Residual infectious virus. Inoculate 0.2 ml of the vaccine into the allantoic cavity of each of 10 fertilised eggs and incubate at 33-37 °C for 3 days. The test is not valid unless at least 8 of the 10 embryos survive. Harvest 0.5 ml of the allantoic fluid from each surviving embryo and pool the fluids. Inoculate 0.2 ml of the pooled fluid into a further 10 fertilised eggs and incubate at 33-37 °C for 3 days. The test is not valid unless at least 8 of the 10 embryos survive. Harvest about 0.1 ml of the allantoic fluid from each surviving embryo and examine each individual harvest for

(5) Reference haemagglutinin antigens are available from the National Institute for Biological Standards and Control, Blanche Lane, South Mimms, Potters Bar, Hertfordshire EN6 3QG, Great Britain.

live virus by a haemagglutination test. If haemagglutination is found for any of the fluids, carry out for that fluid a further passage in eggs and test for haemagglutination; no haemagglutination occurs.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Free formaldehyde (*2.4.18*): maximum 0.2 g/l, where applicable.

Ovalbumin. Not more than the quantity stated on the label and in any case not more than 1 µg per human dose, determined by a suitable immunochemical method (*2.7.1*) using a suitable reference preparation of ovalbumin.

Total protein. Not more than 6 times the total haemagglutinin content of the vaccine as determined in the assay, but in any case, not more than 100 µg of protein per virus strain per human dose and not more than a total of 300 µg of protein per human dose.

Sterility (*2.6.1*). It complies with the test for sterility.

Bacterial endotoxins (*2.6.14*): less than 100 IU per human dose.

ASSAY

Determine the content of haemagglutinin antigen by an immunodiffusion test (*2.7.1*), by comparison with a haemagglutinin antigen reference preparation or with an antigen preparation calibrated against it[1]. Carry out the test at 20-25 °C. The confidence limits (P = 0.95) are not less than 80 per cent and not more than 125 per cent of the estimated haemagglutinin antigen content. The lower confidence limit (P = 0.95) is not less than 80 per cent of the amount stated on the label for each strain.

LABELLING

The label states:

- that the vaccine has been prepared on eggs,
- the strain or strains of influenza virus used to prepare the vaccine,
- the method of inactivation,
- the haemagglutinin content in micrograms per virus strain per dose,
- the maximum amount of ovalbumin,
- the season during which the vaccine is intended to protect.

01/2008:2308

INFLUENZA VACCINE (WHOLE VIRION, INACTIVATED, PREPARED IN CELL CULTURES)

Vaccinum influenzae inactivatum ex cellulis virisque integris praeparatum

DEFINITION

Influenza vaccine (whole virion, inactivated, prepared in cell cultures) is a sterile, aqueous suspension of a strain or strains of influenza virus, type A or B, or a mixture of strains of the 2 types grown individually in cell cultures and inactivated in such a manner that their antigenic properties are retained. The stated amount of haemagglutinin antigen for each strain present in the vaccine is 15 µg per dose, unless clinical evidence supports the use of a different amount. The vaccine is a slightly opalescent or opalescent liquid. The vaccine may contain an adjuvant. This monograph applies to vaccines produced in diploid or continuous cell lines of mammalian origin.

PRODUCTION

GENERAL PROVISIONS

Production of the vaccine is based on a virus seed-lot system and a cell-bank system. The production method shall have been shown to yield consistently vaccines that comply with the requirements for immunogenicity, safety and stability.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (*2.6.9*).

The production method is validated to demonstrate suitable reduction of residual host-cell protein. With the agreement of the competent authority and for each specific product, routine testing for residual host-cell proteins may be omitted based on the results of validation studies for the product. Guidance on the principles of such validation studies is given, for example, in the monograph on *Products of recombinant DNA technology (0784)*, in particular in the chapters on "Validation of the production process - extraction and purification" and "Production consistency - Host-cell-derived proteins".

CHOICE OF VACCINE STRAIN

The World Health Organisation reviews the world epidemiological situation annually and if necessary recommends new strains corresponding to this epidemiological evidence.

Such strains are used in accordance with the regulations in force in the signatory states of the Convention on the Elaboration of a European Pharmacopoeia. It is now common practice to use reassorted strains giving high yields of the appropriate surface antigens. The origin and passage history of virus strains shall be approved by the competent authority.

SUBSTRATE FOR VIRUS PROPAGATION

Influenza virus used in the preparation of seed lots is propagated in fertilised eggs from chicken flocks free from specified pathogens (SPF) (*5.2.2*) or in suitable cell cultures (*5.2.3*), such as chick-embryo fibroblasts, chick kidney cells obtained from SPF chicken flocks (*5.2.2*), or a diploid or continuous cell line. The final passage for establishment of the working seed lot is prepared in the cell line used for routine production. For this production, the virus of each strain is propagated in a diploid or continuous cell line (*5.2.3*).

VIRUS SEED LOT

The production of vaccine is based on a seed-lot system. Each of the strains of influenza virus used shall be identified by historical records that include information on the origin of the strain and its subsequent manipulation. Working seed lots represent not more than 15 passages from the approved reassorted virus or the approved virus isolate. The final vaccine represents 1 passage from the working seed lot.

Only a seed lot that complies with the following requirements may be used for virus propagation.

Identification. The haemagglutinin and neuraminidase antigens of each master and working seed lot are identified as originating from the correct strain of influenza virus by suitable methods.

Virus concentration. The virus concentration of each working seed lot is determined. Where applicable, the virus concentration of each master seed lot is determined.

Extraneous agents (*2.6.16*). The working seed lots comply with the requirements for seed lots. It is recognised that when a vaccine strain changes, there may be time constraints that make testing a virus seed for extraneous agents problematic, and the results of such testing may not be completely available before further processing. Rapid assays (e.g. multiplex PCR) are applied in parallel wherever possible.

If an agent is detected in a virus seed and the mammalian cells used for production are shown to be susceptible to this agent, the virus seed is not used for vaccine production.

If an agent is detected in a virus seed and the mammalian cells are not susceptible to the agent, validation of the production process to demonstrate removal or inactivation of the agent is carried out. If removal or inactivation cannot be demonstrated, the inactivated monovalent harvest is tested to demonstrate absence of any contaminant identified in the virus seed.

PROPAGATION AND SINGLE HARVEST

All processing of the cell bank and subsequent cell cultures is done under aseptic conditions in an area where no other cells are being handled at the same time. Animal serum (but no human serum) may be used in the cell culture media. Serum and trypsin used in the preparation of cell suspensions or media are shown to be free from extraneous agents. The cell culture media may contain a pH indicator, such as phenol red, and antibiotics at the lowest effective concentration. A sufficient quantity of the cell cultures employed for vaccine production are set aside as uninfected cell cultures (control cells).

Only a single harvest that complies with the following requirements may be used in the preparation of the vaccine.

Identification. The test for antigen content also serves to identify the single harvest.

Bacterial and fungal contamination. Carry out the test for sterility (*2.6.1*), using 10 ml for each medium.

Mycoplasmas (*2.6.7*). Carry out the test for mycoplasmas, using 10 ml for each medium.

Control cells. The control cells of the production cell culture comply with a test for identification and the requirements for extraneous agents (*2.6.16*).

Haemagglutinin antigen. Determine the haemagglutinin antigen content by a suitable immunochemical method (*2.7.1*).

INACTIVATED AND PURIFIED MONOVALENT HARVEST

The harvest, which may be a pool of several single harvests of the same strain, is inactivated and purified by validated methods. Before or after the inactivation process, the monovalent harvest is concentrated and purified by high-speed centrifugation or another suitable method. The influenza virus is inactivated by a method that has been demonstrated on 3 consecutive batches to be consistently effective for the manufacturer. The inactivation process shall have been shown to be capable of inactivating the influenza virus without destroying its antigenicity; the process is designed so as to cause minimum alteration of the haemagglutinin and neuraminidase antigens.

If continuous cell lines are used for production, the purification process shall have been validated to reduce consistently host-cell DNA to a suitable level.

Only an inactivated, purified monovalent harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Haemagglutinin antigen. Determine the haemagglutinin antigen content by a suitable immunochemical method (*2.7.1*).

Antigen: total protein ratio. Determine the haemagglutinin antigen content by a suitable immunodiffusion test. Determine the total protein by a validated method. The ratio of haemagglutinin antigen content to total protein content is within the limits approved for the particular product.

Neuraminidase antigen. The presence and type of neuraminidase antigen are confirmed by suitable enzymatic or immunological methods on the first 3 monovalent harvests from each working seed lot.

Sterility (*2.6.1*). Carry out the test for sterility, using 10 ml for each medium.

Residual infectious virus. Carry out the test described below under Tests.

FINAL BULK VACCINE

Appropriate quantities of the inactivated purified monovalent pooled harvests are blended to make the final bulk vaccine. An adjuvant may be added.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Sterility (*2.6.1*). Carry out the test for sterility, using 10 ml for each medium.

Residual host-cell DNA. If a continuous cell line is used for virus propagation, the content of residual host-cell DNA, determined using a suitable method, is not greater than 10 ng in the equivalent of a single human dose.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers. The containers are closed so as to prevent contamination.

Only a final lot that is satisfactory with respect to each of the requirements given below under Tests and Assay may be released for use. Provided that the test for residual infectious virus has been performed with satisfactory results on each inactivated and purified monovalent harvest and that the tests for free formaldehyde, bovine serum albumin and total protein have been performed with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

If the vaccine contains an adjuvant, suitable tests for identity and other relevant quality criteria are carried out on the final lot. These tests may include chemical and physical analysis, determination of particle size and determination of the number of particles per unit volume.

IDENTIFICATION

The assay serves to confirm the antigenic specificity of the vaccine.

TESTS

Residual infectious virus. Carry out an amplification test for residual infectious influenza virus by inoculating not less than 4 ml of the vaccine into cell cultures of the same type as used for production of the vaccine; incubate for not less than 7 days at 32 ± 2 °C. Inoculate not less than 10 ml of the cell culture harvested medium into a new cell culture and incubate as before. At the end of the incubation period, examine for live virus by a haemagglutination test. If

haemagglutination is found for any of the fluids, carry out for that fluid a further passage on cell cultures and test for haemagglutination; no haemagglutination occurs.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Free formaldehyde (*2.4.18*): maximum 0.2 g/l, where applicable.

Bovine serum albumin: maximum 50 ng per human dose, determined by a suitable immunochemical method (*2.7.1*).

Total protein. Not more than 6 times the total haemagglutinin content of the vaccine as determined in the assay, but in any case, not more than 100 µg of protein per virus strain per human dose.

Sterility (*2.6.1*). It complies with the test for sterility.

Bacterial endotoxins (*2.6.14*): less than 25 IU per human dose.

ASSAY

Determine the content of haemagglutinin antigen by an immunodiffusion test (*2.7.1*), by comparison with a haemagglutinin antigen reference preparation[(6)] or with an antigen preparation calibrated against it. Carry out the test at 20-25 °C. The confidence limits (P = 0.95) are not less than 80 per cent and not more than 125 per cent of the estimated content. The lower confidence limit (P = 0.95) is not less than 80 per cent of the amount stated on the label for each strain.

LABELLING

The label states:

- the biological origin of the cells used for the preparation of the vaccine;
- the strain or strains of influenza virus used to prepare the vaccine;
- the method of inactivation;
- the haemagglutinin antigen content in micrograms per virus strain per dose;
- the season during which the vaccine is intended to protect;
- where applicable, the name and the quantity of adjuvant used.

01/2008:1057

MEASLES, MUMPS AND RUBELLA VACCINE (LIVE)

Vaccinum morbillorum, parotitidis et rubellae vivum

DEFINITION

Measles, mumps and rubella vaccine (live) is a freeze-dried preparation of suitable attenuated strains of measles virus, mumps virus and rubella virus.

The vaccine is reconstituted immediately before use, as stated on the label, to give a clear liquid that may be coloured owing to the presence of a pH indicator.

PRODUCTION

The three components are prepared as described in the monographs on *Measles vaccine (live) (0213)*, *Mumps vaccine (live) (0538)* and *Rubella vaccine (live) (0162)* and comply with the requirements prescribed therein.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (*2.6.9*).

FINAL BULK VACCINE

Virus harvests for each component are pooled and clarified to remove cells. A suitable stabiliser may be added and the pooled harvests diluted as appropriate. Suitable quantities of the pooled harvest for each component are mixed.

Only a final bulk vaccine that complies with the following requirement may be used in the preparation of the final lot.

Bacterial and fungal contamination. Carry out the test for sterility (*2.6.1*), using 10 ml for each medium.

FINAL LOT

For each component, a minimum virus concentration for release of the product is established such as to ensure, in the light of stability data, that the minimum concentration stated on the label will be present at the end of the period of validity.

Only a final lot that complies with the requirements for minimum virus concentration of each component for release, with the following requirement for thermal stability and with each of the requirements given below under Identification and Tests may be released for use. Provided that the tests for bovine serum albumin and, where applicable, for ovalbumin have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

Thermal stability. Maintain samples of the final lot of freeze-dried vaccine in the dry state at 37 °C for 7 days. Determine the virus concentration as described under Assay in parallel for the heated vaccine and for unheated vaccine stored at 5 ± 3 °C. For each component, the virus concentration of the heated vaccine is not more than 1.0 $\log_{10}$ lower than that of the unheated vaccine.

IDENTIFICATION

When the vaccine reconstituted as stated on the label is mixed with antibodies specific for measles virus, mumps virus and rubella virus, it is no longer able to infect cell cultures susceptible to these viruses. When the vaccine reconstituted as stated on the label is mixed with quantities of specific antibodies sufficient to neutralise any two viral components, the third viral component infects susceptible cell cultures.

TESTS

Bacterial and fungal contamination. The reconstituted vaccine complies with the test for sterility (*2.6.1*).

Bovine serum albumin. Not more than 50 ng per single human dose, determined by a suitable immunochemical method (*2.7.1*).

Ovalbumin. If the mumps component is produced in chick embryos, the vaccine contains not more than 1 µg of ovalbumin per single human dose, determined by a suitable immunochemical method (*2.7.1*).

Water (*2.5.12*). Not more than 3.0 per cent, determined by the semi-micro determination of water.

(6) Reference haemagglutinin antigens are available from the National Institute for Biological Standards and Control, Blanche Lane, South Mimms, Potters Bar, Hertfordshire EN6 3QG, Great Britain.

ASSAY

A. Mix the vaccine with a sufficient quantity of antibodies specific for mumps virus. Titrate the vaccine for infective measles virus at least in triplicate, using at least five cell cultures for each 0.5 $\log_{10}$ dilution step or by a method of equal precision. Use an appropriate virus reference preparation to validate each assay. The estimated measles virus concentration is not less than that stated on the label; the minimum measles virus concentration stated on the label is not less than 1×10^3 $CCID_{50}$ per single human dose. The assay is not valid if the confidence interval (P = 0.95) of the logarithm of the virus concentration is greater than ± 0.3.

   Measles vaccine (live) BRP is suitable for use as a reference preparation.

B. Mix the vaccine with a sufficient quantity of antibodies specific for measles virus. Titrate the vaccine for infective mumps virus at least in triplicate, using at least five cell cultures for each 0.5 $\log_{10}$ dilution step or by a method of equal precision. Use an appropriate virus reference preparation to validate each assay. The estimated mumps virus concentration is not less than that stated on the label; the minimum mumps virus concentration stated on the label is not less than 5×10^3 $CCID_{50}$ per single human dose. The assay is not valid if the confidence interval (P = 0.95) of the logarithm of the virus concentration is greater than ± 0.3.

   Mumps vaccine (live) BRP is suitable for use as a reference preparation.

C. Mix the vaccine with a sufficient quantity of antibodies specific for mumps virus. Titrate the vaccine for infective rubella virus at least in triplicate, using at least five cell cultures for each 0.5 $\log_{10}$ dilution step or by a method of equal precision. Use an appropriate virus reference preparation to validate each assay. The estimated rubella virus concentration is not less than that stated on the label; the minimum rubella virus concentration stated on the label is not less than 1×10^3 $CCID_{50}$ per single human dose. The assay is not valid if the confidence interval (P = 0.95) of the logarithm of the virus concentration is greater than ± 0.3.

   Rubella vaccine (live) BRP is suitable for use as a reference preparation.

LABELLING

The label states:

– the strains of virus used in the preparation of the vaccine,

– where applicable, that chick embryos have been used for the preparation of the vaccine,

– the type and origin of the cells used for the preparation of the vaccine,

– the minimum virus concentration for each component of the vaccine,

– that contact with disinfectants is to be avoided,

– the time within which the vaccine must be used after reconstitution,

– that the vaccine must not be given to a pregnant woman and that a woman must not become pregnant within 2 months after having the vaccine.

01/2008:0213

MEASLES VACCINE (LIVE)

Vaccinum morbillorum vivum

DEFINITION

Measles vaccine (live) is a freeze-dried preparation of a suitable attenuated strain of measles virus. The vaccine is reconstituted immediately before use, as stated on the label, to give a clear liquid that may be coloured owing to the presence of a pH indicator.

PRODUCTION

The production of vaccine is based on a virus seed-lot system and, if the virus is propagated in human diploid cells, a cell-bank system. The production method shall have been shown to yield consistently live measles vaccines of adequate immunogenicity and safety in man. Unless otherwise justified and authorised, the virus in the final vaccine shall have undergone no more passages from the master seed lot than were used to prepare the vaccine shown in clinical studies to be satisfactory with respect to safety and efficacy; even with authorised exceptions, the number of passages beyond the level used for clinical studies shall not exceed five.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (*2.6.9*).

SUBSTRATE FOR VIRUS PROPAGATION

The virus is propagated in human diploid cells (*5.2.3*) or in cultures of chick-embryo cells derived from a chicken flock free from specified pathogens (*5.2.2*).

SEED LOT

The strain of measles virus used shall be identified by historical records that include information on the origin of the strain and its subsequent manipulation. To avoid the unnecessary use of monkeys in the test for neurovirulence, virus seed lots are prepared in large quantities and stored at temperatures below – 20 °C if freeze-dried, or below – 60 °C if not freeze-dried.

Only a seed lot that complies with the following requirements may be used for virus propagation.

Identification. The master and working seed lots are identified as measles virus by serum neutralisation in cell culture, using specific antibodies.

Virus concentration. The virus concentration of the master and working seed lots is determined to monitor consistency of production.

Extraneous agents (*2.6.16*). The working seed lot complies with the requirements for seed lots.

Neurovirulence (*2.6.18*). The working seed lot complies with the test for neurovirulence of live virus vaccines. *Macaca* and *Cercopithecus* monkeys susceptible to measles virus are suitable for the test.

PROPAGATION AND HARVEST

All processing of the cell bank and subsequent cell cultures is done under aseptic conditions in an area where no other cells are handled. Suitable animal (but not human) serum may be used in the growth medium, but the final medium for maintaining cell growth during virus multiplication does not contain animal serum. Serum and trypsin used in the preparation of cell suspensions and culture media are shown to be free from extraneous agents. The cell culture medium may contain a pH indicator such as phenol red and suitable antibiotics at the lowest effective concentration. It is preferable to have a substrate free from antibiotics during

production. Not less than 500 ml of the production cell culture is set aside as uninfected cell cultures (control cells). The viral suspensions are harvested at a time appropriate to the strain of virus being used.

Only a single harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Identification. The single harvest contains virus that is identified as measles virus by serum neutralisation in cell culture, using specific antibodies.

Virus concentration. The virus concentration in the single harvest is determined as prescribed under Assay to monitor consistency of production and to determine the dilution to be used for the final bulk vaccine.

Extraneous agents (*2.6.16*). The single harvest complies with the tests for extraneous agents.

Control cells. If human diploid cells are used for production, the control cells comply with a test for identification. They comply with the tests for extraneous agents (*2.6.16*).

FINAL BULK VACCINE

Virus harvests that comply with the above tests are pooled and clarified to remove cells. A suitable stabiliser may be added and the pooled harvests diluted as appropriate.

Only a final bulk vaccine that complies with the following requirement may be used in the preparation of the final lot.

Bacterial and fungal contamination. The final bulk vaccine complies with the test for sterility (*2.6.1*), carried out using 10 ml for each medium.

FINAL LOT

A minimum virus concentration for release of the product is established such as to ensure, in the light of stability data, that the minimum concentration stated on the label will be present at the end of the period of validity.

Only a final lot that complies with the requirements for minimum virus concentration for release, with the following requirement for thermal stability and with each of the requirements given below under Identification and Tests may be released for use. Provided that the test for bovine serum albumin has been carried out with satisfactory results on the final bulk vaccine, it may be omitted on the final lot.

Thermal stability. Maintain samples of the final lot of freeze-dried vaccine in the dry state at 37 °C for 7 days. Determine the virus concentration as described under Assay in parallel for the heated vaccine and for unheated vaccine stored at 5 ± 3 °C. The virus concentration of the heated vaccine is not more than 1.0 $\log_{10}$ lower than that of the unheated vaccine.

IDENTIFICATION

When the vaccine reconstituted as stated on the label is mixed with specific measles antibodies, it is no longer able to infect susceptible cell cultures.

TESTS

Bacterial and fungal contamination. The reconstituted vaccine complies with the test for sterility (*2.6.1*).

Bovine serum albumin. Not more than 50 ng per single human dose, determined by a suitable immunochemical method (*2.7.1*).

Water (*2.5.12*). Not more than 3.0 per cent, determined by the semi-micro determination of water.

ASSAY

Titrate the vaccine for infective virus at least in triplicate, using at least five cell cultures for each 0.5 $\log_{10}$ dilution step or by a method of equal precision. Use an appropriate virus reference preparation to validate each assay. The estimated virus concentration is not less than that stated on the label; the minimum virus concentration stated on the label is not less than 1×10^3 $CCID_{50}$ per human dose. The assay is not valid if the confidence interval (P = 0.95) of the logarithm of the virus concentration is greater than ± 0.3.

Measles vaccine (live) BRP is suitable for use as a reference preparation.

LABELLING

The label states:

- the strain of virus used for the preparation of the vaccine,
- the type and origin of the cells used for the preparation of the vaccine,
- the minimum virus concentration,
- that contact with disinfectants is to be avoided,
- the time within which the vaccine must be used after reconstitution.

corrected 6.0

MENINGOCOCCAL GROUP C CONJUGATE VACCINE

Vaccinum meningococcale classis C coniugatum

DEFINITION

Meningococcal group C conjugate vaccine is a liquid or freeze-dried preparation of purified capsular polysaccharide derived from a suitable strain of *Neisseria meningitidis* group C covalently linked to a carrier protein. Meningococcal group C polysaccharide consists of partly *O*-acetylated or *O*-deacetylated repeating units of sialic acids, linked with 2α→ 9 glycosidic bonds. The carrier protein, when conjugated to group C polysaccharide, is capable of inducing a T-cell-dependent B-cell immune response to the polysaccharide. The vaccine may contain an adjuvant.

PRODUCTION

GENERAL PROVISIONS

The production method shall consistently have been shown to yield meningococcal group C conjugate vaccines of satisfactory immunogenicity and safety in man. The production of meningococcal group C polysaccharide and of the carrier protein are based on seed-lot systems.

During development studies and wherever revalidation is necessary, a test for pyrogens in rabbits (*2.6.8*) is carried out by injection of a suitable dose of the final lot. The vaccine is shown to be acceptable with respect to absence of pyrogenic activity.

The production method is validated to demonstrate that the vaccine, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (*2.6.9*).

During development studies and wherever revalidation of the manufacturing process is necessary, it shall be demonstrated by tests in animals that the vaccine consistently induces a T-cell-dependent B-cell immune response.

The stability of the final lot and relevant intermediates is evaluated using 1 or more indicator tests. Such tests may include determination of molecular size, determination of free saccharide in the conjugate or an immunogenicity test in animals.

BACTERIAL SEED LOTS

The bacterial strains used for master seed lots shall be identified by historical records that include information on their origin and the tests used to characterise the strain. Cultures from the working seed lot shall have the same characteristics as the strain that was used to prepare the master seed lot.

Purity of bacterial cultures is verified by methods of suitable sensitivity. These may include inoculation into suitable media, examination of colony morphology, microscopic examination of Gram-stained smears and culture agglutination with suitable specific antisera.

MENINGOCOCCAL GROUP C POLYSACCHARIDE

N. meningitidis is grown in a liquid medium that does not contain high-molecular-mass polysaccharides and is free from ingredients that will form a precipitate upon addition of cetyltrimethylammonium bromide (CTAB). The culture may be inactivated by heat and filtered before the polysaccharide is precipitated by addition of CTAB. The precipitate is further purified using suitable methods to remove nucleic acids, proteins and lipopolysaccharides and the final purification step consists of ethanol precipitation. An *O*-deacetylation step may also be included. Volatile matter, including water, in the purified polysaccharide is determined by a suitable method such as thermogravimetry (*2.2.34*). The value is used to calculate the results of other tests with reference to the dried substance, as prescribed below.

Only meningococcal group C polysaccharide that complies with the following requirements may be used in the preparation of the conjugate.

Protein (*2.5.16*): maximum 1.0 per cent, calculated with reference to the dried substance.

Nucleic acid (*2.5.17*): maximum 1.0 per cent, calculated with reference to the dried substance.

***O*-acetyl groups**. Examine by a suitable method (for example *2.5.19*). An acceptable value is established for the particular product and each batch of meningococcal group C polysaccharide must be shown to comply with this limit.

Sialic acid (*2.5.23*): minimum 0.800 g of sialic acid per gram of meningococcal group C polysaccharide using *N-acetylneuraminic acid R* to prepare the reference solution.

Residual reagents. Where applicable, tests are carried out to determine residues of reagents used during inactivation and purification. An acceptable value for each reagent is established for the particular product and each batch of meningococcal group C polysaccharide must be shown to comply with this limit. Where validation studies have demonstrated removal of a residual reagent, the test on purified meningococcal group C polysaccharide may be omitted.

Molecular-size distribution. Examine by size-exclusion chromatography (*2.2.30*). An acceptable value is established for the particular product and each batch of meningococcal group C polysaccharide must be shown to comply with this limit. Where applicable, the molecular-size distribution is also determined after chemical modification of the meningococcal group C polysaccharide.

Identification and serological specificity. The identity and serological specificity are determined by a suitable immunochemical method (*2.7.1*) or other suitable method, for example ^{1}H nuclear magnetic resonance spectrometry (*2.2.33*).

Bacterial endotoxins (*2.6.14*): less than 100 IU per microgram of meningococcal group C polysaccharide.

CARRIER PROTEIN

The carrier protein is chosen so that when meningococcal group C polysaccharide is conjugated it is able to induce a T-cell-dependent immune response. Tetanus toxoid and the non-toxic mutant of diphtheria toxin-like protein, CRM197 are suitable. The carrier protein is produced by culture of a suitable microorganism, the bacterial purity of which is verified.

Only a carrier protein that complies with the following requirements may be used in preparation of the conjugate.

Identification. The carrier protein is identified by a suitable immunochemical method (*2.7.1*).

Diphtheria toxin-like protein. Where diphtheria toxin-like protein is used as the carrier, it contains not less than 90 per cent of CRM197, determined by a suitable method. Suitable tests are carried out, for validation or routinely, to demonstrate that the product is non-toxic.

Tetanus toxoid. Where tetanus toxoid is used as the carrier, it is produced as described in *Tetanus vaccine (adsorbed) (0452)* and complies with the requirements prescribed therein for bulk purified toxoid , except that the antigenic purity (*2.7.27*) is not less than 1500 Lf per milligram of protein nitrogen.

BULK CONJUGATE

Meningococcal group C polysaccharide is chemically modified to enable conjugation; it is usually partly depolymerised either before or during this procedure. The conjugate is obtained by the covalent bonding of activated meningococcal group C oligosaccharide and carrier protein. The conjugate purification procedures are designed to remove residual reagents used for conjugation. The removal of residual reagents and reaction by-products is confirmed by suitable tests or by validation of the purification process.

Only a bulk conjugate that complies with the following requirements may be used in the preparation of the final bulk vaccine. For each test and for each particular product, limits of acceptance are established and each batch of conjugate must be shown to comply with these limits.

Molecular-size distribution. Examine by size-exclusion chromatography (*2.2.30*). An acceptable value is established for the particular product and each batch of bulk conjugate must be shown to comply with this limit.

Saccharide. The saccharide content is determined by a suitable validated assay, for example (*2.5.23*). Anion-exchange liquid chromatography with pulsed amperometric detection (*2.2.29*) may also be used for determination of saccharide content. An acceptable value is established for the particular product and each batch of bulk conjugate must be shown to comply with this limit.

Protein. The protein content is determined by a suitable chemical method, for example (*2.5.16*). An acceptable value is established for the particular product and each batch of bulk conjugate must be shown to comply with this limit.

Saccharide-to-protein ratio. Determine the ratio by calculation.

Free saccharide. Unbound saccharide is determined after removal of the conjugate, for example by anion-exchange liquid chromatography, size-exclusion or hydrophobic

chromatography, ultrafiltration or other validated methods. An acceptable value is established for the particular product and each batch of bulk conjugate must be shown to comply with this limit.

Free carrier protein. Determine the content, either directly by a suitable method or by deriving the content by calculation from the results of other tests. An acceptable value is established for the particular product and each batch of bulk conjugate must be shown to comply with this limit.

Residual reagents. Removal of residual reagents such as cyanide is confirmed by suitable tests or by validation of the process.

Sterility (*2.6.1*). It complies with the test for sterility, carried out using 10 ml for each medium or the equivalent of 100 doses, whichever is less.

FINAL BULK VACCINE

An adjuvant and a stabiliser may be added to the bulk conjugate before dilution to the final concentration with a suitable diluent.

Only a final bulk vaccine that complies with the following requirement and is within the limits approved for the particular product may be used in preparation of the final lot.

Sterility (*2.6.1*). It complies with the test for sterility, carried out using 10 ml for each medium.

FINAL LOT

Only a final lot that is within the limits approved for the particular product and is satisfactory with respect to each of the requirement given below under Identification, Tests and Assay may be released for use.

IDENTIFICATION

The vaccine is identified by a suitable immunochemical method (*2.7.1*).

TESTS

pH (*2.2.3*). The pH of the vaccine, reconstituted if necessary, is within ± 0.5 pH units of the limit approved for the particular product.

Aluminium (*2.5.13*): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Water (*2.5.12*): maximum 3.0 per cent for freeze-dried vaccines.

Free saccharide. Unbound saccharide is determined after removal of the conjugate, for example by anion-exchange liquid chromatography, size-exclusion or hydrophobic chromatography, ultrafiltration or other validated methods. An acceptable value consistent with adequate immunogenicity, as shown in clinical trials, is established for the particular product and each final lot must be shown to comply with this limit.

Sterility (*2.6.1*). It complies with the test for sterility.

Bacterial endotoxins (*2.6.14*): less than 25 IU per single human dose.

ASSAY

Saccharide: minimum 80 per cent of the amount of meningococcal group C polysaccharide stated on the label. The saccharide content is determined by a suitable validated assay, for example sialic acid assay (*2.5.23*) or anion-exchange liquid chromatography with pulsed amperometric detection (*2.2.29*).

LABELLING

The label states:

- the number of micrograms of meningococcal group C polysaccharide per human dose,
- the type and number of micrograms of carrier protein per human dose.

01/2008:0250

MENINGOCOCCAL POLYSACCHARIDE VACCINE

Vaccinum meningococcale polysaccharidicum

DEFINITION

Meningococcal polysaccharide vaccine is a freeze-dried preparation of one or more purified capsular polysaccharides obtained from one or more suitable strains of *Neisseria meningitidis* group A, group C, group Y and group W135 that are capable of consistently producing polysaccharides.

N. meningitidis group A polysaccharide consists of partly *O*-acetylated repeating units of *N*-acetylmannosamine, linked with 1α→6 phosphodiester bonds.

N. meningitidis group C polysaccharide consists of partly *O*-acetylated repeating units of sialic acid, linked with 2α→9 glycosidic bonds.

N. meningitidis group Y polysaccharide consists of partly *O*-acetylated alternating units of sialic acid and D-glucose, linked with 2α→6 and 1α→4 glycosidic bonds.

N. meningitidis group W135 polysaccharide consists of partly *O*-acetylated alternating units of sialic acid and D-galactose, linked with 2α→6 and 1α→4 glycosidic bonds.

The polysaccharide component or components stated on the label together with calcium ions and residual moisture account for over 90 per cent of the mass of the preparation.

PRODUCTION

Production of the meningococcal polysaccharides is based on a seed-lot system. The production method shall have been shown to yield consistently meningococcal polysaccharide vaccines of satisfactory immunogenicity and safety in man.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (*2.6.9*).

SEED LOTS

The strains of *N. meningitidis* used for the master seed lots shall be identified by historical records that include information on their origin and by their biochemical and serological characteristics.

Cultures from each working seed lot shall have the same characteristics as the strain that was used to prepare the master seed lot. The strains have the following characteristics:

- colonies obtained from a culture are rounded, uniform in shape and smooth with a mucous, opalescent, greyish appearance,
- Gram staining reveals characteristic Gram-negative diplococci in “coffee-bean” arrangement,
- the oxidase test is positive,
- the culture utilises glucose and maltose,
- suspensions of the culture agglutinate with suitable specific antisera.

Purity of bacterial strains used for the seed lots is verified by methods of suitable sensitivity. These may include inoculation into suitable media, examination of colony morphology, microscopic examination of Gram-stained smears and culture agglutination with suitable specific antisera.

PROPAGATION AND HARVEST

The working seed lots are cultured on solid media that do not contain blood-group substances or ingredients of mammalian origin. The inoculum may undergo 1 or more subcultures in liquid medium before being used for inoculating the final medium. The liquid media used and the final medium are semisynthetic and free from substances precipitated by cetrimonium bromide (hexadecyltrimethylammonium bromide) and do not contain blood-group substances or high-molecular-mass polysaccharides.

The bacterial purity of the culture is verified by methods of suitable sensitivity. These may include inoculation into suitable media, examination of colony morphology, microscopic examination of Gram-stained smears and culture agglutination with suitable specific antisera.

The cultures are centrifuged and the polysaccharides precipitated from the supernatant by addition of cetrimonium bromide. The precipitate obtained is harvested and may be stored at – 20 °C awaiting further purification.

PURIFIED POLYSACCHARIDES

The polysaccharides are purified, after dissociation of the complex of polysaccharide and cetrimonium bromide, using suitable procedures to remove successively nucleic acids, proteins and lipopolysaccharides.

The final purification step consists of ethanol precipitation of the polysaccharides which are then dried and stored at – 20 °C. The loss on drying is determined by thermogravimetry (*2.2.34*) and the value is used to calculate the results of the other chemical tests with reference to the dried substance.

Only purified polysaccharides that comply with the following requirements may be used in the preparation of the final bulk vaccine.

Protein (*2.5.16*). Not more than 10 mg of protein per gram of purified polysaccharide, calculated with reference to the dried substance.

Nucleic acids (*2.5.17*). Not more than 10 mg of nucleic acids per gram of purified polysaccharide, calculated with reference to the dried substance.

***O*-Acetyl groups** (*2.5.19*). Not less than 2 mmol of *O*-acetyl groups per gram of purified polysaccharide for group A, not less than 1.5 mmol per gram of polysaccharide for group C, not less than 0.3 mmol per gram of polysaccharide for groups Y and W135, all calculated with reference to the dried substance.

Phosphorus (*2.5.18*). Not less than 80 mg of phosphorus per gram of group A purified polysaccharide, calculated with reference to the dried substance.

Sialic acid (*2.5.23*). Not less than 800 mg of sialic acid per gram of group C polysaccharide and not less than 560 mg of sialic acid per gram of purified polysaccharide for groups Y and W135, all calculated with reference to the dried substance. Use the following reference solutions.

Group C polysaccharide: a 150 mg/l solution of *N-acetylneuraminic acid R*.

Group Y polysaccharide: a solution containing 95 mg/l of *N-acetylneuraminic acid R* and 55 mg/l of *glucose R*.

Group W135 polysaccharide: a solution containing 95 mg/l of *N-acetylneuraminic acid R* and 55 mg/l of *galactose R*.

Calcium. If a calcium salt is used during purification, a determination of calcium is carried out on the purified polysaccharide; the content is within the limits approved for the particular product.

Distribution of molecular size. Examine by size-exclusion chromatography (*2.2.30*) using *agarose for chromatography R* or *cross-linked agarose for chromatography R*. Use a column about 0.9 m long and 16 mm in internal diameter equilibrated with a solvent having an ionic strength of 0.2 mol/kg and a pH of 7.0-7.5. Apply to the column about 2.5 mg of polysaccharide in a volume of about 1.5 ml and elute at about 20 ml/h. Collect fractions of about 2.5 ml and determine the content of polysaccharide by a suitable method. At least 65 per cent of group A polysaccharide, 75 per cent of group C polysaccharide, 80 per cent of group Y polysaccharide and 80 per cent of group W135 polysaccharide is eluted before a distribution coefficient (K_0) of 0.50 is reached. In addition, the percentages eluted before this distribution coefficient are within the limits approved for the particular product.

Identification and serological specificity. The identity and serological specificity are determined by a suitable immunochemical method (*2.7.1*). Identity and purity of each polysaccharide shall be confirmed; it shall be shown that there is not more than 1 per cent *m/m* of group-heterologous *N. meningitidis* polysaccharide.

Pyrogens (*2.6.8*). The polysaccharide complies with the test for pyrogens. Inject into each rabbit per kilogram of body mass 1 ml of a solution containing 0.025 µg of purified polysaccharide per millilitre.

FINAL BULK VACCINE

One or more purified polysaccharides of 1 or more *N. meningitidis* groups are dissolved in a suitable solvent that may contain a stabiliser. When dissolution is complete, the solution is filtered through a bacteria-retentive filter.

Only a final bulk vaccine that complies with the following requirement may be used in the preparation of the final lot.

Sterility (*2.6.1*). The final bulk vaccine complies with the test for sterility, carried out using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile containers. The containers are then closed so as to avoid contamination.

Only a final lot that is satisfactory with respect to each of the requirements prescribed below under Identification, Tests and Assay may be released for use.

CHARACTERS

A white or cream-coloured powder or pellet, freely soluble in water.

IDENTIFICATION

Carry out an identification test for each polysaccharide present in the vaccine by a suitable immunochemical method (*2.7.1*).

TESTS

Distribution of molecular size. Examine by size-exclusion chromatography (*2.2.30*). Use a column about 0.9 m long and 16 mm in internal diameter equilibrated with a solvent having an ionic strength of 0.2 mol/kg and a pH of 7.0-7.5. Apply to the column about 2.5 mg of each polysaccharide

in a volume of about 1.5 ml and elute at about 20 ml/h. Collect fractions of about 2.5 ml and determine the content of polysaccharide by a suitable method.

For a divalent vaccine (group A + group C), use *cross-linked agarose for chromatography R*. The vaccine complies with the test if:

– 65 per cent of group A polysaccharide is eluted before K_0 = 0.50,

– 75 per cent of group C polysaccharide is eluted before K_0 = 0.50.

For a tetravalent vaccine (group A + group C + group Y + group W135), use *cross-linked agarose for chromatography R1* and apply a suitable immunochemical method (*2.7.1*) to establish the elution pattern of the different polysaccharides. The vaccine complies with the test if K_0 for the principal peak is:

– not greater than 0.70 for group A and group C polysaccharide,

– not greater than 0.57 for group Y polysaccharide,

– not greater than 0.68 for group W135 polysaccharide.

Water (*2.5.12*). Not more than 3.0 per cent, determined by the semi-micro determination of water.

Sterility (*2.6.1*). It complies with the test for sterility.

Pyrogens (*2.6.8*). It complies with the test for pyrogens. Inject per kilogram of the rabbit's mass 1 ml of a solution containing:

– 0.025 µg of polysaccharide for a monovalent vaccine,

– 0.050 µg of polysaccharide for a divalent vaccine,

– 0.10 µg of polysaccharide for a tetravalent vaccine.

ASSAY

Carry out an assay of each polysaccharide present in the vaccine.

For a divalent vaccine (group A + group C), use measurement of phosphorus (*2.5.18*) to determine the content of polysaccharide A and measurement of sialic acid (*2.5.23*) to determine the content of polysaccharide C. To determine sialic acid, use as reference solution a 150 mg/l solution of *N-acetylneuraminic acid R*.

For a tetravalent vaccine (group A + group C + group Y + group W135) a suitable immunochemical method (*2.7.1*) is used with a reference preparation of purified polysaccharide for each group.

The vaccine contains not less than 70 per cent and not more than 130 per cent of the quantity of each polysaccharide stated on the label.

LABELLING

The label states:

– the group or groups of polysaccharides (A, C, Y or W135) present in the vaccine,

– the number of micrograms of polysaccharide per human dose.

01/2008:0538

MUMPS VACCINE (LIVE)

Vaccinum parotitidis vivum

DEFINITION

Mumps vaccine (live) is a freeze-dried preparation of a suitable attenuated strain of mumps virus. The vaccine is reconstituted immediately before use, as stated on the label, to give a clear liquid that may be coloured owing to the presence of a pH indicator.

PRODUCTION

The production of vaccine is based on a virus seed-lot system and, if the virus is propagated in human diploid cells, a cell-bank system. The production method shall have been shown to yield consistently live mumps vaccines of adequate immunogenicity and safety in man. Unless otherwise justified and authorised, the virus in the final vaccine shall have undergone no more passages from the master seed lot than were used to prepare the vaccine shown in clinical studies to be satisfactory with respect to safety and efficacy.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (*2.6.9*).

SUBSTRATE FOR VIRUS PROPAGATION

The virus is propagated in human diploid cells (*5.2.3*) or in chick-embryo cells or in the amniotic cavity of chick embryos derived from a chicken flock free from specified pathogens (*5.2.2*).

SEED LOT

The strain of mumps virus used shall be identified by historical records that include information on the origin of the strain and its subsequent manipulation. To avoid the unnecessary use of monkeys in the test for neurovirulence, virus seed lots are prepared in large quantities and stored at temperatures below – 20 °C if freeze-dried, or below – 60 °C if not freeze-dried.

Only a seed lot that complies with the following requirements may be used for virus propagation.

Identification. The master and working seed lots are identified as mumps virus by serum neutralisation in cell culture, using specific antibodies.

Virus concentration. The virus concentration of the master and working seed lots is determined to ensure consistency of production.

Extraneous agents (*2.6.16*). The working seed lot complies with the requirements for seed lots.

Neurovirulence (*2.6.18*). The working seed lot complies with the test for neurovirulence of live virus vaccines. *Macaca* and *Cercopithecus* monkeys are suitable for the test.

PROPAGATION AND HARVEST

All processing of the cell bank and subsequent cell cultures is done under aseptic conditions in an area where no other cells are handled. Suitable animal (but not human) serum may be used in the culture media. Serum and trypsin used in the preparation of cell suspensions and culture media are shown to be free from extraneous agents. The cell culture medium may contain a pH indicator such as phenol red and suitable antibiotics at the lowest effective concentration. It is preferable to have a substrate free from antibiotics during production. Not less than 500 ml of the production cell cultures is set aside as uninfected cell cultures (control cells). If the virus is propagated in chick embryos, 2 per cent

but not less than twenty eggs are set aside as uninfected control eggs. The viral suspensions are harvested at a time appropriate to the strain of virus being used.

Only a single harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Identification. The single harvest contains virus that is identified as mumps virus by serum neutralisation in cell culture, using specific antibodies.

Virus concentration. The virus concentration in the single harvest is determined as prescribed under Assay to monitor consistency of production and to determine the dilution to be used for the final bulk vaccine.

Extraneous agents (*2.6.16*). The single harvest complies with the tests for extraneous agents.

Control cells or eggs. If human diploid cells are used for production, the control cells comply with a test for identification; the control cells and the control eggs comply with the tests for extraneous agents (*2.6.16*).

FINAL BULK VACCINE

Single harvests that comply with the above tests are pooled and clarified to remove cells. A suitable stabiliser may be added and the pooled harvests diluted as appropriate.

Only a final bulk vaccine that complies with the following requirement may be used in the preparation of the final lot.

Bacterial and fungal contamination. The final bulk vaccine complies with the test for sterility (*2.6.1*), carried out using 10 ml for each medium.

FINAL LOT

A minimum virus concentration for release of the product is established such as to ensure, in the light of stability data, that the minimum concentration stated on the label will be present at the end of the period of validity.

Only a final lot that complies with the requirements for minimum virus concentration for release, with the following requirement for thermal stability and with each of the requirements given below under Identification and Tests may be released for use. Provided that the tests for bovine serum albumin and, where applicable, for ovalbumin have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

Thermal stability. Maintain samples of the final lot of freeze-dried vaccine in the dry state at 37 °C for 7 days. Determine the virus concentration as described under Assay in parallel for the heated vaccine and for unheated vaccine stored at 5 ± 3 °C. The virus concentration of the heated vaccine is not more than 1.0 $\log_{10}$ lower than that of the unheated vaccine.

IDENTIFICATION

When the vaccine reconstituted as stated on the label is mixed with specific mumps antibodies, it is no longer able to infect susceptible cell cultures.

TESTS

Bacterial and fungal contamination. The reconstituted vaccine complies with the test for sterility (*2.6.1*).

Bovine serum albumin. Not more than 50 ng per single human dose, determined by a suitable immunochemical method (*2.7.1*).

Ovalbumin. If the vaccine is produced in chick embryos, it contains not more than 1 µg of ovalbumin per single human dose, determined by a suitable immunochemical method (*2.7.1*).

Water (*2.5.12*). Not more than 3.0 per cent, determined by the semi-micro determination of water.

ASSAY

Titrate the vaccine for infective virus at least in triplicate, using at least five cell cultures for each 0.5 $\log_{10}$ dilution step or by a method of equal precision. Use an appropriate virus reference preparation to validate each assay. The estimated virus concentration is not less than that stated on the label; the minimum virus concentration stated on the label is not less than 5×10^3 $CCID_{50}$ per human dose. The assay is not valid if the confidence interval (P = 0.95) of the logarithm of the virus concentration is greater than ± 0.3.

Mumps vaccine (live) BRP is suitable for use as a reference preparation.

LABELLING

The label states:

- the strain of virus used for the preparation of the vaccine,
- that the vaccine has been prepared in chick embryos or the type and origin of cells used for the preparation of the vaccine,
- the minimum virus concentration,
- that contact with disinfectants is to be avoided,
- the time within which the vaccine must be used after reconstitution.

01/2008:0160

PERTUSSIS VACCINE

Vaccinum pertussis

DEFINITION

Pertussis vaccine is a sterile saline suspension of inactivated whole cells of one or more strains of *Bordetella pertussis*.

PRODUCTION

INACTIVATED B. PERTUSSIS SUSPENSION

The inactivated *B. pertussis* suspension is prepared as described in the monograph on *Pertussis vaccine (adsorbed) (0161)* and complies with the requirements prescribed therein.

FINAL BULK VACCINE

Suitable quantities of the inactivated single harvests are pooled to prepare the final bulk vaccine. Suitable antimicrobial preservatives may be added. The bacterial concentration of the final bulk vaccine does not exceed that corresponding to an opacity of 20 IU per single human dose. If 2 or more strains of *B. pertussis* are used, the composition of consecutive lots of the final bulk vaccine shall be consistent with respect to the proportion of each strain as measured in opacity units.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Sterility (*2.6.1*). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers. The containers are closed so as to prevent contamination.

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use. Provided the tests for specific toxicity, free formaldehyde and antimicrobial preservative and the assay have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

IDENTIFICATION

Identify pertussis vaccine by agglutination of the bacteria in the vaccine by antisera specific to *B. pertussis*.

TESTS

Specific toxicity. Use not fewer than 5 healthy mice each weighing 14 g to 16 g for the vaccine group and for the saline control. Use mice of the same sex or distribute males and females equally between the groups. Allow the animals access to food and water for at least 2 h before injection and during the test. Inject each mouse of the vaccine group intraperitoneally with 0.5 ml, containing a quantity of the vaccine equivalent to not less than half the single human dose. Inject each mouse of the control group with 0.5 ml of a 9 g/l sterile solution of *sodium chloride R*, preferably containing the same amount of antimicrobial preservative as that injected with the vaccine. Weigh the groups of mice immediately before the injection and 72 h and 7 days after the injection. The vaccine complies with the test if: (a) at the end of 72 h the total mass of the group of vaccinated mice is not less than that preceding the injection; (b) at the end of 7 days the average increase in mass per vaccinated mouse is not less than 60 per cent of that per control mouse; and (c) not more than 5 per cent of the vaccinated mice die during the test. The test may be repeated and the results of the tests combined.

Free formaldehyde (*2.4.18*): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Sterility (*2.6.1*). The vaccine complies with the test for sterility.

ASSAY

Carry out the assay of pertussis vaccine (*2.7.7*).

The estimated potency is not less than 4 IU per single human dose and the lower confidence limit (P = 0.95) of the estimated potency is not less than 2 IU per single human dose.

LABELLING

The label states:

– the minimum number of International Units per single human dose,

– that the vaccine must be shaken before use,

– that the vaccine is not to be frozen.

01/2008:1356
corrected 6.0

PERTUSSIS VACCINE (ACELLULAR, COMPONENT, ADSORBED)

Vaccinum pertussis sine cellulis ex elementis praeparatum adsorbatum

DEFINITION

Pertussis vaccine (acellular, component, adsorbed) is a preparation of individually prepared and purified antigenic components of *Bordetella pertussis* adsorbed on a mineral carrier such as aluminium hydroxide or hydrated aluminium phosphate.

The vaccine contains either pertussis toxoid or a pertussis-toxin-like protein free from toxic properties, produced by expression of a genetically modified form of the corresponding gene. Pertussis toxoid is prepared from pertussis toxin by a method that renders the latter harmless while maintaining adequate immunogenic properties and avoiding reversion to toxin. The vaccine may also contain filamentous haemagglutinin, pertactin (a 69 kDa outer-membrane protein) and other defined components of *B. pertussis* such as fimbrial-2 and fimbrial-3 antigens. The latter 2 antigens may be copurified. The antigenic composition and characteristics are based on evidence of protection and freedom from unexpected reactions in the target group for which the vaccine is intended.

PRODUCTION

GENERAL PROVISIONS

The production method shall have been shown to yield consistently vaccines comparable with the vaccine of proven clinical efficacy and safety in man.

Where a genetically modified form of *B. pertussis* is used for production consistency and genetic stability shall be established in conformity with the requirements of the monograph *Products of recombinant DNA technology (0784)*.

Reference vaccine. A batch of vaccine shown to be effective in clinical trials or a batch representative thereof is used as a reference vaccine. For the preparation of a representative batch, strict adherence to the production process used for the batch tested in clinical trials is necessary. The reference vaccine is preferably stabilised by a method that has been shown to have no significant effect on the assay procedure when the stabilised and non-stabilised batches are compared.

CHARACTERISATION OF COMPONENTS

During development of the vaccine, the production process shall be validated to demonstrate that it yields consistently individual components that comply with the following requirements; after demonstration of consistency, the tests need not be applied routinely to each batch.

Adenylate cyclase. Not more than 500 ng in the equivalent of 1 dose of the final vaccine, determined by immunoblot analysis or another suitable method.

Tracheal cytotoxin. Not more than 2 pmol in the equivalent of 1 dose of the final vaccine, determined by a suitable method such as a biological assay or liquid chromatography (*2.2.29*).

Absence of residual dermonecrotic toxin. Inject intradermally into each of 3 unweaned mice, in a volume of 0.1 ml, the amount of component or antigenic fraction equivalent to 1 dose of the final vaccine. Observe for 48 h. No dermonecrotic reaction is demonstrable.

Specific properties. The components of the vaccine are analysed by one or more of the methods shown below in order to determine their identity and specific properties (activity per unit amount of protein) in comparison with reference preparations.

Pertussis toxin. Chinese hamster ovary (CHO) cell-clustering effect and haemagglutination as *in vitro* methods; lymphocytosis-promoting activity, histamine-sensitising activity and insulin secretory activity as *in vivo* methods. The toxin shows ADP-ribosyl transferase activity using transducin as the acceptor.

Filamentous haemagglutinin. Haemagglutination and inhibition by specific antibody.

Pertactin, fimbrial-2 and fimbrial-3 antigens. Reactivity with specific antibody.

Pertussis toxoid. The toxoid induces in animals production of antibodies capable of inhibiting all the properties of pertussis toxin.

PURIFIED COMPONENTS

Production of each component is based on a seed-lot system. The seed cultures from which toxin is prepared are managed to conserve or where necessary restore toxinogenicity by deliberate selection.

None of the media used at any stage contains blood or blood products of human origin. Media used for the preparation of seed lots and inocula may contain blood or blood products of animal origin.

Pertussis toxin and, where applicable, filamentous haemagglutinin and pertactin are purified and, after appropriate characterisation, detoxified using suitable chemical reagents, by a method that avoids reversion of the toxoid to toxin, particularly on storage or exposure to heat. Other components such as fimbrial-2 and fimbrial-3 antigens are purified either separately or together, characterised and shown to be free from toxic substances. The purification procedure is validated to demonstrate appropriate clearance of substances used during culture or purification.

The content of bacterial endotoxins (*2.6.14*) is determined to monitor the purification procedure and to limit the amount in the final vaccine. The limits applied for the individual components are such that the final vaccine contains less than 100 IU per single human dose.

Before detoxification, the purity of the components is determined by a suitable method such as polyacrylamide gel electrophoresis (PAGE) or liquid chromatography. SDS-PAGE or immunoblot analysis with specific monoclonal or polyclonal antibodies may be used to characterise subunits. Requirements are established for each individual product.

Only purified components that comply with the following requirements may be used in the preparation of the final bulk vaccine.

Sterility (*2.6.1*). Carry out the test for sterility using for each medium a quantity of purified component equivalent to not less than 100 doses.

Absence of residual pertussis toxin. *This test is not necessary for the product obtained by genetic modification.* Use a group of not fewer than 5 histamine-sensitive mice each weighing 18-26 g. Inject into each mouse the equivalent of 1 human dose intravenously or twice the human dose intraperitoneally, diluted to not more than 0.5 ml with phosphate-buffered saline solution containing 2 g/l of gelatin. Inject diluent intraperitoneally into a second group of control mice. After 5 days, inject 2 mg of histamine base intraperitoneally in a volume not exceeding 0.5 ml and observe for 24 h. If no animal dies, the preparation complies with the test.

The histamine sensitivity of the strain of mice used is verified at suitable intervals as follows: inject threefold dilutions of a reference pertussis toxin preparation in phosphate-buffered saline solution containing 2 g/l of gelatin and challenge with histamine as above; the strain is suitable if more than 50 per cent of the animals are sensitised by 50 ng of pertussis toxin and none of the control animals injected with only diluent and challenged similarly with histamine show symptoms of sensitisation.

Pertussis toxin BRP is suitable for use as a reference pertussis toxin.

A validated test based on the clustering effect of the toxin for Chinese hamster ovary (CHO) cells may be used instead of the test in mice.

Residual detoxifying agents and other reagents. The content of residual detoxifying agents and other reagents is determined and shown to be below approved limits unless validation of the process has demonstrated acceptable clearance.

Antigen content. Determine the antigen content by a suitable immunochemical method (*2.7.1*) and protein nitrogen by sulphuric acid digestion (*2.5.9*) or another suitable method. The ratio of antigen content to protein nitrogen is within the limits established for the product.

FINAL BULK VACCINE

The vaccine is prepared by adsorption of suitable quantities of purified components, separately or together, onto aluminium hydroxide or hydrated aluminium phosphate. A suitable antimicrobial preservative may be added.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physico-chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended content.

Sterility (*2.6.1*). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use. Provided that the tests for absence of residual pertussis toxin and irreversibility of pertussis toxoid, antimicrobial preservative, free formaldehyde and the assay have been carried out with satisfactory results on the final bulk vaccine, these tests may be omitted on the final lot.

IDENTIFICATION

Subject the vaccine to a suitable desorption procedure such as the following: dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 10 g/l solution; maintain at 37 °C for about 16 h and centrifuge until a clear supernatant liquid is obtained. Examined by a suitable immunochemical method (*2.7.1*), the clear supernatant liquid reacts with specific antisera to the components stated on the label.

TESTS

Absence of residual pertussis toxin and irreversibility of pertussis toxoid. *This test is not necessary for the product obtained by genetic modification*. Use 3 groups each of not fewer than 5 histamine-sensitive mice. Inject

intraperitoneally into the first group twice the single human dose of the vaccine stored at 2-8 °C. Inject intraperitoneally into the second group twice the single human dose of the vaccine incubated at 37 °C for 4 weeks. Inject diluent intraperitoneally into the third group of mice. After 5 days, inject into each mouse 2 mg of histamine base intraperitoneally in a volume not exceeding 0.5 ml and observe for 24 h. The test is invalid if 1 or more control mice die following histamine challenge. The vaccine complies with the test if no animal in the first or second group dies following histamine challenge. If 1 mouse dies in either or both of the first and second groups, the test may be repeated with the same number of mice or with a greater number and the results of valid tests combined; the vaccine complies with the test if, in both of the groups given the vaccine, not more than 5 per cent of the total number of mice die following histamine challenge.

The histamine sensitivity of the strain of mice used is verified at suitable intervals as follows: inject intravenously threefold dilutions of a reference pertussis toxin preparation in phosphate-buffered saline solution containing 2 g/l of gelatin and challenge with histamine as above; the strain is suitable if more than 50 per cent of the animals are sensitised by 50 ng of pertussis toxin and none of the control animals injected with only diluent and challenged similarly with histamine show symptoms of sensitisation.

Aluminium (*2.5.13*): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (*2.4.18*): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physico-chemical method. The amount is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Sterility (*2.6.1*). It complies with the test for sterility.

ASSAY

The capacity of the vaccine to induce the formation of specific antibodies is compared with the same capacity of a reference preparation examined in parallel; antibodies are determined using suitable immunochemical methods (*2.7.1*) such as enzyme-linked immunosorbent assay (ELISA). The test in mice shown below uses a three-point model but, after validation, for routine testing a single-dilution method may be used.

Requirement. The capacity to induce antibodies is not significantly ($P = 0.95$) less than that of the reference vaccine.

The following test model is given as an example of a method that has been found to be satisfactory.

Selection and distribution of test animals. Use in the test healthy mice (for example, CD1 strain) of the same stock 4 to 8 weeks old. Distribute the animals in 6 groups of a number appropriate to the requirements of the assay. Use 3 dilutions of the vaccine to be examined and 3 dilutions of a reference preparation and attribute each dilution to a group of mice. Inject intraperitoneally or subcutaneously into each mouse 0.5 ml of the dilution attributed to its group.

Collection of serum samples. 4 to 5 weeks after vaccination, bleed the mice individually under anaesthesia. Store the sera at – 20 °C until tested for antibody content.

Antibody determination. Assay the individual sera for content of specific antibodies to each component using a validated method such as the ELISA test shown below.

ELISA test. Microtitre plates (poly(vinyl chloride) or polystyrene as appropriate for the specific antigen) are coated with the purified antigen at a concentration of 100 ng per well. After washing, unreacted sites are blocked by incubating with a solution of bovine serum albumin and then washed. Two-fold dilutions of sera from mice immunised with test or reference vaccines are made on the plates. After incubation at 22-25 °C for 1 h, the plates are washed. A suitable solution of anti-mouse IgG enzyme conjugate is added to each well and incubated at 22-25 °C for 1 h. After washing, a substrate is added from which the bound enzyme conjugate liberates a chromophore which can be quantified by measurement of absorbance (*2.2.25*). The test conditions are designed to obtain a linear response for absorbance with respect to antibody content over the range of measurement used and absorbance values within the range 0.1 to 2.0.

A reference antiserum of assigned potency is used in the test and serves as the basis for calculation of the antibody levels in test sera. A standardised control serum is also included in the test.

The test is not valid if:

- the value found for the control serum differs by more than 2 standard deviations from the assigned value,
- the confidence limits ($P = 0.95$) are less than 50 per cent or more than 200 per cent of the estimated potency.

Calculation. The antibody titres in the sera of mice immunised with reference and test vaccines are calculated and from the values obtained the potency of the test vaccine in relation to the reference vaccine is calculated by the usual statistical methods.

LABELLING

The label states:

- the names and amounts of the components present in the vaccine,
- where applicable, that the vaccine contains a pertussis toxin-like protein produced by genetic modification,
- the name and amount of the adsorbent,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen.

corrected 6.0

PERTUSSIS VACCINE (ACELLULAR, CO-PURIFIED, ADSORBED)

Vaccinum pertussis sine cellulis copurificatum adsorbatum

DEFINITION

Pertussis vaccine (acellular, co-purified, adsorbed) is a preparation of antigenic components of *Bordetella pertussis* adsorbed on a mineral carrier such as aluminium hydroxide or hydrated aluminium phosphate.

The vaccine contains an antigenic fraction purified without separation of the individual components. The antigenic fraction is treated by a method that transforms pertussis toxin to toxoid, rendering it harmless while maintaining adequate immunogenic properties of all the components and avoiding reversion to toxin. The antigenic fraction is composed of pertussis toxoid, filamentous haemagglutinin, pertactin (a 69 kDa outer-membrane protein) and other defined components of *B. pertussis* such as fimbrial-2 and fimbrial-3 antigens. It may contain residual pertussis toxin

up to a maximum level approved by the competent authority. The antigenic composition and characteristics are based on evidence of protection and freedom from unexpected reactions in the target group for which the vaccine is intended.

PRODUCTION

GENERAL PROVISIONS

The production method shall have been shown to yield consistently vaccines comparable with the vaccine of proven clinical efficacy and safety in man.

Reference vaccine. A batch of vaccine shown to be effective in clinical trials or a batch representative thereof is used as a reference vaccine. For the preparation of a representative batch, strict adherence to the production process used for the batch tested in clinical trials is necessary. The reference vaccine is preferably stabilised, by a method that has been shown to have no significant effect on the assay procedure when the stabilised and non-stabilised batches are compared.

CHARACTERISATION OF COMPONENTS

During development of the vaccine, the production process shall be validated to demonstrate that it yields consistently an antigenic fraction that complies with the following requirements; after demonstration of consistency, the tests need not be applied routinely to each batch.

Adenylate cyclase. Not more than 500 ng in the equivalent of 1 dose of the final vaccine, determined by immunoblot analysis or another suitable method.

Tracheal cytotoxin. Not more than 2 pmol in the equivalent of 1 dose of the final vaccine, determined by a suitable method such as a biological assay or liquid chromatography (*2.2.29*).

Absence of residual dermonecrotic toxin. Inject intradermally into each of 3 unweaned mice, in a volume of 0.1 ml, the amount of antigenic fraction equivalent to 1 dose of the final vaccine. Observe for 48 h. No dermonecrotic reaction is demonstrable.

Specific properties. The antigenic fraction is analysed by one or more of the methods shown below in order to determine the identity and specific properties (activity per unit amount of protein) of its components in comparison with reference preparations.

Pertussis toxin. Chinese hamster ovary (CHO) cell-clustering effect and haemagglutination as *in vitro* methods; lymphocytosis-promoting activity, histamine-sensitising activity and insulin secretory activity as *in vivo* methods. The toxin shows ADP-ribosyl transferase activity using transducin as the acceptor.

Filamentous haemagglutinin. Haemagglutination and inhibition by specific antibody.

Pertactin, fimbrial-2 and fimbrial-3 antigens. Reactivity with specific antibody.

Pertussis toxoid. The toxoid induces in animals the production of antibodies capable of inhibiting all the properties of pertussis toxin.

PURIFIED ANTIGENIC FRACTION

Production of the antigenic fraction is based on a seed-lot system. The seed cultures are managed to conserve or, where necessary, restore toxinogenicity by deliberate selection. None of the media used at any stage contains blood or blood products of human origin. Media used for the preparation of seed batches and inocula may contain blood or blood products of animal origin.

The antigenic fraction is purified and, after appropriate characterisation, detoxified using suitable reagents by a method that ensures minimal reversion of toxoid to toxin, particularly on storage or exposure to heat. The purification procedure is validated to demonstrate appropriate clearance of substances used during culture or purification.

The content of bacterial endotoxins (*2.6.14*) is determined to monitor the purification procedure and to limit the amount in the final vaccine. The limits applied are such that the final vaccine contains not more than 100 IU per single human dose.

Before detoxification, the purity of the antigenic fraction is determined by a suitable method such as polyacrylamide gel electrophoresis (PAGE) or liquid chromatography. SDS-PAGE or immunoblot analysis with specific monoclonal or polyclonal antibodies may be used to characterise subunits. Requirements are established for each individual product.

Only a purified antigenic fraction that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Sterility (*2.6.1*). Carry out the test for sterility using for each medium a quantity of purified antigenic fraction equivalent to not less than 100 doses of the final vaccine.

Test for residual pertussis toxin. Use 3 groups of not fewer than 5 histamine-sensitive mice each weighing 18 g to 26 g. Using phosphate-buffered saline containing 2 g/l of gelatin, prepare a series of dilutions of the purified antigenic fraction that have been shown to yield a graded response and attribute each dilution to a separate group of mice. Inject intraperitoneally into each mouse the dilution attributed to its group. Inject diluent intraperitoneally into a fourth group of control mice. After 5 days, inject intraperitoneally into each mouse 1 mg of histamine base in a volume not exceeding 0.5 ml. Record the number of animals that die within 24 h of histamine challenge. Calculate the weight or volume of a preparation that sensitises 50 per cent of the mice injected using a suitable statistical method such as probit analysis (see *5.3*). The residual activity of pertussis toxin does not exceed that of batches shown to be safe in clinical studies.

The histamine sensitivity of the strain of mice used is verified at suitable intervals as follows: inject threefold dilutions of a reference pertussis toxin preparation in phosphate-buffered saline solution containing 2 g/l of gelatin and challenge with histamine as described above; the strain is suitable if more than 50 per cent of the animals are sensitised by 50 ng of pertussis toxin and none of the control animals injected with only diluent and challenged similarly with histamine show symptoms of sensitisation.

Pertussis toxin BRP is suitable for use as a reference pertussis toxin.

A validated test based on the clustering effect of the toxin for Chinese hamster ovary (CHO) cells may be used instead of the test in mice.

Residual detoxifying agents and other reagents. The content of residual detoxifying agents and other reagents is determined and shown to be below approved limits unless validation of the process has demonstrated acceptable clearance.

Antigen content. Determine the complete quantitative antigen composition of the antigenic fraction by suitable immunochemical methods (*2.7.1*) and protein nitrogen by sulphuric acid digestion (*2.5.9*) or another suitable method. The ratio of total antigen content to protein nitrogen is within the limits established for the product.

FINAL BULK VACCINE

The vaccine is prepared by adsorption of a suitable quantity of the antigenic fraction onto aluminium hydroxide or hydrated aluminium phosphate. A suitable antimicrobial preservative may be added.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physico-chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended content.

Sterility (*2.6.1*). The final bulk vaccine complies with the test for sterility, carried out using 10 ml for each medium.

FINAL LOT

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use.

Provided that the tests for residual pertussis toxin, reversibility of toxoid, antimicrobial preservative, free formaldehyde and the assay have been carried out with satisfactory results on the final bulk vaccine, these tests may be omitted on the final lot.

IDENTIFICATION

Subject the vaccine to a suitable desorption procedure such as the following: dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 10 g/l solution; maintain at 37 °C for about 16 h and centrifuge until a clear supernatant liquid is obtained. Examined by a suitable immunochemical method (*2.7.1*), the clear supernatant liquid reacts with specific antisera to the components in the vaccine.

TESTS

Test for residual pertussis toxin. Use 3 groups of not fewer than 5 histamine-sensitive mice (see under Production) each weighing 18 g to 26 g. Using phosphate-buffered saline containing 2 g/l of gelatin, prepare a series of dilutions of the vaccine to be examined that have been shown to yield a graded response and attribute each dilution to a separate group of mice. Inject intraperitoneally into each mouse the dilution attributed to its group. Inject diluent intraperitoneally into a fourth group of control mice. After 5 days, inject intraperitoneally into each mouse 1 mg of histamine base in a volume not exceeding 0.5 ml. Note the number of animals that die within 24 h of histamine challenge. Calculate the weight or volume of a preparation that sensitises 50 per cent of the mice injected using a suitable statistical method such as probit analysis (see *5.3*). The residual activity of pertussis toxin does not exceed that of batches shown to be safe in clinical studies.

Reversibility of toxoid. Carry out the test for residual pertussis toxin described above using the vaccine incubated at 37 °C for 4 weeks in parallel with a sample stored at 2 °C to 8 °C. The degree of reversibility does not exceed that of batches shown to be safe in clinical studies.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physico-chemical method. The amount is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Aluminium (*2.5.13*): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (*2.4.18*): maximum 0.2 g/l.

Sterility (*2.6.1*). It complies with the test for sterility.

ASSAY

The vaccine complies with the assay of pertussis vaccine (acellular) (*2.7.16*).

LABELLING

The label states:

- the names and amounts of the antigenic components present in the vaccine,
- the maximum amount of residual pertussis toxin present in the vaccine,
- the maximum degree of reversion of toxoid to toxin during the period of validity,
- the name and amount of the adsorbent,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen.

01/2008:0161

PERTUSSIS VACCINE (ADSORBED)

Vaccinum pertussis adsorbatum

DEFINITION

Pertussis vaccine (adsorbed) is a sterile saline suspension of inactivated whole cells of one or more strains of *Bordetella pertussis* with a mineral adsorbent such as hydrated aluminium phosphate or aluminium hydroxide.

PRODUCTION

INACTIVATED B. PERTUSSIS SUSPENSION

Production is based on a seed-lot system. One or more strains of *B. pertussis* with known origin and history are used. Strains, culture medium and cultivation method are chosen in such a way that agglutinogens 1, 2 and 3 are present in the final vaccine. Each strain is grown for 24 h to 72 h in a liquid medium or on a solid medium; the medium used in the final cultivation stage does not contain blood or blood products. Human blood or blood products are not used in any culture media. The bacteria are harvested, washed to remove substances derived from the medium and suspended in a 9 g/l solution of sodium chloride or other suitable isotonic solution. The opacity of the suspension is determined not later than 2 weeks after harvest by comparison with the International Reference Preparation of Opacity and used as the basis of calculation for subsequent stages in vaccine preparation. The equivalence in International Units of the International Reference Preparation is stated by the World Health Organisation.

Single harvests are not used for the final bulk vaccine unless they have been shown to contain *B. pertussis* cells with the same characteristics, with regard to growth and agglutinogens, as the parent strain and to be free from contaminating bacteria and fungi. The bacteria are killed and detoxified in controlled conditions by means of a suitable chemical agent or by heating or by a combination of these methods. Freedom from live *B. pertussis* is tested using a suitable culture medium. The suspension is maintained at 5 ± 3 °C for a suitable period to diminish its toxicity.

FINAL BULK VACCINE

Suitable quantities of the inactivated single harvests are pooled to prepare the final bulk vaccine. A mineral adsorbent such as hydrated aluminium phosphate or aluminium hydroxide is added to the cell suspension. Suitable antimicrobial preservatives may be added. The bacterial concentration of the final bulk vaccine does not

exceed that corresponding to an opacity of 20 IU per single human dose. If 2 or more strains of *B. pertussis* are used, the composition of consecutive lots of the final bulk vaccine shall be consistent with respect to the proportion of each strain as measured in opacity units.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Sterility (*2.6.1*). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers. The containers are closed so as to prevent contamination.

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use. Provided the tests for specific toxicity, free formaldehyde and antimicrobial preservative and the assay have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

IDENTIFICATION

Dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 100 g/l solution. Maintain at 37 °C for about 16 h and centrifuge to obtain a bacterial precipitate. Other suitable methods for separating the bacteria from the adsorbent may also be used. Identify pertussis vaccine by agglutination of the bacteria from the resuspended precipitate by antisera specific to *B. pertussis* or by the assay.

