| > 100 - 250 | 0.25 |
| > 250 - 500 | 0.20 |
| > 500 - 1000 | 0.18 |
| > 1000 - 2500 | 0.15 |
| > 2500 - 5000 | 0.10 |
| > 5000 - 10 000 | 0.08 |
| > 10 000 - 25 000 | 0.05 |

NOTE: if the mass of the batch is greater than 25 000 kg, it is divided into sub-batches, and the procedure is applied to each sub-batch as though it were a homogeneous batch.

* subject to a minimum total mass of 125 g for the bulk sample; if this minimum requirement represents more than 10.0 per cent of the mass of herbal drug in the batch, the whole batch may be used as the sample.

Prepare the bulk sample by combining and thoroughly mixing the samples taken from each of the randomly selected containers (see Table 2.8.20.-1).

## TEST SAMPLE

Unless otherwise prescribed in the monograph, prepare the test sample as follows.

Reduce the size of the bulk sample by quartering (see Note below) or by any other method that produces a homogeneous sample, making sure that each retained portion remains representative of the whole, until the minimum retained quantity complies with the following conditions.

| Type of herbal drug | Minimum weight of test sample |
|---|---|
| Roots, rhizomes, bark, herbs | 500 g or mass of whole sample if bulk sample is less than 500 g |
| Leaves, flowers, seeds, fruits | 250 g or mass of whole sample if bulk sample is less than 250 g |
| Broken or fragmented drugs (where average mass of the pieces is less than 0.5 g) | 125 g |

*NOTE: quartering consists of placing the bulk sample, thoroughly mixed, as a level and square-shaped heap and dividing it diagonally into 4 equal parts. 2 opposite quarters are retained and carefully remixed. The process is repeated as necessary until the required minimum mass is obtained for the test sample.*

Mill the test sample in a single pass through a 1 mm screen or the screen size specified in the monograph. The use of a milling machine is recommended.

Pass the milled sample through a 1 mm standard sieve or the sieve specified in the monograph. The residue retained on the sieve must not be more than 10 per cent of the total mass of the milled sample, of which not more than 2 per cent of the total mass of the milled sample may be of a particle size greater than 1.5 mm or 1.5 times the specified particle size in the monograph. If these conditions are met, the sample and residue are to be well mixed to form the test sample for analysis.

In those cases where these requirements are not met, the test sample for analysis is composed of the 2 parts measured separately. Therefore, the quantity required for each analysis is derived by weighing proportional quantities of the powder and the residue.

*NOTE: for determination of microscopic characters, a portion of the milled test sample is re-milled through a 0.355 mm screen.*

Table 2.8.20.-1. – *Operation of the sampling procedure in order to obtain the prescribed bulk sample*

| Mass of herbal drug in container (kg) | 0.5 | | | 1 | | | 5 | | |
|---|---|---|---|---|---|---|---|---|---|
| Total mass of herbal drug in the batch (kg) | No. of containers in batch | No. of containers to be sampled | Total mass of samples (g) | No. of containers in batch | No. of containers to be sampled | Total mass of samples (g) | No. of containers in batch | No. of containers to be sampled | Total mass of samples (g) |
| 0.5 | 1 | 1 | 125 | – | – | – | – | – | – |
| 1 | 2 | 2 | 125 | 1 | 1 | 125 | – | – | – |

# 2.8.21. TEST FOR ARISTOLOCHIC ACIDS IN HERBAL DRUGS

*CAUTION: aristolochic acids are very toxic and carcinogenic. Perform manipulations in a fume cupboard whenever possible. Take particular precautions, such as use of a glove box, when the substance is in dry form because of its electrostatic properties and the tendency to disperse through the working areas.*

Methods A and B are intended to be cross-referenced in monographs on herbal drugs that, according to chemotaxonomic knowledge, are expected to be free from aristolochic acids, but that may be subject to adulteration or substitution with plant material containing aristolochic acids. Methods A and B are intended to be used in the screening of herbal drugs for aristolochic acids at the stated limits and will usually be complemented by macroscopic and/or microscopic tests to exclude plant material containing aristolochic acids.

Method C will not be used in specific monographs but is provided as a method to confirm the presence of aristolochic acid I at levels equal to or greater than 2 ppm. It may be applied if chromatographic data suggests the presence of aristolochic acid I.

These methods are not designed for inclusion as assay methods in monographs on those drugs that produce aristolochic acids as secondary metabolites; for these, a more sensitive, validated method is required.

METHOD A: SCREENING TEST FOR ARISTOLOCHIC ACIDS

Thin-layer chromatography (*2.2.27*).

*Solvent mixture*: *anhydrous formic acid R*, *water R*, *methanol R* (1:9:40 *V/V/V*).

*Test solution.* To 1.0 g of the powdered herbal drug (710) (*2.9.12*) add 10.0 mL of the solvent mixture, sonicate for 10 min and centrifuge.

*Reference solution (a).* Disperse an amount of *aristolochia HRS* corresponding to 0.10 mg of aristolochic acid I in 20.0 mL of the solvent mixture, sonicate for 10 min and centrifuge.

*Reference solution (b).* Dilute 1.0 mL of reference solution (a) to 25.0 mL with *methanol R*.

*Plate*: *TLC silica gel $F_{254}$ plate R* (2-10 µm).

*Mobile phase*: *anhydrous formic acid R*, *water R*, *ethyl acetate R*, *toluene R* (3:3:30:60 *V/V/V/V*); use the upper layer.

*Application*: 20 µL as bands of 8 mm.

*Development*: over a path of 6 cm.

*Drying*: in a current of cold air for 5 min.

*Detection*: spray with a 100 g/L solution of *stannous chloride R* in *dilute hydrochloric acid R* until the plate is slightly wet, heat at 100 °C for 1 min and examine in ultraviolet light at 365 nm.

*System suitability*:

– the chromatogram obtained with reference solution (a) shows 2 greenish-blue zones due to aristolochic acids I and II between $R_F$ = 0.35 and $R_F$ = 0.55, which may not be completely separated;

– the chromatogram obtained with reference solution (b) shows at least 1 of these zones (corresponding to 2 ppm of aristolochic acid I).

*Results*: in the chromatogram obtained with the test solution no zone is similar in position and fluorescence to any of the zones due to aristolochic acids in the chromatogram obtained with reference solution (a).

If the chromatogram obtained with the test solution shows any zones similar in position and fluorescence to any of the zones due to aristolochic acids I and II in the chromatogram obtained with reference solution (a), apply method B.

METHOD B: LIMIT TEST FOR ARISTOLOCHIC ACID I

Liquid chromatography (*2.2.29*).

*Solvent mixture*: *acetonitrile R*, *water R* (50:50 *V/V*).

*Test solution.* Weigh 2.0 g of the powdered herbal drug (710) (*2.9.12*) into a 250 mL, brown, screw-cap bottle and add 100.0 mL of the solvent mixture. Stir for 30 min at about 300 r/min and filter through a membrane filter (nominal pore size 0.45 µm).

*Reference solution (a).* Dissolve the contents of a vial of *aristolochic acid I CRS* in the solvent mixture to obtain a concentration of 0.04 µg/mL of aristolochic acid I.

*Reference solution (b).* Dissolve the contents of a vial of *aristolochic acid for system suitability CRS* (containing aristolochic acids I and II) in the solvent mixture and dilute to 20.0 mL with the solvent mixture.

*Column*:

– *size*: *l* = 0.15 m, Ø = 2.1 mm;
– *stationary phase*: *octadecylsilyl silica gel for chromatography R* (3.5 µm);
– *temperature*: 40 °C.

*Mobile phase*:

– *mobile phase A*: *trifluoroacetic acid R*, *water R* (0.1:99.9 *V/V*);
– *mobile phase B*: *trifluoroacetic acid R*, *acetonitrile R* (0.1:99.9 *V/V*);

| Time (min) | Mobile phase A (per cent *V/V*) | Mobile phase B (per cent *V/V*) |
|---|---|---|
| 0 - 25 | 85 → 35 | 15 → 65 |
| 25 - 30 | 35 → 0 | 65 → 100 |
| 30 - 31 | 0 → 85 | 100 → 15 |

*Flow rate*: 0.3 mL/min.

*Detection*: spectrophotometer at 390 nm.

*Injection*: 25 µL.

*System suitability*:

– *resolution*: minimum 3.0 between the peaks due to aristolochic acids I and II in the chromatogram obtained with reference solution (b);
– *signal-to-noise ratio*: minimum 10 for the peak due to aristolochic acid I in the chromatogram obtained with reference solution (a).

*Limit*:

– the sample complies with the test if the chromatogram obtained with the test solution shows no peak with the same retention time as the peak due to aristolochic acid I in the chromatogram obtained with reference solution (a) (2 ppm).

METHOD C: CONFIRMATORY TEST FOR ARISTOLOCHIC ACID I

Liquid chromatography (*2.2.29*) coupled with mass spectrometry (*2.2.43*).

*Solvent mixture*: *acetonitrile R*, *water R* (50:50 *V/V*).

*Test solution.* Weigh 2.0 g of the powdered herbal drug (710) (*2.9.12*) into a 250 mL, brown, screw-cap bottle and add 100.0 mL of the solvent mixture. Sonicate for 30 min and filter through a membrane filter (nominal pore size 0.45 µm).

*Reference solution (a).* Dissolve the contents of a vial of *aristolochic acid I CRS* in the solvent mixture to obtain a concentration of 0.04 µg/mL of aristolochic acid I.

*Reference solution (b).* Prepare a solution according to the instructions supplied with *aristolochic acid I CRS* to obtain a concentration of 0.45 µg of aristolochic acid I in 10.0 mL of the test solution.

*Column*:

– *size*: *l* = 0.15 m, Ø = 2.1 mm;
– *stationary phase*: *octadecylsilyl silica gel for chromatography R* (3.5 µm);
– *temperature*: 40 °C.

*Mobile phase*:

– *mobile phase A*: *anhydrous formic acid R*, 1 g/L solution of *ammonium acetate R* in *water R* (0.1:99.9 *V/V*);
– *mobile phase B*: *anhydrous formic acid R*, 1 g/L solution of *ammonium acetate R* in *methanol R* (0.1:99.9 *V/V*);

| Time (min) | Mobile phase A (per cent *V/V*) | Mobile phase B (per cent *V/V*) |
|---|---|---|
| 0 - 15 | 70 → 0 | 30 → 100 |
| 15 - 16 | 0 | 100 |
| 16 - 17 | 0 → 70 | 100 → 30 |

*Flow rate*: 0.4 mL/min.

*Injection*: 20 µL; inject reference solution (a) twice, the test solution twice, reference solution (a) twice, then reference solution (b) twice.

*Detection*: mass detector as described below under A or B. Adjust the flow rate, the temperature and the detector settings so as to comply with the system suitability criterion.

A. Ion-trap mass spectrometer equipped with an electrospray ionisation (ESI) interface and $MS^n$ analyser.

Set the mass spectrometer parameters for the $MS^3$ mode as follows:

| Mode | Parent (*m/z*) | Isolation width (*m/z*) | Relative collision energy (per cent) |
|---|---|---|---|
| $MS^2$ | 359 $[M + NH_4]^+$ | 2.0 | 30 |
| $MS^3$ | 298 | 2.0 | 35 |

– full scan of product ions: from *m/z* 80 to *m/z* 370;
– product ions to be monitored: *m/z* 252, *m/z* 268 and *m/z* 281.

*System suitability*:

– *signal-to-noise ratio*: minimum 100 for the monitored product ions in the chromatogram obtained with reference solution (a);
– *matrix interference test*: the average of the 2 ratios of reference solution (b) is inside the ± 40 per cent interval of the average of the 2 ratios of reference solution (a); otherwise it is necessary to adjust the detector settings.

*Results*: evaluate the average ratios (252/268 and 281/268) of the relative intensity of the 3 product ions of aristolochic acid I in the test solution; evaluate the average of the 2 ratios of the signals at the retention time of aristolochic acid I in reference solution (a); if the average of the 2 ratios of the test solution is within the ± 40 per cent interval of the average of the 2 ratios of reference solution (a), aristolochic acid I is present in the test solution.

B. Triple-quadrupole mass spectrometer equipped with an ESI interface and $MS^n$ analyser.

Set the mass spectrometer parameters for the $MS^2$ mode as follows:

- precursor ion: *m/z* 359 $[M + NH_4]^+$;
- product ions to be monitored: *m/z* 265, *m/z* 281 and *m/z* 296.

*System suitability*:

- *signal-to-noise ratio*: minimum 100 for the monitored product ions in the chromatogram obtained with reference solution (a);
- *matrix interference test*: the average of the 2 ratios of reference solution (b) is inside the ± 40 per cent interval of the average of the 2 ratios of reference solution (a); otherwise it is necessary to adjust the detector settings.

*Results*: evaluate the average ratios (265/281 and 296/281) of the relative intensity of the 3 product ions of aristolochic acid I in the test solution; evaluate the average of the 2 ratios of the signals at the retention time of aristolochic acid I in reference solution (a); if the average of the 2 ratios of the test solution is within the ± 40 per cent interval of the average of the 2 ratios of reference solution (a), aristolochic acid I is present in the test solution.

**01/2010:20822**

## 2.8.22. DETERMINATION OF OCHRATOXIN A IN HERBAL DRUGS

*CAUTION: ochratoxin A is nephrotoxic and nephrocarcinogenic. Perform manipulations in a fume cupboard. Take particular precautions, such as use of a glove box, when toxins are in dry form because of their electrostatic properties and the tendency to disperse through the working areas. Decontamination procedures for laboratory glassware containing ochratoxin A are necessary (see appendix).*

Herbal drugs that are subject to contamination by ochratoxin A are tested by a validated method.

The method described below is cited as an example of a method that has been shown to be suitable for liquorice extract and liquorice root. Its suitability for other herbal drugs must be demonstrated or another validated method used.

METHOD

Liquid chromatography (*2.2.29*).

Use brown glassware that is free from detergent residues. If necessary rinse glassware before use with a 10 per cent *V/V* solution of *sulfuric acid R* and then rinse carefully with *distilled water R* until no more acid is present.

*Solution A*. Mix 80 volumes of *water R*, previously adjusted to pH 2.3 with *anhydrous formic acid R*, and 20 volumes of *acetonitrile R*.

*Test solution*. Use an immunoaffinity column containing antibodies against ochratoxin A with a capacity of not less than 100 ng of ochratoxin A and which gives a recovery of not less than 70 per cent. Allow the immunoaffinity column to reach room temperature.

To 2.00 g of the powdered drug (250) (*2.9.12*) add 80 mL of a 30 g/L solution of *sodium hydrogen carbonate R* and extract by sonication for 30 min (change water of ultrasonic bath after 15 min). Cool to room temperature and dilute to 100.0 mL ($V_1$) with the same solution. Centrifuge. Mix thoroughly 5.0 mL ($V_i$) of the clear supernatant with 30 mL *buffer solution pH 7.4 R* and pass the whole solution through the immunoaffinity column at a flow rate of 3 mL/min (do not exceed 5 mL/min). Wash the column first with 10 mL *buffer solution pH 7.4 R* then with 2 quantities, each of 10 mL, of *water R* at a flow rate not exceeding 5 mL/min and dry by applying a slight vacuum for 5-10 s or by passing air through the immunoaffinity column by means of a syringe for 10 s. Apply 0.5 mL of *methanol R* to the column and allow to pass through by gravity.

Collect the eluate in a 4 mL glass vial. After 30 s, apply a 2nd quantity of 0.5 mL of *methanol R* and allow to pass through the column by gravity into the same glass vial. After a further 30 s, repeat with a 3rd portion of 0.5 mL of *methanol R*. Collect any solvent retained on the column by pressing air through or applying vacuum to the column. Evaporate the combined eluates completely to dryness using a thermal block with a nitrogen blanket (40 °C). Dissolve the residue in 0.5 mL ($V_2$) of solution A. If the solution is clear it can be used directly for analysis. Otherwise, pass it through a disposable filter unit prior to injection. Use a disposable filter unit (e.g. 0.45 µm pore size polytetrafluoroethylene filter) that has been shown not to cause loss of ochratoxin A by retention.

*Ochratoxin A primary stock solution*. Dilute 1.0 mL of *ochratoxin A solution R* to 100.0 mL with *methanol R* and shake thoroughly.

*Ochratoxin A secondary stock solution*. Dilute 10.0 mL of ochratoxin A primary stock solution to 100.0 mL with *methanol R* and shake thoroughly.

*Ochratoxin A standard solutions*. Place the volumes of ochratoxin A primary stock solution or ochratoxin A secondary stock solution indicated in Table 2.8.22.-1 into separate flasks and make up to 50.0 mL with solution A.

Table 2.8.22.-1. – *Ochratoxin A standard solutions*

| Standard solution | Volume of ochratoxin A primary stock solution (µL) | Final concentration of ochratoxin A in standard solution (ng/mL) |
|---|---|---|
| 1 | 5000 | 50 |
| 2 | 2500 | 25 |
| 3 | 1000 | 10 |
| 4 | 500 | 5 |
| 5 | 250 | 2.5 |
| **Standard solution** | **Volume of ochratoxin A secondary stock solution (µL)** | **Final concentration of ochratoxin A in standard solution (ng/mL)** |
| 6 | 500 | 0.5 |
| 7 | 100 | 0.1 |

*Calibration curve*. Prepare the calibration curve using ochratoxin A standard solutions 1 to 7, which cover a range equivalent to 0.5-250 µg/kg of ochratoxin A in the herbal drug. Check the plot for linearity. If the content of ochratoxin A in the sample to be examined is outside of the calibration range, the test solution must be diluted to an ochratoxin A content that is appropriate for the established calibration curve.

*Column*:

- *size*: *l* = 0.15 m, Ø = 4.6 mm;
- *stationary phase*: *octadecylsilyl silica gel for chromatography R* (5 µm);
- *temperature*: 45 °C.

*Mobile phase*:

- *mobile phase A*: *water R* adjusted to pH 2.3 with *phosphoric acid R*;
- *mobile phase B*: *acetonitrile R*;

| Time (min) | Mobile phase A (per cent *V/V*) | Mobile phase B (per cent *V/V*) |
|---|---|---|
| 0 - 30 | 80 → 40 | 20 → 60 |
| 30 - 35 | 40 → 20 | 60 → 80 |
| 35 - 37 | 20 | 80 |
| 37 - 40 | 20 → 80 | 80 → 20 |

*Flow rate*: 0.8 mL/min.

*Detection*: fluorescence detector; recommended settings for adjustable detectors are 330 nm (excitation wavelength) and 460 nm (emission wavelength).

*Injection*: 20 µL.

*Calculation*: calculate the calibration curve $y = ax + b$, with ochratoxin A concentration (in nanograms per millilitre) on the x-axis and the signal ($S$) on the y-axis. The ochratoxin A concentration ($C$) in a measured solution is equal to $\frac{S-b}{a}$.

Calculate the ochratoxin A content of the herbal drug, in nanograms per gram, using the following expression:

$$\frac{V_1 \times V_2 \times C}{m \times V_i}$$

$m$ = mass of the herbal drug used to prepare the test solution, in grams;

$V_1$ = volume of dilution, in millilitres;

$V_i$ = aliquot taken for immunoaffinity clean-up, in millilitres;

$V_2$ = volume in which the residue is taken up, in millilitres;

$C$ = measured ochratoxin A concentration of the test solution, in nanograms per millilitre.

## Appendix: Decontamination procedures for laboratory glassware

Rinse glassware with *methanol R* and decontaminate by immersion in *strong sodium hypochlorite solution R* for at least 2 h, then wash thoroughly with water.

**04/2010:20823**

# 2.8.23. MICROSCOPIC EXAMINATION OF HERBAL DRUGS

The microscopic examination of herbal drugs is carried out on the powdered drug (355) (*2.9.12*) unless otherwise prescribed in the monograph.

*Chloral hydrate solution R* is the most commonly prescribed reagent. However, certain features are not visible or not easily seen after mounting in this reagent. In this case, other reagents are used, for example, a 50 per cent *V/V* solution of *glycerol R*, which makes it possible to visualise starch granules. It may also be necessary to prescribe specific reagents in a monograph, for example: *lactic reagent R* which is used to show the presence of various features, 10 per cent *V/V* alcoholic solution of *phloroglucinol R* and *hydrochloric acid R*, which are used to identify the presence of lignin in cells or tissues, *ruthenium red solution R*, which is used to show the presence of mucilage in cells or *glycerol R* used to show the presence of starch and inulin.

Examination under polarised light (between crossed nicol prisms) is used to identify starch granules (black cross phenomenon), calcium oxalate crystals (refringence) or lignified structures.

MOUNTING IN CHLORAL HYDRATE SOLUTION

Place 2-3 drops of *chloral hydrate solution R* on a glass microscope slide. Disperse a very small quantity of the powdered drug in the liquid and cover the preparation with a cover slip. Heat the preparation very gently to boiling on a hot plate or a micro gas burner. Maintain gentle boiling for a short time. Make sure that the quantity of mounting fluid is sufficient. If necessary, add more fluid using a tapered glass pipette. Allow to cool and then examine under a microscope. Repeat the heating until the starch granules and the water-soluble contents of the cells are no longer visible. Examine under a microscope.

Chloral hydrate tends to crystallise as long needles. To avoid this, proceed as follows: after heating, remove the cover slip; to the preparation add 1 drop of a 10 per cent *V/V* mixture of *chloral hydrate solution R* in *glycerol R*; place a clean cover slip on the preparation; examine under a microscope.

MOUNTING IN A 50 PER CENT *V/V* SOLUTION OF GLYCEROL

Place 2 drops of a 50 per cent *V/V* solution of *glycerol R* on a glass microscope slide. Disperse a very small quantity of the powdered drug in the liquid and cover the preparation with a cover slip. Examine under a microscope.

MOUNTING IN A 10 PER CENT *V/V* ALCOHOLIC SOLUTION OF PHLOROGLUCINOL AND HYDROCHLORIC ACID

Place a very small quantity of the powdered drug on a glass microscope slide. Add 1-2 drops of a 10 per cent *V/V* alcoholic solution of *phloroglucinol R*. Mix and allow the solvent to evaporate almost completely. Add 1-2 drops of *hydrochloric acid R* and cover the preparation with a cover slip. Examine immediately under a microscope. The red colour indicates the presence of lignin.

MOUNTING IN LACTIC REAGENT

Place 2-3 drops of *lactic reagent R* on a glass microscope slide. Disperse a very small quantity of the powdered drug in the liquid and cover the preparation with a cover slip. Heat the preparation very gently to boiling. Maintain gentle boiling for a short time. Make sure that the quantity of mounting fluid is sufficient. If necessary, add more fluid using a tapered glass pipette. Allow to cool and then examine under a microscope. Lignified structures stain bright yellow; structures containing cellulose remain colourless. Starch granules stain more or less violet; certain secretions (e.g., essential oils, resins, oleoresins) stain orange and cork stains red.

MOUNTING IN RUTHENIUM RED SOLUTION

Place 2 drops of *ruthenium red solution R* on a glass microscope slide. Disperse a very small quantity of the powdered drug in the liquid and cover the preparation with a cover slip. After about 1 minute, allow a drop of *distilled water R* to be taken up between the slide and the cover slip. Examine under a microscope. The mucilage stains violet red.

**07/2019:20824**

# 2.8.24. FOAM INDEX

PRINCIPLE

The foam index is determined by measuring the height of the foam produced by the equivalent of 1 g of herbal drug or herbal drug preparation under the stated test conditions.

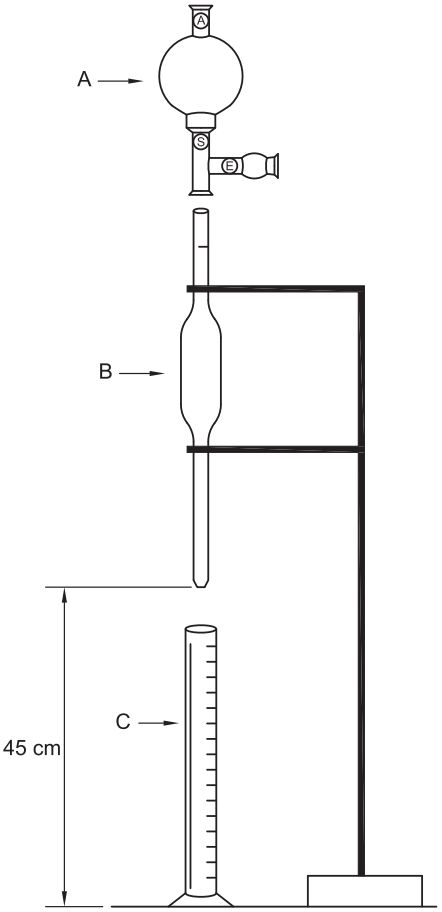
EQUIPMENT

The equipment (see Figure 2.8.24.-1) typically consists of:

- a pipette stand;
- a 50 mL class A pipette with a rubber filler bulb;
- a 250 mL glass measuring cylinder with 2 mL graduations and an internal diameter of 38 ± 3 mm.

Mount the pipette on its stand so that the tip will be located 45 cm from the base of the cylinder placed under it. Position the cylinder so that the pipette tip is aligned with its centre. Before performing the test, fill the pipette and cylinder with

water to check that the liquid dispensed from the pipette runs into the centre of the measuring cylinder. Mark the location of the measuring cylinder.



A. rubber pipette filler

B. 50 mL class A pipette

C. 250 mL glass measuring cylinder with 2 mL graduations and an internal diameter of 38 ± 3 mm

Figure 2.8.24.-1. – *Apparatus suitable for measuring the foam index*

PROCEDURE

**Preparation of the test solution**. Introduce the quantity of powdered herbal drug (355) (*2.9.12*) or herbal drug preparation prescribed in the monograph into a 250 mL beaker. Add 50 mL of *distilled water R* and allow to stand for 30 min, mixing 3-5 times with a spatula during this period to disperse the powder without producing any foam. Rinse the spatula and the internal walls of the beaker with a further 50 mL of *distilled water R* to ensure that as much of the herbal drug or herbal drug preparation as possible is contained within the liquid. Allow to stand undisturbed for 30 min. Filter through a filter paper 125 mm in diameter. Use the filtrate as the test solution.

**Method**. Mount the pipette on the stand. Take up 50.0 mL of the test solution using the pipette. Rinse the measuring cylinder with *water R* to wet its walls, then introduce the remaining 50.0 mL of test solution, taking care not to produce any foam. Position the measuring cylinder on its mark under the pipette. Open pipette filler valve E to allow the solution to run from the pipette into the measuring cylinder. Record the maximum height of the foam before it starts to collapse. Repeat the test twice, carefully rinsing the pipette and the measuring cylinder with *distilled water R* between tests.

**Results**. Determine the foam index ($I_F$) using the following equation:

$$I_F = \frac{H}{m}$$

$H$ = height of the resulting foam, in centimetres;

$m$ = mass of the herbal drug or herbal drug preparation used to prepare the test solution, in grams.

Record the average of 3 determinations as the result.

This result represents the height of the foam for a test solution with a theoretical concentration of 1 g in 100 mL.

**01/2020:20825**

# 2.8.25. HIGH-PERFORMANCE THIN-LAYER CHROMATOGRAPHY OF HERBAL DRUGS AND HERBAL DRUG PREPARATIONS

High-performance thin-layer chromatography (HPTLC) is used for qualitative analysis of herbal drugs and herbal drug preparations. It is a thin-layer chromatographic technique (*2.2.27*) that usually uses a glass plate coated with a uniform, porous layer (average pore size 6 nm), typically 200 µm thick, of irregular particles of silica gel between 2 µm and 10 µm in size and with an average size of 5 µm, a polymeric binder and a fluorescence indicator ($F_{254}$). The results are qualified using a system suitability test.

EQUIPMENT

The equipment used for qualitative HPTLC typically consists of:

- glass plates, as described above, usually 20 × 10 cm in size;
- devices suitable for the application of specified volumes of solutions as bands and allowing control of the dimensions and position of application;
- a device suitable for conditioning the stationary phase at the prescribed relative humidity;
- a suitable chromatographic tank (for example, a twin trough chamber);
- a device suitable for the reproducible drying of the developed plate;
- devices suitable for the application of reagents to, and heating of, the plate as part of the derivatisation procedure;
- a system suitable for the electronic documentation of chromatograms under 254 nm UV, 366 nm UV and white light.

*NOTE*: normal thin-layer chromatographic methods using glass plates or sheets coated with particles of 5-40 µm or HPTLC aluminium-backed sheets may be used, provided that the results obtained fulfil the general system suitability criteria that the bands develop perpendicular to the lower edge of the plate and the solvent front is parallel to the upper edge of the plate, and satisfy the system suitability test stated in the individual monograph.

METHOD

**Preparation of test solution**. The test solution is prescribed in the individual monograph and is usually prepared as follows.

For dry herbal drugs or dry herbal extracts, mix 0.5 g of the powdered herbal drug or 0.1 g of the dry herbal extract with 5.0 mL of *methanol R* and sonicate for 15 min; filter or centrifuge and use the filtrate or supernatant as the test solution.

For essential oils, dissolve 50 µL of the essential oil in 1.0 mL of *toluene R* and use this solution as the test solution.

**Preparation of reference solutions**. Reference solutions are prescribed in the individual monograph and are usually prepared as follows. Prepare a 1 mg/mL solution (identified as 'R' in the chromatograms associated with the monograph) of suitable reagent(s) or reference standard(s) in *methanol R* or, for essential oils, in *toluene R*. Prepare a second reference solution (diluted reference solution, identified as 'R1/4' in the chromatograms associated with the monograph) by mixing 1 volume of this solution and 3 volumes of the same solvent (in some cases a different diluted reference solution, e.g. 'R1/20', may be prescribed instead). Both solutions are used as intensity references.

**Intensity marker**. Use one or more of the substances in the reference solution and in the diluted reference solution as intensity marker(s) for the evaluation of the chromatogram.

**Preparation of system suitability test solution**. Prepare the system suitability test (SST) solution as stated in the individual monograph.

**Sample application and plate layout**. Samples are usually applied as narrow bands 8 mm in length at a distance of 8 mm from the lower edge of the plate. The centre of the first track, which is used for the system suitability test solution, is positioned 20 mm from the left edge of the plate. The minimum distance between tracks (centre to centre) is 11 mm. A maximum of 15 tracks are applied onto a standard plate. If no electronic solvent front detection device is used, the development distance is marked with a pencil close to the right or left edge of the plate.

**Conditioning of the plate**. Following sample application and unless otherwise stated in the individual monograph, expose the plate to air with a suitable relative humidity obtained using a saturated solution of *magnesium chloride R* (for example, by allowing the plate to stand in a closed chamber containing such a solution for 1 h or by using preconditioned air).

**Preparation of the tank and development of the plate**. Unless otherwise stated in the individual monograph, the chromatographic separation is performed in a saturated tank. Where a twin trough chamber is used, place a piece of filter paper in the rear trough. Load the tank with a sufficient quantity of mobile phase to wet the filter paper completely and achieve a level of 5 mm in both troughs. With the lid closed, leave the tank for 20 min for saturation. Introduce the plate in a vertical position into the front trough of the tank so that the coating layer faces the filter paper. When the mobile phase has reached the prescribed distance (usually 70 mm from the lower edge of the plate), remove the plate from the tank and dry in a vertical position in a stream of air at room temperature. Other tank configurations and development distances may be specified in an individual monograph.

*NOTE*: other tanks may be employed if the results obtained fulfil all of the system suitability criteria.

**Visualisation**. Chromatograms on the plate are visualised as stated in the individual monograph under Detection. Where derivatisation reagents are used, typically 3.5 mL of reagent solution is homogenously sprayed onto a plate of size 20 × 10 cm, or the plate is immersed into the reagent solution, typically at a speed of 5 mm/s for a dwell time of 1 s. Observation may be performed under 254 nm UV, 366 nm UV or white light prior to and/or after derivatisation. When pictures are digitally recorded, exposure time should be adjusted based on the track used for the system suitability test solution.

**System suitability test**. This test is based on the separation of 2 substances that have similar retardation factors ($R_F$ values) but that are barely separable under the specified chromatographic conditions (for example, chlorogenic acid and hyperoside in chromatographic systems used for flavonoids). The results for the test and reference solutions are only valid when the system suitability test solution satisfies the separation requirement stated in the individual monograph.

**Visual evaluation**. The chromatograms obtained with the test and reference solutions are compared with the descriptions in the results section of the individual monograph, with respect to zone position and colour, as well as intensity for the test solution. Zones of the test solution described as 'equivalent' or without an indication of intensity have intensities similar to the zone of the intensity marker in the reference solution (R). Zones described as 'intense' are visually more intense than the zone of the intensity marker in the reference solution; zones described as 'faint' are visually less intense than the zone of the intensity marker in the reference solution, but equal to or more intense than the zone of the intensity marker in the diluted reference solution (R1/4, R1/20, etc.); zones described as 'very faint' are visually less intense than the zone of the intensity marker in the diluted reference solution.

# 2.9. PHARMACEUTICAL TECHNICAL PROCEDURES

01/2020:20901

## 2.9.1. DISINTEGRATION OF TABLETS AND CAPSULES[(1)]

This test is provided to determine whether tablets or capsules disintegrate within the prescribed time when placed in a liquid medium under the experimental conditions presented below.

For the purposes of this test, disintegration does not imply complete dissolution of the unit or even of its active constituent. Complete disintegration is defined as that state in which any residue of the unit, except fragments of insoluble coating or capsule shell, remaining on the screen of the test apparatus or adhering to the lower surface of the discs, if used, is a soft mass having no palpably firm core.

♦Use apparatus A for tablets and capsules that are not greater than 18 mm long. For larger tablets or capsules use apparatus B.♦

TEST A - TABLETS AND CAPSULES OF NORMAL SIZE

**Apparatus**. The apparatus consists of a basket-rack assembly, a 1 L, low-form beaker, 149 ± 11 mm in height and having an inside diameter of 106 ± 9 mm for the immersion fluid, a thermostatic arrangement for heating the fluid between 35 °C and 39 °C, and a device for raising and lowering the basket in the immersion fluid at a constant frequency rate between 29 and 32 cycles per minute, through a distance of 55 ± 2 mm. The volume of the fluid in the vessel is such that at the highest point of the upward stroke the wire mesh remains at least 15 mm below the surface of the fluid, and descends to not less than 25 mm from the bottom of the vessel on the downward stroke. At no time should the top of the basket-rack assembly become submerged. The time required for the upward stroke is equal to the time required for the downward stroke, and the change in stroke direction is a smooth transition, rather than an abrupt reversal of motion. The basket-rack assembly moves vertically along its axis. There is no appreciable horizontal motion or movement of the axis from the vertical.

*Basket-rack assembly*. The basket-rack assembly consists of 6 open-ended transparent tubes, each 77.5 ± 2.5 mm long and having an inside diameter of 21.85 ± 1.15 mm and a wall 1.9 ± 0.9 mm thick; the tubes are held in a vertical position by 2 plates, each 90 ± 2 mm in diameter and 6.75 ± 1.75 mm in thickness, with 6 holes, each 24 ± 2 mm in diameter, equidistant from the centre of the plate and equally spaced from one another. Attached to the under surface of the lower plate is a woven stainless steel wire cloth, which has a plain square weave with 2.0 ± 0.2 mm mesh apertures and with a wire diameter of 0.615 ± 0.045 mm. The parts of the apparatus are assembled and rigidly held by means of 3 bolts passing through the 2 plates. A suitable means is provided to suspend the basket-rack assembly from the raising and lowering device using a point on its axis.

The design of the basket-rack assembly may be varied somewhat provided the specifications for the glass tubes and the screen mesh size are maintained. The basket-rack assembly conforms to the dimensions shown in Figure 2.9.1.-1.

*Discs*. The use of discs is permitted only where specified or allowed. Each tube is provided with a cylindrical disc 9.5 ± 0.15 mm thick and 20.7 ± 0.15 mm in diameter. The disc is made of a suitable, transparent plastic material having a specific gravity of 1.18-1.20. 5 parallel 2 ± 0.1 mm holes extend between the ends of the cylinder. One of the holes is centered on the cylindrical axis. The other holes are parallel to the cylindrical axis and centered 6 ± 0.2 mm from the axis on imaginary lines perpendicular to the axis and to each other, as defined in Figure 2.9.1.-1. 4 identical trapezoidal-shaped planes are cut into the wall of the cylinder, nearly perpendicular to the ends of the cylinder. The trapezoidal shape is symmetrical; its parallel sides coincide with the ends of the cylinder and are parallel to an imaginary line connecting the centres of 2 adjacent holes 6 mm from the cylindrical axis. The parallel side of the trapezoid on the bottom of the cylinder has a length of 1.6 ± 0.1 mm and its bottom edges lie at a depth of 1.5 mm to 1.8 mm from the cylinder's circumference. The parallel side of the trapezoid on the top of the cylinder has a length of 9.4 ± 0.2 mm and its centre lies at a depth of 2.6 ± 0.1 mm from the cylinder's circumference. All surfaces of the disc are smooth.

If the use of discs is specified, add a disc to each tube and operate the apparatus as directed under Procedure. The discs conform to the dimensions shown in Figure 2.9.1.-1.

The use of automatic detection employing modified discs is permitted where the use of discs is specified or allowed. Such discs must comply with the requirements of density and dimension given in this chapter.

**Procedure**. Place 1 dosage unit in each of the 6 tubes of the basket and, if prescribed, add a disc. Operate the apparatus using the specified medium, maintained at 37 ± 2 °C, as the immersion fluid. At the end of the specified time, lift the basket from the fluid and observe the dosage units: all of the dosage units have disintegrated completely. If 1 or 2 dosage units fail to disintegrate, repeat the test on 12 additional dosage units. The requirements of the test are met if not less than 16 of the 18 dosage units tested have disintegrated.

♦TEST B – LARGE TABLETS AND LARGE CAPSULES

**Apparatus**. The main part of the apparatus (Figure 2.9.1.-2.) is a rigid basket-rack assembly supporting 3 cylindrical transparent tubes 77.5 ± 2.5 mm long, 33.0 mm ± 0.5 mm in internal diameter, and with a wall thickness of 2.5 ± 0.5 mm. Each tube is provided with a cylindrical disc 31.4 ± 0.13 mm in diameter and 15.3 ± 0.15 mm thick, made of transparent plastic with a relative density of 1.18-1.20. Each disc is pierced by 7 holes, each 3.15 ± 0.1 mm in diameter, 1 in the centre and the other 6 spaced equally on a circle of radius 4.2 mm from the centre of the disc. The tubes are held vertically by 2 separate and superimposed rigid plastic plates 97 mm in diameter and 9 mm thick, with 3 holes. The holes are equidistant from the centre of the plate and equally spaced. Attached to the under side of the lower plate is a piece of woven gauze made from stainless steel wire 0.63 ± 0.03 mm in diameter and having mesh apertures of 2.0 ± 0.2 mm. The plates are held rigidly in position and 77.5 mm apart by vertical metal rods at the periphery. A metal rod is also fixed to the centre of the upper plate to enable the assembly to be attached to a mechanical device capable of raising and lowering it smoothly at a constant frequency of between 29 and 32 cycles per minute, through a distance of 55 ± 2 mm.

The assembly is suspended in the specified liquid medium in a suitable vessel, preferably a 1 L beaker. The volume of the liquid is such that when the assembly is in the highest position the wire mesh is at least 15 mm below the surface of the liquid, and when the assembly is in the lowest position the wire mesh is at least 25 mm above the bottom of the beaker and the upper open ends of the tubes remain above the surface of the liquid. A suitable device maintains the temperature of the liquid at 35-39 °C.

The design of the basket-rack assembly may be varied provided the specifications for the tubes and wire mesh are maintained.

(1) This chapter has undergone pharmacopoeial harmonisation. See chapter *5.8. Pharmacopoeial harmonisation*.

**Method**. Test 6 tablets or capsules either by using 2 basket-rack assemblies in parallel or by repeating the procedure. In each of the 3 tubes, place 1 tablet or capsule and, if prescribed, add a disc; suspend the assembly in the beaker containing the specified liquid. Operate the apparatus for the prescribed period, withdraw the assembly and examine the state of the tablets or capsules. To pass the test, all 6 of the tablets or capsules must have disintegrated. ♦

## 2.9.2. DISINTEGRATION OF SUPPOSITORIES AND PESSARIES

The disintegration test determines whether the suppositories or pessaries soften or disintegrate within the prescribed time when placed in a liquid medium in the experimental conditions described below.

Disintegration is considered to be achieved when:

a) dissolution is complete,

b) the components of the suppository or pessary have separated: melted fatty substances collect on the surface of the liquid, insoluble powders fall to the bottom and soluble components dissolve, depending on the type of preparation, the components may be distributed in one or more of these ways,

c) there is softening of the sample that may be accompanied by appreciable change of shape without complete separation of the components, the softening is such that the suppository or pessary no longer has a solid core offering resistance to pressure of a glass rod,

d) rupture of the gelatin shell of rectal or vaginal capsules occurs allowing release of the contents,

e) no residue remains on the perforated disc or if a residue remains, it consists only of a soft or frothy mass having no solid core offering resistance to pressure of a glass rod (vaginal tablets).

*Apparatus.* The apparatus (Figure 2.9.2.-1) consists of a sleeve of glass or suitable transparent plastic, of appropriate thickness, to the interior of which is attached by means of three hooks a metal device consisting of two perforated stainless metal discs each containing 39 holes 4 mm in diameter; the diameter of the discs is similar to that of the interior of the sleeve; the discs are about 30 mm apart. The test is carried out using three such apparatuses each containing a single sample. Each apparatus is placed in a beaker with a capacity of at least 4 L filled with water maintained at 36-37 °C, unless otherwise prescribed. The apparatuses may also be placed together in a

vessel with a capacity of at least 12 L. The beaker is fitted with a slow stirrer and a device that will hold the cylinders vertically not less than 90 mm below the surface of the water and allow them to be inverted without emerging from the water.

*Method.* Use three suppositories or pessaries. Place each one on the lower disc of a device, place the latter in the sleeve and secure. Invert the apparatuses every 10 min. Examine the samples after the period prescribed in the monograph. To pass the test all the samples must have disintegrated.

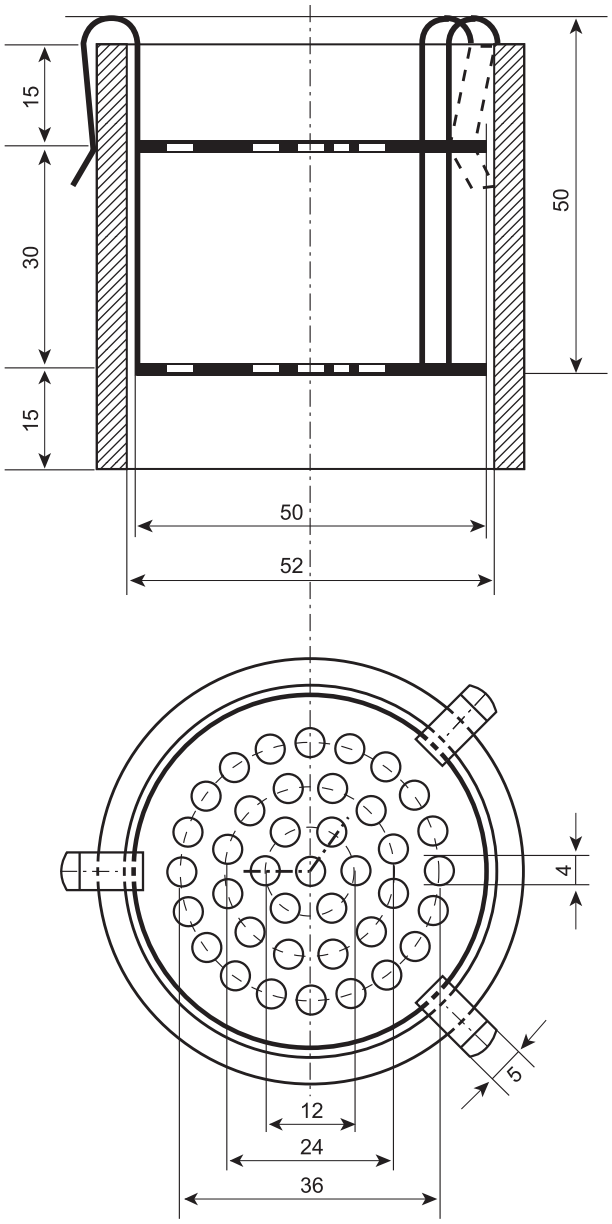

Figure 2.9.2.-1. – *Apparatus for disintegration of suppositories and pessaries*

*Dimensions in millimetres*

METHOD OF OPERATION FOR VAGINAL TABLETS

Use the apparatus described above, arranged so as to rest on the hooks (see Figure 2.9.2.-2). Place it in a beaker of suitable diameter containing water maintained at 36-37 °C with the level just below the upper perforated disc. Using a pipette, adjust the level with water at 36-37 °C until a uniform film covers the perforations of the disc. Use three vaginal tablets. Place each one on the upper plate of an apparatus and cover the latter with a glass plate to maintain appropriate conditions of humidity. Examine the state of the samples after the period prescribed in the monograph. To pass the test all the samples must have disintegrated.

## 2.9.3. DISSOLUTION TEST FOR SOLID DOSAGE FORMS[(2)]

This test is provided to determine compliance with the dissolution requirements for solid dosage forms administered orally. In this chapter, a dosage unit is defined as 1 tablet or 1 capsule or the amount specified.

APPARATUS

**Apparatus 1 (Basket apparatus).** The assembly consists of the following: a vessel, which may be covered, made of glass or other inert, transparent material[(3)]; a motor; a drive shaft; and a cylindrical basket (stirring element). The vessel is partially immersed in a suitable water-bath of any convenient size or heated by a suitable device such as a heating jacket. The water-bath or heating device permits maintaining the temperature inside the vessel at 37 ± 0.5 °C during the test and keeping the dissolution medium in constant, smooth motion. No part of the assembly, including the environment in which the assembly is placed, contributes significant motion, agitation, or vibration beyond that due to the smoothly rotating stirring element. Apparatus that permits observation of the preparation and stirring element during the test is preferable. The vessel is cylindrical, with a hemispherical bottom and a capacity of 1 L. Its height is 160-210 mm and its inside diameter is 98-106 mm. Its sides are flanged at the top. A fitted cover may be used to retard evaporation[(4)]. The shaft is positioned so that its axis is not more than 2 mm at any point from the vertical axis of the vessel and rotates smoothly and without significant wobble that could affect the results. A

(2) This chapter has undergone pharmacopoeial harmonisation. See chapter *5.8. Pharmacopoeial harmonisation.*
(3) The materials must not sorb, react, or interfere with the preparation to be tested.
(4) If a cover is used, it provides sufficient openings to allow ready insertion of the thermometer and withdrawal of samples.

speed-regulating device is used that allows the shaft rotation speed to be selected and maintained at a specified rate, within ± 4 per cent.

Shaft and basket components of the stirring element are fabricated of stainless steel, type 316 or equivalent, to the specifications shown in Figure 2.9.3.-1.

A basket having a gold coating of about 2.5 µm (0.0001 inch) thick may be used. The dosage unit is placed in a dry basket at the beginning of each test. The distance between the inside bottom of the vessel and the bottom of the basket is maintained at 25 ± 2 mm during the test.

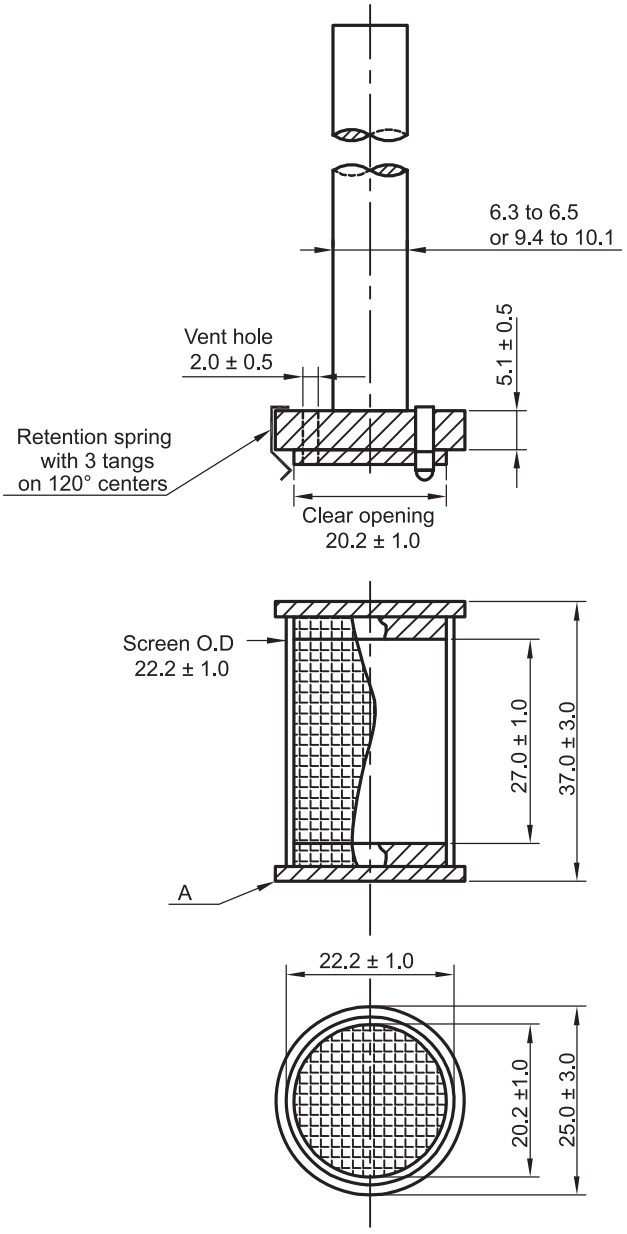
**Apparatus 2 (Paddle apparatus)**. Use the assembly from Apparatus 1, except that a paddle formed from a blade and a shaft is used as the stirring element. The shaft is positioned so that its axis is not more than 2 mm from the vertical axis of the vessel, at any point, and rotates smoothly without significant wobble that could affect the results. The vertical center line of the blade passes through the axis of the shaft so that the bottom of the blade is flush with the bottom of the shaft. The paddle conforms to the specifications shown in Figure 2.9.3.-2. The distance of 25 ± 2 mm between the bottom of the blade and the inside bottom of the vessel is maintained during the test. The metallic or suitably inert, rigid blade and shaft comprise a single entity. A suitable two-part detachable design may be used provided the assembly remains firmly engaged during the test. The paddle blade and shaft may be coated with a suitable coating so as to make them inert. The dosage unit is allowed to sink to the bottom of the vessel before rotation of the blade is started. A small, loose piece of non-reactive material, such as not more than a few turns of wire helix, may be attached to dosage units that would otherwise float. An alternative sinker device is shown in Figure 2.9.3.-3. Other validated sinker devices may be used.

**Apparatus 3 (Reciprocating cylinder)**. The assembly consists of a set of cylindrical, flat-bottomed glass vessels; a set of glass reciprocating cylinders; inert fittings (stainless steel type 316 or other suitable material) and screens that are made of suitable nonsorbing and nonreactive material, and that are designed to fit the tops and bottoms of the reciprocating cylinders; a motor and drive assembly to reciprocate the cylinders vertically inside the vessels, and if desired, index the reciprocating cylinders horizontally to a different row of vessels. The vessels are partially immersed in a suitable water-bath of any convenient size that permits holding the temperature at 37 ± 0.5 °C during the test. No part of the assembly, including the environment in which the assembly is placed, contributes significant motion, agitation, or vibration beyond that due to the smooth, vertically reciprocating cylinder. A device is used that allows the reciprocation rate to be selected and maintained at the specified dip rate, within ± 5 per cent. An apparatus that permits observation of the preparations and reciprocating cylinders is preferable. The vessels are provided with an evaporation cap that remains in place for the duration of the test. The components conform to the dimensions shown in Figure 2.9.3.-4 unless otherwise specified.

**Apparatus 4 (Flow-through cell)**. The assembly consists of a reservoir and a pump for the dissolution medium; a flow-through cell; a water-bath that maintains the dissolution medium at 37 ± 0.5 °C. Use the specified cell size.

The pump forces the dissolution medium upwards through the flow-through cell. The pump has a delivery range between 240 mL/h and 960 mL/h, with standard flow rates of 4 mL/min, 8 mL/min, and 16 mL/min. It must deliver a constant flow (± 5 per cent of the nominal flow rate); the flow profile is sinusoidal with a pulsation of 120 ± 10 pulses/min. A pump without pulsation may also be used. Dissolution test procedures using the flow-through cell must be characterised with respect to rate and any pulsation.

The flow-through cell (see Figures 2.9.3.-5 and 2.9.3.-6) of transparent and inert material is mounted vertically, with a filter system that prevents escape of undissolved particles from the top of the cell; standard cell diameters are 12 mm and 22.6 mm; the bottom cone is usually filled with small glass beads of about 1 mm diameter, with 1 bead of about 5 mm positioned at the apex to protect the fluid entry tube; a tablet holder (see Figures 2.9.3.-5 and 2.9.3.-6) is available for positioning of special dosage forms. The cell is immersed in a water-bath, and the temperature is maintained at 37 ± 0.5 °C.