TESTS

Specific toxicity. Use not fewer than 5 healthy mice each weighing 14 g to 16 g for the vaccine group and for the saline control. Use mice of the same sex or distribute males and females equally between the groups. Allow the animals access to food and water for at least 2 h before injection and during the test. Inject each mouse of the vaccine group intraperitoneally with 0.5 ml, containing a quantity of the vaccine equivalent to not less than half the single human dose. Inject each mouse of the control group with 0.5 ml of a 9 g/l sterile solution of *sodium chloride R*, preferably containing the same amount of antimicrobial preservative as that injected with the vaccine. Weigh the groups of mice immediately before the injection and 72 h and 7 days after the injection. The vaccine complies with the test if: (a) at the end of 72 h the total mass of the group of vaccinated mice is not less than that preceding the injection; (b) at the end of 7 days the average increase in mass per vaccinated mouse is not less than 60 per cent of that per control mouse; and (c) not more than 5 per cent of the vaccinated mice die during the test. The test may be repeated and the results of the tests combined.

Aluminium (*2.5.13*): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (*2.4.18*): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Sterility (*2.6.1*). The vaccine complies with the test for sterility.

ASSAY

Carry out the assay of pertussis vaccine (*2.7.7*).

The estimated potency is not less than 4 IU per single human dose and the lower confidence limit (P = 0.95) of the estimated potency is not less than 2 IU per single human dose.

LABELLING

The label states:

- the minimum number of International Units per single human dose,
- the name and the amount of the adsorbent,
- that the vaccine must be shaken before use,
- that the vaccine is not to be frozen.

01/2008:2150

PNEUMOCOCCAL POLYSACCHARIDE CONJUGATE VACCINE (ADSORBED)

Vaccinum pneumococcale polysaccharidicum coniugatum adsorbatum

DEFINITION

Pneumococcal polysaccharide conjugate vaccine (adsorbed) is a sterile solution of capsular purified antigens (polysaccharides) obtained from *Streptococcus pneumoniae* serotypes individually conjugated to a carrier protein. The vaccine may be adsorbed on a suitable adjuvant or adsorbant.

Each serotype, produced from suitable pathogenic strains of *S. pneumoniae*, is grown in an appropriate medium.

The individual polysaccharides are purified through suitable purification methods (for example centrifugation, precipitation, ultrafiltration and column chromatography).

Each polysaccharide has a defined composition and a defined molecular size range.

The choice of polysaccharide depends on the frequency of the serotypes responsible for acute pathologies and their geographical distribution. It contains immunochemically different capsular polysaccharides.

PRODUCTION

GENERAL PROVISIONS

The production method shall have been shown to yield consistently *S. pneumoniae* conjugate vaccines of adequate safety and immunogenicity in man. The production of polysaccharides and the carrier are based on a seed-lot system.

During development studies and wherever revalidation is necessary, a test for pyrogens in rabbits (*2.6.8*) is carried out by injection of a suitable dose of the final lot. The vaccine is shown to be acceptable with respect to absence of pyrogenic activity.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (*2.6.9*).

During development studies and whenever revalidation of the manufacturing process is necessary, it shall be demonstrated by tests in animals that the vaccine consistently induces a T-cell-dependent B-cell immune response.

The stability of the final lot and pneumococcal saccharide is evaluated using suitable indicator tests. Such tests may include determination of molecular size, quantification of saccharide content and free polysaccharide content in the conjugate.

BACTERIAL SEED LOTS

The bacterial strains used for master seed lots shall be identified by historical records that include information on their origin and the tests used to characterise the strain.

Cultures obtained from the working seed lot shall have the same characteristics as the strain that was used to prepare the master seed lot.

Purity of bacterial cultures is verified by methods of suitable sensitivity. These may include inoculation into suitable media, examination of colony morphology, microscopic examination of Gram-stained smears and culture agglutination with suitable specific antisera.

PNEUMOCOCCAL POLYSACCHARIDES

Each strain of *S. pneumoniae* serotypes is individually grown in a liquid medium that does not contain high-molecular-mass polysaccharides; if any ingredient of the medium contains blood-group substances, the process is validated to demonstrate that after the purification step they are no longer detectable. The bacterial purity of the culture is verified by suitable methods. The culture is then inactivated. The polysaccharide is separated from the liquid culture and purified by suitable methods. Volatile matter, including water, in the purified polysaccharide is determined by a suitable method such as thermogravimetry (*2.2.34*); the value is used to calculate the results of other chemical tests with reference to the dried substance, as prescribed below.

Only polysaccharides that comply with the following requirements may be used in the preparation of the conjugate.

Identification. Each polysaccharide is identified by an immunochemical method (*2.7.1*) or other suitable methods, for example ^{1}H nuclear magnetic resonance spectrometry (*2.2.33*) (assay for functional group).

Protein (*2.5.16*): depending on the serotype used, not more than the limit approved for the product, calculated with reference to the dried substance.

Nucleic acid (*2.5.17*): depending on the serotype used, not more than the limit approved for the product, calculated with reference to the dried substance.

Molecular size. The molecular size is evaluated by liquid chromatography (*2.2.29*) with multiple-angle laser light scattering detection or other suitable methods. The values are within the limit approved for each serotype. A validated determination of the degree of polymerisation or of the weight-average molecular weight and the dispersion of molecular masses may be used instead of the determination of molecular size distribution.

Sterility (*2.6.1*). It complies with the test for sterility, carried out using 10 ml for each medium or the equivalent of 100 doses for each medium, whichever is less.

Bacterial endotoxins (*2.6.14*): less than 0.5 IU of endotoxin per microgram of polysaccharide.

Residual reagents. Where applicable, suitable tests are carried out to determine residues of reagents used during inactivation and purification. An acceptable value for each reagent is established for the particular product and each batch of polysaccharide must be shown to comply with this limit. Where validation studies have demonstrated removal of residual reagents, the test on polysaccharides may be omitted.

ACTIVATED PNEUMOCOCCAL POLYSACCHARIDES

The polysaccharide is chemically activated prior to conjugation; it is usually partly depolymerised either before or during this procedure.

Only activated polysaccharides that comply with the following requirements may be used in the preparation of the conjugate.

Degree of oxidation. The degree of oxidation is represented by the ratio of the moles of saccharide repeat unit per mole of aldehyde and determined by a suitable method. The values are within the limits approved for each serotype.

Molecular size. The molecular size is evaluated by liquid chromatography (*2.2.29*) with multiple-angle laser light scattering detection or other suitable methods. The values are within the limits approved for each serotype.

CARRIER PROTEIN

The carrier protein is produced by culture of suitable micro-organisms; the bacterial purity of the culture is verified. The culture is inactivated. The carrier protein is purified by a suitable method.

Only a carrier protein that complies with the following requirements may be used in the preparation of the conjugate.

Identification. The carrier protein is identified by a suitable immunochemical method (*2.7.1*).

Sterility (*2.6.1*). It complies with the test for sterility, carried out using 10 ml for each medium or the equivalent of 100 doses for each medium, whichever is less.

Endotoxin content (*2.6.14*): less than 1 IU per microgram of protein.

Carrier protein: not less than 90 per cent of the total protein content, determined by a suitable method. Suitable tests are carried out for validation to demonstrate that the product is non-toxic.

MONOVALENT BULK CONJUGATE

The conjugate is obtained by the covalent binding of activated polysaccharides to the carrier protein.

The conjugate purification procedures are designed to remove residual reagents used for conjugation. The removal of residual reagents is confirmed by suitable tests or by validation of the purification process.

Only a bulk conjugate that complies with the following requirements may be used in the preparation of the final bulk vaccine. For each test, limits of acceptance are established and each batch of conjugate must be shown to comply with these limits.

Saccharide. The polysaccharide content is determined by a suitable physical or chemical method or by an immunochemical method (*2.7.1*). The value complies with the requirement approved for each serotype.

Protein. The protein content is determined by a suitable physical or chemical method (*2.5.16*, for example). The value complies with the requirement approved for each serotype.

Saccharide-to-protein ratio. Determine the saccharide-to-protein ratio by calculation. The value complies with the requirement approved for each serotype.

Free saccharide. Unbound polysaccharide is determined after removal of the conjugate, for example by anion-exchange, size-exclusion or hydrophobic chromatography, ultrafiltration or other validated methods. A value consistent with adequate immunogenicity as shown in clinical trials is established for each serotype and each lot must be shown to comply with this limit.

Free carrier protein. Determine the content by a suitable method, either directly or by deriving the content by calculation from the results of other tests. The value complies with the requirement approved for each serotype.

Molecular size. The molecular size is evaluated by liquid chromatography (*2.2.29*) with multiple-angle laser light scattering detection or other suitable methods. The values are within the limits approved for each serotype.

Residual reagents. Where applicable, suitable tests are carried out to determine residues of reagents used during inactivation and purification. An acceptable value for each reagent is established for the particular product and each batch of conjugate must be shown to comply with this limit. Where validation studies have demonstrated removal of residual reagents, the test on conjugate polysaccharides may be omitted.

Sterility (*2.6.1*). It complies with the test for sterility, carried out using 10 ml for each medium or the equivalent of 100 doses for each medium, whichever is less.

Bacterial endotoxins (*2.6.14*): less than 0.75 IU of endotoxin per microgram of polysaccharide.

FINAL BULK VACCINE

The individual monovalent bulk conjugates are compounded to formulate the vaccine. An adjuvant may be added before the final dilution.

Only a final bulk vaccine that complies with the following requirements and is within the limits approved for the particular product may be used in the preparation of the final lot.

Sterility (*2.6.1*). It complies with the test for sterility, carried out using 10 ml for each medium.

FINAL LOT

Only a final lot that is within the limits approved for the particular product and is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use.

IDENTIFICATION

Each polysaccharide present in the vaccine is identified by a suitable immunochemical method (*2.7.1*).

TESTS

Aluminium (*2.5.13*): maximum 1.25 mg per single human dose.

Sterility (*2.6.1*). It complies with the test for sterility.

Bacterial endotoxins (*2.6.14*): less than 12.5 IU per single human dose, unless otherwise justified and authorised.

ASSAY

Saccharide content. The polysaccharide content for each serotype is determined by a suitable immunochemical method (for example, nephelometry assay). The vaccine contains not less than 70 per cent and not more than 130 per cent of the quantity stated on the label for each polysaccharide. The confidence limits (P = 0.95) are not less than 80 per cent and not more than 120 per cent of the estimated content.

LABELLING

The label states:

– the number of micrograms of each polysaccharide per single human dose;

– the number of micrograms of carrier protein per single human dose.

01/2008:0966

PNEUMOCOCCAL POLYSACCHARIDE VACCINE

Vaccinum pneumococcale polysaccharidicum

DEFINITION

Pneumococcal polysaccharide vaccine consists of a mixture of equal parts of purified capsular polysaccharide antigens prepared from suitable pathogenic strains of *Streptococcus pneumoniae* whose capsules have been shown to be made up of polysaccharides that are capable of inducing satisfactory levels of specific antibodies in man. It contains the 23 immunochemically different capsular polysaccharides listed in Table 0966-1.

The vaccine is a clear, colourless liquid.

PRODUCTION

Production of the vaccine is based on a seed-lot system for each type. The production method shall have been shown to yield consistently pneumococcal polysaccharide vaccines of adequate safety and immunogenicity in man.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (*2.6.9*) modified as follows for the test in guinea-pigs: inject 10 human doses into each guinea-pig and observe for 12 days.

MONOVALENT BULK POLYSACCHARIDES

The bacteria are grown in a suitable liquid medium that does not contain blood-group substances or high-molecular-mass polysaccharides. The bacterial purity of the culture is verified and the culture is inactivated with phenol. Impurities are removed by such techniques as fractional precipitation, enzymatic digestion and ultrafiltration. The polysaccharide is obtained by fractional precipitation, washed, and dried in a vacuum to a residual moisture content shown to be favourable to the stability of the polysaccharide. The residual moisture content is determined by drying under reduced pressure over diphosphorus pentoxide or by thermogravimetric analysis and the value obtained is used to calculate the results of the tests shown below with reference to the dried substance. The monovalent bulk polysaccharide is stored at a suitable temperature in conditions that avoid the uptake of moisture.

Only a monovalent bulk polysaccharide that complies with the following requirements may be used in the preparation of the final bulk vaccine. Percentage contents of components, determined by the methods prescribed below, are shown in Table 0966-1.

Protein (*2.5.16*).

Nucleic acids (*2.5.17*).

Total nitrogen (*2.5.9*).

Phosphorus (*2.5.18*).

Molecular size. Determine by size-exclusion chromatography (*2.2.30*) using *cross-linked agarose for chromatography R* or *cross-linked agarose for chromatography R1*.

Identification (*2.7.1*). Confirm the identity of the monovalent bulk polysaccharide by double immunodiffusion or electroimmunodiffusion (except for polysaccharides 7F, 14 and 33F), using specific antisera.

Specificity. No reaction occurs when the antigens are tested against all the antisera specific for the other polysaccharides of the vaccine, including factor sera for distinguishing types within groups. The polysaccharides are tested at a concentration of 50 µg/ml using a method capable of detecting 0.5 µg/ml.

FINAL BULK VACCINE

The final bulk vaccine is obtained by aseptically mixing the different polysaccharide powders. The uniform mixture is aseptically dissolved in a suitable isotonic solution so that one human dose of 0.50 ml contains 25 µg of each polysaccharide. An antimicrobial preservative may be added. The solution is sterilised by filtration through a bacteria-retentive filter.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Sterility (*2.6.1*). The final bulk vaccine complies with the test for sterility, using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers.

Only a final lot that is satisfactory with respect to each of the requirements given below under identification, tests and assay may be released for use. Provided that the tests for phenol and for antimicrobial preservative have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot. When consistency of production has been established on a suitable number of consecutive batches, the assay may be replaced by a qualitative test that identifies each polysaccharide, provided that an assay has been performed on each monovalent bulk polysaccharide used in the preparation of the final lot.

IDENTIFICATION

The assay serves also to identify the vaccine.

TESTS

pH (*2.2.3*). The pH of the vaccine is 4.5 to 7.4.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Phenol (*2.5.15*). Not more than 2.5 g/l.

Sterility (*2.6.1*). It complies with the test for sterility.

Pyrogens (*2.6.8*). It complies with the test for pyrogens. Inject per kilogram of the rabbit's mass 1 ml of a dilution of the vaccine containing 2.5 µg/ml of each polysaccharide.

ASSAY

Determine the content of each polysaccharide by a suitable immunochemical method (*2.7.1*), using antisera specific for each polysaccharide contained in the vaccine, including factor sera for types within groups, and purified polysaccharides of each type as standards.

The vaccine contains not less than 70 per cent and not more than 130 per cent of the quantity stated on the label for each polysaccharide. The confidence limits (P = 0.95) are not less than 80 per cent and not more than 120 per cent of the estimated content.

LABELLING

The label states:

- the number of micrograms of each polysaccharide per human dose,
- the total amount of polysaccharide in the container.

01/2008:0214

POLIOMYELITIS VACCINE (INACTIVATED)

Vaccinum poliomyelitidis inactivatum

DEFINITION

Poliomyelitis vaccine (inactivated) is a liquid preparation of suitable strains of human poliovirus types 1, 2 and 3 grown in suitable cell cultures and inactivated by a validated method. It is a clear liquid that may be coloured owing to the presence of a pH indicator.

PRODUCTION

The production method shall have been shown to yield consistently vaccines of acceptable safety and immunogenicity in man.

Production of the vaccine is based on a virus seed-lot system. Cell lines are used according to a cell-bank system. If primary, secondary or tertiary monkey kidney cells are used, production complies with the requirements indicated below.

Unless otherwise justified and authorised, the virus in the final vaccine shall not have undergone more passages from the master seed lot than was used to prepare the vaccine shown in clinical studies to be satisfactory with respect to safety and efficacy.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (*2.6.9*).

SUBSTRATE FOR VIRUS PROPAGATION

The virus is propagated in a human diploid cell line (*5.2.3*), in a continuous cell line (*5.2.3*) or in primary, secondary or tertiary monkey kidney cells.

Primary, secondary or tertiary monkey kidney cells. The following special requirements for the substrate for virus propagation apply to primary, secondary or tertiary monkey kidney cells.

Monkeys used in the preparation of kidney cell cultures for production and control of the vaccine. The animals used are of a species approved by the competent authority, in good health and, unless otherwise justified and authorised, have not been previously employed for experimental purposes. Kidney cells used for vaccine production and control are derived from monitored, closed colonies of monkeys bred in captivity, not from animals caught in the wild; a previously approved seed lot prepared using virus passaged in cells from wild monkeys may, subject to approval by the competent authority, be used for vaccine production if historical data on safety justify this.

Monitored, closed colonies of monkeys. The monkeys are kept in groups in cages. Freedom from extraneous agents is achieved by the use of animals maintained in closed colonies that are subject to continuous and systematic veterinary and laboratory monitoring for the presence of infectious agents. The supplier of animals is certified by the competent authority. Each monkey is tested serologically at regular intervals during a quarantine period of not less than 6 weeks imposed before entering the colony, and then during its stay in the colony.

The monkeys used are shown to be tuberculin-negative and free from antibodies to simian virus 40 (SV40) and simian immunodeficiency virus. The blood sample used in testing for SV40 antibodies must be taken as close as possible to the time of removal of the kidneys. If *Macaca* sp. monkeys are used for production, the monkeys are also shown to be free from antibodies to herpesvirus B (cercopithecine herpesvirus 1) infection. Human herpesvirus 1 has been used as an indicator for freedom from herpesvirus B antibodies on account of the danger of handling herpesvirus B (cercopithecine herpesvirus 1).

Monkeys from which kidneys are to be removed are thoroughly examined, particularly for evidence of tuberculosis and herpesvirus B (cercopithecine herpesvirus 1) infection. If a monkey shows any pathological lesion relevant to the use of its kidneys in the preparation of a seed lot or vaccine, it is not to be used nor are any of the remaining monkeys of the group concerned unless it is evident that their use will not impair the safety of the product.

All the operations described in this section are conducted outside the area where the vaccine is produced.

Monkey cell cultures for vaccine production. Kidneys that show no pathological signs are used for preparing cell cultures. Each group of cell cultures derived from a single monkey forms a separate production cell culture giving rise to a separate single harvest.

The primary monkey kidney cell suspension complies with the test for mycobacteria (*2.6.2*); disrupt the cells before carrying out the test.

If secondary or tertiary cells are used, it shall be demonstrated by suitable validation tests that cell cultures beyond the passage level used for production are free from tumorigenicity.

SEED LOTS

Each of the 3 strains of poliovirus used shall be identified by historical records that include information on the origin of the strain and its subsequent manipulation.

Only a working seed lot that complies with the following requirements may be used for virus propagation.

Identification. Each working seed lot is identified as human poliovirus types 1, 2 or 3 by virus neutralisation in cell cultures using specific antibodies.

Virus concentration. The virus concentration of each working seed lot is determined to define the quantity of virus to be used for inoculation of production cell cultures.

Extraneous agents. The working seed lot complies with the requirements for seed lots for virus vaccines (*2.6.16*). In addition, if primary, secondary or tertiary monkey kidney cells have been used for isolation of the strain, measures are taken to ensure that the strain is not contaminated with simian viruses such as simian immunodeficiency virus, simian virus 40, filoviruses and herpesvirus B (cercopithecine herpesvirus 1). A working seed lot produced in primary, secondary or tertiary monkey kidney cells complies with the requirements given below under Virus propagation and harvest for single harvests produced in such cells.

PROPAGATION AND HARVEST

All processing of the cell bank and cell cultures is done under aseptic conditions in an area where no other cells or viruses are being handled. Approved animal serum (but not human serum) may be used in the cell culture media. Serum and trypsin used in the preparation of cell suspensions and media are shown to be free from extraneous agents. The cell culture media may contain a pH indicator such as phenol red and approved antibiotics at the lowest effective concentration. Not less than 500 ml of the cell cultures employed for vaccine production is set aside as uninfected cell cultures (control cells); where continuous cell lines in a fermenter are used for production, 200×10^6 cells are set aside to prepare control cells; where primary, secondary or tertiary monkey kidney cells are used for production, a cell sample equivalent to at least 500 ml of the cell suspension, at the concentration employed for vaccine production, is taken to prepare control cells.

Only a single harvest that complies with the following requirements may be used in the preparation of the vaccine. The tests for identification and bacterial and fungal contamination may be carried out instead on the purified, pooled monovalent harvest. After demonstration of consistency of production at the stage of the single harvest, the test for virus concentration may be carried out instead on the purified, pooled monovalent harvest.

Control cells. The control cells of the production cell culture comply with a test for identification (if a cell-bank system is used for production) and with the requirements for extraneous agents (*2.6.16*; where primary, secondary or tertiary monkey kidney cells are used, the tests in cell cultures are carried out as shown below under Test in rabbit kidney cell cultures and Test in cercopithecus kidney cell cultures).

Test in rabbit kidney cell cultures. Test a sample of at least 10 ml of the pooled supernatant fluid from the control cultures for the absence of herpesvirus B (cercopithecine herpesvirus 1) and other viruses by inoculation onto rabbit kidney cell cultures. The dilution of supernatant in the nutrient medium is not greater than 1/4 and the area of the cell layer is at least 3 cm^2 per millilitre of inoculum. Set aside one or more containers of each batch of cells with the same medium as non-inoculated control cells. Incubate the cultures at 37 °C and observe for at least 2 weeks. The test is not valid if more than 20 per cent of the control cell cultures are discarded for non-specific, accidental reasons.

Test in cercopithecus kidney cell cultures. Test a sample of at least 10 ml of the pooled supernatant fluid from the control cultures for the absence of SV40 virus and other extraneous agents by inoculation onto cell cultures prepared from the kidneys of cercopithecus monkeys, or other cells shown to be at least as sensitive for SV40, by the method described under Test in rabbit kidney cell cultures. The test is not valid if more than 20 per cent of the control cell cultures are discarded for non-specific, accidental reasons.

Identification. The single harvest is identified as containing human poliovirus types 1, 2 or 3 by virus neutralisation in cell cultures using specific antibodies.

Virus concentration. The virus concentration of each single harvest is determined by titration of infectious virus in cell cultures.

Bacterial and fungal contamination. The single harvest complies with the test for sterility (*2.6.1*), carried out using 10 ml for each medium.

Mycoplasmas (*2.6.7*). The single harvest complies with the test for mycoplasmas, carried out using 10 ml.

Test in rabbit kidney cell cultures. Where primary, secondary or tertiary monkey kidney cells are used for production, test a sample of at least 10 ml of the single harvest for the absence of herpesvirus B (cercopithecine herpesvirus 1) and other viruses by inoculation onto rabbit kidney cell cultures as described above for the control cells.

Test in cercopithecus kidney cell cultures. Where primary, secondary or tertiary monkey kidney cells are used for production, test a sample of at least 10 ml of the single harvest for the absence of SV40 virus and other extraneous agents. Neutralise the sample by a high-titre antiserum against the specific type of poliovirus. Test the sample in primary cercopithecus kidney cell cultures or cells that have been demonstrated to be at least as susceptible for SV40. Incubate the cultures at 37 °C and observe for 14 days. At the end of this period, make at least one subculture of fluid in the same cell culture system and observe both primary cultures and subcultures for an additional 14 days.

PURIFICATION AND PURIFIED MONOVALENT HARVEST

Several single harvests of the same type may be pooled and may be concentrated. The monovalent harvest or pooled monovalent harvest is purified by validated methods. If continuous cell lines are used for production, the purification process shall have been shown to reduce consistently the content of substrate-cell DNA to not more than 100 pg per single human dose.

Only a purified monovalent harvest that complies with the following requirements may be used for the preparation of the inactivated monovalent harvest.

Identification. The virus is identified by virus neutralisation in cell cultures using specific antibodies or by determination of D-antigen.

Virus concentration. The virus concentration is determined by titration of infectious virus.

Specific activity. The ratio of the virus concentration or the D-antigen content, determined by a suitable immunochemical method (*2.7.1*), to the total protein content (specific activity) of the purified monovalent harvest is within the limits approved for the particular product.

INACTIVATION AND INACTIVATED MONOVALENT HARVEST

Several purified monovalent harvests of the same type may be mixed before inactivation. To avoid failures in inactivation caused by the presence of virus aggregates, filtration is carried out before and during inactivation; inactivation is started within a suitable period, preferably not more than 24 h and in any case not more than 72 h, of the prior filtration. The virus suspension is inactivated by a validated method that has been shown to inactivate poliovirus without

destruction of immunogenicity; during validation studies, an inactivation curve with at least 4 points (for example, time 0 h, 24 h, 48 h and 96 h) is established showing the decrease in concentration of live virus with time. If formaldehyde is used for inactivation, the presence of an excess of formaldehyde at the end of the inactivation period is verified.

Only an inactivated monovalent harvest that complies with the following requirements may be used in the preparation of a trivalent pool of inactivated monovalent harvests or a final bulk vaccine.

Test for effective inactivation. After neutralisation of the formaldehyde with sodium bisulphite (where applicable), verify the absence of residual live poliovirus by inoculation on suitable cell cultures of 2 samples of each inactivated monovalent harvest, corresponding to at least 1500 human doses. Take one sample not later than 3/4 of the way through the inactivation period and the other at the end. Inoculate the samples in cell cultures such that the dilution of vaccine in the nutrient medium is not greater than 1/4 and the area of the cell layer is at least 3 cm^2 per millilitre of inoculum. Set aside one or more containers with the same medium as non-inoculated control cells. Observe the cell cultures for at least 3 weeks. Make not fewer than 2 passages from each container, one at the end of the observation period and the other 1 week before; for the passages, use cell culture supernatant and inoculate as for the initial sample. Observe the subcultures for at least 2 weeks. No sign of poliovirus multiplication is present in the cell cultures. At the end of the observation period, test the susceptibility of the cell culture used by inoculation of live poliovirus of the same type as that present in the inactivated monovalent harvest.

Sterility (*2.6.1*). The inactivated monovalent harvest complies with the test for sterility, carried out using 10 ml for each medium.

D-antigen content. The content of D-antigen determined by a suitable immunochemical method (*2.7.1*) is within the limits approved for the particular preparation.

FINAL BULK VACCINE

The final bulk vaccine is prepared directly from the inactivated monovalent harvests of human poliovirus types 1, 2 and 3 or from a trivalent pool of inactivated monovalent harvests. If a trivalent pool of inactivated monovalent harvests is used, a test for effective inactivation is carried out on this pool instead of on the final bulk vaccine. A suitable stabiliser and a suitable antimicrobial preservative may be added.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Sterility (*2.6.1*). The final bulk vaccine complies with the test for sterility, carried out using 10 ml for each medium.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physicochemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Inactivation. Before addition of any antimicrobial preservative, a sample of at least 1500 ml or, for a purified and concentrated vaccine, the equivalent of 1500 doses is tested for residual live poliovirus in cell cultures, as described for the inactivated monovalent harvest. If the final bulk vaccine is prepared from a trivalent pool of inactivated monovalent harvests, the test for inactivation is carried out on that pool rather than on the final bulk vaccine.

FINAL LOT

Only a final lot that complies with each of the requirements given below under Identification, Tests and Assay may be released for use. Provided that the tests for free formaldehyde and antimicrobial preservative and the *in vivo* assay have been performed with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

The *in vivo* assay may be omitted once it has been demonstrated for a given product and for each poliovirus type that the acceptance criteria for the D-antigen determination are such that it yields the same result as the *in vivo* assay in terms of acceptance or rejection of a batch. This demonstration must include testing of subpotent batches, produced experimentally if necessary, for example by heat treatment or other means of diminishing the immunogenic activity. Where there is a significant change in the manufacturing process of the antigens or their formulation, any impact on the *in vivo* and *in vitro* assays must be evaluated, and the need for revalidation considered.

Provided that the test for bovine serum albumin has been performed with satisfactory results on the trivalent pool of inactivated monovalent harvests or on the final bulk vaccine, it may be omitted on the final lot.

IDENTIFICATION

The vaccine is shown to contain human poliovirus types 1, 2 and 3 by a suitable immunochemical method (*2.7.1*) such as the determination of D-antigen by enzyme-linked immunosorbent assay (ELISA).

TESTS

Free formaldehyde (*2.4.18*): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical or physicochemical method. The amount is not less than the minimum amount shown to be effective and is not greater than 115 per cent of that stated on the label.

Protein nitrogen content (*Lowry method*): maximum 10 µg per single human dose.

Bovine serum albumin: maximum 50 ng per single human dose, determined by a suitable immunochemical method (*2.7.1*).

Sterility (*2.6.1*). It complies with the test.

Bacterial endotoxins (*2.6.14*): less than 5 IU per single human dose.

ASSAY

D-antigen content. As a measure of consistency of production, determine the D-antigen content for human poliovirus types 1, 2 and 3 by a suitable immunochemical method (*2.7.1*) using a reference preparation calibrated in European Pharmacopoeia Units of D-antigen. For each type, the content, expressed with reference to the amount of D-antigen stated on the label, is within the limits approved for the particular product. *Poliomyelitis vaccine (inactivated) BRP* is calibrated in European Pharmacopoeia Units and intended for use in the assay of D-antigen. The European Pharmacopoeia Unit and the International Unit are equivalent.

***In vivo* test**. The vaccine complies with the *in vivo* assay of poliomyelitis vaccine (inactivated) (*2.7.20*).

LABELLING

The label states:

– the types of poliovirus contained in the vaccine;

– the nominal amount of virus of each type (1, 2 and 3), expressed in European Pharmacopoeia Units of D-antigen, per single human dose;
– the cell substrate used to prepare the vaccine.

01/2008:0215

POLIOMYELITIS VACCINE (ORAL)

Vaccinum poliomyelitidis perorale

DEFINITION

Oral poliomyelitis vaccine is a preparation of approved strains of live attenuated poliovirus type 1, 2 or 3 grown in *in vitro* cultures of approved cells, containing any one type or any combination of the 3 types of Sabin strains, presented in a form suitable for oral administration.

The vaccine is a clear liquid that may be coloured owing to the presence of a pH indicator.

PRODUCTION

The vaccine strains and the production method shall have been shown to yield consistently vaccines that are both immunogenic and safe in man.

The production of vaccine is based on a virus seed-lot system. Cell lines are used according to a cell-bank system. If primary monkey kidney cell cultures are used, production complies with the requirements indicated below. Unless otherwise justified and authorised, the virus in the final vaccine shall not have undergone more than 2 passages from the master seed lot.

REFERENCE STANDARDS

Poliomyelitis vaccine (oral) types 1, 2, 3 BRP is suitable for use as a virus reference preparation for the assay.

The International Standards for poliovirus type 2 (Sabin) for MAPREC (Mutant Analysis by PCR and Restriction Enzyme Cleavage) assays and poliovirus, type 3 (Sabin) synthetic DNA for MAPREC assays are suitable for use in the tests for genetic markers and the molecular tests for consistency of production.

Reference preparations of each poliovirus type at the Sabin Original + 2 passage level, namely WHO (SO + 2)/I for type 1 virus, WHO (SO + 2)/II for type 2 virus and WHO (SO + 2)/III for type 3 virus are available for comparison of the *in vivo* neurovirulence with that of homotypic vaccines. Requests for the WHO reference preparations for *in vivo* neurovirulence tests are to be directed to WHO, Biologicals, Geneva, Switzerland.

A suitable reference preparation is to be included in each test.

SUBSTRATE FOR VIRUS PROPAGATION

The virus is propagated in human diploid cells (*5.2.3*), in continuous cell lines (*5.2.3*) or in primary monkey kidney cell cultures (including serially passaged cells from primary monkey kidney cells).

Primary monkey kidney cell cultures. *The following special requirements for the substrate for virus propagation apply to primary monkey kidney cell cultures.*

Monkeys used for preparation of primary monkey kidney cell cultures and for testing of virus. If the vaccine is prepared in primary monkey kidney cell cultures, animals of a species approved by the competent authority, in good health, kept in closed or intensively monitored colonies and not previously employed for experimental purposes shall be used.

The monkeys shall be kept in well-constructed and adequately ventilated animal rooms in cages spaced as far apart as possible. Adequate precautions shall be taken to prevent cross-infection between cages. Not more than 2 monkeys shall be housed per cage and cage-mates shall not be interchanged. The monkeys shall be kept in the country of manufacture of the vaccine in quarantine groups for a period of not less than 6 weeks before use. A quarantine group is a colony of selected, healthy monkeys kept in one room, with separate feeding and cleaning facilities, and having no contact with other monkeys during the quarantine period. If at any time during the quarantine period the overall death rate of a shipment consisting of one or more groups reaches 5 per cent (excluding deaths from accidents or where the cause was specifically determined not to be an infectious disease), monkeys from that entire shipment shall continue in quarantine from that time for a minimum of 6 weeks. The groups shall be kept continuously in isolation, as in quarantine, even after completion of the quarantine period, until the monkeys are used. After the last monkey of a group has been taken, the room that housed the group shall be thoroughly cleaned and decontaminated before being used for a fresh group. If kidneys from near-term monkeys are used, the mother is quarantined for the term of pregnancy.

Monkeys from which kidneys are to be removed shall be anaesthetised and thoroughly examined, particularly for evidence of tuberculosis and cercopithecid herpesvirus 1 (B virus) infection.

If a monkey shows any pathological lesion relevant to the use of its kidneys in the preparation of a seed lot or vaccine, it shall not be used, nor shall any of the remaining monkeys of the quarantine group concerned be used unless it is evident that their use will not impair the safety of the product.

All the operations described in this section shall be conducted outside the areas where the vaccine is produced.

The monkeys used shall be shown to be free from antibodies to simian virus 40 (SV40), simian immunodeficiency virus and spumaviruses. The blood sample used in testing for SV40 antibodies must be taken as close as possible to the time of removal of the kidneys. If *Macaca* spp. are used for production, the monkeys shall also be shown to be free from antibodies to cercopithecid herpesvirus 1 (B virus). Human herpesvirus has been used as an indicator for freedom from B virus antibodies on account of the danger of handling cercopithecid herpesvirus 1 (B virus). Monkeys used for the production of new seed lots are shown to be free from antibodies to simian cytomegalovirus (sCMV).

Primary monkey kidney cell cultures for vaccine production. Kidneys that show no pathological signs are used for preparing cell cultures. If the monkeys are from a colony maintained for vaccine production, serially passaged monkey kidney cell cultures from primary monkey kidney cells may be used for virus propagation, otherwise the monkey kidney cells are not propagated in series. Virus for the preparation of vaccine is grown by aseptic methods in such cultures. If animal serum is used in the propagation of the cells, the maintenance medium after virus inoculation shall contain no added serum.

Each group of cell cultures derived from a single monkey or from foetuses from no more than 10 near-term monkeys is prepared and tested as an individual group.

VIRUS SEED LOTS

The strains of poliovirus used shall be identified by historical records that include information on the origin and subsequent manipulation of the strains.

Working seed lots are prepared by a single passage from a master seed lot and at an approved passage level from the original Sabin virus. Virus seed lots are prepared in large quantities and stored at a temperature below – 60 °C.

Only a virus seed lot that complies with the following requirements may be used for virus propagation.

Identification. Each working seed lot is identified as poliovirus of the given type, using specific antibodies.

Virus concentration. Determined by the method described below, the virus concentration is the basis for the quantity of virus used in the neurovirulence test.

Extraneous agents (*2.6.16*). If the working seed lot is produced in human diploid cells or in a continuous cell line, it complies with the requirements for seed lots for virus vaccines. If the working seed lot is produced in primary monkey kidney cell cultures, it complies with the requirements given below under Virus Propagation and Harvest and Monovalent Pooled Harvest and with the tests in adult mice, suckling mice and guinea-pigs given in chapter *2.6.16*.

In addition to the requirements in chapter *2.6.16*, for vaccines produced in cell lines and when the seed lot was produced in primary monkey kidney cell cultures, a validated test for sCMV is performed.

Working seed lots shall be free from detectable DNA sequences from simian virus 40 (SV40).

Neurovirulence. Each master and working seed lot complies with the test for neurovirulence of poliomyelitis vaccine (oral) in monkeys (*2.6.19*). In addition, at least the first 4 consecutive batches of monovalent pooled harvest prepared from these seed lots shall be shown to comply with the test for neurovirulence of poliomyelitis vaccine (oral) in monkeys (*2.6.19*) before the seed lot is deemed suitable for use. Furthermore, the seed lot shall cease to be used in vaccine production if the frequency of failure of the monovalent pooled harvests produced from it is greater than predicted statistically. This statistical prediction is calculated after each test on the basis of all the monovalent pooled harvests tested; it is equal to the probability of false rejection on the occasion of a first test (i.e. 1 per cent), the probability of false rejection on retest being negligible. If the test is carried out only by the manufacturer, the test slides are provided to the control authority for assessment.

Genetic markers. Each working seed lot is tested for its replicating properties at temperatures ranging from 36 °C to 40 °C as described under Monovalent pooled harvest. A profile (i.e. percentage of mutant) of the seed virus using the MAPREC assay is prepared. Type 3 virus seed lots comply with the MAPREC assay as described under Monovalent pooled harvest.

VIRUS PROPAGATION AND HARVEST

All processing of the cell banks and subsequent cell cultures is done under aseptic conditions in an area where no other cells are handled. Approved animal (but not human) serum may be used in the media, but the final medium for maintaining cell growth during virus multiplication does not contain animal serum. Serum and trypsin used in the preparation of cell suspensions and media are shown to be free from live extraneous agents. The cell-culture medium may contain a pH indicator such as phenol red and approved antibiotics at the lowest effective concentration. It is preferable to have a substrate free from antibiotics during production. On the day of inoculation with the virus working seed lot, not less than 5 per cent or 1000 ml, whichever is the less, of the cell cultures employed for vaccine production are set aside as uninfected cell cultures (control cells); special requirements, given below, apply to control cells when the vaccine is produced in primary monkey kidney cell cultures. The virus suspension is harvested not later than 4 days after virus inoculation. After inoculation of the production cell culture with the virus working seed lot, inoculated cells are maintained at a fixed temperature, shown to be suitable, within the range 33 °C to 35 °C; the temperature is maintained constant to ± 0.5 °C; control cell cultures are maintained at 33-35 °C for the relevant incubation periods.

Only a single virus harvest that complies with the following requirements may be used in the preparation of the monovalent pooled harvest.

Virus concentration. The virus concentration of virus harvests is determined as prescribed under Assay to monitor consistency of production and to determine the dilution to be used for the final bulk vaccine.

Molecular tests for consistency of production. The MAPREC assay is performed on each virus harvest. The acceptance/rejection criteria for consistency of production are determined for each manufacturer and for each working seed by agreement with the competent authority. These criteria are periodically reviewed and updated to the satisfaction of the competent authority. An investigation of consistency occurs if a virus harvest gives results that are inconsistent with previous production history.

Control cells. The control cells of the production cell culture from which the virus harvest is derived comply with a test for identity and with the requirements for extraneous agents (*2.6.16*) or, where primary monkey kidney cell cultures are used, as shown below.

Primary monkey kidney cell cultures. *The following special requirements apply to virus propagation and harvest in primary monkey kidney cell cultures.*

Cell cultures. On the day of inoculation with virus working seed lot, each cell culture is examined for degeneration caused by an infective agent. If, in this examination, evidence is found of the presence in a cell culture of any extraneous agent, the entire group of cultures concerned shall be rejected.

On the day of inoculation with the virus working seed lot, a sample of at least 30 ml of the pooled fluid removed from the cell cultures of the kidneys of each single monkey or from foetuses from not more than 10 near-term monkeys is divided into 2 equal portions. 1 portion of the pooled fluid is tested in monkey kidney cell cultures prepared from the same species, but not the same animal, as that used for vaccine production. The other portion of the pooled fluid is, where necessary, tested in monkey kidney cell cultures from another species so that tests on the pooled fluids are done in cell cultures from at least 1 species known to be sensitive to SV40. The pooled fluid is inoculated into bottles of these cell cultures in such a way that the dilution of the pooled fluid in the nutrient medium does not exceed 1 in 4. The area of the cell sheet is at least 3 cm^2/ml of pooled fluid. At least 1 bottle of each kind of cell culture remains uninoculated to serve as a control. If the monkey species used for vaccine production is known to be sensitive to SV40, a test in a second species is not required. Animal serum may be used in the propagation of the cells, provided that it does not contain SV40 antibody, but the maintenance medium after inoculation of test material contains no added serum except as described below.

The cultures are incubated at a temperature of 35-37 °C and are observed for a total period of at least 4 weeks. During this observation period and after not less than 2 weeks' incubation, at least 1 subculture of fluid is made from each of these cultures in the same cell culture system. The subcultures are also observed for at least 2 weeks.

Serum may be added to the original culture at the time of subculturing, provided that the serum does not contain SV40 antibody.

Fluorescent-antibody techniques may be useful for detecting SV40 virus and other viruses in the cells.

A further sample of at least 10 ml of the pooled fluid is tested for cercopithecid herpesvirus 1 (B virus) and other viruses in rabbit kidney cell cultures. Serum used in the nutrient medium of these cultures shall have been shown to be free from inhibitors of B virus. Human herpesvirus has been used as an indicator for freedom from B virus inhibitors on account of the danger of handling cercopithecid herpesvirus 1 (B virus). The sample is inoculated into bottles of these cell cultures in such a way that the dilution of the pooled fluid in the nutrient medium does not exceed 1 in 4. The area of the cell sheet is at least 3 cm^2/ml of pooled fluid. At least 1 bottle of the cell cultures remains uninoculated to serve as a control.

The cultures are incubated at a temperature of 35-37 °C and observed for at least 2 weeks.

A further sample of 10 ml of the pooled fluid removed from the cell cultures on the day of inoculation with the seed lot virus is tested for the presence of extraneous agents by inoculation into human cell cultures sensitive to measles virus.

The tests are not valid if more than 20 per cent of the culture vessels have been discarded for non-specific accidental reasons by the end of the respective test periods.

If, in these tests, evidence is found of the presence of an extraneous agent, the single harvest from the whole group of cell cultures concerned is rejected.

If the presence of cercopithecid herpesvirus 1 (B virus) is demonstrated, the manufacture of oral poliomyelitis vaccine shall be discontinued and the competent authority shall be informed. Manufacturing shall not be resumed until a thorough investigation has been completed and precautions have been taken against any reappearance of the infection, and then only with the approval of the competent authority.

If these tests are not done immediately, the samples of pooled cell-culture fluid shall be kept at a temperature of – 60 °C or below, with the exception of the sample for the test for B virus, which may be held at 4 °C, provided that the test is done not more than 7 days after it has been taken.

Control cell cultures. On the day of inoculation with the virus working seed lot, 25 per cent (but not more than 2.5 litres) of the cell suspension obtained from the kidneys of each single monkey or from not more than 10 near-term monkeys is taken to prepare uninoculated control cell cultures. These control cell cultures are incubated in the same conditions as the inoculated cultures for at least 2 weeks and are examined during this period for evidence of cytopathic changes. The tests are not valid if more than 20 per cent of the control cell cultures have been discarded for non-specific, accidental reasons. At the end of the observation period, the control cell cultures are examined for degeneration caused by an infectious agent. If this examination or any of the tests required in this section shows evidence of the presence in a control culture of any extraneous agent, the poliovirus grown in the corresponding inoculated cultures from the same group shall be rejected.

Tests for haemadsorbing viruses. At the time of harvest or within 4 days of inoculation of the production cultures with the virus working seed lot, a sample of 4 per cent of the control cell cultures is taken and tested for haemadsorbing viruses. At the end of the observation period, the remaining control cell cultures are similarly tested. The tests are made as described in chapter *2.6.16*.

Tests for other extraneous agents. At the time of harvest, or within 7 days of the day of inoculation of the production cultures with the working seed lot, a sample of at least 20 ml of the pooled fluid from each group of control cultures is taken and tested in 2 kinds of monkey kidney cell culture, as described above.

At the end of the observation period for the original control cell cultures, similar samples of the pooled fluid are taken and the tests referred to in this section in the 2 kinds of monkey kidney cell culture and in the rabbit cell cultures are repeated, as described above under Cell cultures.

If the presence of cercopithecid herpesvirus 1 (B virus) is demonstrated, the production cell cultures shall not be used and the measures concerning vaccine production described above must be undertaken.

The fluids collected from the control cell cultures at the time of virus harvest and at the end of the observation period may be pooled before testing for extraneous agents. A sample of 2 per cent of the pooled fluid is tested in each of the cell culture systems specified.

Single harvests

Tests for neutralised single harvests in primary monkey kidney cell cultures. A sample of at least 10 ml of each single harvest is neutralised by a type-specific poliomyelitis antiserum prepared in animals other than monkeys. In preparing antisera for this purpose, the immunising antigens used shall be prepared in non-simian cells.

Half of the neutralised suspension (corresponding to at least 5 ml of single harvest) is tested in monkey kidney cell cultures prepared from the same species, but not the same animal, as that used for vaccine production. The other half of the neutralised suspension is tested, if necessary, in monkey kidney cell cultures from another species so that the tests on the neutralised suspension are done in cell cultures from at least 1 species known to be sensitive to SV40.

The neutralised suspensions are inoculated into bottles of these cell cultures in such a way that the dilution of the suspension in the nutrient medium does not exceed 1 in 4. The area of the cell sheet is at least 3 cm^2/ml of neutralised suspension. At least 1 bottle of each type of cell culture remains uninoculated to serve as a control and is maintained by nutrient medium containing the same concentration of the specific antiserum used for neutralisation.

Animal serum may be used in the propagation of the cells, provided that it does not contain SV40 antibody, but the maintenance medium, after the inoculation of the test material, contains no added serum other than the poliovirus neutralising antiserum, except as described below.

The cultures are incubated at a temperature of 35-37 °C and observed for a total period of at least 4 weeks. During this observation period and after not less than 2 weeks' incubation, at least 1 subculture of fluid is made from each of these cultures in the same cell-culture system. The subcultures are also observed for at least 2 weeks.

Serum may be added to the original cultures at the time of subculturing, provided that the serum does not contain SV40 antibody.

Additional tests are made for extraneous agents on a further sample of the neutralised single harvests by inoculation of 10 ml into human cell cultures sensitive to measles virus. This test is also validated for the detection of sCMV.

Fluorescent-antibody techniques may be useful for detecting SV40 virus and other viruses in the cells.

The tests are not valid if more than 20 per cent of the culture vessels have been discarded for non-specific accidental reasons by the end of the respective test periods.

If any cytopathic changes occur in any of the cultures, the causes of these changes are investigated. If the cytopathic changes are shown to be due to unneutralised poliovirus, the test is repeated. If there is evidence of the presence of SV40 or other extraneous agents attributable to the single harvest, that single harvest is rejected.

MONOVALENT POOLED HARVEST

Monovalent pooled harvests are prepared by pooling a number of satisfactory single harvests of the same virus type. Monovalent pooled harvests from continuous cell lines may be purified. Each monovalent pooled harvest is filtered through a bacteria-retentive filter.

Only a monovalent pooled harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Identification. Each monovalent pooled harvest is identified as poliovirus of the given type, using specific antibodies.

Virus concentration. The virus concentration is determined by the method described below and serves as the basis for calculating the dilutions for preparation of the final bulk, for the quantity of virus used in the neurovirulence test and to establish and monitor production consistency.

Genetic markers. For Sabin poliovirus type 3, a validated MAPREC assay is performed. In this analysis the amount of the mutation at position 472 of the genome (472-C) is estimated and expressed as a ratio relative to the International Standard for MAPREC analysis of poliovirus type 3 (Sabin). A poliovirus type 3 monovalent pooled harvest found to have significantly more 472-C than the International Standard for MAPREC analysis of poliovirus type 3 (Sabin) fails in the MAPREC assay.

The MAPREC analysis of poliovirus type 3 (Sabin) is carried out using a standard operating procedure approved by the competent authority. A suitable procedure (*Mutant analysis by PCR and restriction enzyme cleavage (MAPREC) for oral poliovirus (Sabin) vaccine*) is available from WHO, Quality and Safety of Biologicals (QSB), Geneva. A laboratory must demonstrate to the competent authority that it is competent to perform the assay. The manufacturer and the competent authority shall agree on the procedure and the criteria for deciding whether a monovalent pooled harvest contains significantly more 472-C than the International Standard.

Acceptance/rejection criteria for assessment of consistency of production are determined for each manufacturer and for each working seed lot by agreement with the competent authority. These criteria are updated as each new bulk is prepared and analysed. An investigation of consistency occurs if a monovalent pooled harvest gives results that are inconsistent with previous production history.

As the MAPREC assay for type 3 poliovirus (Sabin) is highly predictive of *in vivo* neurovirulence, if a filtered monovalent pooled harvest of type 3 poliovirus (Sabin) fails the MAPREC assay then this triggers an investigation of the consistency of the manufacturing process. This investigation also includes a consideration of the suitability of the working seed lot.

Monovalent pooled harvests passing the MAPREC assay are subsequently tested for *in vivo* neurovirulence.

For poliovirus type 3, results from the MAPREC assay and the monkey neurovirulence test (*2.6.19*) are used concomitantly to assess the impact of changes in the production process or when a new manufacturer starts production.

Pending validation of MAPREC assays for poliovirus types 1 and 2, for these viruses filtered bulk suspension is tested for the property of reproducing at temperatures of 36 °C and 40 °C. A ratio of the replication capacities of the virus in the monovalent pooled harvest is obtained over a temperature range between 36 °C and 40 °C in comparison with the seed lot or a reference preparation for the marker tests and with appropriate rct/40– and rct/40+ strains of poliovirus of the same type. The incubation temperatures used in this test are controlled to within ± 0.1 °C. The monovalent pooled harvest passes the test if, for both the virus in the harvest and the appropriate reference material, the titre determined at 36 °C is at least 5.0 log greater than that determined at 40 °C. If growth at 40 °C is so low that a valid comparison cannot be established, a temperature in the region of 39.0-39.5 °C is used, at which temperature the reduction in titre of the reference material must be in the range 3.0-5.0 log of its value at 36 °C; the acceptable minimum reduction is determined for each virus strain at a given temperature. If the titres obtained for 1 or more of the reference viruses are not concordant with the expected values, the test must be repeated.

Neurovirulence (*2.6.19*). Each monovalent pooled harvest complies with the test for neurovirulence of poliomyelitis vaccine (oral). If the monkey neurovirulence test is carried out only by the manufacturer, the test slides are provided to the competent authority for assessment. The TgPVR21 transgenic mouse model provides a suitable alternative to the monkey neurovirulence test for neurovirulence testing of types 1, 2 or 3 vaccines once a laboratory qualifies as being competent to perform the test and the experience gained is to the satisfaction of the competent authority. The test is carried out using a standard operating procedure approved by the competent authority. A suitable procedure (*Neurovirulence test of type 1, 2 or 3 live poliomyelitis vaccines (oral) in transgenic mice susceptible to poliovirus*) is available from WHO, Quality and Safety of Biologicals, Geneva.

Primary monkey kidney cell cultures. *The following special requirements apply to monovalent pooled harvests derived from primary monkey kidney cell cultures.*

Retroviruses. The monovalent pooled harvest is examined using a reverse transcriptase assay. No indication of the presence of retroviruses is found.

Test in rabbits. A sample of the monovalent pooled harvest is tested for cercopithecid herpesvirus 1 (B virus) and other viruses by injection of not less than 100 ml into not fewer than 10 healthy rabbits each weighing 1.5-2.5 kg. Each rabbit receives not less than 10 ml and not more than 20 ml, of which 1 ml is given intradermally at multiple sites, and the remainder subcutaneously. The rabbits are observed for at least 3 weeks for death or signs of illness.

All rabbits that die after the first 24 h of the test and those showing signs of illness are examined by autopsy, and the brain and organs removed for detailed examination to establish the cause of death.

The test is not valid if more than 20 per cent of the inoculated rabbits show signs of intercurrent infection during the observation period. The monovalent pooled harvest passes the test if none of the rabbits shows evidence of infection with B virus or with other extraneous agents or lesions of any kind attributable to the bulk suspension.

If the presence of B virus is demonstrated, the measures concerning vaccine production described above under Cell cultures are taken.

Test in guinea-pigs. If the primary monkey kidney cell cultures are not derived from monkeys kept in a closed colony, the monovalent pooled harvest shall be shown to comply with the following test. Administer to not fewer than 5 guinea-pigs, each weighing 350-450 g, 0.1 ml of the monovalent pooled harvest by intracerebral injection and 0.5 ml by intraperitoneal injection. Measure the rectal

temperature of each animal on each working day for 6 weeks. At the end of the observation period carry out autopsy on each animal.

In addition, administer to not fewer than 5 guinea-pigs 0.5 ml by intraperitoneal injection and observe as described above for 2-3 weeks. At the end of the observation period, carry out a passage from these animals to not fewer than 5 guinea-pigs using blood and a suspension of liver or spleen tissue. Measure the rectal temperature of the latter guinea-pigs for 2-3 weeks. Examine by autopsy all animals that, after the first day of the test, die or are euthanised because they show disease or show on 3 consecutive days a body temperature higher than 40.1 °C; carry out histological examination to detect infection with filoviruses; in addition, inject a suspension of liver or spleen tissue or of blood intraperitoneally into not fewer than 3 guinea-pigs. If any signs of infection with filoviruses are noted, confirmatory serological tests are carried out on the blood of the affected animals. The monovalent pooled harvest complies with the test if not fewer than 80 per cent of the guinea-pigs survive to the end of the observation period and remain in good health and no animal shows signs of infection with filoviruses.

FINAL BULK VACCINE

The final bulk vaccine is prepared from one or more satisfactory monovalent pooled harvests and may contain more than one virus type. Suitable flavouring substances and stabilisers may be added.

Only a final bulk vaccine that complies with the following requirement may be used in the preparation of the final lot.

Bacterial and fungal contamination. Carry out the test for sterility (*2.6.1*), using 10 ml for each medium.

FINAL LOT

Only a final lot that complies with the following requirement for thermal stability and is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use.

IDENTIFICATION

The vaccine is shown to contain poliovirus of each type stated on the label, using specific antibodies.

TESTS

Bacterial and fungal contamination. The vaccine complies with the test for sterility (*2.6.1*).

Thermal stability. Maintain not fewer than 3 vials of the final lot at 37 ± 1 °C for 48 h. Determine the total virus concentration as described under Assay in parallel for the heated vaccine and for vaccine maintained at the temperature recommended for storage. The estimated difference between the total virus concentration of the unheated and heated vaccines is not greater than 0.5 $\log_{10}$ infectious virus units ($CCID_{50}$) per single human dose.

The test is not valid if:

- the confidence interval (P = 0.95) of the logarithm of the virus concentration of the reference preparation is greater than ± 0.3;
- the virus concentration of the reference preparation differs by more than 0.5 log $CCID_{50}$ from the assigned value;
- the range of virus concentrations found for the replicates of any sample is greater than 0.8 log $CCID_{50}$.

ASSAY

Titrate for infectious virus using not fewer than 3 separate vials of vaccine, following the method described below. Use 1 vial of an appropriate virus reference preparation to validate each assay. If the vaccine contains more than one poliovirus type, titrate each type separately, using appropriate type-specific antiserum (or preferably a monoclonal antibody) to neutralise each of the other types present.

For a trivalent vaccine, the estimated mean virus titres must be: not less than $1 \times 10^{6.0}$ infectious virus units ($CCID_{50}$) per single human dose for type 1; not less than $1 \times 10^{5.0}$ infectious virus units ($CCID_{50}$) for type 2; and not less than $1 \times 10^{5.5}$ infectious virus units ($CCID_{50}$) for type 3.

For a monovalent or divalent vaccine, the minimum virus titres are decided by the competent authority.

Method. Inoculate groups of 8 to 12 flat-bottomed wells in a microtitre plate with 0.1 ml of each of the selected dilutions of virus followed by a suitable cell suspension of the Hep-2 (Cincinnati) line. Incubate the plates at a suitable temperature. Examine the cultures on days 7-9.

The assay is not valid if:

- the confidence interval (P = 0.95) of the logarithm of the virus concentration of the reference preparation is greater than ± 0.3;
- the virus concentration of the reference preparation differs by more than 0.5 log $CCID_{50}$ from the assigned value;
- the range of virus concentrations found for the replicates for any sample is greater than 0.8 log $CCID_{50}$.

LABELLING

The label states:

- the types of poliovirus contained in the vaccine,
- the minimum amount of virus of each type contained in 1 single human dose,
- the cell substrate used for the preparation of the vaccine,
- that the vaccine is not to be injected.

01/2008:0216

RABIES VACCINE FOR HUMAN USE PREPARED IN CELL CULTURES

Vaccinum rabiei ex cellulis ad usum humanum

DEFINITION

Rabies vaccine for human use prepared in cell cultures is a freeze-dried preparation of a suitable strain of fixed rabies virus grown in cell cultures and inactivated by a validated method.

The vaccine is reconstituted immediately before use as stated on the label to give a clear liquid that may be coloured owing to the presence of a pH indicator.

PRODUCTION

GENERAL PROVISIONS

The production of the vaccine is based on a virus seed-lot system and, if a cell line is used for virus propagation, a cell-bank system. The production method shall have been shown to yield consistently vaccines that comply with the requirements for immunogenicity, safety and stability. Unless otherwise justified and authorised, the virus in the final vaccine must not have undergone more passages from the master seed lot than were used to prepare the vaccine shown in clinical studies to be satisfactory with respect to safety and efficacy; even with authorised exceptions, the number of passages beyond the level used for clinical studies must not exceed 5.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (*2.6.9*).

SUBSTRATE FOR VIRUS PROPAGATION

The virus is propagated in a human diploid cell line (*5.2.3*), in a continuous cell line approved by the competent authority, or in cultures of chick-embryo cells derived from a flock free from specified pathogens (*5.2.2*).

SEED LOTS

The strain of rabies virus used shall be identified by historical records that include information on the origin of the strain and its subsequent manipulation.

Working seed lots are prepared by not more than 5 passages from the master seed lot.

Only a working seed lot that complies with the following tests may be used for virus propagation.

Identification. Each working seed lot is identified as rabies virus using specific antibodies.

Virus concentration. The virus concentration of each working seed lot is determined by a cell culture method using immunofluorescence, to ensure consistency of production.

Extraneous agents (*2.6.16*). The working seed lot complies with the requirements for virus seed lots. If the virus has been passaged in mouse brain, specific tests for murine viruses are carried out.

VIRUS PROPAGATION AND HARVEST

All processing of the cell bank and subsequent cell cultures is done under aseptic conditions in an area where no other cells are handled. Approved animal (but not human) serum may be used in the media, but the final medium for maintaining cell growth during virus multiplication does not contain animal serum; the media may contain human albumin. Serum and trypsin used in the preparation of cell suspensions and media are shown to be free from extraneous agents. The cell culture media may contain a pH indicator such as phenol red and approved antibiotics at the lowest effective concentration. Not less than 500 ml of the cell cultures employed for vaccine production are set aside as uninfected cell cultures (control cells). The virus suspension is harvested on one or more occasions during incubation. Multiple harvests from the same production cell culture may be pooled and considered as a single harvest.

Only a single harvest that complies with the following requirements may be used in the preparation of the inactivated viral harvest.

Identification. The single harvest contains virus that is identified as rabies virus using specific antibodies.

Virus concentration. Titrate for infective virus in cell cultures; the titre is used to monitor consistency of production.

Control cells. The control cells of the production cell culture from which the single harvest is derived comply with a test for identification and with the requirements for extraneous agents (*2.6.16*).

PURIFICATION AND INACTIVATION

The virus harvest may be concentrated and/or purified by suitable methods; the virus harvest is inactivated by a validated method at a fixed, well-defined stage of the process, which may be before, during or after any concentration or purification. The method shall have been shown to be capable of inactivating rabies virus without destruction of the immunogenic activity. If betapropiolactone is used, the concentration shall at no time exceed 1:3500.

Only an inactivated viral suspension that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Residual infectious virus. Carry out an amplification test for residual infectious rabies virus immediately after inactivation or using a sample frozen immediately after inactivation and stored at −70 °C. Inoculate a quantity of inactivated viral suspension equivalent to not less than 25 human doses of vaccine into cell cultures of the same type as those used for production of the vaccine. A passage may be made after 7 days. Maintain the cultures for a total of 21 days and then examine the cell cultures for rabies virus using an immunofluorescence test. The inactivated virus harvest complies with the test if no rabies virus is detected.

Residual host-cell DNA. If a continuous cell line is used for virus propagation, the content of residual host-cell DNA, determined using a suitable method as described in *Products of recombinant DNA technology (0784)*, is not greater than 10 ng per single human dose.

FINAL BULK VACCINE

The final bulk vaccine is prepared from one or more inactivated viral suspensions. An approved stabiliser may be added to maintain the activity of the product during and after freeze-drying.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Glycoprotein content. Determine the glycoprotein content by a suitable immunochemical method (*2.7.1*), for example, single-radial immunodiffusion, enzyme-linked immunosorbent assay or an antibody-binding test. The content is within the limits approved for the particular product.

Sterility (*2.6.1*). The final bulk vaccine complies with the test for sterility, carried out using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile containers and freeze-dried to a moisture content shown to be favourable to the stability of the vaccine. The containers are then closed so as to avoid contamination and the introduction of moisture.

Only a final lot that complies with each of the requirements given below under Identification, Tests and Assay may be released for use. Provided that the test for residual infectious virus has been carried out with satisfactory results on the inactivated viral suspension and the test for bovine serum albumin has been carried out with satisfactory results on the final bulk vaccine, these tests may be omitted on the final lot.

IDENTIFICATION

The vaccine is shown to contain rabies virus antigen by a suitable immunochemical method (*2.7.1*) using specific antibodies, preferably monoclonal; alternatively, the assay serves also to identify the vaccine.

TESTS

Residual infectious virus. Inoculate a quantity equivalent to not less than 25 human doses of vaccine into cell cultures of the same type as those used for production of the vaccine. A passage may be made after 7 days. Maintain the cultures for a total of 21 days and then examine the cell cultures for rabies virus using an immunofluorescence test. The vaccine complies with the test if no rabies virus is detected.

Bovine serum albumin: maximum 50 ng per single human dose, determined by a suitable immunochemical method (*2.7.1*).

Sterility (*2.6.1*). It complies with the test.

Bacterial endotoxins (*2.6.14*): less than 25 IU per single human dose.

Pyrogens (*2.6.8*). It complies with the test. Unless otherwise justified and authorised, inject into each rabbit a single human dose of the vaccine diluted to 10 times its volume.

Water (*2.5.12*): maximum 3.0 per cent.

ASSAY

The potency of rabies vaccine is determined by comparing the dose necessary to protect mice against the effects of a lethal dose of rabies virus, administered intracerebrally, with the quantity of a reference preparation of rabies vaccine necessary to provide the same protection. For this comparison a reference preparation of rabies vaccine, calibrated in International Units, and a suitable preparation of rabies virus for use as the challenge preparation are necessary.

The International Unit is the activity contained in a stated quantity of the International Standard. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

The test described below uses a parallel-line model with at least 3 points for the vaccine to be examined and the reference preparation. Once the analyst has experience with the method for a given vaccine, it is possible to carry out a simplified test using a single dilution of the vaccine to be examined. Such a test enables the analyst to determine that the vaccine has a potency significantly higher than the required minimum, but does not give full information on the validity of each individual potency determination. The use of a single dilution allows a considerable reduction in the number of animals required for the test and must be considered by each laboratory in accordance with the provisions of the European Convention for the Protection of Vertebrate Animals used for Experimental and other Scientific Purposes.

Selection and distribution of the test animals. Use healthy female mice, about 4 weeks old, each weighing 11-15 g, and from the same stock. Distribute the mice into 6 groups of a size suitable to meet the requirements for validity of the test and, for titration of the challenge suspension, 4 groups of 5.

Preparation of the challenge suspension. Inoculate mice intracerebrally with the Challenge Virus Standard (CVS) strain of rabies virus and when the mice show signs of rabies, but before they die, euthanise them, then remove the brains and prepare a homogenate of the brain tissue in a suitable diluent. Separate gross particulate matter by centrifugation and use the supernatant liquid as the challenge suspension. Distribute the suspension in small volumes in ampoules, seal and store at a temperature below – 60 °C. Thaw one ampoule of the suspension and make serial dilutions in a suitable diluent. Allocate each dilution to a group of 5 mice and inject intracerebrally into each mouse 0.03 ml of the dilution allocated to its group. Observe the mice for 14 days. Calculate the LD_{50} of the undiluted suspension using the number in each group that, between the 5^{th} and 14^{th} days, die or develop signs of rabies.

Determination of potency of the vaccine. Prepare 3 fivefold serial dilutions of the vaccine to be examined and 3 fivefold serial dilutions of the reference preparation. Prepare the dilutions such that the most concentrated suspensions may be expected to protect more than 50 per cent of the animals to which they are administered and the least concentrated suspensions may be expected to protect less than 50 per cent of the animals to which they are administered. Allocate the 6 dilutions, 1 to each of the 6 groups of mice, and inject by the intraperitoneal route into each mouse 0.5 ml of the dilution allocated to its group. After 7 days, prepare 3 identical dilutions of the vaccine to be examined and of the reference preparation and repeat the injections. 7 days after the second injection, prepare a suspension of the challenge virus such that, on the basis of the preliminary titration, 0.03 ml contains about 50 LD_{50}. Inject intracerebrally into each vaccinated mouse 0.03 ml of this suspension. Prepare 3 suitable serial dilutions of the challenge suspension. Allocate the challenge suspension and the 3 dilutions, 1 to each of the 4 groups of 5 control mice, and inject intracerebrally into each mouse 0.03 ml of the suspension or dilution allocated to its group. Observe the animals in each group for 14 days and record the number in each group that die or show signs of rabies in the period 5-14 days after challenge.

The test is not valid unless:

- for both the vaccine to be examined and the reference preparation the 50 per cent protective dose lies between the largest and smallest doses given to the mice;
- the titration of the challenge suspension shows that 0.03 ml of the suspension contained not less than 10 LD_{50};
- the statistical analysis shows a significant slope and no significant deviations from linearity or parallelism of the dose-response curves;
- the confidence limits (P = 0.95) are not less than 25 per cent and not more than 400 per cent of the estimated potency.

The vaccine complies with the test if the estimated potency is not less than 2.5 IU per human dose.

LABELLING

The label states the biological origin of the cells used for the preparation of the vaccine.

01/2008:0162

RUBELLA VACCINE (LIVE)

Vaccinum rubellae vivum

DEFINITION

Rubella vaccine (live) is a freeze-dried preparation of a suitable attenuated strain of rubella virus. The vaccine is reconstituted immediately before use, as stated on the label, to give a clear liquid that may be coloured owing to the presence of a pH indicator.

PRODUCTION

The production of vaccine is based on a virus seed-lot system and a cell-bank system. The production method shall have been shown to yield consistently live rubella vaccines of adequate immunogenicity and safety in man. Unless otherwise justified and authorised, the virus in the final vaccine shall have undergone no more passages from the master seed lot than were used to prepare the vaccine shown in clinical studies to be satisfactory with respect to safety and efficacy.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (*2.6.9*).

SUBSTRATE FOR VIRUS PROPAGATION

The virus is propagated in human diploid cells (*5.2.3*).

SEED LOT

The strain of rubella virus used shall be identified by historical records that include information on the origin of the strain and its subsequent manipulation. To avoid the unnecessary use of monkeys in the test for neurovirulence,

virus seed lots are prepared in large quantities and stored at temperatures below – 20 °C if freeze-dried, or below – 60 °C if not freeze-dried.

Only a seed lot that complies with the following requirements may be used for virus propagation.

Identification. The master and working seed lots are identified as rubella virus by serum neutralisation in cell culture, using specific antibodies.

Virus concentration. The virus concentration of the master and working seed lots is determined to ensure consistency of production.

Extraneous agents (*2.6.16*). The working seed lot complies with the requirements for seed lots.

Neurovirulence (*2.6.18*). The working seed lot complies with the test for neurovirulence of live virus vaccines. *Macaca* and *Cercopithecus* monkeys are suitable for the test.

PROPAGATION AND HARVEST

All processing of the cell bank and subsequent cell cultures is done under aseptic conditions in an area where no other cells are handled. Suitable animal (but not human) serum may be used in the growth medium, but the final medium for maintaining cell growth during virus multiplication does not contain animal serum. Serum and trypsin used in the preparation of cell suspensions and culture media are shown to be free from extraneous agents. The cell culture medium may contain a pH indicator such as phenol red and suitable antibiotics at the lowest effective concentration. It is preferable to have a substrate free from antibiotics during production. Not less than 500 ml of the production cell cultures is set aside as uninfected cell cultures (control cells). The temperature of incubation is controlled during the growth of the virus. The virus suspension is harvested, on one or more occasions, within 28 days of inoculation. Multiple harvests from the same production cell culture may be pooled and considered as a single harvest.

Only a single harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Identification. The single harvest contains virus that is identified as rubella virus by serum neutralisation in cell culture, using specific antibodies.

Virus concentration. The virus concentration in the single harvest is determined as prescribed under Assay to monitor consistency of production and to determine the dilution to be used for the final bulk vaccine.

Extraneous agents (*2.6.16*). The single harvest complies with the tests for extraneous agents.

Control cells. The control cells comply with a test for identification and with the tests for extraneous agents (*2.6.16*).

FINAL BULK VACCINE

Single harvests that comply with the above tests are pooled and clarified to remove cells. A suitable stabiliser may be added and the pooled harvests diluted as appropriate.

Only a final bulk vaccine that complies with the following requirement may be used in the preparation of the final lot.

Bacterial and fungal contamination. The final bulk vaccine complies with the test for sterility (*2.6.1*), carried out using 10 ml for each medium.

FINAL LOT

A minimum virus concentration for release of the product is established such as to ensure, in the light of stability data, that the minimum concentration stated on the label will be present at the end of the period of validity.

Only a final lot that complies with the requirements for minimum virus concentration for release, with the following requirement for thermal stability and with each of the requirements given below under Identification and Tests may be released for use. Provided that the test for bovine serum albumin has been carried out with satisfactory results on the final bulk vaccine, it may be omitted on the final lot.

Thermal stability. Maintain samples of the final lot of freeze-dried vaccine in the dry state at 37 °C for 7 days. Determine the virus concentration as described under Assay in parallel for the heated vaccine and for unheated vaccine stored at 5 ± 3 °C. The virus concentration of the heated vaccine is not more than 1.0 $\log_{10}$ lower than that of the unheated vaccine.

IDENTIFICATION

When the vaccine reconstituted as stated on the label is mixed with specific rubella antibodies, it is no longer able to infect susceptible cell cultures.

TESTS

Bacterial and fungal contamination. The reconstituted vaccine complies with the test for sterility (*2.6.1*).

Bovine serum albumin. Not more than 50 ng per single human dose, determined by a suitable immunochemical method (*2.7.1*).

Water (*2.5.12*). Not more than 3.0 per cent, determined by the semi-micro determination of water.

ASSAY

Titrate the vaccine for infective virus at least in triplicate, using at least 5 cell cultures for each 0.5 $\log_{10}$ dilution step or by a method of equal precision. Use an appropriate virus reference preparation to validate each assay. The estimated virus concentration is not less than that stated on the label; the minimum virus concentration stated on the label is not less than 1×10^3 $CCID_{50}$ per human dose. The assay is not valid if the confidence interval (P = 0.95) of the logarithm of the virus concentration is greater than ± 0.3.

Rubella vaccine (live) BRP is suitable for use as a reference preparation.

LABELLING

The label states:

- the strain of virus used for the preparation of the vaccine,
- the type and origin of the cells used for the preparation of the vaccine,
- the minimum virus concentration,
- that contact with disinfectants is to be avoided,
- the time within which the vaccine must be used after reconstitution,
- that the vaccine must not be given to a pregnant woman and that a woman must not become pregnant within 2 months after having the vaccine.

corrected 6.0

SMALLPOX VACCINE (LIVE)

Vaccinum variolae vivum

DEFINITION

Smallpox vaccine (live) is a liquid or freeze-dried preparation of live vaccinia virus grown *in ovo* in the membranes of the chick embryo, in cell cultures or in the skin of living animals.