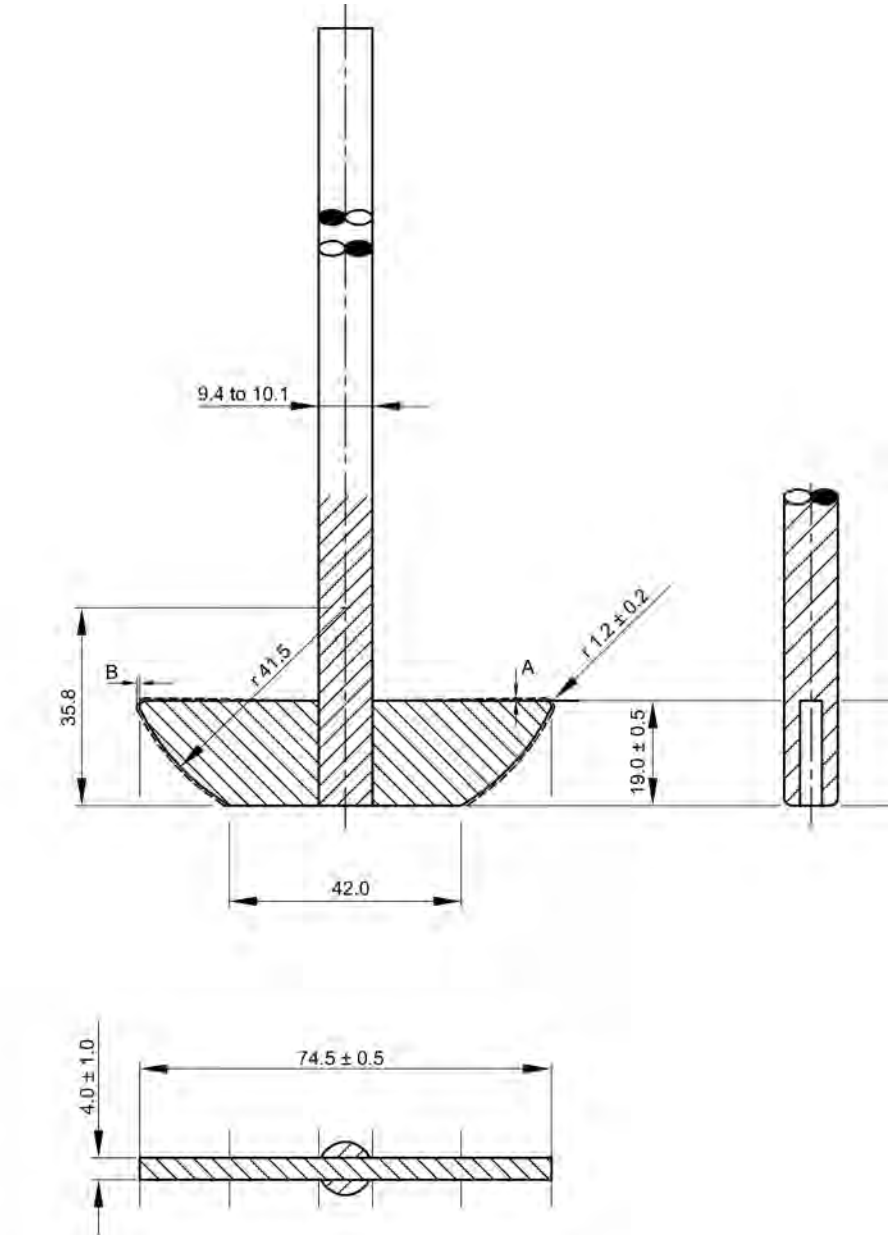
1) Screen with welded seam: 0.22-0.31 mm wire diameter with wire opening of 0.36-0.44 mm. After welding the screen may be slighty altered.

2) Maximum allowable runout at "A" is 1.0 mm when the part is rotated on center line axis with basket mounted.

Figure 2.9.3.-1. – *Apparatus 1, Basket stirring element*

*Dimensions in millimetres*

The apparatus uses a clamp mechanism and 2 O-rings for the fixation of the cell assembly. The pump is separated from the dissolution unit in order to shield the latter against any vibrations originating from the pump. The position of the pump must not be on a level higher than the reservoir flasks.



A and B dimensions do not vary more than 0.5 mm when part is rotated on center line axis. Tolerances are ± 1.0 mm unless otherwise stated.

Figure 2.9.3.-2. – *Apparatus 2, Paddle stirring element*
*Dimensions in millimetres*

Tube connections are as short as possible. Use suitably inert tubing, such as polytetrafluoroethylene, with a 1.6 mm inner diameter and inert flanged-end connections.

*Apparatus suitability.* The determination of suitability of the apparatus to perform dissolution testing must include conformance to the dimensions and tolerances of the apparatus as given above. In addition, critical test parameters that have to be monitored periodically during use include volume and temperature of the dissolution medium, rotation speed (Apparatus 1 and 2), dip rate (Apparatus 3), and flow rate of medium (Apparatus 4).

Determine the acceptable performance of the dissolution test assembly periodically.

PROCEDURE

*APPARATUS 1 AND 2*

**Conventional-release solid dosage forms**

*Procedure.* Place the stated volume of the dissolution medium (± 1 per cent) in the vessel of the specified apparatus. Assemble the apparatus, equilibrate the dissolution medium to 37 ± 0.5 °C, and remove the thermometer. ◊The test may also be carried out with the thermometer in place, provided it is shown that results equivalent to those obtained without the thermometer are obtained.◊

Place 1 dosage unit in the apparatus, taking care to exclude air bubbles from the surface of the dosage unit. Operate the apparatus at the specified rate. Within the time interval specified, or at each of the times stated, withdraw a specimen from a zone midway between the surface of the dissolution medium and the top of the rotating basket or blade, not less than 1 cm from the vessel wall. Where multiple sampling times are specified, replace the aliquots withdrawn for analysis with equal volumes of fresh dissolution medium at 37 °C or, where it can be shown that replacement of the medium is not necessary, correct for the volume change in the calculation. Keep the vessel covered for the duration of the test and verify

the temperature of the medium at suitable times. Perform the analysis using a suitable assay method[5]. Repeat the test with additional dosage units.

If automated equipment is used for sampling or the apparatus is otherwise modified, verification that the modified apparatus will produce results equivalent to those obtained with the apparatus described in this chapter, is necessary.

*Dissolution medium*. A suitable dissolution medium is used. The volume specified refers to measurements made between 20 °C and 25 °C. If the dissolution medium is a buffered solution, adjust the solution so that its pH is within 0.05 units of the specified pH. Dissolved gases can cause bubbles to form, which may change the results of the test. In such cases, dissolved gases must be removed prior to testing[6].

*Time*. Where a single time specification is given, the test may be concluded in a shorter period if the requirement for minimum amount dissolved is met. Samples are to be withdrawn only at the stated times, within a tolerance of ± 2 per cent.

**Prolonged-release solid dosage forms**

*Procedure*. Proceed as described for conventional-release dosage forms.

*Dissolution medium*. Proceed as described for conventional-release dosage forms.

*Time*. The test-time points, generally 3, are expressed in hours.

**Delayed-release solid dosage forms**

*Procedure*. Use Method A or Method B.

Method A

- *Acid stage*. Place 750 mL of *0.1 M hydrochloric acid* in the vessel, and assemble the apparatus. Allow the medium to equilibrate to a temperature of 37 ± 0.5 °C. Place 1 dosage unit in the apparatus, cover the vessel and operate the apparatus at the specified rate. After 2 h of operation in *0.1 M hydrochloric acid*, withdraw an aliquot of the fluid and proceed immediately as directed under Buffer stage. Perform an analysis of the aliquot using a suitable assay method.
- *Buffer stage*. Complete the operations of adding the buffer and adjusting the pH within 5 min. With the apparatus operating at the rate specified, add to the fluid in the vessel 250 mL of a 0.20 M solution of *trisodium phosphate dodecahydrate R* that has been equilibrated to 37 ± 0.5 °C. Adjust, if necessary, with *2 M hydrochloric acid R* or *2 M sodium hydroxide R* to a pH of 6.8 ± 0.05. Continue to operate the apparatus for 45 min, or for the specified time. At the end of the time period, withdraw an aliquot of the fluid and perform the analysis using a suitable assay method.

Method B

- *Acid Stage*. Place 1000 mL of *0.1 M hydrochloric acid* in the vessel and assemble the apparatus. Allow the medium to equilibrate to a temperature of 37 ± 0.5 °C. Place 1 dosage unit in the apparatus, cover the vessel, and operate the apparatus at the specified rate. After 2 h of operation in *0.1 M hydrochloric acid*, withdraw an aliquot of the fluid, and proceed immediately as directed under Buffer stage. Perform an analysis of the aliquot using a suitable assay method.
- *Buffer stage*. For this stage of the procedure use buffer that has previously been equilibrated to a temperature of 37 ± 0.5 °C. Drain the acid from the vessel and add 1000 mL of pH 6.8 phosphate buffer, prepared by mixing 3 volumes of *0.1 M hydrochloric acid* with 1 volume of a 0.20 M solution of *trisodium phosphate dodecahydrate R* and adjusting, if necessary, with *2 M hydrochloric acid R* or *2 M sodium hydroxide R* to a pH of 6.8 ± 0.05. This may also be accomplished by removing from the apparatus the vessel containing the acid and replacing it with another vessel, containing the buffer and transferring the dosage unit to the vessel containing the buffer. Continue to operate the apparatus for 45 min, or for the specified time. At the end of the time period, withdraw an aliquot of the fluid and perform the analysis using a suitable assay method.

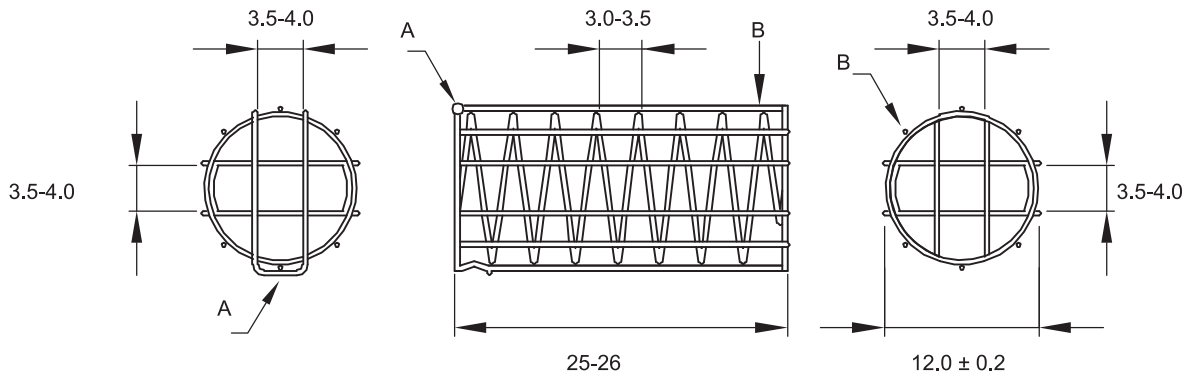
*Time*. All test times stated are to be observed within a tolerance of ± 2 per cent, unless otherwise specified.

*APPARATUS 3*

**Conventional-release solid dosage forms**

*Procedure*. Place the stated volume of the dissolution medium (± 1 per cent) in each vessel of the apparatus. Assemble the apparatus, equilibrate the dissolution medium to 37 ± 0.5 °C, and remove the thermometer. Place 1 dosage unit in each of the reciprocating cylinders, taking care to exclude air bubbles from the surface of each dosage unit, and immediately operate the apparatus as specified. During the upward and downward stroke, the reciprocating cylinder moves through a total distance of 9.9-10.1 cm. Within the time interval specified, or at each of the times stated, raise the reciprocating cylinders and withdraw a portion of the medium from a zone midway between the surface of the dissolution medium and the bottom of each vessel. Perform the analysis as directed. If necessary, repeat the test with additional dosage units.

Replace the aliquot withdrawn for analysis with equal volumes of fresh dissolution medium at 37 °C or, where it can be shown that replacement of the medium is not necessary, correct for the volume change in the calculation. Keep the vessel covered with the evaporation cap for the duration of the test and verify the temperature of the medium at suitable times.



A: acid-resistant wire clasp B: acid-resistant wire support

Figure 2.9.3.-3. – *Alternative sinker*
*Dimensions in millimetres*

(5) Test specimens are filtered immediately upon sampling unless filtration is demonstrated to be unnecessary. Use an inert filter that does not cause adsorption of the active substance or contain extractable substances that would interfere with the analysis.
(6) A method of deaeration is as follows: heat the medium, while stirring gently, to about 41 °C, immediately filter under vacuum using a filter having a porosity of 0.45 µm or less, with vigorous stirring, and continue stirring under vacuum for about 5 min. Other validated deaeration techniques for removal of dissolved gases may be used.

*Dissolution medium.* Proceed as described for conventional-release dosage forms under Apparatus 1 and 2.

*Time.* Proceed as described for conventional-release dosage forms under Apparatus 1 and 2.

**Prolonged-release dosage forms**

*Procedure.* Proceed as described for conventional-release dosage forms under Apparatus 3.

*Dissolution medium.* Proceed as described for prolonged-release dosage forms under Apparatus 1 and 2.

*Time.* Proceed as described for prolonged-release dosage forms under Apparatus 1 and 2.

**Delayed-release dosage forms**

*Procedure.* Proceed as described for delayed-release dosage forms, Method B, under Apparatus 1 and 2, using one row of vessels for the acid stage media and the following row of vessels for the buffer stage media, and using the volume of medium specified (usually 300 mL).

*Time.* Proceed as directed for delayed-release dosage forms under Apparatus 1 and 2.

*APPARATUS 4*

**Conventional-release dosage forms**

*Procedure.* Place the glass beads into the cell specified. Place 1 dosage unit on top of the beads or, if specified, on a wire carrier. Assemble the filter head and fix the parts together by means of a suitable clamping device. Introduce by the pump the dissolution medium warmed to 37 ± 0.5 °C through the bottom of the cell to obtain the flow rate specified and measured with an accuracy of 5 per cent. Collect the eluate by fractions at each of the times stated. Perform the analysis as directed. Repeat the test with additional dosage units.

*Dissolution medium.* Proceed as described for conventional-release dosage forms under Apparatus 1 and 2.

*Time.* Proceed as described for conventional-release dosage forms under Apparatus 1 and 2.

**Prolonged-release dosage forms**

*Procedure.* Proceed as described for conventional-release dosage forms under Apparatus 4.

*Dissolution medium.* Proceed as described for conventional-release dosage forms under Apparatus 4.

*Time.* Proceed as described for conventional-release dosage forms under Apparatus 4.

**Delayed-release dosage forms**

*Procedure.* Proceed as described for delayed-release dosage forms under Apparatus 1 and 2, using the specified media.

*Time.* Proceed as described for delayed-release dosage forms under Apparatus 1 and 2.

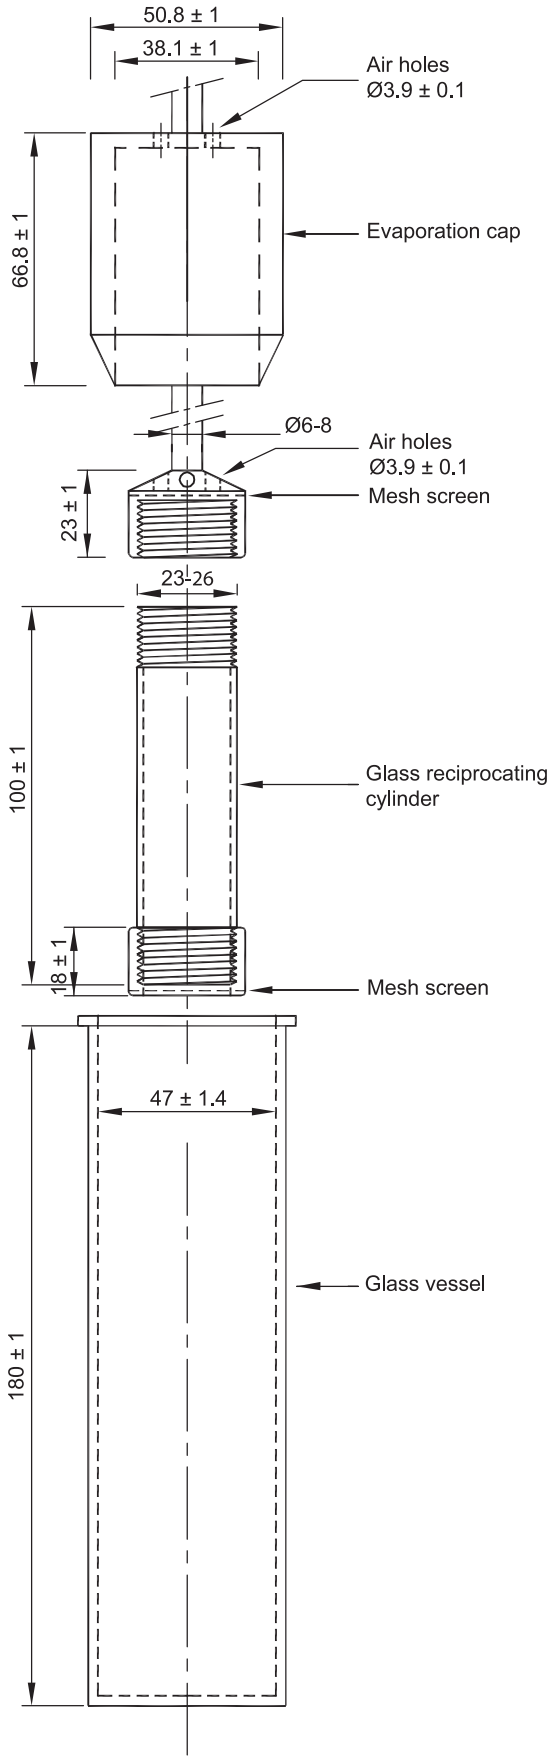


Figure 2.9.3.-4. – *Apparatus 3, glass vessel and reciprocating cylinder*
*Dimensions in millimetres*

INTERPRETATION

**Conventional-release solid dosage forms**

Unless otherwise specified, the requirements are met if the quantities of active substance dissolved from the dosage units tested conform to Table 2.9.3.-1. Continue testing through the 3 levels unless the results conform at either $S_1$ or $S_2$. The quantity $Q$, is the specified amount of dissolved active substance, expressed as a percentage of the labelled content; the 5 per cent, 15 per cent, and 25 per cent values in the Table are percentages of the labelled content so that these values and $Q$ are in the same terms.

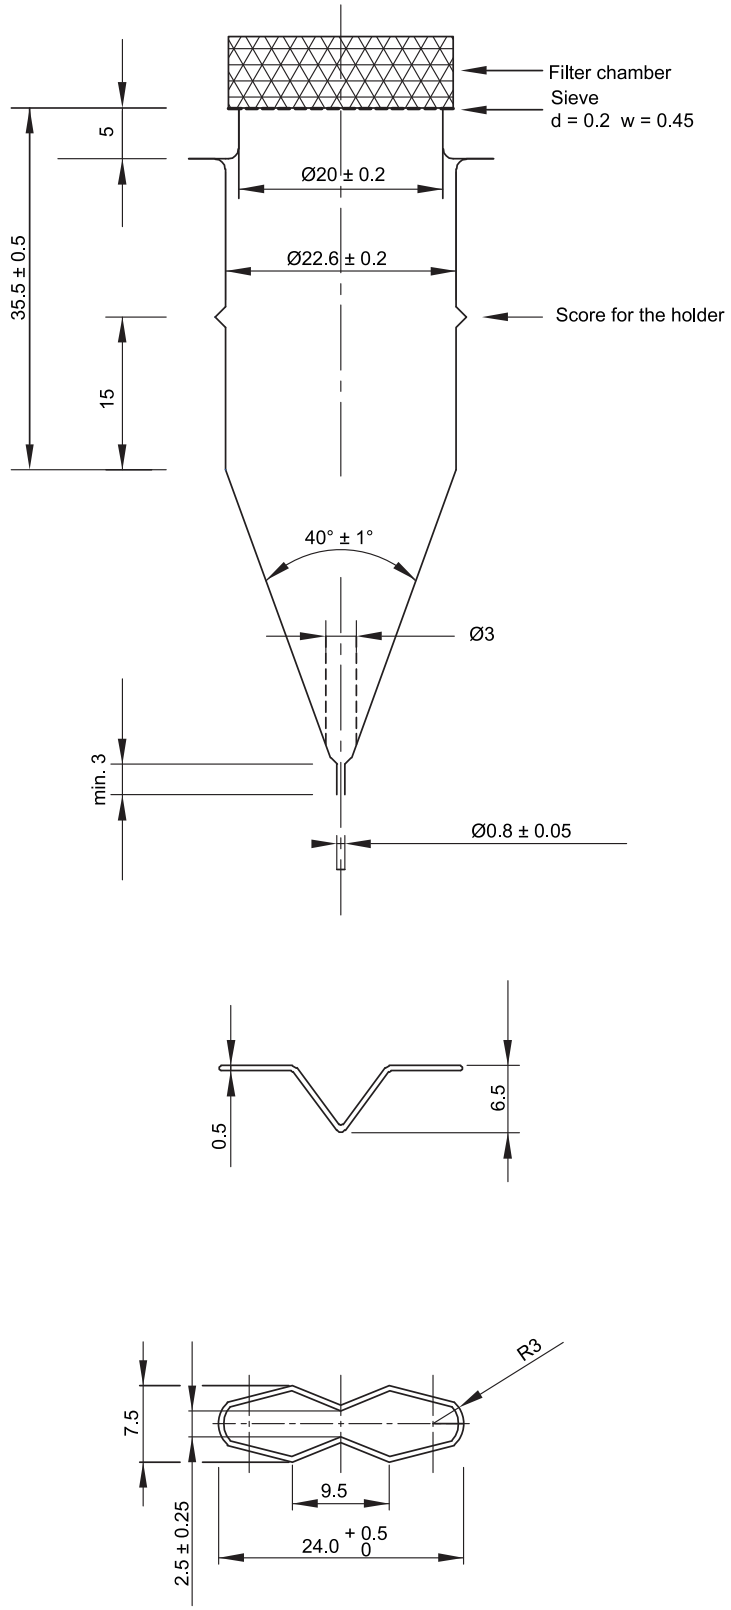

Figure 2.9.3.-5. – *Apparatus 4, large cell for tablets and capsules (top), tablet holder for the large cell (bottom)*

*Dimensions in millimetres unless otherwise specified*

Table 2.9.3.-1

| Level | Number tested | Acceptance criteria |
|---|---|---|
| $S_1$ | 6 | Each unit is not less than $Q$ + 5 per cent. |
| $S_2$ | 6 | Average of 12 units ($S_1$ + $S_2$) is equal to or greater than $Q$, and no unit is less than $Q$ − 15 per cent. |
| $S_3$ | 12 | Average of 24 units ($S_1$ + $S_2$ + $S_3$) is equal to or greater than $Q$, not more than 2 units are less than $Q$ − 15 per cent, and no is less than $Q$ − 25 per cent. |

**Prolonged-release dosage forms**

Unless otherwise specified, the requirements are met if the quantities of active substance dissolved from the dosage units tested conform to Table 2.9.3.-2. Continue testing through the 3 levels unless the results conform at either $L_1$ or $L_2$. Limits on the amounts of active substance dissolved are expressed in terms of the percentage of labelled content. The limits embrace each value of $Q_i$, the amount dissolved at each specified fractional dosing interval. Where more than one range is specified, the acceptance criteria apply individually to each range.

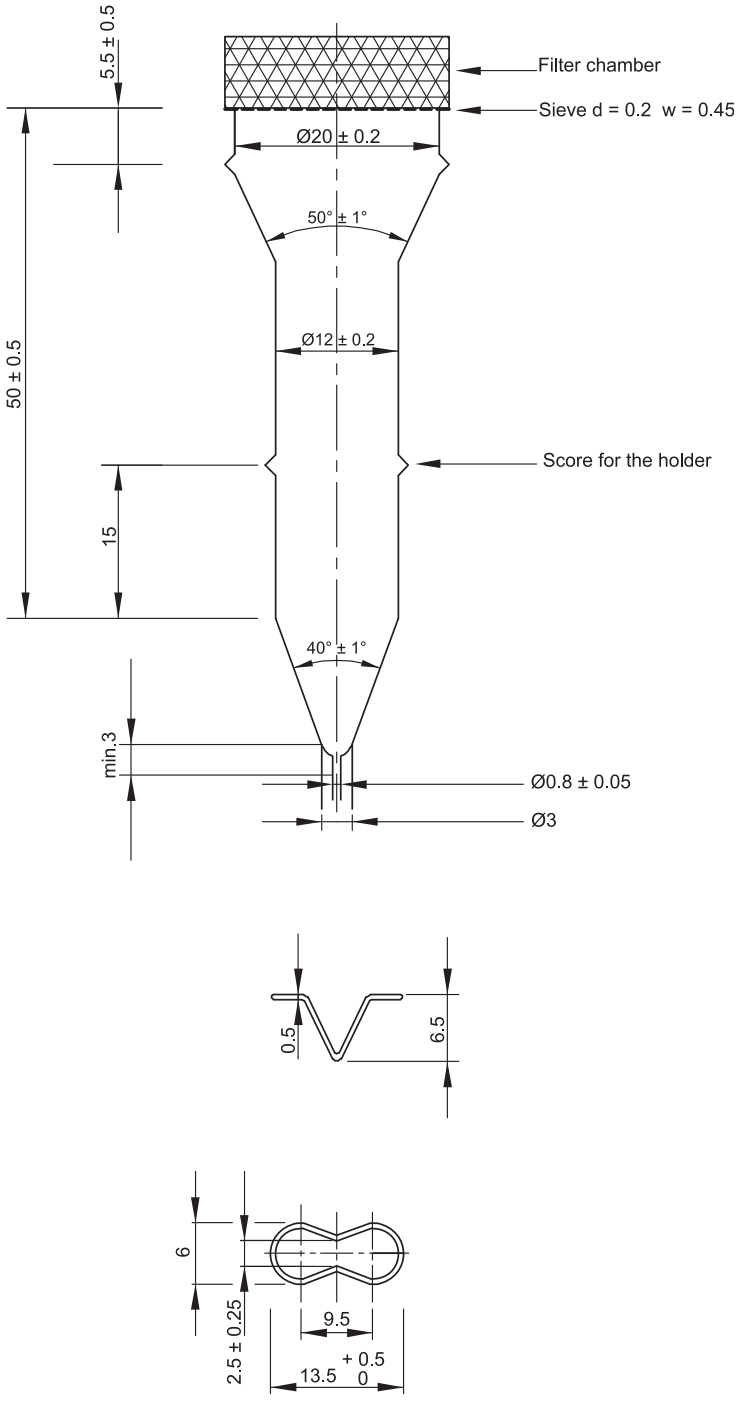

Figure 2.9.3.-6. – *Apparatus 4, small cell for tablets and capsules (top), tablet holder for the small cell (bottom)*

*Dimensions in millimetres unless otherwise specified*

Table 2.9.3.-2

| Level | Number tested | Acceptance criteria |
|---|---|---|
| $L_1$ | 6 | No individual value lies outside each of the stated ranges and no individual value is less than the stated amount at the final test time. |
| $L_2$ | 6 | The average value of the 12 units ($L_1 + L_2$) lies within each of the stated ranges and is not less than the stated amount at the final test time; none is more than 10 per cent of labelled content outside each of the stated ranges; and none is more than 10 per cent of labelled content below the stated amount at the final test time. |
| $L_3$ | 12 | The average value of the 24 units ($L_1 + L_2 + L_3$) lies within each of the stated ranges, and is not less than the stated amount at the final test time; not more than 2 of the 24 units are more than 10 per cent of labelled content outside each of the stated ranges; not more than 2 of the 24 units are more than 10 per cent of labelled content below the stated amount at the final test time; and none of the units is more than 20 per cent of labelled content outside each of the stated ranges or more than 20 per cent of labelled content below the stated amount at the final test time. |

**Delayed-release dosage forms**

*Acid stage.* Unless otherwise specified, the requirements of this portion of the test are met if the quantities, based on the percentage of the labelled content of active substance dissolved from the units tested conform to Table 2.9.3.-3. Continue testing through the 3 levels unless the results of both acid and buffer stages conform at an earlier level.