This monograph applies to vaccines produced using strains of confirmed efficacy in man, in particular those used during eradication of smallpox, for example the Lister strain (sometimes referred to as the Lister/Elstree strain) and the New York City Board of Health (NYCBOH) strain. It does not apply to non-replicative strains such as Modified Virus Ankara (MVA).

PRODUCTION

GENERAL PROVISIONS

The production method shall have been shown to yield consistently smallpox vaccines of adequate safety and immunogenicity in man. The strain used shall have been shown to produce typical vaccinia skin lesions in man. Production is based on a seed-lot system.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity of immunosera and vaccines for human use (*2.6.9*).

The International Reference Preparation for smallpox vaccine is suitable for use as a reference preparation in virus titration.

SUBSTRATE FOR VIRUS PROPAGATION

Animals used for production of skin-derived vaccines. If the vaccine is prepared in animals skins, the animals used are of a species approved by the competent authority, are in good health, are kept in closed or intensively monitored colonies, and have not previously been employed for experimental purposes. Only animals susceptible to infection by dermal inoculations with vaccinia virus may be used for vaccine production.

The animals are kept in well-constructed and adequately ventilated animals rooms with cages spaced as far apart as possible. Adequate precautions are taken to prevent cross-infection between cages. Not more than 1 large animal is housed per stall. Not more than 2 small animals are housed per cage and cage-mates must not be interchanged. The animals must be kept in the country of production of the vaccine in quarantine groups for a period of not less than 6 weeks before use.

If at any time during the quarantine period the overall death rate of the group reaches 5 per cent, no animals from that entire group may be used for vaccine production.

The groups are kept continuously in isolation, as in quarantine, even after completion of the quarantine period, until the animals are used. After the last animal of a group has been taken, the room that housed the group is thoroughly cleaned and decontaminated before receiving a new group.

Animals that are to be inoculated are anaesthetised and thoroughly examined. If an animal shows any pathological lesion, it is not used in the preparation of a seed lot or a vaccine, nor are any of the remaining animals of the quarantine group concerned unless it is evident that their use will not impair the safety of the product.

The prophylactic and diagnostic measures adopted to exclude the presence of infectious disease are approved by the competent authority. According to the species of animals used and the diseases to which that animal is liable in the country where the vaccine is being produced, these measures could vary. Consideration must also be given to the danger of spreading diseases to other countries to which the vaccine may be shipped. Special attention must always be given to foot-and-mouth disease, brucellosis, Q fever, tuberculosis and dermatomycosis, and it may also be necessary to consider diseases such as contagious pustular dermatitis (orf), anthrax, rinderpest, haemorrhagic septicaemia, Rift valley fever and others.

Embryonated eggs. Embryonated eggs used for production are obtained from a flock free from specified pathogens (SPF) (*5.2.2*).

Human diploid cells, continuous cell lines. Human diploid cells and continuous cell lines comply with the requirements for cell substrates (*5.2.3*).

Primary chick embryo cells. Primary chick embryo cells are derived from an SPF flock (*5.2.2*).

Primary rabbit kidney cells. Only healthy rabbits derived from a closed colony approved by the competent authority are used as a source. The animals, preferably 2-4 weeks old, are tested to ensure freedom from specified pathogens or their antibodies.

Where new animals are introduced into the colony, they are maintained in quarantine for a minimum of 2 months and shown to be free from specified pathogens. Animals to be used to provide kidneys have not been previously employed for experimental purposes, especially those involving infectious agents. The colony is monitored for zoonotic viruses and markers of contamination at regular intervals.

At the time the colony is established, all animals are tested to determine freedom from antibodies to possible viral contaminants for which there is evidence of capacity for infecting humans or evidence of capacity to replicate *in vitro* in cells of human origin. A test for retroviruses using a sensitive polymerase chain reaction (PCR)-based reverse transcriptase assay is also included. Nucleic acid amplification tests (*2.6.21*) for retroviruses may also be used.

After the colony is established, it is monitored by testing a representative group of at least 5 per cent of the animals, which are then bled at suitable (for example monthly) intervals. In addition, the colony is screened for pathogenic micro-organisms, including mycobacteria, fungi and mycoplasmas. The screening programme is designed to ensure that all animals are tested within a given period of time.

Any animal that dies is examined to determine the cause of death. If the presence of a causative infectious agent is demonstrated in the colony, the production of smallpox vaccine is discontinued.

At the time of kidney harvest, the animals are examined for the presence of abnormalities and, if any are noted, the animals are not used for vaccine production.

Each set of control cultures derived from a single group of animals used to produce a single virus harvest must remain identifiable as such until all testing, especially for extraneous agents, is completed.

VIRUS SEED LOT

The vaccinia virus isolate used for the master seed lot is identified by historical records that include information on its origin and the tests used in its characterisation.
Virus from the working seed lot must have the same characteristics as the strain that was used to prepare the master seed lot. The number of passages required to produce single harvests from the original isolate is limited and approved by the competent authority. Vaccine is produced from the working seed with a minimum number of intervening passages.

Since cell culture production and clonal selection (e.g plaque purification) may lead to altered characteristics of the virus, the master seed virus must be characterised as fully as possible, for example by comparing the safety profile and biological characteristics of the strain with that of the parental isolate. The characterisation shall include the following:

– antigenic analyses using specific antisera and/or monoclonal antibodies;
– biological studies such as infectivity titre, chorioallantoic membrane (CAM) assay, *in vitro* yield and *in vivo* growth characteristics in a suitable animal model;
– genetic analyses such as restriction mapping/southern blotting, PCR analyses and limited sequencing studies;
– phenotypic and genetic stability upon passage in the substrate;
– neurovirulence testing and immunogenicity studies.

The characterisation tests are also carried out on each working seed lot and on 3 batches of vaccine from the first working seed lot to verify genetic stability of the vaccine strain.

Only a virus seed that complies with the following requirements may be used for virus propagation.

Identification. Each working seed is identified as vaccinia virus using specific antibodies and molecular tests. Suitable tests are conducted to exclude the presence of variola virus and other orthopoxviruses.

Virus concentration. Determined by the CAM assay or by a suitable validated *in vitro* assay (plaque assay or $CCID_{50}$ assay). The virus concentration is the basis for the quantity of virus used in the neurovirulence test.

Extraneous agents (*2.6.16*). If the working seed lot is produced in embryonated eggs, human diploid cells, or in a continuous cell line, it complies with the requirements for seed lots for virus vaccines. Seed lots produced in embryonated eggs and seed lots produced in primary cell cultures comply with the additional requirements described below.

Where the tests prescribed cannot be carried out because complete neutralisation of the seed virus is not possible, the seed lot may be diluted to a concentration equivalent to that of the dilution used as inoculum for production of vaccine prior to testing for extraneous viruses. Supplementary specific testing for extraneous viruses using validated nucleic acid amplification techniques (*2.6.21*) or immunochemical methods (*2.7.1*) may be envisaged. Where the indicator cell culture method for mycoplasma detection (*2.6.7*) cannot be carried out, nucleic acid amplification testing is performed instead.

Seed lots to be used for embryonated egg or cell culture production are in addition to be tested for carry-over of potential extraneous agents from the original seed. Given that the complete passage history of the original seed is unlikely to be known and that more than one species may have been used, this additional testing must at least cover important extraneous agents of concern.

The bioburden of master and working seed lots prepared in animal skins is limited by meticulous controls of facilities, personnel, and animals used for production, and by specific tests on the seeds. However, it may be difficult to ensure that seed lots produced in animal skins are totally free from extraneous agents, and consideration must be given to production procedures which remove or reduce them. Such lots must comply with the requirements indicated below. The absence of specific human pathogens is confirmed by additional testing procedures, for example, bacterial and fungal cultures, virus culture, nucleic acid amplification testings (*2.6.21*) for viral agents.

Neurovirulence. The neurovirulence of master and working seed lots is assessed using a suitable animal model, for example in monkeys or mice. The parental isolate is used as comparator. Where the original isolate is not available for this purpose, equivalent materials may be used.

VIRUS PROPAGATION AND HARVEST

VACCINE PRODUCED IN LIVING ANIMALS

Before inoculation the animals are cleaned and thereafter kept in scrupulously clean stalls until the vaccinia material is harvested. For 5 days before inoculation and during incubation the animals remain under veterinary supervision and must remain free from any sign of disease, and daily rectal temperatures are recorded. If any abnormal rise in temperature occurs or any clinical sign of disease is observed, the production of vaccine from the group of animals concerned must be suspended until the cause has been resolved.

The inoculation of seed virus is carried out on such parts of the animal that are not liable to be soiled by urine and faeces. The surface used for inoculation is shaved and cleaned so as to achieve conditions that are as close as possible to surgical asepsis. If any antiseptic substance deleterious to the virus is used in the cleaning process it is removed by thorough rinsing with sterile water prior to inoculation. During inoculation the exposed surface of the animal not used for inoculation is covered with a sterile covering. By historical experience the ventral surface of female animals is appropriate for inoculation and inoculation of male animals is more appropriate on the flank.

Before the collection of the vaccinia material, any antibiotic is removed and the inoculated area is cleaned. The uninoculated surfaces are covered with a sterile covering. Before harvesting the animals are euthanised and exsanguinated to avoid heavy mixtures of the vaccinia material with blood. The vaccinia material from each animal is collected separately with aseptic precautions. All animals used in the production of vaccine are examined by autopsy. If evidence of any generalised or systemic disease other than vaccinia is found, the vaccinia material from that animal is discarded. If the disease is considered to be a communicable one, the harvest from the entire group of animals exposed must be discarded unless otherwise justified and authorised.

VACCINE PRODUCED IN EGGS

All processing of embryonated eggs is done under aseptic conditions in an area where no other infectious agents or cells are handled at the same time. After inoculation and incubation at a controlled temperature only living and suitable chick embryos are harvested. The age of the embryos at the time of virus harvest is reckoned from the initial introduction of the egg into the incubator and shall be not more than 12 days. After homogenisation and clarification by centrifugation, the extract of embryonic pulp is tested as described below and kept at – 70 °C or below until further processing. Virus harvests that comply with the prescribed tests may be pooled. No human protein is added to the virus suspension at any stage during production. If stabilisers are added, they shall have been shown to have no antigenic or sensitising properties for man.

Only a single harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Control eggs. Control eggs comply with the tests for extraneous agents (*2.6.16*). A sample of 2 per cent of uninoculated embryonated eggs (not less than 20 and

not more than 50) from the batch used for vaccine production shall be incubated under the same conditions as the inoculated eggs. At the time of virus harvest the uninoculated eggs are processed in the same manner as the inoculated eggs.

Sterility (*2.6.1*). It complies with the test for sterility, carried out using 10 ml for each medium.

VACCINE PRODUCED IN CELL CULTURES (PRIMARY CHICK EMBRYO CELLS, PRIMARY RABBIT KIDNEY CELLS, HUMAN DIPLOID CELLS OR CONTINUOUS CELL LINES)

All processing of the cell bank and subsequent cell cultures is done under aseptic conditions in an area where no other cells are handled at the same time. Approved animal (but not human) serum may be used in the media, but the final medium for maintaining cell viability during virus multiplication does not contain animal serum. Serum and trypsin used in the preparation of cell suspensions and media are shown to be free from extraneous agents. The cell culture media may contain a pH indicator such as phenol red and approved antibiotics at the lowest effective concentration. It is preferable to have a substrate free from antibiotics during production. On the day of inoculation with the virus working seed lot, not less than 5 per cent or 1000 ml, whichever is the least, of the cell cultures employed for vaccine production are set aside as uninfected cell cultures (control cells); special requirements, given below, apply to control cells when the vaccine is produced in primary rabbit kidney cell cultures.

After inoculation of the production cell culture with the working seed lot, inoculated cells are maintained at a suitable fixed temperature, and the virus suspension is harvested after a suitable incubation period.

Only a single harvest that complies with the following requirements may be used in the preparation of the monovalent pooled harvest.

Control cells. The control cells of the production cell culture from which the virus harvest is derived comply with a test for identity and with the requirements for extraneous agents (*2.6.16*) or, where primary rabbit kidney cells cultures are used, with specific tests as mentioned hereafter. The test is invalid if more than 20 per cent of the control cell cultures have been discarded at the end of the observation period.

Extraneous agents (*2.6.16*). The single harvest complies with the tests for extraneous agents. Complete neutralisation of vaccinia virus may be difficult to achieve at high virus concentration. In this case specific tests such as nucleic acid amplification (*2.6.21*) and immunochemical tests (*2.7.1*) can replace non-specific testing in cell culture or eggs. To save biological reagents such as vaccinia neutralising antisera, testing for extraneous agents may be performed on the final bulk instead of on the single harvests.

Vaccine prepared in primary chick embryo cells. A sample of fluids pooled from the control cultures is tested for adenoviruses and for avian retroviruses such as avian leukosis virus. In addition, a volume of each neutralised virus pool equivalent to 100 human doses of vaccine or 10 ml, whichever is the greater, is tested in a group of fertilised eggs by the allantoic route of inoculation, and a similar sample is tested in a separate group of eggs by the yolk-sac route of inoculation. In both cases 0.5 ml of inoculum is used per egg. The virus pool passes the test if, after 3-7 days, there is no evidence of the presence of any extraneous agent.

Vaccine prepared in primary rabbit kidney cell cultures. The following special requirements apply to virus propagation, harvest and testing. On the day of inoculation with virus working seed, a sample of at least 30 ml of the pooled fluid is removed from the cell cultures of the kidneys of each group of animals used to prepare the primary cell suspension. The pooled fluid is inoculated in primary kidney cell cultures in such a way that the dilution of the pooled fluid does not exceed 1 in 4. The cultures are incubated at a temperature of 34-36 °C and observed for a period of at least 4 weeks. During this observation period and after not less than 2 weeks of incubation, at least 1 subculture of fluid is made from each of these cultures and observed also for a period of 2 weeks. The test is invalid if more than 20 per cent of the cultures are discarded. If evidence is found of the presence of an extraneous agent, no cell cultures from the entire group may be used for vaccine production.

- *Control cell cultures.* Cultures prepared on the day of inoculation with the working virus seed lot from 25 per cent of the cell suspensions obtained from the kidneys of each group of animals are maintained as controls. These control cell cultures are incubated under the same conditions as the inoculated cultures for at least 2 weeks. The test is invalid if more than 20 per cent of the control cell cultures are discarded for non-specific reasons.
- *Test for haemadsorbing viruses.* At the time of harvest or not more than 4 days after the day of inoculation of the production cultures with the virus working seed, a sample of 4 per cent of the control cell cultures is tested for haemadsorbing viruses by addition of guinea-pig red blood cells.
- *Test for other extraneous agents.* At the time of harvest or not more than 7 days after the day of inoculation of the production cultures with the virus working seed, a sample of at least 20 ml of the pooled fluid from each group of control cultures is tested for other extraneous agents.
- *Tests of neutralised single harvest in primary rabbit kidney cell cultures.* Each neutralised single harvest is additionally tested in primary kidney cell cultures prepared from a different group of animals to that used for production.

POOLED HARVEST

Only a pooled harvest that complies with the following requirements and is within the limits approved for the product may be used in the preparation of the final lot.

Identity. The vaccinia virus in the pooled harvest is identified by serological methods, which may be supplemented by molecular methods. Molecular tests such as restriction fragment length polymorphism or partial sequencing, especially of terminal DNA sequences which show the greatest variation between vaccinia strains, may be useful.

Virus concentration. The vaccinia virus concentration of the pooled harvest is determined by chick egg CAM assay or in cell cultures. A reference preparation is assayed in the same system in parallel for validation of the pooled harvest titration. The virus concentration serves as the basis for the quantity of virus used in the neurovirulence test in mice.

Consistency of virus characteristics. Vaccinia virus in the pooled harvest or the final bulk is examined by tests that are able to determine that the phenotypic and genetic characteristics of the vaccinia virus have not undergone changes during the multiplication in the production system. The master seed or an equivalent preparation is used as a comparator in these tests and the comparator and the tests to be used are approved by the competent authority.

Neurovirulence. The neurovirulence of the pooled harvest is assessed versus a comparator original seed (or equivalent) by intracerebral inoculation into suckling mice. Other tests may be useful to discriminate between acceptable and unacceptable batches.

Residual DNA. For viruses grown in continuous cells the pooled harvest is tested for residual DNA. The production process demonstrates a level of cellular DNA of less than 10 ng per human dose.

Bacterial and fungal contamination. For vaccines other than those prepared on animal skins, the final bulk complies with the test for sterility (*2.6.1*) using 10 ml for each medium.

Mycoplasma (*2.6.7*). For vaccines other than those prepared on animal skins, the final bulk complies with the test for mycoplasma, carried out using 10 ml.

FINAL BULK VACCINE

A minimum virus concentration for release of the product is established such as to ensure, in the light of stability data, that the minimum concentration stated on the label will be present at the end of the period of validity.

VACCINE PRODUCED IN LIVING ANIMALS

The pooled harvest is centrifuged. If the vaccine is intended for issue in the liquid form, treatment to reduce the presence of extraneous agents may consist of the addition of glycerol or another suitable diluent, with or without an antimicrobial substance, and temporary storage at a suitable temperature. If the vaccine is intended for issue in the dried form, the treatment may consist of the addition of a suitable antimicrobial substance. The following special requirements apply to the bulk vaccine for vaccines produced in living animals.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Total bacterial count: for vaccines produced on animal skins only, maximum 50 per millilitre, determined by plate count using a suitable volume of the final bulk vaccine.

Escherichia coli. At least 1 ml samples of a 1:100 dilution of the final bulk vaccine is cultured on plates of a medium suitable for differentiating *E. coli* from other bacteria. The plates are incubated at 35-37 °C for 48 h. If *E. coli* is detected the final bulk is discarded or, subject to approval by the competent authority, processed further.

Haemolytic streptococci, coagulase-positive staphylococci or any other pathogenic micro-organisms which are known to be harmful to man by vaccination. At least 1 ml samples of a 1:100 dilution of the final bulk vaccine are cultured on blood agar. The plates are incubated at 35-37 °C for 48 h. If micro-organisms are detected, the final bulk vaccine is discarded.

Bacillus anthracis. Any colony seen on any of the plates that morphologically resembles *B. anthracis* is examined. If the organisms contained in the colony are non-motile, further tests for the cultural character of *B. anthracis* are carried out, including pathogenicity tests in suitable animals. If *B. anthracis* is found to be present, the final bulk vaccine and any other associated bulks are discarded. Additional validated molecular testing may be performed.

***Clostridium tetani* and other pathogenic spore-forming anaerobes**. A total volume of not less than 10 ml of the final bulk vaccine is distributed in equal amounts into 10 tubes, each containing not less than 10 ml of suitable medium for the growth of anaerobic micro-organisms. The tubes are kept at 65 °C for 1 h in order to reduce the content of non-spore-forming organisms, after which they are anaerobically incubated at 35-37 °C for at least 1 week. From every tube or plate showing growth, subcultures are made on plates of a suitable medium. Tubes and plates are incubated anaerobically at the same temperature. All anaerobic colonies are examined and identified and if *C. tetani* or other pathogenic spore-forming anaerobes are present, the final bulk is discarded.

VACCINE PRODUCED IN EGGS

The pooled harvest is clarified and may be further purified.

VACCINE PRODUCED IN CELL CULTURES (PRIMARY CHICK EMBRYOS FIBROBLASTS, HUMAN DIPLOID CELLS OR CONTINUOUS CELL LINES)

The pooled harvest is clarified to remove cells and may be further purified.

FINAL LOT

Only a final lot that complies with the requirements for minimum virus concentration for release, with the following requirement for thermal stability and with each of the requirements given below under Identification, Tests and Assay may be released for use. Provided that the tests for antimicrobial preservative, protein content, bovine serum albumin and ovalbumin have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

Thermal stability. Representative final containers of the vaccine are incubated at an elevated temperature for a defined period.

For liquid products, the conditions of the test and the requirements are approved by the competent authority.

For freeze-dried vaccines, maintain at least 3 vials of the final lot in the dry state at 37 ± 1 °C for 28 days. The total virus content in the 3 treated vials is assayed in parallel alongside 3 vials of vaccine maintained at the recommended storage temperature. An appropriate reference preparation is also included to validate each assay. The vaccine complies with the test if the loss in titre after exposure at elevated temperature is not greater than 1.0 $\log_{10}$ infectious units per human dose and if the virus concentration after exposure at elevated temperature is not less than the minimum stated on the label.

The assay is not valid if:

- the confidence interval (P = 0.95) of the logarithm of the virus concentration of the reference preparation is greater than ± 0.5;
- the virus concentration of the reference preparation differs by more than 0.5 $\log_{10}$ infectious units from the assigned value;
- the range of virus concentrations found for replicates of any sample is greater than 0.8 $\log_{10}$ infectious units.

IDENTIFICATION

The vaccinia virus is identified by an appropriate method.

TESTS

Antimicrobial preservative. Where applicable determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Phenol (*2.5.15*): maximum 0.5 per cent, if phenol is used.

Protein content. The protein content of each filling lot, if not done on the final bulk, is determined and is within the limits approved by the competent authority.

Bovine serum albumin: maximum 50 ng per single human dose, determined by a suitable immunochemical method (*2.7.1*), where bovine serum albumin is used during cell culture.

Ovalbumin. For vaccines produced in embryonated eggs, the ovalbumin content is within the limits approved by the competent authority.

Residual moisture. The residual moisture content of each final lot of freeze-dried vaccines is within the limits approved by the competent authority.

Bacterial count. For skin-derived vaccines, examine the vaccine by suitable microscopic and culture methods for micro-organisms pathogenic for man and, in particular, haemolytic streptococci, staphylococci, pathogenic spore-bearing organisms, especially *B. anthracis*, and *E. coli*. The vaccine is free from such contaminants. The total number of non-pathogenic bacteria does not exceed 50 per millilitre.

Sterility (*2.6.1*). Except for skin derived vaccines, the vaccine complies with the test for sterility.

Bacterial endotoxins (*2.6.14*). The vaccine complies with the specification approved by the competent authority.

ASSAY

Reconstitue the vaccine if necessary and titrate for infectious virus using at least 3 separate vials of vaccine. Use 1 vial of an appropriate virus reference preparation to validate the assay of each vial. The vaccine contains not less than 8.0 $\log_{10}$ pock-forming units per millilitre or the validated equivalent in plaque-forming units or 50 per cent cell culture infective doses, unless a lower titre is justified by clinical studies.

The assay is not valid if:

- the confidence interval (P = 0.95) of the logarithm of the virus concentration of the reference preparation is greater than ± 0.5;
- the virus concentration of the reference preparation differs by more than 0.5 $\log_{10}$ infectious units from the assigned value;
- the range of virus concentrations found for replicates of any sample is greater than 0.8 $\log_{10}$ infectious units.

The assay is repeated if the confidence interval (P = 0.95) of the logarithm of the virus concentration of the sample is greater than ± 0.5. All data generated from valid assays are used to calculate the mean virus concentration of the sample.

LABELLING

The label states:

- the designation of the vaccinia virus strain;
- the minimum amount of virus per millilitre;
- the substrate used for the preparation of the vaccine;
- the nature and amount of stabiliser, preservative or additive present in the vaccine and/or in the diluent.

corrected 6.0

TETANUS VACCINE (ADSORBED)

Vaccinum tetani adsorbatum

DEFINITION

Tetanus vaccine (adsorbed) is a preparation of tetanus formol toxoid with a mineral adsorbent. The formol toxoid is prepared from the toxin produced by the growth of *Clostridium tetani*.

PRODUCTION

GENERAL PROVISIONS

Specific toxicity. The production method is validated to demonstrate that the product, if tested, would comply with the following test: inject subcutaneously 5 times the single human dose stated on the label into each of 5 healthy guinea-pigs, each weighing 250-350 g, that have not previously been treated with any material that will interfere with the test. If within 21 days of the injection any of the animals shows signs of or dies from tetanus, the vaccine does not comply with the test. If more than 1 animal dies from non-specific causes, repeat the test once; if more than 1 animal dies in the second test, the vaccine does not comply with the test.

BULK PURIFIED TOXOID

For the production of tetanus toxin, from which toxoid is prepared, seed cultures are managed in a defined seed-lot system in which toxinogenicity is conserved and, where necessary, restored by deliberate reselection. A highly toxinogenic strain of *Clostridium tetani* with known origin and history is grown in a suitable liquid medium. At the end of cultivation, the purity of each culture is tested and contaminated cultures are discarded. Toxin-containing culture medium is collected aseptically. The toxin content (Lf per millilitre) is checked (*2.7.27*) to monitor consistency of production. Single harvests may be pooled to prepare the bulk purified toxoid. The toxin is purified to remove components likely to cause adverse reactions in humans. The purified toxin is detoxified with formaldehyde by a method that avoids destruction of the immunogenic potency of the toxoid and reversion of toxoid to toxin, particularly on exposure to heat. Alternatively, purification may be carried out after detoxification.

Only bulk purified toxoid that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Sterility (*2.6.1*). Carry out the test for sterility using 10 ml for each medium.

Absence of toxin and irreversibility of toxoid. Using the same buffer solution as for the final vaccine, without adsorbent, prepare a solution of bulk purified toxoid at the same concentration as in the final vaccine. Divide the dilution into 2 equal parts. Keep one of them at 5 ± 3 °C and the other at 37 °C for 6 weeks. Test both dilutions as described below. Use 15 guinea-pigs, each weighing 250-350 g and that have not previously been treated with any material that will interfere with the test. Inject subcutaneously into each of 5 guinea-pigs 5 ml of the dilution incubated at 5 ± 3 °C. Inject subcutaneously into each of 5 other guinea-pigs 5 ml of the dilution incubated at 37 °C. Inject subcutaneously into each of 5 guinea-pigs at least 500 Lf of the non-incubated bulk purified toxoid in a volume of 1 ml. The bulk purified toxoid complies with the test if during the 21 days following the injection no animal shows signs of or dies from tetanus. If more than 1 animal dies from non-specific causes, repeat the test; if more than 1 animal dies in the second test, the toxoid does not comply with the test.

Antigenic purity (*2.7.27*). Not less than 1000 Lf per milligram of protein nitrogen.

FINAL BULK VACCINE

The final bulk vaccine is prepared by adsorption of a suitable quantity of bulk purified toxoid onto a mineral carrier such as hydrated aluminium phosphate or aluminium hydroxide; the resulting mixture is approximately isotonic with blood. Suitable antimicrobial preservatives may be added. Certain antimicrobial preservatives, particularly those of the phenolic type, adversely affect the antigenic activity and must not be used.

Only final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended amount.

Sterility (*2.6.1*). Carry out the test for sterility using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers. The containers are closed so as to prevent contamination.

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use. Provided the test for antimicrobial preservative and the assay have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

Provided the free formaldehyde content has been determined on the bulk purified toxoid or on the final bulk and it has been shown that the content in the final lot will not exceed 0.2 g/l, the test for free formaldehyde may be omitted on the final lot.

IDENTIFICATION

Tetanus toxoid is identified by a suitable immunochemical method (*2.7.1*). The following method, applicable to certain vaccines, is given as an example. Dissolve in the vaccine to be examined sufficient *sodium citrate R* to give a 100 g/l solution. Maintain at 37 °C for about 16 h and centrifuge until a clear supernatant liquid is obtained. The clear supernatant liquid reacts with a suitable tetanus antitoxin, giving a precipitate.

TESTS

Aluminium (*2.5.13*): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (*2.4.18*): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable chemical method. The content is not less than the minimum amount shown to be effective and is not greater than 115 per cent of the quantity stated on the label.

Sterility (*2.6.1*). The vaccine complies with the test for sterility.

ASSAY

Carry out one of the prescribed methods for the assay of tetanus vaccine (adsorbed) (*2.7.8*).

The lower confidence limit (P = 0.95) of the estimated potency is not less than 40 IU per single human dose.

LABELLING

The label states:

– the minimum number of International Units per single human dose,

– the name and the amount of the adsorbent,

– that the vaccine must be shaken before use,

– that the vaccine is not to be frozen.

01/2008:1375

TICK-BORNE ENCEPHALITIS VACCINE (INACTIVATED)

Vaccinum encephalitidis ixodibus advectae inactivatum

DEFINITION

Tick-borne encephalitis vaccine (inactivated) is a liquid preparation of a suitable strain of tick-borne encephalitis virus grown in cultures of chick-embryo cells or other suitable cell cultures and inactivated by a suitable, validated method.

PRODUCTION

GENERAL PROVISIONS

Production of the vaccine is based on a virus seed-lot system. The production method shall have been shown to yield consistently vaccines comparable with the vaccine of proven clinical efficacy and safety in man. Unless otherwise justified and authorised, the virus in the final vaccine shall not have undergone more passages from the master seed lot than the virus in the vaccine used in clinical trials.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (*2.6.9*).

SUBSTRATE FOR VIRUS PROPAGATION

The virus is propagated in chick embryo cells prepared from eggs derived from a chicken flock free from specified pathogens (*5.2.2*) or in other suitable cell cultures (*5.2.3*).

SEED LOTS

The strain of virus used is identified by historical records that include information on the origin of the strain and its subsequent manipulation. Virus seed lots are stored at or below – 60 °C.

Only a seed lot that complies with the following requirements may be used for virus propagation.

Identification. Each seed lot is identified as containing the vaccine strain of tick-borne encephalitis virus by a suitable immunochemical method (*2.7.1*), preferably using monoclonal antibodies.

Virus concentration. The virus concentration of each seed lot is determined by titration in suitable cell cultures to monitor consistency of production.

Extraneous agents (*2.6.16*). Each seed lot complies with the requirements for extraneous agents in viral vaccines for human use. For neutralisation of the vaccine virus, the use of monoclonal antibodies is preferable.

VIRUS PROPAGATION AND HARVEST

If the virus has been passaged in mouse brain during preparation of the master seed lot, not fewer than 2 passages of the master seed virus in cell culture are made before inoculation of the production cell culture.

All processing of the cell cultures is performed under aseptic conditions in an area where no other cells are being handled. Serum and trypsin used in the preparation of cell suspensions and media used must be shown to be free from extraneous agents. The cell culture media may contain a pH indicator such as phenol red and approved antibiotics at the lowest effective concentration. At least 500 ml of the cell cultures employed for vaccine production is set aside as uninfected cell cultures (control cells).

Only a single harvest that complies with the following requirements may be used in the preparation of the inactivated harvest.

Identification. The single harvest is shown to contain tick-borne encephalitis virus by a suitable immunochemical method (*2.7.1*), preferably using monoclonal antibodies, or by virus neutralisation in cell cultures.

Bacterial and fungal contamination (*2.6.1*). The single harvest complies with the test for sterility, carried out using 10 ml for each medium.

Mycoplasmas (*2.6.7*). The single harvest complies with the test for mycoplasmas carried out using 1 ml for each medium.

Control cells. The control cells comply with the tests for extraneous agents (*2.6.16*). If the vaccine is produced using a cell-bank system, the control cells comply with a test for identification.

Virus concentration. Determine the virus concentration by titration in suitable cell cultures to monitor consistency of production.

INACTIVATION

To avoid interference, viral aggregates are removed, where necessary, by filtration immediately before the inactivation process. The virus suspension is inactivated by a validated method; the method shall have been shown to be consistently capable of inactivating tick-borne encephalitis virus without destroying the antigenic and immunogenic activity; as part of the validation studies, an inactivation curve is plotted representing residual live virus concentration measured on not fewer than 3 occasions. If formaldehyde is used for inactivation, the presence of an excess of free formaldehyde is verified at the end of the inactivation process.

Only an inactivated harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Residual infective virus. Inoculate a quantity of the inactivated harvest equivalent to not less than 10 human doses of vaccine in the final lot into primary chicken fibroblast cell cultures, or other cells shown to be at least as sensitive to tick-borne encephalitis virus, with not less than 3 cm^2 of cell sheet per millilitre of inoculum. Incubate at 37 ± 1 °C for 14 days. No cytopathic effect is detected at the end of the incubation period. Collect the culture fluid and examine for the presence of infective tick-borne encephalitis virus by the following test in mice or by a validated *in vitro* method: inoculate 0.03 ml intracerebrally into each of not fewer than 10 mice about 4 weeks old. Observe the mice for 14 days. They show no evidence of tick-borne encephalitis virus infection.

PURIFICATION

Several inactivated single harvests may be pooled before concentration and purification by suitable methods, preferably by continuous-flow, sucrose density-gradient centrifugation.

Several purified inactivated harvests may be pooled.

Only a purified, inactivated harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Sterility (*2.6.1*). The purified, inactivated harvest complies with the test for sterility carried out using 10 ml for each medium.

Specific activity. Determine the antigen content of the purified, inactivated harvest by a suitable immunochemical method (*2.7.1*). Determine the total protein content by a suitable method. The specific activity, calculated as the antigen content per unit mass of protein, is within the limits approved for the specific product.

FINAL BULK VACCINE

The final bulk vaccine is prepared from one or more purified, inactivated harvests.

Only a final bulk vaccine that complies with the following requirement may be used in the preparation of the final lot.

Sterility (*2.6.1*). The final bulk vaccine complies with the test for sterility, carried out using 10 ml for each medium.

FINAL LOT

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use. Provided that the tests for free formaldehyde, bovine serum albumin (where applicable) and pyrogens and the assay have been carried out with satisfactory results on the final bulk vaccine, they may be omitted on the final lot.

IDENTIFICATION

The vaccine is shown to contain tick-borne encephalitis virus antigen by a suitable immunochemical method (*2.7.1*) using specific antibodies. The assay also serves to identify the vaccine.

TESTS

Aluminium (*2.5.13*): maximum 1.25 mg per single human dose, if aluminium hydroxide or hydrated aluminium phosphate is used as the adsorbent.

Free formaldehyde (*2.4.18*): maximum 0.1 g/l.

Bovine serum albumin: maximum 50 ng per single human dose, determined by a suitable immunochemical method (*2.7.1*), if bovine serum albumin has been used during production.

Sterility (*2.6.1*). The vaccine complies with the test for sterility.

Pyrogens (*2.6.8*). The vaccine complies with the test for pyrogens. Inject into each rabbit, per kilogram of body mass, 1 dose of vaccine.

ASSAY

The potency is determined by comparing the dose necessary to protect a given proportion of mice against the effects of a lethal dose of tick-borne encephalitis virus, administered intraperitoneally, with the quantity of a reference preparation of tick-borne encephalitis vaccine necessary to provide the same protection. For this comparison an approved reference preparation and a suitable preparation of tick-borne encephalitis virus from an approved strain for use as the challenge preparation are necessary.

The following is cited as an example of a method that has been found suitable for a given vaccine.

Selection and distribution of test animals. Use healthy mice weighing 11-17 g and derived from the same stock. Distribute the mice into not fewer than 6 groups of a suitable size to meet the requirements for validity of the test; for titration of the challenge suspension, use not fewer than 4 groups of 10 mice. Use mice of the same sex or distribute males and females equally between groups.

Determination of potency of the vaccine. Prepare not fewer than 3 suitable dilutions of the vaccine to be examined and of the reference preparation; in order to comply with validity criteria 4 or 5 dilutions will usually be necessary. Prepare dilutions such that the most concentrated suspension is expected to protect more than 50 per cent of the animals and the least concentrated suspension less than 50 per

cent. Allocate each dilution to a different group of mice and inject subcutaneously into each mouse 0.2 ml of the dilution allocated to its group. 7 days later make a second injection using the same dilution scale. 14 days after the second injection prepare a suspension of the challenge virus containing not less than 100 LD_{50} in 0.2 ml. Inject 0.2 ml of this virus suspension intraperitoneally into each vaccinated mouse. To verify the challenge dose, prepare a series of not fewer than 3 dilutions of the challenge virus suspension at not greater than one-hundredfold intervals. Allocate the challenge suspension and all of the dilutions, one to each of the groups of 10 mice, and inject intraperitoneally into each mouse 0.2 ml of the challenge suspension or the dilution allocated to its group. Observe the animals for 21 days after the challenge and record the number of mice that die in the period between 7 and 21 days after the challenge. Humane endpoints may be used to avoid unnecessary suffering of animals after the virulent challenge.

Calculations. Calculate the results for an assay with quantal responses by the usual statistical methods (for example, *5.3.*).

Validity criteria. The test is not valid unless:

- the concentration of the challenge virus is not less than 100 LD_{50},
- for both the vaccine to be examined and the reference preparation the 50 per cent protective dose (PD_{50}) lies between the largest and smallest doses given to the mice,
- the statistical analysis shows a significant slope and no significant deviation from linearity and parallelism of the dose-response lines,
- the confidence limits (P = 0.95) are not less than 33 per cent and not more than 300 per cent of the estimated potency.

Potency requirement. Include all valid tests to estimate the mean potency and the confidence limits (P = 0.95) for the mean potency; compute weighted means with the inverse of the squared standard error as weights. The vaccine complies with the test if the estimated potency is not less than that approved by the competent authority, based on data from clinical efficacy trials.

LABELLING

The label states:

- the strain of virus used in preparation,
- the type of cells used for production of the vaccine.

01/2008:1160

TYPHOID POLYSACCHARIDE VACCINE

Vaccinum febris typhoidis polysaccharidicum

DEFINITION

Typhoid polysaccharide vaccine is a preparation of purified Vi capsular polysaccharide obtained from *Salmonella typhi* Ty 2 strain or some other suitable strain that has the capacity to produce Vi polysaccharide.

Capsular Vi polysaccharide consists of partly 3-*O*-acetylated repeated units of 2-acetylamino-2-deoxy-D-galactopyranuronic acid with α-(1→4) linkages.

PRODUCTION

The production of Vi polysaccharide is based on a seed-lot system. The method of production shall have been shown to yield consistently typhoid polysaccharide vaccines of adequate immunogenicity and safety in man.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (*2.6.9*).

BACTERIAL SEED LOTS

The strain of *S. typhi* used for the master seed lot shall be identified by historical records that include information on its origin and by its biochemical and serological characteristics. Cultures from the working seed lot shall have the same characteristics as the strain that was used to prepare the master seed lot.

Only a strain that has the following characteristics may be used in the preparation of the vaccine: (a) stained smears from a culture are typical of enterobacteria; (b) the culture utilises glucose without production of gas; (c) colonies on agar are oxidase-negative; (d) a suspension of the culture agglutinates specifically with a suitable Vi antiserum or colonies form haloes on an agar plate containing a suitable Vi antiserum.

Purity of bacterial strain used for the seed lot is verified by methods of suitable sensitivity. These may include inoculation into suitable media, examination of colony morphology, microscopic examination of Gram-stained smears and culture agglutination with suitable specific antisera.

CULTURE AND HARVEST

The working seed lot is cultured on a solid medium, which may contain blood-group substances, or a liquid medium; the inoculum obtained is transferred to a liquid medium which is used to inoculate the final medium. The liquid medium used and the final medium are semi-synthetic, free from substances that are precipitated by cetrimonium bromide and do not contain blood-group substances or high-molecular-mass polysaccharides, unless it has been demonstrated that they are removed by the purification process.

The bacterial purity of the culture is verified by methods of suitable sensitivity. These may include inoculation into suitable media, examination of colony morphology, microscopic examination of Gram-stained smears and culture agglutination with suitable specific antisera.

The culture is then inactivated at the beginning of the stationary phase by the addition of formaldehyde. Bacterial cells are eliminated by centrifugation; the polysaccharide is precipitated from the culture medium by addition of hexadecyltrimethylammonium bromide (cetrimonium bromide). The precipitate is harvested and may be stored at – 20 °C before purification.

PURIFIED VI POLYSACCHARIDE

The polysaccharide is purified, after dissociation of the polysaccharide/cetrimonium bromide complex, using suitable procedures to eliminate successively nucleic acids, proteins and lipopolysaccharides. The polysaccharide is precipitated as the calcium salt in the presence of ethanol and dried at 2-8 °C; the powder obtained constitutes the purified Vi polysaccharide. The loss on drying is determined by thermogravimetry (*2.2.34*) and is used to calculate the results of the chemical tests shown below with reference to the dried substance.

Only a purified Vi polysaccharide that complies with the following requirements may be used in the preparation of the final bulk.

Protein (*2.5.16*): maximum 10 mg per gram of polysaccharide, calculated with reference to the dried substance.

Nucleic acids (*2.5.17*): maximum 20 mg per gram of polysaccharide, calculated with reference to the dried substance.

***O*-Acetyl groups** (*2.5.19*): minimum 2 mmol per gram of polysaccharide, calculated with reference to the dried substance.

Molecular size. Examine by size-exclusion chromatography (*2.2.30*) using *cross-linked agarose for chromatography R*. Use a column 0.9 m long and 16 mm in internal diameter equilibrated with a solvent having an ionic strength of 0.2 mol/kg and a pH of 7.0-7.5. Apply about 5 mg of polysaccharide in a volume of 1 ml to the column and elute at about 20 ml/h. Collect fractions of about 2.5 ml. Determine the point corresponding to K_0 = 0.25 and make 2 pools consisting of fractions eluted before and after this point. Determine *O*-acetyl groups on the 2 pools (*2.5.19*). Not less than 50 per cent of the polysaccharide is found in the pool containing fractions eluted before K_0 = 0.25.

Identification. Carry out an identification test using a suitable immunochemical method (*2.7.1*).

Bacterial endotoxins. The content of bacterial endotoxins determined by a suitable method (*2.6.14*) is within the limits approved for the specific product.

FINAL BULK VACCINE

One or more batches of purified Vi polysaccharide are dissolved in a suitable solvent, which may contain an antimicrobial preservative, so that the volume corresponding to 1 dose contains 25 µg of polysaccharide and the solution is isotonic with blood (250 mosmol/kg to 350 mosmol/kg).

Only a final bulk vaccine that complies with the following tests may be used in the preparation of the final lot.

Sterility (*2.6.1*). The final bulk vaccine complies with the test for sterility, carried out using 10 ml for each medium.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable physicochemical method. The amount is not less than 85 per cent and not greater than 115 per cent of the intended amount.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile tamper-proof containers that are then closed so as to prevent contamination.

Only a final lot that is satisfactory with respect to each of the requirements prescribed below under Identification, Tests and Assay and with the requirement for bacterial endotoxins may be released for use. Provided the tests for free formaldehyde and antimicrobial preservative have been carried out on the final bulk vaccine, they may be omitted on the final lot.

Bacterial endotoxins. The content of bacterial endotoxins determined by a suitable method (*2.6.14*) is within the limit approved for the specific product.

CHARACTERS

Clear colourless liquid, free from visible particles.

IDENTIFICATION

Carry out an identification test using a suitable immunochemical method (*2.7.1*).

TESTS

pH (*2.2.3*): 6.5 to 7.5.

***O*-Acetyl groups**: 0.085 (± 25 per cent) µmol per dose (25 µg of polysaccharide).

Test solution. Place 3 ml of the vaccine in each of 3 tubes (2 reaction solutions and 1 correction solution).

Reference solutions. Dissolve 0.150 g of *acetylcholine chloride R* in 10 ml of *water R* (stock solution containing 15 g/l of acetylcholine chloride). Immediately before use, dilute 0.5 ml of the stock solution to 50 ml with *water R* (working dilution containing 150 µg/ml of acetylcholine chloride). In 10 tubes, place in duplicate (reaction and correction solutions) 0.1 ml, 0.2 ml, 0.5 ml, 1.0 ml and 1.5 ml of the working dilution.

Prepare a blank using 3 ml of *water R*.

Make up the volume in each tube to 3 ml with *water R*. Add 0.5 ml of a mixture of 1 volume of *water R* and 2 volumes of *dilute hydrochloric acid R* to each of the correction tubes and to the blank. Add 1.0 ml of *alkaline hydroxylamine solution R* to each tube. Allow the reaction to proceed for exactly 2 min and add 0.5 ml of a mixture of 1 volume of *water R* and 2 volumes of *dilute hydrochloric acid R* to each of the reaction tubes. Add 0.5 ml of a 200 g/l solution of *ferric chloride R* in *0.2 M hydrochloric acid* to each tube, stopper the tubes and shake vigorously to remove bubbles.

Measure the absorbance (*2.2.25*) of each solution at 540 nm using the blank as the compensation liquid. For each reaction solution, subtract the absorbance of the corresponding correction solution. Draw a calibration curve from the corrected absorbances for the 5 reference solutions and the corresponding content of acetylcholine chloride and read from the curve the content of acetylcholine chloride in the test solution for each volume tested. Calculate the mean of the 2 values.

1 mole of acetylcholine chloride (181.7 g) is equivalent to 1 mole of *O*-acetyl (43.05 g).

Free formaldehyde (*2.4.18*): maximum 0.2 g/l.

Antimicrobial preservative. Where applicable, determine the amount of antimicrobial preservative by a suitable physicochemical method. The content is not less than the minimum amount shown to be effective and not more than 115 per cent of the content stated on the label. If phenol has been used in the preparation, the content is not more than 2.5 g/l (*2.5.15*).

Sterility (*2.6.1*). The vaccine complies with the test for sterility.

ASSAY

Determine Vi polysaccharide by a suitable immunochemical method (*2.7.1*), using a reference purified polysaccharide. The estimated amount of polysaccharide per dose is 80 per cent to 120 per cent of the content stated on the label. The confidence limits (P = 0.95) of the estimated amount of polysaccharide are not less than 80 per cent and not more than 120 per cent.

LABELLING

The label states:

– the number of micrograms of polysaccharide per human dose (25 µg),

– the total quantity of polysaccharide in the container.

01/2008:0156

TYPHOID VACCINE

Vaccinum febris typhoidi

DEFINITION

Typhoid vaccine is a sterile suspension of inactivated *Salmonella typhi* containing not less than 5×10^8 and not more than 1×10^9 bacteria (*S. typhi*) per human dose. The human dose does not exceed 1.0 ml.

PRODUCTION

The vaccine is prepared using a seed-lot system from a suitable strain, such as Ty 2[(7)], of *S. typhi*. The final vaccine represents not more than 3 subcultures from the strain on which were made the laboratory and clinical tests that showed it to be suitable. The bacteria are inactivated by acetone, by formaldehyde, by phenol or by heating or by a combination of the last 2 methods.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (*2.6.9*) modified as follows: inject 0.5 ml of the vaccine into each mouse and 1.0 ml into each guinea pig.

IDENTIFICATION

It is identified by specific agglutination.

TESTS

Phenol (*2.5.15*). If phenol has been used in the preparation, the concentration is not more than 5 g/l.

Antigenic power. When injected into susceptible laboratory animals, it elicits anti-O, anti-H and, to a lesser extent, anti-Vi agglutinins.

Sterility (*2.6.1*). It complies with the test for sterility.

LABELLING

The label states:

– the method used to inactivate the bacteria,
– the number of bacteria per human dose.

01/2008:0157

TYPHOID VACCINE, FREEZE-DRIED

Vaccinum febris typhoidi cryodesiccatum

DEFINITION

Freeze-dried typhoid vaccine is a freeze-dried preparation of inactivated *Salmonella typhi*. The vaccine is reconstituted as stated on the label to give a uniform suspension containing not less than 5×10^8 and not more than 1×10^9 bacteria (*S. typhi*) per human dose. The human dose does not exceed 1.0 ml of the reconstituted vaccine.

PRODUCTION

The vaccine is prepared using a seed-lot system from a suitable strain, such as Ty 2[(8)], of *S. typhi*. The final vaccine represents not more than 3 subcultures from the strain on which were made the laboratory and clinical tests that showed it to be suitable. The bacteria are inactivated either by acetone or by formaldehyde or by heat. Phenol is not used in the preparation. The vaccine is distributed into sterile containers and freeze-dried to a moisture content favourable to the stability of the vaccine. The containers are then closed so as to exclude contamination.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (*2.6.9*) modified as follows: inject 0.5 ml of the vaccine into each mouse and 1.0 ml into each guinea pig.

IDENTIFICATION

The vaccine reconstituted as stated on the label is identified by specific agglutination.

TESTS

Phenol (*2.5.15*). If phenol has been used in the preparation, the concentration is not more than 5 g/l.

Antigenic power. When injected into susceptible laboratory animals, the reconstituted vaccine elicits anti-O, anti-H and, to a lesser extent, anti-Vi agglutinins.

Sterility (*2.6.1*). The reconstituted vaccine complies with the test for sterility.

LABELLING

The label states:

– the method used to inactivate the bacteria,
– the number of bacteria per human dose,
– that the vaccine should be used within 8 h of reconstitution.

01/2008:1055

TYPHOID VACCINE (LIVE, ORAL, STRAIN Ty 21a)

Vaccinum febris typhoidis vivum perorale (stirpe Ty 21a)

DEFINITION

Typhoid vaccine (live, oral, strain Ty 21a) is a freeze-dried preparation of live *Salmonella typhi* strain Ty 21a grown in a suitable medium. When presented in capsules, the vaccine complies with the monograph on *Capsules (0016)*.

PRODUCTION

CHOICE OF VACCINE STRAIN

The main characteristic of the strain is the defect of the enzyme uridine diphosphate-galactose-4-epimerase. The activities of galactopermease, galactokinase and galactose-1-phosphate uridyl-transferase are reduced by 50 per cent to 90 per cent. Whatever the growth conditions, the strain does not contain Vi antigen. The strain agglutinates to anti-O:9 antiserum only if grown in medium containing galactose. It contains the flagellar H:d antigen and does not produce hydrogen sulphide on Kligler iron agar. The strain is nonvirulent for mice. Cells of strain Ty 21a lyse if grown in the presence of 1 per cent of galactose.

BACTERIAL SEED LOTS

The vaccine is prepared using a seed-lot system. The working seed lots represent not more than one subculture from the master seed lot. The final vaccine represents not more than

(7) This strain is issued by the World Health Organisation Collaborating Centre for Reference and Research on Bacterial Vaccines, Human Serum and Vaccine Institute, Szallas Utea 5, H-1107, Budapest, Hungary.
(8) This strain is issued by the World Health Organisation Collaborating Centre for Reference and Research on Bacterial Vaccines, Human Serum and Vaccine Institute, Szallas Utea 5, H-1107, Budapest, Hungary.

four subcultures from the original vaccine on which were made the laboratory and clinical tests showing the strain to be suitable.

Only a master seed lot that complies with the following requirements may be used in the preparation of working seed lots.

Galactose metabolism. In a spectrophotometric assay, no activity of the enzyme uridine diphosphate-galactose-4-epimerase is found in the cytoplasm of strain Ty 21a compared to strain Ty 2.

Biosynthesis of lipopolysaccharide. Lipopolysaccharides are extracted by the hot-phenol method and examined by size-exclusion chromatography. Strain Ty 21a grown in medium free of galactose shows only the rough (R) type of lipopolysaccharide.

Serological characteristics. Strain Ty 21a grown in a synthetic medium without galactose does not agglutinate to specific anti-O:9 antiserum. Whatever the growth conditions, strain Ty 21a does not agglutinate to Vi antiserum. Strain Ty 21a agglutinates to H:d flagellar antiserum.

Biochemical markers. Strain Ty 21a does not produce hydrogen sulphide on Kligler iron agar. This property serves to distinguish Ty 21a from other galactose-epimerase-negative *S. typhi* strains.

Cell growth. Strain Ty 21a cells lyse when grown in the presence of 1 per cent of galactose.

BACTERIAL PROPAGATION AND HARVEST

The bacteria from the working seed lot are multiplied in a preculture, subcultured once and are then grown in a suitable medium containing 0.001 per cent of galactose at 30 °C for 13 h to 15 h. The bacteria are harvested. The harvest must be free from contaminating micro-organisms.

Only a single harvest that complies with the following requirements may be used for the preparation of the freeze-dried harvest.

pH. The pH of the culture is 6.8 to 7.5.

Optical density. The optical density of the culture, measured at 546 nm, is 6.5 to 11.0. Before carrying out the measurement, dilute the culture so that a reading in the range 0.1 to 0.5 is obtained and correct the reading to take account of the dilution.

Identification. Culture bacteria on an agar medium containing 1 per cent of galactose and bromothymol blue. Light blue, concave colonies, transparent due to lysis of cells, are formed. No yellow colonies (galactose-fermenting) are found.

FREEZE-DRIED HARVEST

The harvest is mixed with a suitable stabiliser and freeze-dried by a process that ensures the survival of at least 10 per cent of the bacteria and to a water content shown to be favourable to the stability of the vaccine. No antimicrobial preservative is added to the vaccine.

Only a freeze-dried harvest that complies with the following tests may be used for the preparation of the final bulk.

Identification. Culture bacteria are examined on an agar medium containing 1 per cent of galactose and bromothymol blue. Light blue, concave colonies, transparent due to lysis of cells, are formed. No yellow colonies (galactose-fermenting) are found.

Number of live bacteria. Not fewer than 1×10^{11} live *S. typhi* strain Ty 21a per gram.

Water (*2.5.12*): 1.5 per cent to 4.0 per cent, determined by the semi-micro determination of water.

FINAL BULK VACCINE

The final bulk vaccine is prepared by aseptically mixing one or more freeze-dried harvests with a suitable sterile excipient.

Only a final bulk that complies with the following requirement may be used in the preparation of the final lot.

Number of live bacteria. Not fewer than 40×10^9 live *S. typhi* strain Ty 21a per gram.

FINAL LOT

The final bulk vaccine is distributed under aseptic conditions into capsules with a gastro-resistant shell or into suitable containers.

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification, Tests and Number of live bacteria may be released for use, except that in the determination of the number of live bacteria each dosage unit must contain not fewer than 4×10^9 live bacteria.

IDENTIFICATION

Culture bacteria from the vaccine to be examined on an agar medium containing 1 per cent of galactose and bromothymol blue. Light blue, concave colonies, transparent due to lysis of cells, are formed. No yellow colonies (galactose-fermenting) are found.

TESTS

Contaminating micro-organisms (*2.6.12*, *2.6.13*). Carry out the test using suitable selective media. Determine the total viable count using the plate-count method. The number of contaminating micro-organisms per dosage unit is not greater than 10^2 bacteria and 20 fungi. No pathogenic bacterium, particularly *Escherichia coli, Staphylococcus aureus, Pseudomonas aeruginosa,* and no salmonella other than strain Ty 21a are found.

Water (*2.5.12*): 1.5 per cent to 4.0 per cent, determined on the contents of the capsule or of the container by the semi-micro determination of water.

NUMBER OF LIVE BACTERIA

Carry out the test using not fewer than five dosage units. Homogenise the contents of the dosage units in a 9 g/l solution of *sodium chloride R* at 4 °C using a mixer in a cold room with sufficient glass beads to emerge from the liquid. Immediately after homogenisation prepare a suitable dilution of the suspension using cooled diluent and inoculate brain heart infusion agar; incubate at 36 ± 1 °C for 20 h to 36 h. The vaccine contains not fewer than 2×10^9 live *S. typhi* Ty 21a bacteria per dosage unit.

LABELLING

The label states:

– the minimum number of live bacteria per dosage unit,
– that the vaccine is for oral use only.

01/2008:0648

VARICELLA VACCINE (LIVE)

Vaccinum varicellae vivum

DEFINITION

Varicella vaccine (live) is a freeze-dried preparation of a suitable attenuated strain of *Herpesvirus varicellae*. The vaccine is reconstituted immediately before use, as stated on the label, to give a clear liquid that may be coloured owing to the presence of a pH indicator.

PRODUCTION

The production of vaccine is based on a virus seed-lot system and a cell-bank system. The production method shall have been shown to yield consistently live varicella vaccines of adequate immunogenicity and safety in man. The virus in the final vaccine shall not have been passaged in cell cultures beyond the 38th passage from the original isolated virus.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (*2.6.9*).

SUBSTRATE FOR VIRUS PROPAGATION

The virus is propagated in human diploid cells (*5.2.3*).

VIRUS SEED LOT

The strain of varicella virus shall be identified as being suitable by historical records which shall include information on the origin of the strain and its subsequent manipulation. The virus shall at no time have been passaged in continuous cell lines. Seed lots are prepared in the same kind of cells as those used for the production of the final vaccine. To avoid the unnecessary use of monkeys in the test for neurovirulence, virus seed lots are prepared in large quantities and stored at temperatures below – 20 °C, if freeze-dried, or below – 60 °C, if not freeze-dried.

Only a virus seed lot that complies with the following requirements may be used for virus propagation.

Identification. The master and working seed lots are identified as varicella virus by serum neutralisation in cell culture, using specific antibodies.

Virus concentration. The virus concentration of the master and working seed lots is determined as prescribed under Assay to monitor consistency of production.

Extraneous agents (*2.6.16*). The working seed lot complies with the requirements for seed lots for live virus vaccines; a sample of 50 ml is taken for the test in cell cultures.

Neurovirulence (*2.6.18*). The working seed lot complies with the test for neurovirulence of live virus vaccines.

VIRUS PROPAGATION AND HARVEST

All processing of the cell bank and subsequent cell cultures is done under aseptic conditions in an area where no other cells are handled. Approved animal (but not human) serum may be used in the media. Serum and trypsin used in the preparation of cell suspensions and media are shown to be free from extraneous agents. The cell culture medium may contain a pH indicator such as phenol red and approved antibiotics at the lowest effective concentration. It is preferable to have a substrate free from antibiotics during production. 5 per cent, but not less than 50 ml, of the cell cultures employed for vaccine production is set aside as uninfected cell cultures (control cells). The infected cells constituting a single harvest are washed, released from the support surface and pooled. The cell suspension is disrupted by sonication.

Only a virus harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Identification. The virus harvest contains virus that is identified as varicella virus by serum neutralisation in cell culture, using specific antibodies.

Virus concentration. The concentration of infective virus in virus harvests is determined as prescribed under Assay to monitor consistency of production and to determine the dilution to be used for the final bulk vaccine.

Extraneous agents (*2.6.16*). Use 50 ml for the test in cell cultures.

Control cells. The control cells of the production cell culture from which the single harvest is derived comply with a test for identity and with the requirements for extraneous agents (*2.6.16*).

FINAL BULK VACCINE

Virus harvests that comply with the above tests are pooled and clarified to remove cells. A suitable stabiliser may be added and the pooled harvests diluted as appropriate.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Bacterial and fungal contamination. Carry out the test for sterility (*2.6.1*) using 10 ml for each medium.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers and freeze-dried to a moisture content shown to be favourable to the stability of the vaccine. The containers are then closed so as to prevent contamination and the introduction of moisture.

Only a final lot that is satisfactory with respect to each of the requirements given below under Identification, Tests and Assay may be released for use. Provided that the test for bovine serum albumin has been carried out with satisfactory results on the final bulk vaccine, it may be omitted on the final lot.

IDENTIFICATION

When the vaccine reconstituted as stated on the label is mixed with specific *Herpesvirus varicellae* antibodies, it is no longer able to infect susceptible cell cultures.

TESTS

Bacterial and fungal contamination. The reconstituted vaccine complies with the test for sterility (*2.6.1*).

Bovine serum albumin. Not more than 0.5 µg per human dose, determined by a suitable immunochemical method (*2.7.1*).

Water (*2.5.12*). Not more than 3.0 per cent, determined by the semi-micro determination of water.

ASSAY

Titrate for infective virus, using at least 10 cell cultures for each fourfold dilution or by a technique of equal precision. Use a suitable virus reference preparation to validate each assay. The virus concentration is not less than the minimum stated on the label.

LABELLING

The label states:

- the strain of virus used for the preparation of the vaccine,
- the type and origin of the cells used for the preparation of the vaccine,
- that contact with disinfectants is to be avoided,
- the minimum virus concentration,
- that the vaccine is not to be administered to pregnant women,
- the time within which the vaccine must be used after reconstitution.

01/2008:0537

YELLOW FEVER VACCINE (LIVE)

Vaccinum febris flavae vivum

DEFINITION

Yellow fever vaccine (live) is a freeze-dried preparation of the 17D strain of yellow fever virus grown in fertilised hen eggs. The vaccine is reconstituted immediately before use, as stated on the label, to give a clear liquid.

PRODUCTION

The production of vaccine is based on a virus seed-lot system. The production method shall have been shown to yield consistently yellow fever vaccine (live) of acceptable immunogenicity and safety for man.

The production method is validated to demonstrate that the product, if tested, would comply with the test for abnormal toxicity for immunosera and vaccines for human use (*2.6.9*) modified as follows for the test in guinea-pigs: inject 10 human doses into each guinea-pig and observe for 21 days.

Reference preparation. In the test for neurotropism, a suitable batch of vaccine known to have satisfactory properties in man is used as the reference preparation.

SUBSTRATE FOR VIRUS PROPAGATION

Virus for the preparation of master and working seed lots and of all vaccine batches is grown in the tissues of chick embryos from a flock free from specified pathogens (SPF) (*5.2.2*).

SEED LOTS

The 17D strain shall be identified by historical records that include information on the origin of the strain and its subsequent manipulation. Virus seed lots are prepared in large quantities and stored at a temperature below – 60 °C. Master and working seed lots shall not contain any human protein or added serum.

Unless otherwise justified and authorised, the virus in the final vaccine shall be between passage levels 204 and 239 from the original isolate of strain 17D. A working seed lot shall be only 1 passage from a master seed lot. A working seed lot shall be used without intervening passage as the inoculum for infecting the tissues used in the production of a vaccine lot, so that no vaccine virus is more than 1 passage from a seed lot that has passed all the safety tests.

Only a virus seed lot that complies with the following requirements may be used for virus propagation.

Identification. The master and working seed lots are identified as containing yellow fever virus by serum neutralisation in cell culture, using specific antibodies.

Extraneous agents (*2.6.16*). Each master seed lot complies with the following tests:

- test in guinea-pigs (as described in chapter *2.6.16* under Virus seed lot),
- bacterial and fungal sterility (as described in chapter *2.6.16* under Virus seed lot and virus harvests),
- mycoplasmas (as described in chapter *2.6.16* under Virus seed lot and virus harvests).

Avian leucosis viruses (*2.6.24*). Each master seed lot complies with the test for avian leucosis viruses.

Extraneous agents (*2.6.16*). Each working seed lot complies with the following tests:

- test in adult mice (intraperitoneal inoculation only) (as described in chapter *2.6.16* under Virus seed lot),
- test in guinea-pigs (as described in chapter *2.6.16* under Virus seed lot),
- bacterial and fungal sterility (as described in chapter *2.6.16* under Virus seed lot and virus harvests),
- mycoplasmas (as described in chapter *2.6.16* under Virus seed lot and virus harvests),
- mycobacteria (as described in chapter *2.6.16* under Virus seed lot and virus harvests),
- test in cell culture for other extraneous agents (as described in chapter *2.6.16* under Virus seed lot and virus harvests),
- avian viruses (as described in chapter *2.6.16* under Virus seed lot and virus harvests).

Avian leucosis viruses (*2.6.24*). Each working seed lot complies with the test for avian leucosis viruses.

Tests in monkeys. Each master and working seed lot complies with the following tests in monkeys for viraemia (viscerotropism), immunogenicity and neurotropism.

The monkeys shall be *Macaca* sp. susceptible to yellow fever virus and shall have been shown to be non-immune to yellow fever at the time of injecting the seed virus. They shall be healthy and shall not have received previously intracerebral or intraspinal inoculation. Furthermore, they shall not have been inoculated by other routes with neurotropic viruses or with antigens related to yellow fever virus. Not fewer than 10 monkeys are used for each test.

Use a test dose of 0.25 ml containing the equivalent of not less than 5000 mouse LD_{50} and not more than 50 000 mouse LD_{50}, determined by a titration for infectious virus and using the established equivalence between virus concentration and mouse LD_{50} (see under Assay). Inject the test dose into 1 frontal lobe of each monkey under anaesthesia and observe the monkeys for not less than 30 days.

Viraemia (Viscerotropism). Viscerotropism is indicated by the amount of virus present in serum. Take blood from each of the test monkeys on the 2nd, 4th and 6th days after inoculation and prepare serum from each sample. Prepare 1:10, 1:100 and 1:1000 dilutions from each serum and inoculate each dilution into a group of at least 6 cell culture vessels used for the determination of the virus concentration. The seed lot complies with the test if none of the sera contains more than the equivalent of 500 mouse LD_{50} in 0.03 ml and at most 1 serum contains more than the equivalent of 100 mouse LD_{50} in 0.03 ml.

Immunogenicity. Take blood from each monkey 30 days after the injection of the test dose and prepare serum from each sample. The seed lot complies with the test if at least 90 per cent of the test monkeys are shown to be immune, as determined by examining their sera in the test for neutralisation of yellow fever virus described below.

It has been shown that a low dilution of serum (for example, 1:10) may contain non-specific inhibitors that influence this test; such serum shall be treated to remove inhibitors. Mix dilutions of at least 1:10, 1:40 and 1:160 of serum from each monkey with an equal volume of 17D vaccine virus at a dilution that will yield an optimum number of plaques with the titration method used. Incubate the serum-virus mixtures in a water-bath at 37 °C for 1 h and then cool in iced water; add 0.2 ml of each serum-virus mixture to each of 4 cell-culture plates and proceed as for the determination of virus concentration. Inoculate similarly 10 plates with the same amount of virus plus an equal volume of a 1:10 dilution of monkey serum known to contain no neutralising antibodies to yellow fever virus. At the end of the observation period, compare the mean number of plaques

in the plates receiving virus plus non-immune serum with the mean number of plaques in the plates receiving virus plus dilutions of each monkey serum. Not more than 10 per cent of the test monkeys have serum that fails to reduce the number of plaques by 50 per cent at the 1:10 dilution.

Neurotropism. Neurotropism is assessed from clinical evidence of encephalitis, from incidence of clinical manifestations and by evaluation of histological lesions, in comparison with 10 monkeys injected with the reference preparation. The seed lot is not acceptable if either the onset and duration of the febrile reaction or the clinical signs of encephalitis and pathological findings are such as to indicate a change in the properties of the virus.

Clinical evaluation

The monkeys are examined daily for 30 days by personnel familiar with clinical signs of encephalitis in primates (if necessary, the monkeys are removed from their cage and examined for signs of motor weakness or spasticity). The seed lot is not acceptable if in the monkeys injected with it the incidence of severe signs of encephalitis, such as paralysis or inability to stand when stimulated, or mortality is greater than for the reference vaccine. These and other signs of encephalitis, such as paresis, incoordination, lethargy, tremors or spasticity are assigned numerical values for the severity of symptoms by a grading method. Each day each monkey in the test is given a score based on the following scale:

- grade 1: rough coat, not eating,
- grade 2: high-pitched voice, inactive, slow moving,
- grade 3: shaky, tremors, unco-ordinated, limb weakness,
- grade 4: inability to stand, limb paralysis or death (a dead monkey receives a daily score of 4 from the day of death until day 30).

A clinical score for a particular monkey is the average of its daily scores; the clinical score for the seed lot is the mean of the individual monkey scores. The seed lot is not acceptable if the mean of the clinical severity scores for the group of monkeys inoculated with it is significantly greater ($P = 0.95$) than the mean for the group of monkeys injected with the reference preparation. In addition, special consideration is given to any animal showing unusually severe signs when deciding on the acceptability of the seed lot.

Histological evaluation

5 levels of the brain are examined including:

- block I: the corpus striatum at the level of the optic chiasma,
- block II: the thalamus at the level of the mamillary bodies,
- block III: the mesencephalon at the level of the superior colliculi,
- block IV: the pons and cerebellum at the level of the superior olives,
- block V: the medulla oblongata and cerebellum at the level of the mid-inferior olivary nuclei.

Cervical and lumbar enlargements of the spinal cord are each divided equally into 6 blocks; 15 µm sections are cut from the tissue blocks embedded in paraffin wax and stained with gallocyanin. Numerical scores are given to each hemisection of the cord and to structures in each hemisection of the brain as listed below. Lesions are scored as follows:

- grade 1 - minimal: 1 to 3 small focal inflammatory infiltrates; degeneration or loss of a few neurons;
- grade 2 - moderate: 4 or more focal inflammatory infiltrates; degeneration or loss of neurons affecting not more than one third of cells;
- grade 3 - severe: moderate focal or diffuse inflammatory infiltration; degeneration or loss of up to two thirds of the neurons;
- grade 4 - overwhelming: variable but often severe inflammatory reaction; degeneration or loss of more than 90 per cent of neurons.

It has been found that inoculation of yellow fever vaccine into the monkey brain causes histological lesions in different anatomical formations of the central nervous system with varying frequency and severity (I. S. Levenbook *et al.*, *Journal of Biological Standardization*, 1987, 15, 305-313). Based on these 2 indicators, the anatomical structures can be divided into target, spared and discriminator areas. Target areas are those which show more severe specific lesions in a majority of monkeys irrespective of the degree of neurovirulence of the seed lot. Spared areas are those which show only minimal specific lesions and in a minority of monkeys. Discriminator areas are those where there is a significant increase in the frequency of more severe specific lesions with seed lots having a higher degree of neurovirulence. Discriminator and target areas for *Macaca cynomolgus* and *Macaca rhesus* monkeys are shown in the table below.

Type of monkey	Discriminator areas	Target areas
Macaca cynomolgus	Globus pallidus	Substantia nigra
	Putamen	
	Anterior/median thalamic nucleus	
	Lateral thalamic nucleus	
Macaca rhesus	Caudate nucleus	Substantia nigra
	Globus pallidus	Cervical enlargement
	Putamen	Lumbar enlargement
	Anterior/median thalamic nucleus	
	Lateral thalamic nucleus	
	Cervical enlargement	
	Lumbar enlargement	

Scores for discriminator and target areas are used for the final evaluation of the seed lot. The individual monkey score is calculated from the sum of individual target area scores in each hemisection divided by the number of areas examined. A separate score is calculated similarly for the discriminator areas.

Mean scores for the test group are calculated in 2 ways: (1) by dividing the sum of the individual monkey discriminator scores by the number of monkeys and (2) by dividing the sum of the individual monkey target and discriminator scores by the number of monkeys. These 2 mean scores are taken into account when deciding on the acceptability of the seed lot. The seed lot is not acceptable if either of the mean lesion scores is significantly greater ($P = 0.95$) than for the reference preparation.

PROPAGATION AND HARVEST

All processing of the fertilised eggs is done under aseptic conditions in an area where no other infectious agents or cells are handled at the same time. At least 2 per cent but not less than 20 and not more than 80 eggs are maintained as uninfected control eggs. After inoculation and incubation at a controlled temperature, only living and typical chick embryos are harvested. At the time of harvest, the control eggs are treated in the same way as the inoculated eggs to obtain a control embryonic pulp. The age of the embryo

at the time of virus harvest is reckoned from the initial introduction of the egg into the incubator and shall be not more than 12 days. After homogenisation and clarification by centrifugation, the extract of embryonic pulp is tested as described below and kept at – 70 °C or colder until further processing. Virus harvests that comply with the prescribed tests may be pooled. No human protein is added to the virus suspension at any stage during production. If stabilisers are added, they shall have been shown to have no antigenic or sensitising properties for man.

Only a single harvest that complies with the following requirements may be used in the preparation of the final bulk vaccine.

Identification. The single harvest contains virus that is identified as yellow fever virus by serum neutralisation in cell culture, using specific antibodies.

Sterility (*2.6.1*). The harvest complies with the test for sterility, carried out using 10 ml for each medium.

Mycoplasmas (*2.6.7*).The single harvest complies with the test for mycoplasma, carried out using 10 ml.

Mycobacteria (*2.6.2*). A 5 ml single harvest sample is tested for the presence of *Mycobacterium spp.* by culture methods known to be sensitive for the detection of these organisms.

Embryonic pulp of control eggs. The extract of the control eggs shows no evidence of the presence of any extraneous agents in the tests described below.

Test in cell culture for other extraneous agents. Inoculate a 5 ml sample of embryonic pulp of the control eggs into continuous simian kidney and human cell cultures as well as into primary chick-embryo-fibroblast cells. The cells are incubated at 36 ± 1 °C and observed for a period of 14 days. The embryonic pulp of the control eggs passes the test if there is no evidence of the presence of any extraneous agents. The test is not valid unless at least 80 per cent of the cell cultures remain viable.

Avian viruses. Using 0.1 ml per egg, inoculate the embryonic pulp of control eggs: by the allantoic route into a group of 10 fertilised SPF eggs (*5.2.2*) (9 to 11 days old); into the yolk sac of a group of 10 fertilised SPF eggs (*5.2.2*), 5 to 7 days old. Incubate for 7 days. The embryonic pulp lot of the control eggs complies if the allantoic and yolk sac fluids show no signs of haemagglutinating agents and if the embryos and chorio-allantoic membranes examined to detect any macroscopic pathology are typical. The test is not valid unless at least 80 per cent of the inoculated eggs survive during the 7 day observation period.

Virus concentration. In order to calculate the dilution for formulation of the final bulk, each single harvest is titrated as described under Assay.

FINAL BULK VACCINE

Single harvests that comply with the tests prescribed above are pooled and clarified again. A test for protein nitrogen content is carried out. A suitable stabiliser may be added and the pooled harvests diluted as appropriate.

Only a final bulk vaccine that complies with the following requirements may be used in the preparation of the final lot.

Sterility (*2.6.1*). The final bulk vaccine complies with the test for sterility, carried out using 10 ml for each medium.

Protein nitrogen content: maximum 0.25 mg per human dose before the addition of any stabiliser.

FINAL LOT

The final bulk vaccine is distributed aseptically into sterile, tamper-proof containers and freeze-dried to a moisture content shown to be favourable to the stability of the vaccine. The containers are then closed so as to prevent contamination and the introduction of moisture.

Only a final lot that is satisfactory with respect to thermal stability and each of the requirements given below under Identification, Tests and Assay may be released for use. Provided that the test for ovalbumin has been performed with satisfactory results on the final bulk vaccine, it may be omitted on the final lot.

Thermal stability. Maintain samples of the final lot of freeze-dried vaccine in the dry state at 37 °C for 14 days. Determine the virus concentration as described under Assay in parallel for the heated vaccine and for unheated vaccine. The difference in the virus concentration between unheated and heated vaccine does not exceed 1.0 $\log_{10}$ and the virus concentration of the heated vaccine is not less than the number of plaque-forming units (PFU) equivalent to 1×10^3 mouse LD_{50} per human dose.

IDENTIFICATION

When the vaccine reconstituted as stated on the label is mixed with specific yellow fever virus antibodies, there is a significant reduction in its ability to infect susceptible cell cultures.

TESTS

Ovalbumin: maximum 5 µg of ovalbumin per human dose, determined by a suitable immunochemical method (*2.7.1*).

Water (*2.5.12*): maximum 3.0 per cent.

Sterility (*2.6.1*). The reconstituted vaccine complies with the test for sterility.

Bacterial endotoxins (*2.6.14*): less than 5 IU per single human dose.

ASSAY

Titrate for infective virus in cell cultures. Use an appropriate virus reference preparation to validate each assay.

The virus concentration is not less than the equivalent in PFU of 1×10^3 mouse LD_{50} per human dose. The relationship between mouse LD_{50} and PFU is established by each laboratory and approved by the competent authority.

The method shown below, or another suitable technique, may be used to determine the mouse LD_{50}.

Suggested method for determination of the mouse LD_{50}

Mouse LD_{50}. The statistically calculated quantity of virus suspension that is expected to produce fatal specific encephalitis in 50 per cent of mice of a highly susceptible strain, 4 to 6 weeks of age, after intracerebral inoculation.

Appropriate serial dilutions of the reconstituted vaccine are made in diluent for yellow fever virus (a 7.5 g/l solution of *bovine albumin R* in *phosphate-buffered saline pH 7.4 R*, or any other diluent that has been shown to be equivalent for maintaining the infectivity of the virus).

Mice of a highly susceptible strain, 4 to 6 weeks of age, are injected intracerebrally under anaesthesia with 0.03 ml of the vaccine dilution. Groups of not fewer than 6 mice are used for each dilution; the series of dilutions is chosen so as to cover the range 0-100 per cent mortality of the mice. Injection of the mice is performed immediately after the dilutions have been made. The mice are observed for 21 days and all deaths are recorded. Only survivors and deaths

caused by typical yellow fever infections are counted in the computations. Mice paralysed on the 21st day of observation are counted as survivors.

LABELLING

The label states:

- the strain of virus used in preparation of the vaccine,
- that the vaccine has been prepared in chick embryos,
- the minimum virus concentration,
- that contact with disinfectants is to be avoided,
- the period of time within which the vaccine is to be used after reconstitution.

ANTHRAX SPORE VACCINE (LIVE) FOR VETERINARY USE

Vaccinum anthracis vivum ad usum veterinarium

1. DEFINITION

Anthrax spore vaccine (live) for veterinary use is a preparation of live spores of a suitable attenuated, non-capsulated strain of *Bacillus anthracis*. This monograph applies to vaccines intended for the active immunisation of animals against disease caused by *B. anthracis*.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

B. anthracis is grown in an appropriate medium. At the end of growth the spores are suspended in a stabilising solution and counted. The vaccine may be adjuvanted.

2-2. *CHOICE OF VACCINE STRAIN*

The strain used is:

– not lethal to the guinea-pig or the mouse,

– or lethal to the guinea-pig but not to the rabbit,

– or lethal to some rabbits.

The vaccine strain is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the animals for which it is intended.

The following test for Immunogenicity (2-3-1.) may be used during the demonstration of efficacy.

2-2-1. **Immunogenicity**. For a strain of *B. anthracis* which is not lethal to the guinea-pig or the mouse, the test may be carried out in guinea-pigs. For a strain which is lethal to the guinea-pig but not to the rabbit, the test may be carried out in rabbits. For a strain which is lethal to some rabbits, carry out the test in sheep.

If the test is carried out in guinea-pigs or in rabbits, use not fewer than 13 healthy animals (group a). Inject by the subcutaneous or the intradermal route into each of not fewer than 10 animals $1/10^{th}$ of the smallest dose to be recommended for sheep. Maintain not fewer than 3 animals of the same species and the same origin as controls. Observe the animals at least daily for 21 days. If more than 2 animals die from non-specific causes, repeat the test.

If the test is carried out in sheep, use not fewer than 8 healthy sheep (group b). Vaccinate by the subcutaneous or the intradermal route each of not fewer than 5 sheep 1/10 of the smallest dose of the vaccine stated on the label for sheep. Maintain not fewer than 3 sheep of the same origin as controls. Observe the sheep at least daily for 21 days.

Challenge each vaccinated animal of group (a) or group (b) by a subcutaneous route with at least 100 MLD, and challenge each control animal by a subcutaneous route with at least 10 MLD of a strain of *B. anthracis* pathogenic for the species of animal used in the test. Observe all the animals at least daily for 10 days after challenge.

The vaccine complies with the test if during the observation period after challenge, all the vaccinated animals survive and all the controls die from anthrax. If a vaccinated animal dies after the challenge, repeat the test. If in the second test a vaccinated animal dies, the vaccine fails the test.

3. BATCH TESTS

3-1. **Identification**. *B. anthracis* present in the vaccine is identified by means of morphological and serological tests, culture and biochemical tests.

3-2. **Bacteria and fungi**. Carry out the test by microscopic examination and by inoculation of suitable media. The vaccine does not contain contaminating bacteria and fungi.

3-3. **Safety**. Carry out the test on one of the species of animals for which the vaccine is intended. If the vaccine is intended for several species, including goat, carry out the test on goats. Use 2 animals of the minimum age recommended for vaccination and that do not have antibodies against *B. anthracis*. Administer by the subcutaneous or the intradermal route to each animal twice the dose stated on the label for the species used. Observe the animals at least daily for 14 days.

The vaccine complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine. A local reaction may occur at the site of injection. The severity of the local reaction may vary according to the strain of the spores and the adjuvants used in the preparation, but necrosis does not occur.

3-4. **Live spore**. Make a count of live spores by plate count. The vaccine complies with the test if the number of live spores is not less than 80 per cent of that stated on the label.

3-5. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-2-1.). It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum number of live spores stated on the label.

01/2008:0744

AUJESZKY'S DISEASE VACCINE (INACTIVATED) FOR PIGS

Vaccinum morbi Aujeszkyi ad suem inactivatum

1. DEFINITION

Aujeszky's disease vaccine (inactivated) for pigs is a preparation of a suitable strain of Aujeszky's disease virus, inactivated while maintaining adequate immunogenic properties or a preparation of an inactivated fraction of the virus having adequate immunogenic properties. This monograph applies to vaccines intended for the active immunisation of pigs and for passive protection of their progeny against Aujeszky's disease.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures. The viral suspension is harvested and inactivated; it may be treated to fragment the virus and the viral fragments may be purified and concentrated. The vaccine may be adjuvanted.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the pigs for which it is intended. The following tests for safety (section 2-3-1) and immunogenicity (section 2-3-2) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**.

2-3-1-1. *Laboratory tests.* Carry out the tests for each route and method of administration to be recommended for vaccination and where applicable, in pigs of each category for which the vaccine is intended (sows, fattening pigs). Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine.

2-3-1-1-1. General safety. For each test, use not fewer than 10 pigs that do not have antibodies against Aujeszky's disease virus or against a fraction of the virus. Administer to each pig a double dose of the vaccine, then one dose after 14 days. Observe the pigs at least daily until 14 days after the last administration.

The vaccine complies with the test if no pig shows abnormal local or systemic reactions or dies from causes attributable to the vaccine during the 28 days of the test.

2-3-1-1-2. Safety in pregnant sows. If the vaccine is intended for use in pregnant sows, use for the test not fewer than 10 pregnant sows at the stage or at different stages of pregnancy according to the schedule to be recommended. Administer to each sow a double dose of the vaccine, then one dose after 14 days. Observe the sows at least daily until farrowing.

The vaccine complies with the test if no sow shows abnormal local or systemic reactions or dies from causes attributable to the vaccine and if no adverse effects on the pregnancy or the offspring are noted.

2-3-1-1-3. Safety in the pigs used in tests 2-3-2 for immunogenicity. The pigs used in the tests for immunogenicity are also used to evaluate safety. Measure the rectal temperature of each vaccinated pig at the time of vaccination and 6 h, 24 h and 48 h later. Examine the injection site at slaughter for local reactions.

The vaccine complies with the test if no pig shows:

- a temperature rise greater than 1.5 °C and the number of pigs showing a temperature greater than 41 °C does not exceed 10 per cent of the group;
- other systemic reactions (for example, anorexia);
- abnormal local reactions attributable to the vaccine.

2-3-1-2. *Field studies.* The pigs used for field trials are also used to evaluate safety. Carry out a test in each category of pigs for which the vaccine is intended (sows, fattening pigs). Use not fewer than 3 groups each of not fewer than 20 pigs with corresponding groups of not fewer than 10 controls. Measure the rectal temperature of each vaccinated pig at the time of vaccination and 6 h, 24 h and 48 h later. Examine the injection site at slaughter for local reactions.

The vaccine complies with the test if no pig shows:

- a temperature rise greater than 1.5 °C and the number of pigs showing a temperature greater than 41 °C does not exceed 25 per cent of the group;
- abnormal local reactions attributable to the vaccine.

2-3-2. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended, using in each case pigs of the age to be recommended for vaccination. The vaccine administered to each pig is of minimum potency.

2-3-2-1. *Vaccines intended for active immunisation.* Use for the test not fewer than 15 fattening pigs that do not have antibodies against Aujeszky's disease virus or against a fraction of the virus. The body mass of none of the pigs differs from the average body mass of the group by more than 20 per cent. Vaccinate not fewer than 10 pigs, according to the schedule to be recommended. Maintain not fewer than 5 pigs as controls. At the end of the fattening period (80-90 kg), weigh and challenge each pig by the intranasal route with a sufficient quantity of virulent Aujeszky's disease virus (challenge with at least 10^6 $CCID_{50}$ of a virulent strain having undergone not more than 3 passages and administered in not less than 4 ml of diluent has been found to be satisfactory). The titre of excreted virus is determined in swabs taken from the nasal cavity of each pig daily from the day before challenge until virus is no longer detected. Each pig is weighed 7 days after challenge or at the time of death if this occurs earlier and the average daily gain is calculated as a percentage. For each group (vaccinated and controls), the average of the average daily gains is calculated.

The test is invalid unless all the control pigs display signs of Aujeszky's disease and the average of their daily gains is less than – 0.5 kg. The vaccine complies with the test if:

- all the vaccinated pigs survive and the difference between the averages of the daily gains for the 2 groups is not less than 1.5 kg,
- the geometrical mean titres and the duration of excretion of the challenge virus are significantly lower in vaccinates than in controls.

2-3-2-2. *Vaccines intended for passive immunisation.* If the vaccine is intended for use in sows for the passive protection of piglets, the suitability of the strain for this purpose may be demonstrated by the following method.

Use for the test not fewer than 12 sows that do not have antibodies against Aujeszky's disease virus or against a fraction of the virus. Vaccinate not fewer than 8 sows, according to the schedule to be recommended. Maintain not fewer than 4 sows as controls. At 6-10 days of age, challenge the piglets from the sows with a sufficient quantity of virulent Aujeszky's disease virus. Observe the piglets at least daily for 21 days.

The test is invalid if the average number of piglets per litter for each group is less than 6. The vaccine complies with the test if not less than 80 per cent protection against mortality is found in the piglets from the vaccinated sows compared to those from the control sows.

2-4. *MANUFACTURER'S TESTS*

2-4-1. **Residual live virus**. The test for residual live virus is carried out using 2 passages in the same type of cell culture as that used in the production of the vaccine or cells shown to be at least as sensitive. The quantity of inactivated virus harvest used in the test is equivalent to not less than 25 doses of the vaccine. The inactivated virus harvest complies with the test if no live virus is detected.

2-4-2. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-6) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. The test described under Potency is carried out for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority. Where this test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency.

3. BATCH TESTS

3-1. **Identification**. In animals that do not have antibodies against Aujeszky's disease virus or against a fraction of the virus, the vaccine stimulates the production of specific antibodies against Aujeszky's disease virus or the fraction of the virus used in the production of the vaccine.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use not fewer than 2 piglets of the minimum age recommended for vaccination and that do not have antibodies against Aujeszky's disease virus or against a fraction of the virus. Administer to each piglet by a recommended route a double dose of the vaccine, then one dose after 14 days. Observe the piglets at least daily until 14 days after the last administration.

The vaccine complies with the test if no piglet shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual live virus**. Wherever possible, carry out a suitable test for residual live Aujeszky's disease virus using 2 passages in the same type of cell culture as used in the production of the vaccine or cells shown to be at least as sensitive. Otherwise, inject one dose of the vaccine subcutaneously into each of 5 healthy non-immunised rabbits. Observe the rabbits for 14 days after the injection. The vaccine complies with the test if no abnormal reaction (in particular a local rash) occurs. If the vaccine strain is not pathogenic for the rabbit, carry out the test in 2 sheep.

3-5. **Extraneous agents**. On the pigs used for the safety test carry out tests for antibodies. The vaccine complies with the test if it does not stimulate the formation of antibodies, other than those against Aujeszky's disease virus, against viruses pathogenic for pigs or against viruses that could interfere with the diagnosis of infectious diseases of pigs (including the viruses of the pestivirus group).

3-6. **Potency**. The vaccine complies with the requirements of the test described below when administered by a recommended route and method.

Use for the test not fewer than 10 pigs weighing 15-35 kg, that do not have antibodies against Aujeszky's disease virus or against a fraction of the virus. The body mass of none of the pigs differs from the average body mass of the group by more than 25 per cent. Vaccinate not fewer than 5 pigs with one dose of the vaccine. Maintain not fewer than 5 pigs as controls. After 3 weeks, weigh each pig, then challenge them by the intranasal route with a sufficient quantity of virulent Aujeszky's disease virus. Weigh each animal 7 days after challenge or at the time of death if this occurs earlier and calculate the average daily gain as a percentage. For each group (vaccinated and controls), calculate the average of the average daily gains.

The test is invalid unless all the control pigs display signs of Aujeszky's disease and the average of their daily gains is less than – 0.5 kg. The vaccine complies with the test if the vaccinated pigs survive and the difference between the averages of the daily gains for the 2 groups is not less than 1.1 kg.

4. LABELLING

The label states whether the vaccine strain is pathogenic for the rabbit.

corrected 6.0

AUJESZKY'S DISEASE VACCINE (LIVE) FOR PIGS FOR PARENTERAL ADMINISTRATION

Vaccinum morbi Aujeszkyi ad suem vivum ad usum parenteralem

1. DEFINITION

Aujeszky's disease vaccine (live) for pigs for parenteral administration is a preparation of a suitable strain of Aujeszky's disease virus. This monograph applies to vaccines intended for the active immunisation of pigs and for passive protection of their progeny against Aujeszky's disease. The vaccine may be administered after mixing with an adjuvant.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in embryonated hens' eggs or in cell cultures.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Embryonated hens' eggs**. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from flocks free from specified pathogens (SPF) (*5.2.2*).

2-2-2. **Cell cultures**. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE VIRUS*

The vaccine virus is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the pigs for which it is intended. The virus may have a genetic marker.

The following tests for safety (section 2-3-1.), virus excretion (section 2-3-2.), transmissibility, including transmission across the placenta and by semen (section 2-3-3.), increase in virulence (section 2-3-4.) and immunogenicity (2-3-5.) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**

2-3-1-1. *General safety.* Carry out the test for each route and method of administration to be recommended for vaccination, using in each case piglets 3-4 weeks old. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine.

For each test, use not fewer than 20 piglets that do not have antibodies against Aujeszky's disease virus or against a fraction of the virus. Administer to not fewer than 10 piglets a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in one dose of the vaccine. Maintain not fewer than 10 piglets as controls. Observe the piglets at least daily for 21 days.

The vaccine virus complies with the test if the weight curve of the vaccinated piglets does not differ significantly from that of the controls and if no piglet shows signs of disease or dies from causes attributable to the vaccine virus.

2-3-1-2. *Safety of the pigs used in tests* 2-3-5. *for immunogenicity.* The pigs used in the tests for immunogenicity are also used to evaluate safety. Measure the rectal temperature of each vaccinated pig at the time of vaccination and 6 h, 24 h and 48 h later. Examine the injection site at slaughter for local reactions.

The vaccine virus complies with the test if no pig shows:

– a temperature rise greater than 1.5 °C and the number of pigs showing a temperature greater than 41 °C does not exceed 10 per cent of the group;

– other systemic reactions (for example, anorexia);

– abnormal local reactions attributable to the vaccine virus.

2-3-1-3. *Safety in field studies.* The pigs used for field trials are also used to evaluate safety. Carry out a test in each category of pigs for which the vaccine is intended (sows, fattening pigs). Use not fewer than 3 groups each of not fewer than 20 pigs with corresponding groups of not fewer than 10 controls. Measure the rectal temperature of each pig at the time of vaccination and 6 h, 24 h and 48 h later. Examine the injection site at slaughter for local reactions.

The vaccine virus complies with the test if no pig shows:

– a temperature rise greater than 1.5 °C and the number of pigs showing a temperature greater than 41 °C does not exceed 25 per cent of the group;

– abnormal local reactions attributable to the vaccine virus.

2-3-1-4. *Neurological safety.* Use for the test not fewer than 10 piglets, 3-5 days old and that do not have antibodies against Aujeszky's disease virus or against a fraction of the virus. Administer to each piglet by the intranasal route a quantity of the vaccine virus equivalent to not less than 10 times the maximum dose likely to be contained in one dose of the vaccine. Observe the piglets at least daily for 21 days.

The vaccine virus complies with the test if none of the piglets dies or shows signs of neurological disorder attributable to the vaccine virus.

2-3-1-5. *Neurological safety for strains other than gE-negative.* This test is not necessary for gE-negative strains. Administer to not fewer than 5 piglets, 3-5 days old, by the intracerebral route $10^{4.5}$ $CCID_{50}$ of vaccine virus.

The vaccine virus complies with the test if none of the piglets dies or shows signs of neurological disorder.

2-3-1-6. *Absence of latent infections.* Use for the test not fewer than 10 piglets, 3-4 weeks old and that do not have antibodies against Aujeszky's disease virus or against a fraction of the virus. Administer to each piglet a daily injection of 2 mg of prednisolone per kilogram of body mass for 5 consecutive days. On the 3rd day administer to each piglet a quantity of vaccine virus equivalent to not less than the maximum virus titre likely to be contained in one dose of the vaccine by a route to be recommended. Antimicrobial agents may be administered to prevent aspecific signs. Observe the piglets at least daily for 21 days.

The vaccine virus complies with the test if no piglet shows signs of disease or dies from causes attributable to the vaccine virus.

2-3-1-7. *Safety in pregnant sows and absence of transmission across the placenta.* Use for the test not fewer than 15 pregnant sows that do not have antibodies against Aujeszky's disease virus or against a fraction of the virus. Administer to not fewer than 5 sows by a route to be recommended a quantity of vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in one dose of the vaccine during the 4th or 5th week of gestation. Administer to not fewer than 5 other sows the same dose of the virus by the same route during the 10th or 11th weeks of gestation. Maintain not fewer than 5 other pregnant sows as controls. For the piglets from vaccinated sows: carry out tests for serum antibodies against Aujeszky's disease virus; carry out tests for Aujeszky's disease virus antigen in the liver and lungs of those piglets showing abnormalities and in a quarter of the remaining healthy piglets.

The vaccine virus complies with the test if:

– the number of piglets born to the vaccinated sows, any abnormalities in the piglets and the duration of gestation do not differ significantly from those of the controls;

– no Aujeszky's disease virus antigen is found in piglets born to the vaccinated sows;

– no antibodies against Aujeszky's disease virus are found in the serum taken before ingestion of the colostrum.

2-3-2. **Virus excretion**. Use for the test not fewer than 18 pigs, 3-4 weeks old and that do not have antibodies against Aujeszky's disease virus or against a fraction of the virus. Administer to not fewer than 14 pigs a quantity of the vaccine virus equivalent to not less than the maximum virus titre likely to be contained in one dose of the vaccine by a route and a site to be recommended. Maintain not fewer than 4 pigs as contact controls. Carry out suitably sensitive tests for the virus individually on the nasal and oral secretions as follows: collect nasal and oral swabs daily from the day before vaccination until 10 days after vaccination.

The vaccine complies with the test if the virus is not isolated from the secretions collected.

2-3-3. **Transmissibility**. Carry out the test on 4 separate occasions. Each time, administer to not fewer than 4 piglets, 3-4 weeks old and that do not have antibodies against Aujeszky's disease virus or against a fraction of the virus, by a route to be recommended, a quantity of the vaccine virus equivalent to not less than the maximum virus titre likely to be contained in one dose of the vaccine. After one day, keep not fewer than 2 other piglets of the same age and that do not have antibodies against Aujeszky's disease virus or against a fraction of the virus close together with them. After 5 weeks, test all the piglets for the presence of antibodies against Aujeszky's disease virus.

The test is invalid if any vaccinated piglet does not show an antibody response. The vaccine virus complies with the test if no antibodies against Aujeszky's disease virus are detected in any group of contact controls and if all the vaccinated piglets show an antibody response.

2-3-4. **Increase in virulence**. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to 2 piglets, 3-5 days old, that do not have antibodies against Aujeszky's disease virus or against a fraction of the virus, sequential passages, 5 times where possible, to further similar groups and testing of the final recovered virus for increase in virulence. Passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages.

Administer to each piglet by the intranasal route a quantity of the vaccine virus that will allow recovery of virus for the passages described below. After 3-5 days, prepare a suspension from the brain, lung, tonsils and local lymph glands of each piglet and pool the samples. Administer 1 ml of the pooled samples by the intranasal route to each of 2 other piglets of the same age. Carry out this passage operation not fewer than 5 times, the last time in not fewer than 5 piglets; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages.

The vaccine virus complies with the test if no piglet dies or shows neurological disorders from causes attributable to the vaccine virus and no indication of increased virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-3-5. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended for vaccination. The quantity of vaccine virus to be administered to each pig is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of vaccine.

2-3-5-1. *Vaccines intended for active immunisation*. Use for the test not fewer than 15 fattening pigs of the age to be recommended and that do not have antibodies against Aujeszky's disease virus or against a fraction of the virus. The body mass of none of the pigs differs from the average body mass of the group by more than 20 per cent. Vaccinate not fewer than 10 pigs, according to the schedule to be recommended. Maintain not fewer than 5 pigs as controls. At the end of the fattening period (80-90 kg), weigh and challenge each pig by the intranasal route with a sufficient quantity of virulent Aujeszky's disease virus (challenge with at least 10^6 $CCID_{50}$ of a virulent strain having undergone not more than 3 passages and administered in not less than 4 ml of diluent has been found to be satisfactory). Determine the titre of virus in swabs taken from the nasal cavity of each pig daily from the day before challenge until virus is no longer detected. Weigh each pig 7 days after challenge or at the time of death if this occurs earlier and calculate the average daily gain as a percentage. For each group (vaccinated and controls), calculate the average of the average daily gains.

The test is invalid unless all the control pigs display signs of Aujeszky's disease and the average of their average daily gains is less than – 0.5 kg. The vaccine complies with the test if:

– all the vaccinated pigs survive and the difference between the averages of the average daily gains for the 2 groups is not less than 1.5 kg,

– the geometrical mean titres and the duration of excretion of the challenge virus are significantly lower in vaccinates than in controls.

2-3-5-2. *Vaccines intended for passive protection*. If the vaccine is intended for use in sows for the passive protection of piglets, the suitability of the vaccine virus for this purpose may be demonstrated by the following method.

Use for the test not fewer than 12 sows that do not have antibodies against Aujeszky's disease virus or against a fraction of the virus. Vaccinate not fewer than 8 sows, according to the schedule to be recommended. Maintain not fewer than 4 sows as controls. At 6-10 days of age, challenge the piglets from the sows with a sufficient quantity of virulent Aujeszky's disease virus. Observe the piglets at least daily for 21 days.

The test is invalid if the average number of piglets per litter for each group is less than 6.

The vaccine complies with the test if not less than 80 per cent protection against mortality is found in the piglets from the vaccinated sows compared to those from the control sows.

2-4. *MANUFACTURER'S TESTS*

2-4-1. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-7) for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label. The test described under Potency is carried out for a given vaccine, on one or more occasions, as decided by or with the agreement of the competent authority. Where this test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency.

3. BATCH TESTS

3-1. **Identification**. In animals that do not have antibodies against Aujeszky's disease virus or against a fraction of the virus, the vaccine stimulates the production of specific neutralising antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas** (*2.6.7*). The vaccine complies with the test for mycoplasmas.

3-4. **Extraneous agents**. Neutralise the vaccine virus with a suitable monospecific antiserum or monoclonal antibodies against Aujeszky's disease virus or against a fraction of the virus and inoculate into cell cultures known for their susceptibility to viruses pathogenic for pigs and to pestiviruses. Carry out at least one passage and maintain the cultures for 14 days. The vaccine complies with the test if no cytopathic effect develops and there is no sign of the presence of haemadsorbing agents. Carry out a specific test for pestiviruses.

3-5. **Safety**. Use 2 pigs of the minimum age recommended for vaccination and that do not have antibodies against Aujeszky's disease virus or against a fraction of the virus. Administer to each pig by a recommended route 10 doses of the vaccine. Observe the pigs at least daily for 14 days.

The vaccine complies with the test if no pig shows notable signs of disease or dies from causes attributable to the vaccine virus.

3-6. **Virus titre**. Titrate the vaccine virus on the same substrate as used for production (cell cultures or inoculation into the allantoic cavity of fertilised hen eggs). The vaccine complies with the test if one dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency**. The vaccine complies with the requirements of the test described below when administered by a recommended route and method.

Use not fewer than 10 pigs weighing 15-35 kg, that do not have antibodies against Aujeszky's disease virus or against a fraction of the virus. The body mass of none of the pigs differs from the average body mass of the group by more than 25 per cent. Vaccinate not fewer than 5 pigs with one dose of the vaccine. Maintain not fewer than 5 pigs as controls. After 3 weeks, weigh each pig, then challenge them by the intranasal route with a sufficient quantity of virulent Aujeszky's disease virus. Weigh each pig 7 days after challenge or at the time of death if this occurs earlier and calculate the average daily gain as a percentage. For each group (vaccinated and controls), calculate the average of the average daily gains.

The test is invalid unless all the control pigs display signs of Aujeszky's disease and the average of their average daily gains is less than – 0.5 kg. The vaccine complies with the test if all the vaccinated pigs survive and the difference between the averages of the average daily gains for the 2 groups is not less than 1.6 kg.

4. LABELLING

The label states the substrate used for production of the vaccine (cell cultures or eggs).

01/2008:0959

AVIAN INFECTIOUS BRONCHITIS VACCINE (INACTIVATED)

Vaccinum bronchitidis infectivae aviariae inactivatum

1. DEFINITION

Avian infectious bronchitis vaccine (inactivated) is a preparation of one or more suitable strains of one or more serotypes of avian infectious bronchitis virus, inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended to protect birds against a drop in egg production or quality; for vaccines also intended for protection against respiratory signs, a demonstration of efficacy additional to that described under Potency is required.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is propagated in fertilised hens' eggs or in cell cultures. The vaccine may be adjuvanted.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Embryonated hens' eggs**. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from healthy flocks.

2-2-2. **Cell cultures**. If the vaccine is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *SEED LOTS*

2-3-1. **Extraneous agents**. The master seed lot complies with the test for extraneous agents in seed lots (*2.6.24*). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the test.

2-4. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the birds for which it is intended.

The following test for Immunogenicity (section 2-4-1) may be used during the demonstration of efficacy.

2-4-1. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended, using in each case chickens from a flock free from specified pathogens (SPF) (*5.2.2*) and for each serotype in the vaccine. The vaccine administered to each chicken is of minimum potency.

Use for the test 4 groups of not fewer than 30 chickens treated as follows.

Group A: unvaccinated controls.

Group B: vaccinated with inactivated avian infectious bronchitis vaccine.

Group C: vaccinated with live avian infectious bronchitis vaccine and inactivated avian infectious bronchitis vaccine according to the recommended schedule.

Group D: vaccinated with live avian infectious bronchitis vaccine.

Monitor egg production and quality in all chickens from point of lay until at least 4 weeks after challenge. At the peak of lay, challenge all groups with a quantity of virulent avian infectious bronchitis virus sufficient to cause a drop in egg production or quality over 3 consecutive weeks during the 4 weeks following challenge. The test is invalid unless there is a drop in egg production in group A compared to the normal level noted before challenge of at least 35 per cent where challenge has been made with a Massachusetts-type strain; where it is necessary to carry out a challenge with a strain of another serotype for which there is documented evidence that the strain will not cause a 35 per cent drop in egg production, the challenge must produce a drop in egg production commensurate with the documented evidence and in any case not less than 15 per cent. The vaccine complies with the test if egg production or quality is significantly better in group C than in group D and significantly better in group B than in group A.

2-5. *MANUFACTURER'S TESTS*

2-5-1. **Residual live virus**. An amplification test for residual live avian infectious bronchitis virus is carried out on each batch of antigen immediately after inactivation and on the final bulk vaccine or, if the vaccine contains an adjuvant, on the bulk antigen or mixture of bulk antigens immediately before the addition of adjuvant; the test is carried out in embryonated hen eggs from SPF flocks (*5.2.2*) or in suitable cell cultures (*5.2.4*), whichever is the most sensitive for the vaccine strain. The quantity of inactivated virus harvest used in the test is equivalent to not less than 10 doses of vaccine. The vaccine complies with the test if no live virus is detected.

2-5-2. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-6) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

Administer 1 dose of vaccine by the intramuscular route to each of not fewer than 10 chickens, between 2 weeks of age and the minimum age stated for vaccination and from an SPF flock (*5.2.2*), and maintain 5 hatch mates as unvaccinated controls. Collect serum samples from each chicken just before administration of the vaccine and after the period defined when testing the reference vaccine; determine the antibody titre of each serum, for each serotype in the vaccine, by a suitable serological method, for example, serum neutralisation. The test is invalid unless the sera collected from the unvaccinated controls and from the chickens just before the administration of the vaccine are free from detectable specific antibody. The vaccine complies with the test if the antibody levels are not significantly less than those obtained with a batch that has given satisfactory results in the test described under Potency.

3. BATCH TESTS

3-1. **Identification**. When injected into chickens that do not have antibodies against each of the virus serotypes in the vaccine, the vaccine stimulates the production of such antibodies, detectable by virus neutralisation.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 10 chickens, 14 to 28 days old, from an SPF flock (*5.2.2*). Inject a double dose of vaccine by a recommended route into each chicken. Observe the chickens at least daily for 21 days.

The vaccine complies with the test if no chicken shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual live virus**. A test for residual live virus is carried out to confirm inactivation of avian infectious bronchitis virus.

A. For vaccine prepared with embryo-adapted strains of virus, inject 2/5th of a dose into the allantoic cavity of ten 9- to 11-day-old embryonated hens' eggs from an SPF flock (*5.2.2*) and incubate. Observe for 5 to 6 days and pool separately the allantoic liquid from eggs containing live embryos and that from eggs containing dead embryos, excluding those that die within the first 24 h after injection. Examine for abnormalities all embryos which die after 24 h of injection or which survive 5 to 6 days. No death or abnormality attributable to the vaccine virus occurs. Inject into the allantoic cavity of each of ten 9- to 11-day-old embryonated hens' eggs from an SPF flock (*5.2.2*) 0.2 ml of the pooled allantoic liquid from the live embryos and into each of 10 similar eggs 0.2 ml of the pooled liquid from the dead embryos and incubate for 5 to 6 days. Examine for abnormalities all embryos which die after 24 h of injection or which survive 5 to 6 days. If more than 20 per cent of the embryos die at either stage repeat the test from that stage. The vaccine complies with the test if there is no death or abnormality attributable to the vaccine virus.

B. For vaccine prepared with cell-culture-adapted strains of virus, inoculate 10 doses of the vaccine into suitable cell cultures. If the vaccine contains an oil adjuvant, eliminate it by suitable means. Incubate at 38 ± 1 °C for 7 days. Make a passage on another set of cell cultures and incubate at 38 ± 1 °C for 7 days. The vaccine complies with the test if none of the cultures show signs of infection.

3-5. **Extraneous agents**. Use the chickens from the safety test. 21 days after injection of the double dose of vaccine, inject 1 dose by the same route into each chicken. Collect serum samples from each chicken 2 weeks later and carry out tests for antibodies against the following agents by the methods prescribed in general chapter *5.2.2. Chicken flocks free from specified pathogens for the production and quality control of vaccines*: avian encephalomyelitis virus, avian leucosis viruses, egg-drop syndrome virus, avian infectious bursal disease virus, avian infectious laryngotracheitis virus, influenza A virus, Marek's disease virus, Newcastle disease virus. The vaccine complies with the test if it does not stimulate the formation of antibodies against these agents.

3-6. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-4-1) when administered by a recommended route and method.

4. LABELLING

The label states whether the strain in the vaccine is embryo-adapted or cell-culture-adapted.

01/2008:0442

AVIAN INFECTIOUS BRONCHITIS VACCINE (LIVE)

Vaccinum bronchitidis infectivae aviariae vivum

1. DEFINITION

Avian infectious bronchitis vaccine (live) is a preparation of one or more suitable strains of different types of avian infectious bronchitis virus. This monograph applies to vaccines intended for administration to chickens for active immunisation against respiratory disease caused by avian infectious bronchitis virus.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in embryonated hens' eggs or in cell cultures.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Embryonated hens' eggs**. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from flocks free from specified pathogens (SPF) (*5.2.2*).

2-2-2. **Cell cultures**. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *SEED LOTS*

2-3-1. **Extraneous agents**. The master seed lot complies with the tests for extraneous agents in seed lots (*2.6.24*). In these tests on the master seed lot, the organisms used are not more that 5 passages from the master seed lot at the start of the test.

2-4. *CHOICE OF VACCINE VIRUS*

The vaccine virus shall be shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the chickens for which it is intended.

The following tests for safety (section 2-4-1), increase in virulence (section 2-4-2) and immunogenicity (section 2-4-3) may be used during the demonstration of safety and immunogenicity.

2-4-1. **Safety**

2-4-1-1. *Safety for the respiratory tract and kidneys*. Carry out the test in chickens not older than the youngest age to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. Use not fewer than 15 chickens from an SPF flock (*5.2.2*) and from the same origin. Administer to each chicken by the oculonasal route a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in 1 dose of the vaccine. On each of days 5, 7 and 10 after administration of the virus, euthanise not fewer than 5 of the chickens, take samples of trachea and kidney. Fix kidney samples for histological examination. Remove the tracheas and cut 10 rings from each trachea (3 from the top, 4 from the mid-part and 3 from the bottom); examine each ring under low magnification and score for ciliostasis on a scale from 0 (100 per cent ciliary activity) to 4 (no activity, complete ciliostasis); calculate the mean ciliostasis score (the maximum for each trachea being 40) for the 5 chickens euthanised on each of days 5, 7 and 10. The test is not valid if more than 10 per cent of the chickens die from causes not

attributable to the vaccine virus. The vaccine virus complies with the test if:

– no chicken shows notable clinical signs of avian infectious bronchitis or dies from causes attributable to the vaccine virus,
– the average ciliostasis score is not more than 25,
– at most moderate inflammatory lesions are seen during kidney histological examination.

2-4-1-2. *Safety for the reproductive tract.* If the recommendations for use state or imply that the vaccine may be used in females of less than 3 weeks old that are subsequently kept to sexual maturity, it shall be demonstrated that there is no damage to development of the reproductive tract when the vaccine is given to chickens of the minimum age to be recommended for vaccination. The following test may be carried out: use not fewer than 40 female chickens not older than the minimum age recommended for vaccination and from an SPF flock (*5.2.2*); use the vaccine virus at the least attenuated passage level that will be present in a batch of vaccine; administer to each chicken by a recommended route a quantity of virus equivalent to not less than the maximum titre likely to be present in 1 dose of vaccine; at least 10 weeks after administration of the vaccine virus, euthanise the chickens and carry out macroscopic examination of the oviducts. The vaccine virus complies with the test if abnormalities are present in not more than 5 per cent of the oviducts.

2-4-2. **Increase in virulence**. The test for increase in virulence consists of the administration of the vaccine virus, at the least attenuated virus passage level that will be present between the master seed lot and a batch of the vaccine, to a group of five 2-week-old chickens from an SPF flock (*5.2.2*), sequential passages, 5 times where possible, to further similar groups and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages. Administer by eye-drop a quantity of the vaccine virus that will allow recovery of virus for the passages described below. 2 to 4 days after administration of the vaccine virus, prepare a suspension from the mucosa of the trachea of each chicken and pool these samples. Administer 0.05 ml of the pooled samples by eye-drop to each of 5 other 2-week-old chickens from an SPF flock (*5.2.2*). Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages. Carry out the test for safety for the respiratory tract and kidney (section 2-4-1-1) and, where applicable, the test for safety for the reproductive tract (section 2-4-1-2) using the unpassaged vaccine virus and the maximally passaged virus that has been recovered. Administer the virus by the route to be recommended for vaccination likely to be the least safe. The vaccine virus complies with the test if no indication of increase in virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-4-3. **Immunogenicity**. Immunogenicity is demonstrated for each strain of virus to be included in the vaccine. A test is carried out for each route and method of administration to be recommended using in each case chickens from an SPF flock (*5.2.2*) not older than the youngest age to be recommended for vaccination. The quantity of the vaccine virus administered to each chicken is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of the vaccine. 1 or both of the tests below may be used during the demonstration of immunogenicity.

2-4-3-1. *Ciliary activity of tracheal explants.* Use not fewer than 25 chickens of the same origin and from an SPF flock (*5.2.2*). Vaccinate by a recommended route not fewer than 20 chickens. Maintain not fewer than 5 chickens as controls. Challenge each chicken after 21 days by eye-drop with a sufficient quantity of virulent avian infectious bronchitis virus of the same type as the vaccine virus to be tested. Euthanise the chickens 4 to 7 days after challenge and prepare transverse sections from the upper part (3), the middle part (4) and the lower part (3) of the trachea of each chicken. Examine all explants as soon as possible and at the latest 2 h after sampling by low-magnification microscopy for ciliary activity. For a given tracheal section, ciliary activity is considered as normal when at least 50 per cent of the internal ring shows vigorous ciliary movement. A chicken is considered not affected if not fewer than 9 out of 10 rings show normal ciliary activity.

The test is not valid if:

– fewer than 80 per cent of the control chickens show cessation or extreme loss of vigour of ciliary activity,
– and/or during the period between the vaccination and challenge more than 10 per cent of vaccinated or control chickens show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine virus complies with the test if not fewer than 80 per cent of the vaccinated chickens show normal ciliary activity.

2-4-3-2. *Virus recovery from tracheal swabs.*Use not fewer than 30 chickens of the same origin and from an SPF flock (*5.2.2*). Vaccinate by a recommended route not fewer than 20 chickens. Maintain not fewer than 10 chickens as controls. Challenge each chicken after 21 days by eye-drop with a sufficient quantity of virulent avian infectious bronchitis virus of the same type as the vaccine virus to be tested. Kill the chickens 4 to 7 days after challenge and prepare a suspension from swabs of the tracheal mucosa of each chicken. Inoculate 0.2 ml of the suspension into the allantoic cavity of each of 5 embryonated hens' eggs, 9 to 11 days old, from an SPF flock (*5.2.2*). Incubate the eggs for 6-8 days after inoculation. Eggs that after 1 day of incubation do not contain a live embryo are eliminated and considered as non-specific deaths. Record the other eggs containing a dead embryo and after 6-8 days' incubation examine each egg containing a live embryo for lesions characteristic of avian infectious bronchitis. Make successively 3 such passages. If 1 embryo of a series of eggs dies or shows characteristic lesions, the inoculum is considered to be a carrier of avian infectious bronchitis virus. The examination of a series of eggs is considered to be definitely negative if no inoculum concerned is a carrier. The test is not valid if:

– the challenge virus is re-isolated from fewer than 80 per cent of the control chickens,
– and/or during the period between vaccination and challenge more than 10 per cent of the vaccinated or control chickens show abnormal clinical signs or die from causes not attributable to the vaccine,
– and/or more than 1 egg in any group is eliminated because of non-specific embryo death.

The vaccine virus complies with the test if the challenge virus is re-isolated from not more than 20 per cent of the vaccinated chickens.

3. BATCH TESTS

3-1. **Identification**

3-1-1. *Vaccines containing one type of virus.* The vaccine, diluted if necessary and mixed with avian infectious bronchitis virus antiserum specific for the virus type, no longer infects embryonated hens' eggs from an SPF flock (*5.2.2*) or susceptible cell cultures (*5.2.4*) into which it is inoculated.

3-1-2. *Vaccines containing more than one type of virus.* The vaccine, diluted if necessary and mixed with type-specific antisera against each strain present in the vaccine except that to be identified, infects embryonated hens' eggs from an SPF flock (*5.2.2*) or susceptible cell cultures (*5.2.4*) into which it is inoculated whereas after further admixture with type-specific antiserum against the strain to be identified it no longer produces such infection.

3-2. **Bacteria and fungi**

Vaccines intended for administration by injection comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062).*

Vaccines not intended for administration by injection either comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)* or with the following test: carry out a quantitative test for bacterial and fungal contamination; carry out identification tests for microorganisms detected in the vaccine; the vaccine does not contain pathogenic microorganisms and contains not more than 1 non-pathogenic microorganism per dose.

Any liquid supplied with the vaccine complies with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062).*

3-3. **Mycoplasmas**. The vaccine complies with the test for mycoplasmas (*2.6.7*).

3-4. **Extraneous agents**. The vaccine complies with the tests for extraneous agents in batches of finished product (*2.6.25*).

3-5. **Safety**. Use not fewer than 10 chickens from an SPF flock (*5.2.2*) and of the youngest age recommended for vaccination. Administer by a recommended route to each chicken, 10 doses of the vaccine. Observe the chickens at least daily for 21 days. The test is not valid if more than 20 per cent of the chickens show abnormal clinical signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no chicken shows notable clinical signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**. Titrate the vaccine virus by inoculation into embryonated hens' eggs from an SPF flock (*5.2.2*) or into suitable cell cultures (*5.2.4*). If the vaccine contains more than 1 strain of virus, titrate each strain after having neutralised the others with type-specific avian infectious bronchitis antisera. The vaccine complies with the test if 1 dose contains for each vaccine virus not less than the minimum titre stated on the label.

3-7. **Potency**. The vaccine complies with the requirements of 1 of the tests prescribed under Immunogenicity (section 2-4-3) when administered according to the recommended schedule by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2008:0960

AVIAN INFECTIOUS BURSAL DISEASE VACCINE (INACTIVATED)

Vaccinum bursitidis infectivae aviariae inactivatum

1. DEFINITION

Avian infectious bursal disease vaccine (inactivated) is a preparation of a suitable strain of avian infectious bursal disease virus type 1, inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for use in breeding chickens to protect their progeny from avian infectious bursal disease.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in embryonated hens' eggs or in cell cultures.

The vaccine may be adjuvanted.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Embryonated hens' eggs**. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from healthy flocks.

2-2-2. **Cell cultures**. If the vaccine is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *SEED LOTS*

2-3-1. **Extraneous agents**. The master seed lot complies with the tests for extraneous agents in seed lots (*2.6.24*). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the test.

2-4. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the birds for which it is intended.

The following test for immunogenicity (2-4-1) may be used during the demonstration of efficacy.

2-4-1. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended using in each case chickens from a flock free from specified pathogens (SPF) (*5.2.2*) and not older than the youngest age to be recommended for vaccination (close to the point of lay). The dose of vaccine administered to each chicken contains not more than the minimum potency to be stated on the label.

Where a challenge test is to be carried out, the following test may be used. Use 2 groups of not less than 20 hens treated as follows:

– group A: unvaccinated controls;
– group B: vaccinated with inactivated avian infectious bursal disease vaccine.

Serum samples are collected from each unvaccinated control (group A) hen just before administration of the vaccine, 4-6 weeks later, and at the time of egg collection for hatching. If a serological test is to be carried out for demonstration of immunogenicity by other routes, serum samples are also collected from each vaccinated (group B) hen at the time of egg collection for hatching. The antibody response is measured in a serum-neutralisation test.

Eggs are collected for hatching not less than 5 weeks after vaccination and the test described below is carried out with chickens at least 3 weeks old from that egg collection.

25 chickens from vaccinated (group B) hens and 10 control chickens of the same breed and age from unvaccinated (group A) hens are challenged with an eye-drop application of a quantity of a virulent strain of avian infectious bursal disease virus sufficient to produce severe signs of disease, including lesions of the bursa of Fabricius, in all unvaccinated chickens. 3-4 days after challenge, the bursa of Fabricius is removed from each chicken. The bursae are examined for evidence of infection by histological examination and by testing for the presence of avian infectious bursal disease antigen by a suitable method. The vaccine complies with the test if 3 or fewer of the chickens from group B hens show evidence of avian infectious bursal disease. The test is invalid unless all the chickens from group A hens show evidence of avian infectious bursal disease.

Where there is more than one recommended route of administration, the test described under Potency is carried out in parallel with the above immunogenicity test, using different groups of birds for each recommended route. The serological response of the birds inoculated by routes other than that used in the immunogenicity test is not significantly less than that of the group vaccinated by that route.

2-5. *MANUFACTURER'S TESTS*

2-5-1. **Residual live virus**. An amplification test for residual live avian infectious bursal disease virus is carried out on each batch of antigen immediately after inactivation to confirm inactivation; the test is carried out in embryonated hens' eggs or in suitable cell cultures (*5.2.4*), whichever is the most sensitive for the vaccine strain; the quantity of inactivated virus harvest used in the test is equivalent to not less than 10 doses of the vaccine. The vaccine complies with the test if no live virus is detected.

2-5-2. **Batch potency test**. It is not necessary to carry out the potency test (section 3-6) for each batch of the vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

Vaccinate each of not fewer than 10 chickens, 14-28 days old and from an SPF flock (*5.2.2*), with 1 dose of vaccine by a recommended route. 4-6 weeks later, collect serum samples from each bird and 10 unvaccinated control birds of the same age and from the same source. Measure the antibody response in a serum-neutralisation test.

The test is invalid if there are specific antibodies in the sera of the unvaccinated birds. The vaccine complies with the test if the mean antibody titre in the sera from the vaccinated birds is equal to or greater than the titres obtained with a batch that has given satisfactory results in the test described under Immunogenicity (section 2-4-1).

3. BATCH TESTS

3-1. **Identification**. When injected into chickens that do not have antibodies against avian infectious bursal disease virus type 1, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine, and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 10 chickens, 14-28 days old, from SPF flocks (*5.2.2*). Administer to each chicken by a recommended route a double dose of vaccine. Observe the birds at least daily for not less than 21 days.

The vaccine complies with the test if no bird shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual live virus**. A test for residual live virus is carried out to confirm inactivation of avian infectious bursal disease type 1.

A. For vaccine prepared with embryo-adapted strains of virus, inject $2/5^{th}$ of a dose into the allantoic cavity or onto the chorio-allantoic membrane of ten 9- to 11-day-old embryonated hen eggs from an SPF flock (*5.2.2*). Incubate the eggs and observe at least daily for 6 days. Pool separately the allantoic liquid or membranes from eggs containing live embryos, and that from eggs containing dead embryos, excluding those that die from non-specific causes within 24 h of the injection.

   Inject into the allantoic cavity or onto the chorio-allantoic membrane of each of ten 9- to 11-day-old SPF eggs 0.2 ml of the pooled allantoic liquid or crushed chorio-allantoic membranes from the live embryos and, into each of 10 similar eggs, 0.2 ml of the pooled liquid or membranes from the dead embryos and incubate for 6 days. Examine each embryo for lesions of avian infectious bursal disease.

   If more than 20 per cent of the embryos die at either stage repeat that stage. The vaccine complies with the test if there is no evidence of lesions of avian infectious bursal disease and if, in any repeat test, not more than 20 per cent of the embryos die from non-specific causes.

   Antibiotics may be used in the test to control extraneous bacterial infection.

B. For vaccine prepared with cell-culture-adapted strains of virus, inoculate 10 doses of the vaccine into suitable cell cultures. If the vaccine contains an oil adjuvant, eliminate it by suitable means. Incubate at 38 ± 1 °C for 7 days. Make a passage on another set of cell cultures and incubate at 38 ± 1 °C for 7 days. The vaccine complies with the test if the cultures show no signs of infection.

3-5. **Extraneous agents**. Use 10 chickens, 14-28 days old, from an SPF flock (*5.2.2*). Vaccinate each chicken by a recommended route with a double dose of the vaccine. After 3 weeks, administer 1 dose by the same route. Collect serum samples from each chicken 2 weeks later and carry out tests for antibodies against the following agents by the methods prescribed in general chapter *5.2.2. Chicken flocks free from specified pathogens for the production and quality control of vaccines*: avian encephalomyelitis virus, avian leucosis viruses, egg-drop syndrome virus, avian infectious bronchitis virus, avian infectious laryngotracheitis virus, influenza A virus, Marek's disease virus, Newcastle disease virus.

The vaccine complies with the test if it does not stimulate the formation of antibodies against these agents.

3-6. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-4-1) when administered by a recommended route and method.

4. LABELLING

The label states whether the strain in the vaccine is embryo-adapted or cell-culture-adapted.

01/2008:0587

AVIAN INFECTIOUS BURSAL DISEASE VACCINE (LIVE)

Vaccinum bursitidis infectivae aviariae vivum

1. DEFINITION

Avian infectious bursal disease vaccine (live) [Gumboro disease vaccine (live)] is a preparation of a suitable strain of infectious bursal disease virus type 1. This monograph applies to vaccines intended for administration to chickens for active immunisation; it applies to vaccines containing strains of low virulence but not to those containing strains of higher virulence that may be needed for disease control in certain epidemiological situations.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in embryonated hens' eggs or in cell cultures.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Embryonated hens' eggs**. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from flocks free from specified pathogens (SPF) (*5.2.2*).

2-2-2. **Cell cultures**. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *SEED LOTS*

2-3-1. **Extraneous agents**. The master seed lot complies with the tests for extraneous agents in seed lots (*2.6.24*). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the tests.

2-4. *CHOICE OF VACCINE VIRUS*

The vaccine virus shall be shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the chickens for which it is intended.

The following tests for safety (section 2-4-1), damage to the bursa of Fabricius (section 2-4-2), immunosuppression (section 2-4-3), increase in virulence (section 2-4-4) and immunogenicity (section 2-4-5) may be used during the demonstration of safety and immunogenicity.

2-4-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination using in each case chickens not older than the youngest age to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. For each test, use not fewer than 20 chickens from an SPF flock (*5.2.2*). Administer to each chicken a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in 1 dose of the vaccine. Observe the chickens at least daily for 21 days. The test is not valid if more than 10 per cent of the chickens die from causes not attributable to the vaccine virus. The vaccine virus complies with the test if no chicken shows notable clinical signs of avian infectious bursal disease or dies from causes attributable to the vaccine virus.

2-4-2. **Damage to the bursa of Fabricius**. Carry out the test for the route to be recommended for vaccination likely to be the least safe using chickens not older than the youngest age to be recommended for vaccination. Use virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. Use not fewer than 20 chickens from an SPF flock (*5.2.2*). Administer to each chicken a quantity of the vaccine virus equivalent to 10 times the maximum titre likely to be contained in a dose of the vaccine. On each of days 7, 14, 21 and 28 after administration of the vaccine virus, euthanise not fewer than 5 chickens and prepare a section from the site with the greatest diameters of the bursa of Fabricius of each chicken. Carry out histological examination of the section and score the degree of bursal damage using the following scale.

0 No lesion, normal bursa.

1 1 per cent to 25 per cent of the follicles show lymphoid depletion (i.e. less than 50 per cent depletion in 1 affected follicle) influx of heterophils in lesions.

2 26 per cent to 50 per cent of the follicles show nearly complete lymphoid depletion (i.e. more than 75 per cent depletion in 1 affected follicle), affected follicles show necrosis and severe influx of heterophils may be detected.

3 51 per cent to 75 per cent of the follicles show lymphoid depletion; affected follicles show necrosis and severe influx of heterophils is detected.

4 76 per cent to100 per cent of the follicles show nearly complete lymphoid depletion, hyperplasia and cyst structures are detected; affected follicles show necrosis and severe influx of heterophils is detected.

5 100 per cent of the follicles show nearly complete lymphoid depletion; complete loss of follicular structure, thickened and folded epithelium, fibrosis of bursal tissue.

Calculate the average score for each group of chickens. The vaccine virus complies with the test if:

– no chicken shows notable clinical signs of disease or dies from causes attributable to the vaccine virus,
– the average score for bursal damage 21 days after administration of the vaccine virus is less than or equal to 2.0 and 28 days after administration is less than or equal to 0.6,
– during the 21 days after administration a notable repopulation of the bursae by lymphocytes has taken place.

2-4-3. **Immunosuppression**. Carry out the tests for the route recommended for vaccination likely to be the least safe using chickens not older than the youngest age recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. Use not fewer than 30 chickens from an SPF flock (*5.2.2*). Divide them randomly into 3 groups each of not fewer than 10 and maintain the groups separately. Administer by eye-drop to each chicken of 1 group a quantity of the vaccine virus equivalent to not less than the maximum titre likely to be contained in 1 dose of the vaccine. At the time after administration when maximal bursal damage is likely to be present, as judged from the results obtained in the test for damage to the bursa of Fabricius (section 2-4-2), administer to each vaccinated chicken and to each chicken of another group 1 dose of Hitchner B1 strain Newcastle disease vaccine (live). Determine the seroresponse of each chicken of the 2 groups to the Newcastle disease virus 14 days after administration. Challenge each chicken of the 3 groups by the intramuscular route with not less

than 10^5 EID_{50} of virulent Newcastle disease virus and note the degree of protection in the 2 groups vaccinated with Hitchner B1 strain Newcastle vaccine compared with the non-vaccinated group. The test is not valid if 1 or more of the non-vaccinated chickens does not die within 7 days of challenge. The degree of immunosuppression is estimated from the comparative seroresponses and protection rates of the 2 Hitchner B1 vaccinated groups. The vaccine complies with the test if there is no significant difference between the 2 groups.

2-4-4. **Increase in virulence**. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to a group of 5 chickens from an SPF flock (*5.2.2*) and not older than the youngest age to be recommended for vaccination, sequential passages, 5 times where possible, to further similar groups and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages. Administer by eye-drop a quantity of the vaccine virus that will allow recovery of virus for the passages described below. Prepare 3 to 4 days after administration a suspension from the bursa of Fabricius of each chicken and pool these samples. Administer 0.05 ml of the pooled samples by eye-drop to each of 5 other chickens of the same age and origin. Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages. Carry out the test for damage to the bursa of Fabricius (section 2-4-2) using the unpassaged vaccine virus and the maximally passaged virus that has been recovered. Administer the virus by the route recommended for vaccination likely to be the least safe. The vaccine virus complies with the test if no indication of increasing virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-4-5. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended using in each case chickens not older than the youngest age to be recommended for vaccination. The quantity of vaccine virus administered to each chicken is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of the vaccine. Use not fewer than 30 chickens of the same origin and from an SPF flock (*5.2.2*). Vaccinate by a recommended route not fewer than 20 chickens. Maintain not fewer than 10 chickens as controls. Challenge each chicken after 14 days by eye-drop with a sufficient quantity of virulent avian infectious bursal disease virus. Observe the chickens at least daily for 10 days after challenge. Record the deaths due to infectious bursal disease and the surviving chickens that show clinical signs of disease. At the end of the observation period, euthanise all the surviving chickens and carry out histological examination for lesions of the bursa of Fabricius. The test is not valid if one or more of the following applies:

– during the observation period following challenge, fewer than 50 per cent of the control chickens show characteristic signs of avian infectious bursal disease,
– 1 or more of the surviving control chickens does not show degree 3 lesions of the bursa of Fabricius,
– during the period between the vaccination and challenge more than 10 per cent of the vaccinated or control chickens show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine virus complies with the test if during the observation period after challenge not fewer than 90 per cent of the vaccinated chickens survive and show no notable clinical signs of disease nor degree 3 lesions of the bursa of Fabricius.

3. BATCH TESTS

3-1. **Identification**. The vaccine, diluted if necessary and mixed with a monospecific infectious bursal disease virus type 1 antiserum, no longer infects embryonated hens' eggs from an SPF flock (*5.2.2*) or susceptible cell cultures (*5.2.4*) into which it is inoculated.

3-2. **Bacteria and fungi**

Vaccines intended for administration by injection comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

Vaccines not intended for administration by injection either comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)* or with the following test: carry out a quantitative test for bacterial and fungal contamination; carry out identification tests for microorganisms detected in the vaccine; the vaccine does not contain pathogenic microorganisms and contains not more than 1 non-pathogenic microorganism per dose.

Any liquid supplied with the vaccine complies with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas**. The vaccine complies with the test for mycoplasmas (*2.6.7*).

3-4. **Extraneous agents**. The vaccine complies with the tests for extraneous agents in batches of finished product (*2.6.25*).

3-5. **Safety**. Use not fewer than 10 chickens from an SPF flock (*5.2.2*) and of the youngest age recommended for vaccination. Administer by a recommended route and method to each chicken 10 doses of the vaccine. Observe the chickens at least daily for 21 days. The test is not valid if more than 20 per cent of the chickens show abnormal clinical signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no chicken shows notable clinical signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**. Titrate the vaccine virus by inoculation into embryonated hens' eggs from an SPF flock (*5.2.2*) or into suitable cell cultures (*5.2.4*). The vaccine complies with the test if 1 dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-4-5) when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2008:0588

AVIAN INFECTIOUS ENCEPHALOMYELITIS VACCINE (LIVE)

Vaccinum encephalomyelitidis infectivae aviariae vivum

1. DEFINITION

Avian infectious encephalomyelitis vaccine (live) is a preparation of a suitable strain of avian encephalomyelitis virus. This monograph applies to vaccines intended for administration to non-laying breeder chickens to protect passively their future progeny and/or to prevent vertical transmission of virus via the egg.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in embryonated hens' eggs or in cell cultures.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Embryonated hens' eggs**. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from flocks free from specified pathogens (SPF) (*5.2.2*).

2-2-2. **Cell cultures**. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *SEED LOTS*

2-3-1. **Extraneous agents**. The master seed lot complies with the tests for extraneous agents in seed lots (*2.6.24*). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the tests.

2-4. *CHOICE OF VACCINE VIRUS*

The vaccine virus shall be shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the chickens for which it is intended.

The following tests for safety (section 2-4-1), increase in virulence (section 2-4-2) and immunogenicity (section 2-4-3) may be used during the demonstration of safety and immunogenicity.

2-4-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination using in each case non-laying breeder chickens not older than the youngest age to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. For each test, use not fewer than 20 chickens from an SPF flock (*5.2.2*). Administer to each chicken a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in 1 dose of the vaccine. Observe the chickens at least daily for 21 days. The test is not valid if more than 10 per cent of the chickens show abnormal clinical signs or die from causes not attributable to the vaccine virus. The vaccine virus complies with the test if no chicken shows notable clinical signs of avian infectious encephalomyelitis or dies from causes attributable to the vaccine virus.

2-4-2. **Increase in virulence**. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of vaccine to a group of five 1-day-old chickens from an SPF flock (*5.2.2*), sequential passages, 5 times where possible, to further similar groups of 1-day-old chickens, and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages. Administer by a recommended route and method, a quantity of the vaccine virus that will allow recovery of virus for the passages described below. 5 to 7 days later, prepare a suspension from the brain of each chick and pool these samples. Administer a suitable volume of the pooled samples by the oral route to each of 5 other chickens of the same age and origin. Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages. Carry out the test for safety (section 2-4-1) using the unpassaged vaccine virus and the maximally passaged vaccine virus that has been recovered. The vaccine virus complies with the test if no indication of increase in virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-4-3. **Immunogenicity**. If the vaccine is recommended for passive protection of future progeny carry out test 2-4-3-1. If the vaccine is recommended for prevention of vertical transmission of virus via the egg, carry out test 2-4-3-2. A test is carried out for each route and method of administration to be recommended, using in each case chickens from an SPF flock (*5.2.2*) not older than the youngest age to be recommended for vaccination. The quantity of the vaccine virus administered to each chicken is not greater than the minimum titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of the vaccine.

2-4-3-1. *Passive immunity in chickens.* Vaccinate not fewer than 20 breeder chickens from an SPF flock (*5.2.2*). Maintain separately not fewer than 10 breeder chickens of the same age and origin as controls. At the peak of lay, hatch not fewer than 25 chickens from eggs from vaccinated breeder chickens and 10 chickens from non-vaccinated breeder chickens. At 2 weeks of age, challenge each chicken by the intracerebral route with a sufficient quantity of virulent avian encephalomyelitis virus. Observe the chickens at least daily for 21 days after challenge. Record the deaths and the number of surviving chickens that show clinical signs of disease. The test is not valid if:

- during the observation period after challenge fewer than 80 per cent of the control chickens die or show severe clinical signs of avian infectious encephalomyelitis,
- and/or during the period between the vaccination and challenge more than 15 per cent of control or vaccinated chickens show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine virus complies with the test if during the observation period after challenge not fewer than 80 per cent of the progeny of vaccinated chickens survive and show no notable clinical signs of disease.

2-4-3-2. *Passive immunity in embryos.* Vaccinate not fewer than 20 breeder chickens from an SPF flock (*5.2.2*). Maintain separately not fewer than 10 breeder chickens of the same age and origin as controls. At the peak of lay, incubate not fewer than 36 eggs from the 2 groups, vaccinated and controls, and carry out an embryo sensitivity test. On the sixth day of incubation inoculate 100 EID_{50} of the Van Roekel strain of avian encephalomyelitis virus into the yolk sacs of

the eggs. 12 days after inoculation examine the embryos for specific lesions of avian encephalomyelitis (muscular atrophy). Deaths during the first 24 h are considered to be non-specific. The test is not valid if fewer than 80 per cent of the control embryos show lesions of avian encephalomyelitis. The test is not valid if fewer than 80 per cent of the embryos can be given an assessment. The vaccine virus complies with the test if not fewer than 80 per cent of the embryos in the vaccinated group show no lesions of avian encephalomyelitis.

3. BATCH TESTS

3-1. **Identification**. The vaccine, diluted if necessary and mixed with a monospecific avian encephalomyelitis virus antiserum, no longer infects embryonated hens' eggs from an SPF flock (*5.2.2*) or susceptible cell cultures (*5.2.4*) into which it is inoculated.

3-2. **Bacteria and fungi**

Vaccines intended for administration by injection comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

Vaccines not intended for administration by injection either comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)* or with the following test: carry out a quantitative test for bacterial and fungal contamination; carry out identification tests for microorganisms detected in the vaccine; the vaccine does not contain pathogenic microorganisms and contains not more than 1 non-pathogenic microorganism per dose.

Any liquid supplied with the vaccine complies with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas**. The vaccine complies with the test for mycoplasmas (*2.6.7*).

3-4. **Extraneous agents**. The vaccine complies with the tests for extraneous agents in batches of finished product (*2.6.25*).

3-5. **Safety**. Use not fewer than 10 chickens not older than the minimum age recommended for vaccination and from an SPF flock (*5.2.2*). Administer by a recommended route and method to each chicken 10 doses of the vaccine. Observe the chickens at least daily for 21 days. The test is not valid if more than 20 per cent of the chickens show abnormal clinical signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no chicken shows notable clinical signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**. Titrate the vaccine virus by inoculation into embryonated hens' eggs from an SPF flock (*5.2.2*) or into suitable cell cultures (*5.2.4*). The vaccine complies with the test if 1 dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency**. Depending on the indications, the vaccine complies with the requirements of 1 or both of the tests prescribed under Immunogenicity (section 2-4-3-1, 2-4-3-2), when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2008:1068

AVIAN INFECTIOUS LARYNGOTRACHEITIS VACCINE (LIVE)

Vaccinum laryngotracheitidis infectivae aviariae vivum

1. DEFINITION

Avian infectious laryngotracheitis vaccine (live) is a preparation of a suitable strain of avian infectious laryngotracheitis virus (gallid herpesvirus 1). This monograph applies to vaccines intended for administration to chickens for active immunisation.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in embryonated hens' eggs or in cell cultures.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Embryonated hens' eggs**. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from flocks free from specified pathogens (SPF) (*5.2.2*).

2-2-2. **Cell cultures**. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *SEED LOTS*

2-3-1. **Extraneous agents**. The master seed lot complies with the tests for extraneous agents in seed lots (*2.6.24*). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the tests.

2-4. *CHOICE OF VACCINE VIRUS*

The vaccine virus shall be shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the chickens for which it is intended.

The following tests for index of respiratory virulence (section 2-4-1), safety (section 2-4-2), increase in virulence (section 2-4-3) and immunogenicity (section 2-4-4) may be used during the demonstration of safety and immunogenicity.

2-4-1. **Index of respiratory virulence**. Use for the test not fewer than sixty 10-day-old chickens from an SPF flock (*5.2.2*). Divide them randomly into 3 groups, maintained separately. Prepare 2 tenfold serial dilutions starting from a suspension of the vaccine virus having a titre of 10^5 EID_{50} or 10^5 $CCID_{50}$ per 0.2 ml or, if not possible, having the maximum attainable titre. Use vaccine virus at the least attenuated passage level that will be present in a batch of the vaccine. Allocate the undiluted virus suspension and the 2 virus dilutions each to a different group of chickens. Administer by the intratracheal route to each chicken 0.2 ml of the virus suspension attributed to its group. Observe the chickens for 10 days after administration and record the number of deaths. The index of respiratory virulence is the total number of deaths in the 3 groups divided by the total number of chickens. The vaccine virus complies with the test if its index of respiratory virulence is not greater than 0.33.

2-4-2. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination, using in each case chickens not older than the youngest age to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. For each test use not fewer than 20 chickens, from an SPF flock (*5.2.2*).

Administer to each chicken a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in 1 dose of the vaccine. Observe the chickens at least daily for 21 days. The test is not valid if more than 10 per cent of the chickens die from causes not attributable to the vaccine virus. The vaccine virus complies with the test if no chicken shows notable clinical signs of avian infectious laryngotracheitis or dies from causes attributable to the vaccine virus.

2-4-3. **Increase in virulence**. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to a group of 5 chickens not more than 2 weeks old, from an SPF flock (*5.2.2*), sequential passages, 5 times where possible, to further similar groups and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages. Administer by eye-drop a quantity of the vaccine virus that will allow recovery of virus for the passages described below. After the period shown to correspond to maximum replication of the virus, prepare a suspension from the mucosae of suitable parts of the respiratory tract of each chicken and pool these samples. Administer 0.05 ml of the pooled samples by eye-drop to each of 5 other chickens that are 2 weeks old and from an SPF flock (*5.2.2*). Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages. Determine the index of respiratory virulence (section 2-4-1) using the unpassaged vaccine virus and the maximally passaged virus that has been recovered; if the titre of the maximally passaged virus is less than 10^5 EID_{50} or 10^5 $CCID_{50}$, prepare the tenfold, serial dilutions using the highest titre available. The vaccine virus complies with the test if no indication of increase in virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-4-4. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended using in each case chickens not older than the youngest age to be recommended for vaccination. The quantity of the vaccine virus administered to each chicken is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of the vaccine. Use for the test not fewer than 30 chickens of the same origin and from an SPF flock (*5.2.2*). Vaccinate by a recommended route not fewer than 20 chickens. Maintain not fewer than 10 chickens as controls. Challenge each chicken after 21 days by the intratracheal route with a sufficient quantity of virulent infectious laryngotracheitis virus. Observe the chickens at least daily for 7 days after challenge. Record the deaths and the number of surviving chickens that show clinical signs of disease. At the end of the observation period euthanise all the surviving chickens and carry out examination for macroscopic lesions: mucoid, haemorrhagic and pseudomembraneous inflammation of the trachea and orbital sinuses. The test is not valid if:

– during the observation period after challenge fewer than 90 per cent of the control chickens die or show severe clinical signs of avian infectious laryngotracheitis or notable macroscopic lesions of the trachea and orbital sinuses,

– or if during the period between the vaccination and challenge more than 10 per cent of the vaccinated or control chickens show notable clinical signs of disease or die from causes not attributable to the vaccine.

The vaccine virus complies with the test if during the observation period after challenge not fewer than 90 per cent of the vaccinated chickens survive and show no notable clinical signs of disease and/or macroscopical lesions of the trachea and orbital sinuses.

3. BATCH TESTS

3-1. **Identification**. The vaccine, diluted if necessary and mixed with a monospecific infectious laryngotracheitis virus antiserum, no longer infects embryonated hens' eggs from an SPF flock (*5.2.2*) or susceptible cell cultures (*5.2.4*) into which it is inoculated.

3-2. **Bacteria and fungi**

Vaccines intended for administration by injection comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

Vaccines not intended for administration by injection either comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)* or with the following test: carry out a quantitative test for bacterial and fungal contamination; carry out identification tests for micro-organisms detected in the vaccine; the vaccine does not contain pathogenic micro-organisms and contains not more than 1 non-pathogenic micro-organism per dose.

Any liquid supplied with the vaccine complies with test for sterility in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas**. The vaccine complies with the test for mycoplasmas (*2.6.7*).

3-4. **Extraneous agents**. The vaccine complies with the tests for extraneous agents in batches of finished product (*2.6.25*).

3-5. **Safety**. Use not fewer than 10 chickens from an SPF flock (*5.2.2*) and of the youngest age recommended for vaccination. Administer by eye-drop to each chicken 10 doses of the vaccine. Observe the chickens at least daily for 21 days. The test is not valid if more than 20 per cent of the chickens show abnormal clinical signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no chicken shows notable clinical signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**. Titrate the vaccine virus by inoculation into embryonated hens' eggs from an SPF flock (*5.2.2*) or into suitable cell cultures (*5.2.4*). The vaccine complies with the test if 1 dose contains not less than the minimum titre stated on the label.