Table 2.9.3.-3

| Level | Number tested | Acceptance criteria |
|---|---|---|
| $A_1$ | 6 | No individual value exceeds 10 per cent dissolved. |
| $A_2$ | 6 | The average value of the 12 units ($A_1 + A_2$) is not more than 10 per cent dissolved, and no individual unit is greater than 25 per cent dissolved. |
| $A_3$ | 12 | The average value of the 24 units ($A_1 + A_2 + A_3$) is not more than 10 per cent dissolved, and no individual unit is greater than 25 per cent dissolved. |

*Buffer stage.* Unless otherwise specified, the requirements are met if the quantities of active substance dissolved from the units tested conform to Table 2.9.3.-4. Continue testing through the 3 levels unless the results of both stages conform at an earlier level. The value of *Q* in Table 2.9.3.-4 is 75 per cent dissolved unless otherwise specified. The quantity, *Q*, is the specified total amount of active substance dissolved in both the acid and buffer stages, expressed as a percentage of the labelled content. The 5 per cent, 15 per cent and 25 per cent values in the Table are percentages of the labelled content so that these values and *Q* are in the same terms.

Table 2.9.3.-4

| Level | Number tested | Acceptance criteria |
|---|---|---|
| $B_1$ | 6 | No unit is less than $Q$ + 5 per cent. |
| $B_2$ | 6 | The average value of the 12 units ($B_1 + B_2$) is equal to or greater than $Q$, and no unit is less than $Q$ − 15 per cent. |
| $B_3$ | 12 | The average value of the 24 units ($B_1 + B_2 + B_3$) is equal to or greater than $Q$, not more than 2 units are less than $Q$ − 15 per cent, and no unit is less than $Q$ − 25 per cent. |

*Recommendations on dissolution testing are given in general chapter 5.17.1.*

**01/2008:20904**

# 2.9.4. DISSOLUTION TEST FOR TRANSDERMAL PATCHES

This test is used to determine the dissolution rate of the active ingredients of transdermal patches.

1. DISK ASSEMBLY METHOD

**Equipment**. Use the paddle and vessel assembly from the paddle apparatus described in the dissolution test for solid oral dosage forms (*2.9.3*) with the addition of a stainless steel disk assembly (SSDA) in the form of a net with an aperture of 125 µm (see Figure 2.9.4.-1).

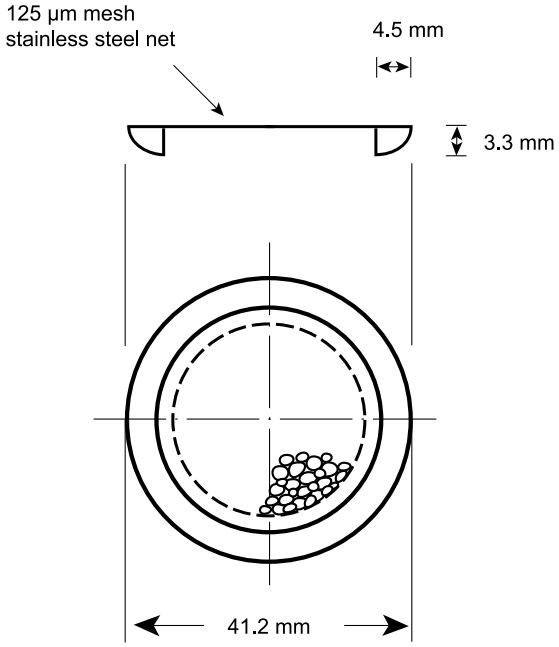

Figure 2.9.4.-1. – *Disk assembly*

The SSDA holds the system at the bottom of the vessel and is designed to minimise any dead volume between the SSDA and the bottom of the vessel. The SSDA holds the patch flat, with the release surface uppermost and parallel to the bottom of the paddle blade. A distance of 25 ± 2 mm between the bottom of the paddle blade and the surface of the SSDA is maintained during the test (see Figure 2.9.4.-2). The temperature is maintained at 32 ± 0.5 °C. The vessel may be covered during the test to minimise evaporation.

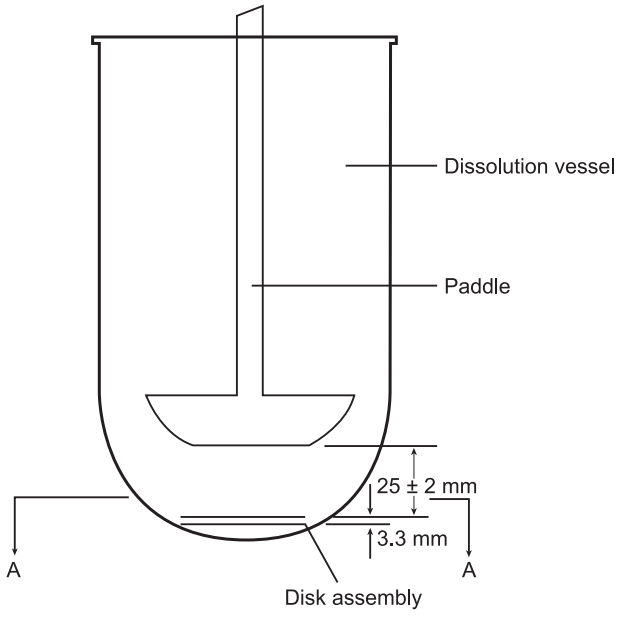

Figure 2.9.4.-2. – *Paddle and disk*

**Procedure**. Place the prescribed volume of the dissolution medium in the vessel and equilibrate the medium to the prescribed temperature. Apply the patch to the SSDA, ensuring that the release surface of the patch is as flat as possible. The patch may be attached to the SSDA by a

prescribed adhesive or by a strip of a double-sided adhesive tape. The adhesive or tape are previously tested for the absence of interference with the assay and of adsorption of the active ingredient(s). Press the patch, release surface facing up, onto the side of the SSDA made adhesive. The applied patch must not overlap the borders of the SSDA. For this purpose and provided that the preparation is homogeneous and uniformly spread on the outer covering, an appropriate and exactly measured piece of the patch may be cut and used for testing the dissolution rate. This procedure may also be necessary to achieve appropriate sink conditions. This procedure must not be applied to membrane-type patches. Place the patch mounted on the SSDA flat at the bottom of the vessel with the release surface facing upwards. Immediately rotate the paddle at 100 r/min, for example. At predetermined intervals, withdraw a sample from the zone midway between the surface of the dissolution medium and the top of the blade, not less than 1 cm from the vessel wall.

Perform the assay on each sample, correcting for any volume losses, as necessary. Repeat the test with additional patches.

2. CELL METHOD

**Equipment**. Use the paddle and vessel assembly from the paddle apparatus described in the dissolution test for solid oral dosage forms (*2.9.3*) with the addition of the extraction cell (*cell*).

The *cell* is made of chemically inert materials and consists of a *support*, a *cover* and, if necessary, a *membrane* placed on the patch to isolate it from the medium that may modify or adversely affect the physico-chemical properties of the patch (see Figure 2.9.4.-3).

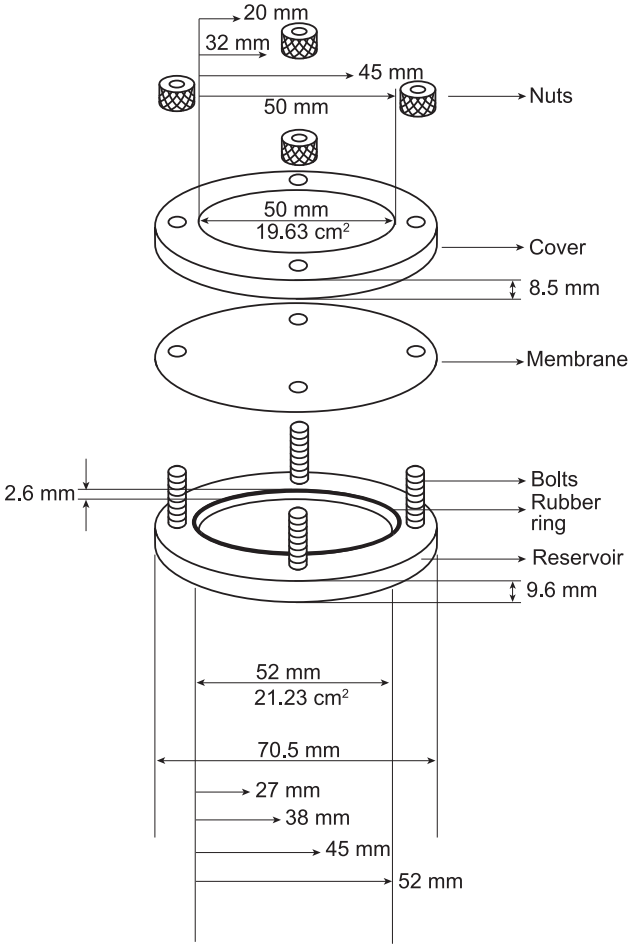

Figure 2.9.4.-3. – *Extraction cell*

*Support*. The central part of the support forms a cavity intended to hold the patch. The cavity has a depth of 2.6 mm and a diameter that is appropriate to the size of the patch to be examined. The following diameters can be used: 27 mm, 38 mm, 45 mm, 52 mm, corresponding to volumes of 1.48 mL, 2.94 mL, 4.13 mL, 5.52 mL, respectively.

*Cover*. The cover has a central opening with a diameter selected according to the size of the patch to be examined. The patch can thus be precisely centred, and its releasing surface limited. The following diameters may be used: 20 mm, 32 mm, 40 mm, 50 mm corresponding to areas of 3.14 $cm^2$, 8.03 $cm^2$, 12.56 $cm^2$, 19.63 $cm^2$, respectively. The cover is held in place by nuts screwed onto bolts projecting from the support. The cover is sealed to the support by a rubber ring set on the reservoir.

*Extraction cell*. The *cell* holds the patch flat, with the release surface uppermost and parallel to the bottom of the paddle blade. A distance of 25 ± 2 mm is maintained between the paddle blade and the surface of the patch (see Figure 2.9.4.-4). The temperature is maintained at 32 ± 0.5 °C. The vessel may be covered during the test to minimise evaporation.

**Procedure**. Place the prescribed volume of the dissolution medium in the vessel and equilibrate the medium to the prescribed temperature. Precisely centre the patch in the *cell* with the releasing surface uppermost. Close the *cell*, if necessary applying a hydrophobic substance (for example, petrolatum) to the flat surfaces to ensure the seal, and ensure that the patch stays in place. Introduce the cell flat into the bottom of the vessel with the cover facing upwards. Immediately rotate the paddle, at 100 r/min for example. At predetermined intervals, withdraw a sample from the zone midway between the surface of the dissolution medium and the top of the paddle blade, not less than 1 cm from the vessel wall.

Perform the assay on each sample, correcting for any volume losses, as necessary. Repeat the test with additional patches.

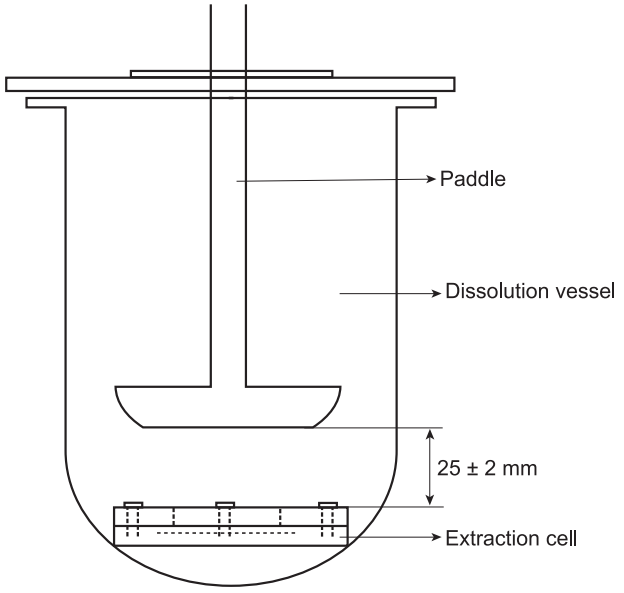

Figure 2.9.4.-4. – *Paddle over extraction cell*

3. ROTATING CYLINDER METHOD

**Equipment**. Use the assembly of the paddle apparatus described in the dissolution test for solid oral dosage forms (*2.9.3*). Replace the paddle and shaft with a stainless steel cylinder stirring element (*cylinder*) (see Figure 2.9.4.-5). The patch is placed on the *cylinder* at the beginning of each test. The distance between the inside bottom of the vessel and the *cylinder* is maintained at 25 ± 2 mm during the test. The temperature is maintained at 32 ± 0.5 °C. The vessel is covered during the test to minimise evaporation.

**Procedure**. Place the prescribed volume of the dissolution medium in the vessel and equilibrate the medium to the prescribed temperature. Remove the protective liner from

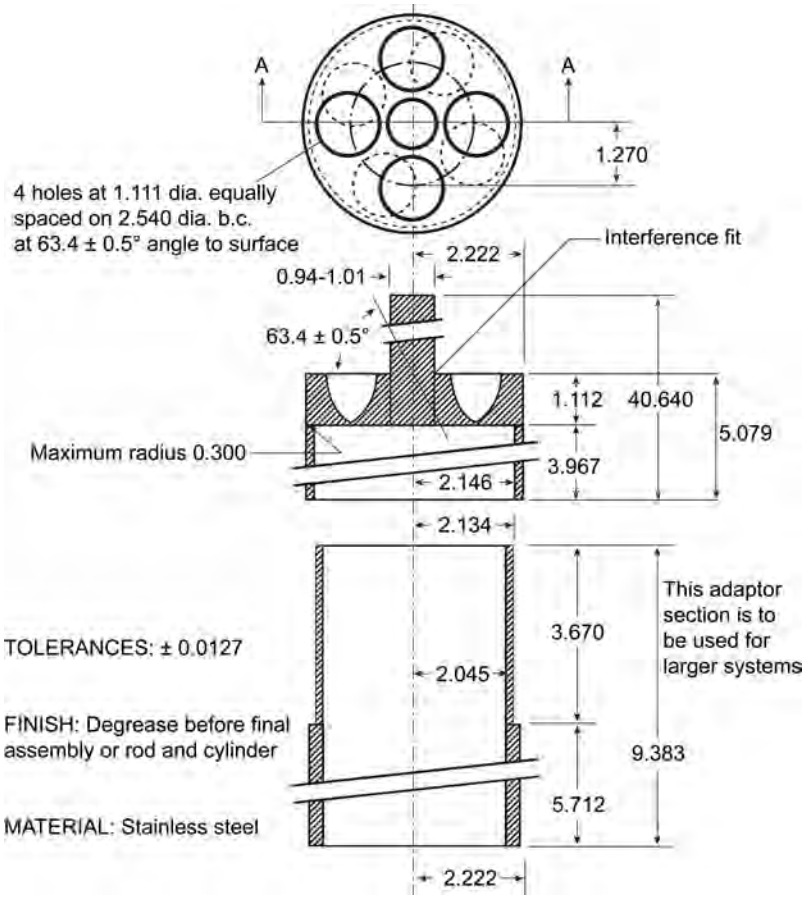

Figure 2.9.4.-5. – *Cylinder stirring element*

*Dimensions in centimetres*

the patch and place the adhesive side on a piece of suitable inert porous membrane that is at least 1 cm larger on all sides than the patch. Place the patch on a clean surface with the membrane in contact with this surface. Two systems for adhesion to the *cylinder* may be used:

– apply a suitable adhesive to the exposed membrane borders and, if necessary, to the back of the patch,

– apply a double-sided adhesive tape to the external wall of the *cylinder*.

Using gentle pressure, carefully apply the non-adhesive side of the patch to the *cylinder*, so that the release surface is in contact with the dissolution medium and the long axis of the patch fits around the circumference of the *cylinder*.

The system for adhesion used is previously tested for absence of interference with the assay and of adsorption of the active ingredient(s).

Place the *cylinder* in the apparatus, and immediately rotate the *cylinder* at 100 r/min, for example. At determined intervals, withdraw a sample of dissolution medium from a zone midway between the surface of the dissolution medium and the top of the rotating *cylinder*, and not less than 1 cm from the vessel wall.

Perform the assay on each sample as directed in the individual monograph, correcting for any volume withdrawn, as necessary. Repeat the test with additional patches.

**Interpretation**. The requirements are met if the quantity of active ingredient(s) released from the patch, expressed as the amount per surface area per time unit, is within the prescribed limits at the defined sampling times.

**01/2008:20905**

## 2.9.5. UNIFORMITY OF MASS OF SINGLE-DOSE PREPARATIONS

Weigh individually 20 units taken at random or, for single-dose preparations presented in individual containers, the contents of 20 units, and determine the average mass. Not more than 2 of the individual masses deviate from the average mass by more than the percentage deviation shown in Table 2.9.5.-1 and none deviates by more than twice that percentage.

For capsules and powders for parenteral administration, proceed as described below.

CAPSULES

Weigh an intact capsule. Open the capsule without losing any part of the shell and remove the contents as completely as possible. For soft shell capsules, wash the shell with a suitable solvent and allow to stand until the odour of the solvent is no longer perceptible. Weigh the shell. The mass of the contents is the difference between the weighings. Repeat the procedure with another 19 capsules.

Table 2.9.5.-1

| Pharmaceutical Form | Average Mass | Percentage deviation |
|---|---|---|
| Tablets (uncoated and film-coated) | 80 mg or less | 10 |
| | More than 80 mg and less than 250 mg | 7.5 |
| | 250 mg or more | 5 |
| Capsules, granules (uncoated, single-dose) and powders (single-dose) | Less than 300 mg | 10 |
| | 300 mg or more | 7.5 |
| Powders for parenteral administration* (single-dose) | More than 40 mg | 10 |
| Suppositories and pessaries | All masses | 5 |
| Powders for eye-drops and powders for eye lotions (single-dose) | Less than 300 mg | 10 |
| | 300 mg or more | 7.5 |

* When the average mass is equal to or below 40 mg, the preparation is not submitted to the test for uniformity of mass but to the test for uniformity of content of single-dose preparations (*2.9.6*).

POWDERS FOR PARENTERAL ADMINISTRATION

Remove any paper labels from a container and wash and dry the outside. Open the container and without delay weigh the container and its contents. Empty the container as completely as possible by gentle tapping, rinse it if necessary with *water R* and then with *alcohol R* and dry at 100-105 °C for 1 h, or, if the nature of the container precludes heating at this temperature, dry at a lower temperature to constant mass. Allow to cool in a desiccator and weigh. The mass of the contents is the difference between the weighings. Repeat the procedure with another 19 containers.

**01/2017:20906**

## 2.9.6. UNIFORMITY OF CONTENT OF SINGLE-DOSE PREPARATIONS

The test for uniformity of content of single-dose preparations is based on the assay of the individual contents of active substance(s) of a number of single-dose units to determine whether the individual contents are within limits set with reference to the average content of the sample.

The test is not required for multivitamin and trace-element preparations and in other justified and authorised circumstances.

*Method.* Using a suitable analytical method, determine the individual contents of active substance(s) of 10 dosage units taken at random.

Apply the criteria of test A, test B or test C as specified in the monograph for the dosage form in question.

TEST A

The preparation complies with the test if each individual content is between 85 per cent and 115 per cent of the average content. The preparation fails to comply with the test if more than one individual content is outside these limits or if one individual content is outside the limits of 75 per cent to 125 per cent of the average content.

If one individual content is outside the limits of 85 per cent to 115 per cent but within the limits of 75 per cent to 125 per cent, determine the individual contents of another 20 dosage units taken at random. The preparation complies with the test if not more than one of the individual contents of the 30 units is outside 85 per cent to 115 per cent of the average content and none is outside the limits of 75 per cent to 125 per cent of the average content.

TEST B

The preparation complies with the test if not more than one individual content is outside the limits of 85 per cent to 115 per cent of the average content and none is outside the limits of 75 per cent to 125 per cent of the average content. The preparation fails to comply with the test if more than 3 individual contents are outside the limits of 85 per cent to 115 per cent of the average content or if one or more individual contents are outside the limits of 75 per cent to 125 per cent of the average content.

If 2 or 3 individual contents are outside the limits of 85 per cent to 115 per cent but within the limits of 75 per cent to 125 per cent, determine the individual contents of another 20 dosage units taken at random. The preparation complies with the test if not more than 3 individual contents of the 30 units are outside the limits of 85 per cent to 115 per cent of the average content and none is outside the limits of 75 per cent to 125 per cent of the average content.

TEST C

The preparation complies with the test if the average content of the 10 dosage units is between 90 per cent and 110 per cent of the content stated on the label and if the individual content of each dosage unit is between 75 per cent and 125 per cent of the average content.

## 2.9.7. FRIABILITY OF UNCOATED TABLETS(7)

This chapter provides guidelines for the friability determination of compressed, uncoated tablets. The test procedure presented in this chapter is generally applicable to most compressed tablets. Measurement of tablet friability supplements other physical strength measurements, such as tablet breaking force.

Use a drum, with an internal diameter between 283-291 mm and a depth between 36-40 mm, of transparent synthetic polymer with polished internal surfaces, and subject to minimum static build-up (see Figure 2.9.7.-1.). One side of the drum is removable. The tablets are tumbled at each turn of the drum by a curved projection with an inside radius between 75.5-85.5 mm that extends from the middle of the drum to the outer wall. The outer diameter of the central ring is between 24.5-25.5 mm. The drum is attached to the horizontal axis of a device that rotates at 25 ± 1 r/min. Thus, at each turn the tablets roll or slide and fall onto the drum wall or onto each other.

For tablets with a unit mass equal to or less than 650 mg, take a sample of whole tablets corresponding as near as possible to 6.5 g. For tablets with a unit mass of more than 650 mg, take a sample of 10 whole tablets. The tablets are carefully dedusted prior to testing. Accurately weigh the tablet sample, and place the tablets in the drum. Rotate the drum 100 times, and remove the tablets. Remove any loose dust from the tablets as before, and accurately weigh.

Generally, the test is run once. If obviously cracked, cleaved, or broken tablets are present in the tablet sample after tumbling, the sample fails the test. If the results are difficult to interpret or if the weight loss is greater than the targeted value, the test is repeated twice and the mean of the 3 tests determined. A

(7) This chapter has undergone pharmacopoeial harmonisation. See chapter *5.8. Pharmacopoeial harmonisation.*

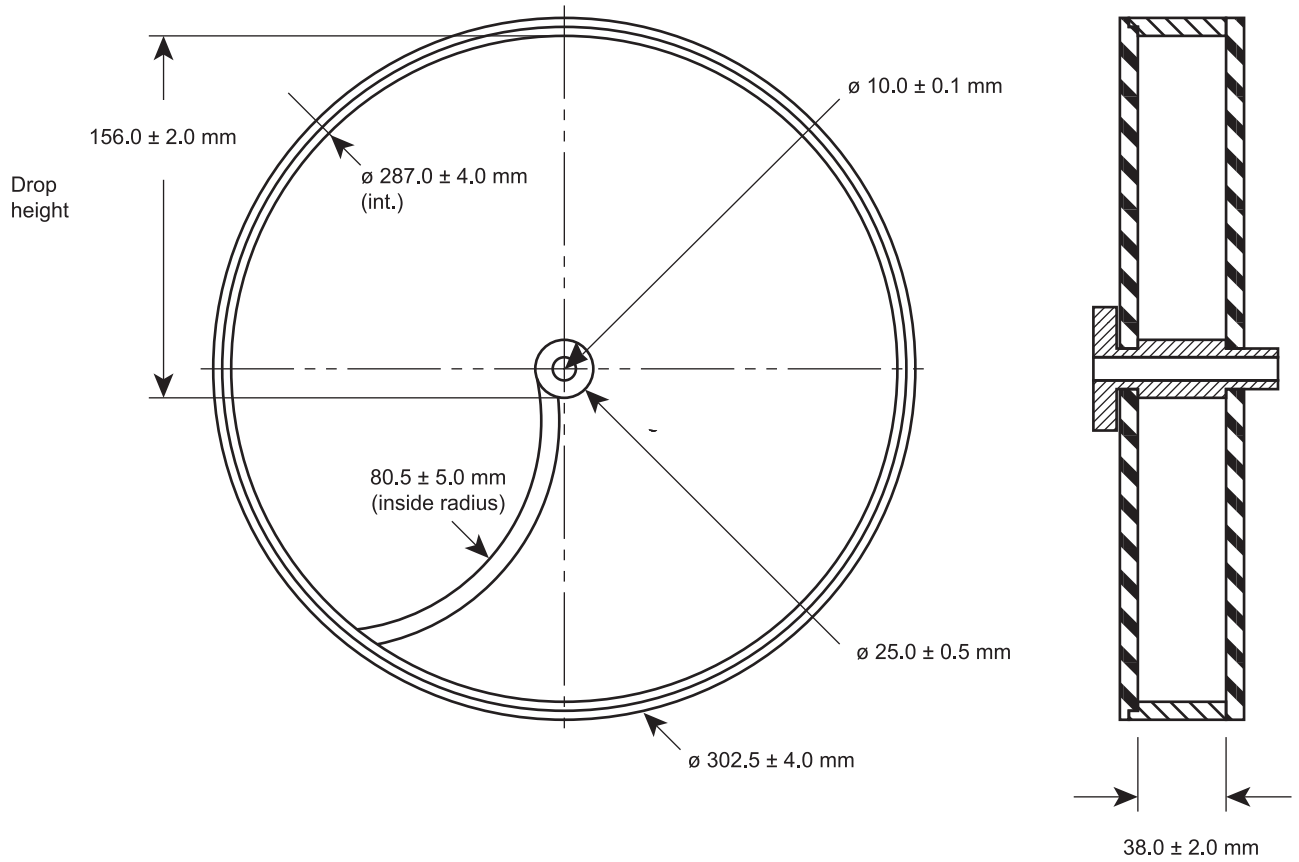

Figure 2.9.7.-1. – *Tablet friability apparatus*

maximum loss of mass (obtained from a single test or from the mean of 3 tests) not greater than 1.0 per cent is considered acceptable for most products.

If tablet size or shape causes irregular tumbling, adjust the drum base so that the base forms an angle of about 10° with the horizontal and the tablets no longer bind together when lying next to each other, which prevents them from falling freely.

Effervescent tablets and chewable tablets may have different specifications as far as friability is concerned. In the case of hygroscopic tablets, a humidity-controlled environment is required for testing.

A drum with dual scooping projections, or apparatus with more than one drum, for the running of multiple samples at one time, are also permitted.

**01/2008:20908**

## 2.9.8. RESISTANCE TO CRUSHING OF TABLETS

This test is intended to determine, under defined conditions, the resistance to crushing of tablets, measured by the force needed to disrupt them by crushing.

APPARATUS

The apparatus consists of 2 jaws facing each other, one of which moves towards the other. The flat surfaces of the jaws are perpendicular to the direction of movement. The crushing surfaces of the jaws are flat and larger than the zone of contact with the tablet. The apparatus is calibrated using a system with a precision of 1 newton.

OPERATING PROCEDURE

Place the tablet between the jaws, taking into account, where applicable, the shape, the break-mark and the inscription; for each measurement orient the tablet in the same way with respect to the direction of application of the force. Carry out the measurement on 10 tablets, taking care that all fragments of tablets have been removed before each determination.

*This procedure does not apply when fully automated equipment is used.*

EXPRESSION OF RESULTS

Express the results as the mean, minimum and maximum values of the forces measured, all expressed in newtons.

Indicate the type of apparatus and, where applicable, the orientation of the tablets.