3-7. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-4-4) when administered according to the recommended schedule by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2008:1392

AVIAN PARAMYXOVIRUS 3 VACCINE (INACTIVATED)

Vaccinum paramyxoviris 3 aviarii inactivatum

1. DEFINITION

Avian paramyxovirus 3 vaccine (inactivated) is a preparation of a suitable strain of avian paramyxovirus 3, inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for protection of turkeys against a drop in egg production and loss of egg quality.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is propagated in embryonated eggs or in cell cultures. The vaccine may be adjuvanted.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Embryonated eggs**. If the vaccine virus is grown in embryonated eggs, they are obtained from healthy flocks.

2-2-2. **Cell cultures**. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *SEED LOTS*

2-3-1. **Extraneous agents**. The master seed lot complies with the tests for extraneous agents in seed lots (*2.6.24*). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the test.

2-4. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for each category of turkeys for which it is intended.

The following test for Immunogenicity (section 2-4-1) may be used during the demonstration of efficacy.

2-4-1. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended, using in each case turkeys of the minimum age to be recommended. The vaccine administered to each turkey is of minimum potency.

Use for the test 2 groups each of not fewer than 20 turkeys that do not have antibodies against avian paramyxovirus 3. Vaccinate one group in accordance with the recommendations to be stated on the label. Maintain the other group as controls.

The test is invalid if serological tests carried out on serum samples obtained at the time of first vaccination show the presence of antibodies against avian paramyxovirus 3 in either vaccinates or controls or if tests carried out at the time of challenge show such antibodies in controls.

At the egg-production peak, challenge the 2 groups by the oculo-nasal route with a sufficient quantity of a virulent strain of avian paramyxovirus 3. For not less than 6 weeks after challenge, record the number of eggs laid weekly for each group, distinguishing between normal and abnormal eggs. The vaccine complies with the test if egg production and quality are significantly better in the vaccinated group than in the control group.

2-5. *MANUFACTURER'S TESTS*

2-5-1. **Residual live virus**. The test for residual live virus is carried out in embryonated eggs or suitable cell cultures (*5.2.4*), whichever is the most sensitive for the vaccine strain. The quantity of inactivated virus harvest used in the test is equivalent to not less than 10 doses of vaccine. The vaccine complies with the test if no live virus is detected.

2-5-2. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-6) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency.

3. BATCH TESTS

3-1. **Identification**. When injected into animals that do not have antibodies against avian paramyxovirus 3, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 10 turkeys, 14 to 28 days old old and that do not have antibodies against avian paramyxovirus 3. Administer to each turkey by a recommended route a double dose of vaccine. Observe the birds at least daily for 21 days.

The vaccine complies with the test if no bird shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual live virus**. A test for residual live virus is carried out to confirm inactivation of avian paramyxovirus 3.

Inject 2/5th of a dose into the allantoic cavity of each of not fewer than 10 embryonated hen eggs 9-11 days old, from flocks free from specified pathogens (SPF) (*5.2.2*) and incubate. Observe for 6 days and pool separately the allantoic fluid from eggs containing live embryos, and that from eggs containing dead embryos, excluding those dying within 24 h of the injection. Examine embryos that die within 24 h of injection for the presence of avian paramyxovirus 3.

The vaccine does not comply with the test if avian paramyxovirus 3 is found.

Inject into the allantoic cavity of each of not fewer than ten 9- to 11-day-old fertilised hen eggs from an SPF flock (*5.2.2*), 0.2 ml of the pooled allantoic fluid from the live embryos and, into each of 10 similar eggs, 0.2 ml of the pooled fluid from the dead embryos, and incubate for 5 to 6 days. Test the allantoic fluid from each egg for the presence of haemagglutinins using chicken erythrocytes.

The vaccine complies with the test if there is no evidence of haemagglutinating activity and if not more than 20 per cent of the embryos die at either stage. If more than 20 per cent of the embryos die at one of the stages, repeat that stage; the vaccine complies with the test if there is no evidence of haemagglutinating activity and not more than 20 per cent of the embryos die at that stage. Antibiotics may be used in the test to control extraneous bacterial infection.

3-5. **Extraneous agents**. Administer to each chicken by a recommended route a double dose of the vaccine. Use 10 chickens, 14 to 28 days old and from a flock free from specified pathogens (*5.2.2*). After 3 weeks, inject one dose by the same route. Collect serum samples from each chicken 2 weeks later and carry out tests for antibodies against the following agents by the methods prescribed in general chapter *5.2.2. Chicken flocks free from specified pathogens for the production and quality control of vaccines*: avian

encephalomyelitis virus, avian infectious bronchitis virus, avian leucosis viruses, egg-drop syndrome virus, avian bursal disease virus, avian infectious laryngotracheitis virus, influenza A virus, Marek's disease virus. The vaccine complies with the test if it does not stimulate the formation of antibodies against these agents.

3-6. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-4-1) when administered by a recommended route and method.

01/2008:1956

AVIAN VIRAL TENOSYNOVITIS VACCINE (LIVE)

Vaccinum tenosynovitidis viralis aviariae vivum

1. DEFINITION

Avian viral tenosynovitis vaccine (live) is a preparation of a suitable strain of avian tenosynovitis virus (avian orthoreovirus). This monograph applies to vaccines intended for administration to chickens for active immunisation.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. Cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *SEED LOTS*

2-3-1. **Extraneous agents**. The master seed lot complies with the tests for extraneous agents in seed lots (*2.6.24*). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the tests.

2-4. *CHOICE OF VACCINE VIRUS*

The vaccine virus shall be shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the chickens for which it is intended.

The following tests for safety (section 2-4-1), increase in virulence (section 2-4-2) and immunogenicity (section 2-4-3) may be used during the demonstration of safety and immunogenicity.

2-4-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination using in each case chickens not older than the youngest age to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. For each test use not fewer than 20 chickens, from an SPF flock (*5.2.2*). Administer to each chicken a quantity of the vaccine virus not less than 10 times the maximum virus titre likely to be contained in 1 dose of the vaccine. Observe the chickens at least daily for 21 days. Carry out histological examination of the joints and tendon sheaths of the legs and feet at the end of the observation period (as a basis for comparison in the test for increase in virulence). The test is not valid if more than 10 per cent of the chickens die from causes not attributable to the vaccine virus. The vaccine virus complies with the test if no chicken shows notable clinical signs of avian viral tenosynovitis or dies from causes attributable to the vaccine virus.

2-4-2. **Increase in virulence**. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to a group of five 1-day-old chicks from an SPF flock (*5.2.2*), sequential passages, 5 times where possible, to further groups of 1-day-old chicks and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages. Administer by a suitable route a quantity of the vaccine virus that will allow recovery of virus for the passages described below. Euthanise the chickens at the moment when the virus concentration in the most suitable material (for example, tendons, tendon sheaths and liquid exudates from the hock joints, spleen) is sufficient. Prepare a suspension from this material from each chicken and pool these samples. Administer 0.1 ml of the pooled samples by the route of administration most likely to lead to increase in virulence to each of 5 other chickens of the same age and origin. Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages. Carry out the test for safety (section 2-4-1) using the unpassaged vaccine virus and the maximally passaged vaccine virus that has been recovered. The vaccine virus complies with the test if no indication of increase in virulence of the maximally passaged virus compared with the unpassaged virus is observed. If the virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-4-3. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended using in each case chickens not older than the youngest age to be recommended for vaccination. The quantity of the vaccine virus administered to each chicken is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of the vaccine. Use not fewer than 30 chickens of the same origin and from an SPF flock (*5.2.2*). Administer the vaccine by a recommended route to not fewer than 20 chickens. Maintain not fewer than 10 chickens as controls. Challenge each chicken after 21 days by a suitable route with a sufficient quantity of virulent avian tenosynovitis virus. Observe the chickens at least daily for 21 days after challenge. Record the deaths and the surviving chickens that show clinical signs of disease. If the challenge is administered by the foot pad, any transient swelling of the foot pad during the first 5 days after challenge may be considered non-specific. At the end of the observation period, euthanise all the surviving chickens and carry out macroscopic and/or microscopic examination for lesions of the joints and tendon sheaths of the legs and feet, e.g. exudate and swelling. The test is not valid if:

– during the observation period after challenge fewer than 80 per cent of the control chickens die or show severe clinical signs of avian viral tenosynovitis or show macroscopical and/or microscopical lesions in the joints and tendon sheaths of the legs and feet,

– or if during the period between vaccination and challenge more than 10 per cent of the control or vaccinated chickens show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine virus complies with the test if during the observation period after challenge not fewer than 90 per cent of the vaccinated chickens survive and show no notable clinical signs of disease or show macroscopical and/or microscopical lesions in the joints and tendon sheaths of the legs and feet.

3. BATCH TESTS

3-1. **Identification**. Carry out an immunostaining test in cell cultures to identify the vaccine virus.

3-2. **Bacteria and fungi**

Vaccines intended for administration by injection comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

Vaccines not intended for administration by injection either comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)* or with the following test: carry out a quantitative test for bacterial and fungal contamination; carry out identification tests for microorganisms detected in the vaccine; the vaccine does not contain pathogenic microorganisms and contains not more than 1 non-pathogenic microorganism per dose.

Any liquid supplied with the vaccine complies with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas**. The vaccine complies with the test for mycoplasmas (*2.6.7*).

3-4. **Extraneous agents**. The vaccine complies with the tests for extraneous agents in batches of finished product (*2.6.25*).

3-5. **Safety**. Use not fewer than 10 chickens from an SPF flock (*5.2.2*) and of the youngest age recommended for vaccination. Administer by a recommended route and method to each chicken 10 doses of the vaccine. Observe the chickens at least daily for 21 days. The test is not valid if more than 20 per cent of the chickens show abnormal clinical signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no chicken shows notable clinical signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**. Titrate the vaccine virus by inoculation into suitable cell cultures (*5.2.4*). The vaccine complies with the test if 1 dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-4-3) when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2008:1939

BOVINE LEPTOSPIROSIS VACCINE (INACTIVATED)

Vaccinum leptospirosis bovinae inactivatum

1. DEFINITION

Bovine leptospirosis vaccine (inactivated) is a preparation of inactivated whole organisms and/or antigenic extract(s) of one or more suitable strains of one or more of *Leptospira borgpetersenii* serovar hardjo, *Leptospira interrogans* serovar hardjo or other *L. interrogans* serovars, inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for the active immunisation of cattle against leptospirosis.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The seed material is cultured in a suitable medium; each strain is cultivated separately. During production, various parameters such as growth rate are monitored by suitable methods; the values are within the limits approved for the particular product. Purity and identity are verified on the harvest using suitable methods. After cultivation, the bacterial harvest is inactivated by a suitable method. The antigen may be concentrated. The vaccine may be adjuvanted.

2-2. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the cattle for which it is intended.

The following tests for safety (section 2-2-1) and immunogenicity (section 2-2-2) may be used during the demonstration of safety and efficacy.

2-2-1. **Safety**

2-2-1-1. *Laboratory tests.* Carry out the test for each route and method of administration to be recommended for vaccination and in cattle of each category for which the vaccine is intended (for example, young calves, pregnant cattle). Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine.

2-2-1-1-1. General safety. For each test, use not fewer than 10 cattle that do not have antibodies against *L. borgpetersenii* serovar hardjo and the principal serovars of *L. interrogans* (icterohaemorrhagiae, canicola, grippotyphosa, sejroe, hardjo, hebdomonadis, pomona, australis and autumnalis). Administer to each animal a double dose of the vaccine. If the schedule to be recommended requires a 2nd dose, administer one dose after the interval to be recommended. Observe the cattle at least daily for at least 14 days after the last administration. Record body temperatures the day before each vaccination, at vaccination, 4 h later and daily for 4 days.

The vaccine complies with the test if no animal shows abnormal local or systemic reactions, signs of disease, or dies from causes attributable to the vaccine.

2-2-1-1-2. Safety in pregnant cattle. If the vaccine is intended for use or may be used in pregnant cattle, use not fewer than 10 cows at the relevant stages of pregnancy. Administer to each cow a double dose of the vaccine. If the schedule to be recommended requires a 2nd dose, administer one dose after the interval to be recommended. Observe the cows at least daily until one day after calving. Record body temperatures the day before each vaccination, at vaccination, 4 h later and daily for 4 days.

The vaccine complies with the test if no cow shows notable signs of disease or dies from causes attributable to the vaccine and if no adverse effects on the pregnancy and offspring are noted.

2-2-1-2. *Field studies.* The cattle used for the field trials are also used to evaluate safety. Use not fewer than 3 groups of 20 cattle with corresponding groups of not fewer than 10 controls in 3 different locations. Examine the injection sites for local reactions after vaccination. Record body temperatures the day before vaccination, at vaccination and on the 2 days following vaccination.

The vaccine complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine. In addition, if the vaccine is for use in pregnant cattle, no adverse effects on the pregnancy and offspring are noted.

2-2-2. **Immunogenicity**. Carry out a separate test for each of the serovars for which a claim is made for a beneficial effect on the rates of infection and urinary excretion. If claims are to be made for protection against reproductive or production losses, further specific studies will be required.

Each test is carried out for each route and method of administration to be recommended, using in each case cattle of the minimum age to be recommended for vaccination. The vaccine administered to each animal is of minimum potency.

2-2-2-1. *Immunogenicity against L. borgpetersenii serovar hardjo*. Use not fewer than 15 cattle that do not have antibodies against *L. borgpetersenii* serovar hardjo and the principal serovars of *L. interrogans* (icterohaemorrhagiae, canicola, grippotyphosa, sejroe, hardjo, hebdomonadis, pomona, australis and autumnalis). Vaccinate not fewer than 10 cattle according to the schedule to be recommended. Maintain not fewer than 5 cattle as controls. 21 days after the last vaccination, challenge all the cattle by a suitable mucosal route with a sufficient quantity of a virulent strain of the relevant serovar. Observe the cattle at least daily for a further 35 days. Collect urine samples from each animal on days 0, 14, 21, 28 and 35 post-challenge. Euthanise surviving cattle at the end of the observation period. Carry out post-mortem examination on any animal that dies and on those euthanised at the end of the observation period. In particular, examine the kidneys for macroscopic and microscopic signs of leptospira infection. A sample of each kidney is collected and each urine and kidney sample is tested for the presence of the challenge organisms by re-isolation or by another suitable method.

For the test conducted with *L. borgpetersenii* serovar hardjo, control cattle are regarded as infected if the challenge organisms are re-isolated from at least 2 samples. The test is invalid if infection has been established in fewer than 80 per cent of the control cattle.

The vaccine complies with the test if the challenge organisms are re-isolated from any urine or kidney sample from not more than 20 per cent of the vaccinated cattle.

2-2-2-2. *Immunogenicity against other leptospira species*. For leptospiral species other than *L. borgpetersenii* serovar hardjo, the test is conducted as described in 2-2-2-1 but urine samples are collected on appropriate days, determined by the characteristics of the challenge model. In the case of serovars for which there is published evidence that the serovar has a lower tropism for the urinary tract, a lower rate of infection may be justified. Depending on their tissue tropism, for some leptospira serovars, samples from other tissues/body fluids can be used to establish whether the cattle are infected or not by the challenge organism.

2-3. *MANUFACTURER'S TESTS*

2-3-1. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-5) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

For each of the serovars for which protection is claimed, the antibody response from vaccinated animals is measured. Use not fewer than 12 guinea-pigs weighing 250-350 g that do not have antibodies against *L. borgpetersenii* serovar hardjo and the principal serovars of *L. interrogans* (icterohaemorrhagiae, canicola, grippotyphosa, sejroe, hardjo, hebdomonadis, pomona, australis and autumnalis) and that have been obtained from a regularly tested and certified leptospira-free source. The dose to be administered to the guinea-pigs is that fraction of a cattle dose which has been shown in the validation studies to provide a suitably sensitive test. Vaccinate each of 10 guinea-pigs with the suitable dose. Maintain not fewer than 2 guinea-pigs as controls. At a given interval within the range of 19-23 days after the injection, collect blood from each guinea-pig and prepare serum samples. Use a suitable validated method such as a micro-agglutination test to measure the antibodies in each sample.

The vaccine complies with the test if antibody levels are equal to or greater than those obtained with a batch that has given satisfactory results in the test described under Potency and there is no significant increase in antibody titre in the controls.

3. BATCH TESTS

3-1. **Identification**. When injected into healthy animals that do not have specific antibodies against the leptospira serovar(s) present in the vaccine, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. For vaccines recommended for use in cattle older than 6 months of age, use cattle not older than the minimum age recommended for vaccination and not younger than 6 months of age. For vaccines recommended for use in cattle less than 6 months of age, use cattle of the minimum age recommended for vaccination. Use 2 cattle that do not have antibodies against the leptospira serovar(s) present in the vaccine. Administer to each animal by a recommended route a double dose of the vaccine. Observe the cattle at least daily for 14 days.

The vaccine complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual live bacteria**. Carry out a test for live leptospirae by inoculation of a specific medium. Inoculate 1 ml of the vaccine into 100 ml of the medium. Incubate at 30 °C for 14 days, subculture into a further quantity of the medium and incubate both media at 30 °C for 14 days: the vaccine complies with the test if no growth occurs in either medium. At the same time, carry out a control test by inoculating a further quantity of the medium with the vaccine together with a quantity of a culture containing approximately 100 leptospirae and incubating at 30 °C: the test is invalid if growth of leptospirae does not occur within 14 days.

3-5. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-2-2) when administered by a recommended route and method.

corrected 6.0

BOVINE PARAINFLUENZA VIRUS VACCINE (LIVE)

Vaccinum viri parainfluenzae bovini vivum

1. DEFINITION

Bovine parainfluenza virus vaccine (live) is a preparation of a suitable strain of bovine parainfluenza 3 virus. This monograph applies to vaccines intended for the active immunisation of cattle against infection with bovine parainfluenza virus.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE VIRUS*

The vaccine virus is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the cattle for which it is intended.

The following tests for safety (section 2-3-1), increase in virulence (section 2-3-2) and immunogenicity (2-3-3) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine.

For each test, use not fewer than 5 calves of the minimum age to be recommended for vaccination and preferably that do not have antibodies against bovine parainfluenza 3 virus or, where justified, use calves with a very low level of such antibodies as long as they have not been vaccinated against bovine parainfluenza virus and administration of the vaccine does not cause an anamnestic response. Administer to each calf a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in one dose of the vaccine. Observe the calves at least daily for 21 days. Measure the body temperature of each calf on the day before vaccination, at the time of vaccination and for the 4 subsequent days.

The vaccine virus complies with the test if no abnormal effect on body temperature occurs and if no calf shows abnormal, local or systemic reactions or dies from causes attributable to the vaccine virus.

2-3-2. **Increase in virulence**. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to 2 calves that do not have antibodies against bovine parainfluenza 3 virus, sequential passages, 5 times where possible, to further similar groups and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages.

Administer to each calf by the intranasal route a quantity of the vaccine virus that will allow recovery of virus for the passages described below. On each of days 3 to 7 after administration of the virus, take nasal swabs from each calf and collect in not more than 5 ml of a suitable medium which is then used to inoculate cell cultures to verify the presence of virus. Administer about 1 ml of the suspension from the swabs that contain the maximum amount of virus, as indicated by the titration of cell cultures, to each of 2 other calves of the same age. Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages.

The vaccine virus complies with the test if no calf shows signs attributable to the vaccine virus and no indication of increased virulence of the maximally passaged virus compared with the unpassaged virus is observed; account is taken of the titre of excreted virus in the nasal swabs. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-3-3. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended for vaccination using in each case calves of the minimum age to be recommended. The quantity of vaccine to be administered to each calf is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of vaccine.

Use for the test not fewer than 10 calves that do not have antibodies against bovine parainfluenza 3 virus; calves having low levels of such antibodies may be used if it has been demonstrated that valid results are obtained in these conditions. Collect sera from the calves before vaccination, 7 days and 14 days after the time of vaccination and just before challenge. Vaccinate not fewer than 5 calves, according to the schedule to be recommended. Maintain not fewer than 5 calves as controls. Challenge each calf after 21 days by a respiratory tract route with a sufficient quantity of a suspension of a low-passage virulent bovine parainfluenza 3 virus. Observe the calves at least daily for 14 days after challenge and monitor each of them for signs, in particular respiratory signs and virus shedding (by nasal swabs or tracheobronchial washing).

The test is invalid if tests for antibodies against bovine parainfluenza 3 virus on the sera indicate that there was intercurrent infection with the virus during the test or if, during the observation period after challenge, more than 2 of the 5 control calves show no excretion of the challenge virus, as shown by nasal swabs or samples harvested by tracheobronchial washing. The vaccine virus complies with the test if during the observation period after challenge, in vaccinated calves compared to controls there is (a) a significant reduction in mean titre and in mean duration of virus excretion and (b) a notable reduction in general and local signs (if the challenge virus used produces such signs).

3. BATCH TESTS

3-1. **Identification**. Carry out an immunostaining test in suitable cell cultures, using a monospecific antiserum.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas** (*2.6.7*). The vaccine complies with the test for mycoplasmas.

3-4. **Extraneous agents**. Neutralise the vaccine virus with a suitable monospecific antiserum against bovine parainfluenza 3 virus and inoculate into cell cultures known for their susceptibility to viruses pathogenic for cattle. Carry out at least one passage and maintain the cultures for 14 days. The vaccine complies with the test if no cytopathic effect develops and there is no sign of the presence of haemadsorbing agents. Carry out a specific test for pestiviruses.

3-5. **Safety**. Use 2 calves of the minimum age recommended for vaccination and preferably that do not have antibodies against bovine parainfluenza 3 virus or, where justified, use calves with a very low level of such antibodies as long as they have not been vaccinated against bovine parainfluenza virus and administration of the vaccine does not cause an anamnestic response. Administer to each calf by a recommended route 10 doses of the vaccine. Observe the calves at least daily for 21 days.

The vaccine complies with the test if no calf shows notable signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**. Titrate the vaccine virus in suitable cell cultures. The vaccine complies with the test if one dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-3-3) when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

BOVINE RESPIRATORY SYNCYTIAL VIRUS VACCINE (LIVE)

Vaccinum viri syncytialis meatus spiritus bovini vivum

1. DEFINITION

Bovine respiratory syncytial virus vaccine (live) is a preparation of a suitable strain of bovine respiratory syncytial virus. This monograph applies to vaccines intended for the active immunisation of cattle against infection with bovine respiratory syncytial virus.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE VIRUS*

The vaccine virus is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the cattle for which it is intended.

The following tests for safety (section 2-3-1.), increase in virulence (section 2-3-2.) and immunogenicity (2-3-3.) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination, using in each case calves of the minimum age to be recommended. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine.

2-3-1-1. *Laboratory test.* For each test, use not fewer than 5 calves that do not have antibodies against bovine respiratory syncytial virus. Administer to each calf a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in one dose of the vaccine. Observe the calves at least daily for 21 days. Measure the rectal temperature of each calf on the day before vaccination, at the time of vaccination and daily for the following 7 days.

The vaccine virus complies with the test if no abnormal effect on body temperature occurs and if no calf shows abnormal local or systemic reactions or dies from causes attributable to the vaccine virus.

2-3-1-2. *Field studies.* The calves used for the field trials are also used to evaluate the incidence of hypersensitivity reactions in vaccinated calves following subsequent exposure to the vaccine or to wild virus. The vaccine complies with the test if it is not associated with an abnormal incidence of immediate hypersensitivity reactions.

2-3-2. **Increase in virulence**. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to 2 calves that do not have antibodies against bovine respiratory syncytial virus, sequential passages, 5 times where possible, to further similar groups and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages.

Administer to each calf by the intranasal route a quantity of the vaccine virus that will allow recovery of virus for the passages described below. On each of days 3 to 7 after administration of the virus, take nasal swabs from each calf and collect in not more than 5 ml of a suitable medium which is then used to inoculate cell cultures to verify the presence of virus. Administer about 1 ml of the suspension from the swabs that contain the maximum amount of virus, as indicated by the titration of cell cultures, to each of 2 other calves of the same age. Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages.

The vaccine virus complies with the test if no calf shows signs attributable to the vaccine virus and no indication of increased virulence of the maximally passaged virus compared with the unpassaged virus is observed; account is taken of the titre of excreted virus in the nasal swabs. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-3-3. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended for vaccination using in each case calves of the minimum age to be recommended. The quantity of vaccine to be administered

to each calf is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of vaccine.

Use for the test not fewer than 10 calves that do not have antibodies against bovine respiratory syncytial virus. Collect sera from the calves before the time of vaccination, 7 and 14 days after the time of vaccination and just before challenge. Vaccinate not fewer than 5 calves, according to the schedule to be recommended. Maintain not fewer than 5 calves as controls. Challenge each calf after 21 days by a respiratory tract route with a sufficient quantity of a suspension of a low-passage virulent bovine respiratory syncytial virus. Observe the calves at least daily for 14 days after challenge and monitor each of them for signs, in particular respiratory signs and virus shedding (by nasal swabs or tracheobronchial washing).

The test is invalid if antibodies against bovine respiratory syncytial virus are detected in any sample from control calves before challenge or if more than 2 of the 5 control calves show no excretion of the challenge virus, as shown by nasal swabs or samples harvested by tracheobronchial washing. The vaccine virus complies with the test if during the observation period after challenge, there is: (a) a significant reduction in mean titre and in mean duration of virus excretion in vaccinates compared to controls and (b) a notable reduction in general and local signs in vaccinated calves (if the challenge virus used produces such signs).

3. BATCH TESTS

3-1. **Identification**. Identify the vaccine by an immunostaining test in suitable cell cultures using a monospecific antiserum.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas** (*2.6.7*). The vaccine complies with the test for mycoplasmas.

3-4. **Extraneous agents**. Neutralise the vaccine virus with a suitable monospecific antiserum against bovine respiratory syncytial virus and inoculate into cell cultures known for their susceptibility to viruses pathogenic for cattle. Carry out at least one passage and maintain the cultures for 14 days. The vaccine complies with the test if no cytopathic effect develops and there is no sign of the presence of haemadsorbing agents. Carry out a specific test for pestiviruses.

3-5. **Safety**. Use 2 calves of the minimum age recommended for vaccination and that do not have antibodies against bovine respiratory syncytial virus. Administer to each calf by a recommended route 10 doses of the vaccine. Observe the calves at least daily for 21 days.

The vaccine complies with the test if no calf shows notable signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**. Titrate the vaccine virus in suitable cell cultures. The vaccine complies with the test if one dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-3-3.) when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2008:1952

BOVINE VIRAL DIARRHOEA VACCINE (INACTIVATED)

Vaccinum diarrhoeae viralis bovinae inactivatum

1. DEFINITION

Bovine viral diarrhoea vaccine (inactivated) is a preparation of one or more suitable strains of bovine diarrhoea virus inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for the active immunisation of heifers and cows for protection of their progeny against transplacental infection.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures. The viral suspensions of each vaccine virus are harvested separately and inactivated by a method that maintains immunogenicity. The viral suspensions may be purified and concentrated. The vaccine may be adjuvanted.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the cattle for which it is intended.

The following tests for safety (section 2-3-1.) and immunogenicity (section 2-3-2.) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination and in each category of cattle for which the vaccine is intended. Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine.

2-3-1-1. *General safety*. For each test, use not fewer than 10 cattle of the minimum age to be recommended for vaccination and that do not have bovine diarrhoea virus nor antibodies against the virus. Administer to each animal a double dose of the vaccine. Observe the cattle at least daily for 14 days.

The vaccine complies with the test if no animal shows abnormal local or systemic reactions or dies from causes attributable to the vaccine.

2-3-1-2. *Safety in pregnant cattle*. If the vaccine is intended for use in pregnant cattle, use not fewer than 10 cattle at the beginning of each semester for which use is not contraindicated. Administer to each animal a double dose of the vaccine. Observe the cattle at least daily until calving.

The vaccine complies with the test if no animal shows abnormal local or systemic reactions or dies from causes attributable to the vaccine and if no adverse effects on the pregnancy or the offspring are noted.

2-3-1-3. *Examination of reproductive performance*. If the vaccine is intended for administration shortly before or at insemination, absence of undesirable effects on conception rate must be demonstrated.

2-3-2. **Immunogenicity**. The following test is suitable to demonstrate the immunogenicity of the vaccine with respect to bovine diarrhoea virus of genotype 1; if protection against

bovine diarrhoea virus of genotype 2 is claimed, an additional test, similar to that described below, but using bovine diarrhoea virus of genotype 2 for challenge, is carried out.

A test is carried out for each route and method of administration to be recommended. The vaccine administered to each heifer is of minimum potency.

Use for the test not fewer than 20 heifers free from bovine diarrhoea virus and that do not have antibodies against bovine diarrhoea virus. Vaccinate not fewer than 13 heifers according to the schedule to be recommended. Maintain not fewer than 7 heifers as controls. Keep all the animals as one group. Inseminate the heifers. Take a blood sample from non-vaccinated heifers shortly before challenge. The test is discontinued if fewer than 10 vaccinated heifers or 5 non-vaccinated heifers are pregnant at the time of challenge. Challenge each heifer between the 60th and 90th days of gestation. For both test models described (observation until calving and harvest of foetuses at 28 days), challenge may be made by the intranasal route with a sufficient quantity of a non-cytopathic strain of bovine diarrhoea virus or alternatively, where the heifers are observed until calving, challenge may be made by contact with a persistently viraemic animal. Observe the heifers clinically at least daily from challenge either until the end of gestation or until harvest of foetuses after 28 days. If abortion occurs, examine the aborted foetus for bovine diarrhoea virus by suitable methods. If cattle are observed until calving, immediately after birth and prior to ingestion of colostrum, examine all calves for viraemia and antibodies against bovine diarrhoea virus. If foetuses are harvested 28 days after challenge, examine the foetuses for bovine diarrhoea virus by suitable methods. Transplacental infection is considered to have occurred if virus is detected in foetal organs or in the blood of newborn calves or if antibodies are detected in precolostral sera of calves.

The test is invalid if any of the control heifers have neutralising antibody before challenge or if transplacental infection fails to occur in more than 10 per cent of the calves from the control heifers. The vaccine complies with the test if at least 90 per cent of the calves from the vaccinated heifers are protected from transplacental infection.

2-4. *MANUFACTURER'S TESTS*

2-4-1. **Residual live virus**. The test for residual live virus is carried out using a quantity of inactivated virus harvest equivalent to not less than 25 doses of vaccine in cells of the same type as those used for production of the vaccine or cells shown to be at least as sensitive; the cells are passaged after 7 days and observed for a total of not less than 14 days. The inactivated virus harvest complies with the test if no live virus is detected.

2-4-2. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-5.) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

Use for the test 7 suitable laboratory animals or calves that do not have antibodies against bovine diarrhoea virus. Administer by the subcutaneous route to 5 animals a suitable dose of the vaccine. Maintain 2 animals as controls. A 2nd dose of vaccine may be administered after a suitable interval if this has been shown to provide a suitably discriminating test system. Collect blood samples before the first vaccination and at a given interval between 14 and 21 days after the last vaccination. Determine the antibody titres against bovine diarrhoea virus by seroneutralisation on suitable cell cultures.

The test is invalid if the control animals show antibodies against bovine diarrhoea virus. The vaccine complies with the test if the level of antibodies in the vaccinates is not lower than that found for a batch of vaccine that has given satisfactory results in the test described under Potency.

3. BATCH TESTS

3-1. **Identification**. When administered to animals that do not have specific neutralising antibodies against bovine diarrhoea virus, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 cattle not older than the minimum age recommended for vaccination and that do not have bovine diarrhoea virus nor antibodies against the virus. Administer to each animal by a recommended route a double dose of the vaccine. Observe the cattle at least daily for 14 days.

The vaccine complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual live virus**. Carry out a test for residual live bovine diarrhoea virus by inoculating not less than 10 doses onto cells known to be sensitive to bovine diarrhoea virus; passage the cells after 7 days and observe the second culture for not less than 7 days. The vaccine complies with the test if no live virus is detected. If the vaccine contains an adjuvant, separate the adjuvant if possible from the liquid phase by a method that does not interfere with the detection of possible live virus.

3-5. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-3-2.) when administered by a recommended route and method.

corrected 6.0

BRUCELLOSIS VACCINE (LIVE) (BRUCELLA MELITENSIS REV. 1 STRAIN) FOR VETERINARY USE

Vaccinum brucellosis (Brucella melitensis stirpe Rev. 1) vivum ad usum veterinarium

1. DEFINITION

Brucellosis vaccine (live) (Brucella melitensis Rev. 1 strain) for veterinary use is a suspension of live *Brucella melitensis* Rev. 1 strain. The vaccine contains not fewer than 0.5×10^9 and not more than 4×10^9 live bacteria per dose. This monograph applies to vaccines intended for the active immunisation of sheep and goats against disease caused by *B. melitensis*.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

B. Melitensis Rev. 1 strain is cultured in a suitable medium. The method of culture is such as to avoid bacterial dissociation and thus maintain the smooth characteristic of the culture. The bacteria are suspended in a buffer solution which may contain a suitable stabiliser. The suspension is distributed into containers.

2-2. *CHOICE OF VACCINE STRAIN*

The vaccine strain is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the sheep and goats for which it is intended.

The following test for immunogenicity (section 2-2-1) may be used during the demonstration of efficacy.

2-2-1. **Immmunogenicity**. Each test is carried out for each route and method of administration to be recommended, using in each case ewe lambs of 4-5 months old. The quantity of the vaccine strain to be administered to each ewe lamb is not greater than the minimum live bacteria titre to be stated on the label.

Use for the test not fewer than 40 ewe lambs from a non-vaccinated flock free from brucellosis. For the challenge strain, a 24-hour culture of *B. melitensis* strain H38 in trypticase agar is used. Carry out a preliminary test using ewe lambs of the same breed and age as for the main test to determine the challenge dose, which is between 10^7 and 10^8 colony-forming units and is chosen so as to produce abortion in all non-vaccinated ewes. Vaccinate not fewer than 20 ewe lambs at 4-6 months of age, according to the schedule to be recommended. Maintain not fewer than 20 ewe lambs as controls. Oestrus is synchronised in the 40 ewes which are then inseminated at 10-12 months of age. Make a diagnosis of pregnancy on all ewes 2-3 months after insemination and exclude all non-gravid ewes from the test. Challenge each gravid ewe by the conjunctival route with a sufficient quantity of *B. melitensis* strain H38. Note the occurrence of abortion and confirm aetiology by testing for the presence of the challenge strain in the aborted foetus and in the ewe (using selective media of Kuzdas and Morse or of Farrell). Carry out tests for the presence of the challenge strain on each ewe at lambing. Carry out tests for the presence of the challenge strain in the prescapular and retromammary lymph nodes at slaughter of the ewes 4-6 weeks after lambing.

The test is invalid unless at least 70 per cent of non-vaccinated ewes:

– show abortion caused by the challenge strain;
– show infection with the challenge strain at lambing;
– show infection of the prescapular and retromammary lymph nodes at slaughter.

The vaccine complies with the test if:

– not more than 30 per cent of vaccinated ewes show abortion caused by the challenge strain;
– the challenge strain is found in not more than 50 per cent of vaccinated ewes at lambing;
– the challenge strain is found in not more than 40 per cent of vaccinated ewes at slaughter.

3. BATCH TESTS

3-1. **Identification**. *B. melitensis* present in the vaccine is identified by suitable morphological, serological and biochemical tests and by culture: Rev. 1 strain is inhibited by addition to the suitable culture medium of 3 µg of benzylpenicillin sodium per millilitre; the strain grows on agar containing 2.5 µg of streptomycin per millilitre.

3-2. **Safety**. Use 2 sheep 4-6 months old and that do not have antibodies against *B. melitensis*. Administer to each sheep by a recommended route one dose of the vaccine. Observe the sheep at least daily for 21 days.

The vaccine complies with the test if no sheep shows notable signs of disease or dies from causes attributable to the vaccine.

3-3. **Determination of dissociation phase**. Examine not fewer than 200 colonies by a suitable technique. The culture of the vaccine strain is seen to be in the smooth (S) phase.

The vaccine complies with the test if not fewer than 95 per cent of the colonies are of the smooth type.

3-4. **Extraneous micro-organisms**. The vaccine complies with the test if it does not contain extraneous micro-organisms. Verify the absence of micro-organisms other than *Brucella melitensis* Rev. 1 strain as described in the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

3-5. **Live bacteria**. Make a count of live bacteria on a solid medium suitable for the culture of *Brucella melitensis* Rev. 1 strain.

The vaccine complies with the test if it contains not fewer than 0.5×10^9 and not more than 4×10^9 live bacteria per dose.

3-6. **Fifty per cent persistence time**. Use 32 female CD1 mice, 5-6 weeks old. Vaccinate each mouse by the subcutaneous route with a suspension containing 10^8 live bacteria of the vaccine to be examined. Euthanise the mice in groups of 8, selected at random, 3, 6, 9 and 12 weeks later. Remove the spleens and homogenise individually and aseptically in 10 volumes of *phosphate buffered saline pH 6.8 R*. Spread the suspension on plates containing a suitable culture medium, using 0.4 ml per plate and not fewer than 3 plates per spleen (lower limit of detection: 5 bacteria per spleen). Carry out in parallel a similar test using *Brucella melitensis Rev. 1 strain BRP* (reference strain). Calculate the 50 per cent persistence time by the usual statistical methods (*5.3*) for probit analysis.

The vaccine complies with the test if the 50 per cent persistence time for the vaccine strain does not differ significantly from that of the reference strain.

4. LABELLING

The label states:

– that the vaccine may be dangerous for man;
– that the vaccine is not to be used in pregnant or lactating animals;
– that the vaccine may be dangerous for cattle and that they are not to be kept in contact with vaccinated animals.

01/2008:1953

CALF CORONAVIRUS DIARRHOEA VACCINE (INACTIVATED)

Vaccinum inactivatum diarrhoeae vituli coronaviro illatae

1. DEFINITION

Calf coronavirus diarrhoea vaccine (inactivated) is a preparation of one or more suitable strains of bovine coronavirus, inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for the active immunisation of dams for passive protection of their progeny against coronavirus diarrhoea during the first few weeks of life.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

Each vaccine virus is grown separately in cell cultures. The viral suspensions of each vaccine virus are harvested separately and inactivated by a method that maintains immunogenicity. The viral suspensions may be purified and concentrated. The vaccine may be adjuvanted.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the pregnant cows for which it is intended.

The following tests for safety (section 2-3-1.) and immunogenicity (section 2-3-2.) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination, using in each case cows that have not been vaccinated against bovine coronavirus. Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine.

For each test, use not fewer than 10 cows at the stage or at different stages of pregnancy according to the schedule to be recommended. Administer to each cow a double dose of the vaccine, then one dose after the interval to be recommended. After each injection, measure the body temperature on the day of the injection and on the 4 following days. Observe the cows at least daily until calving.

The vaccine complies with the test if no cow shows abnormal local or systemic reactions or dies from causes attributable to the vaccine and if no adverse effects on the pregnancy or the offspring are noted.

2-3-2. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended. The vaccine administered to each cow is of minimum potency.

Use for the test not fewer than 15 pregnant cows, preferably that do not have antibodies against bovine coronavirus. Where such cows are not available, use cows that: have not been vaccinated against bovine coronavirus; come from a farm where there is no recent history of infection with bovine coronavirus; and have a low level of antibodies against bovine coronavirus, the levels being comparable in all cows. Vaccinate not fewer than 10 pregnant cows according to the schedule to be recommended. Maintain not fewer than 5 pregnant cows as controls. Starting at calving, take the colostrum and then milk from each cow and keep it in suitable conditions. Determine individually the protective activity of the colostrum and milk from each cow using calves born from healthy cows, and which may be born by Caesarean section, and maintained in an environment where they are not exposed to infection by bovine coronavirus. Feed colostrum and then milk to each calf every 6 h or according to the recommended schedule. At 5-7 days after birth, challenge each calf by the oral route with a sufficient quantity of a virulent strain of bovine coronavirus. Observe the calves at least daily for 7 days. Note the incidence, severity and duration of diarrhoea and the duration and quantity of virus excretion.

The vaccine complies with the test if there is a significant reduction in diarrhoea and virus excretion in calves given colostrum and milk from vaccinated cows compared to those given colostrum and milk from controls.

2-4. *MANUFACTURER'S TESTS*

2-4-1. **Residual live virus**. The test for residual live virus is carried out using 2 passages in cell cultures of the same type as those used for production or in cells shown to be at least as sensitive. The quantity of inactivated virus harvest used in the test is equivalent to not less than 10 doses of vaccine. The inactivated virus harvest complies with the test if no live virus is detected.

2-4-2. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-6.) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

To obtain a valid assay, it may be necessary to carry out a test using several groups of animals, each receiving a different dose. For each dose required, carry out the test as follows. Use for the test not fewer than 7 animals of a suitable species, that do not have specific antibodies against bovine coronavirus. Vaccinate not fewer than 5 animals using 1 injection of a suitable dose. Maintain not fewer than 2 animals as controls. Where the recommended schedule requires a booster injection to be given, a booster vaccination may also be given in this test provided it has been demonstrated that this will still provide a suitably sensitive test system. At a given interval not less than 14 days after the last injection, collect blood from each animal and prepare serum samples. Use a suitable validated test to measure the antibody response. The vaccine complies with the test if the antibody level in the vaccinates is not significantly less than that obtained with a batch that has given satisfactory results in the test described under Potency and there is no significant increase in antibody titre in the controls.

3. BATCH TESTS

3-1. **Identification**. Injected into animals that do not have specific antibodies against bovine coronavirus, the vaccine stimulates the formation of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 cattle not less than 6 months old and preferably, that do not have antibodies against bovine coronavirus or where justified, use cattle with a low level of such antibodies as long as they have not been vaccinated against bovine coronavirus and administration of the vaccine does not cause an anamnestic response. Administer to each animal by a recommended route a double dose of the vaccine, then one dose after 14 days. Observe the cattle at least daily until 14 days after the last administration.

The vaccine complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual live virus**. Carry out a test for residual live virus using 10 doses of vaccine and 2 passages in cell cultures of the same type as those used for production of the vaccine or other cell cultures of suitable sensitivity. The vaccine complies with the test if no live virus is detected. If the vaccine contains an adjuvant which interferes with the test, separate it if possible from the liquid phase of the vaccine by a method that does not inactivate virus nor interfere in any other way with detection of live viruses.

3-5. **Extraneous agents**. Carry out tests for antibodies on the cattle used for the safety test. Take a blood sample at the end of the second observation period. The vaccine complies with the test if it does not stimulate the formation of antibodies against bovine herpesvirus 1 (BHV1), bovine leukaemia virus (BLV) and bovine viral diarrhoea virus (BVDV).

3-6. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-3-2.) when administered by a recommended route and method.

4. LABELLING

The label states the recommended schedule for administering colostrum and milk, *post-partum*.

01/2008:1954

CALF ROTAVIRUS DIARRHOEA VACCINE (INACTIVATED)

Vaccinum inactivatum diarrhoeae vituli rotaviro illatae

1. DEFINITION

Calf rotavirus diarrhoea vaccine (inactivated) is a preparation of one or more suitable strains of bovine rotavirus, inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for the active immunisation of dams for passive protection of their progeny against rotavirus diarrhoea during the first few weeks of life.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

Each vaccine virus is grown separately in cell cultures. The viral suspensions of each vaccine virus are harvested separately and inactivated by a method that maintains immunogenicity. The viral suspensions may be purified and concentrated. The vaccine may be adjuvanted.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the pregnant cows for which it is intended.

The following tests for safety (section 2-3-1.) and immunogenicity (section 2-3-2.) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination, using in each case cows that have not been vaccinated against bovine rotavirus. Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine.

For each test, use not fewer than 10 cows at the stage or at different stages of pregnancy according to the schedule to be recommended. Administer to each cow a double dose of the vaccine, then one dose after the interval to be recommended. After each injection, measure the body temperature on the day of the injection and on the 4 following days. Observe the cows at least daily until calving.

The vaccine complies with the test if no cow shows abnormal local or systemic reactions or dies from causes attributable to the vaccine and if no adverse effects on the pregnancy or the offspring are noted.

2-3-2. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended. The vaccine administered to each cow is of minimum potency.

Use for the test not fewer than 15 pregnant cows, preferably that do not have antibodies against bovine rotavirus. Where such cows are not available, use cows that: have not been vaccinated against bovine rotavirus; come from a farm where there is no recent history of infection with bovine rotavirus; and have a low level of antibodies against bovine rotavirus, the levels being comparable in all cows. Vaccinate not fewer than 10 pregnant cows according to the schedule to be recommended. Maintain not fewer than 5 pregnant cows as controls. Starting at calving, take the colostrum and then milk from each cow and keep it in suitable conditions. Determine individually the protective activity of the colostrum and milk from each cow using calves born from healthy cows, and which may be born by Caesarean section, and maintained in an environment where they are not exposed to infection by bovine rotavirus. Feed colostrum and then milk to each calf every 6 h or according to the recommended schedule. At 5-7 days after birth, challenge each calf by the oral route with a sufficient quantity of a virulent strain of bovine rotavirus. Observe the calves at least daily for 7 days. Note the incidence, severity and duration of diarrhoea and the duration and quantity of virus excretion.

The vaccine complies with the test if there is a significant reduction in diarrhoea and virus excretion in calves given colostrum and milk from vaccinated cows compared to those given colostrum and milk from controls.

2-4. *MANUFACTURER'S TESTS*

2-4-1. **Residual live virus**. The test for residual live virus is carried out using 2 passages in cell cultures of the same type as those used for production or in cells shown to be at least as sensitive. The quantity of inactivated virus harvest used in the test is equivalent to not less than 100 doses of vaccine. The inactivated viral harvest complies with the test if no live virus is detected.

2-4-2. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-6.) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

To obtain a valid assay, it may be necessary to carry out a test using several groups of animals, each receiving a different dose. For each dose required, carry out the test as follows. Use for the test not fewer than 7 animals of a suitable species that do not have antibodies against bovine rotavirus. Vaccinate not fewer than 5 animals, using 1 injection of a suitable dose. Maintain not fewer than 2 animals as controls. Where the recommended schedule requires a booster injection to be given, a booster vaccination may also be given in this test provided it has been demonstrated that this will still provide a suitably sensitive test system. At a given interval not less than 14 days after the last injection, collect blood from each animal and prepare serum samples. Use a suitable validated test to measure the antibody response. The vaccine complies with the test if the antibody level in the vaccinates is not significantly less than that obtained with a batch that has given satisfactory results in the test

described under Potency and there is no significant increase in antibody titre in the controls.

3. BATCH TESTS

3-1. **Identification**. Injected into animals that do not have specific antibodies against bovine rotavirus, the vaccine stimulates the formation of such antibodies.

3-2. **Bacteria and fungi**. The vaccine complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 cattle not less than 6 months old and preferably, that do not have antibodies against bovine rotavirus or where justified, use cattle with a low level of such antibodies as long as they have not been vaccinated against bovine rotavirus and administration of the vaccine does not cause an anamnestic response. Administer to each animal by a recommended route a double dose of the vaccine, then one dose after 14 days. Observe the cattle at least daily until 14 days after the last administration.

The vaccine complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual live virus**. Carry out a test for residual live virus using 10 doses of vaccine and 2 passages in cell cultures of the same type as those used for production of the vaccine or other cell cultures of suitable sensitivity. The vaccine complies with the test if no live virus is detected. If the vaccine contains an adjuvant which interferes with the test, separate it if possible from the liquid phase of the vaccine by a method that does not inactivate virus nor interfere in any other way with detection of live viruses.

3-5. **Extraneous agents**. Carry out tests for antibodies on the cattle used for the safety test. Take a blood sample at the end of the second observation period. The vaccine complies with the test if it does not stimulate the formation of antibodies against bovine herpesvirus 1 (BHV 1), bovine leukaemia virus (BLV) and bovine viral diarrhoea virus (BVDV).

3-6. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-3-2.) when administered by a recommended route and method.

4. LABELLING

The label states the recommended schedule for administering colostrum and milk, *post-partum*.

01/2008:1298

CANINE ADENOVIRUS VACCINE (INACTIVATED)

Vaccinum adenovirosis caninae inactivatum

1. DEFINITION

Canine adenovirus vaccine (inactivated) is a preparation of one or more suitable strains of canine adenovirus 1 (canine contagious hepatitis virus) and/or canine adenovirus 2, inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for the active immunisation of dogs against canine contagious hepatitis caused by canine adenovirus.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures. The virus harvest is inactivated. The vaccine may be adjuvanted.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the dogs for which it is intended.

The following tests for safety (section 2-3-1) and immunogenicity (section 2-3-2) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination. Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine.

2-3-1-1. *General safety*. For each test, use not fewer than 10 dogs of the minimum age to be recommended and that do not have antibodies against canine adenovirus 1 or 2. Administer to each dog a double dose of the vaccine. If the schedule to be recommended requires a second dose, administer one dose after the interval to be recommended. Observe the dogs at least daily until 14 days after the last administration.

The vaccine complies with the test if no dog shows abnormal local or systemic reactions or dies from causes attributable to the vaccine.

2-3-1-2. *Safety in pregnant bitches*. If the vaccine is intended for use in pregnant bitches, use not fewer than 10 bitches at the stage of pregnancy or at different stages of pregnancy according to the schedule to be recommended. Administer to each bitch a double dose of the vaccine. If the schedule to be recommended requires a second dose, administer one dose after the interval to be recommended. Observe the bitches at least daily until one day after whelping.

The vaccine complies with the test if no bitch shows abnormal local or systemic reactions or dies from causes attributable to the vaccine and if no adverse effects on the pregnancy or the offspring are noted.

2-3-2. **Immunogenicity**. For vaccines intended to protect against hepatitis, the test described below is suitable for demonstration of immunogenicity. If the vaccine is indicated for protection against respiratory signs, a further test to demonstrate immunogenicity for this indication is also necessary.

A test is carried out for each route and method of administration to be recommended for vaccination, using in each case dogs of the minimum age to be recommended. The vaccine administered to each dog is of minimum potency.

Use for the test not fewer than 7 dogs that do not have antibodies against canine adenovirus. Vaccinate not fewer than 5 dogs, according to the schedule to be recommended. Maintain not fewer than 2 dogs as controls. Challenge each dog after 21 days by the intravenous route with a sufficient quantity of a suspension of pathogenic canine adenovirus. Observe the dogs at least daily for 21 days after challenge. Dogs displaying typical signs of serious infection with canine adenovirus are euthanised to avoid unnecessary suffering.

The test is invalid if, during the observation period after challenge, fewer than 100 per cent of the control dogs die from or show typical signs of serious infection with canine adenovirus. The vaccine complies with the test if, during the observation period, all the vaccinated dogs survive and show no signs of disease.

2-4. *MANUFACTURER'S TESTS*

2-4-1. **Residual live virus**. The test for residual live virus is carried out using a quantity of inactivated virus harvest equivalent to at least 10 doses of vaccine with 2 passages in cell cultures of the same type as those used for production or in cell cultures shown to be at least as sensitive. The inactivated viral harvest complies with the test if no live virus is detected.

2-4-2. **Batch potency**. It is not necessary to carry out the Potency test (section 3-5) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency.

3. BATCH TESTS

3-1. **Identification**. When injected into animals that do not have specific antibodies against the type or types of canine adenovirus stated on the label, the vaccine stimulates the formation of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 dogs of the minimum age recommended for vaccination and preferably, that do not have canine adenovirus-neutralising antibodies or, where justified, use dogs with a low level of such antibodies as long as they have not been vaccinated against canine adenovirosis and administration of the vaccine does not cause an anamnestic response. Administer to each dog by a recommended route a double dose of the vaccine. Observe the dogs at least daily for 14 days.

The vaccine complies with the test if no dog shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual live virus**. Carry out a test for residual canine adenovirus using 10 doses of vaccine by inoculation into sensitive cell cultures; make a passage after 6-8 days and maintain the cultures for 14 days. The vaccine complies with the test if no live virus is detected. If the vaccine contains an adjuvant, separate the adjuvant from the liquid phase by a method that does not inactivate or otherwise interfere with the detection of live virus.

3-5. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-3-2) when administered by a recommended route and method.

01/2008:1951

CANINE ADENOVIRUS VACCINE (LIVE)

Vaccinum adenovirosidis caninae vivum

1. DEFINITION

Canine adenovirus vaccine (live) is a preparation of one or more suitable strains of canine adenovirus 2. This monograph applies to vaccines intended for the active immunisation of dogs against canine contagious hepatitis and/or respiratory disease caused by canine adenovirus.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE VIRUS*

The vaccine virus is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the dogs for which it is intended.

The following tests for safety (section 2-3-1), increase in virulence (section 2-3-2) and immunogenicity (2-3-3) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine.

2-3-1-1. *General safety*. For each test, use not fewer than 5 dogs of the minimum age to be recommended for vaccination, that do not have antibodies against canine adenovirus. Administer to each dog a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in one dose of the vaccine. Observe the dogs at least daily for 14 days.

The vaccine virus complies with the test if no dog shows abnormal local or systemic reactions, signs of disease or dies from causes attributable to the vaccine virus.

2-3-1-2. *Safety in pregnant bitches*. If the vaccine is intended for use or may be used in pregnant bitches, use not fewer than 5 bitches, at the stage of pregnancy to be recommended or at a range of stages of pregnancy according to the schedule to be recommended. Administer to each bitch a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in one dose of the vaccine. Observe the bitches at least daily until one day after whelping.

The vaccine virus complies with the test if no bitch shows abnormal local or systemic reactions, signs of disease or dies from causes attributable to the vaccine virus and if no adverse effects on the pregnancy or the offspring are noted.

2-3-2. **Increase in virulence**. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to 2 dogs 5-7 weeks-old, that do not have antibodies against canine adenovirus, sequential passages, 5 times where possible, to further similar groups and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages.

Administer to each dog by a route to be recommended a quantity of the vaccine virus that will allow recovery of virus for the passages described below. Administer the virus by the route to be recommended for vaccination most likely to lead to reversion of virulence. After 4-6 days, prepare a suspension from the nasal and pharyngeal mucosa, tonsils, lung, spleen and if they are likely to contain virus, liver and kidney of each dog and pool the samples. Administer 1 ml of the pooled samples by a suitable route - for example, the intranasal route - to each of 2 other dogs of the same age. Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. If the virus

is not found at a passage level, carry out a second series of passages.

Carry out the test for safety (section 2-3-1) using unpassaged vaccine virus and the maximally passaged virus that has been recovered.

The vaccine virus complies with the test if no indication of increased virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-3-3. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended for vaccination using in each case dogs of the minimum age to be recommended. The quantity of vaccine virus to be administered to each dog is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of vaccine.

2-3-3-1. *Vaccines intended to protect against hepatitis.* Use for the test not fewer than 7 dogs that do not have antibodies against canine adenovirus. Vaccinate not fewer than 5 dogs, according to the schedule to be recommended. Maintain not fewer than 2 dogs as controls. Challenge each dog after 21 days by the intravenous route with a sufficient quantity of a suspension of virulent canine adenovirus 1 (canine contagious hepatitis virus). Observe the dogs at least daily for 21 days after challenge. Dogs displaying typical signs of serious infection with canine adenovirus are euthanised to avoid unnecessary suffering.

The test is invalid if during the observation period after challenge, fewer than 100 per cent of the control dogs die or show notable signs of canine adenovirosis. The vaccine virus complies with the test if during the observation period after challenge, all the vaccinated dogs survive and show no signs of disease except for a possible transient elevated rectal temperature.

2-3-3-2. *Vaccine intended to protect against respiratory signs.* Use for the test not fewer than 20 dogs that do not have antibodies against canine adenovirus. Vaccinate not fewer than 10 dogs, according to the schedule to be recommended. Maintain not fewer than 10 dogs as controls. Challenge each dog after 21 days by the intranasal route with a quantity of a suspension of virulent canine adenovirus 2 sufficient to cause typical signs of respiratory disease in a dog that does not have antibodies against canine adenovirus. Observe the dogs at least daily for 10 days after challenge. Record the incidence of signs of respiratory and general disease in each dog (for example, sneezing, coughing, nasal and lachrymal discharge, loss of appetite). Collect nasal swabs or washings from each dog daily from days 2 to 10 after challenge and test these samples to determine the presence and titre of excreted virus.

The vaccine complies with the test if there is a notable decrease in the incidence and severity of signs and in virus excretion in vaccinates compared to controls.

3. BATCH TESTS

3-1. **Identification**. The vaccine mixed with monospecific antiserum against canine adenovirus 2 no longer infects susceptible cell cultures.

3-2. **Bacteria and fungi**. The vaccine and where applicable, the liquid supplied with it, comply with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas** (*2.6.7*). The vaccine complies with the test for mycoplasmas.

3-4. **Extraneous agents**. Neutralise the vaccine virus with a suitable monospecific antiserum against canine adenovirus 2 and inoculate into cell cultures known for their susceptibility to viruses pathogenic for the dog. Carry out a passage after 6-8 days and maintain the cultures for a total of 14 days. The vaccine complies with the test if no cytopathic effect develops and there is no sign of the presence of haemadsorbing agents.

3-5. **Safety**. Use 2 dogs not older than the minimum age recommended for vaccination and that do not have antibodies against canine adenovirus. Administer to each dog by a recommended route 10 doses of the vaccine. Observe the dogs at least daily for 14 days. The vaccine complies with the test if no dog shows notable signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**. Titrate the vaccine virus in suitable cell cultures. The vaccine complies with the test if one dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency**. The vaccine complies with the requirements of one or both of the tests prescribed under Immunogenicity (section 2-3-3) when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

CANINE DISTEMPER VACCINE (LIVE)

Vaccinum morbi Carrei vivum ad canem

1. DEFINITION

Canine distemper vaccine (live) is a preparation of a suitable strain of distemper virus. This monograph applies to vaccines intended for the active immunisation of dogs against canine distemper.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in embryonated hens' eggs or in cell cultures.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Embryonated hens' eggs**. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from flocks free from specified pathogens (SPF) (*5.2.2*).

2-2-2. **Cell cultures**. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE VIRUS*

The vaccine virus is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the dogs for which it is intended.

The following tests for safety (section 2-3-1), increase in virulence (section 2-3-2) and immunogenicity (2-3-3) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine.

2-3-1-1. *General safety.* For each test, use not fewer than 5 dogs of the minimum age to be recommended for vaccination, that do not have antibodies against canine distemper virus.

Administer to each dog a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in one dose of the vaccine. Observe the dogs at least daily for 42 days.

The vaccine virus complies with the test if no dog shows abnormal local or systemic reactions, signs of disease or dies from causes attributable to the vaccine virus.

2-3-1-2. *Safety in pregnant bitches.* If the vaccine is intended for use in pregnant bitches, use not fewer than 5 bitches at the stage of pregnancy to be recommended or at a range of stages of pregnancy according to the schedule to be recommended. Administer to each bitch a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in one dose of the vaccine. Observe the bitches at least daily until one day after whelping.

The vaccine virus complies with the test if no bitch shows abnormal local or systemic reactions, signs of disease or dies from causes attributable to the vaccine virus and if no adverse effects on the pregnancy or the offspring are noted.

2-3-2. **Increase in virulence**. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to 2 dogs 5-7 weeks-old, that do not have antibodies against canine distemper virus, sequential passages, 5 times where possible, to further similar groups and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages.

Administer to each dog by a route to be recommended a quantity of the vaccine virus that will allow recovery of virus for the passages described below. Administer the virus by the route to be recommended for vaccination most likely to lead to reversion to virulence. After 5-10 days, prepare a suspension from the nasal mucosa, tonsils, thymus, spleen and the lungs and their local lymph nodes of each dog and pool the samples. Administer 1 ml of the pooled samples by the intranasal route to each of 2 other dogs of the same age. Carry out this passage operation not fewer than 5 times ; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages.

Carry out the test for safety (section 2-3-1) using unpassaged vaccine virus and the maximally passaged virus that has been recovered.

The vaccine virus complies with the test if no indication of increased virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-3-3. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended for vaccination using in each case dogs 8-16 weeks old. The quantity of vaccine virus to be administered to each dog is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of vaccine.

Use for the test not fewer than 7 dogs that do not have antibodies against canine distemper virus. Vaccinate not fewer than 5 dogs according to the schedule to be recommended. Maintain not fewer than 2 dogs as controls.

Challenge each dog after 21 days by the intravenous route with a sufficient quantity of a suspension of virulent canine distemper virus. Observe the dogs at least daily for 21 days after challenge. Dogs displaying typical signs of serious infection with canine distemper virus are euthanised to avoid unnecessary suffering.

The test is invalid if during the observation period after challenge, fewer than 100 per cent of the control dogs die or show notable signs of canine distemper. The vaccine virus complies with the test if during the observation period after challenge, all the vaccinated dogs survive and show no signs of disease.

3. BATCH TESTS

3-1. **Identification**. The vaccine mixed with a monospecific distemper antiserum against canine distemper virus no longer provokes cytopathic effects in susceptible cell cultures.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas** (*2.6.7*). The vaccine complies with the test for mycoplasmas.

3-4. **Extraneous agents**. Neutralise the vaccine virus with a suitable monospecific antiserum against canine distemper virus and inoculate into cell cultures known for their susceptibility to viruses pathogenic for the dog. Carry out a passage after 6-8 days and maintain the cultures for 14 days. The vaccine complies with the test if no cytopathic effect develops and there is no sign of the presence of haemadsorbing agents.

3-5. **Safety**. Use 2 dogs of the minimum age recommended for vaccination and that do not have antibodies against canine distemper virus. Administer to each dog by a recommended route 10 doses of the vaccine. Observe the dogs at least daily for 14 days.

The vaccine complies with the test if no dog shows notable signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**. Titrate the vaccine virus in suitable cell cultures. The vaccine complies with the test if one dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-3-3) when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2008:0447

CANINE LEPTOSPIROSIS VACCINE (INACTIVATED)

Vaccinum leptospirosis caninae inactivatum

1. DEFINITION

Canine leptospirosis vaccine (inactivated) is a preparation of inactivated whole organisms and/or antigenic extract(s) of one or more suitable strains of one or more of *Leptospira interrogans* serovar canicola, serovar icterohaemorrhagiae or any other epidemiologically appropriate serovar,

inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for the active immunisation of dogs against leptospirosis.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The seed material is cultured in a suitable medium; each strain is cultivated separately. During production, various parameters such as growth rate are monitored by suitable methods; the values are within the limits approved for the particular product. Purity and identity are verified on the harvest using suitable methods. After cultivation, the bacterial harvests are collected separately and inactivated by a suitable method. The antigen may be concentrated. The vaccine may be adjuvanted.

2-2. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the dogs for which it is intended.

The following tests for safety (section 2-2-1) and immunogenicity (section 2-2-2) may be used during the demonstration of safety and efficacy.

2-2-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination and in dogs of each category for which the vaccine is to be intended. Use a batch of vaccine containing not less than the maximum antigen content and/or potency that may be expected in a batch of vaccine.

2-2-1-1. *General safety*. For each test, use not fewer than 10 dogs that do not have antibodies against the principal *L. interrogans* serovars (icterohaemorrhagiae, canicola, grippotyphosa, sejroe, hardjo, hebdomonadis, pomona, australis and autumnalis). Administer to each dog a double dose of the vaccine. If the recommended schedule requires a second dose, administer one dose after the recommended interval. Observe the dogs at least daily until 14 days after the last administration. Record body temperatures the day before each vaccination, at vaccination, 4 h later and daily for 4 days.

The vaccine complies with the test if no dog shows abnormal local or systemic reactions, signs of disease or dies from causes attributable to the vaccine.

2-2-1-2. *Safety in pregnant bitches*. If the vaccine is intended for use or may be used in pregnant bitches, use not fewer than 10 bitches at the stage of pregnancy in accordance with the schedule to be recommended or at different stages of pregnancy. Administer to each bitch a double dose of the vaccine. If the recommended schedule requires a second dose, administer one dose after the recommended interval. Observe the bitches at least daily until one day after whelping.

The vaccine complies with the test if no bitch shows abnormal local or systemic reactions, signs of disease or dies from causes attributable to the vaccine and if no adverse effects on the pregnancy or the offspring are noted.

2-2-2. **Immunogenicity**. For each type of the serovars against which protective immunity is claimed on the label, carry out a separate test with a challenge strain representative of that serovar.

Each test is carried out for each route and method of administration to be recommended for vaccination, using in each case dogs of the minimum age to be recommended. The vaccine administered to each dog is of minimum antigen content and/or potency.

Use for the test not fewer than 12 dogs that do not have antibodies against the principal serovars of *L. interrogans* (icterohaemorrhagiae, canicola, grippotyphosa, sejroe, hardjo, hebdomonadis, pomona, australis and autumnalis). Vaccinate not fewer than 6 dogs, according to the schedule to be recommended. Maintain not fewer than 6 dogs as controls. Challenge each dog after 25-28 days by the conjunctival and/or intraperitoneal route with a sufficient quantity of a suspension of the relevant pathogenic *L. interrogans* serovar. Observe the dogs at least daily for 28 days after challenge.

Examine the dogs daily and record and score clinical signs observed post-challenge and any deaths that occur. If a dog shows marked signs of disease, it is euthanised. Monitor body temperatures each day for the first week after challenge. Collect blood samples from each dog on days 0, 2, 3, 4, 5, 8 and 11 post challenge. Collect urine samples from each dog on days 0, 3, 5, 8, 11, 14, 21 and 28 post challenge. Euthanise surviving dogs at the end of the observation period. Carry out post-mortem examination on any dog that dies during the observation period and on the remainder when euthanised at the end of the observation period. In particular, examine the liver and kidneys for macroscopic and microscopic signs of leptospira infection. Take a sample of each kidney and test each blood, urine and kidney sample for the presence of challenge organisms by re-isolation or by another suitable method. Analyse blood samples to detect biochemical and haematological changes indicative of infection and score these.

The test is invalid if: samples give positive results on day 0; *L. interrogans* serovar challenge strain is re-isolated from or demonstrated by another suitable method to be present in fewer than 2 samples on fewer than 2 different days, to show infection has been established in fewer than 80 per cent of the control dogs.

The vaccine complies with the test if: at least 80 per cent of the vaccinates show no more than mild signs of disease (for example, transient hyperthermia) and, depending on the *L. interrogans* serovar used for the challenge, one or more of the following is also shown:

- where the vaccine is intended to have a beneficial effect against signs of disease, the clinical scores and haematological and biochemical scores are statistically lower for the vaccinates than for the controls,
- where the vaccine is intended to have a beneficial effect against infection, the number of days that the organisms are detected in the blood is statistically lower for the vaccinates than for the controls,
- where the vaccine is intended to have a beneficial effect against urinary tract infection and excretion, the number of days that the organisms are detected in the urine and the number of kidney samples in which the organisms are detected is statistically lower for the vaccinates than for the controls.

2-3. *MANUFACTURER'S TESTS*

2-3-1. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-5.) for each batch of the vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following tests may be used.

2-3-1-1. *For vaccines with or without adjuvants*. If leptospira from more than one serovar (for example *L. interrogans* serovar canicola and serovar icterohaemorrhagiae) has been used to prepare the vaccine, carry out a batch potency test for

each serovar against which protective immunity is claimed on the label. Use for the test 10 healthy hamsters not more than 3 months old, that do not have antibodies against the principal serovars of *L. interrogans* (icterohaemorrhagiae, canicola, grippotyphosa, sejroe, hardjo, hebdomonadis, pomona, australis and autumnalis) and which have been obtained from a regularly tested and certified leptospira-free source. Administer 1/40 of the dose for dogs by the subcutaneous route to 5 hamsters. Maintain 5 hamsters as controls. Challenge each hamster after 15-20 days by the intraperitoneal route with a sufficient quantity of a virulent culture of leptospirae of the serovar against which protective immunity is claimed on the label. The vaccine complies with the test if not fewer than 4 of the 5 control hamsters die showing typical signs of leptospira infection within 14 days of receiving the challenge suspension and if not fewer than 4 of the 5 vaccinated hamsters remain in good health for 14 days after the death of 4 control hamsters.

2-3-1-2. *For vaccines with or without adjuvants.* A suitable validated sero-response test may be carried out. Vaccinate each animal in a group of experimental animals with a suitable dose. Collect blood samples after a suitable, fixed time after vaccination. For each of the serovars present in the vaccine, an *in vitro* test is carried out on individual blood samples to determine the antibody response to one or more antigenic components which are indicators of protection and which are specific for that serovar. The criteria for acceptance are set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency.

2-3-1-3. *For vaccines without adjuvants.* For each of the serovars present in the vaccine, a suitable validated *in vitro* test may be carried out to determine the content of one or more antigenic components which are indicators of protection and which are specific for that serovar. The criteria for acceptance are set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency.

3. BATCH TESTS

3-1. **Identification**. When injected into healthy animals that do not have specific antibodies against leptospira serovar(s) present in the vaccine, the vaccine stimulates the production of such antibodies. If test 2-3-1-3 is used for batch potency test, it also serves to identify the vaccine.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 dogs of the minimum age recommended for vaccination and that do not have antibodies against the leptospira serovar(s) present in the vaccine. Administer to each dog by a recommended route a double dose of the vaccine. Observe the dogs at least daily for 14 days.

The vaccine complies with the test if no dog shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual live bacteria**. Carry out a test for live leptospirae by inoculation of a specific medium. Inoculate 1 ml of the vaccine into 100 ml of the medium. Incubate at 30 °C for 14 days, subculture into a further quantity of the medium and incubate both media at 30 °C for 14 days: the vaccine complies with the test if no growth occurs in either medium. At the same time, carry out a control test by inoculating a further quantity of the medium with the vaccine together with a quantity of a culture containing approximately 100 leptospirae and incubating at 30 °C: the test is invalid if growth of leptospirae does not occur within 14 days.

3-5. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-3-2.) when administered by a recommended route and method.

01/2008:1955

CANINE PARAINFLUENZA VIRUS VACCINE (LIVE)

Vaccinum parainfluenzae viri canini vivum

1. DEFINITION

Canine parainfluenza virus vaccine (live) is a preparation of a suitable strain of parainfluenza virus of canine origin. This monograph applies to vaccines intended for the active immunisation of dogs against respiratory signs of infection with parainfluenza virus of canine origin.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE VIRUS*

The vaccine virus is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the dogs for which it is intended.

The following tests for safety (section 2-3-1), increase in virulence (section 2-3-2) and immunogenicity (2-3-3) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine.

2-3-1-1. *General safety.* For each test, use not fewer than 5 dogs of the minimum age to be recommended for vaccination, that do not have antibodies against parainfluenza virus of canine origin. Administer to each dog a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in one dose of the vaccine. Observe the dogs at least daily for 21 days.

The vaccine virus complies with the test if no dog shows abnormal local or systemic reactions, signs of disease or dies from causes attributable to the vaccine virus.

2-3-1-2. *Safety in pregnant bitches.* If the vaccine is intended for use in pregnant bitches, use not fewer than 5 bitches at the stage of pregnancy to be recommended or at a range of stages of pregnancy according to the schedule to be recommended. Administer to each bitch a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in one dose of the vaccine. Observe the bitches at least daily until one day after whelping.

The vaccine virus complies with the test if no bitch shows abnormal local or systemic reactions, signs of disease or dies from causes attributable to the vaccine virus and if no adverse effects on the pregnancy or the offspring are noted.

2-3-2. **Increase in virulence**. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to 2 dogs 5-7 weeks-old, that do not have antibodies against parainfluenza virus of canine origin, sequential passages, 5 times where possible, to further similar groups and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages.

Administer to each dog by the intranasal route and by a route to be recommended a quantity of the vaccine virus that will allow recovery of virus for the passages described below. Administer the virus by the route to be recommended for vaccination most likely to lead to reversion of virulence. After 3-10 days, prepare a suspension from nasal swabs of each dog. Administer 1 ml of the suspension from the swabs that contain the maximum amount of virus by the intranasal route to each of 2 other dogs of the same age. Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages.

Carry out the test for safety (section 2-3-1) using unpassaged vaccine virus and the maximally passaged virus that has been recovered.

The vaccine virus complies with the test if no indication of increased virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-3-3. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended for vaccination, using in each case dogs of the minimum age to be recommended. The quantity of vaccine virus to be administered to each dog is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of vaccine.

Use for the test not fewer than 15 dogs that do not have antibodies against parainfluenza virus of canine origin. Vaccinate not fewer than 10 dogs according to the schedule to be recommended. Maintain not fewer than 5 dogs as controls. Challenge each dog after not less than 21 days by the intratracheal or intranasal route with a sufficient quantity of a suspension of virulent parainfluenza virus of canine origin. Observe the dogs at least daily for 14 days after challenge. Collect nasal swabs or washings from each dog daily from day 2 to 10 after challenge and test these samples for the presence of excreted virus. Use a scoring system to record the incidence of coughing in each dog.

The test is invalid if more than one of the control dogs shows neither coughing nor the excretion of the challenge virus. The vaccine complies with the test if the scores for coughing or virus excretion for the vaccinated dogs are significantly lower than in the controls.

3. BATCH TESTS

3-1. **Identification**. Carry out an immunofluorescence test in suitable cell cultures, using a monospecific antiserum.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas** (*2.6.7*). The vaccine complies with the test for mycoplasmas.

3-4. **Extraneous agents**. Neutralise the vaccine virus with a suitable monospecific antiserum against parainfluenza virus of canine origin and inoculate into cell cultures known for their susceptibility to viruses pathogenic for the dog. Carry out a passage after 6-8 days and maintain the cultures for a total of 14 days. The vaccine complies with the test if no cytopathic effect develops and there is no sign of the presence of haemadsorbing agents.

3-5. **Safety**. Use 2 dogs not older than the minimum age recommended for vaccination and that do not have antibodies against parainfluenza virus of canine origin. Administer to each dog by a recommended route 10 doses of the vaccine. Observe the dogs at least daily for 14 days.

The vaccine complies with the test if no dog shows notable signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**. Titrate the vaccine virus in suitable cell cultures. The vaccine complies with the test if one dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-3-3) when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2008:0795

CANINE PARVOVIROSIS VACCINE (INACTIVATED)

Vaccinum parvovirosis caninae inactivatum

1. DEFINITION

Canine parvovirosis vaccine (inactivated) is a preparation of a suitable strain of canine parvovirus inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for the active immunisation of dogs against canine parvovirosis.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures. The virus harvest is inactivated. The vaccine may be adjuvanted.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the dogs for which it is intended.

The following test for immunogenicity (section 2-3-1) may be used during the demonstration of efficacy.

2-3-1. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended for vaccination using in each case dogs of the minimum age to be recommended. The vaccine administered to each dog is of minimum potency.

Use for the test not fewer than 7 dogs that do not have antibodies against canine parvovirus. Vaccinate not fewer than 5 dogs according to the schedule to be recommended. Maintain not fewer than 2 dogs as controls. Challenge each dog after 20-22 days by the oronasal route with a sufficient quantity of a suspension of pathogenic canine parvovirus. Observe the dogs at least daily for 14 days after challenge. At the end of the observation period, carry out haemagglutination tests for and titration of the virus in the faeces.

The test is invalid if fewer than 100 per cent of the control dogs show notable signs of the disease or leucopenia and excretion of the virus. The vaccine complies with the test if all the vaccinated dogs survive and show no signs of disease nor leucopenia and if the maximum titre of virus excreted in the faeces is less than 1/100 of the geometric mean of the maximum titres found in the controls.

2-4. *MANUFACTURER'S TESTS*

2-4-1. **Residual live virus**. A test for residual live virus is carried out on the bulk harvest of each batch to confirm inactivation of the canine parvovirus. The quantity of inactivated virus harvest used in the test is equivalent to not less than 100 doses of the vaccine. The inactivated viral harvest is inoculated into suitable non-confluent cells; after incubation for 8 days, a subculture is made using trypsinised cells. After incubation for a further 8 days, the cultures are examined for residual live parvovirus by an immunofluorescence test. The immunofluorescence test may be supplemented by a haemagglutination test or other suitable tests on the supernatant of the cell cultures. The inactivated viral harvest complies with the test if no live virus is detected.

3. BATCH TESTS

3-1. **Identification**. When injected into animals that do not have antibodies against canine parvovirus, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 dogs of the minimum age recommended for vaccination and that do not have antibodies against canine parvovirus or, where justified, use dogs with a low level of such antibodies as long as they have not been vaccinated against canine parvovirosis and administration of the vaccine does not cause an anamnestic response. Administer to each dog by a recommended route a double dose of the vaccine. Observe the dogs at least daily for 14 days.

The vaccine complies with the test if no dog shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Potency**. Carry out test 3-4-1 or test 3-4-2.

3-4-1. *Test in guinea-pigs for haemagglutination-inhibiting antibodies.* Use for the test not fewer than 5 guinea-pigs that do not have specific antibodies. Administer to each guinea-pig by the subcutaneous route half of the dose to be recommended. After 14 days, inject again half of the dose to be recommended. 14 days later, collect blood samples and separate the serum. Inactivate each serum by heating at 56 °C for 30 min. To 1 volume of each serum add 9 volumes of a 200 g/l suspension of *light kaolin R* in *phosphate buffered saline pH 7.4 R*. Shake each mixture for 20 min. Centrifuge, collect the supernatant liquid and mix with 1 volume of a concentrated suspension of pig erythrocytes. Allow to stand at 4 °C for 60 min and centrifuge. The dilution of the serum obtained is 1:10. Using each serum, prepare a series of twofold dilutions. To 0.025 ml of each of the latter dilutions add 0.025 ml of a suspension of canine parvovirus antigen containing 4 haemagglutinating units. Allow to stand at 37 °C for 30 min and add 0.05 ml of a suspension of pig erythrocytes containing 30×10^6 cells per millilitre. Allow to stand at 4 °C for 90 min and note the last dilution of serum that still completely inhibits haemagglutination. The vaccine complies with the test if the median antibody titre of the sera collected after the second vaccination is not less than 1/80.

3-4-2. *Test in dogs for virus-neutralising antibodies.* Use for the test not fewer than 2 healthy dogs, 8-12 weeks old, that have antibody titres less than 4 ND_{50} per 0.1 ml of serum, measured by the method described below. Vaccinate each dog according to the schedule to be recommended. 14 days after vaccination, examine the serum of each dog as follows. Heat the serum at 56 °C for 30 min and prepare serial dilutions using a medium suitable for canine cells. Add to each dilution an equal volume of a virus suspension containing an amount of virus such that when the volume of serum-virus mixture appropriate for the assay system is inoculated into cell cultures, each culture receives approximately 10^4 $CCID_{50}$. Incubate the mixtures at 37 °C for 1 h and inoculate 4 canine cell cultures with a suitable volume of each mixture. Incubate the cell cultures at 37 °C for 7 days, passage and incubate for a further 7 days. Examine the cultures for evidence of specific cytopathic effects and calculate the antibody titre. The vaccine complies with the test if the mean titre is not less than 32 ND_{50} per 0.1 ml of serum. If one dog fails to respond, repeat the test using 2 more dogs and calculate the result as the mean of the titres obtained from all of the 3 dogs that have responded.

01/2008:0964

CANINE PARVOVIROSIS VACCINE (LIVE)

Vaccinum parvovirosis caninae vivum

1. DEFINITION

Canine parvovirosis vaccine (live) is a preparation of a suitable strain of canine parvovirus. This monograph applies to vaccines intended for the active immunisation of dogs against canine parvovirosis.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE VIRUS*

The vaccine virus is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the dogs for which it is intended.

The following tests for safety (section 2-3-1), increase in virulence (section 2-3-2) and immunogenicity (section 2-3-3) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination, using in each case dogs of the minimum age to be recommended. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine.

2-3-1-1. *General safety*. For each test, use not fewer than 5 dogs that do not have haemagglutination-inhibiting antibodies against canine parvovirus. A count of white blood cells in circulating blood is made on days 4, 2 and 0 before injection of the vaccine strain. Administer to each dog a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in one dose of the vaccine. Observe the dogs at least daily for 21 days. A count of white blood cells in circulating blood is made on days 3, 5, 7 and 10 after the injection.

The test is invalid if a diminution in the number of circulating white blood cells greater than 50 per cent of the initial number - determined as the average of the 3 values found before injection of the vaccine strain - is noted. The vaccine virus complies with the test if no dog shows abnormal local or systemic reactions, notable signs of disease or dies from causes attributable to the vaccine virus.

2-3-1-2. *Effects on the thymus*. For each test, use not fewer than 10 dogs that do not have haemagglutination-inhibiting antibodies against canine parvovirus. Administer to each of not fewer than 5 dogs a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in one dose of the vaccine. Maintain not fewer than 5 dogs as controls. Observe the dogs at least daily. After 14 days, euthanise 2 dogs from each group and after 21 days, the remaining dogs from each group. Carry out histological examination of the thymus of each dog.

The vaccine virus complies with the test if there is no more than slight hypoplasia of the thymus after 14 days and no damage is evident after 21 days.

2-3-2. **Increase in virulence**. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to 2 dogs of the minimum age to be recommended for vaccination, that do not have haemagglutination-inhibiting antibodies against canine parvovirus, sequential passages, 5 times where possible, to further similar groups and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages.

Administer to each dog by a route to be recommended a quantity of the vaccine virus that will allow recovery of virus for the passages described below. Collect the faeces from each dog from the 2nd to the 10th day after administration of the virus, check them for the presence of the virus and pool the faeces containing virus. Administer 1 ml of the suspension of pooled faeces by the oronasal route to each of 2 other dogs of the same age. Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages.

The vaccine virus complies with the test if no indication of increased virulence of the maximally passaged virus compared with the unpassaged virus is observed; account is taken, notably, of the count of white blood cells, of results of histological examination of the thymus and of the titre of excreted virus. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-3-3. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended using in each case dogs of the minimum age to be recommended for vaccination. The quantity of vaccine virus to be administered to each dog is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of vaccine.

Use for the test not fewer than 7 dogs that do not have haemagglutination-inhibiting antibodies against canine parvovirus. Vaccinate not fewer than 5 dogs. Maintain not fewer than 2 dogs as controls. Challenge each dog after 20-22 days by the oronasal route with a sufficient quantity of a suspension of virulent canine parvovirus. Observe the dogs at least daily for 14 days after challenge. At the end of the observation period, carry out a haemagglutination test for and titration of the virus in the faeces.

The test is invalid if fewer than 100 per cent of the control dogs show typical signs of the disease and/or leucopenia and excretion of the virus. The vaccine virus complies with the test if all the vaccinated dogs survive and show no sign of disease nor leucopenia and if the maximum titre of virus excreted in the faeces is less than 1/100 of the geometric mean of the maximum titres found in the controls.

3. BATCH TESTS

3-1. **Identification**. The vaccine is grown in a susceptible cell line in a substrate suitable for presenting for fluorescent antibody or immunoperoxidase tests. Suitable controls are included. A proportion of the cells is tested with a monoclonal antibody specific for canine parvovirus and a proportion of the cells tested with a monoclonal antibody specific for feline parvovirus. Canine parvovirus antigen is detected but no feline parvovirus is detected in the cells inoculated with the vaccine.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas** (*2.6.7*). The vaccine complies with the test for mycoplasmas.

3-4. **Extraneous agents**. Neutralise the vaccine virus with a suitable monospecific antiserum against canine parvovirus and inoculate into cell cultures known for their susceptibility to viruses pathogenic for the dog. The vaccine complies with the test if no cytopathic effect develops and there is no sign of haemagglutinating or haemadsorbing agents and no other sign of the presence of extraneous viruses.

3-5. **Safety**. Use 2 dogs of the minimum age recommended for vaccination and that do not have haemagglutination-inhibiting antibodies against canine parvovirus. Administer to each dog by a recommended route 10 doses of the vaccine. Observe the dogs at least daily for 14 days.

The vaccine complies with the test if no dog shows notable signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**. Titrate the vaccine virus by inoculation into suitable cell cultures. The vaccine complies with the test if one dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-3-3) when administered by a recommended route and method. It

is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2008:0360

CLOSTRIDIUM BOTULINUM VACCINE FOR VETERINARY USE

Vaccinum Clostridii botulini ad usum veterinarium

1. DEFINITION

Clostridium botulinum vaccine for veterinary use is prepared from liquid cultures of suitable strains of *Clostridium botulinum* type C or type D or a mixture of these types. The whole culture or its filtrate or a mixture of the two is inactivated to eliminate its toxicity while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for active immunisation of animals against botulism.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

C. botulinum used for production is grown in an appropriate liquid medium.

The preparation may be adsorbed, precipitated or concentrated. It may be treated with a suitable adjuvant and may be freeze-dried.

2-2. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the animals for which it is intended.

2-3. *MANUFACTURER'S TESTS*

2-3-1. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-5) for each batch of the vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency.

3. BATCH TESTS

The identification, the tests and the determination of potency apply to the liquid preparation and to the freeze-dried preparation reconstituted as stated on the label.

3-1. **Identification**. When injected into a healthy animal free from antibodies against the type or types of *C. botulinum* from which the vaccine was prepared, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 animals of one of the species for which the vaccine is intended and that have not been vaccinated against *C. botulinum*. Administer to each animal, by a recommended route, twice the maximum recommended dose. Observe the animals at least daily for 7 days.

The vaccine complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual toxicity**. Inject 0.5 ml of the vaccine by the subcutaneous route into each of 5 mice, each weighing 17-22 g. Observe the animals at least daily for 7 days.

The vaccine complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine.

3-5. **Potency**.

Use for the test healthy white mice from a uniform stock, each weighing 18-20 g. Use as challenge dose a quantity of a toxin of *C. botulinum* of the same type as that used in the preparation of the vaccine corresponding to 25 times the paralytic dose 50 per cent, a paralytic dose 50 per cent being the quantity of toxin which, when injected by the intraperitoneal route into mice, causes paralysis in 50 per cent of the animals within an observation period of 7 days. If 2 types of *C. botulinum* have been used in the preparation of the vaccine, carry out the potency determination for each. Dilute the vaccine to be examined 1 in 8 using a 9 g/l solution of *sodium chloride R*. Inject 0.2 ml of the dilution subcutaneously into each of 20 mice. After 21 days, inject the challenge dose by the intraperitoneal route into each of the vaccinated mice and into each of 10 control mice. Observe the mice for 7 days and record the number of animals which show signs of botulism. The test is not valid unless all the control mice show signs of botulism during the observation period. The vaccine complies with the test if not fewer than 80 per cent of the vaccinated mice are protected.

4. LABELLING

The label states:

- the type or types of *C. botulinum* from which the vaccine has been prepared,
- whether the preparation is a toxoid or a vaccine prepared from a whole inactivated culture or a mixture of the two.

01/2008:0361

CLOSTRIDIUM CHAUVOEI VACCINE FOR VETERINARY USE

Vaccinum Clostridii chauvoei ad usum veterinarium

1. DEFINITION

Clostridium chauvoei vaccine for veterinary use is prepared from liquid cultures of one or more suitable strains of *Clostridium chauvoei*. The whole culture is inactivated to eliminate its toxicity while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for active immunisation of animals against disease caused by *C. chauvoei*.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

C. chauvoei used for production is grown in an appropriate liquid medium. Inactivated cultures may be treated with a suitable adjuvant.

2-2. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the animals for which it is intended.

3. BATCH TESTS

3-1. **Identification**. The vaccine protects susceptible animals against infection with *C. chauvoei*. The potency test may also serve for identification.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 animals of one of the species for which the vaccine is intended and that have not been vaccinated against *C. chauvoei*. Administer to each animal at a single site, by a recommended route, twice the maximum recommended dose. Observe the animals at least daily for 7 days.

The vaccine complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Potency**

Use for the test not fewer than 10 healthy guinea-pigs, each weighing 350-450 g. Administer to each rabbit by the subcutaneous route a quantity of the vaccine not greater than the minimum dose stated on the label as the first dose. After 28 days, administer into the same animals a quantity of the vaccine not greater than the minimum dose stated on the label as the second dose. 14 days after the second vaccination, inoculate by the intramuscular route into each of the vaccinated guinea-pigs and into each of 5 control animals a suitable quantity of a virulent culture, or of a spore suspension, of *C. chauvoei*, activated if necessary with an activating agent such as calcium chloride.

The vaccine complies with the test if not more than 10 per cent of the vaccinated guinea-pigs die from *C. chauvoei* infection within 5 days and all the control animals die from *C. chauvoei* infection within 48 h of challenge or within 72 h if a spore suspension was used for the challenge. If more than 10 per cent but not more than 20 per cent of the vaccinated animals die, repeat the test. The vaccine complies with the test if not more than 10 per cent of the second group of vaccinated animals die within 5 days and all of the second group of control animals die within 48 h of challenge or within 72 h if a spore suspension was used for the challenge. To avoid unnecessary suffering following virulent challenge, moribund animals are euthanised and are then considered to have died from *C. chauvoei* infection.

01/2008:0362

CLOSTRIDIUM NOVYI (TYPE B) VACCINE FOR VETERINARY USE

Vaccinum Clostridii novyi B ad usum veterinarium

1. DEFINITION

Clostridium novyi (type B) vaccine for veterinary use is prepared from a liquid culture of a suitable strain of *Clostridium novyi* (type B).

The whole culture or its filtrate or a mixture of the two is inactivated to eliminate its toxicity while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for active immunisation of animals and/or to protect passively their progeny against disease caused by *C. novyi* (type B).

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

C. novyi (type B) used for production is grown in an appropriate liquid medium. Toxoids and/or inactivated cultures may be treated with a suitable adjuvant, after concentration if necessary.

2-2. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the animals for which it is intended. For the latter, it shall be demonstrated that for each target species the vaccine, when administered according to the recommended schedule, stimulates an immune response (for example, induction of antibodies) consistent with the claims made for the product.

2-3. *MANUFACTURER'S TESTS*

2-3-1. **Residual toxicity**. A test for detoxification is carried out immediately after the detoxification process and, when there is risk of reversion, a second test is carried out at as late a stage as possible during the production process. The test for residual toxicity (section 3-4) may be omitted by the manufacturer.

2-3-2. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-5) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency.

Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency and that has been shown to be satisfactory with respect to immunogenicity in the target species. The following test may be used after a satisfactory correlation with the test under Potency (section 3-5) has been established.

Vaccinate rabbits as described under Potency and prepare sera. Determine the level of antibodies against the alpha toxin of *C. novyi* in the individual sera by a suitable method such as an immunochemical method (*2.7.1*) or neutralisation in cell cultures. Use a homologous reference serum calibrated in International Units of *C. novyi* alpha antitoxin. *Clostridia (multicomponent) rabbit antiserum BRP* is suitable for use as a reference serum. The vaccine complies with the test if the level of antibodies is not less than that found for a batch of vaccine that has given satisfactory results in the test described under Potency and that has been shown to be satisfactory with respect to immunogenicity in the target species.

3. BATCH TESTS

3-1. **Identification**. The vaccine stimulates the formation of novyi alpha antitoxin when injected into animals that do not have this antitoxin.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Administer by a recommended route, to each of 2 sheep that have not been vaccinated against *C. novyi* (type B) twice the maximum recommended dose of the vaccine. Observe the animals at least daily for not less than 14 days.

The vaccine complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual toxicity**. Inject 0.5 ml of the vaccine by the subcutaneous route into each of 5 mice, each weighing 17-22 g. Observe the animals at least daily for 7 days.

The vaccine complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine.

3-5. **Potency**

Use for the test not fewer than 10 healthy rabbits, 3-6 months old. Administer to each rabbit by the subcutaneous route

a quantity of vaccine not greater than the minimum dose stated on the label as the first dose. After 21 to 28 days, administer into the same animals a quantity of the vaccine not greater than the minimum dose stated on the label as the second dose. 10 to 14 days after the second injection, bleed the rabbits and pool the sera.

The vaccine complies with the test if the potency of the pooled sera is not less than 3.5 IU/ml.

The International Unit is the specific neutralising activity for *C. novyi* alpha toxin contained in a stated amount of the International Standard, which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

The potency of the pooled sera obtained from the rabbits is determined by comparing the quantity necessary to protect mice or other suitable animals against the toxic effects of a fixed dose of *C. novyi* alpha toxin with the quantity of a reference preparation of Clostridium novyi alpha antitoxin, calibrated in International Units, necessary to give the same protection. For this comparison, a suitable preparation of *C. novyi* alpha toxin for use as a test toxin is required. The dose of the test toxin is determined in relation to the reference preparation; the potency of the serum to be examined is determined in relation to the reference preparation using the test toxin.

Clostridia (multicomponent) rabbit antiserum BRP is suitable for use as a reference serum.

3-5-1. *Preparation of test toxin.* Prepare the test toxin from a sterile filtrate of an approximately 5-day culture in liquid medium of *C. novyi* type B and dry by a suitable method. Select the test toxin by determining for mice the L+/10 dose and the LD_{50}, the observation period being 72 h.

A suitable alpha toxin contains not less than one L+/10 dose in 0.05 mg and not less than 10 LD_{50} in each L+/10 dose.

3-5-2. *Determination of test dose of toxin.* Prepare a solution of the reference preparation in a suitable liquid so that it contains 1 IU/ml. Prepare a solution of the test toxin in a suitable liquid so that 1 ml contains a precisely known amount such as 1 mg. Prepare mixtures of the solution of the reference preparation and the solution of the test toxin such that each mixture contains 1.0 ml of the solution of the reference preparation (1 IU), one of a series of graded volumes of the solution of the test toxin and sufficient of a suitable liquid to bring the total volume to 2.0 ml. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 mice, each weighing 17-22 g, for each mixture, inject a dose of 0.2 ml by the intramuscular or the subcutaneous route into each mouse. Observe the mice for 72 h. If all the mice die, the amount of toxin present in 0.2 ml of the mixture is in excess of the test dose. If none of the mice die, the amount of toxin present in 0.2 ml of the mixture is less than the test dose. Prepare fresh mixtures such that 2.0 ml of each mixture contains 1.0 ml of the solution of the reference preparation (1 IU) and one of a series of graded volumes of the solution of the test toxin separated from each other by steps of not more than 20 per cent and covering the expected end-point. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 mice for each mixture, inject a dose of 0.2 ml by the intramuscular or the subcutaneous route into each mouse. Observe the mice for 72 h. Repeat the determination at least once and combine the results of the separate tests that have been made with mixtures of the same composition so that a series of totals is obtained, each total representing the mortality due to a mixture of a given composition.

The test dose of toxin is the amount present in 0.2 ml of that mixture which causes the death of one half of the total number of mice injected with it.

3-5-3. *Determination of the potency of the serum obtained from rabbits*

Preliminary test. Dissolve a quantity of the test toxin in a suitable liquid so that 1 ml contains 10 times the test dose (solution of the test toxin). Prepare a series of mixtures of the solution of the test toxin and of the serum to be examined such that each mixture contains 1.0 ml of the solution of the test toxin, one of a series of graded volumes of the serum to be examined and sufficient of a suitable liquid to bring the final volume to 2.0 ml. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 mice for each mixture, inject a dose of 0.2 ml by the intramuscular or the subcutaneous route into each mouse. Observe the mice for 72 h. If none of the mice dies, 0.2 ml of the mixture contains more than 0.1 IU. If all the mice die, 0.2 ml of the mixture contains less than 0.1 IU.

Final test. Prepare a series of mixtures of the solution of the test toxin and of the serum to be examined such that 2.0 ml of each mixture contains 1.0 ml of the solution of the test toxin and one of a series of graded volumes of the serum to be examined, separated from each other by steps of not more than 20 per cent and covering the expected end-point as determined by the preliminary test. Prepare further mixtures of the solution of the test toxin and of the solution of the reference preparation such that 2.0 ml of each mixture contains 1.0 ml of the solution of the test toxin and one of a series of graded volumes of the solution of the reference preparation, in order to confirm the test dose of the toxin. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 mice for each mixture, proceed as described in the preliminary test. The test mixture which contains 0.1 IU in 0.2 ml is that mixture which kills the same or almost the same number of mice as the reference mixture containing 0.1 IU in 0.2 ml. Repeat the determination at least once and calculate the average of all valid estimates. The test is valid only if the reference preparation gives a result within 20 per cent of the expected value.

The confidence limits (P = 0.95) have been estimated to be:

- 85 per cent and 114 per cent when 2 animals per dose are used,
- 91.5 per cent and 109 per cent when 4 animals per dose are used,
- 93 per cent and 108 per cent when 6 animals per dose are used.

4. LABELLING

The label states:

- whether the product is a toxoid, a vaccine prepared from a whole inactivated culture or a mixture of the two,
- for each target species, the immunising effect produced (for example, antibody production, protection against signs of disease or infection).

01/2008:0363

CLOSTRIDIUM PERFRINGENS VACCINE FOR VETERINARY USE

Vaccinum Clostridii perfringentis ad usum veterinarium

1. DEFINITION

Clostridium perfringens vaccine for veterinary use is prepared from liquid cultures of suitable strains of *Clostridium perfringens* type B, *C. perfringens* type C or *C. perfringens* type D or a mixture of these types.

The whole cultures or their filtrates or a mixture of the two are inactivated to eliminate their toxicity while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for active immunisation of animals and/or to protect passively their progeny against disease caused by *C. perfringens*.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

C. perfringens used for production is grown in an appropriate liquid medium. Toxoids and/or inactivated cultures may be treated with a suitable adjuvant.

2-2. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the animals for which it is intended. For the latter, it shall be demonstrated that for each target species the vaccine, when administered according to the recommended schedule, stimulates an immune response (for example, induction of antibodies) consistent with the claims made for the product.

2-3. *MANUFACTURER'S TESTS*

2-3-1. **Residual toxicity**. A test for detoxification is carried out immediately after the detoxification process and, when there is risk of reversion, a second test is carried out at as late a stage as possible during the production process. The test for residual toxicity (section 3-4) may be omitted by the manufacturer.

2-3-2. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-5) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency.

Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency and that has been shown to be satisfactory with respect to immunogenicity in the target species. The following test may be used after a satisfactory correlation with the test under Potency (section 3-5) has been established.

Vaccinate rabbits as described under Potency and prepare sera. Determine the level of antibodies against the beta and/or epsilon toxins of *C. perfringens* in the individual sera by a suitable method such as an immunochemical method (*2.7.1*) or neutralisation in cell cultures. Use a homologous reference serum calibrated in International Units of *C. perfringens* beta and/or epsilon antitoxin. *Clostridia (multicomponent) rabbit antiserum BRP* is suitable for use as a reference serum.

The vaccine complies with the test if the level or levels of antibodies are not less than that found for a batch of vaccine that has given satisfactory results in the test described under Potency and that has been shown to be satisfactory with respect to immunogenicity in the target species.

3. BATCH TESTS

3-1. **Identification**

Type B. When injected into animals that do not have beta and epsilon antitoxins, the vaccine stimulates the formation of such antitoxins.

Type C. When injected into animals that do not have beta antitoxin, the vaccine stimulates the formation of such antitoxin.

Type D. When injected into animals that do not have epsilon antitoxin, the vaccine stimulates the formation of such antitoxin.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 animals of one of the species for which the vaccine is intended and that have not been vaccinated against *C. perfringens*. Administer by a recommended route to each animal, twice the maximum recommended dose. Observe the animals at least daily for 14 days.

The vaccine complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual toxicity**. Administer 0.5 ml of the vaccine by the subcutaneous route into each of 5 mice, each weighing 17-22 g. Observe the mice at least daily for 7 days.

The vaccine complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine.

3-5. **Potency**

Use for the test not fewer than 10 healthy rabbits, 3-6 months old. Administer to each rabbit by the subcutaneous route a quantity of vaccine not greater than the minimum dose stated on the label as the first dose. After 21 to 28 days, administer to the same animals a quantity of the vaccine not greater than the minimum dose stated on the label as the second dose. 10 to 14 days after the second injection, bleed the rabbits and pool the sera.

Type B. The vaccine complies with the test if the potency of the pooled sera is not less than 10 IU of beta antitoxin and not less than 5 IU of epsilon antitoxin per millilitre.

Type C. The vaccine complies with the test if the potency of the pooled sera is not less than 10 IU of beta antitoxin per millilitre.

Type D. The vaccine complies with the test if the potency of the pooled sera is not less than 5 IU of epsilon antitoxin per millilitre.

3-5-1. *International standard for Clostridium perfringens beta antitoxin*

The International Unit is the specific neutralising activity for *C. perfringens* beta toxin contained in a stated amount of the International Standard which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

3-5-2. *International standard for Clostridium perfringens epsilon antitoxin*

The International Unit is the specific neutralising activity for *C. perfringens* epsilon toxin contained in a stated amount of the International Standard which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

The potency of the pooled sera obtained from the rabbits is determined by comparing the quantity necessary to protect mice or other suitable animals against the toxic effects of a fixed dose of *C. perfringens* beta toxin or *C. perfringens* epsilon toxin with the quantity of a reference preparation of Clostridium perfringens beta antitoxin or Clostridium perfringens epsilon antitoxin, as appropriate, calibrated in International Units, necessary to give the same protection. For this comparison, a suitable preparation of *C. perfringens* beta or epsilon toxin for use as a test toxin is required. The dose of the test toxin is determined in relation to the appropriate reference preparation; the potency of the serum to be examined is determined in relation to the appropriate reference preparation using the appropriate test toxin.

Clostridia (multicomponent) rabbit antiserum BRP is suitable for use as a reference serum.

3-5-3. *Preparation of test toxin*. Prepare the test toxin from a sterile filtrate of an early culture in liquid medium of *C. perfringens* type B, type C or type D as appropriate and dry by a suitable method. Use a beta or epsilon toxin as appropriate. Select the test toxin by determining for mice the L+ and the LD_{50} for the beta toxin and the L+/10 dose and the LD_{50} for the epsilon toxin, the observation period being 72 h.

A suitable beta toxin contains not less than one L+ in 0.2 mg and not less than 25 LD_{50} in one L+ dose. A suitable epsilon toxin contains not less than one L+/10 dose in 0.005 mg and not less than 20 LD_{50} in one L+/10 dose.

3-5-4. *Determination of test dose of toxin*. Prepare a solution of the reference preparation in a suitable liquid so that it contains 5 IU/ml for Clostridium perfringens beta antitoxin and 0.5 IU/ml for Clostridium perfringens epsilon antitoxin. Prepare a solution of the test toxin in a suitable liquid so that 1 ml contains a precisely known amount such as 10 mg for beta toxin and 1 mg for epsilon toxin. Prepare mixtures of the solution of the reference preparation and the solution of the test toxin such that each contains 2.0 ml of the solution of the reference preparation, one of a series of graded volumes of the solution of the test toxin and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than 2 mice, each weighing 17-22 g, for each mixture, inject a dose of 0.5 ml by the intravenous or the intraperitoneal route to each mouse. Observe the mice for 72 h. If all the mice die, the amount of toxin present in 0.5 ml of the mixture is in excess of the test dose. If none of the mice dies the amount of toxin present in 0.5 ml of the mixture is less than the test dose. Prepare fresh mixtures such that 5.0 ml of each mixture contains 2.0 ml of the solution of the reference preparation and one of a series of graded volumes of the solution of the test toxin separated from each other by steps of not more than 20 per cent and covering the expected end-point. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than 2 mice for each mixture, inject a dose of 0.5 ml by the intravenous or the intraperitoneal route to each mouse. Observe the mice for 72 h. Repeat the determination at least once and add together the results of the separate tests that have been made with mixtures of the same composition so that a series of totals is obtained, each total representing the mortality due to a mixture of given composition.

The test dose of toxin is the amount present in 0.5 ml of that mixture which causes the death of one half of the total number of mice injected with it.

3-5-5. *Determination of the potency of the serum obtained from rabbits*

Preliminary test. Dissolve a quantity of the test toxin in a suitable liquid so that 2.0 ml contains 10 times the test dose (solution of the test toxin). Prepare a series of mixtures of the solution of the test toxin and of the serum to be examined such that each contains 2.0 ml of the solution of the test toxin, one of a series of graded volumes of the serum to be examined and sufficient of a suitable liquid to bring the final volume to 5.0 ml. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than 2 mice for each mixture, inject a dose of 0.5 ml by the intravenous or the intraperitoneal route into each mouse. Observe the mice for 72 h. If none of the mice die, 0.5 ml of the mixture contains more than 1 IU of beta antitoxin or 0.1 IU of epsilon antitoxin. If all the mice die, 0.5 ml of the mixture contains less than 1 IU of beta antitoxin or 0.1 IU of epsilon antitoxin.

Final test. Prepare a series of mixtures of the solution of the test toxin and the serum to be examined such that 5.0 ml of each mixture contains 2.0 ml of the solution of the test toxin and one of a series of graded volumes of the serum to be examined separated from each other by steps of not more than 20 per cent and covering the expected end-point as determined by the preliminary test. Prepare further mixtures of the solution of the test toxin and of the solution of the reference preparation such that 5.0 ml of each mixture contains 2.0 ml of the solution of the test toxin and one of a series of graded volumes of the solution of the reference preparation, in order to confirm the test dose of the toxin. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than 2 mice for each mixture proceed as described in the preliminary test.

Beta antitoxin. The test mixture which contains 1 IU in 0.5 ml is that mixture which kills the same or almost the same number of mice as the reference mixture containing 1 IU in 0.5 ml.

Epsilon antitoxin. The test mixture which contains 0.1 IU in 0.5 ml is that mixture which kills the same or almost the same number of mice as the reference mixture containing 0.1 IU in 0.5 ml. Repeat the determination at least once and calculate the average of all valid estimates. The test is valid only if the reference preparation gives a result within 20 per cent of the expected value.

The confidence limits (P = 0.95) have been estimated to be:

- 85 per cent and 114 per cent when 2 animals per dose are used,
- 91.5 per cent and 109 per cent when 4 animals per dose are used,
- 93 per cent and 108 per cent when 6 animals per dose are used.

4. LABELLING

The label states:

- whether the preparation is a toxoid or a vaccine prepared from a whole inactivated culture or a mixture of the two,
- for each target species, the immunising effect produced (for example, antibody production, protection against signs of disease or infection).

01/2008:0364

CLOSTRIDIUM SEPTICUM VACCINE FOR VETERINARY USE

Vaccinum Clostridii septici ad usum veterinarium

1. DEFINITION

Clostridium septicum vaccine for veterinary use is prepared from a liquid culture of a suitable strain of *Clostridium septicum*.

The whole culture or its filtrate or a mixture of the two is inactivated to eliminate its toxicity while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for active immunisation of animals and/or to protect passively their progeny against disease caused by *C. septicum*.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

C. septicum used for production is grown in an appropriate liquid medium. Toxoid and/or inactivated cultures may be treated with a suitable adjuvant.

2-2. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the animals for which it is intended. For the latter, it shall be demonstrated that for each target species the vaccine, when administered according to the recommended schedule, stimulates an immune response (for example, induction of antibodies) consistent with the claims made for the product.

2-3. *MANUFACTURER'S TESTS*

2-3-1. **Residual toxicity**. A test for detoxification is carried out immediately after the detoxification process and, when there is risk of reversion, a second test is carried out at as late a stage as possible during the production process. The test for residual toxicity (section 3-4) may be omitted by the manufacturer.

2-3-2. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-5) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency.

Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency and that has been shown to be satisfactory with respect to immunogenicity in the target species. The following test may be used after a satisfactory correlation with the test under Potency (section 3-5) has been established.

Vaccinate rabbits as described under Potency and prepare sera. Determine the level of antibodies against the toxin of *C. septicum* in the individual sera by a suitable method such as an immunochemical method (*2.7.1*) or neutralisation in cell cultures. Use a homologous reference serum calibrated in International Units of *C. septicum* antitoxin. *Clostridia (multicomponent) rabbit antiserum BRP* is suitable for use as a reference serum. The vaccine complies with the test if the level of antibodies is not less than that found for a batch of vaccine that has given satisfactory results in the test described under Potency and that has been shown to be satisfactory with respect to immunogenicity in the target species.

3. BATCH TESTS

3-1. **Identification**. When injected into animals that do not have *C. septicum* antitoxin, the vaccine stimulates the formation of such antitoxin.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 animals of one of the species for which the vaccine is intended and that have not been vaccinated against *C. septicum*. Administer to each animal, by a recommended route, twice the maximum recommended dose. Observe the animals at least daily for 14 days.

The vaccine complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual toxicity**. Inject 0.5 ml of the vaccine by the subcutaneous route into each of 5 mice, each weighing 17-22 g. Observe the mice at least daily for 7 days.

The vaccine complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine.

3-5. **Potency**

Use for the test not fewer than 10 healthy rabbits, 3-6 months old. Administer to each rabbit by the subcutaneous route a quantity of vaccine not greater than the minimum dose stated on the label as the first dose. After 21 to 28 days, administer to the same animals a quantity of the vaccine not greater than the minimum dose stated on the label as the second dose. 10 to 14 days after the second injection, bleed the rabbits and pool the sera.

The vaccine complies with the test if the potency of the pooled sera is not less than 2.5 IU/ml.

The International Unit is the specific neutralising activity for *C. septicum* toxin contained in a stated amount of the International Standard which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

The potency of the pooled sera obtained from the rabbits is determined by comparing the quantity necessary to protect mice or other suitable animals against the toxic effects of a dose of *C. septicum* toxin with the quantity of a reference preparation of Clostridium septicum antitoxin, calibrated in International Units, necessary to give the same protection. For this comparison, a suitable preparation of *C. septicum* toxin for use as a test toxin is required. The dose of the test toxin is determined in relation to the reference preparation; the potency of the serum to be examined is determined in relation to the reference preparation using the test toxin.

Clostridia (multicomponent) rabbit antiserum BRP is suitable for use as a reference serum.

3-5-1. *Preparation of test toxin*. Prepare the test toxin from a sterile filtrate of a 1- to 3-day culture of *C. septicum* in liquid medium and dry by a suitable method. Select the test toxin by determining for mice the L+/5 dose and the LD_{50} the observation period being 72 h.

A suitable toxin contains not less than one L+/5 dose in 1.0 mg and not less than 10 LD_{50} in each L+/5 dose.

3-5-2. *Determination of test dose of toxin*. Prepare a solution of the reference preparation in a suitable liquid so that it contains 1.0 IU/ml. Prepare a solution of the test toxin in a suitable liquid so that 1 ml contains a precisely known amount, such as 4 mg. Prepare mixtures of the solution of the reference preparation and the solution of the test toxin such that each mixture contains 2.0 ml of the solution of the reference preparation (2 IU), one of a series of graded volumes of the solution of the test toxin and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 mice, each weighing 17-22 g, for each mixture, inject a dose of 0.5 ml by the intravenous or the intraperitoneal route into each mouse. Observe the mice for 72 h. If all the mice die, the amount of toxin present in 0.5 ml of the mixture is in excess of the test dose. If none of the mice die, the amount of toxin present in 0.5 ml of the mixture is less than the test dose. Prepare fresh mixtures such that 5.0 ml of each mixture contains 2.0 ml of the reference preparation (2 IU) and one of a series of graded volumes of the solution of the test toxin separated from each other by steps of not more than 20 per cent and covering the expected end-point. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 mice for each mixture, inject a dose of 0.5 ml by the intravenous or the intraperitoneal route into each mouse. Observe the mice for 72 h. Repeat the determination at least once and add together the results of the separate tests that have been made with mixtures of the same composition so that a series of totals is obtained, each total representing the mortality due to a mixture of a given composition.

The test dose of toxin is the amount present in 0.5 ml of that mixture which causes the death of one half of the total number of mice injected with it.

3-5-3. *Determination of the potency of the serum obtained from rabbits*

Preliminary test. Dissolve a quantity of the test toxin in a suitable liquid so that 2.0 ml contains 10 times the test dose (solution of the test toxin). Prepare a series of mixtures of the solution of the test toxin and of the serum to be examined such that each contains 2.0 ml of the solution of the test toxin, one of a series of graded volumes of the serum to be examined and sufficient of a suitable liquid to bring the final volume to 5.0 ml. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 mice for each mixture, inject a dose of 0.5 ml by the intravenous or the intraperitoneal route into each mouse. Observe the mice for 72 h. If none of the mice dies, 0.5 ml of the mixture contains more than 0.2 IU. If all the mice die, 0.5 ml of the mixture contains less than 0.2 IU.

Final test. Prepare a series of mixtures of the solution of the test toxin and of the serum to be examined such that 5.0 ml of each mixture contains 2.0 ml of the solution of the test toxin and one of a series of graded volumes of the serum to be examined, separated from each other by steps of not more than 20 per cent and covering the expected end-point as determined by the preliminary test. Prepare further mixtures of the solution of the test toxin and of the solution of the reference preparation such that 5.0 ml of each mixture contains 2.0 ml of the solution of the test toxin and one of a series of graded volumes of the solution of the reference preparation to confirm the test dose of the toxin. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 mice for each mixture proceed as described in the preliminary test. The test mixture which contains 0.2 IU in 0.5 ml is that mixture which kills the same or almost the same number of mice as the reference mixture containing 0.2 IU in 0.5 ml. Repeat the determination at least once and calculate the average of all valid estimates. The test is valid only if the reference preparation gives a result within 20 per cent of the expected value.

The confidence limits (P = 0.95) have been estimated to be:

- 85 per cent and 114 per cent when 2 animals per dose are used,
- 91.5 per cent and 109 per cent when 4 animals per dose are used,
- 93 per cent and 108 per cent when 6 animals per dose are used.

4. LABELLING

The label states:

- whether the preparation is a toxoid or a vaccine prepared from a whole inactivated culture, or a mixture of the two,
- for each target species, the immunising effect produced (for example, antibody production, protection against signs of disease or infection).

DISTEMPER VACCINE (LIVE) FOR MUSTELIDS

Vaccinum morbi Carrei vivum ad mustelidas

1. DEFINITION

Distemper vaccine (live) for mustelids is a preparation of a suitable strain of distemper virus that is attenuated for ferrets. This monograph applies to vaccines intended for the active immunisation of ferrets against disease caused by distemper virus.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in embryonated hens' eggs or in cell cultures.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Embryonated hens' eggs**. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from healthy flocks.

2-2-2. **Cell cultures**. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE VIRUS*

The vaccine virus is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the ferrets for which it is intended.

The following tests for Attenuation (section 2-3-1) and Immunogenicity (2-3-2) may be used during the demonstration of safety and efficacy.

2-3-1. **Attenuation**. When a volume of a viral suspension equivalent to 5 doses of the vaccine is injected by the intramuscular route into each of 2 ferrets that do not have antibodies against distemper virus, it does not provoke pathogenic effects within 21 days.

2-3-2. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended for vaccination using in each case ferrets of the minimum age to be recommended. The quantity of the vaccine virus to be administered to each ferret is not greater than the minimum

virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of vaccine.

Use for the test not fewer than 7 ferrets that do not have antibodies against distemper virus. Vaccinate not fewer than 5 ferrets, according to the schedule to be recommended. Maintain not fewer than 2 ferrets as controls. Challenge each ferret after 21 days by the intramuscular route with a quantity of a suspension of virulent distemper virus sufficient to cause the death of a ferret. Observe the animals at least daily for 21 days after challenge. Ferrets displaying typical signs of serious infection with distemper virus are euthanised to avoid unecessary suffering.

The test is invalid if one or both of the control ferrets do not die of distemper. The vaccine virus complies with the test if the vaccinated ferrets remain in normal health.

3. BATCH TESTS

3-1. **Identification**. The vaccine mixed with a specific distemper antiserum no longer provokes cytopathic effects in susceptible cell cultures or lesions on the chorio-allantoic membranes of fertilised hen eggs 9-11 days old.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas** (*2.6.7*). The vaccine complies with the test for mycoplasmas.

3-4. **Extraneous agents**. Neutralise the vaccine virus with a suitable monospecific antiserum against distemper virus and inoculate into susceptible cell cultures. The vaccine complies with the test if no cytopathic effect develops and there is no sign of the presence of haemagglutinating or haemadsorbing agents.

3-5. **Safety**. Use 2 ferrets that do not have antibodies against distemper virus. Administer to each ferret by a recommended route twice the dose of the vaccine. Observe the ferrets at least daily for 21 days.

The vaccine complies with the test if no ferret shows notable signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**. Titrate the vaccine virus in suitable cell cultures or fertilised hens' eggs 9-11 days old. The vaccine complies with the test if one dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-3-2) when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2008:1938

DUCK PLAGUE VACCINE (LIVE)

Vaccinum pestis anatis vivum

1. DEFINITION

Duck plague vaccine (live) is a preparation of a suitable strain of duck plague virus (anatid herpesvirus 1). This monograph applies to vaccines intended for the active immunisation of ducks.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in embryonated hens' eggs or in cell cultures. The vaccine may be freeze-dried.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Embryonated hens' eggs**. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from flocks free from specified pathogens (SPF) (*5.2.2*).

2-2-2. **Cell cultures**. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *SEED LOTS*

2-3-1. **Extraneous agents**. The master seed lot complies with the test for extraneous agents in seed lots (*2.6.24*). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the tests.

2-4. *CHOICE OF VACCINE VIRUS*

The vaccine virus shall be shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the ducks for which the vaccine is intended.

The following tests for safety (section 2-4-1), increase in virulence (section 2-4-2) and immunogenicity (section 2-4-3) may be used during demonstration of safety and immunogenicity.

2-4-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination, using in each case ducks from a species considered to be the most susceptible among the species to be recommended for vaccination and not older than the youngest age to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present in a batch of vaccine. For each test, use not fewer than 20 susceptible ducks that do not have antibodies against duck plague virus. Administer to each duck a quantity of vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in 1 dose of the vaccine. Observe the ducks at least daily for 21 days. The test is not valid if more than 10 per cent of the ducks die from causes not attributable to the vaccine virus. The vaccine virus complies with the test if no duck shows notable signs of duck plague or dies from causes attributable to the vaccine virus.

2-4-2. **Increase in virulence**. The test for increase in virulence consists of the administration of the vaccine virus, at the least attenuated passage level that will be present between the master seed lot and a batch of vaccine, to a group of 5 domestic ducks that do not have antibodies against duck plague virus and of an age suitable for the multiplication of the virus then its sequential passage, 5 times where possible, to further similar groups of ducks of an age suitable for the multiplication of the virus and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages. Administer by a recommended route a quantity of the vaccine virus that will allow recovery of virus for the passages described below. 2 to 4 days later, take samples of liver and spleen from each duck and pool all samples. Administer 0.1 ml of the pooled suspension by the oro-nasal or a parenteral route to each of 5 other domestic ducks of the same age that do not have antibodies against duck plague virus. Carry out this passage operation not fewer than 5 times; verify the presence of the

virus at each passage. If the virus is not found at a passage level, carry out a second series of passages. Carry out the test for safety (section 2-4-1) using the unpassaged vaccine virus and the maximally passaged vaccine virus that has been recovered. The vaccine virus complies with the test if no indication of increase in virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-4-3. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended for vaccination, using in each case domestic ducks not older than the youngest age to be recommended for vaccination. The quantity of the vaccine virus administered to each duck is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of the vaccine. For each test, use not fewer than 30 ducks of the same origin and that do not have antibodies against duck plague virus. Vaccinate by a recommended route not fewer than 20 ducks. Maintain not fewer than 10 ducks as controls. After 5 days, challenge each duck by a suitable route with a sufficient quantity of virulent duck plague virus. Observe the ducks at least daily for 14 days after challenge. Record the deaths and the number of surviving ducks that show clinical signs of disease. The test is not valid if during the observation period after challenge fewer than 80 per cent of the control ducks die or show typical signs of duck plague and/or if during the period between the vaccination and challenge more than 10 per cent of control or vaccinated ducks show abnormal clinical signs of disease or die from causes not attributable to the vaccine. The vaccine virus complies with the test if during the observation period after challenge not fewer than 80 per cent of the vaccinated ducks survive and show no notable clinical signs of duck plague.

3. BATCH TESTS

3-1. **Identification**. The vaccine, diluted if necessary and mixed with a monospecific duck plague virus antiserum, no longer infects embryonated hens' eggs from an SPF flock (*5.2.2*) or susceptible cell cultures (*5.2.4*) into which it is inoculated.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the requirement for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas**. The vaccine complies with the test for mycoplasmas (*2.6.7*).

3-4. **Extraneous agents**. The vaccine complies with the tests for extraneous agents in batches of finished product (*2.6.25*).

3-5. **Safety**. Use not fewer than 10 domestic ducks that do not have antibodies against duck plague virus and not older than the minimum age recommended for vaccination. Administer by a recommended route and method to each duck 10 doses of the vaccine in a volume suitable for the test. Observe the ducks at least daily for 21 days. The test is not valid if more than 20 per cent of the ducks show abnormal clinical signs of disease or die from causes not attributable to the vaccine. The vaccine complies with the test if no duck shows notable clinical signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**. Titrate the vaccine virus by inoculation into embryonated hens' eggs from an SPF flock (*5.2.2*) or into suitable cell cultures (*5.2.4*). The vaccine complies with the test if 1 dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency**. The vaccine complies with the test prescribed under immunogenicity (section 2-4-3), when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2008:1315

DUCK VIRAL HEPATITIS TYPE I VACCINE (LIVE)

Vaccinum hepatitidis viralis anatis stirpe I vivum

1. DEFINITION

Duck viral hepatitis type I vaccine (live) is a preparation of a suitable strain of duck hepatitis virus type I. This monograph applies to vaccines intended for the active immunisation of breeder ducks in order to protect passively their progeny and/or for the active immunisation of ducklings.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in embryonated hens' eggs or in cell cultures.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Embryonated hens' eggs**. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from flocks free from specified pathogens (SPF) (*5.2.2*).

2-2-2. **Cell cultures**. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *SEED LOTS*

2-3-1. **Extraneous agents**. The master seed lot complies with the tests for extraneous agents in seed lots (*2.6.24*). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the tests.

2-4. *CHOICE OF VACCINE VIRUS*

The vaccine virus shall be shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the ducks for which it is intended.

The following tests for safety (section 2-4-1), increase in virulence (section 2-4-2) and immunogenicity (section 2-4-3) may be used during demonstration of safety and immunogenicity.

2-4-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination using in each case ducks not older than the youngest age to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. For each test, use not fewer than 20 susceptible domestic ducklings (*Anas platyrhynchos*) that do not have antibodies against duck hepatitis virus type I. Administer to each duckling a quantity of vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in 1 dose of vaccine. Observe the ducklings at least daily for 21 days. The test is not valid if more than 10 per cent of the ducklings die from causes not attributable to the vaccine virus. The vaccine virus complies with the test if no duckling shows notable signs of duck viral hepatitis or dies from causes attributable to the vaccine virus.

2-4-2. **Increase in virulence**. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of vaccine to a group of five 1-day-old domestic ducklings that do not have antibodies against duck hepatitis virus type I, sequential passages, 5 times where possible, to further similar groups of 1-day-old ducklings and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages. Administer by the oro-nasal route a quantity of vaccine virus that will allow recovery of virus for the passages described below. 2 to 4 days later, take samples of liver from each duckling and pool the samples. Administer 1 ml of the pooled liver suspension by the oro-nasal route to each of five 1-day-old seronegative domestic ducklings. Carry out this operation 5 times. Verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages. Observe the ducklings given the last passage at least daily for 21 days. Compare the results obtained with unpassaged virus in the safety studies and those obtained with maximally passaged virus to assess the degree of increase in virulence. If the virus is not recovered at any passage level in the first and second series of passages, it is considered not to show increase in virulence.

2-4-3. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended, using in each case domestic ducks not older than the youngest age to be recommended for vaccination. The quantity of the vaccine virus administered to each bird is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of the vaccine.

2-4-3-1. *Vaccines for passive immunisation of ducklings.* Use for the test not fewer than 15 laying ducks or ducks intended for laying, as appropriate, of the same origin and that do not have antibodies against duck hepatitis virus type I. Vaccinate by a recommended route not fewer than 10 ducks using the schedule to be recommended. Maintain not fewer than 5 ducks as controls. Starting from 4 weeks after onset of lay, collect embryonated eggs from vaccinated and control ducks and incubate them. Challenge not fewer than twenty 1-week-old ducklings representative of the vaccinated group and not fewer than 10 from the control group by the oro-nasal route with a sufficient quantity of virulent duck hepatitis virus type I. Observe the ducklings at least daily for 14 days after challenge. Record the deaths and the number of surviving ducklings that show clinical signs of disease.

The test is not valid if:

- during the observation period after challenge fewer than 70 per cent of the challenged ducklings from the control ducks die or show typical signs of the disease,
- and/or during the period between vaccination and collection of the eggs more than 10 per cent of the control or vaccinated ducks show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine virus complies with the test if during the observation period after challenge the percentage relative protection calculated using the following expression is not less than 80 per cent:

$$\frac{V - C}{100 - C} \times 100$$

V = percentage of challenged ducklings from vaccinated ducks that survive to the end of the observation period without clinical signs of the disease.

C = percentage of challenged ducklings from unvaccinated control ducks that survive to the end of the observation period without clinical signs of the disease.

2-4-3-2. *Vaccines for active immunisation of ducklings.* Use for the test not fewer than 30 ducklings of the same origin and that do not have antibodies against duck hepatitis virus type I. Vaccinate by a recommended route not fewer than 20 ducklings. Maintain not fewer than 10 ducklings as controls. Challenge each duckling after at least 5 days by the oro-nasal route with a sufficient quantity of virulent duck hepatitis virus type I. Observe the ducklings at least daily for 14 days after challenge. Record the deaths and the number of surviving ducklings that show clinical signs of disease.

The test is not valid if:

- during the observation period after challenge fewer than 70 per cent of the control ducklings die or show typical signs of the disease,
- and/or during the period between vaccination and challenge more than 10 per cent of the control or vaccinated ducklings show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine virus complies with the test if during the observation period after challenge the percentage relative protection calculated using the following expression is not less than 80 per cent:

$$\frac{V - C}{100 - C} \times 100$$

V = percentage of challenged vaccinated ducklings that survive to the end of the observation period without clinical signs of the disease.

C = percentage of challenged unvaccinated control ducklings that survive to the end of the observation period without clinical signs of the disease.

3. BATCH TESTS

3-1. **Identification**. The vaccine, diluted if necessary and mixed with a monospecific duck hepatitis virus type I antiserum, no longer infects embryonated hens' eggs from an SPF flock (*5.2.2*) or susceptible cell cultures (*5.2.4*) into which it is inoculated.

3-2. **Bacteria and fungi**

Vaccines intended for administration by injection comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

Vaccines not intended for administration by injection either comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)* or with the following test: carry out a quantitative test for bacterial and fungal contamination; carry out identification tests for

micro-organisms detected in the vaccine; the vaccine does not contain pathogenic micro-organisms and contains not more than 1 non-pathogenic micro-organism per dose.

Any liquid supplied with the vaccine complies with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas**. The vaccine complies with the test for mycoplasmas (*2.6.7*).

3-4. **Extraneous agents**. The vaccine complies with the tests for extraneous agents in batches of finished product (*2.6.25*).

3-5. **Safety**. Use not fewer than 10 domestic ducks that do not have antibodies against duck hepatitis virus type I and of the youngest age recommended for vaccination. For vaccines recommended for use in ducks older than 2 weeks, ducks 2 weeks old may be used. Administer by a recommended route and method to each duck 10 doses of the vaccine. Observe the ducks at least daily for 21 days. The test is not valid if more than 20 per cent of ducks show abnormal clinical signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no duck shows notable clinical signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**. Titrate the vaccine virus by inoculation into embryonated hens' eggs from an SPF flock (*5.2.2*) or into suitable cell cultures (*5.2.4*). The vaccine complies with the test if 1 dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency**. Depending on the indications, the vaccine complies with 1 or both of the tests prescribed under Immunogenicity (section 2-4-3), when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

4. LABELLING

If it has been found that the vaccine may show reversion to virulence, the label indicates the precautions necessary to avoid transmission of virulent virus to unvaccinated ducklings.

01/2008:1202

EGG DROP SYNDROME '76 VACCINE (INACTIVATED)

Vaccinum morbi partus diminutionis mcmlxxvi inactivatum ad pullum

1. DEFINITION

Egg drop syndrome '76 vaccine (inactivated) is a preparation of a suitable strain of egg drop syndrome '76 virus (haemagglutinating avian adenovirus), inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for protection of laying birds against a drop in egg production and/or for prevention of loss of egg quality.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine strain is propagated in embryonated hens' or ducks' eggs or in cell cultures. The vaccine may be adjuvanted.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Embryonated hens' or ducks' eggs**. If the vaccine virus is grown in embryonated hens' or ducks' eggs, they are obtained from healthy flocks.

2-2-2. **Cell cultures**. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *SEED LOTS*

2-3-1. **Extraneous agents**. The master seed lot complies with the test for extraneous agents in seed lots (*2.6.24*). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the test.

2-4. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the birds for which it is intended.

The following test for Immunogenicity (section 2-4-1) may be used during the demonstration of efficacy.

2-4-1. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended, using in each case hens from a flock free from specified pathogens (SPF) (*5.2.2*) and of the age at which vaccination is recommended. The vaccine administered to each hen is of minimum potency.

Vaccinate each of 2 groups of 30 hens. Maintain 2 control groups one of 10 hens and the other of 30 hens, of the same age and from the same source as the vaccinates. Maintain individual egg production records from point of lay until 4 weeks after challenge. At 30 weeks of age, challenge each bird from 1 group of 30 vaccinates and the group of 10 control birds with a quantity of egg drop syndrome '76 virus sufficient to cause a well marked drop in egg production and/or quality. The test is invalid unless there is a well marked drop in egg production and/or quality in the control birds. The vaccine complies with the test if the vaccinated birds show no marked drop in egg production and/or quality.

When the second group of vaccinated birds and the group of 30 control birds are nearing the end of lay, challenge these birds, as before. The test is invalid unless there is a well marked drop in egg production and/or quality in the control birds. The vaccine complies with the test if the vaccinated birds show no marked drop in egg production and/or quality.

Carry out serological tests on serum samples obtained at the time of vaccination, 4 weeks later and just prior to challenge. The test is invalid if antibodies against egg drop syndrome '76 virus are detected in any sample from control birds.

2-5. *MANUFACTURER'S TESTS*

2-5-1. **Residual live virus**. The test for residual live virus is carried out in embryonated ducks' eggs from a flock free from egg drop syndrome '76 virus infection, or in embryonated hens' eggs from an SPF flock (*5.2.2*), or in suitable cell cultures, whichever is the most sensitive for the vaccine strain. The quantity of inactivated virus harvest used in the test is equivalent to not less than 10 doses of the vaccine. The inactivated virus harvest complies with the test if no live virus is detected.

2-5-2. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-6) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being

set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

Vaccinate not fewer than ten 14- to 28-day-old chickens from an SPF flock (*5.2.2*) with 1 dose of vaccine by one of the recommended routes. 4 weeks later, collect serum samples from each bird and from 5 unvaccinated control birds of the same age and from the same source. Measure the antibody response in a haemagglutination (HA) inhibition test on each serum using 4 HA units of antigen and chicken erythrocytes. The test is invalid if there are specific antibodies in the sera of the unvaccinated birds. The vaccine complies with the test if the mean titre of the vaccinated group is not less than that found previously for a batch of vaccine that has given satisfactory results in the test described under Potency.

3. BATCH TESTS

3-1. **Identification**. When injected into chickens that do not have antibodies against egg drop syndrome '76 virus, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 10 chickens, 14 to 28 days old, from an SPF flock (*5.2.2*). Administer a double dose of vaccine by a recommended route into each chicken. Observe the chickens at least daily for 21 days.

The vaccine complies with the test if no chicken shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual live virus**. A test for residual live virus is carried out to confirm inactivation of egg drop syndrome '76 virus.

A. For a vaccine prepared in eggs, carry out the test in embryonated ducks' eggs from a flock free from egg drop syndrome '76 virus infection or, if it is known to provide a more sensitive test system, in hens' eggs from an SPF flock (*5.2.2*). Inject $2/5^{th}$ of a dose into the allantoic cavity of each of ten 10- to 14-day-old embryonated eggs that are free from parental antibodies to egg drop syndrome '76 virus. Incubate the eggs and observe for 8 days. Pool separately the allantoic fluid from eggs containing live embryos, and that from eggs containing dead embryos, excluding those that die from non-specific causes within 24 h of the injection. Inject into the allantoic cavity of each of ten 10- to 14-day-old embryonated eggs that do not have parental antibodies to egg drop syndrome '76 virus, 0.2 ml of the pooled allantoic fluid from the live embryos and into each of 10 similar eggs, 0.2 ml of the pooled allantoic fluid from the dead embryos and incubate for 8 days. Examine the allantoic fluid from each egg for the presence of haemagglutinating activity using chicken erythrocytes. If more than 20 per cent of the embryos die at either stage, repeat that stage. The vaccine complies with the test if there is no evidence of haemagglutinating activity and if, in any repeat test, not more than 20 per cent of the embryos die from non-specific causes. Antibiotics may be used in the test to control extraneous bacterial infection.

B. For a vaccine adapted to growth in cell cultures, inoculate 10 doses into suitable cell cultures. If the vaccine contains an oily adjuvant, eliminate it by suitable means. Incubate the cultures at 38 ± 1 °C for 7 days. Make a passage on another set of cell cultures and incubate at 38 ± 1 °C for 7 days. Examine the cultures regularly and at the end of the incubation period examine the supernatant liquid for the presence of haemagglutinating activity. The vaccine complies with the test if the cell cultures show no sign of infection and if there is no haemagglutinating activity in the supernatant liquid.

3-5. **Extraneous agents**. Use the chickens from the safety test. 21 days after administration of the double dose of vaccine, administer one dose by the same route into each chicken. Collect serum samples from each chicken 2 weeks later and carry out tests for antibodies against the following agents by the methods prescribed in general chapter *5.2.2. Chicken flocks free from specified pathogens for the production and quality control of vaccines*: avian encephalomyelitis virus, avian leucosis viruses, infectious bronchitis virus, infectious bursal disease virus, infectious laryngotracheitis virus, influenza A virus, Marek's disease virus, Newcastle disease virus and, for vaccine produced in duck eggs, *Chlamydia* (by a complement-fixation test or agar gel precipitation test), duck hepatitis virus type I (by a fluorescent-antibody test or serum-neutralisation test) and Derzsy's disease virus (by a serum-neutralisation test). The vaccine complies with the test if it does not stimulate the formation of antibodies against these agents.

3-6. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-4-1) when administered by a recommended route and method.

4. LABELLING

The label states whether the strain in the vaccine is duck- or hen-embryo-adapted or cell-culture-adapted.

01/2008:1613

EQUINE HERPESVIRUS VACCINE (INACTIVATED)

Vaccinum herpesviris equini inactivatum

1. DEFINITION

Equine herpesvirus vaccine (inactivated) is a preparation of one or more suitable strains of equid herpesvirus 1 and/or equid herpesvirus 4, inactivated while maintaining adequate immunogenic properties or a suspension of an inactivated fraction of the virus. This monograph applies to vaccines intended for the active immunisation of horses against disease caused by equid herpesvirus 1 and/or equid herpesvirus 4.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

Each strain of vaccine virus is grown separately in cell cultures. The viral suspensions may be purified and concentrated and are inactivated; they may be treated to fragment the virus and the viral fragments may be purified and concentrated. The vaccine may be adjuvanted.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the horses for which it is intended. Where a particular breed of horse is known to be especially sensitive to the vaccine, horses from that breed are included in the test for safety.

The following tests for safety (section 2-3-1) and immunogenicity (section 2-3-2) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination and in horses of each category for which the vaccine is intended. Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine.

2-3-1-1-1. *General safety.* Use for the test not fewer than 10 horses that have not been previously vaccinated with an equine herpesvirus vaccine, that have at most a low antibody titre not indicative of recent infection and that do not excrete equid herpesvirus. Administer to each horse a double dose of the vaccine, then one dose after 14 days. Observe the horses at least daily until 14 days after the last administration.

The vaccine complies with the test if no horse shows abnormal local or systemic reactions or dies from causes attributable to the vaccine during the 28 days of the test.

2-3-1-1-2. *Safety in pregnant horses.* If the vaccine is intended for use in pregnant horses, use for the test not fewer than 10 pregnant horses at the relevant trimester or trimesters of pregnancy according to the schedule to be recommended. Administer to each horse a double dose of the vaccine, then one dose after 14 days. Observe the horses at least daily until foaling.

The vaccine complies with the test if no horse shows abnormal local or systemic reactions or dies from causes attributable to the vaccine and if no adverse effects on the pregnancy or the offspring are noted.

2-3-2. **Immunogenicity**. The type of immunogenicity test depends on the claims for the product. For vaccines intended to protect against the disease of the respiratory tract, carry out test 2-3-2-1, using equid herpesvirus 1 and/or equid herpesvirus 4 depending on the claims for protection. For vaccines intended to protect against abortion carry out test 2-3-2-2.

A test is carried out for each route and method of administration to be recommended, using in each case horses that have not been vaccinated with an equine herpesvirus vaccine, that have at most a low antibody titre not indicative of recent infection, and that do not excrete equid herpesvirus. To demonstrate that no recent infection occurs, immediately before vaccination: draw a blood sample from each horse and test individually for antibodies against equid herpesviruses 1 and 4; collect 10 ml of heparinised blood and test the washed leucocytes for equid herpesviruses 1 and 4; collect a nasopharyngeal swab and test for equid herpesviruses 1 and 4. There is no indication of an active infection. Immediately before challenge collect a nasopharyngeal swab and test for equid herpesviruses 1 and 4. If there is an indication of virus excretion remove the horse from the test. Keep the horses in strict isolation. The vaccine administered to each horse is of minimum potency.

2-3-2-1. *Vaccines intended for protection against disease of the respiratory tract.* Use for the test not fewer than 10 horses, not less than 6 months old. Vaccinate not fewer than 6 horses according to the schedule to be recommended. Maintain not fewer than 4 horses as controls. At least 2 weeks after the last vaccination, challenge each horse by nasal instillation with a quantity of equid herpesvirus 1 or 4, sufficient to produce in a susceptible horse characteristic signs of the disease such as pyrexia and virus excretion (and possibly nasal discharge and coughing). Observe the horses at least daily for 14 days. Collect nasopharyngeal swabs daily from each individual horse to isolate the virus.

The vaccine complies with the test if the vaccinated horses show no more than slight signs; the signs in vaccinates are less severe than in controls. The average number of days on which virus is excreted, and the respective virus titres are significantly lower in vaccinated horses than in controls.

2-3-2-2. *Vaccines intended for protection against abortion.* Use not fewer than 10 pregnant horses. In addition to the testing described above, 6, 4, 3, 2 and 1 month before the first vaccination draw a blood sample from each horse and test individually for antibodies against equid herpesvirus 1 and equid herpesvirus 4. There is no evidence of recent infection or virus excretion. Vaccinate not fewer than 6 horses according to the schedule to be recommended. Maintain not fewer than 4 horses as controls. Between day 260 and 290 of pregnancy but not earlier than 3 weeks after the last vaccination challenge each horse, by nasal instillation, with a quantity of equid herpesvirus 1 sufficient to produce abortion in susceptible horses. Observe the horses at least daily up to foaling or abortion. Collect samples of fetal lung and liver tissues from aborted fetuses and carry out tests for virus in cell cultures.

The test is invalid if more than one control horse gives birth to a healthy foal and if the challenge virus is not isolated from the aborted fetuses. The vaccine complies with the test if not more than one vaccinated horse aborts.

2-4. *MANUFACTURER'S TESTS*

2-4-1. **Residual live virus**. The test for residual live virus is carried out using 2 passages in the same type of cell culture as that used in the production or in cell cultures shown to be at least as sensitive. The quantity of inactivated virus harvest used in the test is equivalent to not less than 25 doses of the vaccine. The inactivated virus harvest complies with the test if no live virus is detected.

2-4-2. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-5) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

Vaccinate not fewer than 5 rabbits, guinea-pigs or mice with a single injection of a suitable dose. Where the schedule to be recommended requires a second injection to be given, the schedule to be recommended may be used in laboratory animals provided it has been demonstrated that this will still provide a suitably sensitive test system. At a given interval within the range of 14-21 days after the last injection, collect blood from each animal and prepare serum samples. Use a suitable validated test such as an enzyme-linked immunosorbent assay to measure the response to each of the antigens stated on the label. The vaccine complies with the test if the antibody levels are not significantly less than those obtained with a batch that has given satisfactory results in the test described under Potency.

3. BATCH TESTS

3-1. **Idenfication**. In animals that do not have antibodies against equid herpesvirus 1 and equid herpesvirus 4 or a fraction of the viruses, the vaccine stimulates the production of specific antibodies against the virus type or types included in the product. The method used must distinguish between antibodies against equid herpesviruses 1 and 4.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use not fewer than 2 horses that have not been vaccinated against equid herpesviruses 1 and 4. Administer to each horse by a recommended route a double dose of the vaccine, then one dose after 2 weeks. Observe the horses at least daily until 10 days after the last administration.

The vaccine complies with the test if no horse shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual live virus**. Carry out a test for residual live virus using not less than 25 doses of vaccine by inoculating cell cultures sensitive to equid herpesviruses 1 and 4; make a passage after 5-7 days and maintain the cultures for 14 days. The vaccine complies with the test if no live virus is detected. If the vaccine contains an adjuvant, separate the adjuvant from the liquid phase, by a method that does not inactivate or otherwise interfere with the detection of live virus, or carry out a test for inactivation on the mixture of bulk antigens before addition of the adjuvant.

3-5. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-3-2) when administered by a recommended route and method.

01/2008:0249

EQUINE INFLUENZA VACCINE (INACTIVATED)

Vaccinum influenzae equi inactivatum

1. DEFINITION

Equine influenza vaccine (inactivated) is a preparation of one or more suitable strains of equine influenza virus, inactivated while maintaining adequate immunogenic properties. Suitable strains contain both haemagglutinin and neuraminidase. This monograph applies to vaccines intended for the active immunisation of horses against equine influenza.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

Each strain of virus is grown separately in embryonated hens' eggs or in cell cultures. The viral suspensions may be purified and concentrated. The antigen content of the vaccine is based on the haemagglutinin content of the viral suspensions determined as described under Manufacturer's Tests; the amount of haemagglutinin for each strain is not less than that in the vaccine shown to be satisfactory in the test for potency. The vaccine may be adjuvanted.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Embryonated hens' eggs**. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from a healthy flock.

2-2-2. **Cell cultures**. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE COMPOSITION*

The choice of strains used in the vaccine is based on epidemiological data. The Office international des épizooties reviews the epidemiological data periodically and if necessary recommends new strains corresponding to prevailing epidemiological evidence. Such strains are used in accordance with the regulations in force in the signatory States of the Convention on the Elaboration of a European Pharmacopoeia.

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the horses for which it is intended. Where a particular breed of horse is known to be especially sensitive to the vaccine, horses from that breed are included in the tests for safety.

The following tests for safety (section 2-3-1) and immunogenicity (section 2-3-2) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination and in horses of each category for which the vaccine is intended. Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine.

2-3-1-1. *General safety.* Use for the test not fewer than 10 horses that preferably do not have antibodies against equine influenza virus or, where justified, use horses with a low level of such antibodies as long as they have not been vaccinated against equine influenza and administration of the vaccine does not cause an anamnestic response. Administer to each horse a double dose of the vaccine, then one dose after 14 days. Observe the horses at least daily until 14 days after the last administration.

The vaccine complies with the test if no horse shows abnormal local or systemic reactions or dies from causes attributable to the vaccine during the 28 days of the test.

2-3-1-2. *Safety in pregnant horses.* If the vaccine is intended for use in pregnant horses, use for the test not fewer than 10 pregnant horses at the stage or at different stages of pregnancy according to the schedule to be recommended. Administer to each horse a double dose of the vaccine, then one dose after 14 days. Observe the horses at least daily until foaling.

The vaccine complies with the test if no horse shows abnormal local or systemic reactions or dies from causes attributable to the vaccine and if no adverse effects on the pregnancy or the offspring are noted.