**07/2008:20909**

## 2.9.9. MEASUREMENT OF CONSISTENCY BY PENETROMETRY

This test is intended to measure, under determined and validated conditions, the penetration of an object into the product to be examined in a container with a specified shape and size.

APPARATUS

The apparatus consists of a penetrometer made up of a stand and a penetrating object. A suitable apparatus is shown in Figure 2.9.9.-1.

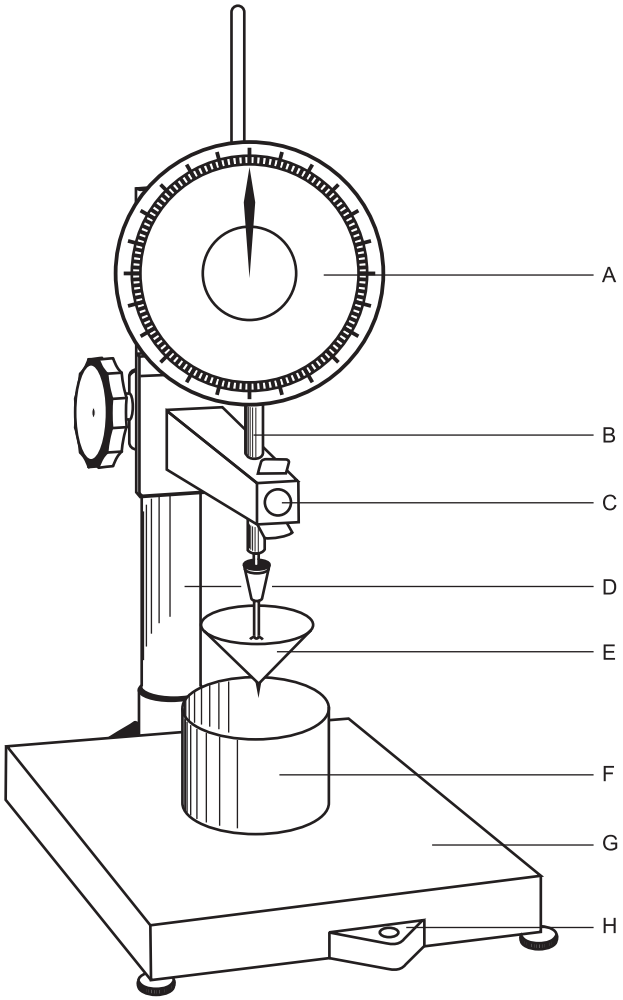

Figure 2.9.9.-1. – *Penetrometer*

A. Scale showing the depth of penetration, graduated in tenths of millimetres.
B. Vertical shaft to maintain and guide the penetrating object.
C. Device to retain and to release the penetrating object automatically and for a constant time.
D. Device to ensure that the penetrating object is vertical and that the base is horizontal.
E. Penetrating object (see Figures 2.9.9.-2 and 3).
F. Container.
G. Horizontal base.
H. Control for the horizontal base.

The stand is made up of:
- a vertical shaft to maintain and guide the penetrating object;
- a horizontal base;
- a device to ensure that the penetrating object is vertical;
- a device to check that the base is horizontal;
- a device to retain and release the penetrating object;
- a scale showing the depth of penetration, graduated in tenths of a millimetre.

The penetrating object, made of a suitable material, has a smooth surface, and is characterised by its shape, size and mass (*m*).

Suitable penetrating objects are shown in Figures 2.9.9.-2 and 2.9.9.-3.

PROCEDURE

Prepare the test samples according to one of the following procedures.

A. Carefully and completely fill 3 containers, without forming air bubbles. Level if necessary to obtain a flat surface. Store the samples at 25 ± 0.5 °C for 24 h, unless otherwise prescribed.
B. Store 3 samples at 25 ± 0.5 °C for 24 h, unless otherwise prescribed. Apply a suitable shear to the samples for 5 min. Carefully and completely fill 3 containers, without forming air bubbles, and level if necessary to obtain a flat surface.
C. Melt 3 samples and carefully and completely fill 3 containers, without forming air bubbles. Store the samples at 25 ± 0.5 °C for 24 h, unless otherwise prescribed.

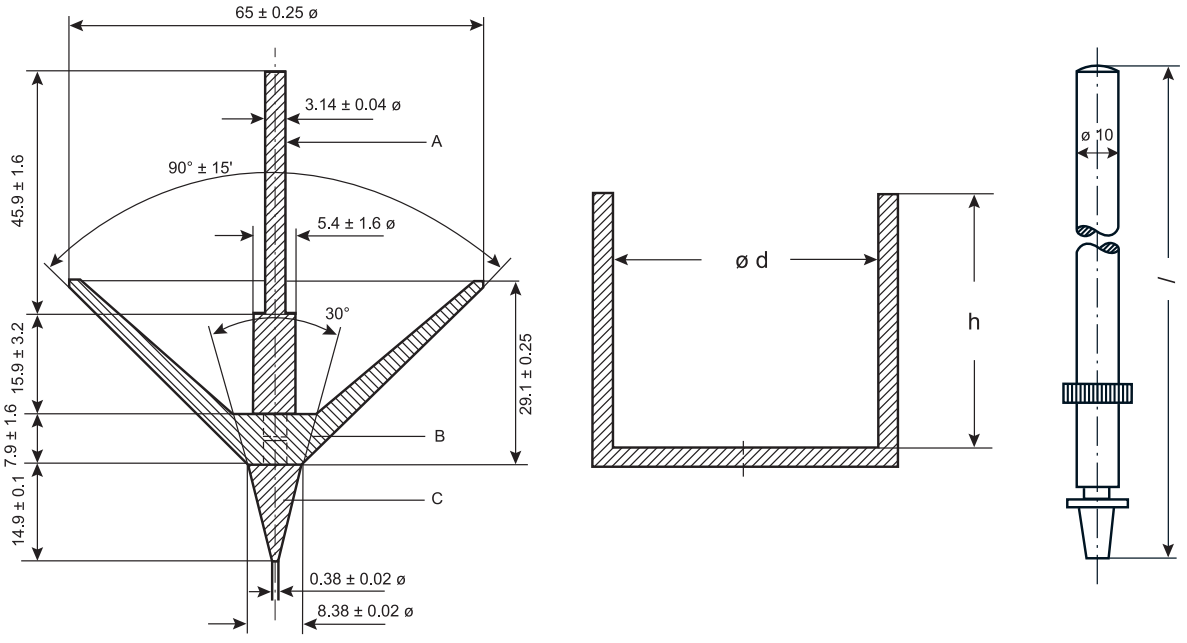

Figure 2.9.9.-2. – *Cone (m = 102.5 ± 0.05 g), suitable container (d = 102 mm or 75 mm; h ≥ 62 mm) and shaft (l = 162 mm; m = 47.5 ± 0.05 g).*
*Dimensions in millimetres*

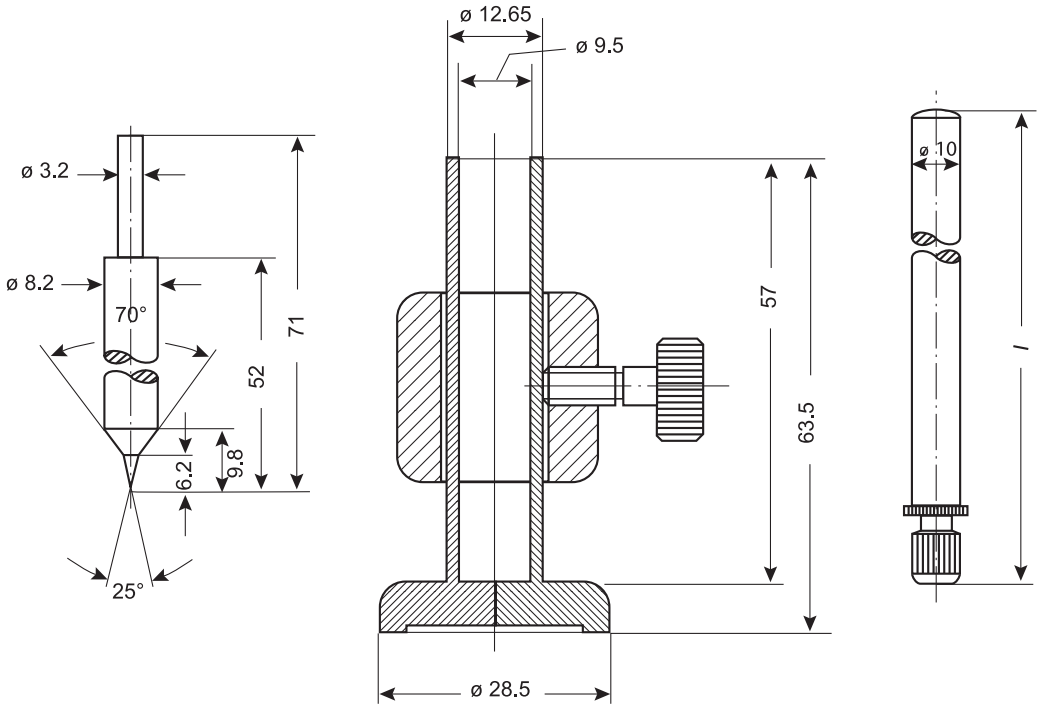

Figure 2.9.9.-3 – *Micro-cone (m = 7.0 g), suitable container and shaft (l = 116 mm; m = 16.8 g)*
*Dimensions in millimetres*

**Determination of penetration**. Place the test sample on the base of the penetrometer. Verify that its surface is perpendicular to the vertical axis of the penetrating object. Bring the temperature of the penetrating object to 25 ± 0.5 °C and then adjust its position such that its tip just touches the surface of the sample. Release the penetrating object and hold it free for 5 s. Clamp the penetrating object and measure the depth of penetration. Repeat the test with the 2 remaining containers.

EXPRESSION OF THE RESULTS

The penetration is expressed in tenths of a millimetre as the arithmetic mean of the 3 measurements. If any of the individual results differ from the mean by more than 3 per cent, repeat the test and express the results of the 6 measurements as the mean and the relative standard deviation.

**07/2019:20910**
**corrected 10.0**

## 2.9.10. ETHANOL CONTENT

*These methods are intended for the examination of liquid pharmaceutical preparations and their ingredients that contain ethanol.*

*The ethanol content of a liquid is expressed as the number of volumes of ethanol contained in 100 volumes of the liquid, the volumes being measured at 20 ± 0.1 °C. This is known as the 'percentage of ethanol by volume' (per cent V/V). The content may also be expressed in grams of ethanol per 100 g of the liquid. This is known as the 'percentage of ethanol by mass' (per cent m/m).*

METHOD A

Where preparations contain dissolved substances, the dissolved substances must be separated from the ethanol that is to be determined by distillation. Where distillation would distil volatile substances other than ethanol and water, the appropriate precautions are stated in the monograph.

The relation between the density at 20 ± 0.1 °C, the relative density (corrected to vacuum) and the ethanol content of a mixture of water and ethanol is given in the tables of the International Organisation for Legal Metrology (1972), International Recommendation No. 22.

**Apparatus**. The apparatus (see Figure 2.9.10.-1) consists of a round-bottomed flask (*A*) fitted with a distillation head (*B*) with a steam trap and attached to a vertical condenser (*C*). The latter is fitted at its lower part with a tube (*D*), which carries the distillate into the lower part of a 100 mL or 250 mL volumetric flask. The volumetric flask is immersed in a mixture of ice and water (*E*) during the distillation. A disc having a circular aperture 6 cm in diameter is placed under the flask (*A*) to reduce the risk of charring any dissolved substances.

**Method**

*Pycnometer method/oscillating transducer density meter method*. Transfer 25.0 mL of the preparation to be examined, measured at 20 ± 0.1 °C, to the distillation flask. Dilute with 100-150 mL of *distilled water R* and add a few pieces of pumice. Attach the distillation head and condenser. Distil and collect not less than 90 mL of distillate in a 100 mL volumetric flask. Adjust the temperature to 20 ± 0.1 °C and dilute to 100.0 mL with *distilled water R* at 20 ± 0.1 °C. Determine the relative density at 20 ± 0.1 °C using a pycnometer or an oscillating transducer density meter.

The values indicated in Table 2.9.10.-1, column 3, are multiplied by 4 to obtain the percentage of ethanol by volume (*V/V*) contained in the preparation. After calculation of the ethanol content using the table, round off the result to 1 decimal place.

| 998.0 | 0.9998 | 0.13 |

*Hydrometer method.* Transfer 50.0 mL of the preparation to be examined, measured at 20 ± 0.1 °C, to the distillation flask, add 200-300 mL of *distilled water R* and distil, as described above, into a volumetric flask until at least 180 mL has been collected. Adjust the temperature to 20 ± 0.1 °C and dilute to 250.0 mL with *distilled water R* at 20 ± 0.1 °C.

Transfer the distillate to a cylinder whose diameter is at least 6 mm wider than the bulb of the hydrometer. If the volume is insufficient, double the quantity of the sample and dilute the distillate to 500.0 mL with *distilled water R* at 20 ± 0.1 °C.

Multiply the strength by 5 to allow for the dilution during the determination. After calculation of the ethanol content using Table 2.9.10.-1, round off the result to 1 decimal place.

METHOD B

Head-space gas chromatography (*2.2.28*).

*Internal standard solution.* Dilute 1.0 mL of *propanol R1* to 100.0 mL with *water R*. Dilute 1.0 mL of the solution to 20.0 mL with *water R*.

*Test solution.* Dilute a volume of the preparation to be examined corresponding to 0.4 g of ethanol to 50.0 mL with *water R*. Dilute 1.0 mL of the solution to 20.0 mL with *water R*. To 2.0 mL of this solution add 1.0 mL of the internal standard solution and dilute to 20.0 mL with *water R*. Transfer 2.0 mL of this solution into an injection vial.

*Reference solution (a).* Dilute 5.0 mL of *anhydrous ethanol R* to 100.0 mL with *water R*. Dilute 25.0 mL of the solution to 100.0 mL with *water R*. Dilute 1.0 mL of this solution to 20.0 mL with *water R*.

*Reference solution (b).* Mix 0.5 mL of reference solution (a) and 1.0 mL of the internal standard solution and dilute to 20.0 mL with *water R*. Transfer 2.0 mL of this solution into an injection vial.

*Reference solution (c).* Mix 1.0 mL of reference solution (a) and 1.0 mL of the internal standard solution and dilute to 20.0 mL with *water R*. Transfer 2.0 mL of this solution into an injection vial.

*Reference solution (d).* Mix 1.5 mL of reference solution (a) and 1.0 mL of the internal standard solution and dilute to 20.0 mL with *water R*. Transfer 2.0 mL of this solution into an injection vial.

*Reference solution (e).* Dilute 1.0 mL of *methanol R2* to 100.0 mL with *water R*. Dilute 1.0 mL of the solution to 20.0 mL with *water R*.

*Reference solution (f).* Mix 1.0 mL of the internal standard solution, 2.0 mL of reference solution (a) and 2.0 mL of reference solution (e) and dilute to 20.0 mL with *water R*. Transfer 2.0 mL of this solution into an injection vial.

*Close the vials immediately with a tight rubber membrane stopper coated with polytetrafluoroethylene and secure with an aluminium crimp cap.*

*Column*:

- *material*: fused silica;
- *size*: *l* = 30 m, Ø = 0.53 mm;
- *stationary phase*: *cyanopropyl(3)phenyl(3)methyl(94)polysiloxane R* (film thickness 3 µm).

*Carrier gas*: *helium for chromatography R.*

*Flow rate*: 3 mL/min.

*Split ratio*: 1:50.

*Static head-space conditions that may be used*:

- *equilibration temperature*: 85 °C;
- *equilibration time*: 20 min.

*Temperature*:

| | Time (min) | Temperature (°C) |
|---|---|---|
| Column | 0 - 1.6 | 40 |
| | 1.6 - 9.9 | 40 → 65 |
| | 9.9 - 13.6 | 65 → 175 |
| | 13.6 - 20 | 175 |
| Injection port | | 200 |
| Detector | | 200 |

*Detection*: flame ionisation.

*Injection*: 1.0 mL of the gaseous phase of the test solution and reference solutions (b), (c), (d) and (f), at least 3 times.

*Elution order*: methanol, ethanol, propanol.

*Relative retention* with reference to ethanol (retention time = about 5.3 min): methanol = about 0.8; propanol = about 1.6.

*System suitability*: reference solution (f):

- *resolution*: minimum 5 between the peaks due to methanol and ethanol.

Establish a calibration curve with the concentration of ethanol in reference solutions (b), (c), (d) and (f) as the abscissa and the mean ratio of the peak area of ethanol to the peak area of the internal standard in the corresponding chromatograms as the ordinate.

Calculate the percentage content of ethanol in the preparation to be examined.

METHOD C

Gas chromatography (*2.2.28*).

*Internal standard solution.* Dilute 1.0 mL of *propanol R1* to 100.0 mL with *water R*.

*Test solution.* Dilute a volume of the preparation to be examined corresponding to 1 g of ethanol to 50.0 mL with *water R*. To 1.0 mL of this solution add 1.0 mL of the internal standard solution and dilute to 20.0 mL with *water R*.

*Reference solution (a).* Dilute 1.0 mL of *anhydrous ethanol R* to 50.0 mL with *water R*.

*Reference solution (b).* Dilute 1.0 mL of *methanol R2* to 100.0 mL with *water R*. Dilute 1.0 mL of the solution to 20.0 mL with *water R*.

*Reference solution (c).* Mix 1.0 mL of the internal standard solution, 1.0 mL of reference solution (a) and 2.0 mL of reference solution (b) and dilute to 20.0 mL with *water R*.

*Column*:

- *material*: fused silica;
- *size*: *l* = 30 m, Ø = 0.53 mm;
- *stationary phase*: *cyanopropyl(3)phenyl(3)methyl(94)polysiloxane R* (film thickness 3 µm).

*Carrier gas*: *helium for chromatography R.*

*Flow rate*: 3 mL/min.

*Split ratio*: 1:50.

*Temperature*:

| | Time (min) | Temperature (°C) |
|---|---|---|
| Column | 0 - 1.6 | 40 |
| | 1.6 - 9.9 | 40 → 65 |
| | 9.9 - 13.6 | 65 → 175 |
| | 13.6 - 20 | 175 |
| Injection port | | 200 |
| Detector | | 200 |

*Detection*: flame ionisation.

*Injection*: 1.0 µL of the test solution and reference solution (c), at least 3 times.

*Elution order*: methanol, ethanol, propanol.

*Relative retention* with reference to ethanol (retention time = about 5.3 min): methanol = about 0.8; propanol = about 1.6.

*System suitability*: reference solution (c):

- *resolution*: minimum 5 between the peaks due to methanol and ethanol.

Calculate the ethanol content in per cent *V/V* using the following expression:

$$\frac{A_1 \times I_2 \times 100}{A_2 \times I_1 \times V_1}$$

$A_1$ = area of the peak due to ethanol in the chromatogram obtained with the test solution;

$A_2$ = area of the peak due to ethanol in the chromatogram obtained with reference solution (c);

$I_1$ = area of the peak due to the internal standard in the chromatogram obtained with the test solution;

$I_2$ = area of the peak due to the internal standard in the chromatogram obtained with reference solution (c);

$V_1$ = volume of the preparation to be examined in the test solution, in millilitres.

**07/2019:20911 corrected 10.0**

## 2.9.11. TEST FOR METHANOL AND 2-PROPANOL

METHOD A

Head-space gas chromatography (*2.2.28*).

*Internal standard solution.* Dilute 1.0 mL of *propanol R1* to 100.0 mL with *water R*. Dilute 1.0 mL of the solution to 20.0 mL with *water R*.

*Test solution.* Mix 1.0 mL of the internal standard solution and 4.0 mL of the preparation to be examined and dilute to 20.0 mL with *water R*. Transfer 2.0 mL of this solution into an injection vial.

*Reference solution (a).* Mix 1.0 mL of *methanol R2* and 1.0 mL of *2-propanol R2* and dilute to 100.0 mL with *water R*. Dilute 1.0 mL of the solution to 20.0 mL with *water R*.

*Reference solution (b).* Dilute 5.0 mL of *anhydrous ethanol R* to 100.0 mL with *water R*. Dilute 25.0 mL of the solution to 100.0 mL with *water R*. Dilute 1.0 mL of this solution to 20.0 mL with *water R*.

*Reference solution (c).* Mix 1.0 mL of the internal standard solution, 2.0 mL of reference solution (a) and 2.0 mL of reference solution (b) and dilute to 20.0 mL with *water R*. Transfer 2.0 mL of this solution into an injection vial.

*Close the vials immediately with a tight rubber membrane stopper coated with polytetrafluoroethylene and secure with an aluminium crimp cap.*

*Column*:

- *material*: fused silica;
- *size*: *l* = 30 m, Ø = 0.53 mm;
- *stationary phase*: *cyanopropyl(3)phenyl(3)methyl(94)polysiloxane R* (film thickness 3 µm).

*Carrier gas*: *helium for chromatography R*.

*Flow rate*: 3 mL/min.

*Split ratio*: 1:50.

*Static head-space conditions that may be used*:

- *equilibration temperature*: 85 °C;
- *equilibration time*: 20 min.

*Temperature*:

| | Time (min) | Temperature (°C) |
|---|---|---|
| Column | 0 - 1.6 | 40 |
| | 1.6 - 9.9 | 40 → 65 |
| | 9.9 - 13.6 | 65 → 175 |
| | 13.6 - 20 | 175 |
| Injection port | | 200 |
| Detector | | 200 |

*Detection*: flame ionisation.

*Injection*: 1.0 mL of the gaseous phase of the test solution and reference solution (c), at least 3 times.

*Elution order*: methanol, ethanol, 2-propanol, 1-propanol.

*Relative retention* with reference to ethanol (retention time = about 5.3 min): methanol = about 0.8; 2-propanol = about 1.2; 1-propanol = about 1.6.

*System suitability*: reference solution (c):

- *resolution*: minimum 5 between the peaks due to methanol and ethanol.

Calculate the methanol content in per cent *V/V* using the following expression:

$$\frac{A_1 \times I_2}{A_2 \times I_1 \times 40}$$

$A_1$ = area of the peak due to methanol in the chromatogram obtained with the test solution;

$A_2$ = area of the peak due to methanol in the chromatogram obtained with reference solution (c);

$I_1$ = area of the peak due to the internal standard in the chromatogram obtained with the test solution;

$I_2$ = area of the peak due to the internal standard in the chromatogram obtained with reference solution (c).

Calculate the 2-propanol content in per cent *V/V* using the following expression:

$$\frac{A_3 \times I_2}{A_4 \times I_1 \times 40}$$

$A_3$ = area of the peak due to 2-propanol in the chromatogram obtained with the test solution;

$A_4$ = area of the peak due to 2-propanol in the chromatogram obtained with reference solution (c);

$I_1$ = area of the peak due to the internal standard in the chromatogram obtained with the test solution;

$I_2$ = area of the peak due to the internal standard in the chromatogram obtained with reference solution (c).

METHOD B

Gas chromatography (*2.2.28*).

*Internal standard solution.* Dilute 1.0 mL of *propanol R1* to 100.0 mL with *water R*.

*Test solution.* Mix 1.0 mL of the internal standard solution and 4.0 mL of the preparation to be examined and dilute to 20.0 mL with *water R*.

*Reference solution (a).* Mix 1.0 mL of *methanol R2* and 1.0 mL of *2-propanol R2* and dilute to 100.0 mL with *water R*. Dilute 1.0 mL of the solution to 20.0 mL with *water R*.

*Reference solution (b).* Dilute 1.0 mL of *anhydrous ethanol R* to 50.0 mL with *water R*.

*Reference solution (c).* Mix 1.0 mL of the internal standard solution, 1.0 mL of reference solution (b) and 2.0 mL of reference solution (a) and dilute to 20.0 mL with *water R*.

*Column*:

– *material*: fused silica;

– *size*: *l* = 30 m, Ø = 0.53 mm;

– *stationary phase*: *cyanopropyl(3)phenyl(3)methyl(94)polysiloxane R* (film thickness 3 µm).

*Carrier gas*: *helium for chromatography R*.

*Flow rate*: 3 mL/min.

*Split ratio*: 1:50.

*Temperature*:

| | Time (min) | Temperature (°C) |
|---|---|---|
| Column | 0 - 1.6 | 40 |
| | 1.6 - 9.9 | 40 → 65 |
| | 9.9 - 13.6 | 65 → 175 |
| | 13.6 - 20 | 175 |
| Injection port | | 200 |
| Detector | | 200 |

*Detection*: flame ionisation.

*Injection*: 1.0 µL of the test solution and reference solution (c), at least 3 times.

*Elution order*: methanol, ethanol, 2-propanol, 1-propanol.

*Relative retention* with reference to ethanol (retention time = about 5.3 min): methanol = about 0.8; 2-propanol = about 1.2; 1-propanol = about 1.6.

*System suitability*: reference solution (c):

– *resolution*: minimum 5 between the peaks due to methanol and ethanol.

Calculate the methanol content in per cent *V/V* using the following expression:

$$\frac{A_1 \times I_2}{A_2 \times I_1 \times 40}$$

$A_1$ = area of the peak due to methanol in the chromatogram obtained with the test solution;

$A_2$ = area of the peak due to methanol in the chromatogram obtained with reference solution (c);

$I_1$ = area of the peak due to the internal standard in the chromatogram obtained with the test solution;

$I_2$ = area of the peak due to the internal standard in the chromatogram obtained with reference solution (c).

Calculate the 2-propanol content in per cent *V/V* using the following expression:

$$\frac{A_3 \times I_2}{A_4 \times I_1 \times 40}$$

$A_3$ = area of the peak due to 2-propanol in the chromatogram obtained with the test solution;

$A_4$ = area of the peak due to 2-propanol in the chromatogram obtained with reference solution (c);

$I_1$ = area of the peak due to the internal standard in the chromatogram obtained with the test solution;

$I_2$ = area of the peak due to the internal standard in the chromatogram obtained with reference solution (c).

**01/2008:20912**

## 2.9.12. SIEVE TEST

The degree of fineness of a powder may be expressed by reference to sieves that comply with the specifications for non-analytical sieves (*2.1.4*).

Where the degree of fineness of powders is determined by sieving, it is defined in relation to the sieve number(s) used either by means of the following terms or, where such terms cannot be used, by expressing the fineness of the powder as a percentage *m/m* passing the sieve(s) used.

The following terms are used in the description of powders:

**Coarse powder**. Not less than 95 per cent by mass passes through a number 1400 sieve and not more than 40 per cent by mass passes through a number 355 sieve.

**Moderately fine powder**. Not less than 95 per cent by mass passes through a number 355 sieve and not more than 40 per cent by mass passes through a number 180 sieve.

**Fine powder**. Not less than 95 per cent by mass passes through a number 180 sieve and not more than 40 per cent by mass passes through a number 125 sieve.

**Very fine powder**. Not less than 95 per cent by mass passes through a number 125 sieve and not more than 40 per cent by mass passes through a number 90 sieve.

If a single sieve number is given, not less than 97 per cent of the powder passes through the sieve of that number, unless otherwise prescribed.

Assemble the sieves and operate in a suitable manner until sifting is practically complete. Weigh the separated fractions of the powder.