2-3-2. **Immunogenicity**. The test described under 2-3-2-1. is suitable to demonstrate the immunogenicity of the strains present in the vaccine.

A test with virulent challenge is carried out for at least one vaccine strain (see test 2-3-2-1). For other strains in the vaccine, demonstration of immunogenicity may, where justified, be based on the serological response induced in horses by the vaccine (see tests 2-3-2-2); justification for protection against these strains may be based on published data on the correlation of the antibody titre with protection against antigenically related strains.

Where serology is used, the test is carried out as described under 2-3-2-1 but instead of virulent challenge, a blood sample is drawn 2 weeks after the last vaccination and the antibody titre of each serum is determined by a suitable immunochemical method (*2.7.1*), such as the single radial haemolysis test or the haemagglutination-inhibition test shown below; a reference serum is used to validate the test. The acceptance criteria depend on the strain and are based on available data; for A/equine-2 virus, vaccines have usually been found satisfactory if the antibody titre of each serum is not less than 85 mm^2 where the single radial haemolysis test is used, or not less than 1:64 (before mixture with the suspension of antigen and erythrocytes) where the haemagglutination-inhibition test is used.

Equine influenza subtype 1 horse antiserum BRP, equine influenza subtype 2 American-like horse antiserum BRP and *equine influenza subtype 2 European-like horse antiserum BRP* are suitable for use as reference sera for the single radial haemolysis test.

The claims for the product reflect the type of immunogenicity demonstrated (protection against challenge or antibody production).

2-3-2-1. Protection from signs of disease and reduction of virus excretion. Carry out the immunogenicity test using a challenge strain against which the vaccine is stated to provide protection. Use where possible a recent isolate.

A test is carried out for each route and method of administration to be recommended, using in each case horses not less than 6 months old. The vaccine administered to each horse is of minimum potency.

Use for the test not fewer than 10 horses that do not have antibodies against equine influenza virus. Draw a blood sample from each horse and test individually for antibodies against equine influenza virus to determine seronegativity. Vaccinate not fewer than 6 horses according to the schedule to be recommended. Maintain not fewer than 4 horses as controls. Draw a second blood sample from each vaccinated horse 7 days after the first vaccination and test individually for antibodies against equine influenza virus, to detect an anamnestic sero-response. Horses showing sero-conversion at this stage are excluded from the test. At least 2 weeks after the last vaccination, challenge each horse by aerosol with a quantity of equine influenza virus sufficient to produce characteristic signs of disease such as fever, nasal discharge and coughing in a susceptible horse. Observe the horses at least daily for 14 days. Collect nasal swabs daily from each individual horse to isolate the virus.

The vaccine complies with the test if the vaccinated horses show no more than slight signs; the controls show characteristic signs. The average number of days on which virus is excreted, and the respective virus titres are significantly lower in vaccinated horses than in control horses.

2-3-2-2. Presence of antibodies after vaccination

2-3-2-2-1. *Single radial haemolysis.* Heat each serum at 56 °C for 30 min. Perform tests on each serum using respectively the antigen or antigens prepared from the strain(s) used in the production of the vaccine. Mix 1 ml of sheep erythrocyte suspension in barbital buffer solution (1 volume of erythrocytes in 10 volumes of final suspension) with 1 ml of a suitable dilution of the influenza virus strain in barbital buffer solution and incubate the mixture at 4 °C for 30 min. To 2 ml of the virus/erythrocyte mixture, add 1 ml of a 3 g/l solution of *chromium(III) trichloride hexahydrate R*, mix and allow to stand for 10 min. Heat the sensitised erythrocytes to 47 °C in a water-bath. Mix 15 ml of a 10 g/l solution of *agarose for electrophoresis R* in barbital buffer solution, 0.7 ml of sensitised erythrocyte suspension and the appropriate amount of diluted guinea-pig complement in barbital buffer solution at 47 °C. Pour the mixture into Petri dishes and allow the agar to set. Punch holes in the agar layer and place in each hole, 5 µl of the undiluted serum to be tested or control serum. Incubate the Petri dishes at 37 °C for 18 h. Measure the diameter of the haemolysis zone and calculate its area, which expresses the antibody titre, in square millimetres.

Equine influenza subtype 1 horse antiserum BRP, *equine influenza subtype 2 American-like horse antiserum BRP* and *equine influenza subtype 2 European-like horse antiserum BRP* are suitable for use as reference sera for the single radial haemolysis test.

2-3-2-2-2. *Haemagglutination-inhibition test.* Inactivate each serum by heating at 56 °C for 30 min. To one volume of each serum add three volumes of *phosphate-buffered saline pH 7.4 R* and four volumes of a 250 g/l suspension of *light kaolin R* in the same buffer solution. Shake each mixture for 10 min. Centrifuge, collect the supernatant liquid and mix with a concentrated suspension of chicken erythrocytes. Allow to stand at 37 °C for 60 min and centrifuge. The dilution of the serum obtained is 1:8. Perform tests on each serum using each antigen prepared from the strains used in the production of the vaccine. Using each diluted serum, prepare a series of twofold dilutions. To 0.025 ml of each of the latter dilutions add 0.025 ml of a suspension of antigen treated with *ether R* and containing four haemagglutinating units. Allow the mixture to stand for 30 min and add 0.05 ml of a suspension of chicken erythrocytes containing 2×10^7 erythrocytes/ml. Allow to stand for 1 h and note the last dilution of serum that still completely inhibits haemagglutination.

2-4. *MANUFACTURER'S TESTS*

2-4-1. **Residual live virus**. The test for residual live virus is carried out using method 2-4-1-1 or method 2-4-1-2 whichever is more sensitive. The quantity of inactivated virus harvest used is equivalent to not less than 10 doses of vaccine.

2-4-1-1. *Test in cell cultures.* Inoculate the vaccine into suitable cells; after incubation for 8 days, make a subculture. Incubate for a further 6-8 days. Harvest about 0.1 ml of the supernatant and examine for live virus by a haemagglutination test. If haemagglutination is found, carry out a further passage in cell culture and test for haemagglutination; the inactivated virus harvest complies with the test if no haemagglutination occurs.

2-4-1-2. *Test in embryonated eggs.* Inoculate 0.2 ml into the allantoic cavity of each of 10 embryonated eggs and incubate at 33-37 °C for 3-4 days. The test is invalid unless not fewer than 8 of the 10 embryos survive. Harvest 0.5 ml of the allantoic fluid from each surviving embryo and pool the fluids. Inoculate 0.2 ml of the pooled fluid into a further 10 embryonated eggs and incubate at 33-37 °C for 3-4 days. The test is invalid unless at least 8 of the 10 embryonated embryos survive. Harvest about 0.1 ml of the allantoic fluid from each surviving embryo and examine each individual harvest for live virus by a haemagglutination test. If haemagglutination is found for any of the fluids, carry out a further passage of that fluid in eggs and test for haemagglutination; the inactivated virus harvest complies with the test if no haemagglutination occurs.

2-4-2. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-5) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test(s) described under Potency. The following test may be used.

Use 5 guinea-pigs that do not have specific antibodies. Vaccinate each guinea-pig by the subcutaneous route with one dose of vaccine. 21 days later, collect blood samples and separate the serum. Carry out tests on the serum for specific antibodies by a suitable immunochemical method (*2.7.1*) such as single radial haemolysis or haemagglutination-inhibition, using reference sera to validate the test. The vaccine complies with the test if the antibody titres are not significantly lower than those obtained in guinea-pigs with a reference batch of vaccine shown to have satisfactory potency in horses.

2-4-3. **Bacterial endotoxins**. For vaccines produced in eggs, the content of bacterial endotoxins is determined on the virus harvest to monitor production.

2-4-4. **Haemagglutinin content**. The content of haemagglutinin in the inactivated virus suspension, after purification and concentration where applicable, is

determined by a suitable immunochemical method (*2.7.1*), such as single radial immunodiffusion, using a suitable haemagglutinin reference preparation; the inactivated virus suspension complies with the test if the content is shown to be within the limits shown to allow preparation of a satisfactory vaccine.

3. BATCH TESTS

3-1. **Identification**. In animals that do not have specific antibodies against equine influenza virus, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use not fewer than 2 horses that preferably do not have antibodies against equine influenza virus or, where justified, use horses with a low level of such antibodies as long as they have not been vaccinated against equine influenza and administration of the vaccine does not cause an anamnestic response. Administer to each horse by a recommended route a double dose of the vaccine, then one dose after 2 weeks. Observe the horses at least daily until 10 days after the last administration.

The vaccine complies with the test if no horse shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual live virus**. Inoculate 0.2 ml of the vaccine into the allantoic cavity of each of 10 embryonated eggs and incubate at 33-37 °C for 3-4 days. The test is invalid unless at least 8 of the 10 embryos survive. Harvest 0.5 ml of the allantoic fluid from each surviving embryo and pool the fluids. Inoculate 0.2 ml of the pooled fluid into a further 10 embryonated eggs and incubate at 33-37 °C for 3-4 days. The test is invalid unless not fewer than 8 of the 10 embryos survive. Harvest about 0.1 ml of the allantoic fluid from each surviving embryo and examine each individual harvest for live virus by a haemagglutination test. If haemagglutination is found for any of the fluids, carry out for that fluid a further passage in eggs and test for haemagglutination; the vaccine complies with the test if no haemagglutination occurs.

3-5. **Potency**. The vaccine complies with the requirements of the test(s) mentioned under Immunogenicity (section 2-3-2) when administered by a recommended route and method.

01/2008:1101

FELINE CALICIVIROSIS VACCINE (INACTIVATED)

Vaccinum calicivirosis felinae inactivatum

1. DEFINITION

Feline calicivirosis vaccine (inactivated) is a preparation of one or more suitable strains of feline calicivirus inactivated while maintaining adequate immunogenic properties or of fractions of one or more strains of feline calicivirus with adequate immunogenic properties. This monograph applies to vaccines intended for the active immunisation of cats against feline calicivirosis.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures. The virus harvest is inactivated; the virus may be disrupted and the fractions purified and concentrated. The vaccine may be adjuvanted.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the cats for which it is intended.

The following test for immunogenicity (2-3-1) may be used during the demonstration of efficacy.

2-3-1. **Immunogenicity**. A test is carried out for each strain of feline calicivirus in the vaccine and for each route and method of administration to be recommended for vaccination, using in each case cats 8-12 weeks old. The vaccine administered to each cat is of minimum potency.

Use for the test not fewer than 20 cats that do not have antibodies against feline calicivirus. Vaccinate not fewer than 10 cats, according to the schedule to be recommended. Maintain not fewer than 10 cats as controls. Challenge each cat after 4 weeks by the intranasal route with a sufficient quantity of a suspension of virulent feline calicivirus. Observe the cats at least daily for 14 days after challenge. Collect nasal washings daily on days 2 to 14 to test for virus excretion. Note daily the body temperature and signs of disease using the scoring system shown below.

The test is invalid if during the observation period after challenge, fewer than 80 per cent of the control cats show notable signs of feline calicivirosis (hyperthermia, buccal ulcers, respiratory signs). The vaccine complies with the test if during the observation period after challenge, the score for the vaccinated cats is significantly lower than that for the controls.

Observed signs	**Score**
Death	10
Depressed state	2
Temperature ≥ 39.5 °C	1
Temperature ≤ 37 °C	2
Ulcer (nasal or oral)	
– small and few in number	1
– large and numerous	3
Nasal discharge	
– slight	1
– copious	2
Ocular discharge	1
Weight loss	2
Virus excretion (total number of days):	
≤ 4 days	1
5-7 days	2
>7 days	3

2-4. *MANUFACTURER'S TESTS*

2-4-1. **Residual live virus**. The test for residual live calicivirus is carried out using 2 passages in cell cultures of the same type as those used for preparation of the vaccine or in cell cultures shown to be at least as sensitive; the quantity of inactivated virus harvest used in the test is equivalent to not less than 25 doses of vaccine. The inactivated viral harvest complies with the test if no live virus is detected.

2-4-2. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-5) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

Use for the test groups of 15 seronegative mice. Administer to each mouse half a dose of the vaccine and 7 days later, repeat the administration. After 21 days following the first injection, take blood samples and determine the level of antibodies against feline calicivirus by an immunofluorescence technique using pools of serum from groups of 3 mice. The vaccine complies with the test if the antibody levels are not significantly lower than those obtained with a batch of vaccine that has given satisfactory results in the test described under Potency.

3. BATCH TESTS

3-1. **Identification**. When injected into animals that do not have specific antibodies against feline calicivirus, the vaccine stimulates the formation of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 cats, 8-12 weeks old, preferably that do not have antibodies against feline calicivirus or, where justified, use cats that have a low level of such antibodies as long as they have not been vaccinated against feline calicivirosis and administration of the vaccine does not cause an anamnestic response. Administer to each cat by a recommended route a double dose of the vaccine. Observe the cats at least daily for 14 days.

The vaccine complies with the test if no cat shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual live virus**. Carry out a test for residual live calicivirus using 10 doses of vaccine and 2 passages in cell cultures of the same type as those used for preparation of the vaccine or in cell cultures shown to be at least as sensitive. The vaccine complies with the test if no live virus is detected. If the vaccine contains an adjuvant that would interfere with the test, where possible separate the adjuvant from the liquid phase by a method that does not inactivate or otherwise interfere with detection of live virus.

3-5. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-3-1) when administered by a recommended route and method.

corrected 6.0

FELINE CALICIVIROSIS VACCINE (LIVE)

Vaccinum calicivirosis felinae vivum

1. DEFINITION

Feline calicivirosis vaccine (live) is a preparation of one or more suitable strains of feline calicivirus. This monograph applies to vaccines intended for the active immunisation of cats against feline calicivirosis.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE VIRUS*

The vaccine virus is shown to be satisfactory with respect to safety (including safety for pregnant queens if such use is not contra-indicated) (*5.2.6*) and efficacy (*5.2.7*) for the cats for which it is intended.

The following tests for safety (section 2-3-1), increase in virulence (section 2-3-2) and immunogenicity (2-3-3) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine.

For each test, use not fewer than 10 cats of the minimum age to be recommended for vaccination and that do not have antibodies against feline calicivirus. Administer to each cat a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in one dose of the vaccine. Observe the cats at least daily for 21 days.

The vaccine virus complies with the test if no cat shows abnormal local or systemic reactions, or dies from causes attributable to the vaccine virus.

2-3-2. **Increase in virulence**. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to 2 cats that do not have antibodies against feline calicivirus, sequential passages, 5 times where possible, to further similar groups and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages.

Administer to each cat by a route to be recommended a quantity of the vaccine virus that will allow recovery of virus for the passages described below. Administer the virus by the route to be recommended for vaccination most likely to lead to reversion of virulence. After 5 days, remove the nasal mucus, tonsils and trachea of each cat. Mix, homogenise in 10 ml of buffered saline and decant. Administer the supernatant by the intranasal route to each of 2 other cats. Carry out this passage operation 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages.

Carry out the test for safety (section 2-3-1) using unpassaged vaccine virus and the maximally passaged virus that has been recovered.

The vaccine virus complies with the test if no indication of increased virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-3-3. **Immunogenicity**. A test is carried out for each strain of feline calicivirus in the vaccine, for each route and method of administration to be recommended for vaccination, using in each case cats 8-12 weeks old. The quantity of vaccine virus to be administered to each cat is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of vaccine.

Use for the test not fewer than 20 cats that do not have antibodies against feline calicivirus. Vaccinate not fewer than 10 cats, according to the schedule to be recommended. Maintain not fewer than 10 cats as controls. Challenge each cat after 4 weeks by the intranasal route with a sufficient quantity of a suspension of virulent feline calicivirus virus. Observe the cats at least daily for 14 days after challenge. Collect nasal washings daily on days 2 to 14 to test for virus excretion. Note daily the body temperature and signs of disease using the scoring system shown below.

The test is invalid if during the observation period after challenge, fewer than 80 per cent of the control cats show notable signs of feline calicivirosis (hyperthermia, buccal ulcers, respiratory signs). The vaccine virus complies with the test if during the observation period after challenge, the score for the vaccinated cats is significantly lower than that for the controls.

Observed signs	**Score**
Death	10
Depressed state	2
Temperature ≥ 39.5 °C	1
Temperature ≤ 37 °C	2
Ulcer (nasal or oral)	
– small and few in number	1
– large and numerous	3
Nasal discharge	
– slight	1
– copious	2
Ocular discharge	1
Weight loss	2
Virus excretion (total number of days):	
≤ 4 days	1
5-7 days	2
>7 days	3

3. BATCH TESTS

3-1. **Identification**. When neutralised by one or more monospecific antisera, the vaccine no longer infects susceptible cell cultures into which it is inoculated.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas** (*2.6.7*). The vaccine complies with the test for mycoplasmas.

3-4. **Extraneous agents**. Neutralise the vaccine virus with one or more suitable monospecific antisera against feline calicivirus and inoculate into cell cultures known for their susceptibility to viruses pathogenic for the cat. Carry out at least one passage and maintain the cultures for 14 days. The vaccine complies with the test if no cytopathic effect develops and there is no sign of the presence of haemadsorbing agents.

3-5. **Safety**. Use 2 cats 8-12 weeks old, that do not have antibodies against feline calicivirus. Administer to each cat by a recommended route 10 doses of the vaccine. Observe the cats at least daily for 14 days.

The vaccine complies with the test if no cat shows notable signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**. Titrate the vaccine virus in suitable cell cultures at a temperature favourable to replication of the virus. The vaccine complies with the test if one dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-3-3) when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2008:2324

FELINE CHLAMYDIOSIS VACCINE (INACTIVATED)

Vaccinum chlamydiosidis felinae inactivatum

1. DEFINITION

Feline chlamydiosis vaccine (inactivated) is a preparation of one or more suitable strains of *Chlamydophila felis*, which have been inactivated by a suitable method. This monograph applies to vaccines intended for administration to cats for active immunisation.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The seed material is cultured in embryonated hens' eggs from a healthy flock or in suitable cell cultures (*5.2.4*). If the vaccine contains more than one strain of bacterium, the different strains are grown and harvested separately. The bacterial harvests are inactivated using suitable and validated methods. The suspensions may be treated to fragment the micro-organisms and the fragments may be purified and concentrated. The vaccine may contain adjuvants.

2-2. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) in cats for which it is intended.

The following test for immunogenicity (section 2-2-1) may be used during the demonstration of efficacy.

2-2-1. **Immunogenicity**. Carry out the test for each route and method of administration to be recommended for vaccination, using in each case cats not older than the minimum age recommended for vaccination and which do not have antibodies against *C. felis*. Vaccinate 10 cats according to the instructions for use and keep 10 cats as controls. Not later than 4 weeks after the last administration of vaccine, administer by a suitable route to each cat a quantity of a virulent strain of *C. felis* sufficient to produce in susceptible cats typical signs of disease such as conjunctivitis and nasal discharge. Observe the cats for 28 days. Where reduction of chlamydophila excretion is to be claimed, collect nasal washings and/or conjunctival swabs on days 7, 14,

17, 21, 24 and 28 after challenge to test for chlamydophila excretion. The duration of excretion for the vaccinated animals is significantly lower than for the controls. Note daily the body temperature and signs of disease using a suitable scoring system. The vaccine complies with the test if the score for the vaccinated cats is significantly lower than that for the controls.

2-3. *MANUFACTURER'S TESTS*

2-3-1. **Batch potency test**. It is not necessary to carry out the potency test (section 3-5) for each batch of the vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out on a batch, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the potency test (section 3-5). The following test may be used.

Inject a suitable dose by a suitable route into each of 5 seronegative cats or another suitable species. Where the schedule stated on the label requires a booster injection to be given, a booster vaccination may also be given in this test provided it has been demonstrated that this will still provide a suitably sensitive test system. Before the vaccination and at a given interval usually within the range of 14-21 days after the last injection, collect blood from each animal and prepare serum samples. Determine individually for each serum the titre of antibodies against each strain stated on the label, using a suitable test such as enzyme-linked immunosorbent assay (*2.7.1*). The vaccine complies with the test if the antibody levels are not significantly lower than those obtained for a batch that has given satisfactory results in the potency test (section 3-5).

2-3-2. **Bacterial endotoxins**. A test for bacterial endotoxins (*2.6.14*) is carried out on the final lot or, where the nature of the adjuvant prevents performance of a satisfactory test, on the bulk antigen or the mixture of bulk antigens immediately before addition of the adjuvant. The maximum acceptable amount of bacterial endotoxins is that found for a batch of vaccine that has been shown to be satisfactory in the safety test (section 3-4). The method chosen for determining the maximum acceptable amount of bacterial endotoxins is subsequently used for the testing of each batch.

3. BATCH TESTS

3-1. **Identification**. When injected into seronegative animals, the vaccine stimulates the production of antibodies against each of the strains of *C. felis* present in the vaccine.

3-2. **Residual live chlamydophila**. The vaccine complies with a suitable test for residual live chlamydophila.

3-3. **Bacteria and fungi**. The vaccine complies with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-4. **Safety**. Use 2 cats not older than the minimum age recommended for vaccination and free from antibodies against *C. felis*. Administer to each cat by a recommended route a double dose of the vaccine. Observe the cats at least daily for 2 weeks. The vaccine complies with the test if the cats remain in good health and no abnormal local or systemic reactions occur.

3-5. **Potency**. The vaccine complies with the test for immunogenicity (section 2-2-1).

01/2008:0794

FELINE INFECTIOUS ENTERITIS (FELINE PANLEUCOPENIA) VACCINE (INACTIVATED)

Vaccinum panleucopeniae felinae infectivae inactivatum

1. DEFINITION

Feline infectious enteritis (feline panleucopenia) vaccine (inactivated) is a preparation of a suitable strain of feline panleucopenia virus or canine parvovirus inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for the active immunisation of cats against feline infectious enteritis (feline panleucopenia).

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures. The virus harvest is inactivated. The vaccine may be adjuvanted.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the cats for which it is intended.

The following test for immunogenicity (2-3-1) may be used during the demonstration of efficacy.

2-3-1. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended for vaccination, using in each case cats 8-12 weeks old. The vaccine administered to each cat is of minimum potency.

Use for the test not fewer than 10 cats that do not have antibodies against feline panleucopenia virus and canine parvovirus. Vaccinate not fewer than 5 cats, according to the schedule to be recommended. Maintain not fewer than 5 cats as controls. Carry out leucocyte counts 8 days and 4 days before challenge and calculate the mean of the 2 counts to serve as the initial value. Challenge each cat after 20-22 days by the intraperitoneal route with a sufficient quantity of a suspension of virulent feline panleucopenia virus. Observe the cats at least daily for 14 days after challenge. Carry out leucocyte counts on the 4^{th}, 6^{th}, 8^{th} and 10^{th} days after challenge.

The test is invalid if during the observation period after challenge, fewer than 100 per cent of the control cats show on not fewer than one occasion a diminution in the number of leucocytes of at least 75 per cent of the initial value or die from panleucopenia. The vaccine complies with the test if during the observation period after challenge, all the vaccinated cats survive and show no signs of disease nor leucopenia; that is to say, the diminution in the number of leucocytes does not exceed, in any of the 4 counts, 50 per cent of the initial value.

2-4. *MANUFACTURER'S TESTS*

2-4-1. **Residual live virus**. The test for residual live virus is carried out using a quantity of inactivated virus harvest equivalent to not less than 100 doses of the vaccine by a validated method such as the following: inoculate into suitable non-confluent cells and after incubation for 8 days, make a subculture using trypsinised cells. After

incubation for a further 8 days, examine the cultures for residual live parvovirus by an immunofluorescence test. The immunofluorescence test may be supplemented by a haemagglutination test or other suitable tests on the supernatant of the cell cultures. The inactivated viral harvest complies with the test if no live virus is detected.

2-4-2. **Batch potency test**. For routine testing of batches of vaccine, a test based on production of haemagglutination-inhibiting antibodies in guinea-pigs may be used instead of test 3-4-1 or 3-4-2 described under Potency if a satisfactory correlation with the test for immunogenicity has been established.

3. BATCH TESTS

3-1. **Identification**. When injected into animals, the vaccine stimulates the production of antibodies against the parvovirus present in the vaccine.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 cats of the minimum age recommended for vaccination and preferably that do not have antibodies against feline panleucopenia virus or against canine parvovirus or, where justified, use cats that have a low level of such antibodies as long as they have not been vaccinated against feline panleucopenia virus or against canine parvovirus, and administration of the vaccine does not cause an anamnestic response. Administer to each cat by a recommended route a double dose of the vaccine. Observe the cats at least daily for 14 days.

The vaccine complies with the test if no cat shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Potency**. Carry out test 3-4-1 or test 3-4-2.

3-4-1. *Test in cats for haemagglutination-inhibiting antibodies*. Use for the test not fewer than 4 cats, 8-12 weeks old, that do not have antibodies against feline panleucopenia virus and canine parvovirus. Vaccinate not fewer than 2 cats with one dose of the vaccine to be recommended. Maintain not fewer than 2 cats as controls. After 21 days, draw a blood sample from each cat and separate the serum from each sample. Inactivate each serum by heating at 56 °C for 30 min. To 1 volume of each serum add 9 volumes of a 200 g/l suspension of *light kaolin R* in *phosphate buffered saline pH 7.4 R*. Shake each mixture for 20 min. Centrifuge, collect the supernatant liquid and mix with 1 volume of a concentrated suspension of pig erythrocytes. Allow to stand at 4 °C for 60 min and centrifuge. The dilution of the serum obtained is 1:10. Using each serum, prepare a series of twofold dilutions. To 0.025 ml of each of the latter dilutions add 0.025 ml of a suspension of canine parvovirus or feline panleucopenia virus antigen containing 4 haemagglutinating units. Allow to stand at 37 °C for 30 min and add 0.05 ml of a suspension of pig erythrocytes containing 30×10^6 cells per millilitre. Allow to stand at 4 °C for 90 min and note the last dilution of serum that still completely inhibits haemagglutination.

The test is invalid if either control cat develops antibodies against canine parvovirus or feline panleucopenia virus. The vaccine complies with the test if both vaccinated cats have developed titres of at least 1:20.

3-4-2. *Test in cats for virus-neutralising antibodies*. Use for the test not fewer than 2 cats, 8-12 weeks old, that have antibody titres less than $4ND_{50}$ per 0.1 ml of serum measured by the method described below. Vaccinate each cat according to the schedule to be recommended. 14 days after vaccination, examine the serum of each cat as follows. Heat the serum at 56 °C for 30 min and prepare serial dilutions using a medium suitable for feline cells. Add to each dilution an equal volume of a virus suspension containing an amount of virus such that when the volume of serum-virus mixture appropriate for the assay system is inoculated into cell cultures, each culture receives approximately 10^4 $CCID_{50}$. Incubate the mixtures at 37 °C for 1 h and inoculate 4 feline cell cultures with a suitable volume of each mixture. Incubate the cell cultures at 37 °C for 7 days, passage and incubate for a further 7 days. Examine the cultures for evidence of specific cytopathic effects and calculate the antibody titre.

The vaccine complies with the test if the mean titre is not less than 32 ND_{50} per 0.1 ml of serum. If one cat fails to respond, repeat the test using 2 more cats and calculate the result as the mean of the titres obtained from all of the 3 cats that have responded.

01/2008:0251

FELINE INFECTIOUS ENTERITIS (FELINE PANLEUCOPENIA) VACCINE (LIVE)

Vaccinum panleucopeniae felinae infectivae vivum

1. DEFINITION

Feline infectious enteritis (feline panleucopenia) vaccine (live) is a preparation of a suitable strain of feline panleucopenia virus. This monograph applies to vaccines intended for the active immunisation of cats against feline infectious enteritis (feline panleucopenia).

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE VIRUS*

The vaccine virus is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the cats for which it is intended (including safety for pregnant queens if such use is not contra-indicated or if the virus is excreted in the faeces).

The following tests for safety (section 2-3-1), increase in virulence (section 2-3-2) and immunogenicity (2-3-3) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine.

For each test, use not fewer than 5 cats of the minimum age to be recommended for vaccination and that do not have specific haemagglutination-inhibiting antibodies against feline panleucopenia virus and canine parvovirus. Make counts of leucocytes in circulating blood on days 8 and 4 before injection of the vaccine virus and calculate the mean of the 2 counts to serve as the initial value. Administer to each cat a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in one dose of the vaccine. Observe the cats at least daily

for 21 days. Make leucocyte counts on the 4th, 6th, 8th and 10th days after inoculation.

The vaccine virus complies with the test if no cat shows abnormal local or systemic reactions, signs of disease or dies from causes attributable to the vaccine virus and if, for each cat and each blood count, the number of leucocytes is not less than 50 per cent of the initial value.

2-3-2. **Increase in virulence**. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to 2 cats of the minimum age to be recommended for vaccination and that do not have antibodies against feline panleucopenia virus and canine parvovirus, sequential passages, 5 times where possible, to further similar groups and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages.

Administer to each cat by a route to be recommended a quantity of the vaccine virus that will allow recovery of virus for the passages described below. Collect the faeces from each cat from the 2nd to the 10th day after administration of the virus, check them for the presence of the virus and pool the faeces containing virus. Administer 1 ml of the suspension of pooled faeces by the oronasal route to each of 2 other cats of the same age. Carry out this passage operation not fewer than 5 times ; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages.

The vaccine virus complies with the test if no cat dies or shows signs attributable to the vaccine virus and no indication of increasing virulence of the maximally passaged virus compared with the unpassaged virus is observed. Account is taken, notably, of the count of white blood cells, of results of histological examination of the thymus and of the titre of excreted virus. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-3-3. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended for vaccination, using in each case cats 8-12 weeks old. The quantity of vaccine virus to be administered to each cat is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of vaccine.

Use for the test not fewer than 10 cats that do not have antibodies against feline panleucopenia virus and canine parvovirus. Vaccinate not fewer than 5 cats, according to the schedule to be recommended. Maintain not fewer than 5 cats as controls. Carry out leucocyte counts 8 days and 4 days before challenge and calculate the mean of the 2 counts to serve as the initial value. Challenge each cat after 20-22 days by the intraperitoneal route with a sufficient quantity of a suspension of virulent feline panleucopenia virus. Observe the cats at least daily for 14 days after challenge. Carry out leucocyte counts on the 4th, 6th, 8th and 10th days after challenge.

The test is invalid if during the observation period after challenge, fewer than 100 per cent of the control cats show, on fewer than one occasion, a diminution in the number of leucocytes of at least 75 per cent of the initial value or die from feline panleucopenia. The vaccine virus complies with the test if during the observation period after challenge, all the vaccinated cats survive and show no signs of disease nor leucopenia; that is to say, the diminution in the number of leucocytes does not exceed, in any of the 4 counts, 50 per cent of the initial value.

3. BATCH TESTS

3-1. **Identification**. Carry out replication of the vaccine virus in a susceptible cell line in a substrate suitable for a fluorescent antibody test or peroxidase test. Prepare suitable controls. Test a proportion of the cells with monoclonal antibodies specific for feline panleucopenia virus and a proportion with monoclonal antibodies specific for canine parvovirus. Feline panleucopenia virus is detected but no canine parvovirus is detected in the cells inoculated with the vaccine.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas** (*2.6.7*). The vaccine complies with the test for mycoplasmas.

3-4. **Extraneous agents**. Neutralise the vaccine virus with a suitable monospecific antiserum against feline panleucopenia virus and inoculate into cell cultures known for their susceptibility to viruses pathogenic for the cat. Carry out at least one passage and maintain the cultures for 14 days. The vaccine complies with the test if no cytopathic effect develops and there is no sign of the presence of haemadsorbing agents.

3-5. **Safety**. Use 2 cats of the minimum age recommended for vaccination, that do not have antibodies against feline panleucopenia virus or canine parvovirus. Administer to each cat by a recommended route 10 doses of the vaccine. Observe the cats at least daily for 14 days.

The vaccine complies with the test if no cat shows notable signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**. Titrate the vaccine virus in suitable cell cultures. The vaccine complies with the test if one dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-3-3) when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2008:1321

FELINE LEUKAEMIA VACCINE (INACTIVATED)

Vaccinum leucosis felinae inactivatum

1. DEFINITION

Feline leukaemia vaccine (inactivated) is a preparation of immunogens from a suitable strain of feline leukaemia virus. This monograph applies to vaccines intended for the active immunisation of cats against feline leukaemia.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The immunogens consist either of a suitable strain of feline leukaemia virus inactivated while maintaining adequate immunogenic properties or of a fraction of the virus with adequate immunogenic properties; the immunogenic fraction may be produced by recombinant DNA technology. The vaccine may be adjuvanted.

2-2. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the cats for which it is intended (including pregnant queens if such use is not contra-indicated).

The following tests for safety (2-2-1) and immunogenicity (2-2-2) may be used during the demonstration of safety and efficacy.

2-2-1. **Safety**. A test is carried out for each route and method of administration to be recommended, using in each case cats that do not have antibodies against gp 70 antigen of feline leukaemia virus nor display viraemia or antigenaemia at the time of the test; absence of antibodies and antigen is demonstrated by enzyme-linked immunosorbent assay (*2.7.1*). Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine.

2-2-1-1. *Single administration of vaccine.* Use for the test not fewer than 15 cats of the minimum age to be recommended for vaccination. Vaccinate not fewer than 10 cats, according to the schedule to be recommended. Maintain not fewer than 5 cats as controls. Record the rectal temperature of each cat on the day before each vaccination, at the time of vaccination, 4 h and 8 h later, and once per day during the 4 following days. Observe the cats at least daily for not less than 4 weeks after the last vaccination. 1, 2 and 4 weeks after the last vaccination, submit the cats to suitable tests for evidence of an immunosuppressive effect.

The vaccine complies with the test if no cat shows abnormal local or systemic reactions or dies from causes attributable to the vaccine and if in the tests for immunosuppressive effect, no significant difference is observed in vaccinated cats compared with controls.

2-2-1-2. *Repeated administration of vaccine.* Use for the test not fewer than 10 cats of the minimum age to be recommended for vaccination. Vaccinate each cat with 2 doses of the vaccine to be recommended. At the end of the period of time stated in the instructions for use, inject one dose of vaccine to each cat. Where the instructions for use recommend it, administer a 3rd injection after the period indicated. Observe the cats at least daily for 14 days after the last administration. The vaccine complies with the test if no cat shows abnormal local or systemic reactions or dies from causes attributable to the vaccine.

2-2-1-3. *Test in pregnant queens.* If the vaccine is not contra-indicated for use in pregnant queens, use not fewer than 10 queens at different stages of pregnancy. Administer to each cat 2 doses of the vaccine. Observe the queens at least daily until parturition.

The vaccine complies with the test if no queen shows abnormal local or systemic reactions or dies from causes attributable to the vaccine and if no adverse effects on the pregnancy or the offspring are noted.

2-2-2. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended, using in each case cats of the minimum age to be recommended for vaccination. The vaccine administered to each cat is of minimum potency.

Use for the test not fewer than 25 cats that do not have antibodies against the antigens of feline leukaemia virus and against the feline oncogene membrane antigen (anti-FOCMA antibodies), and showing no viraemia or antigenaemia at the time of the test. Vaccinate not fewer than 15 cats according to the schedule to be recommended. Maintain not fewer than 10 cats as controls. Observe the cats at least daily for 14 days after the last administration. Challenge each cat by the peritoneal or oronasal route, on one or several occasions, with a sufficient quantity of suspension of an epidemiologically relevant virulent strain of feline leukaemia virus, consisting predominantly of type A virus. Observe the cats at least daily for 15 weeks and, from the 3rd week onwards, test each week for viraemia or antigenaemia (p27 protein) by suitable methods such as immunofluorescence on circulating leucocytes or enzyme-linked immunosorbent assay. A cat is considered persistently infected if it shows positive viraemia or antigenaemia for 3 consecutive weeks or on 5 occasions, consecutively or not, between the 3rd and the 15th week.

The test is invalid if during the observation period after challenge, fewer than 80 per cent of the control cats show persistant viraemia or antigenaemia. The vaccine complies with the test if during the observation period after challenge, not fewer than 80 per cent of the vaccinated cats show no persistent infection.

2-3. *IN-PROCESS CONTROL TESTS*

During production, suitable immunochemical tests are carried out for the evaluation of the quality and purity of the viral antigens included in the vaccine composition. The values found are within the limits approved for the particular vaccine.

2-4. *MANUFACTURER'S TESTS*

2-4-1. **Residual live virus**. Where applicable, the test for residual live virus is carried out using a quantity of inactivated virus harvest equivalent to not less than 25 doses of vaccine and 2 passages in the same type of cell cultures as used for the production of the vaccine or in cell cultures shown to be at least as sensitive. The inactivated viral harvest complies with the test if no live virus is detected.

2-4-2. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-5) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency.

2-4-3. **Bacterial endotoxins**. For vaccines produced by recombinant DNA technology with a bacterial host cell such as *Escherichia coli*, a test for bacterial endotoxins (*2.6.14*) is carried out on each final lot or, where the nature of the adjuvant prevents performance of a satisfactory test, on the antigen immediately before addition of the adjuvant. The value found is within the limit approved for the particular vaccine and which has been shown to be safe for cats.

3. BATCH TESTS

3-1. **Identification**. When injected into healthy cats that do not have specific antibodies against the antigen or antigens stated on the label, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 cats of the minimum age recommended for vaccination and that do not have antibodies against feline leukaemia virus. Administer to each cat by a recommended route a double dose of the vaccine. Observe the cats at least daily for 14 days.

The vaccine complies with the test if no cat shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual live virus**. If the vaccine contains inactivated virus, carry out a test for residual live feline leukaemia virus by making 2 passages on susceptible cell cultures. The vaccine complies with the test if no virus is detected. If the vaccine contains an adjuvant, if possible separate the adjuvant from the liquid phase by a method that does not inactivate the virus nor interfere in any other way with the detection of virus.

3-5. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-2-2) when administered by a recommended route and method.

01/2008:1207

FELINE VIRAL RHINOTRACHEITIS VACCINE (INACTIVATED)

Vaccinum rhinotracheitidis viralis felinae inactivatum

1. DEFINITION

Feline viral rhinotracheitis vaccine (inactivated) is a preparation of a suitable strain of feline rhinotracheitis virus (feline herpesvirus 1), inactivated while maintaining adequate immunogenic properties, or of an inactivated fraction of the virus having adequate immunogenic properties. This monograph applies to vaccines intended for the active immunisation of cats against feline viral rhinotracheitis.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures. The virus harvest is inactivated; the virus may be disrupted and the fractions purified and concentrated. The vaccine may be adjuvanted.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the cats for which it is intended.

The following test for immunogenicity (2-3-1) may be used during the demonstration of efficacy.

2-3-1. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended for vaccination, using in each case cats 8-12 weeks old. The vaccine administered to each cat is of minimum potency.

Use for the test not fewer than 20 cats that do not have antibodies against feline herpesvirus 1 or against a fraction of the virus. Vaccinate not fewer than 10 cats, according to the schedule to be recommended. Maintain not fewer than 10 cats as controls. Challenge each cat after 4 weeks by the intranasal route with a quantity of a suspension of virulent feline herpesvirus 1 sufficient to produce typical signs of the disease such as fever, nasal discharge and cough in a cat that does not have antibodies against feline herpesvirus 1 or a fraction of the virus. Observe the cats at least daily for 14 days after challenge. Collect nasal washings daily on days 2 to 14 after challenge to test for virus excretion. Note daily the body temperature and signs of disease using the scoring system shown below.

The vaccine complies with the test if the score for the vaccinated cats is significantly lower than that for the controls.

Sign	Score
Death	10
Depressed state	2
Temperature:	
39.5 °C - 40.0 °C	1
≥ 40.0 °C	2
≤ 37.0 °C	3
Glossitis	3
Nasal discharge, slight	1
Nasal discharge, copious	2
Cough	2
Sneezing	1
Sneezing, paroxysmal	2
Ocular discharge, slight	1
Ocular discharge, serious	2
Conjunctivitis	2
Weight loss ≥ 5.0 per cent	5
Virus excretion (total number of days):	
≤ 4 days	1
5-7 days	2
> 7 days	3

2-4. *MANUFACTURER'S TESTS*

2-4-1. **Residual live virus**. The test for residual live virus is carried out using 2 passages in cell cultures of the same type as those used for preparation of the vaccine or in cell cultures shown to be at least as sensitive; the quantity of inactivated virus harvest used in the test is equivalent to not less than 25 doses of vaccine. The inactivated viral harvest complies with the test if no live virus is detected.

2-4-2. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-5) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

Use for the test a group of 15 seronegative mice. Administer to each mouse half a dose of the vaccine and, 7 days later, repeat the administration. 21 days after the first injection, take blood samples and determine the level of antibodies against feline herpesvirus 1 by a suitable immunochemical method (*2.7.1*), such as an immunofluorescence technique using pools of serum from groups of 3 mice. The vaccine complies with the test if the antibody levels are not

significantly lower than those obtained with a batch of vaccine that has given satisfactory results in the test described under Potency.

3. BATCH TESTS

3-1. **Identification**. When administered to animals that do not have specific antibodies against feline herpesvirus 1 or against the fraction of the virus used to produce the vaccine, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 cats, 8-12 weeks old and preferably that do not have antibodies against feline herpesvirus 1 or against a fraction of the virus or, where justified, use cats that have a low level of such antibodies as long as they have not been vaccinated against feline rhinotracheitis and administration of the vaccine does not cause an anamnestic response. Administer to each cat by a recommended route a double dose of the vaccine. Observe the cats at least daily for 14 days.

The vaccine complies with the test if no cat shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual live virus**. Carry out a test for residual live feline herpesvirus 1 using 10 doses of vaccine and 2 passages in cell cultures of the same type as those used for preparation of the vaccine, or in other suitably sensitive cell cultures. The vaccine complies with the test if no live virus is detected. If the vaccine contains an adjuvant that interferes with the test, where possible separate the adjuvant from the liquid phase by a method that does not inactivate or otherwise interfere with detection of live virus.

3-5. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-3-1) when administered by a recommended route and method.

01/2008:1206

FELINE VIRAL RHINOTRACHEITIS VACCINE (LIVE)

Vaccinum rhinotracheitidis viralis felinae vivum

1. DEFINITION

Feline viral rhinotracheitis vaccine (live) is a preparation of a suitable strain of feline rhinotracheitis virus (feline herpesvirus 1). This monograph applies to vaccines intended for the active immunisation of cats against feline viral rhinotracheitis.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE VIRUS*

The vaccine virus is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the cats for which it is intended (including safety for pregnant queens if such use is not contra-indicated).

The following tests for safety (section 2-3-1), increase in virulence (section 2-3-2) and immunogenicity (2-3-3) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination, using in each case cats of the minimum age to be recommended. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine.

For each test, use not fewer than 10 cats that do not have antibodies against feline herpesvirus 1. Administer to each cat a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in one dose of the vaccine. Observe the cats at least daily for 21 days.

The vaccine virus complies with the test if no cat shows abnormal local or systemic reactions, signs of disease or dies from causes attributable to the vaccine virus.

2-3-2. **Increase in virulence**. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to 2 cats that do not have antibodies against feline herpesvirus 1, sequential passages, 5 times where possible, to further similar groups and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages.

Administer to each cat by a route to be recommended a quantity of the vaccine virus that will allow recovery of virus for the passages described below. Administer the virus by the route to be recommended for vaccination most likely to lead to reversion of virulence. After 2-4 days, remove the nasal mucus, tonsils and local lymphatic ganglia and the trachea of each cat. Mix, homogenise in 10 ml of buffered saline and decant. Administer 1 ml of the supernatant by the intranasal route to each of 2 other cats. Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages.

Carry out the test for safety (section 2-3-1) using unpassaged vaccine virus and the maximally passaged virus that has been recovered.

The vaccine virus complies with the test if no indication of increased virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-3-3. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended for vaccination, using in each case cats 8-12 weeks old. The quantity of vaccine virus to be administered to each cat is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of vaccine.

Use for the test not fewer than 20 cats that do not have antibodies against feline herpesvirus 1. Vaccinate not fewer than 10 cats, according to the schedule to be recommended. Maintain not fewer than 10 cats as controls. Challenge each cat after 4 weeks by the intranasal route with a quantity of a suspension of virulent feline herpesvirus 1 sufficient to cause typical signs of disease such as fever, nasal discharge

and cough. Observe the cats at least daily for 14 days after challenge. Collect nasal washings daily on days 2 to 14 after challenge to test for virus excretion. Note daily the body temperature and signs of disease using the scoring system shown below.

The vaccine virus complies with the test if, during the observation period after challenge, the score for the vaccinated cats is significantly lower than that for the controls.

Sign	Score
Death	10
Depressed state	2
Temperature:	
39.5 °C - 40.0 °C	1
≥ 40.0 °C	2
≤ 37.0 °C	3
Glossitis	3
Nasal discharge, slight	1
Nasal discharge, copious	2
Cough	2
Sneezing	1
Sneezing, paroxysmal	2
Ocular discharge, slight	1
Ocular discharge, serious	2
Conjunctivitis	2
Weight loss ≥ 5.0 per cent	5
Virus excretion (total number of days):	
≤ 4 days	1
5-7 days	2
> 7 days	3

3. BATCH TESTS

3-1. **Identification**. When mixed with a monospecific antiserum, the vaccine no longer infects susceptible cell cultures into which it is inoculated.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas** (*2.6.7*). The vaccine complies with the test for mycoplasmas.

3-4. **Extraneous agents**. Neutralise the vaccine virus with a suitable monospecific antiserum against feline herpesvirus 1 and inoculate into cell cultures known for their susceptibility to viruses pathogenic for the cat. Carry out at least one passage and maintain the cultures for 14 days. The vaccine complies with the test if no cytopathic effect develops and there is no sign of the presence of haemadsorbing agents.

3-5. **Safety**. Use 2 cats, 8-12 weeks old, that do not have antibodies against feline herpesvirus 1. Administer to each cat by a recommended route 10 doses of the vaccine. Observe the cats at least daily for 14 days.

The vaccine complies with the test if no cat shows notable signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**. Titrate the vaccine virus in suitable cell cultures and at a temperature favourable to replication of the virus. The vaccine complies with the test if one dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-3-3) when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2008:0063

FOOT-AND-MOUTH DISEASE (RUMINANTS) VACCINE (INACTIVATED)

Vaccinum aphtharum epizooticarum inactivatum ad ruminantes

1. DEFINITION

Foot-and-mouth disease (ruminants) vaccine (inactivated) is a preparation containing one or more serotypes of foot-and-mouth disease virus inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for active immunisation of ruminants against foot-and-mouth disease.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures and then separated from cellular material by filtration or other suitable procedures. The harvested virus is inactivated in suitable conditions and may be concentrated and purified. It is used for the preparation of vaccine immediately or after storage at a temperature shown to be consistent with antigen stability. The vaccine is prepared from inactivated virus by blending with one or more adjuvants. For a given antigen, the quantity of 146S antigen blended in each batch of vaccine is not lower than that of a batch of vaccine that has been found satisfactory with respect to Immunogenicity.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *VALIDATION OF THE INACTIVATION PROCEDURE*

During inactivation, the virus titre is monitored by a sensitive and reproducible technique. The inactivation procedure is not satisfactory unless the decrease in virus titre, plotted logarithmically, is linear and extrapolation indicates that there is less than 1 infectious virus unit per 10^4 litres of liquid preparation at the end of inactivation.

2-4. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for each species for which it is intended.

The following tests for safety (section 2-4-1.) and immunogenicity (section 2-4-2.) may be used during the demonstration of safety and efficacy.

2-4-1. **Safety**

2-4-1-1. *General safety*. Carry out the test for each route and method of administration to be recommended for vaccination and in animals of each species for which the vaccine is intended, using in each case animals of the minimum age

to be recommended. Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine.

For each test, use not fewer than 10 animals that do not have antibodies against foot-and-mouth disease virus. Administer to each animal a double dose of the vaccine. Observe the animals at least daily for 14 days.

The vaccine complies with the test if no animal shows abnormal local or systemic reactions or dies from causes attributable to the vaccine.

2-4-1-2. *Safety in pregnant animals.* If the vaccine is intended for use or may be used in pregnant animals, use not fewer than 10 pregnant animals at the beginning of each trimester for which the use is not contra-indicated. Administer to each animal a double dose of the vaccine. Observe the animals at least daily until parturition.

The vaccine complies with the test if no animal shows abnormal local or systemic reactions or dies from causes attributable to the vaccine and if no adverse effect on the pregnancy and offspring are noted.

2-4-2. **Immunogenicity**. The following test is suitable to demonstrate immunogenicity of the vaccine for cattle. The potency of the vaccine is expressed as the number of 50 per cent cattle protective doses (PD_{50}) contained in the dose stated on the label. The PD_{50} is determined in cattle given primary vaccination and challenged by the inoculation of 10 000 ID_{50} of virulent bovine virus of the same serotype as that used in the preparation of the vaccine in the conditions described below. The vaccine virus may be used for challenge.

Carry out an immunogenicity test for each serotype of foot-and-mouth disease virus that may be included in the vaccine. The immunogenicity test carried out for a particular serotype will be valid for other vaccines provided that they have the same basic composition and that they have a batch potency with regard to that particular serotype that is not lower than that of the vaccine that has given satisfactory results in the test described below.

Each test is carried out for each route and method of administration to be recommended for vaccination, using in each case cattle not less than 6 months old. The vaccine administered to each animal is of minimum potency.

Use for the test not fewer than 17 cattle obtained from areas free from foot-and-mouth disease, that have never been vaccinated against foot-and-mouth disease and do not have antibodies neutralising the different serotypes of foot-and-mouth disease virus. Vaccinate not fewer than 3 groups of not fewer than 5 cattle per group, using a different dose of the vaccine for each group. Administer the different doses by injecting different volumes of the vaccine and not by dilution of the vaccine. For example, if the label states that the injection of 2 ml corresponds to the administration of 1 dose of vaccine, a 1/4 dose of vaccine would be obtained by injecting 0.5 ml, and a 1/10 dose would be obtained by injecting 0.2 ml. Maintain 2 cattle as controls. Challenge all the cattle after 3 weeks by the intradermal route, into 2 sites on the upper surface of the tongue (0.1 ml per site), with a dose equivalent to approximately 10 000 ID_{50} of a suspension of a fully virulent virus, obtained from cattle and of the same serotype as that used in the preparation of the vaccine. Observe the cattle at least daily for 8 days and then euthanise. Unprotected cattle show lesions at sites other than the tongue. Protected cattle may display lingual lesions.

The test is invalid if both control cattle do not show lesions on at least 3 feet. From the number of protected cattle in each group, calculate the PD50 content of the vaccine. The vaccine complies with the test if the potency is not less than that to be stated on the label; the minimum potency to be stated on the label is not less than 3 PD_{50} per dose for cattle.

2-5. *MANUFACTURER'S TESTS*

2-5-1. **Identification**. The bulk inactivated antigen is identified by a suitable immunochemical method (*2.7.1*).

2-5-2. **Residual live virus**. The limit of detection of the cell cultures to be used with respect to the virus to be tested is established by determining the number of $CCID_{50}$ and the 146S antigen content of a sample of live virus. The cells are not suitable if an amount of virus corresponding to 1 µg of 146S antigen has less than 10^6 $CCID_{50}$. A proportion of each batch of bulk inactivated antigen representing at least 200 doses is tested for freedom from live virus by inoculation into suitable cell cultures. A passage is made during culture of the cells. For this purpose, the sample of the inactivated antigen may be concentrated to allow testing of such large samples in cell cultures. It must be shown that the selected concentration and assay systems are not detrimental to detection of infectious virus within the test sample and that the concentrated inactivated antigen does not interfere with virus replication or cause toxic changes. A positive control is included in each test.

2-5-3. **Antigen content**. The 146S antigen content of each batch of bulk inactivated antigen is determined by an *in vitro* method (for example, by sucrose density gradient centrifugation and ultraviolet spectrophotometry at 259 nm).

2-5-4. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-4.) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency and has been shown to be satisfactory with respect to immunogenicity in the target species.

The following test may be used after a satisfactory pass level for a given antigen has been established. Once a pass level has been established for a given antigen, the same level may be used when this antigen is formulated in combination with any other provided that the formulation of the vaccine differs only in the antigens included.

2-5-4-1. *Vaccines for use in cattle.* Use cattle of the minimum age recommended for vaccination obtained from areas free from foot-and-mouth disease, that have never been vaccinated against foot-and-mouth disease and do not have antibodies neutralising the different serotypes of foot-and-mouth disease virus. Vaccinate not fewer than 5 cattle by a recommended route. Use a suitable dose of the vaccine for each animal. After a defined period, not greater than 28 days following vaccination, draw a blood sample and determine individually in each serum the level of antibodies against each serotype used in the preparation of the vaccine by a validated technique (e.g. sero-neutralisation test, ELISA). The vaccine complies with the test if titres at least equal to the pass level are measured in not fewer than 50 per cent of the cattle.

2-5-4-2. *Vaccines for use in other ruminants.* The potency of each batch shall be demonstrated in a suitable, validated test. A test in cattle, following the procedures outlined above for vaccines for use in cattle, may be suitable.

EMERGENCY USE: in situations of extreme urgency and subject to agreement by the competent authority, a batch of vaccine may be released before completion of the tests and the determination of potency if a test for sterility has been carried out on the bulk inactivated antigen and all other components of the vaccine and if the test for safety and the determination of potency have been carried out on a

representative batch of vaccine prepared from the same bulk inactivated antigen. In this context, a batch is not considered to be representative unless it has been prepared with not more than the amount of antigen or antigens and with the same formulation as the batch to be released.

3. BATCH TESTS

3-1. **Identification**. The serum of an animal that did not have antibodies against foot-and-mouth disease virus prior to being immunised with the vaccine neutralises the serotypes of the virus used to prepare the vaccine, when tested by a suitably sensitive method.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 non-vaccinated animals of one of the species for which the vaccine is intended, not less than 6 months old, that do not have antibodies against foot-and-mouth disease virus and coming from regions free from foot-and-mouth disease. Administer to each animal by a recommended route a double dose of the vaccine. Observe the animals at least daily for 14 days.

The vaccine complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-4-2.) when administered by a recommended route and method.

01/2008:1945

FOWL CHOLERA VACCINE (INACTIVATED)

Vaccinum cholerae aviariae inactivatum

1. DEFINITION

Fowl cholera vaccine (inactivated) is a preparation of 1 or more suitable strains of 1 or more serovars of *Pasteurella multocida*, inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for the active immunisation of chickens, turkeys, ducks and geese against acute fowl cholera.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The seed material is cultured in a suitable medium. If the vaccine contains more than 1 strain of bacterium, the different strains are grown and harvested separately. The bacterial harvests are inactivated. The vaccine may be adjuvanted.

2-2. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the species for which it is intended. The following tests for Safety (section 2-2-1) and Immunogenicity (section 2-2-2) may be used during the demonstration of safety and efficacy.

2-2-1. **Safety**. The test is carried out for each route of administration to be recommended for vaccination and for each avian species for which the vaccine is intended.

For each test, use not fewer than 20 birds not older than the minimum age to be recommended for vaccination. In the case of chickens, use chickens from a flock free from specified pathogens (SPF) (*5.2.2*) and in the case of turkeys, ducks or geese, use birds that have not been vaccinated and that do not have antibodies against *P. multocida*. Administer by a recommended route and method to each bird a double dose of vaccine. If the recommended schedule requires a second dose, administer 1 dose after the recommended interval. Observe the birds at least daily until 21 days after the last administration of the vaccine. The test is not valid if more than 10 per cent of the birds show abnormal signs of disease or die from causes not attributable to the vaccine. The vaccine complies with the test if no bird shows abnormal signs of disease or dies from causes attributable to the vaccine.

2-2-2. **Immunogenicity**. The test is carried out for each route and method of administration to be recommended for vaccination, for each avian species for which the vaccine is intended and for each serovar of *P. multocida* against which protection is claimed. Use for each test not fewer than 30 birds not older than the minimum age to be recommended for vaccination. Use birds that have not been vaccinated and that are free from antibodies against *P. multocida*. For each test, administer to each of not fewer than 20 birds a quantity of the vaccine not greater than 1 dose. If re-vaccination is recommended, repeat this operation after the recommended interval. Maintain not fewer than 10 birds as controls. Challenge each of the birds of both groups 21 days after the last administration by the intramuscular route with a sufficient quantity of virulent *P. multocida*. Observe the birds for 14 days after challenge. The test is invalid if during the observation period after challenge, fewer than 70 per cent of the control birds die or show signs of infection (such as either clinical signs or bacterial re-isolation in organs) or if during the period before challenge, more than 10 per cent of the birds from the control group or from the vaccinated group show abnormal signs of disease or die from causes not attributable to the vaccine. The vaccine complies with the test if, at the end of the observation period after challenge, not fewer than 70 per cent of the birds from the vaccinated group survive and show no signs of disease. Mild signs that do not persist beyond the observation period may be tolerated.

2-3. *MANUFACTURER'S TESTS*

2-3-1. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-4) for each batch of vaccine if it has been carried out using a batch of vaccine with minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

Use not fewer than 15 SPF chickens (*5.2.2*), 3 to 4 weeks old. Collect serum samples from each vaccinated and control chicken just before vaccination and check for the absence of antibodies against each serovar of *P. multocida* in the vaccine. Administer to each of 10 chickens 1 dose of the vaccine by the subcutaneous route. Maintain 5 chickens as controls. Collect serum samples 5 weeks after vaccination from each vaccinated and control chicken. Measure the titres of serum antibodies against each serovar of *P. multocida* stated on the label using a suitable validated serological method. Calculate the mean titres for the group of vaccinates. The test is invalid if specific *P. multocida* antibodies are found: before vaccination in 1 or more sera from chickens to be vaccinated or from controls; in 1 or more sera from control chickens 5 weeks after the time of administration of the vaccine. The vaccine complies with the test if the mean antibody titres of the group of vaccinates are equal to or greater than the titres obtained with a batch that has given satisfactory results in the test described under Potency.

2-3-2. **Bacterial endotoxins**. A test for bacterial endotoxins (*2.6.14*) is carried out on the final lot or, where the nature of the adjuvant prevents performance of a satisfactory test, on the bulk antigen or the mixture of bulk antigens immediately before addition of the adjuvant. The maximum acceptable amount of bacterial endotoxins is that found for a batch of vaccine that has been shown satisfactory in safety test (section 2-2-1). The method chosen for determining the maximum acceptable amount of bacterial endotoxins is used subsequently for testing each batch.

3. BATCH TESTS

3-1. **Identification**. When injected into SPF chickens (*5.2.2*), the vaccine stimulates the production of antibodies against each of the serovars of *P. multocida* in the vaccine.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. For vaccines recommended for use in chickens, use not fewer than 10 chickens from an SPF flock (*5.2.2*) and of the minimum age recommended for vaccination. For vaccines recommended for use only in turkeys, ducks or geese, use not fewer than 10 birds of the species likely to be most sensitive to fowl cholera, that do not have antibodies against *P. multocida* and of the minimum age recommended for vaccination. Administer to each bird by a recommended route a double dose of the vaccine. Observe the birds at least daily for 21 days. The test is not valid if more than 20 per cent of the birds show abnormal signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no bird shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-2-2) when administered by a recommended route and method.

LABELLING

The label states:

– the serovar(s) used to prepare the vaccine,

– the serovar(s) against which protection is claimed.

01/2008:0649

FOWL-POX VACCINE (LIVE)

Vaccinum variolae gallinaceae vivum

1. DEFINITION

Fowl-pox vaccine (live) is a preparation of a suitable strain of avian pox virus. This monograph applies to vaccines intended for administration to chickens for active immunisation.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in embryonated hens' eggs or in cell cultures.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Embryonated hens' eggs**. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from flocks free from specified pathogens (SPF) (*5.2.2*).

2-2-2. **Cell cultures**. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *SEED LOTS*

2-3-1. **Extraneous agents**. The master seed lot complies with the tests for extraneous agents in seed lots (*2.6.24*). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the tests.

2-4. *CHOICE OF VACCINE VIRUS*

The vaccine virus shall be shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the chickens for which it is intended.

The following tests for safety (section 2-4-1), increase in virulence (section 2-4-2) and immunogenicity (section 2-4-3) may be used during demonstration of safety and immunogenicity.

2-4-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination using in each case chickens not older than the youngest age to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. For each test use not fewer than 20 chickens, from an SPF flock (*5.2.2*). Administer to each chicken a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in a dose of the vaccine. Observe the chickens at least daily for 21 days. The test is not valid if more than 10 per cent of the chickens die from causes not attributable to the vaccine virus. The vaccine virus complies with the test if no chicken shows notable clinical signs of fowl pox or dies from causes attributable to the vaccine virus.

2-4-2. **Increase in virulence**. Administer by a suitable route a quantity of the vaccine virus that will allow recovery of virus for the passages described below to each of 5 chickens not older than the minimum age to be recommended for vaccination and from an SPF flock (*5.2.2*). Use the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. Prepare 4 to 7 days after administration a suspension from the induced skin lesions of each chicken and pool these samples. Administer 0.2 ml of the pooled samples by cutaneous scarification of the comb or other unfeathered part of the body, or by another suitable method to each of 5 other chickens not older than the minimum age to be recommended for vaccination and from an SPF flock (*5.2.2*). Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. Care must be taken to avoid contamination by virus from previous passages. If the virus is not found at a passage level, carry out a second series of passages. Carry out the test for safety (section 2-4-1) using the unpassaged vaccine virus and the maximally passaged virus that has been recovered. Administer the virus by the route recommended for vaccination likely to be the least safe. The vaccine virus complies with the test if no indication of increase in virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-4-3. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended using in each case chickens not older than the youngest age to be recommended for vaccination. The quantity of the vaccine virus administered to each chicken is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of the vaccine. Use for the test not fewer than 30 chickens of the same origin and from an SPF flock (*5.2.2*). Vaccinate by a recommended route not fewer

than 20 chickens. Maintain not fewer than 10 chickens as controls. Challenge each chicken after 21 days by the feather-follicle route with a sufficient quantity of virulent fowl-pox virus. Observe the chickens at least daily for 21 days after challenge. Record the deaths and the number of surviving chickens that show clinical signs of disease. Examine each surviving chicken for macroscopic lesions: cutaneous lesions of the comb, wattle and other unfeathered areas of the skin and diphtherical lesions of the mucous membranes of the oro-pharyngeal area.

The test is not valid if:

– during the observation period after challenge fewer than 90 per cent of the control chickens die or show severe clinical signs of fowl pox, including notable macroscopical lesions of the skin or mucous membranes of the oro-pharyngeal area,
– and/or during the period between vaccination and challenge, more than 10 per cent of the control or vaccinated chickens show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine virus complies with the test if during the observation period after challenge not less than 90 per cent of the vaccinated chickens survive and show no notable clinical signs of disease, including macroscopical lesions of the skin and mucous membranes of the oro-pharyngeal area.

3. BATCH TESTS

3-1. **Identification**. Carry out an immunostaining test in cell cultures to demonstrate the presence of the vaccine virus. For egg adapted strains, inoculate the vaccine into eggs and notice the characteristic lesions.

3-2. **Bacteria and fungi**

Vaccines intended for administration by injection, scarification or piercing of the wing web comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

Vaccines not intended for administration by injection, scarification or piercing of the wing web either comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)* or with the following test: carry out a quantitative test for bacterial and fungal contamination; carry out identification tests for microorganisms detected in the vaccine; the vaccine does not contain pathogenic microorganisms and contains not more than 1 non-pathogenic microorganism per dose.

Any liquid supplied with the vaccine complies with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas**. The vaccine complies with the test for mycoplasmas (*2.6.7*).

3-4. **Extraneous agents**. The vaccine complies with the tests for extraneous agents in batches of finished product (*2.6.25*).

3-5. **Safety**. Use not fewer than 10 chickens from an SPF flock (*5.2.2*) of the youngest age recommended for vaccination. For vaccines recommended for use in chickens older than 6 weeks, chickens 6 weeks old may be used. Administer 10 doses of the vaccine to each chicken by a recommended route. Observe the chickens at least daily for 21 days. The test is not valid if more than 20 per cent of the chickens show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine complies with the test if no chicken shows notable clinical signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**. Titrate the vaccine virus by inoculation into embryonated hens' eggs from an SPF flock (*5.2.2*) or into suitable cell cultures (*5.2.4*). The vaccine complies with the test if 1 dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-4-3) when administered according to the recommended schedule by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2008:1521

FURUNCULOSIS VACCINE (INACTIVATED, OIL-ADJUVANTED, INJECTABLE) FOR SALMONIDS

Vaccinum furunculosidis ad salmonidas inactivatum cum adiuvatione oleosa ad iniectionem

1. DEFINITION

Furunculosis vaccine (inactivated, oil-adjuvanted, injectable) for salmonids is prepared from cultures of one or more suitable strains of *Aeromonas salmonicida* subsp. *salmonicida*, inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for the active immunisation of salmonids against furunculosis.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The strains of *A. salmonicida* are cultured and harvested separately. The harvests are inactivated by a suitable method. They may be purified and concentrated. Whole or disrupted cells may be used and the vaccine may contain extracellular products of the bacterium released into the growth medium. The vaccine contains an oily adjuvant.

2-2. *CHOICE OF VACCINE STRAIN*

The strains included in the vaccine are shown to be suitable with respect to production of antigens of assumed immunological importance. The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) in the species of fish for which it is intended.
The following tests for safety (section 2-2-1) and immunogenicity (section 2-2-2) may be used during the demonstration of safety and efficacy.

2-2-1. **Safety**

2-2-1-1. *Laboratory test.* During development of the vaccine, safety is tested on 3 different batches.

Carry out the test in each species of fish for which the vaccine is intended, using in each case fish of the minimum body mass to be recommended for vaccination. Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine.

For each test, use not fewer than 50 fish from a population that does not have specific antibodies against *A. salmonicida* subsp. *salmonocida* and has not been vaccinated against nor exposed to furunculosis. The test is carried out in the conditions to be recommended for the use of the vaccine with a water temperature not less than 10 °C. Administer to

each fish by the intraperitoneal route a dose corresponding to double that to be recommended, per mass unit. Observe the fish at least daily for 21 days.

The test is invalid if more than 6 per cent of the fish die from causes not attributable to the vaccine. The vaccine complies with the test if no fish shows abnormal local or systemic reactions or dies from causes attributable to the vaccine.

2-2-1-2. *Field studies.* Safety is also demonstrated in field trials by administering the intended dose to a sufficient number of fish in not fewer than 2 sets of premises. Samples of 30 fish are taken on 3 occasions (after vaccination, at the middle of the rearing period and at slaughter) and examined for local reactions in the body cavity. Moderate lesions involving localised adhesions between viscera or between viscera and the abdominal wall and slight opaqueness and/or sparse pigmentation of the peritoneum are acceptable. Extensive lesions including adhesions between greater parts of the abdominal organs, massive pigmentation and/or obvious thickening and opaqueness of greater areas of the peritoneum are unacceptable if they occur in more than 10 per cent of the fish in any sample. Such lesions include adhesions that give the viscera a "one-unit" appearance and/or lead to manifest laceration of the peritoneum following evisceration.

2-2-2. **Immunogenicity**. Carry out the test according to a protocol defining limits of body mass for the fish, water source, water flow and temperature limits, and preparation of a standardised challenge. A test is carried out for the route and method of administration to be recommended. The vaccine administered to each fish is of minimum potency.

Use for the test not fewer than 200 fish. Vaccinate not fewer than 100 fish by a recommended route, according to the instructions for use. Perform mock vaccination on a control group of not fewer than 100 fish; mark vaccinated and control fish for identification. Keep all the fish in the same tank or mix equal numbers of controls and vaccinates in each tank if more than one tank is used. Challenge each fish, by injection, at a fixed interval after vaccination, defined according to the statement regarding development of immunity, with a sufficient quantity of a culture of *A. salmonicida* subsp. *salmonicida* whose virulence has been verified. Observe the fish daily until at least 60 per cent specific mortality is reached in the control group. Plot for both vaccinates and controls a curve of specific mortality against time from challenge and determine by interpolation the time corresponding to 60 per cent specific mortality in controls.

The test is invalid if the specific mortality is less than 60 per cent in the control group 21 days after the first death in the fish. Read from the curve for vaccinates the mortality (M) at the time corresponding to 60 per cent mortality in controls. Calculate the relative percentage survival (RPS) from the expression:

$$\left(1 - \frac{M}{60}\right) \times 100$$

The vaccine complies with the test if the RPS is not less than 80 per cent.

2-3. *MANUFACTURER'S TESTS*

2-3-1. **Batch potency test**. The Potency test (section 3-4) may be carried out for each batch of vaccine, using not fewer than 30 fish per group. Where the test is not carried out, an alternative validated method based on antibody response may be used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

Use not fewer than 35 fish from a population that does not have specific antibodies against *A. salmonicida* subsp. *salmonicida* and that are within defined limits for body mass. Carry out the test at a defined temperature. Inject intraperitoneally into each of not fewer than 25 fish one dose of vaccine, according to the instructions for use. Perform mock vaccination on a control group of not fewer than 10 fish. Collect blood samples at a defined time after vaccination. Determine for each sample the level of specific antibodies against *A. salmonicida* subsp. *salmonicida* by a suitable immunochemical method (*2.7.1*). The test is invalid if the control group shows antibodies against *A. salmonicida* subsp. *salmonicida*. The vaccine complies with the test if the mean level of antibodies in the vaccinates is not significantly lower than that found for a batch that gave satisfactory results in the test described under Potency.

3. BATCH TESTS

3-1. **Identifcation**. When injected into fish that do not have specific antibodies against *A. salmonicida*, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use not fewer than 10 fish of one of the species for which the vaccine is intended, having, where possible, the minimum body mass recommended for vaccination; if fish of the minimum body mass are not available, use fish not greater than twice this mass. Use fish from a population that preferably does not have specific antibodies against *A. salmonicida* subsp. *salmonicida* or, where justified, use fish from a population with a low level of such antibodies as long as they have not been vaccinated against or exposed to furunculosis and administration of the vaccine does not cause an anamnestic response. Carry out the test in the conditions recommended for use of the vaccine with a water temperature not less than 10 °C. Administer to each fish by the intraperitoneal route a double dose of the vaccine per mass unit. Observe the fish at least daily for 21 days.

The test is invalid if more than 10 per cent of the fish die from causes not attributable to the vaccine. The vaccine complies with the test if no fish shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-2-2) when administered by the recommended route and method.

4. LABELLING

The label states information on the time needed for development of immunity after vaccination under the range of conditions corresponding to the recommended use.

INFECTIOUS BOVINE RHINOTRACHEITIS VACCINE (LIVE)

Vaccinum rhinotracheitidis infectivae bovinae vivum

1. DEFINITION

Infectious bovine rhinotracheitis vaccine (live) is a preparation of one or more suitable strains of infectious bovine rhinotracheitis virus (bovine herpesvirus 1). This monograph applies to vaccines intended for the active immunisation of cattle against bovine rhinotracheitis caused by bovine herpesvirus 1.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE VIRUS*

The vaccine virus is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the cattle for which it is intended.

The following tests for safety (section 2-3-1), abortigenicity and passage through the placenta (section 2-3-2), increase in virulence (section 2-3-3) and immunogenicity (2-3-4) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine.

For each test, use not fewer than 5 calves, 3 months old, or of the minimum age to be recommended for vaccination if this is less than 3 months and that do not have antibodies against infectious bovine rhinotracheitis virus. Administer to each calf a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in one dose of the vaccine. Observe the calves at least daily for 21 days.

The vaccine virus complies with the test if no calf shows abnormal local or systemic reactions or dies from causes attributable to the vaccine virus.

2-3-2. **Abortigenicity and passage through the placenta**. Use not fewer than 24 pregnant cows that do not have antibodies against infectious bovine rhinotracheitis virus: 8 of the cows are in the 4th month of pregnancy, 8 in the 5th and 8 in the 6th or 7th month. Administer to each cow by a route to be recommended a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in one dose of the vaccine. Observe the cows at least daily until the end of pregnancy.