**04/2017:20914**

## 2.9.14. SPECIFIC SURFACE AREA BY AIR PERMEABILITY

The test is intended for the determination of the specific surface area of dry powders expressed in square metres per gram in the sub-sieve region. The effect of molecular flow ("slip flow") which may be important when testing powders consisting of particles less than a few micrometres is not taken into account in the equation used to calculate the specific surface area.

APPARATUS

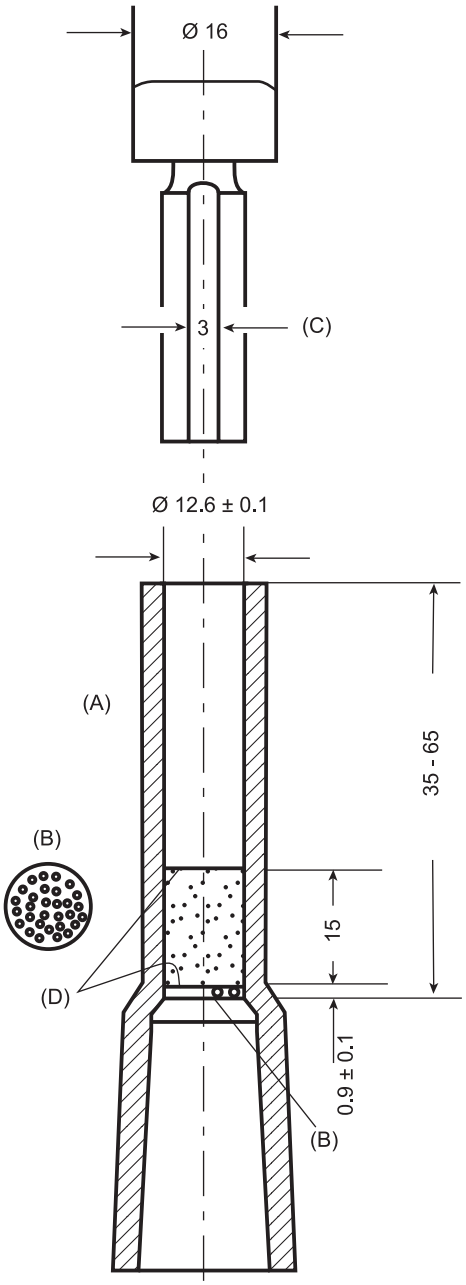

Figure 2.9.14.-1. – *Permeability cell*

*Dimensions in millimetres*

The apparatus consists of the following parts:

(a) a *permeability cell* (see Figure 2.9.14.-1), which consists of a cylinder with an inner diameter of 12.6 ± 0.1 mm (*A*), constructed of glass or non-corroding metal. The bottom of the cell forms an airtight connection (for example, via an adapter) with the manometer (Figure 2.9.14.-2). A ledge 0.5-1 mm in width is located 50 ± 15 mm from the top of the cell. It is an integral part of the cell or firmly fixed so as to be airtight. It supports a perforated metal disk (*B*), constructed of non-corroding metal. The disk has a thickness of 0.9 ± 0.1 mm and is perforated with 30 to 40 holes 1 mm in diameter evenly distributed over this area.

The plunger (*C*) is made of non-corroding metal and fits into the cell with a clearance of not more than 0.1 mm. The bottom of the plunger has sharp square edges at right angles to the principal axis. There is an air vent 3 mm long and 0.3 mm deep on one side of the plunger. The top of the plunger has a collar such that when the plunger is placed in the cell and the collar is brought into contact with the top of the cell, the distance between the bottom of the plunger and the top of the perforated disk (*B*) is 15 ± 1 mm.

The filter paper disks (*D*) have smooth edges and the same diameter as the inside of the cell.

(b) a *U-tube manometer* (*E*) (Figure 2.9.14.-2) is made of nominal 9 mm outer diameter and 7 mm inner diameter glass tubing with standard walls. The top of one arm of the manometer forms an airtight connection with the permeability cell (*F*). The manometer arm connected to the permeability cell has a line etched around the tube at 125-145 mm below the top of the side outlet and three other lines at distances of 15 mm, 70 mm and 110 mm above that line (*G*). The side outlet, 250-305 mm above the bottom of the manometer, is used to evacuate the manometer arm connected to the permeability cell. A tap is provided on the side outlet not more than 50 mm from the manometer arm.

The manometer is mounted firmly in such a manner that the arms are vertical. It is filled to the lowest mark with the liquid recommended by the manufacturer of the equipment or water.

METHOD

If prescribed, dry the powder to be examined and sift through a suitable sieve (for example no. 125) to disperse agglomerates. Calculate the mass (*M*) of the powder to be used from the following expression:

$$V \times \rho \times (1 - \varepsilon) \qquad (1)$$

$V$ = bulk volume of the compacted bed of powder,

$\rho$ = density of the substance to be examined in grams per millilitre,

$\varepsilon$ = porosity of the compacted bed of powder.

Assume first a porosity of 0.5 and introduce this value in expression (1) to calculate the mass (*M*) of the powder to be examined.

Place a filter paper disk on top of the perforated metal disk (*B*). Weigh the calculated mass (*M*) of the powder to be examined to the nearest 1 mg. Carefully transfer the powder into the cleaned, tared permeability cell and carefully tap the cell so that the surface of the powder bed is level and cover it with a second filter paper disk. Slowly compact the powder by means of the plunger, avoiding rotary movement. Maintain the pressure until the plunger is completely inserted into the permeability cell. If this is not possible, decrease the quantity of the powder used. If, on the contrary, there is not enough resistance, increase the quantity of the powder. In this case calculate the porosity again. After at least 10 s, remove the plunger.

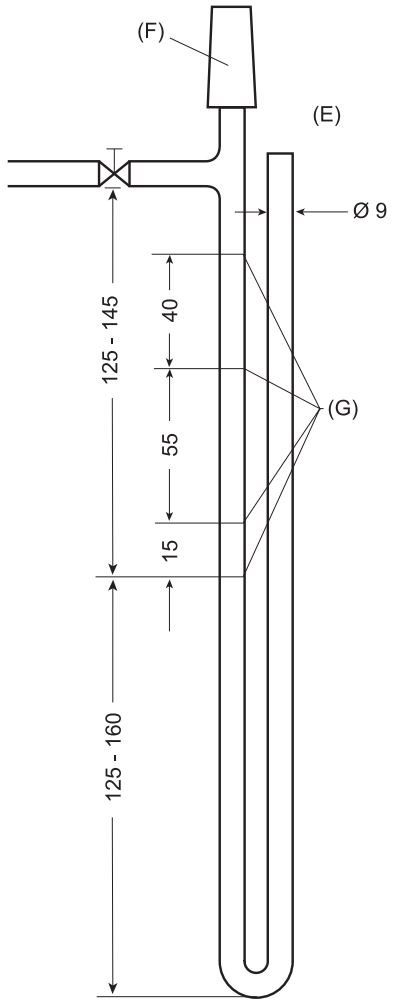

Figure 2.9.14.-2. – *Manometer*
*Dimensions in millimetres*

Attach the permeability cell to the tube of the manometer by means of an airtight connection. Evacuate the air from the manometer by means of a rubber bulb until the level of the coloured liquid is at the highest mark. Close the tap and check that the apparatus is airtight by closing the upper end of the cell, for example with a rubber stopper. Remove the stopper and, using a timer, measure the time taken for the liquid to fall from the second to the third mark.

Using the measured flow time, calculate the specific surface area (*S*), expressed in square metres per gram, from the following expression:

$$\frac{K \times \sqrt{\varepsilon^3} \times \sqrt{t}}{\rho \times (1 - \varepsilon) \times \sqrt{\eta}} \qquad (2)$$

$t$ = flow time in seconds,

$\eta$ = dynamic viscosity of air in millipascal seconds (see Table 2.9.14.-1),

$K$ = apparatus constant determined according to expression (4),

$\rho$ = density of the substance to be examined in grams per millilitre,

$\varepsilon$ = porosity of the compacted bed of powder.

## CALIBRATION OF THE APPARATUS

**Bulk volume of the compacted powder bed**. It is determined by the mercury displacement method as follows:

Place two filter paper disks in the permeability cell, pressing down the edges with a rod slightly smaller than the cell diameter until the filter disks lie flat on the perforated metal disk; fill the cell with mercury, removing any air bubbles adhering to the wall of the cell and wipe away the excess to create a plane surface of mercury at the top of the cell. If the cell is made of material that will amalgamate, grease the cell and the metal disk first with a thin layer of liquid paraffin. Pour out the mercury into a tared beaker and determine the mass ($M_A$) and the temperature of the mercury.

Make a compacted bed using the reference powder and again fill the cell with mercury with a planar surface at the top of the cell. Pour out the mercury in a tared beaker and again determine the mass of the mercury ($M_B$). Calculate the bulk volume ($V$) of the compacted bed of powder from the following expression:

$$\frac{M_A - M_B}{\rho_{\mathrm{Hg}}} \qquad (3)$$

$M_A - M_B$ = difference between the determined masses of mercury in grams,

$\rho_{\mathrm{Hg}}$ = density of mercury at the determined temperature in grams per millilitre.

Repeat the procedure twice, changing the powder each time; the range of values for the calculated volume ($V$) is not greater than 0.01 mL. Use the mean value of the three determined volumes for the calculations.

**Apparatus constant (*K*)**. It is determined using a reference powder with known specific surface area and density as follows:

Calculate the required quantity of the reference powder to be used (expression (1)) using the stated density and the determined volume of the compacted powder bed (expression (3)).

Homogenise and loosen up the powder by shaking it for 2 min in a 100 mL bottle. Prepare a compacted powder bed and measure the flow time of air as previously described. Calculate the apparatus constant ($K$) from the following expression:

$$\frac{S_{sp} \times \rho \times (1 - \varepsilon) \times \sqrt{\eta}}{\sqrt{\varepsilon^3} \times \sqrt{t}} \qquad (4)$$

$S_{sp}$ = stated specific surface area of the reference powder,

$\rho$ = density of the substance to be examined in grams per millilitre,

$\varepsilon$ = porosity of the compacted bed of powder,

$t$ = flow time in seconds,

$\eta$ = dynamic viscosity of air in millipascal seconds (see Table 2.9.14.-1).

The density of mercury and the viscosity of air over a range of temperatures are shown in Table 2.9.14.-1.

Table 2.9.14.-1.

| Temperature (°C) | Density of mercury (g/mL) | Viscosity of air ($\eta$) (mPa·s) | $\sqrt{\eta}$ |
|---|---|---|---|
| 16 | 13.56 | 0.01800 | 0.1342 |
| 17 | 13.56 | 0.01805 | 0.1344 |
| 18 | 13.55 | 0.01810 | 0.1345 |

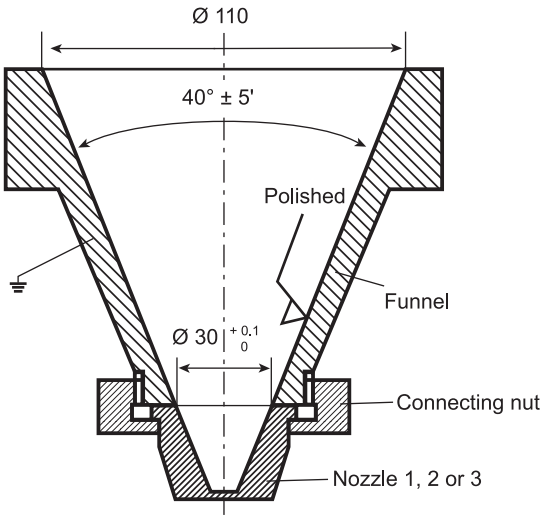
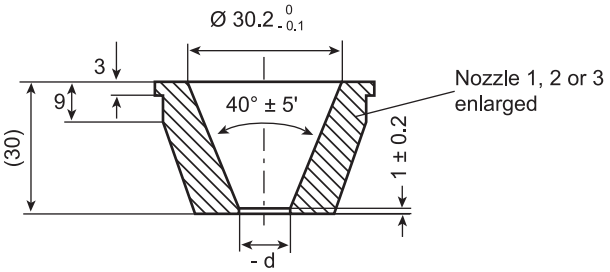
# 2.9.16. FLOWABILITY

The test for flowability is intended to determine the ability of divided solids (for example, powders and granules) to flow vertically under defined conditions.

APPARATUS

According to the flow properties of the material to be tested, funnels with or without stem, with different angles and orifice diameters are used. Typical apparatuses are shown in Figures 2.9.16.-1 and 2.9.16.-2. The funnel is maintained upright by a suitable device. The assembly must be protected from vibrations.





| Nozzle | Diameter (*d*) of the outflow opening (millimetres) |
|---|---|
| 1 | 10 ± 0.01 |
| 2 | 15 ± 0.01 |
| 3 | 25 ± 0.01 |

Figure 2.9.16.-1. – *Flow funnel and nozzle. Nozzle is made of stainless, acid-resistant steel (V4A,CrNi)*
*Dimensions in millimetres*

METHOD

Into a dry funnel, whose bottom opening has been blocked by suitable means, introduce without compacting a test sample weighed with 0.5 per cent accuracy. The amount of the sample depends on the apparent volume and the apparatus used. Unblock the bottom opening of the funnel and measure the time needed for the entire sample to flow out of the funnel. Carry out three determinations.

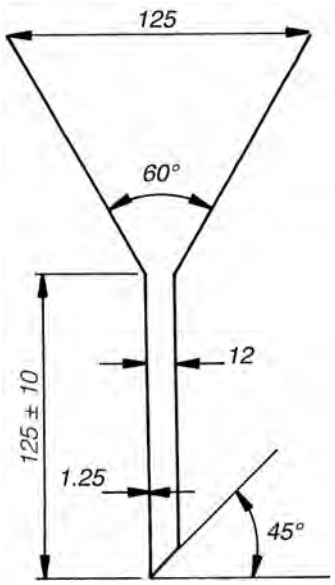


Figure 2.9.16.-2
*Dimensions in millimetres*

EXPRESSION OF RESULTS

The flowability is expressed in seconds and tenths of seconds, related to 100 g of sample.

The results depend on the storage conditions of the material to be tested.

The results can be expressed as the following:

a) the mean of the determinations, if none of the individual values deviates from the mean value by more than 10 per cent;

b) as a range, if the individual values deviate from the mean value by more than 10 per cent;

c) as a plot of the mass against the flow time;

d) as an infinite time, if the entire sample fails to flow through.

04/2010:20917

## 2.9.17. TEST FOR EXTRACTABLE VOLUME OF PARENTERAL PREPARATIONS[8]

Suspensions and emulsions are shaken before withdrawal of the contents and before the determination of the density. Oily and viscous preparations may be warmed according to the instructions on the label, if necessary, and thoroughly shaken immediately before removing the contents. The contents are then cooled to 20-25 °C before measuring the volume.

SINGLE-DOSE CONTAINERS

Select 1 container if the nominal volume is 10 mL or more, 3 containers if the nominal volume is more than 3 mL and less than 10 mL, or 5 containers if the nominal volume is 3 mL or less. Take up individually the total contents of each container selected into a dry syringe of a capacity not exceeding 3 times the volume to be measured, and fitted with a 21-gauge needle not less than 2.5 cm in length. Expel any air bubbles from the syringe and needle, then discharge the contents of the syringe without emptying the needle into a standardised dry cylinder (graduated to contain rather than to deliver the designated volumes) of such size that the volume to be measured occupies at least 40 per cent of its graduated volume. Alternatively, the volume of the contents in millilitres may be calculated as the mass in grams divided by the density.

For containers with a nominal volume of 2 mL or less, the contents of a sufficient number of containers may be pooled to obtain the volume required for the measurement provided that a separate, dry syringe assembly is used for each container. The contents of containers holding 10 mL or more may be determined by opening them and emptying the contents directly into the graduated cylinder or tared beaker.

The volume is not less than the nominal volume in case of containers examined individually, or, in case of containers with a nominal volume of 2 mL or less, is not less than the sum of the nominal volumes of the containers taken collectively.

MULTIDOSE CONTAINERS

For injections in multidose containers labelled to yield a specific number of doses of a stated volume, select one container and proceed as directed for single-dose containers using the same number of separate syringe assemblies as the number of doses specified.

The volume is such that each syringe delivers not less than the stated dose.

CARTRIDGES AND PREFILLED SYRINGES

Select 1 container if the nominal volume is 10 mL or more, 3 containers if the nominal volume is more than 3 mL and less than 10 mL, or 5 containers if the nominal volume is 3 mL or less. If necessary, fit the containers with the accessories required for their use (needle, piston, syringe) and transfer the entire contents of each container without emptying the needle into a dry tared beaker by slowly and constantly depressing the piston. Determine the volume in millilitres calculated as the mass in grams divided by the density.

The volume measured for each of the containers is not less than the nominal volume.

PARENTERAL INFUSIONS

Select one container. Transfer the contents into a dry measuring cylinder of such a capacity that the volume to be determined occupies at least 40 per cent of the nominal volume of the cylinder. Measure the volume transferred.

The volume is not less than the nominal volume.

01/2008:20918

## 2.9.18. PREPARATIONS FOR INHALATION: AERODYNAMIC ASSESSMENT OF FINE PARTICLES

This test is used to determine the fine particle characteristics of the aerosol clouds generated by preparations for inhalation.

Unless otherwise justified and authorised, one of the following apparatus and test procedures is used.

*Stage mensuration* is performed periodically together with confirmation of other dimensions critical to the effective operation of the impactor.

*Re-entrainment (for apparatus D and E).* To ensure efficient particle capture, coat each plate with glycerol, silicone oil or similar high viscosity liquid, typically deposited from a volatile solvent. Plate coating must be part of method validation and may be omitted where justified and authorised.

*Mass balance.* The total mass of the active substance is not less than 75 per cent and not more than 125 per cent of the average delivered dose determined during testing for uniformity of delivered dose. This is not a test of the inhaler but it serves to ensure that the results are valid.

APPARATUS A - GLASS IMPINGER

The apparatus is shown in Figure 2.9.18.-1 (see also Table 2.9.18.-1).

**Procedure for nebulisers**

Introduce 7 mL and 30 mL of a suitable solvent into the upper and lower impingement chambers, respectively.

Connect all the component parts. Ensure that the assembly is vertical and adequately supported and that the jet spacer peg of the lower jet assembly just touches the bottom of the lower impingement chamber. Connect a suitable pump fitted with a filter (of suitable pore size) to the outlet of the apparatus. Adjust the air flow through the apparatus, as measured at the inlet to the throat, to 60 ± 5 L/min.

Introduce the liquid preparation for inhalation into the reservoir of the nebuliser. Fit the mouthpiece and connect it by means of an adapter to the device.

Switch on the pump of the apparatus and after 10 s switch on the nebuliser.

After 60 s, unless otherwise justified, switch off the nebuliser, wait for about 5 s and then switch off the pump of the apparatus. Dismantle the apparatus and wash the inner surface of the upper impingement chamber collecting the washings in a volumetric flask. Wash the inner surface of the lower impingement chamber collecting the washings in a second volumetric flask. Finally, wash the filter preceding the pump and its connections to the lower impingement chamber and combine the washings with those obtained from the lower impingement chamber. Determine the amount of active substance collected in each of the 2 flasks. Express the results for each of the 2 parts of the apparatus as a percentage of the total amount of active substance.

(8) This chapter has undergone pharmacopoeial harmonisation. See chapter *5.8. Pharmacopoeial harmonisation*.

**Procedure for pressurised inhalers**

Place the actuator adapter in position at the end of the throat so that the mouthpiece end of the actuator, when inserted to a depth of about 10 mm, lines up along the horizontal axis of the throat and the open end of the actuator, which accepts the pressurised container, is uppermost and in the same vertical plane as the rest of the apparatus.

Introduce 7 mL and 30 mL of a suitable solvent into the upper and lower impingement chambers, respectively.

Connect all the component parts. Ensure that the assembly is vertical and adequately supported and that the lower jet-spacer peg of the lower jet assembly just touches the bottom of the lower impingement chamber. Connect a suitable pump to the outlet of the apparatus. Adjust the air flow through the apparatus, as measured at the inlet to the throat, to 60 ± 5 L/min.

Prime the metering valve by shaking for 5 s and discharging once to waste; after not less than 5 s, shake and discharge again to waste. Repeat a further 3 times.

Shake for about 5 s, switch on the pump to the apparatus and locate the mouthpiece end of the actuator in the adapter, discharge once immediately. Remove the assembled inhaler from the adapter, shake for not less than 5 s, relocate the mouthpiece end of the actuator in the adapter and discharge again. Repeat the discharge sequence. The number of discharges should be minimised and typically would not be greater than 10. After the final discharge wait for not less than 5 s and then switch off the pump. Dismantle the apparatus.

Wash the inner surface of the inlet tube to the lower impingement chamber and its outer surface that projects into the chamber with a suitable solvent, collecting the washings in the lower impingement chamber. Determine the content of active substance in this solution. Calculate the amount of active substance collected in the lower impingement chamber per discharge and express the results as a percentage of the dose stated on the label.

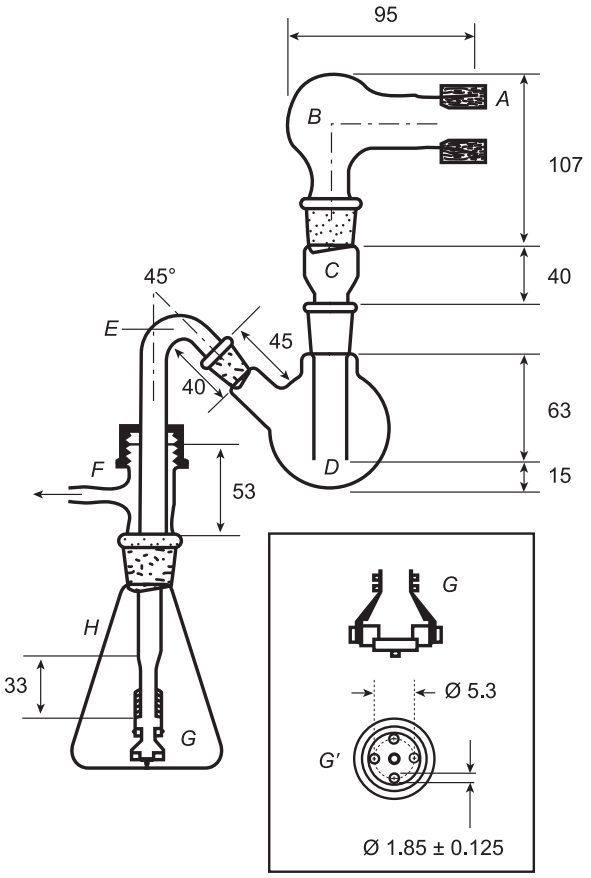

Figure 2.9.18.-1. – *Apparatus A: glass impinger*

*Dimensions in millimetres (tolerances ± 1 mm unless otherwise prescribed)*

**Procedure for powder inhalers**

Introduce 7 mL and 30 mL of a suitable solvent into the upper and lower impingement chambers, respectively.

Connect all the component parts. Ensure that the assembly is vertical and adequately supported and that the jet-spacer peg of the lower jet assembly just touches the bottom of the lower impingement chamber. Without the inhaler in place, connect a suitable pump to the outlet of the apparatus. Adjust the air flow through the apparatus, as measured at the inlet to the throat, to 60 ± 5 L/min.

Prepare the inhaler for use and locate the mouthpiece in the apparatus by means of a suitable adapter. Switch on the pump for 5 s. Switch off the pump and remove the inhaler. Repeat the discharge sequence. The number of discharges should be minimised and typically would not be greater than 10. Dismantle the apparatus.

Wash the inner surface of the inlet tube to the lower impingement chamber and its outer surface that projects into the chamber with a suitable solvent, collecting the washings in the lower impingement chamber. Determine the content of active substance in this solution. Calculate the amount of active substance collected in the lower impingement chamber per discharge and express the results as a percentage of the dose stated on the label.

## Fine particle dose and particle size distribution

APPARATUS C - MULTI-STAGE LIQUID IMPINGER

The multi-stage liquid impinger consists of impaction stages 1 (pre-separator), 2, 3 and 4 and an integral filter stage (stage 5), see Figures 2.9.18.-4/6. An impaction stage comprises an upper horizontal metal partition wall (B) through which a metal inlet jet tube (A) with its impaction plate (D) is protruding. A glass cylinder (E) with sampling port (F) forms the vertical wall of the stage, and a lower horizontal metal partition wall (G) through which the tube (H) connects to the next lower stage. The tube into stage 4 (U) ends in a multi-jet arrangement. The impaction plate (D) is secured in a metal frame (J) which is fastened by 2 wires (K) to a sleeve (L) secured on the jet tube. The horizontal face of the collection plate is perpendicular to the axis of the jet tube and centrally aligned. The upper surface of the impaction plate is slightly raised above the edge of the metal frame. A recess around the perimeter of the horizontal partition wall guides the position of the glass cylinder. The glass cylinders are sealed against the horizontal partition walls with gaskets (M) and clamped together by 6 bolts (N). The sampling ports are sealed by stoppers. The bottom-side of the lower partition wall of stage 4 has a concentrical protrusion fitted with a rubber O-ring (P) which seals against the edge of a filter placed in the filter holder. The filter holder (R) is constructed as a basin with a concentrical recess in which a perforated filter support (S) is flush-fitted. The filter holder is dimensioned for 76 mm diameter filters. The assembly of impaction stages is clamped onto the filter holder by 2 snap-locks (T). Connect an induction port (see Figure 2.9.18.-7) onto the stage 1 inlet jet tube of the impinger. A rubber O-ring on the jet tube provides an airtight connection to the induction port. A suitable mouthpiece adapter is used to provide an airtight seal between the inhaler and the induction port. The front face of the inhaler mouthpiece must be flush with the front face of the induction port.

**Procedure for pressurised inhalers**

Dispense 20 mL of a solvent, capable of dissolving the active substance into each of stages 1 to 4 and replace the stoppers. Tilt the apparatus to wet the stoppers, thereby neutralising electrostatic charge. Place a suitable filter capable of quantitatively collecting the active substance in stage 5 and assemble the apparatus. Place a suitable mouthpiece adapter in position at the end of the induction port so that the mouthpiece end of the actuator, when inserted, lines up along the horizontal axis of the induction port and the inhaler is positioned in the same orientation as intended for use. Connect a suitable vacuum pump to the outlet of the apparatus and adjust the air flow through the apparatus, as measured at the inlet to the induction port, to 30 L/min (± 5 per cent). Switch off the pump.

Unless otherwise prescribed in the patient instructions, shake the inhaler for 5 s and discharge 1 delivery to waste. Switch on the pump to the apparatus, locate the mouthpiece end of the actuator in the adapter and discharge the inhaler into the apparatus, depressing the valve for a sufficient time to ensure complete discharge. Wait for 5 s before removing the assembled inhaler from the adapter. Repeat the procedure. The number of discharges should be minimised and typically would not be greater than 10. The number of discharges is sufficient to ensure an accurate and precise determination of the fine particle dose. After the final discharge, wait for 5 s and then switch off the pump.

Dismantle the filter stage of the apparatus. Carefully remove the filter and extract the active substance into an aliquot of the solvent. Remove the induction port and mouthpiece adapter from the apparatus and extract the active substance into an aliquot of the solvent. If necessary, rinse the inside of the inlet jet tube to stage 1 with solvent, allowing the solvent to flow into the stage. Extract the active substance from the inner walls and the collection plate of each of the 4 upper stages of the apparatus into the solution in the respective stage by carefully tilting and rotating the apparatus, observing that no liquid transfer occurs between the stages.

Using a suitable method of analysis, determine the quantity of active substance contained in each of the aliquots of solvent.

Calculate the fine particle dose (see Calculations).

**Procedure for powder inhalers**

Place a suitable low resistance filter capable of quantitatively collecting the active substance in stage 5 and assemble the apparatus. Connect the apparatus to a flow system according to the scheme specified in Figure 2.9.18.-8 and Table 2.9.18.-4. Unless otherwise defined, conduct the test at the flow rate, $Q_{out}$, used in the test for uniformity of delivered dose, drawing 4 L of air from the mouthpiece of the inhaler and through the apparatus.

Connect a flowmeter to the induction port. Use a flowmeter calibrated for the volumetric flow leaving the meter, or calculate the volumetric flow leaving the meter ($Q_{out}$) using the ideal gas law. For a meter calibrated for the entering volumetric flow ($Q_{in}$), use the following expression:

$$Q_{out} = \frac{Q_{in} \times P_0}{P_0 - \Delta P}$$

$P_0$ = atmospheric pressure,

$\Delta P$ = pressure drop over the meter.

Adjust the flow control valve to achieve steady flow through the system at the required rate, $Q_{out}$ (± 5 per cent). Switch off the pump. Ensure that critical flow occurs in the flow control valve by the following procedure.

With the inhaler in place and the test flow rate established, measure the absolute pressure on both sides of the control valve (pressure reading points P2 and P3 in Figure 2.9.18.-8). A ratio P3/P2 of less than or equal to 0.5 indicates critical flow. Switch to a more powerful pump and re-measure the test flow rate if critical flow is not indicated.

Dispense 20 mL of a solvent, capable of dissolving the active substance into each of the 4 upper stages of the apparatus and replace the stoppers. Tilt the apparatus to wet the stoppers, thereby neutralising electrostatic charge. Place a suitable mouthpiece adapter in position at the end of the induction port.

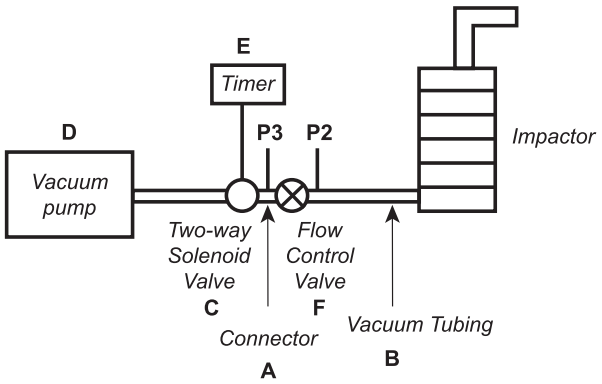

Figure 2.9.18.-8. – *Experimental set-up for testing powder inhalers*

Table 2.9.18.-4. – *Component specification for Figure 2.9.18.-8*

| Code | Item | Description |
|---|---|---|
| A | Connector | ID ≥ 8 mm, e.g., short metal coupling, with low-diameter branch to P3. |
| B | Vacuum tubing | A length of suitable tubing having an ID ≥ 8 mm and an internal volume of 25 ± 5 mL. |
| C | 2-way solenoid valve | A 2-way, 2-port solenoid valve having a minimum airflow resistance orifice with ID ≥ 8 mm and an opening time ≤ 100 ms. (e.g. type 256-A08, Bürkert GmbH, D-74653 Ingelfingen), or equivalent. |
| D | Vacuum pump | Pump must be capable of drawing the required flow rate through the assembled apparatus with the powder inhaler in the mouthpiece adapter (e.g. product type 1023, 1423 or 2565, Gast Manufacturing Inc., Benton Harbor, MI 49022), or equivalent. Connect the pump to the 2-way solenoid valve using short and/or wide (ID ≥ 10 mm) vacuum tubing and connectors to minimise pump capacity requirements. |
| E | Timer | Timer capable to drive the 2-way solenoid valve for the required duration (e.g. type G814, RS Components International, Corby, NN17 9RS, UK), or equivalent. |
| P2 P3 | Pressure measurements | Determine under steady-state flow condition with an absolute pressure transducer. |
| F | Flow control valve | Adjustable regulating valve with maximum $C_v \geq 1$, (e.g. type 8FV12LNSS, Parker Hannifin plc., Barnstaple, EX31 1NP, UK), or equivalent. |

Prepare the powder inhaler for use according to patient instructions. With the pump running and the 2-way solenoid valve closed, locate the mouthpiece of the inhaler in the mouthpiece adapter. Discharge the powder into the apparatus by opening the valve for the required time, T (± 5 per cent). Repeat the procedure. The number of discharges should be minimised and typically would not be greater than 10. The number of discharges is sufficient to ensure an accurate and precise determination of fine particle dose.

Dismantle the filter stage of the apparatus. Carefully remove the filter and extract the active substance into an aliquot of the solvent. Remove the induction port and mouthpiece adapter from the apparatus and extract the active substance into an aliquot of the solvent. If necessary, rinse the inside of the inlet jet tube to stage 1 with solvent, allowing the solvent to flow into the stage. Extract the active substance from the inner walls and the collection plate of each of the 4 upper stages

of the apparatus into the solution in the respective stage by carefully tilting and rotating the apparatus, observing that no liquid transfer occurs between the stages.

Using a suitable method of analysis, determine the amount of active substance contained in each of the aliquots of solvent.

Calculate the fine particle dose (see Calculations).

APPARATUS D - ANDERSEN CASCADE IMPACTOR

The Andersen 1 ACFM non-viable cascade impactor consists of 8 stages together with a final filter. Material of construction may be aluminium, stainless steel or other suitable material. The stages are clamped together and sealed with O-rings. Critical dimensions applied by the manufacturer of apparatus D are provided in Table 2.9.18.-5. In use, some occlusion and wear of holes will occur. In-use mensuration tolerances need to be justified. In the configuration used for pressurised inhalers (Figure 2.9.18.-9) the entry cone of the impactor is connected to an induction port (see Figure 2.9.18.-7). A suitable mouthpiece adapter is used to provide an airtight seal between the inhaler and the induction port. The front face of the inhaler mouthpiece must be flush with the front face of the induction port.

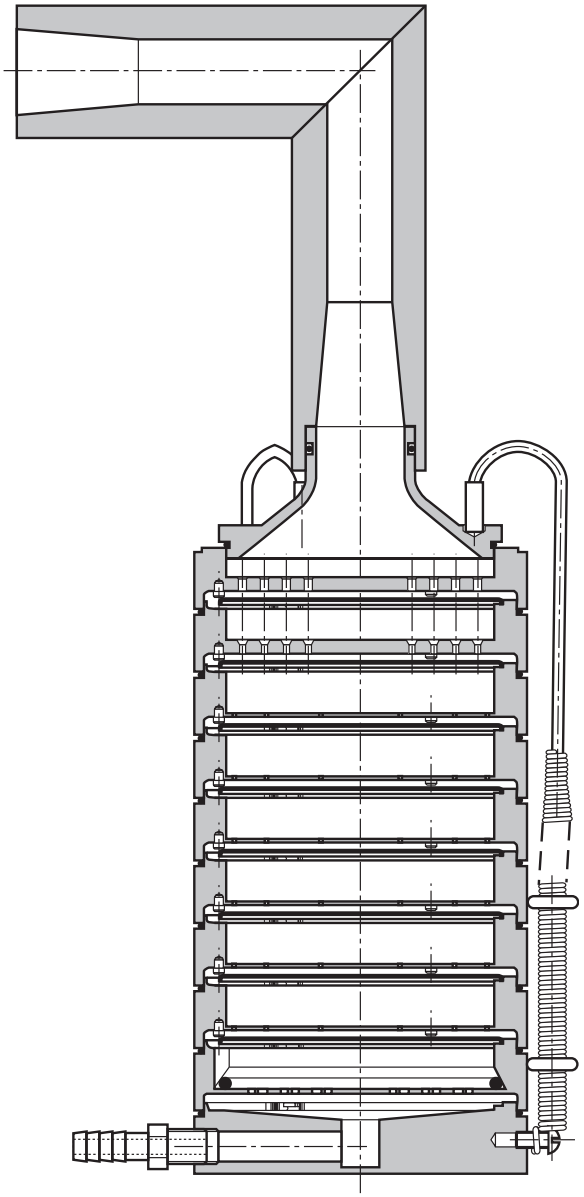

Figure 2.9.18.-9. – *Apparatus D: Andersen cascade impactor used for pressurised inhalers*

In the configuration for powder inhalers, a pre-separator is placed above the top stage to collect large masses of non-respirable powder. It is connected to the induction port as shown in Figure 2.9.18.-10. To accommodate high flow rates through the impactor, the outlet nipple, used to connect the impactor to the vacuum system is enlarged to have an internal diameter of greater than or equal to 8 mm.

Table 2.9.18.-5. – *Critical dimensions for apparatus D*

| Description | Number | Dimension (mm) |
|---|---|---|
| Stage 0 nozzle diameter | 96 | 2.55 ± 0.025 |
| Stage 1 nozzle diameter | 96 | 1.89 ± 0.025 |
| Stage 2 nozzle diameter | 400 | 0.914 ± 0.0127 |
| Stage 3 nozzle diameter | 400 | 0.711 ± 0.0127 |
| Stage 4 nozzle diameter | 400 | 0.533 ± 0.0127 |
| Stage 5 nozzle diameter | 400 | 0.343 ± 0.0127 |
| Stage 6 nozzle diameter | 400 | 0.254 ± 0.0127 |
| Stage 7 nozzle diameter | 201 | 0.254 ± 0.0127 |

**Procedure for pressurised inhalers**

Assemble the Andersen impactor with a suitable filter in place. Ensure that the system is airtight. In that respect, follow the manufacturer's instructions. Place a suitable mouthpiece adapter in position at the end of the induction port so that the mouthpiece end of the actuator, when inserted, lines up along the horizontal axis of the induction port and the inhaler unit is positioned in the same orientation as the intended use. Connect a suitable pump to the outlet of the apparatus and adjust the air flow through the apparatus, as measured at the inlet to the induction port, to 28.3 L/min (± 5 per cent). Switch off the pump.

Unless otherwise prescribed in the patient instructions, shake the inhaler for 5 s and discharge one delivery to waste. Switch on the pump to the apparatus, locate the mouthpiece end of the actuator in the adapter and discharge the inverted inhaler into the apparatus, depressing the valve for a sufficient time to ensure complete discharge. Wait for 5 s before removing the assembled inhaler from the adapter. Repeat the procedure. The number of discharges should be minimised and typically would not be greater than 10. The number of discharges is sufficient to ensure an accurate and precise determination of the fine particle dose. After the final discharge, wait for 5 s and then switch off the pump.

Dismantle the apparatus. Carefully remove the filter and extract the active substance into an aliquot of the solvent. Remove the induction port and mouthpiece adapter from the apparatus and extract the active substance into an aliquot of the solvent. Extract the active substance from the inner walls and the collection plate of each of the stages of the apparatus into aliquots of solvent.

Using a suitable method of analysis, determine the quantity of active substance contained in each of the aliquots of solvent.

Calculate the fine particle dose (see Calculations).

**Procedure for powder inhalers**

*The aerodynamic cut-off diameters of the individual stages of this apparatus are currently not well-established at flow rates other than 28.3 L/min.* Users must justify and validate the use of the impactor in the chosen conditions, when flow rates different from 28.3 L/min are selected.

Assemble the Andersen impactor with the pre-separator and a suitable filter in place and ensure that the system is airtight. Depending on the product characteristics, the pre-separator may be omitted, where justified and authorised. Stages 6 and 7 may also be omitted at high flow rates, if justified. The pre-separator may be coated in the same way as the plates

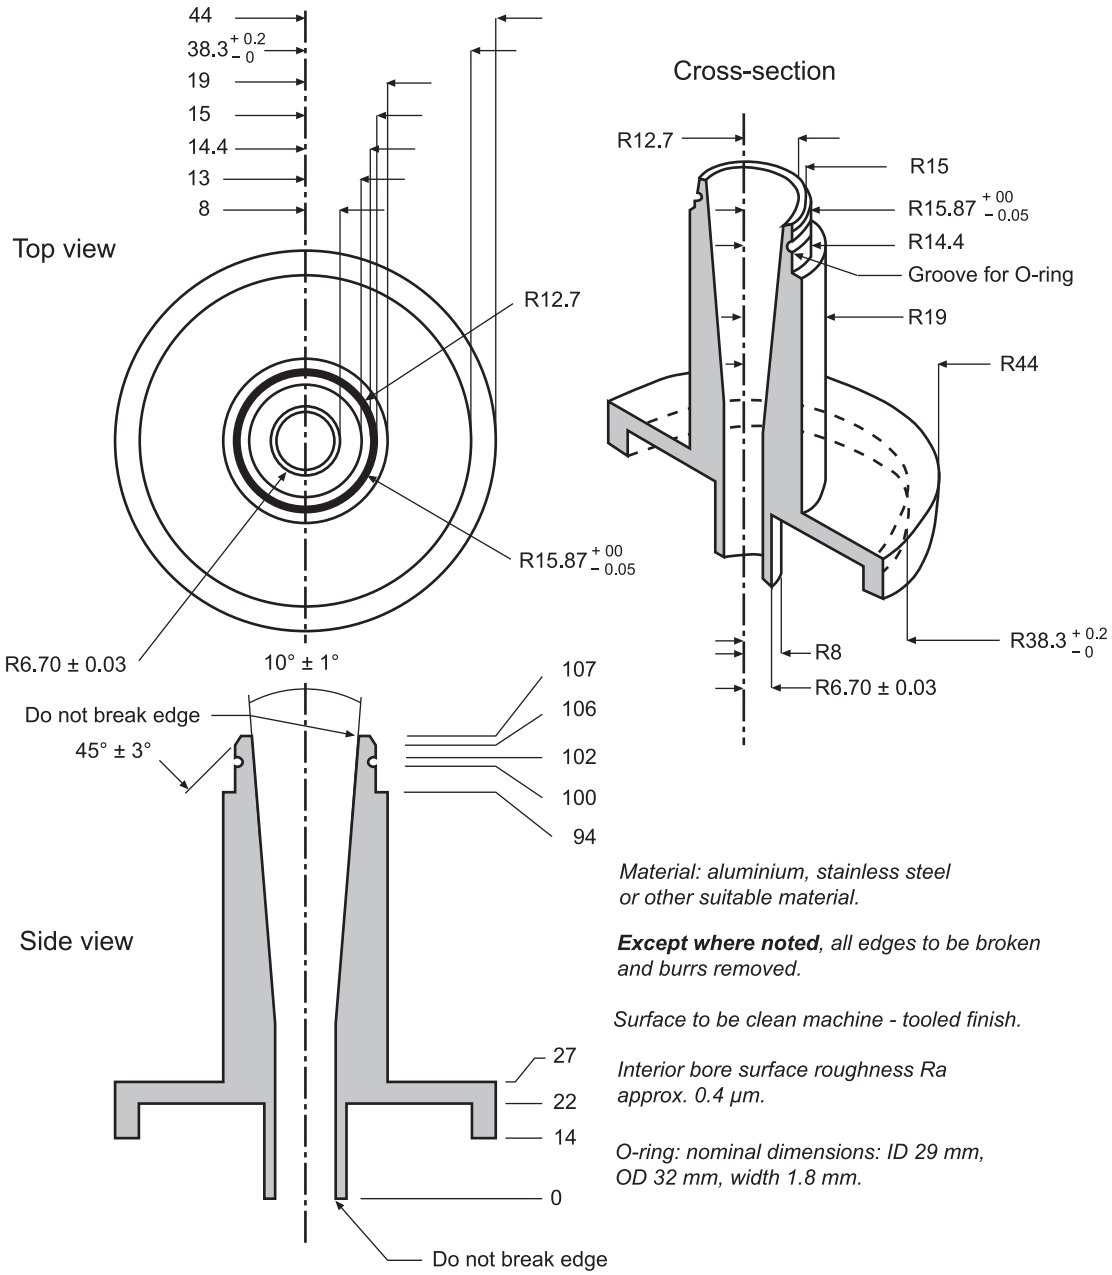

Figure 2.9.18.-10. – *Connection of the induction port to the preseparator of the Andersen cascade impactor*
*Dimensions in millimetres unless otherwise stated*

or may contain 10 mL of a suitable solvent. Connect the apparatus to a flow system according to the scheme specified in Figure 2.9.18.-8 and Table 2.9.18.-4.

Unless otherwise defined, conduct the test at the flow rate, $Q_{out}$, used in the test for uniformity of delivered dose drawing 4 L of air from the mouthpiece of the inhaler and through the apparatus.

Connect a flowmeter to the induction port. Use a flowmeter calibrated for the volumetric flow leaving the meter, or calculate the volumetric flow leaving the meter ($Q_{out}$) using the ideal gas law. For a meter calibrated for the entering volumetric flow ($Q_{in}$), use the following expression:

$$Q_{out} = \frac{Q_{in} \times P_0}{P_0 - \Delta P}$$

$P_0$ = atmospheric pressure,

$\Delta P$ = pressure drop over the meter.

Adjust the flow control valve to achieve steady flow through the system at the required rate, $Q_{out}$ (± 5 per cent). Ensure that critical flow occurs in the flow control valve by the procedure described for Apparatus C. Switch off the pump.

Prepare the powder inhaler for use according to the patient instructions. With the pump running and the 2-way solenoid valve closed, locate the mouthpiece of the inhaler in the mouthpiece adapter. Discharge the powder into the apparatus by opening the valve for the required time, T (± 5 per cent). Repeat the discharge sequence. The number of discharges should be minimised and typically would not be greater than 10. The number of discharges is sufficient to ensure an accurate and precise determination of fine particle dose.

Dismantle the apparatus. Carefully remove the filter and extract the active substance into an aliquot of the solvent. Remove the pre-separator, induction port and mouthpiece adapter from the apparatus and extract the active substance into an aliquot of the solvent. Extract the active substance from the inner walls and the collection plate of each of the stages of the apparatus into aliquots of solvent.

Using a suitable method of analysis, determine the quantity of active substance contained in each of the aliquots of solvent.

Calculate the fine particle dose (see Calculations).

APPARATUS E

Apparatus E is a cascade impactor with 7 stages and a micro-orifice collector (MOC). Over the flow rate range of 30 L/min to 100 L/min the 50 per cent-efficiency cut-off diameters ($D_{50}$ values) range between 0.24 µm to 11.7 µm, evenly spaced on a logarithmic scale. In this flow range, there are always at least 5 stages with $D_{50}$ values between 0.5 µm and 6.5 µm. The collection efficiency curves for each stage are sharp and minimise overlap between stages.

Material of construction may be aluminium, stainless steel or other suitable material.

The impactor configuration has removable impaction cups with all the cups in one plane (Figures 2.9.18.-11/14). There are 3 main sections to the impactor; the bottom frame that holds the impaction cups, the seal body that holds the jets and the lid that contains the interstage passageways (Figures 2.9.18.-11/12). Multiple nozzles are used at all but the first stage (Figure 2.9.18.-13). The flow passes through the impactor in a saw-tooth pattern.

Critical dimensions are provided in Table 2.9.18.-6.

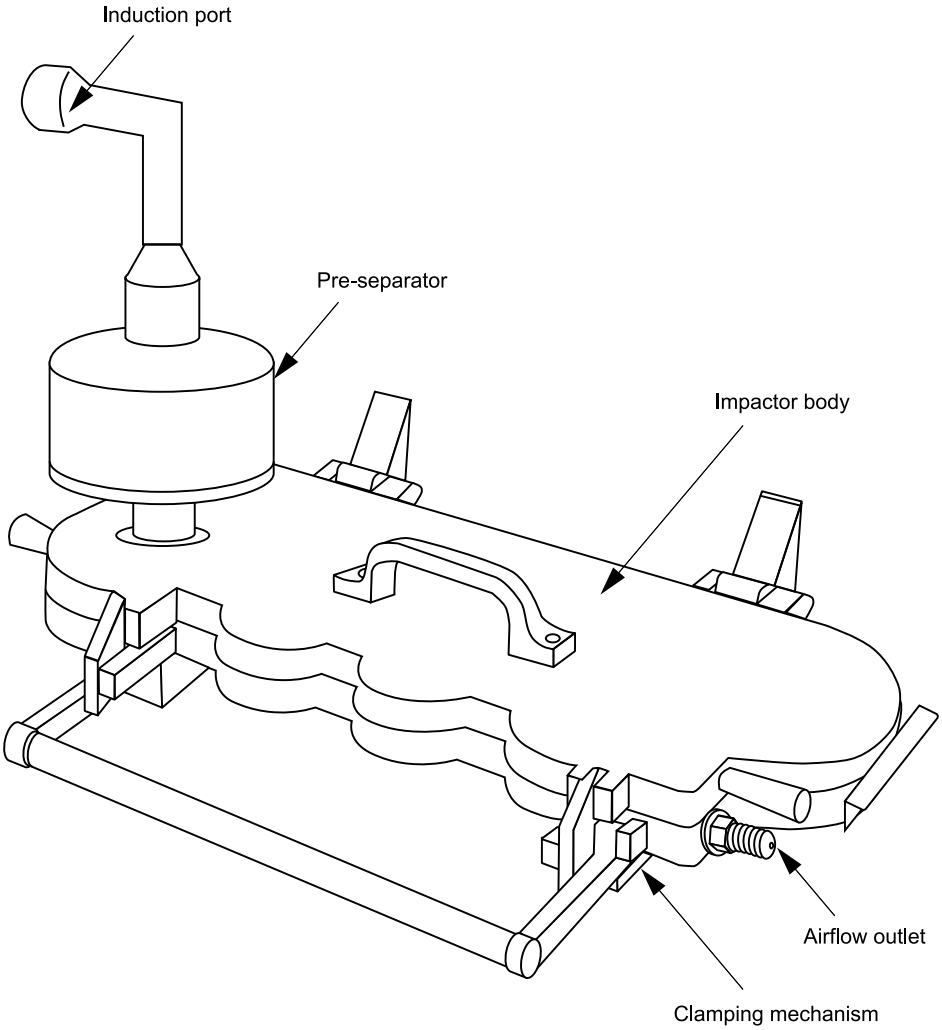

Figure 2.9.18.-11. – *Apparatus E (shown with the pre-separator in place)*

Table 2.9.18.-6. – *Critical dimensions for apparatus E*

| Description | Dimension (mm) |
|---|---|
| Pre-separator (dimension a - see Figure 2.9.18.-15) | 12.8 ± 0.05 |
| Stage 1* Nozzle diameter | 14.3 ± 0.05 |
| Stage 2* Nozzle diameter | 4.88 ± 0.04 |
| Stage 3* Nozzle diameter | 2.185 ± 0.02 |
| Stage 4* Nozzle diameter | 1.207 ± 0.01 |
| Stage 5* Nozzle diameter | 0.608 ± 0.01 |
| Stage 6* Nozzle diameter | 0.323 ± 0.01 |
| Stage 7* Nozzle diameter | 0.206 ± 0.01 |
| MOC* | approx. 0.070 |
| Cup depth (dimension b - see Figure 2.9.18.-14) | 14.625 ± 0.10 |
| Collection cup surface roughness (Ra) | 0.5 - 2 µm |
| Stage 1 nozzle to seal body distance** - dimension c | 0 ± 1.18 |
| Stage 2 nozzle to seal body distance** - dimension c | 5.236 ± 0.736 |
| Stage 3 nozzle to seal body distance** - dimension c | 8.445 ± 0.410 |
| Stage 4 nozzle to seal body distance** - dimension c | 11.379 ± 0.237 |
| Stage 5 nozzle to seal body distance** - dimension c | 13.176 ± 0.341 |
| Stage 6 nozzle to seal body distance** - dimension c | 13.999 ± 0.071 |
| Stage 7 nozzle to seal body distance** - dimension c | 14.000 ± 0.071 |
| MOC nozzle to seal body distance** - dimension c | 14.429 to 14.571 |

* See Figure 2.9.18.-13
** See Figure 2.9.18.-14

In routine operation, the seal body and lid are held together as a single assembly. The impaction cups are accessible when this assembly is opened at the end of an inhaler test. The cups are held in a support tray, so that all cups can be removed from the impactor simultaneously by lifting out the tray.

An induction port with internal dimensions (relevant to the airflow path) defined in Figure 2.9.18.-7 connects to the impactor inlet. A pre-separator can be added when required, typically with powder inhalers, and connects between the induction port and the impactor. A suitable mouthpiece adapter is used to provide an airtight seal between the inhaler and the induction port.

Apparatus E contains a terminal Micro-Orifice Collector (MOC) that for most formulations will eliminate the need for a final filter as determined by method validation. The MOC is an impactor plate with nominally 4032 holes, each approximately 70 µm in diameter. Most particles not captured on stage 7 of the impactor will be captured on the cup surface below the MOC. For impactors operated at 60 L/min, the MOC is capable of collecting 80 per cent of 0.14 µm particles. For formulations with a significant fraction of particles not captured by the MOC, there is an optional filter holder that can replace the MOC or be placed downstream of the MOC (a glass fibre filter is suitable).

**Procedure for pressurised inhalers**

Place cups into the apertures in the cup tray. Insert the cup tray into the bottom frame, and lower into place. Close the impactor lid with the seal body attached and operate the handle to lock the impactor together so that the system is airtight.

Connect an induction port with internal dimensions defined in Figure 2.9.18.-7 to the impactor inlet. Place a suitable mouthpiece adapter in position at the end of the induction port so that the mouthpiece end of the actuator, when inserted, lines up along the horizontal axis of the induction port. The front face of the inhaler mouthpiece must be flush with the front face of the induction port. When attached to the mouthpiece adapter, the inhaler is positioned in the same orientation as intended for use. Connect a suitable pump to the outlet of the apparatus and adjust the air flow through the apparatus, as measured at the inlet to the induction port, to 30 L/min (± 5 per cent). Switch off the pump.

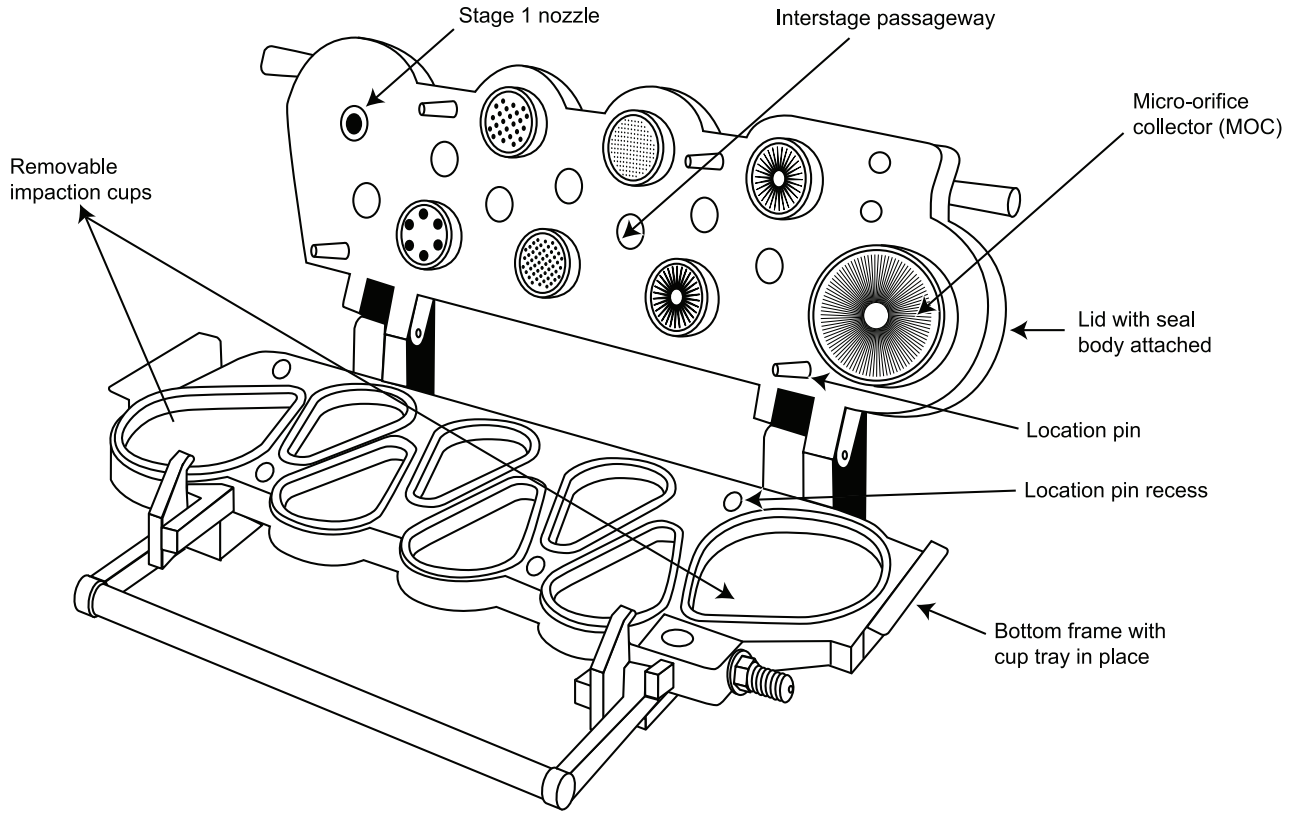

Figure 2.9.18.-12. – *Apparatus E showing component parts*

Unless otherwise prescribed in the patient instructions, shake the inhaler for 5 s and discharge 1 delivery to waste. Switch on the pump to the apparatus. Prepare the inhaler for use according to the patient instructions, locate the mouthpiece end of the actuator in the adapter and discharge the inhaler into the apparatus, depressing the valve for a sufficient time to ensure a complete discharge. Wait for 5 s before removing the assembled inhaler from the adapter. Repeat the procedure. The number of discharges should be minimised, and typically would not be greater than 10. The number of discharges is sufficient to ensure an accurate and precise determination of the fine particle dose. After the final discharge, wait for 5 s and then switch off the pump.

Dismantle the apparatus and recover the active substance as follows: remove the induction port and mouthpiece adapter from the apparatus and recover the deposited active substance into an aliquot of solvent. Open the impactor by releasing the handle and lifting the lid. Remove the cup tray, with the collection cups, and recover the active substance in each cup into an aliquot of solvent.

Using a suitable method of analysis, determine the quantity of active substance contained in each of the aliquots of solvent.

Calculate the fine particle dose (see Calculations).

**Procedure for powder inhalers**

Assemble the apparatus with the pre-separator (Figure 2.9.18.-15). Depending on the product characteristics, the pre-separator may be omitted, where justified.

Place cups into the apertures in the cup tray. Insert the cup tray into the bottom frame, and lower into place. Close the impactor lid with the seal body attached and operate the handle to lock the impactor together so that the system is airtight.

When used, the pre-separator should be assembled as follows: assemble the pre-separator insert into the pre-separator base. Fit the pre-separator base to the impactor inlet. Add 15 mL of the solvent used for sample recovery to the central cup of the pre-separator insert. Place the pre-separator body on top of this assembly and close the 2 catches.

Connect an induction port with internal dimensions defined in Figure 2.9.18.-7 to the impactor inlet or pre-separator inlet. Place a suitable mouthpiece adapter in position at the end of the induction port so that the mouthpiece end of the inhaler, when inserted, lines up along the horizontal axis of the induction port. The front face of the inhaler mouthpiece must be flush with the front face of the induction port. When attached to the mouthpiece adapter, the inhaler is positioned in the same orientation as intended for use. Connect the apparatus to a flow system according to the scheme specified in Figure 2.9.18.-8 and Table 2.9.18.-4.

Unless otherwise prescribed, conduct the test at the flow rate, $Q_{out}$, used in the test for uniformity of delivered dose drawing 4 L of air from the mouthpiece of the inhaler and through the apparatus. Connect a flowmeter to the induction port. Use a flowmeter calibrated for the volumetric flow leaving the

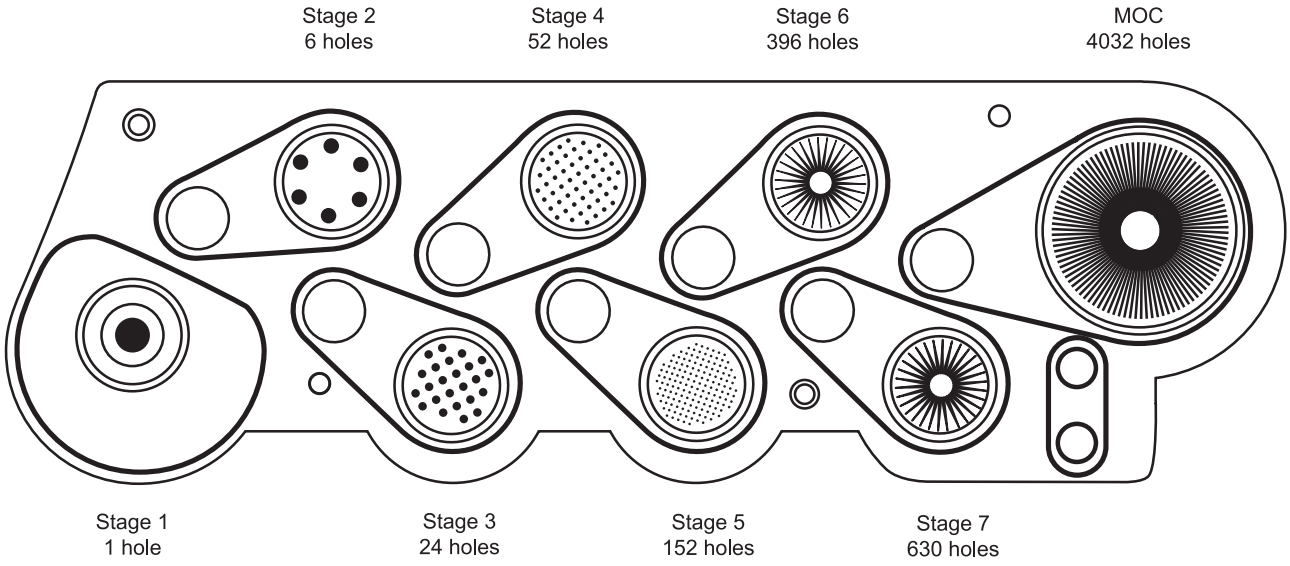

Figure 2.9.18.-13. – *Apparatus E: nozzle configuration*

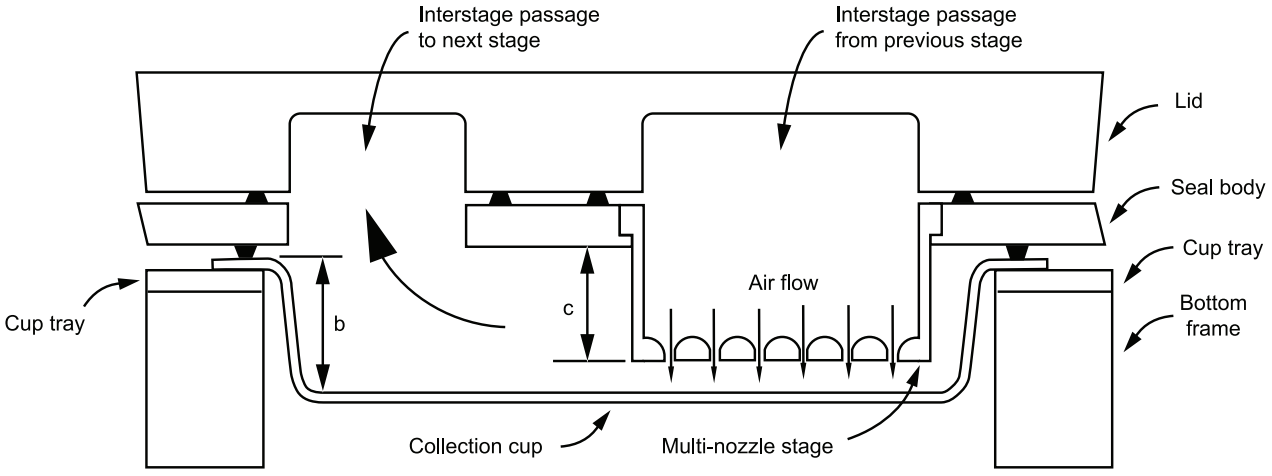

Figure 2.9.18.-14. – *Apparatus E: configuration of interstage passageways*

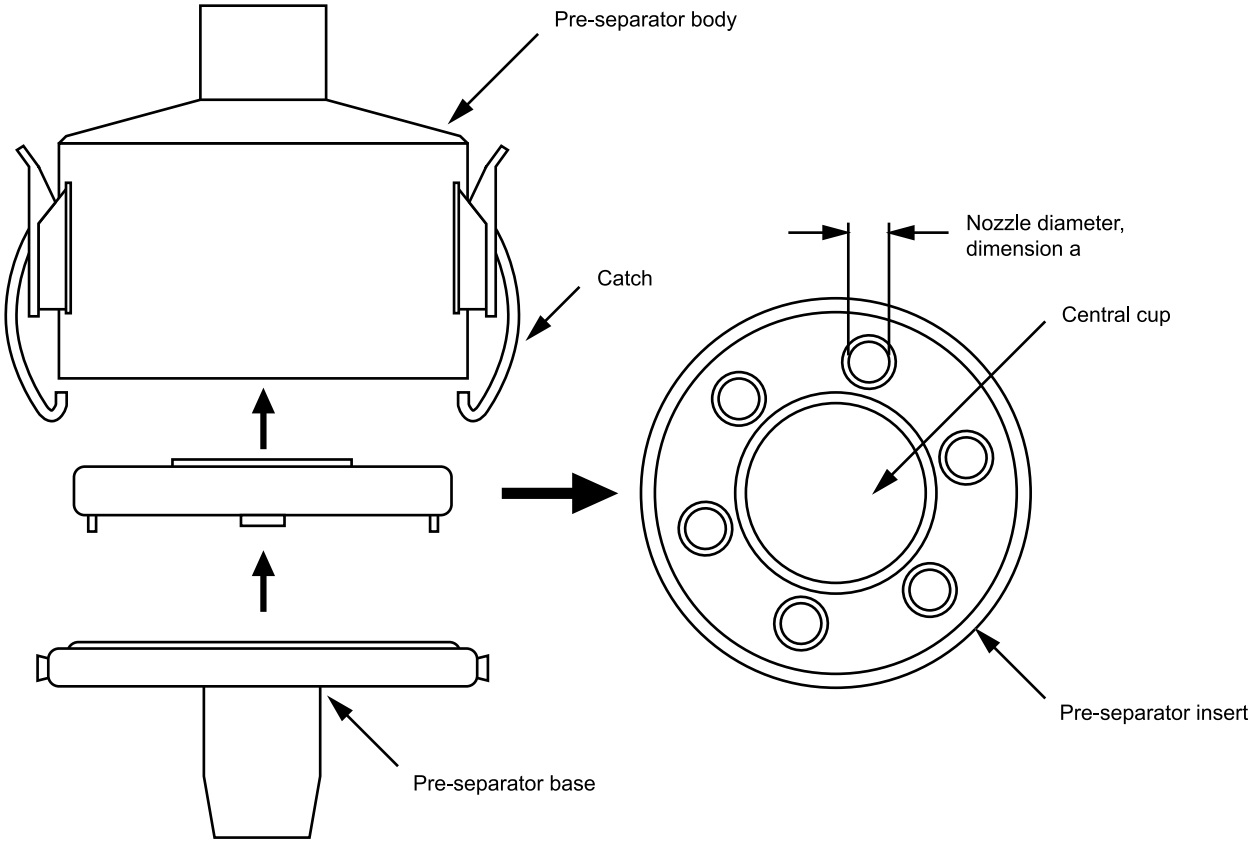

Figure 2.9.18.-15. – *Apparatus E: pre-separator configuration*

meter, or calculate the volumetric flow leaving the meter ($Q_{out}$) using the ideal gas law. For a meter calibrated for the entering volumetric flow ($Q_{in}$), use the following expression:

$$Q_{out} = \frac{Q_{in} \times P_0}{P_0 - \Delta P}$$

$P_0$ = atmospheric pressure,

$\Delta P$ = pressure drop over the meter.

Adjust the flow control valve to achieve steady flow through the system at the required rate, $Q_{out}$ (± 5 per cent). Ensure that critical flow occurs in the flow control valve by the procedure described for Apparatus C. Switch off the pump.

Prepare the powder inhaler for use according to the patient instructions. With the pump running and the 2-way solenoid valve closed, locate the mouthpiece of the inhaler in the mouthpiece adapter. Discharge the powder into the apparatus by opening the valve for the required time, $T$ (± 5 per cent). Repeat the discharge sequence. The number of discharges should be minimised and typically would not be greater than 10. The number of discharges is sufficient to ensure an accurate and precise determination of fine particle dose.

Dismantle the apparatus and recover the active substance as follows: remove the induction port and mouthpiece adapter from the pre-separator, when used, and recover the deposited active substance into an aliquot of solvent. When used, remove the pre-separator from the impactor, being careful to avoid spilling the cup liquid into the impactor. Recover the active substance from the pre-separator.

Open the impactor by releasing the handle and lifting the lid. Remove the cup tray, with the collection cups, and recover the active substance in each cup into an aliquot of solvent.

Using a suitable method of analysis, determine the quantity of active substance contained in each of the aliquots of solvent.

Calculate the fine particle dose (see Calculations).

CALCULATIONS

From the analysis of the solutions, calculate the mass of active substance deposited on each stage per discharge and the mass of active substance per discharge deposited in the induction port, mouthpiece adapter and when used, the pre-separator.

Starting at the final collection site (filter or MOC), derive a table of cumulative mass versus cut-off diameter of the respective stage (see Tables 2.9.18.-7 for Apparatus C, 2.9.18.-8 for Apparatus D, 2.9.18.-9 for Apparatus E). Calculate by interpolation the mass of the active substance less than 5 µm. This is the Fine Particle Dose (FPD).

If necessary, and where appropriate (e.g., where there is a log-normal distribution), plot the cumulative fraction of active substance versus cut-off diameter (see Tables 2.9.18.-7/9) on log probability paper, and use this plot to determine values

Table 2.9.18.-7. – *Calculations for Apparatus C. Use* $q = \sqrt{(60 / Q)}$, *where Q is the test flow rate in litres per minute* ($Q_{out}$ *for powder inhalers)*

| Cut-off diameter (µm) | Mass of active substance deposited per discharge | Cumulative mass of active substance deposited per discharge | Cumulative fraction of active substance (per cent) |
|---|---|---|---|
| $d_4 = 1.7 \times q$ | mass from stage 5, $m_5$* | $c_4 = m_5$ | $f_4 = (c_4/c) \times 100$ |
| $d_3 = 3.1 \times q$ | mass from stage 4, $m_4$ | $c_3 = c_4 + m_4$ | $f_3 = (c_3/c) \times 100$ |
| $d_2 = 6.8 \times q$ | mass from stage 3, $m_3$ | $c_2 = c_3 + m_3$ | $f_2 = (c_2/c) \times 100$ |
| | mass from stage 2, $m_2$ | $c = c_2 + m_2$ | 100 |

* Stage 5 is the filter stage

Table 2.9.18.-8. – *Calculations for Apparatus D when used at a flow rate of 28.3 L/min*

| Cut-off diameter (µm) | Mass of active substance deposited per discharge | Cumulative mass of active substance deposited per discharge | Cumulative fraction of active substance (per cent) |
|---|---|---|---|
| $d_7 = 0.4$ | mass from stage 8, $m_8$ | $c_7 = m_8$ | $f_7 = (c_7/c) \times 100$ |
| $d_6 = 0.7$ | mass from stage 7, $m_7$ | $c_6 = c_7 + m_7$ | $f_6 = (c_6/c) \times 100$ |
| $d_5 = 1.1$ | mass from stage 6, $m_6$ | $c_5 = c_6 + m_6$ | $f_5 = (c_5/c) \times 100$ |

# 2.9.19. PARTICULATE CONTAMINATION: SUB-VISIBLE PARTICLES[9]

Particulate contamination of injections and infusions consists of extraneous, mobile undissolved particles, other than gas bubbles, unintentionally present in the solutions.

For the determination of particulate contamination 2 procedures, Method 1 (Light Obscuration Particle Count Test) and Method 2 (Microscopic Particle Count Test), are specified hereinafter. When examining injections and infusions for sub-visible particles, Method 1 is preferably applied. However, it may be necessary to test some preparations by the light obscuration particle count test followed by the microscopic particle count test to reach a conclusion on conformance to the requirements.

Not all parenteral preparations can be examined for sub-visible particles by one or both of these methods. When Method 1 is not applicable, e.g. in case of preparations having reduced clarity or increased viscosity, the test is carried out according to Method 2. Emulsions, colloids, and liposomal preparations are examples. Similarly, products that produce air or gas bubbles when drawn into the sensor may also require microscopic particle count testing. If the viscosity of the preparation to be tested is sufficiently high so as to preclude its examination by either test method, a quantitative dilution with an appropriate diluent may be made to decrease viscosity, as necessary, to allow the analysis to be performed.

The results obtained in examining a discrete unit or group of units for particulate contamination cannot be extrapolated with certainty to other units that remain untested. Thus, statistically sound sampling plans must be developed if valid inferences are to be drawn from observed data to characterise the level of particulate contamination in a large group of units.

## METHOD 1. LIGHT OBSCURATION PARTICLE COUNT TEST

Use a suitable apparatus based on the principle of light blockage which allows an automatic determination of the size of particles and the number of particles according to size.

The apparatus is calibrated using suitable certified reference materials consisting of dispersions of spherical particles of known sizes between 10 µm and 25 µm. These standard particles are dispersed in *particle-free water R*. Care must be taken to avoid aggregation of particles during dispersion.

### General precautions

The test is carried out under conditions limiting particulate contamination, preferably in a laminar-flow cabinet.

Very carefully wash the glassware and filtration equipment used, except for the membrane filters, with a warm detergent solution and rinse with abundant amounts of water to remove all traces of detergent. Immediately before use, rinse the equipment from top to bottom, outside and then inside, with *particle-free water R*.

Take care not to introduce air bubbles into the preparation to be examined, especially when fractions of the preparation are being transferred to the container in which the determination is to be carried out.

(9) This chapter has undergone pharmacopoeial harmonisation. See chapter *5.8. Pharmacopoeial harmonisation*.

In order to check that the environment is suitable for the test, that the glassware is properly cleaned and that the water to be used is particle-free, the following test is carried out: determine the particulate contamination of 5 samples of *particle-free water R*, each of 5 mL, according to the method described below. If the number of particles of 10 µm or greater size exceeds 25 for the combined 25 mL, the precautions taken for the test are not sufficient. The preparatory steps must be repeated until the environment, glassware and water are suitable for the test.

**Method**

Mix the contents of the sample by slowly inverting the container 20 times successively. If necessary, cautiously remove the sealing closure. Clean the outer surfaces of the container opening using a jet of *particle-free water R* and remove the closure, avoiding any contamination of the contents. Eliminate gas bubbles by appropriate measures such as allowing to stand for 2 min or sonicating.

For large-volume parenterals, single units are tested. For small-volume parenterals less than 25 mL in volume, the contents of 10 or more units are combined in a cleaned container to obtain a volume of not less than 25 mL; where justified and authorised, the test solution may be prepared by mixing the contents of a suitable number of vials and diluting to 25 mL with *particle-free water R* or with an appropriate solvent without contamination of particles when *particle-free water R* is not suitable. Small-volume parenterals having a volume of 25 mL or more may be tested individually.

Powders for parenteral administration are reconstituted with *particle-free water R* or with an appropriate solvent without contamination of particles when *particle-free water R* is not suitable.

The number of test specimens must be adequate to provide a statistically sound assessment. For large-volume parenterals or for small-volume parenterals having a volume of 25 mL or more, fewer than 10 units may be tested, based on an appropriate sampling plan.

Remove 4 portions, each of not less than 5 mL, and count the number of particles equal to or greater than 10 µm and 25 µm. Disregard the result obtained for the first portion, and calculate the mean number of particles for the preparation to be examined.

**Evaluation**

For preparations supplied in containers with a nominal volume of more than 100 mL, apply the criteria of test 1.A.

For preparations supplied in containers with a nominal volume of less than 100 mL, apply the criteria of test 1.B.

♦For preparations supplied in containers with a nominal volume of 100 mL, apply the criteria of test 1.B.♦

If the average number of particles exceeds the limits, test the preparation by the microscopic particle count test.

*Test 1.A – Solutions for infusion or solutions for injection supplied in containers with a nominal content of more than 100 mL*

The preparation complies with the test if the average number of particles present in the units tested does not exceed 25 per millilitre equal to or greater than 10 µm and does not exceed 3 per millilitre equal to or greater than 25 µm.

*Test 1.B – Solutions for infusion or solutions for injection supplied in containers with a nominal content of less than 100 mL*

The preparation complies with the test if the average number of particles present in the units tested does not exceed 6000 per container equal to or greater than 10 µm and does not exceed 600 per container equal to or greater than 25 µm.

METHOD 2. MICROSCOPIC PARTICLE COUNT TEST

Use a suitable binocular microscope, filter assembly for retaining particulate contamination and membrane filter for examination.

The microscope is equipped with an ocular micrometer calibrated with an objective micrometer, a mechanical stage capable of holding and traversing the entire filtration area of the membrane filter, 2 suitable illuminators to provide episcopic illumination in addition to oblique illumination, and is adjusted to 100 ± 10 magnifications.

The ocular micrometer is a circular diameter graticule (see Figure 2.9.19.-1.) and consists of a large circle divided by crosshairs into quadrants, transparent and black reference circles 10 µm and 25 µm in diameter at 100 magnifications, and a linear scale graduated in 10 µm increments. It is calibrated using a stage micrometer that is certified by either a domestic or international standard institution. A relative error of the linear scale of the graticule within ± 2 per cent is acceptable. The large circle is designated the graticule field of view (GFOV).

2 illuminators are required. One is an episcopic brightfield illuminator internal to the microscope, the other is an external, focusable auxiliary illuminator adjustable to give reflected oblique illumination at an angle of 10-20°.

The filter assembly for retaining particulate contamination consists of a filter holder made of glass or other suitable material, and is equipped with a vacuum source and a suitable membrane filter.

The membrane filter is of suitable size, black or dark grey in colour, non-gridded or gridded, and 1.0 µm or finer in nominal pore size.

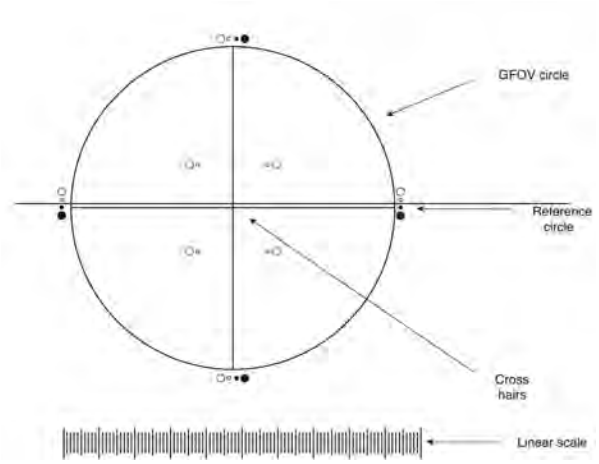

Figure 2.9.19.-1. – *Circular diameter graticule*

**General precautions**

The test is carried out under conditions limiting particulate contamination, preferably in a laminar-flow cabinet.

Very carefully wash the glassware and filter assembly used, except for the membrane filter, with a warm detergent solution and rinse with abundant amounts of water to remove all traces of detergent. Immediately before use, rinse both sides of the membrane filter and the equipment from top to bottom, outside and then inside, with *particle-free water R*.

In order to check that the environment is suitable for the test, that the glassware and the membrane filter are properly cleaned and that the water to be used is particle-free, the following test is carried out: determine the particulate contamination of a 50 mL volume of *particle-free water R* according to the method described below. If more than 20 particles 10 µm or larger in size or if more than 5 particles 25 µm or larger in size are present within the filtration area, the precautions taken for the test are not sufficient. The preparatory steps must be repeated until the environment, glassware, membrane filter and water are suitable for the test.

**Method**

Mix the contents of the samples by slowly inverting the container 20 times successively. If necessary, cautiously remove the sealing closure. Clean the outer surfaces of the container

opening using a jet of *particle-free water R* and remove the closure, avoiding any contamination of the contents.

For large-volume parenterals, single units are tested. For small-volume parenterals less than 25 mL in volume, the contents of 10 or more units are combined in a cleaned container; where justified and authorised, the test solution may be prepared by mixing the contents of a suitable number of vials and diluting to 25 mL with *particle-free water R* or with an appropriate solvent without contamination of particles when *particle-free water R* is not suitable. Small-volume parenterals having a volume of 25 mL or more may be tested individually.

Powders for parenteral administration are constituted with *particle-free water R* or with an appropriate solvent without contamination of particles when *particle-free water R* is not suitable.

The number of test specimens must be adequate to provide a statistically sound assessment. For large-volume parenterals or for small-volume parenterals having a volume of 25 mL or more, fewer than 10 units may be tested, based on an appropriate sampling plan.

Wet the inside of the filter holder fitted with the membrane filter with several millilitres of *particle-free water R*. Transfer to the filtration funnel the total volume of a solution pool or of a single unit, and apply vacuum. If needed, add stepwise a portion of the solution until the entire volume is filtered. After the last addition of solution, begin rinsing the inner walls of the filter holder by using a jet of *particle-free water R*. Maintain the vacuum until the surface of the membrane filter is free from liquid. Place the filter in a Petri dish and allow the filter to air-dry with the cover slightly ajar. After the filter has been dried, place the Petri dish on the stage of the microscope, scan the entire membrane filter under the reflected light from the illuminating device, and count the number of particles that are equal to or greater than 10 µm and the number of particles that are equal to or greater than 25 µm. Alternatively, partial filter count and determination of the total filter count by calculation is allowed. Calculate the mean number of particles for the preparation to be examined.

The particle sizing process with the use of the circular diameter graticule is carried out by transforming mentally the image of each particle into a circle and then comparing it to the 10 µm and 25 µm graticule reference circles. Thereby the particles are not moved from their initial locations within the graticule field of view and are not superimposed on the reference circles for comparison. The inner diameter of the transparent graticule reference circles is used to size white and transparent particles, while dark particles are sized by using the outer diameter of the black opaque graticule reference circles.