The vaccine virus complies with the test if:

– where abortion occurs, tests show that neither virus nor viral antigens are present in the fœtus or placenta;
– on calves born at term before ingestion of colostrums, a test for antibodies against infectious bovine rhinotracheitis virus indicates no such antibodies are found.

2-3-3. **Increase in virulence**. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to the 5 calves used in the test for safety, sequential passages, 5 times where possible, to further similar groups and testing of the final recovered virus for increase in virulence. These calves are 3 months old or of the minimum age to be recommended for vaccination if this is less than 3 months, and do not have antibodies against infectious bovine rhinotracheitis virus. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages.

Take suitable samples from the 5 calves used for the test for safety at a time when the vaccinal virus can be easily detected, verify the presence and titre of the virus in the samples and mix them. Administer the samples by the intranasal route to each of 2 other calves of the same age and that do not have antibodies against bovine rhinotracheitis virus. Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages.

The vaccine virus complies with the test if no calf shows signs attributable to the vaccine virus and if no indication of increased virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-3-4. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended for vaccination using in each case calves 2-3 months old. The quantity of vaccine to be administered to each calf is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of vaccine.

Use for the test not fewer than 7 calves that do not have antibodies against infectious bovine rhinotracheitis virus. Vaccinate not fewer than 5 calves, according to the schedule to be recommended. Maintain not fewer than 2 calves as controls. Challenge each calf after 21 days by the intranasal route with a sufficient quantity of a virulent infectious bovine rhinotracheitis virus. Observe the calves at least daily for 21 days after challenge.

The test is invalid if the controls do not show typical signs of disease such as fever, ocular and nasal discharge and ulceration of the nasal mucosa.

The vaccine virus complies with the test if, during the observation period after challenge:

– the vaccinated calves show no more than mild signs;
– in not fewer than 4 of the 5 vaccinated calves, the maximum virus titre found in the nasal mucus is at least 100 times lower than the average of the maximum titres found in the control calves;
– and the average number of days on which virus is excreted is at least 3 days less in vaccinated calves than in the control calves.

3. BATCH TESTS

3-1. **Identification**

3-1-1. When mixed with a suitable quantity of a monospecific antiserum, the vaccine is no longer able to infect susceptible cell cultures into which it is inoculated.

3-1-2. Any markers of the strain are verified.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas** (*2.6.7*). The vaccine complies with the test for mycoplasmas.

3-4. **Extraneous agents**. Neutralise the vaccine virus with a suitable monospecific antiserum against bovine rhinotracheitis virus and inoculate into cell cultures known for their susceptibility to viruses pathogenic for cattle. Carry out one passage at 7 days and maintain the cultures for 14 days. The vaccine complies with the test if no cytopathic effect develops and there is no sign of the presence of haemadsorbing agents.

3-5. **Safety**. Use 2 calves 3 months old or of the minimum age recommended for vaccination if this is less than 3 months and that do not have antibodies against infectious bovine rhinotracheitis virus. Administer to each calf by a recommended route 10 doses of the vaccine. Observe the calves at least daily for 21 days.

The vaccine complies with the test if no calf shows notable signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**. Titrate the vaccine virus in susceptible cell cultures at a temperature favourable to replication of the virus. The vaccine complies with the test if one dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-3-4) when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2008:2038

INFECTIOUS CHICKEN ANAEMIA VACCINE (LIVE)

Vaccinum anaemiae infectivae pulli vivum

1. DEFINITION

Infectious chicken anaemia vaccine (live) is a preparation of a suitable strain of chicken anaemia virus. This monograph applies to vaccines intended for administration to breeder chickens for active immunisation, to prevent excretion of the virus, to prevent or reduce egg transmission and to protect passively their future progeny.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in embryonated hens' eggs or in cell cultures.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Embryonated hens' eggs**. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from flocks free from specified pathogens (SPF) (*5.2.2*).

2-2-2. **Cell cultures**. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *SEED LOTS*

2-3-1. **Extraneous agents**. The master seed lot complies with the tests for extraneous agents in seed lots (*2.6.24*). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the tests.

2-4. *CHOICE OF VACCINE VIRUS*

The vaccine virus shall be shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the chickens for which it is intended.

The following tests for safety (section 2-4-1), increase in virulence (section 2-4-2) and immunogenicity (section 2-4-3) may be used during the demonstration of safety and immunogenicity.

2-4-1. **Safety**

2-4-1-1. *General test.* Carry out the test for each route and method of administration to be recommended for vaccination in chickens not older than the youngest age to be recommended for vaccination and from an SPF flock (*5.2.2*). Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. For each test use not fewer than 20 chickens. Administer to each chicken a quantity of the vaccine virus not less than 10 times the maximum virus titre likely to be contained in 1 dose of the vaccine. 14 days after vaccination, collect blood samples from half of the chickens and determine the haematocrit value. Euthanise these chickens and carry out post-mortem examination. Note any pathological changes attributable to chicken anaemia virus, such as thymic atrophy and specific bone-marrow lesions. Observe the remaining chickens at least daily for 21 days. The vaccine virus complies with the test if during the observation period no chicken shows notable clinical signs of chicken anaemia or dies from causes attributable to the vaccine virus.

2-4-1-2. *Safety for young chicks.* Use not fewer than twenty 1-day-old chicks from an SPF flock (*5.2.2*). Administer to each chick by the oculonasal route a quantity of the vaccine virus equivalent to not less than the maximum titre likely to be contained in 1 dose of the vaccine. Observe the chicks at least daily. Record the incidence of any clinical signs attributable to the vaccine virus, such as depression, and any deaths. 14 days after vaccination, collect blood samples from half of the chicks and determine the haematocrit value. Euthanise these chicks and carry out post-mortem examination. Note any pathological changes attributable to chicken anaemia virus, such as thymic atrophy and specific bone marrow lesions. Observe the remaining chicks at least daily for 21 days. Assess the extent to which the vaccine strain is pathogenic for 1-day-old susceptible chicks from the results of the clinical observations and mortality rates and the proportion of chicks examined at 14 days that show anaemia (haematocrit value less than 27 per cent) and signs of infectious chicken anaemia on post-mortem examination. The results are used to formulate the label statement on safety for young chicks.

2-4-2. **Increase in virulence**. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to a group of five 1-day-old chicks from an SPF flock (*5.2.2*), sequential passages, 5 times where possible, to further similar groups of 1-day-old chicks and testing of the final recovered virus for increase in virulence. If the properties

of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages. Administer by the intramuscular route a quantity of the vaccine virus that will allow recovery of virus for the passages described below. Prepare 7 to 9 days after administration a suspension from the liver of each chick and pool these samples. Depending on the tropism of the virus, other tissues such as spleen or bone marrow may be used. Administer 0.1 ml of the pooled samples by the intramuscular route to each of 5 other chicks of the same age and origin. Carry out this passage operation at least 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages. Carry out the tests for safety (section 2-4-1) using the unpassaged vaccine virus and the maximally passaged vaccine virus that has been recovered. The vaccine virus complies with the test if no indication of increase in virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-4-3. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended using chickens from an SPF flock (*5.2.2*) not older than the youngest age to be recommended for vaccination. The test for prevention of virus excretion is intended to demonstrate absence of egg transmission. The quantity of the vaccine virus administered to each chicken is not greater than the minimum titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of the vaccine.

2-4-3-1. *Passive immunisation of chickens*. Vaccinate according to the recommended schedule not fewer than 10 breeder chickens not older than the minimum age recommended for vaccination and from an SPF flock (*5.2.2*); keep not fewer than 10 unvaccinated breeder chickens of the same origin and from an SPF flock (*5.2.2*). At a suitable time after excretion of vaccine virus has ceased, collect fertilised eggs from each vaccinated and control breeder chicken and incubate them. Challenge at least 3 randomly chosen 1-day-old chickens from each vaccinated and control breeder chicken by intramuscular administration of a sufficient quantity of virulent chicken anaemia virus. Observe the chickens at least daily for 14 days after challenge. Record the deaths and the surviving chickens that show clinical signs of disease. At the end of the observation period determine the haematocrit value of each surviving chicken. Euthanise these chickens and carry out post-mortem examination. Note any pathological signs attributable to chicken anaemia virus, such as thymic atrophy and specific bone-marrow lesions. The test is not valid if:

– during the observation period after challenge fewer than 90 per cent of the chickens of the control breeder chickens die or show severe clinical signs of infectious chicken anaemia, including haematocrit value under 27 per cent, and/or notable macroscopic lesions of the bone marrow and thymus,

– and/or during the period between vaccination and egg collection more than 10 per cent of vaccinated or control breeder chickens show notable clinical signs of disease or die from causes not attributable to the vaccine.

The vaccine complies with the test if during the observation period after challenge not fewer than 90 per cent of the chickens of the vaccinated breeder chickens survive and show no notable clinical signs of disease and/or macroscopic lesions of the bone marrow and thymus.

2-4-3-2. *Prevention of virus excretion*. Vaccinate according to the recommended schedule not fewer than 10 chickens not older than the minimum age recommended for vaccination and from an SPF flock (*5.2.2*). Maintain separately not fewer than 10 chickens of the same age and origin as controls. At a suitable time after excretion of vaccine virus has ceased, challenge all the chickens by intramuscular administration of a sufficient quantity of virulent chicken anaemia virus. Collect blood and faecal samples from the chickens on days 3, 5 and 7 after challenge and carry out a test for virus isolation to determine whether or not the chickens are viraemic and are excreting the virus. The test is not valid if:

– fewer than 70 per cent of the control chickens are viraemic and excrete the virus at one or more times of sampling,

– and/or during the period between vaccination and challenge more than 10 per cent of control or vaccinated chickens show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine complies with the test if not fewer than 90 per cent of the vaccinated chickens do not develop viraemia or excrete the virus.

3. BATCH TESTING

3-1. **Identification**. The vaccine, diluted if necessary and mixed with a monospecific chicken anaemia virus antiserum, no longer infects susceptible cell cultures or eggs from an SPF flock (*5.2.2*) into which it is inoculated.

3-2. **Bacteria and fungi**. Vaccines intended for administration by injection comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

Vaccines not intended for administration by injection either comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)* or with the following test: carry out a quantitative test for bacterial and fungal contamination; carry out identification tests for microorganisms detected in the vaccine; the vaccine does not contain pathogenic microorganisms and contains not more than 1 non-pathogenic microorganism per dose.

Any liquid supplied with the vaccine complies with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas**. The vaccine complies with the test for mycoplasmas (*2.6.7*).

3-4. **Extraneous agents**. The vaccine complies with the tests for extraneous agents in batches of finished product (*2.6.25*).

3-5. **Safety**. Use not fewer than 10 chickens not older than the minimum age recommended for vaccination and from an SPF flock (*5.2.2*). Administer by a recommended route to each chicken 10 doses of the vaccine. Observe the chickens at least daily for 21 days. The test is not valid if more than 20 per cent of the chickens show abnormal clinical signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no chicken shows notable clinical signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**. Titrate the vaccine virus by inoculation into suitable cell cultures (*5.2.4*) or eggs from an SPF flock (*5.2.2*). The vaccine complies with the test if 1 dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency**. The vaccine complies with the requirements of the tests prescribed under Immunogenicity (sections 2-4-3-1 and 2-4-3-2) when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

4. LABELLING

The label states to which extent the vaccine virus causes disease if it spreads to susceptible young chicks.

01/2008:1944

MANNHEIMIA VACCINE (INACTIVATED) FOR CATTLE

Vaccinum mannheimiae inactivatum ad bovinas

1. DEFINITION

Mannheimia vaccine (inactivated) for cattle is a preparation from cultures of one or more suitable strains of *Mannheimia haemolytica* (formerly *Pasteurella haemolytica*), inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for active immunisation of cattle of different ages against respiratory diseases caused by *M. haemolytica*.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

Production of the vaccine is based on a seed-lot system. The seed material is cultured in a suitable medium; each strain is cultivated separately and identity is verified using a suitable method. During production, various parameters such as growth rate are monitored by suitable methods; the values are within the limits approved for the particular product. Purity and identity of the harvest are verified using suitable methods. After cultivation, the bacterial suspensions are collected separately and inactivated by a suitable method. The vaccine may be adjuvanted.

2-2. *CHOICE OF VACCINE COMPOSITION*

The choice of composition and the strains to be included in the vaccine is based on epidemiological data on the prevalence of the different serovars of *M. haemolytica* and on the claims being made.

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the cattle for which it is intended.

The following tests for safety (section 2-2-1.) and immunogenicity (section 2-2-2.) may be used during the demonstration of safety and efficacy.

2-2-1. **Safety**

2-2-1-1. *Laboratory tests.* Carry out the test for each route and method of administration to be recommended for vaccination and in cattle of each category for which the vaccine is intended. Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine.

2-2-1-1-1. General safety. For each test, use not fewer than 10 cattle that preferably do not have antibodies against the serovars of *M. haemolytica* or against the leucotoxin present in the vaccine. Where justified, cattle with a known history of no previous mannheimia vaccination and with low antibody titres (measured in a sensitive test system such as an ELISA) may be used. Administer to each animal a double dose of the vaccine. If the schedule to be recommended requires a 2nd dose, administer one dose after the interval to be recommended. Observe the cattle at least daily for at least 14 days after the last administration. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 4 days; note the maximum temperature increase for each animal.

The vaccine complies with the test if no animal shows abnormal local or systemic reactions, signs of disease or dies from causes attributable to the vaccine, if the average body temperature increase for all cattle does not exceed 1.5 °C and no animal shows a rise greater than 2 °C.

2-2-1-1-2. Safety in pregnant cows. If the vaccine is intended for use or may be used in pregnant cows, use not fewer than 10 pregnant cows at the relevant stages of pregnancy. Administer to each cow a double dose of the vaccine, then one dose after the interval to be recommended. Observe the cows at least daily until one day after parturition. Record body temperatures the day before each vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 4 days; note the maximum temperature increase for each cow.

The vaccine complies with the test if:

- no cow shows abnormal local or systemic reactions, signs of disease or dies from causes attributable to the vaccine,
- the average body temperature increase for all cows does not exceed 1.5 °C and no cow shows a rise greater than 2 °C,
- and no adverse effects on the pregnancy and offspring are noted.

2-2-1-2. *Field studies.* The cattle used for the field trials are also used to evaluate safety. Carry out a test in each category of cattle for which the vaccine is intended. Use not fewer than 3 groups of 20 cattle with corresponding groups of not fewer than 10 controls in 3 different locations. Examine the injection sites for local reactions after vaccination. Record body temperatures the day before vaccination, at vaccination and on the 2 days following vaccination.

The vaccine complies with the test if no animal shows abnormal local or systemic reactions, signs of disease or dies from causes attributable to the vaccine. The average body temperature increase for all cattle does not exceed 1.5 °C and no animal shows a rise greater than 2 °C. In addition, if the vaccine is intended for use in pregnant cows, no significant effects on the pregnancy and offspring are demonstrated.

2-2-2. **Immunogenicity**. Carry out a test for each serovar for which protection is claimed on the label.

Each test is carried out for each route and method of administration to be recommended, using in each case cattle of the minimum age to be recommended for vaccination. The vaccine administered to each animal is of minimum potency.

Use not fewer than 16 cattle that do not have antibodies against *M. haemolytica* and against the leucotoxin of *M. haemolytica*. Vaccinate not fewer than 8 of the cattle according to the schedule to be recommended. Maintain not fewer than 8 cattle as controls. Challenge each animal 21 days after the last vaccination by the intratracheal route or by another appropriate route, with a sufficient quantity of a low-passage, virulent strain of a serovar of *M. haemolytica*. Observe the cattle at least daily for a further 7 days; to avoid unnecessary suffering, severely ill cattle are euthanised and are then considered to have died from the disease. During the observation period, examine the cattle for signs of disease for example, increased body temperature, dullness, abnormal breathing and record the mortality. Euthanise surviving cattle at the end of the observation period. Carry out post-mortem examination on any animal that dies and those euthanised at the end of the observation period.

Examine the lungs and evaluate the extent of lung lesions due to mannheimiosis. Collect samples of lung tissue for re-isolation of the challenge organisms. Score the clinical observations and lung lesions and compare the results obtained for these parameters and the bacterial re-isolation results for the 2 groups.

The test is invalid if signs of *M. haemolytica* infection occur in less than 70 per cent of the control cattle. The vaccine complies with the test if there is a significant difference between the scores obtained for the clinical and post-mortem observations in the vaccinates compared to the controls. For vaccines with a claim for a beneficial effect on the extent of infection against the serovar, the results for the infection rates are also significantly better for the vaccinates compared to the controls.

2-3. *MANUFACTURER'S TESTS*

2-3-1. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-4.) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency.

2-3-2. **Bacterial endotoxins**. A test for bacterial endotoxins (*2.6.14*) is carried out on the final lot or, where the nature of the adjuvant prevents performance of a satisfactory test, on the bulk antigen or the mixture of bulk antigens immediately before addition of the adjuvant. The maximum acceptable amount of bacterial endotoxins is that found for a batch of vaccine that has been shown satisfactory in safety test 2-2-1-1. given under Choice of vaccine composition or in safety test 3-3. described under Tests, carried out using 10 cattle. Where the latter test is used, note the maximum temperature increase for each animal; the vaccine complies with the test if the average body temperature increase for all cattle does not exceed 1.5 °C. The method chosen for determining the amount of bacterial endotoxin present in the vaccine batch used in the safety test for determining the maximum acceptable level of endotoxin is used subsequently for testing of each batch.

3. BATCH TESTS

3-1. **Identification**. When injected into healthy animals that do not have specific antibodies against the serovars of *M. haemolytica* and/or against the leucotoxin present in the vaccine, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 cattle of the minimum age recommended for vaccination and that have not been vaccinated against mannheimiosis. Administer to each animal by a recommended route a double dose of the vaccine. Observe the cattle at least daily for 14 days. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 2 days.

The vaccine complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine; a transient temperature increase not exceeding 2 °C may occur.

3-4. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-2-2.) when administered by a recommended route and method.

01/2008:1946

MANNHEIMIA VACCINE (INACTIVATED) FOR SHEEP

Vaccinum mannheimiae inactivatum ad ovem

1. DEFINITION

Mannheimia vaccine (inactivated) for sheep is a preparation of one or more suitable strains of *Mannheimia haemolytica* (formerly *Pasteurella haemolytica*), inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for the active immunisation of sheep and/or for the passive protection of their progeny against disease caused by *M. haemolytica*.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

Production of the vaccine is based on a seed lot system. The seed material is cultured in a suitable medium; each strain is cultivated separately and identity is verified using a suitable method. During production, various parameters such as growth rate are monitored by suitable methods; the values are within the limits approved for the particular product. Purity and identity of the harvest are verified using suitable methods. After cultivation, the bacterial suspensions are collected separately and inactivated by a suitable method. The vaccine may be adjuvanted.

2-2. *CHOICE OF VACCINE COMPOSITION*

The choice of composition and the strains to be included in the vaccine are based on epidemiological data on the prevalence of the different serovars of *M. haemolytica* and on the claims being made for the product, for example active and/or passive protection.

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the sheep for which it is intended.

The following tests for safety (section 2-2-1) and immunogenicity (section 2-2-2) may be used during the demonstration of safety and efficacy.

2-2-1. **Safety**

2-2-1-1. *Laboratory tests.* Carry out the tests for each route and method of administration to be recommended for vaccination and in sheep of each category for which the vaccine is intended (for example, young sheep, pregnant ewes). Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine.

2-2-1-1-1. General safety. For each test, use not fewer than 10 sheep that preferably do not have antibodies against the serovars of *M. haemolytica* or against the leucotoxin present in the vaccine. Where justified, sheep with a known history of no previous mannheimia vaccination and with low antibody titres (measured in a sensitive test system such as an ELISA) may be used. Administer to each sheep a double dose of the vaccine then one dose after the interval to be recommended. Observe the sheep at least daily for at least 14 days after the last administration. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 4 days; note the maximum temperature increase for each sheep.

The vaccine complies with the test if no sheep shows abnormal local reactions, notable signs of disease or dies from causes attributable to the vaccine, if the average body temperature increase for all sheep does not exceed 1.5 °C and no sheep shows a rise greater than 2 °C.

2-2-1-1-2. Safety in pregnant ewes. If the vaccine is intended for use or may be used in pregnant ewes, use not fewer than 10 pregnant ewes at the relevant stages of pregnancy. Administer to each ewe a double dose of the vaccine, then one dose after the interval to be recommended. Observe the ewes at least daily until one day after lambing. Record body temperatures the day before each vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 4 days; note the maximum temperature increase for each ewe.

The vaccine complies with the test if:

– no ewe shows abnormal local reactions, notable signs of disease or dies from causes attributable to the vaccine,
– the average body temperature increase for all ewes does not exceed 1.5 °C and no ewe shows a rise greater than 2 °C,
– and no adverse effects on the pregnancy and offspring are noted.

2-2-1-2. *Field studies.* The sheep used for the field trials are also used to evaluate safety. Carry out a test in each category of sheep for which the vaccine is intended. Use not fewer than 3 groups of 20 sheep with corresponding groups of not fewer than 10 controls in 3 different locations. Examine the injection sites for local reactions after vaccination. Record body temperatures the day before vaccination, at vaccination and on the 2 days following vaccination.

The vaccine complies with the test if no sheep shows abnormal local or systemic reactions, notable signs of disease or dies from causes attributable to the vaccine. The average body temperature increase for all sheep does not exceed 1.5 °C and no sheep shows a rise greater than 2 °C. In addition, if the vaccine is intended for use in pregnant ewes, no adverse effects on the pregnancy and offspring are demonstrated.

2-2-2. **Immunogenicity**.

2-2-2-1. *Active immunisation.* For vaccines with claims for active immunisation against mannheimiosis, carry out a test for each serovar of *M. haemolytica* for which protection is to be claimed on the label.

A test is carried out for each route and method of administration to be recommended, using in each case lambs of the minimum age to be recommended for vaccination. The vaccine administered to each lamb is of minimum potency.

Use not fewer than 20 lambs that do not have antibodies against *M. haemolytica* and against the leucotoxin of *M. haemolytica.* Vaccinate not fewer than 10 lambs according to the schedule to be recommended. Maintain not fewer than 10 lambs as controls. 21 days after the last vaccination, challenge each lamb by the intratracheal route or by another appropriate route, with a sufficient quantity of a low-passage, virulent strain of a serovar of *M. haemolytica.* Where necessary for a given serovar, prechallenge with parainfluenza type 3 (PI3) virus or another appropriate respiratory pathogen may be used. Observe the lambs for a further 7 days; to avoid unnecessary suffering, severely ill lambs are euthanised and are then considered to have died from the disease. During the observation period, examine the lambs for signs of disease (for example, increased body temperature, dullness, abnormal respiration) and record the mortality. Euthanise surviving lambs at the end of the observation period. Carry out post-mortem examination on any lamb that dies and those euthanised at the end of the observation period. Examine the lungs and evaluate the extent of lung lesions due to mannheimiosis. Collect samples of lung tissue for re-isolation of the challenge organisms. Score the clinical observations and lung lesions and compare the results obtained for these parameters and the bacterial re-isolation results for the 2 groups.

The test is invalid if signs of *M. haemolytica* infection occur in less than 70 per cent of the control lambs. The vaccine complies with the test if there is a significant difference between the scores obtained for the clinical and post-mortem observations in the vaccinates compared to the controls. For vaccines with a claim for a beneficial effect on the extent of infection against the serovar, the results for the infection rates are also significantly better for the vaccinates compared to the controls.

2-2-2-2. *Passive protection.* For vaccines with claims for passive protection against mannheimiosis carry out a test for each serovar of *M. haemolytica* for which protection is to be claimed on the label.

A test is carried out for each route and method of administration to be recommended for vaccination. The vaccine administered to each ewe is of minimum potency.

Use not fewer than 6 ewes that preferably do not have antibodies against the serovars of *M. haemolytica* or against the leucotoxin present in the vaccine. Where justified, ewes with a known history of no previous mannheimia vaccination, from a source with a low incidence of respiratory disease and with low antibody titres (measured in a sensitive test system such as an ELISA) may be used. Vaccinate the ewes at the stages of pregnancy and according to the schedule to be recommended. A challenge study is conducted with 20 newborn, colostrum-deprived lambs. 10 of these lambs are given colostrum from the vaccinated ewes and 10 control lambs are given colostrum or colostrum substitute without detectable antibodies to *M. haemolytica.* When the lambs are at the age to be claimed for the duration of the passive protection, challenge each by the intratracheal route with a sufficient quantity of a low-passage, virulent strain of a serovar of *M. haemolytica.* Observe the lambs for a further 7 days; to avoid unnecessary suffering, severely ill lambs are euthanised and are then considered to have died from the disease. Observe the lambs and assess the effect of the challenge on the offspring of the vaccinates and the controls as described in the test for active immunisation.

The test is invalid if signs or lesions of *M. haemolytica* infection occur in less than 70 per cent of the control lambs. The vaccine complies with the test if there is a significant difference between the scores obtained for the clinical and post-mortem observations in the lambs from the vaccinates compared to those from the controls. For vaccines with a claim for a beneficial effect on the extent of infection against the serovar, the results for the infection rates are also significantly better for the lambs from the vaccinates compared to those from the controls.

2-3. *MANUFACTURER'S TESTS*

2-3-1. **Batch potency test**. It is not necessary to carry out the relevant Potency test or tests (section 3-4) for each batch of vaccine if they have been carried out using a batch of vaccine with a minimum potency. Where the relevant test or tests are not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test(s) described under Potency.

2-3-2. **Bacterial endotoxins**. A test for bacterial endotoxins (*2.6.14*) is carried out on the final lot or, where the nature of the adjuvant prevents performance of a satisfactory test, on the bulk antigen or the mixture of bulk antigens immediately before addition of the adjuvant. The maximum acceptable amount of bacterial endotoxins is that found for a batch of vaccine that has been shown satisfactory in safety tests 2-2-1-1 given under Choice of vaccine composition or in safety test 3-3 described under Batch tests, carried out using 10 sheep. Where the latter test is used, note the maximum

temperature increase for each sheep; the vaccine complies with the test if the average body temperature increase for all sheep does not exceed 1.5 °C. The method chosen for determining the amount of bacterial endotoxin present in the vaccine batch used in the safety test for determining the maximum acceptable level of endotoxin is used subsequently for testing of each batch.

3. BATCH TESTS

3-1. **Identification**. When injected into healthy animals that do not have specific antibodies against the serovars *M. haemolytica* and/or against the leucotoxin present in the vaccine, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 sheep of the minimum age recommended for vaccination or, if not available, of an age as close as possible to the minimum recommended age, and that have not been vaccinated against mannheimiosis. Administer to each sheep by a recommended route a double dose of the vaccine. Observe the sheep at least daily for 14 days. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 2 days.

The vaccine complies with the test if no sheep shows notable signs of disease or dies from causes attributable to the vaccine; a transient temperature increase not exceeding 2 °C may occur.

3-4. **Potency**. The vaccine complies with the requirements of the test or test(s) mentioned under Immunogenicity (section 2-2-2) when administered by a recommended route and method.

01/2008:0589

MAREK'S DISEASE VACCINE (LIVE)

Vaccinum morbi Marek vivum

1. DEFINITION

Marek's disease vaccine (live) is a preparation of a suitable strain or strains of Marek's disease virus (gallid herpesvirus 2 or 3) and/or turkey herpesvirus (meleagrid herpesvirus 1). This monograph applies to vaccines intended for administration to chickens and/or chicken embryos for active immunisation.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures. If the vaccine contains more than one type of virus, the different types are grown separately. The vaccine may be freeze-dried or stored in liquid nitrogen.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *SEED LOTS*

2-3-1. **Extraneous agents**. The master seed lot complies with the tests for extraneous agents in seed lots (*2.6.24*). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the tests.

2-4. *CHOICE OF VACCINE VIRUS*

The vaccine virus shall be shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the chickens and/or chicken embryos for which it is intended.

The tests shown below for residual pathogenicity of the strain (section 2-4-1), increase in virulence (section 2-4-2) and immunogenicity (section 2-4-3) may be used during the demonstration of safety and immunogenicity. Additional testing may be needed to demonstrate safety in breeds of chickens known to be particularly susceptible to Marek's disease virus, unless the vaccine is to be contra-indicated.

2-4-1. **Residual pathogenicity of the strain**. Carry out the test for the route to be recommended for vaccination that is likely to be the least safe and in the category of chickens for which the vaccine is intended that is likely to be the most susceptible for Marek's disease. Carry out the test in chickens if the vaccine is intended for chickens; carry out the test in chicken embryos if the vaccine is intended for chicken embryos; carry out the test in chickens and in chicken embryos if the vaccine is intended for both. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine.

Vaccines intended for use in chickens. Use not fewer than 80 one-day-old chickens from a flock free from specified pathogens (SPF) (*5.2.2*). Divide them randomly into 2 groups of not fewer than 40 chickens and maintain the groups separately. Administer by a suitable route to each chicken of one group (I) a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in 1 dose of the vaccine. Administer by a suitable route to each chicken of the other group (II) a quantity of virulent Marek's disease virus that will cause mortality and/or severe macroscopic lesions of Marek's disease in not fewer than 70 per cent of the effective number of chickens within 70 days (initial number reduced by the number that die within the first 7 days of the test).

Vaccines intended for use in chicken embryos. Use not fewer than 150 embryonated eggs from an SPF flock (*5.2.2*). Divide them randomly into 3 groups of not fewer than 50 embryonated eggs and maintain the groups separately but under identical incubation conditions. Not later than the recommended day of vaccination, administer by the recommended method to each embryonated egg of one group (I) a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in 1 dose of the vaccine. Administer by a suitable route to each embryonated egg of another group (II) a quantity of virulent Marek's disease virus that will cause mortality and/or severe macroscopic lesions of Marek's disease in not fewer than 70 per cent of the effective number of hatched chickens within 70 days (initial number reduced by the number that die within the first 7 days after hatching). Keep the last group (III) non-inoculated. The test is invalid if there is a significant difference in hatchability between groups I and III and the hatchability in any of the 3 groups is less than 80 per cent.

Provided that the chickens and chicken embryos are derived from the same flock, a common control group for *in ovo* and parenteral administration can be used.

Irrespective of whether the vaccine was administered to chickens or chicken embryos, observe the chickens of group II at least daily for 70 days and those of group I at least daily for 120 days. The test is invalid if one or more of the following apply:

– more than 10 per cent of the chickens in any of the 3 groups die within the first 7 days;

– fewer than 70 per cent of the effective number of chickens in group II show macroscopic lesions of Marek's disease;

The vaccine virus complies with the test if:

– no chicken of group I shows notable clinical signs or macroscopic lesions of Marek's disease or dies from causes attributable to the vaccine virus;
– at 120 days the number of surviving chickens of group I is not fewer than 80 per cent of the effective number.

2-4-2. **Increase in virulence**. The test for increase in virulence is required for Marek's disease virus vaccine strains but not for turkey herpesvirus vaccine strains, which are naturally apathogenic. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine.

Vaccines intended for use in chickens. Administer by the intramuscular route a quantity of the vaccine virus that will allow recovery of virus for the passages described below to each of 5 one-day-old chickens from an SPF flock (*5.2.2*).

Vaccines intended for use only in chicken embryos or intended for use in chickens and in chicken embryos. Administer by the *in ovo* route, using the recommended method, a quantity of the vaccine virus that will allow recovery of virus for the passages described below to each of 5 embryonated eggs not later than the recommended day for vaccination.

5-7 days after administering the vaccine to chickens or 5-7 days after hatching when the vaccine has been administered *in ovo*, prepare a suspension of white blood cells from each chicken and pool these samples. Administer a suitable volume of the pooled samples by the intraperitoneal route to each of 5 other chickens that are 1 dayold and from an SPF flock (*5.2.2*). Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. Care must be taken to avoid contamination by virus from previous passages. If the virus is not found at a passage level, carry out a second series of passages. Carry out the test for residual pathogenicity (section 2-4-1) using the unpassaged vaccine virus and the maximally passaged virus that has been recovered. Administer the virus by the route to be recommended for vaccination that is likely to be the least safe for use in these chickens or chicken embryos. The vaccine virus complies with the test if no indication of increase in virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-4-3. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended, using in each case chickens of the youngest age to be recommended for vaccination or chicken embryos. The quantity of the vaccine virus administered to each chicken or chicken embryo is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of the vaccine.

Vaccines intended for use in chickens. Use not fewer than 60 chickens of the same origin and from an SPF flock (*5.2.2*). Vaccinate by a recommended route not fewer than 30 chickens. Maintain not fewer than 30 chickens as controls.

Vaccines intended for use in chicken embryos. Use embryonated chickens of the same origin and from an SPF flock (*5.2.2*). Vaccinate by the *in ovo* route using the method to be recommended, 50 per cent of the embryonated eggs. Maintain 50 per cent of the embryonated eggs as controls. The test is invalid if any group consists of fewer than 30 hatched chicks.

Irrespective of whether the vaccine was administered to chickens or chicken embryos, challenge each chicken not later than 9 days after vaccination by a suitable route with a sufficient quantity of virulent Marek's disease virus. Observe the chickens at least daily for 70 days after challenge. Record the deaths and the number of surviving chickens that show clinical signs of disease. At the end of the observation period, euthanise all the surviving chickens and carry out an examination for macroscopic lesions of Marek's disease. The test is not valid if:

– during the observation period after challenge, fewer than 70 per cent of the control chickens die or show severe clinical signs or macroscopic lesions of Marek's disease;
– and/or, during the period between the vaccination and challenge, more than 10 per cent of the control or vaccinated chickens show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine virus complies with the test if the relative protection percentage, calculated using the following expression, is not less than 80 per cent:

$$\frac{V - C}{100 - C} \times 100$$

V = percentage of challenged vaccinated chickens that survive to the end of the observation period without notable clinical signs or macroscopic lesions of Marek's disease;

C = percentage of challenged control chickens that survive to the end of the observation period without notable clinical signs or macroscopic lesions of Marek's disease.

3. BATCH TESTS

3-1. **Identification**. Carry out an immunostaining test in cell cultures using monoclonal antibodies to demonstrate the presence of each type of virus stated on the label.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas**. The vaccine complies with the test for mycoplasmas (*2.6.7*).

3-4. **Extraneous agents**. The vaccine complies with the tests for extraneous agents in batches of finished product (*2.6.25*).

3-5. **Safety**. Administer by a recommended route and method to each chicken or chicken embryo 10 doses of the vaccine.

Vaccines intended for use in chickens. Use not fewer than 10 chickens from an SPF flock (*5.2.2*) and not older than the youngest age recommended for vaccination.

Vaccines intended for use only in chicken embryos or intended for use in chickens and in chicken embryos. Use embryonated eggs from an SPF flock (*5.2.2*) at not later than the recommended day of vaccination of embryos. The test is invalid if the group consists of fewer than 10 hatched chicks and hatchability is less than 80 per cent.

Irrespective of whether the vaccine was administered to chickens or embryos, observe the chickens at least daily for 21 days after vaccination or hatching, as appropriate. The test is not valid if more than 20 per cent of the chickens show abnormal clinical signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no chicken shows notable clinical signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**

3-6-1. *Vaccines containing one type of virus.* Titrate the vaccine virus by inoculation into suitable cell cultures (*5.2.4*). If the virus titre is determined in plaque-forming units (PFU), only primary plaques are taken into consideration. The vaccine complies with the test if one dose contains not less than the minimum virus titre stated on the label.

3-6-2. *Vaccines containing more than one type of virus.* For vaccines containing more than one type of virus, titrate each virus by inoculation into suitable cell cultures (*5.2.4*), reading the results by immunostaining using antibodies. The vaccine complies with the test if one dose contains for each vaccine virus not less than the minimum virus titre stated on the label.

3-7. **Potency**. The vaccine complies with the test for immunogenicity (section 2-4-3) when administered according to the recommended schedule by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2008:1942

MYCOPLASMA GALLISEPTICUM VACCINE (INACTIVATED)

Vaccinum Mycoplasmatis galliseptici inactivatum

1. DEFINITION

Mycoplasma gallisepticum vaccine (inactivated) is a preparation of one or more suitable strains of *Mycoplasma gallisepticum* that have been inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for the active immunisation of chickens and/or turkeys.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

Production of the vaccine is based on a seed-lot system. The seed material is cultured in a suitable solid and/or liquid medium to ensure optimal growth under the chosen incubation conditions. Each strain is cultivated separately and identity is verified using a suitable method. During production, various parameters such as growth rate are monitored by suitable methods; the values are within the limits approved for the particular vaccine. Purity and identity of the harvest are verified using suitable methods. After cultivation, the mycoplasma suspensions are collected separately and inactivated by a suitable method. The mycoplasma suspensions may be treated to fragment the mycoplasmas and the fragments may be purified and concentrated. The vaccine may contain an adjuvant.

2-2. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) in the target animals. The following test for immunogenicity (section 2-2-1) may be used during the demonstration of efficacy. If the indications for the vaccine include protection against a drop in laying performance or protection against infectious sinusitis in turkeys, further suitable immunogenicity testing is necessary.

2-2-1. **Immunogenicity**. The test is carried out for each recommended route of administration and for each avian species for which the vaccine is intended. Use for each test not fewer than 40 birds not older than the youngest age to be recommended for vaccination. Use chickens from a flock free from specified pathogens (SPF) (*5.2.2*) or turkeys that have not been vaccinated and are free from antibodies against *M. gallisepticum*. For each test, administer to each of not fewer than 20 birds a quantity of the vaccine not greater than a single dose. If re-vaccination is recommended, repeat this operation after the recommended interval. Maintain not fewer than 20 birds as controls. Challenge each bird from both groups not more than 28 days after the last administration by a suitable route with a sufficient quantity of virulent *M. gallisepticum* (R-strain). Observe the birds at least daily for 14 days after challenge. Evaluation is carried out 14 days after challenge, at which point the birds are euthanised. Record the deaths and the number of surviving birds that show clinical signs of disease (e.g. respiratory distress, nasal discharge), and record air sac lesions. The test is invalid if:

- during the observation period after challenge, fewer than 70 per cent of the controls die or show lesions or clinical signs of disease;
- and/or during the period between vaccination and challenge, more than 10 per cent of the birds from the control group or from the vaccinated group show abnormal clinical signs of disease or die from causes not attributable to the vaccine.

Thoracic and abdominal air sacs are evaluated individually on each side of the animal. The scoring system presented below may be used. The vaccine complies with the test if the score for the vaccinated birds is significantly lower than that for the controls and if the reduction is not less than 30 per cent.

0	no air sac lesions
1	in a limited area of 1 or 2 air sacs: cloudiness with slight thickening of the air sac membrane or flecks of yellowish exudate
2	in 1 air sac or portions of 2 air sacs: greyish or yellow, sometimes foamy exudate, with thickening of the air sac membrane
3	in 3 air sacs: extensive exudate, with clear thickening of most air sacs
4	severe air-sacculitis with considerable exudate and thickening of most air sacs.

2-3. *MANUFACTURER'S TESTS*

2-3-1. **Batch potency test**. It is not necessary to carry out the potency test (section 3-5) for each batch of the vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out on a batch, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the potency test (section 3-5). The following test may be used.

Use not fewer than 15 chickens, 3-4 weeks old, from an SPF flock (*5.2.2*) or not fewer than 15 turkeys, 3-4 weeks old, that have not been vaccinated against *M. gallisepticum*, do not have antibodies against *M. gallisepticum*, and are obtained from a healthy flock. Collect serum samples from each vaccinate and control bird just before vaccination and check for the absence of antibodies against *M. gallisepticum*. Administer to each of not fewer than 10 birds 1 dose of the vaccine by a recommended route. Maintain not fewer than 5 birds as controls. Collect serum samples 5 weeks after vaccination from each vaccinated and control bird. Measure the titres of serum antibodies against *M. gallisepticum* using a suitable method. Calculate the mean titres for the group of vaccinates. The test is invalid if specific *M. gallisepticum* antibodies are found in any serum samples from the control

birds 5 weeks after the time of administration of the vaccine. The vaccine complies with the test if the mean antibody titres of the group of vaccinates are equal to or greater than the titres obtained with a batch that has given satisfactory results in the potency test (section 3-5).

3. BATCH TESTS

3-1. **Identification**. When injected into chickens from an SPF flock (*5.2.2*) or turkeys from healthy flocks, the vaccine stimulates the production of antibodies against one or more strains of *M. gallisepticum*.

3-2. **Bacteria and fungi**. The vaccine complies with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Residual live mycoplasmas**. The vaccine complies with a validated test for residual live *M. gallisepticum* carried out by a culture method (see for example *2.6.7*, using media shown to be suitable for *M. gallisepticum*).

3-4. **Safety**. Use not fewer than 10 chickens from an SPF flock (*5.2.2*) or, if the vaccine is intended only for turkeys, not fewer than 10 turkeys of the minimum age recommended for vaccination from an unvaccinated flock that is free from antibodies against *M. gallisepticum*. Administer to each bird by a recommended route a double dose of the vaccine. Observe the birds at least daily for 21 days. The vaccine complies with the test if all the birds remain in good health and no abnormal local or systemic reaction occurs.

3-5. **Potency**. The vaccine complies with the test for immunogenicity (section 2-2-1).

01/2008:1943

MYXOMATOSIS VACCINE (LIVE) FOR RABBITS

Vaccinum myxomatosidis vivum ad cuniculum

1. DEFINITION

Myxomatosis vaccine (live) for rabbits is a preparation of a suitable strain of either myxoma virus that is attenuated for rabbits or Shope fibroma virus. This monograph applies to vaccines intended for the active immunisation of rabbits against myxomatosis.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures. The viral suspension is harvested, titrated and may be mixed with a suitable stabilising solution.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE VIRUS*

The vaccine virus is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the rabbits for which it is intended.

The following tests for Safety (section 2-3-1.), Increase in virulence (section 2-3-2.) and Immunogenicity (2-3-3.) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination, using in each case rabbits of the minimum age to be recommended. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine.

2-3-1-1. *General safety*. For each test, use not fewer than 10 rabbits that do not have antibodies against myxoma virus. Administer to each rabbit a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in one dose of the vaccine. Observe the rabbits at least daily for 28 days. Record the body temperature the day before vaccination, at vaccination, 4 h after vaccination and then daily for 4 days; note the maximum temperature increase for each rabbit.

The vaccine virus complies with the test if no rabbit shows notable signs of disease or dies from causes attributable to the vaccine virus; the average temperature increase does not exceed 1 °C and no rabbit shows a rise greater than 2 °C. A local reaction lasting less than 28 days may occur.

2-3-1-2. *Safety in pregnant rabbits*. If the vaccine is intended for use in pregnant rabbits, use not fewer than 10 pregnant rabbits. Administer to each rabbit a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in one dose of the vaccine according to the schedule to be recommended. Observe the rabbits at least daily until 1 day after parturition. The vaccine virus complies with the test if:

– the rabbits remain in good health;

– no rabbit shows notable signs of disease or dies from causes attributable to the vaccine virus;

– no adverse effects on the pregnancy or the offspring are noted.

2-3-2. **Increase in virulence**. (*This test is performed only for vaccines based on attenuated strains of myxoma virus*). The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to 2 rabbits, 5-7 weeks old, that do not have antibodies against myxoma virus, sequential passages, 5 times where possible, to further similar groups and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages.

Administer to each rabbit by a route to be recommended a quantity of the vaccine virus that will allow recovery of virus for the passages described below. Administer the virus by the route to be recommended for vaccination most likely to lead to reversion of virulence. Euthanise the rabbits 5 to 10 days after inoculation and remove from each rabbit organs, or tissues with sufficient virus to allow passage; homogenise the organs and tissues in a suitable buffer solution, centrifuge the suspension and use the supernatant for further passages. Inoculate the supernatant into suitable cell culture to verify the presence of virus. Administer by an appropriate route, at a suitable rate, a suitable volume of the supernatant to each of 2 other rabbits of the same age. Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages.

Carry out the test for Safety (section 2-3-1) using unpassaged vaccine virus and the maximally passaged virus that has been recovered.

The vaccine virus complies with the test if no indication of increased virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-3-3. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended for vaccination using in each case rabbits of the minimum age to be recommended. The quantity of vaccine virus to be administered to each rabbit is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of vaccine.

Use for the test not fewer than 15 rabbits that do not have antibodies against myxoma virus and reared in suitable isolation conditions to ensure absence of contact with myxoma virus. Administer 1 dose of vaccine to each of not fewer than 10 of the rabbits according to the schedule to be recommended. Maintain not fewer than 5 rabbits as controls. Challenge each rabbit not less than 21 days after the last vaccination by a suitable route with a quantity of a virulent strain of myxoma virus sufficient to cause typical signs of myxomatosis in a rabbit. Observe the rabbits at least daily for further 21 days after challenge and monitor each of them.

The test is invalid if fewer than 90 per cent of the control rabbits display typical signs of myxomatosis. A vaccine containing myxoma virus complies with the test if, during the observation period after challenge, not fewer than 90 per cent of vaccinated rabbits show no signs of myxomatosis. A vaccine containing Shope fibroma virus complies with the test if, during the observation period after challenge, not fewer than 75 per cent of vaccinated rabbits show no signs of myxomatosis.

3. BATCH TESTS

3-1. **Identification**. Carry out an immunofluorescence test in suitable cell cultures, using a monospecific antiserum.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas** (*2.6.7*). The vaccine complies with the test for mycoplasmas.

3-4. **Safety**. Use not fewer than 2 rabbits, not older than the minimum age recommended for vaccination and that do not have antibodies against myxoma virus and rabbit haemorrhagic disease virus and that have been reared in suitable isolation conditions to avoid contact with myxoma virus. Administer to each rabbit by a recommended route 10 doses of the vaccine. Observe the rabbits at least daily for 14 days.

The vaccine complies with the test if no rabbit shows notable signs of disease or dies from causes attributable to the vaccine.

3-5. **Extraneous agents**. At the end of the 14 day observation period of the safety test, administer by a recommended route to each rabbit, a further 10 doses of vaccine. After 14 days, take a blood sample from each rabbit and carry out a test for antibodies against rabbit haemorrhagic disease virus. The vaccine complies with the test if no antibodies are found.

3-6. **Virus titre**. Titrate the vaccine virus in suitable cell cultures. The vaccine complies with the test if one dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-3-3.) when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2008:0962

NEONATAL PIGLET COLIBACILLOSIS VACCINE (INACTIVATED)

Vaccinum colibacillosis fetus a partu recentis inactivatum ad suem

1. DEFINITION

Neonatal piglet colibacillosis vaccine (inactivated) is a preparation from cultures of one or more suitable strains of *Escherichia coli*, carrying one or more adhesins or enterotoxins. This monograph applies to vaccines intended for the active immunisation of sows and gilts for passive protection of their newborn progeny against enteric forms of colibacillosis, administered by injection.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The *E. coli* strains used for production are cultured separately in a suitable medium. The cells or toxins are processed to render them safe while maintaining adequate immunogenic properties and are blended. The vaccine may be adjuvanted.

2-2. *CHOICE OF VACCINE COMPOSITION*

The *E. coli* strains used in the production of the vaccine are shown to be satisfactory with respect to expression of antigens and the vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the sows and gilts for which it is intended.

The following tests for expression of antigens (section 2-2-1.), safety (section 2-2-2.) and immunogenicity (section 2-2-3.) may be used during the demonstration of safety and efficacy.

2-2-1. **Expression of antigens**. The expression of antigens that stimulate a protective immune response is verified by a suitable immunochemical method (*2.7.1*) carried out on the antigen obtained from each of the vaccine strains under the conditions used for the production of the vaccine.

2-2-2. **Safety**

2-2-2-1. *Laboratory test.* Carry out the test for each route and method of administration to be recommended for vaccination. Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine.

For each test, use not fewer than 10 pregnant sows that have not been vaccinated against colibacillosis. Administer to each sow a double dose of the vaccine, then one dose after the interval to be recommended. Observe the sows at least daily until farrowing. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 4 days; note the maximum temperature increase for each sow.

The vaccine complies with the test if:

– no sow shows abnormal local or systemic reactions or dies from causes attributable to the vaccine,

– the average temperature increase for all sows does not exceed 1.5 °C and no sow shows a rise greater than 2 °C,

– and no adverse effects on gestation or the offspring are noted.

2-2-2-2. *Field studies.* The pigs used for field trials are also used to evaluate safety. Use not fewer than 3 groups each of not fewer than 20 pigs with corresponding groups of not fewer than 10 controls. Examine the injection site for local reactions after vaccination. Record body temperature the day before vaccination, at vaccination, at the time interval after which a rise in temperature, if any, was seen in test 2-2-2-1., and daily during the 2 days following vaccination; note the maximum temperature increase for each pig.

The vaccine complies with the test if no pig shows abnormal local or systemic reactions or dies from causes attributable to the vaccine, if the average temperature increase for all pigs does not exceed 1.5 °C and no pig shows a rise greater than 2 °C.

2-2-3. **Immunogenicity**. Carry out the test with a challenge strain representing each type of antigen against which the vaccine is intended to protect: if a single strain with all the necessary antigens is not available, repeat the test using different challenge strains.

Each test is carried out for each route and method of administration to be recommended for vaccination. The vaccine administered to each gilt is of minimum potency.

Use not fewer than 8 gilts susceptible to *E. coli* infections, that do not have antibodies against the antigens to be stated on the label. Take not fewer than 4 at random and vaccinate these at the stage of pregnancy and according to the schedule to be recommended. Maintain not fewer than 4 gilts as controls. Within 12 h of their giving birth, take not fewer than 15 healthy piglets from the vaccinated gilts and 15 healthy piglets from the controls, taking at least 3 from each litter. Challenge each piglet by the oral route with a sufficient quantity of a virulent strain of *E. coli* before or after colostrum feeding and using the same conditions for vaccinated piglets and controls. The strain used must not be one used in the manufacture of the vaccine. Return the piglets to their dam and observe at least daily for 8 days.

On each day, note signs in each piglet and score using the following scale:

0 no signs

1 slight diarrhoea

2 marked diarrhoea (watery faeces)

3 dead

Calculate total scores for each piglet over 8 days.

The test is invalid if fewer than 40 per cent of the piglets from the control gilts die and more than 15 per cent of the piglets from the control gilts show no signs of illness. The vaccine complies with the test if there is a significant reduction in score in the group of piglets from the vaccinated gilts compared with the group from the unvaccinated controls.

For some adhesins (for example, F5 and F41), there is published evidence that high mortality cannot be achieved under experimental conditions. If challenge has to be carried out with a strain having such adhesins: the test is invalid if fewer than 70 per cent of the control piglets show signs expected with the challenge strain; the vaccine complies with the test if there is a significant reduction in score in the group of piglets from the vaccinated gilts compared with the group from the unvaccinated controls.

2-3. *MANUFACTURER'S TESTS*

2-3-1. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-4.) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

Use 7 pigs not less than 3 weeks old and that do not have antibodies against the antigens stated on the label. Vaccinate each of 5 pigs by the recommended route and according to the recommended schedule. Maintain 2 pigs as controls. Alternatively, if the nature of the antigens allows reproducible results to be obtained, a test in laboratory animals (for example, guinea-pigs, mice, rabbits or rats) may be carried out. To obtain a valid assay, it may be necessary to carry out a test using several groups of animals, each receiving a different dose. For each dose, carry out the test as follows. Vaccinate not fewer than 5 animals with a single injection of a suitable dose. Maintain not fewer than 2 animals as controls. Where the recommended schedule requires a booster injection to be given, a booster vaccination may also be given in this test provided it has been demonstrated that this will still provide a suitably sensitive test system. At a given interval within the range of 14-21 days after the last injection, collect blood from each animal and prepare serum samples. Use a suitable validated test such as an enzyme-linked immunosorbent assay (*2.7.1*) to measure the antibody response to each of the antigens stated on the label. The vaccine complies with the test if the antibody levels in the vaccinates are not significantly less than those obtained with a batch that has given satisfactory results in the test described under Potency and there is no significant increase in antibody titre in the controls.

Where animals that do not have antibodies against the antigens stated on the label are not available, seropositive animals may be used in the above test. During the development of a test with seropositive animals, particular care will be required during the validation of the test system to establish that the test is suitably sensitive and to specify acceptable pass, fail and retest criteria. It will be necessary to take into account the range of possible prevaccination titres and establish the acceptable minimum titre rise after vaccination in relation to these.

2-3-2. **Bacterial endotoxins**. A test for bacterial endotoxins (*2.6.14*) is carried out on the final lot or, where the nature of the adjuvant prevents performance of a satisfactory test, on the bulk antigen or the mixture of bulk antigens immediately before addition of the adjuvant. The maximum acceptable amount of bacterial endotoxins is that found for a batch of vaccine that has been shown satisfactory in safety test 2-2-2-1. given under Choice of vaccine composition or in the safety test described under Tests, carried out using 10 piglets. Where the latter test is used, note the maximum temperature increase for each piglet; the vaccine complies with the test if the average temperature increase for all piglets does not exceed 1.5 °C. The method chosen for determining the amount of bacterial endotoxin present in the vaccine batch used in the safety test for determining the maximum acceptable level of endotoxin is used subsequently for testing of each batch.

3. BATCH TESTS

3-1. **Identification**. In animals that do not have antibodies against the antigens stated on the label, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 pigs, preferably, that do not have antibodies against the antigens stated on the label or, where justified, use pigs with a low level of such antibodies as long as they have not been vaccinated against colibacillosis and administration of the vaccine does not cause an anamnestic response. Administer to each pig by a recommended route a double dose of the vaccine. Observe the pigs at least daily for 14 days. Record body temperature before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 2 days.

The vaccine complies with the test if no pig shows notable signs of disease or dies from causes attributable to the vaccine; a transient temperature increase not exceeding 2 °C may occur.

3-4. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-2-3.) when administered by a recommended route and method.

01/2008:0961

NEONATAL RUMINANT COLIBACILLOSIS VACCINE (INACTIVATED)

Vaccinum colibacillosis fetus a partu recentis inactivatum ad ruminantes

1. DEFINITION

Neonatal ruminant colibacillosis vaccine (inactivated) is a preparation from cultures of one or more suitable strains of *Escherichia coli*, carrying one or more adhesin factors or enterotoxins. This monograph applies to vaccines intended for the active immunisation of dams for passive protection of their newborn progeny against enteric forms of colibacillosis, administered by injection.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The *E. coli* strains used for production are cultured separately in a suitable medium. The cells or toxins are processed to render them safe while maintaining adequate immunogenic properties and are blended. The vaccine may be adjuvanted.

2-2. *CHOICE OF VACCINE COMPOSITION*

The *E. coli* strains used in the production of the vaccine are shown to be satisfactory with respect to expression of antigens and the vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the ruminants for which it is intended.

The following tests for expression of antigens (section 2-2-1), safety (section 2-2-2) and immunogenicity (section 2-2-3) may be used during the demonstration of safety and efficacy.

2-2-1. **Expression of antigens**. The expression of antigens that stimulate a protective immune response is verified by a suitable immunochemical method (*2.7.1*) carried out on the antigen obtained from each of the vaccine strains under the conditions used for the production of the vaccine.

2-2-2. **Safety**

2-2-2-1. *Laboratory test.* Carry out the test for each route and method of administration to be recommended for vaccination and in pregnant animals of each species for which the vaccine is intended. Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine.

For each test, use not fewer than 10 pregnant animals that have not been vaccinated against colibacillosis. Administer to each animal a double dose of the vaccine. If the schedule to be recommended requires a 2nd dose, administer one dose after the interval to be recommended. Observe the animals at least daily until parturition. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 4 days; note the maximum temperature increase for each animal.

The vaccine complies with the test if:

– no animal shows abnormal local or systemic reactions or dies from causes attributable to the vaccine,

– the average temperature increase for all animals does not exceed 1.5 °C and no animal shows a rise greater than 2 °C,

– and no adverse effects on gestation or the offspring are noted.

2-2-2-2. *Field studies.* Safety is demonstrated in field trials for each species for which the vaccine is intended. Administer the dose to be recommended to not fewer than 60 animals from 3 different stocks by the route and according to the schedule to be recommended. Assign not fewer than 30 animals from the same stocks to control groups. Observe the animals at least daily for 14 days after the last administration.

The vaccine complies with the test if no animal shows abnormal local or systemic reactions or dies from causes attributable to the vaccine and if no rise in temperature of more than 1.5 °C occurs within 2 days of administration of each dose of the vaccine.

2-2-3. **Immunogenicity**. Carry out the test with a challenge strain representing each type of antigen against which the vaccine is intended to protect: if a single strain with all the necessary antigens is not available, repeat the test using different challenge strains. Each test is carried out for each route and method of administration to be recommended for vaccination, using in each case animals of each species for which the vaccine is intended. The vaccine administered to each animal is of minimum potency.

For each test, use not fewer than 15 animals that do not have antibodies against the antigens to be stated on the label. Take not fewer than 10 at random and vaccinate these at the stage of pregnancy and according to the schedule to be recommended. Maintain not fewer than 5 animals as controls. Collect colostrum from all animals after parturition and store the samples individually in conditions that maintain antibody levels. Take not fewer than 15 newborn unsuckled animals and house them in an environment ensuring absence of enteric pathogens. Allocate a colostrum sample from not fewer than 10 vaccinated dams and not fewer than 5 controls to the offspring. After birth, feed the animals with the colostrum sample allocated to it. After feeding the colostrum and within 12 h of birth, challenge all the animals by the oral route with a sufficient quantity of a virulent strain of *E. coli* and observe at least daily for 10 days. The strain must not be one used in the manufacture of the vaccine.

On each day, note daily signs in each animal and score using the following scale:

0 no signs

1 slight diarrhoea

2 marked diarrhoea (watery faeces)

3 dead

Calculate total scores for each animal over 10 days.

The test is invalid if fewer than 80 per cent of the animals given colostrum from the controls die or show severe signs of disease. The vaccine complies with the test if there is a significant reduction in score in the group of animals given colostrum from vaccinated dams compared with the group given colostrum from the unvaccinated controls.

2-3. *MANUFACTURER'S TESTS*

2-3-1. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-4) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

To obtain a valid assay, it may be necessary to carry out a test using several groups of animals, each receiving a different dose. For each dose required, carry out the test as follows. Use not fewer than 7 animals (for example rabbits, guinea-pigs, rats or mice) that do not have antibodies against the antigens stated on the label. Vaccinate not fewer than 5 animals, using one injection of a suitable dose. Maintain 2 animals as controls. Where the recommended schedule requires a booster injection to be given, a booster vaccination may also be given in this test provided it has been demonstrated that this will still provide a suitably sensitive test system. At a given interval within the range of 14-21 days after the last injection, collect blood from each animal and prepare serum samples. Use a suitable validated test such as an enzyme-linked immunosorbent assay (*2.7.1*) to measure the antibody response to each of the protective antigens stated on the label. The vaccine complies with the test if the antibody levels in the vaccinates are not significantly less than those obtained with a batch that has given satisfactory results in the test described under Potency and there is no significant increase in antibody titre in the controls.

Where animals that do not have antibodies against the antigens stated on the label are not available, seropositive animals may be used in the above test. During the development of a test with seropositive animals, particular care will be required during the validation of the test system to establish that the test is suitably sensitive and to specify acceptable pass, fail and retest criteria. It will be necessary to take into account the range of possible prevaccination titres and establish the acceptable minimum titre rise after vaccination in relation to these.

2-3-2. **Bacterial endotoxins**. A test for bacterial endotoxins (*2.6.14*) is carried out on the final lot or, where the nature of the adjuvant prevents performance of a satisfactory test, on the bulk antigen or the mixture of bulk antigens immediately before addition of the adjuvant. The maximum acceptable amount of bacterial endotoxins is that found for a batch of vaccine that has been shown satisfactory in safety test 2-2-2-1 given under Choice of vaccine composition or in the safety test described under Tests, carried out using 10 animals. Where the latter test is used, note the maximum temperature increase for each animal; the vaccine complies with the test if the average temperature increase for all animals does not exceed 1.5 °C. The method chosen for determining the amount of bacterial endotoxin present in the vaccine batch used in the safety test for determining the maximum acceptable level of endotoxins is used subsequently for testing of each batch.

3. BATCH TESTS

3-1. **Identification**. In animals that do not have antibodies against the antigens stated on the label, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 animals of one of the species for which the vaccine is intended and preferably, that do not have antibodies against the antigens stated on the label or, where justified, use animals with a low level of such antibodies as long as they have not been vaccinated against colibacillosis and administration of the vaccine does not cause an anamnestic response. Administer to each animal by a recommended route a double dose of the vaccine. Observe the animals at least daily for 14 days. Record body temperature before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 2 days.

The vaccine complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine; a transient temperature increase not exceeding 2 °C may occur.

3-4. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-2-3) when administered by a recommended route and method.

01/2008:0870

NEWCASTLE DISEASE VACCINE (INACTIVATED)

Vaccinum pseudopestis aviariae inactivatum

1. DEFINITION

Newcastle disease vaccine (inactivated) (also known as avian paramyxovirus 1 vaccine (inactivated) for vaccines intended for some species) is a preparation of a suitable strain of Newcastle disease virus (avian paramyxovirus 1), inactivated while maintaining adequate immunogenic properties.
This monograph applies to vaccines intended for active immunisation of birds against Newcastle disease.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in embryonated hens' eggs or in cell cultures. The virus harvest is inactivated. The vaccine may be adjuvanted.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Embryonated hens' eggs**. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from healthy flocks.

2-2-2. **Cell cultures**. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *SEED LOTS*

2-3-1. **Extraneous agents**. The master seed lot complies with the test for extraneous agents in seed lots (*2.6.24*). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the test.

2-4. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for each species and category of birds for which it is intended. The following tests for Immunogenicity (section 2-3-1) may be used during the demonstration of efficacy.

2-4-1. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended; the vaccine administered to each bird is of minimum potency. For chickens, the test for vaccines for use in chickens (section 2-4-1-1) is suitable for demonstrating immunogenicity. For other species of birds (for example, pigeons or turkeys), the test for vaccines for use in species other than the chicken (section 2-4-1-2) is suitable for demonstrating immunogenicity.

2-4-1-1. *Vaccines for use in chickens.* Use not fewer than 70 chickens, 21-28 days old, of the same origin and from a flock free from specified pathogens (SPF) (*5.2.2*). For vaccination, use not fewer than 3 groups, each of not fewer than 20 chickens. Choose a number of different volumes of the vaccine corresponding to the number of groups: for example, volumes equivalent to 1/25, 1/50 and 1/100 of a dose. Allocate a different volume to each vaccination group. Vaccinate each chicken by the intramuscular route with the volume of vaccine allocated to its group. Maintain not fewer than 10 chickens as controls. Challenge each chicken after 17-21 days by the intramuscular route with 6 $\log_{10}$ embryo LD_{50} of the Herts (Weybridge 33/56) strain of avian paramyxovirus 1. Observe the chickens at least daily for 21 days after challenge. At the end of the observation period, calculate the PD_{50} by standard statistical methods from the number of chickens that survive in each vaccinated group without showing any signs of Newcastle disease during the 21 days. The test is invalid unless all the control birds die within 6 days of challenge. The vaccine complies with the test if the smallest dose stated on the label corresponds to not less than 50 PD_{50} and the lower confidence limit is not less than 35 PD_{50} per dose. If the lower confidence limit is less than 35 PD_{50} per dose, repeat the test; the vaccine must be shown to contain not less than 50 PD_{50} in the repeat test.

2-4-1-2. *Vaccines for use in species other than the chicken.* Use not fewer than 30 birds of the target species, of the same origin and of the same age, that do not have antibodies against avian paramyxovirus 1. Vaccinate in accordance with the recommendations for use not fewer than 20 birds. Maintain not fewer than 10 birds as controls. Challenge each bird after 4 weeks by the intramuscular route with a sufficient quantity of virulent avian paramyxovirus 1. The test is invalid if serum samples obtained at the time of the first vaccination show the presence of antibodies against avian paramyxovirus 1 in either vaccinates or controls, or if tests carried out at the time of challenge show such antibodies in controls. The test is invalid if fewer than 70 per cent of the control birds die or show serious signs of Newcastle disease. The vaccine complies with the test if not fewer than 90 per cent of the vaccinated birds survive and show no serious signs of avian paramyxovirus 1 infection.

2-5. *MANUFACTURER'S TESTS*

2-5-1. **Residual live virus**. The test is carried out in embryonated eggs or suitable cell cultures (*5.2.4*), whichever is the most sensitive for the vaccine strain. The quantity of inactivated virus harvest used in the test is equivalent to not less than 10 doses of vaccine. The vaccine complies with the test if no live virus is detected.

2-5-2. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-6) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following tests may be used. Wherever possible, carry out the test for antigen content (section 2-5-2-1) together with the test for adjuvant (section 2-5-2-2).

Vaccines for use in chickens. The test for antigen content (section 2-5-2-1) together with the test for adjuvant (section 2-5-2-2) may be carried out; if the nature of the product does not allow valid results to be obtained with these tests, or if the vaccine does not comply, the test for serological assay (section 2-5-2-3) may be carried out. If the vaccine does not comply with the latter test, the test for vaccines for use in chickens (section 2-4-1-1) may be carried out. A test using fewer than 20 birds per group and a shorter observation period after challenge may be used if this has been shown to give a valid potency test.

Vaccines for use in species other than the chicken. Carry out a suitable test for which a satisfactory correlation has been established with the test for vaccines for use in species other than the chicken (section 2-4-1-2), the criteria for acceptance being set with reference to a batch that has given satisfactory results in the latter test. A test in chickens from an SPF flock (*5.2.2*) consisting of a measure of the serological response to graded amounts of vaccine (for example, 1/25, 1/50 and 1/100 of a dose with serum sampling 17-21 days later) may be used. Alternatively, the test for antigen content (section 2-5-2-1) together with the test for adjuvant (section 2-5-2-2) may be conducted if shown to provide a valid potency test.

2-5-2-1. *Antigen content.* The relative antigen content is determined by comparing the content of haemagglutinin-neuraminidase antigen per dose of vaccine with a haemagglutinin-neuraminidase antigen reference preparation, by enzyme-linked immunosorbent assay (*2.7.1*). For this comparison, *Newcastle disease virus reference antigen BRP*, *Newcastle disease virus control antigen BRP*, *Newcastle disease virus coating antibody BRP* and *Newcastle disease virus conjugated detection antibody BRP* are suitable. Before estimation, the antigen may be extracted from the emulsion using *isopropyl myristate R* or another suitable method. The vaccine complies with the test if the estimated antigen content is not significantly lower than that of a batch that has been found to be satisfactory with respect to Immunogenicity (section 2-4-1).

2-5-2-2. *Adjuvant.* If the immunochemical assay (section 2-5-2-1) is performed and if the vaccine is adjuvanted, the adjuvant is tested by suitable physical and chemical methods. For oil-adjuvanted vaccines, the adjuvant is tested in accordance with the monograph *Vaccines for veterinary use (0062)*. If the adjuvant cannot be adequately characterised, the antigen content determination cannot be used as the batch potency test.

2-5-2-3. *Serological assay.* Use not fewer than 15 chickens, 21-28 days old, of the same origin and from an SPF flock (*5.2.2*). Vaccinate by the intramuscular route not fewer than 10 chickens with a volume of the vaccine equivalent to 1/50 of a dose. Maintain not fewer than 5 chickens as controls. Collect serum samples from each chicken after 17-21 days. Measure the antibody levels in the sera by the haemagglutination-inhibition (HI) test using the technique

described below or an equivalent technique with the same numbers of haemagglutinating units and red blood cells. The test system used must include negative and positive control sera, the latter having an HI titre of 5.0 $\log_2$ to 6.0 $\log_2$. The vaccine complies with the test if the mean HI titre of the vaccinated group is equal to or greater than 4.0 $\log_2$ and that of the unvaccinated group is 2.0 $\log_2$ or less. If the HI titres are not satisfactory, carry out the test for vaccines for use in chickens (section 2-4-1-1).

Haemagglutination inhibition. Inactivate the test sera by heating at 56 °C for 30 min. Add 25 µl of inactivated serum to the first row of wells in a microtitre plate. Add 25 µl of a buffered 9 g/l solution of *sodium chloride R* at pH 7.2-7.4 to the rest of the wells. Prepare twofold dilutions of the sera across the plate. To each well add 25 µl of a suspension containing 4 haemagglutinating units of inactivated Newcastle disease virus. Incubate the plate at 4 °C for 1 h. Add 25 µl of a 1 per cent *V/V* suspension of red blood cells collected from chickens that are 3-4 weeks old and free from antibodies against Newcastle disease virus. Incubate the plate at 4 °C for 1 h. The HI titre is equal to the highest dilution that produces complete inhibition.

3. BATCH TESTS

3-1. **Identification**. When injected into animals that do not have antibodies against Newcastle disease virus, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Extraneous agents**. Use 10 chickens, 14-28 days old, from an SPF flock (*5.2.2*). Vaccinate each chicken by a recommended route with a double dose of the vaccine. After 3 weeks, administer 1 dose by the same route. Collect serum samples from each chicken 2 weeks later and carry out tests for antibodies to the following agents by the methods prescribed in general chapter *5.2.2. Chicken flocks free from specified pathogens for the production and quality control of vaccines*: avian encephalomyelitis virus, avian infectious bronchitis virus, avian leucosis viruses, egg-drop syndrome virus, avian bursal disease virus, avian infectious laryngotracheitis virus, influenza A virus, Marek's disease virus. The vaccine does not stimulate the formation of antibodies against these agents.

3-4. **Safety**. If the vaccine is intended for use in chickens, use 10 chickens, 14-28 days old, from an SPF flock (*5.2.2*). If the vaccine is not for use in chickens, use 10 birds of one of the species for which the vaccine is intended that do not have antibodies against Newcastle disease virus. Administer to each bird by a recommended route a double dose of the vaccine. Observe the birds at least daily for 21 days. The vaccine complies with the test if no bird shows notable signs of disease or dies from causes attributable to the vaccine.

3-5. **Residual live virus**. A test for residual live virus is carried out to confirm inactivation of Newcastle disease virus.

Inject 2/5th of a dose into the allantoic cavity of each of 10 embryonated hen eggs that are 9-11 days old and from SPF flocks (*5.2.2*) (SPF eggs), and incubate. Observe for 6 days and pool separately the allantoic fluid from eggs containing live embryos and that from eggs containing dead embryos, excluding those dying within 24 h of the injection. Examine embryos that die within 24 h of injection for the presence of Newcastle disease virus: the vaccine does not comply with the test if Newcastle disease virus is found.

Inject into the allantoic cavity of each of 10 SPF eggs, 9-11 days old, 0.2 ml of the pooled allantoic fluid from the live embryos and, into each of 10 similar eggs, 0.2 ml of the pooled fluid from the dead embryos and incubate for 5-6 days. Test the allantoic fluid from each egg for the presence of haemagglutinins using chicken erythrocytes.

The vaccine complies with the test if there is no evidence of haemagglutinating activity and if not more than 20 per cent of the embryos die at either stage. If more than 20 per cent of the embryos die at one of the stages, repeat that stage; the vaccine complies with the test if there is no evidence of haemagglutinating activity and not more than 20 per cent of the embryos die at that stage.

Antibiotics may be used in the test to control extraneous bacterial infection.

3-6. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-4-1) when administered by a recommended route and method.

01/2008:0450

NEWCASTLE DISEASE VACCINE (LIVE)

Vaccinum pseudopestis aviariae vivum

1. DEFINITION

Newcastle disease vaccine (live) is a preparation of a suitable strain of Newcastle disease virus (avian paramyxovirus 1). This monograph applies to vaccines intended for administration to chickens and/or other avian species for active immunisation.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in embryonated hens' eggs or in cell cultures.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Embryonated hens' eggs**. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from flocks free from specified pathogens (SPF) (*5.2.2*).

2-2-2. **Cell cultures**. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *SEED LOTS*

2-3-1. **Extraneous agents**. The master seed lot complies with the tests for extraneous agents in seed lots (*2.6.24*). In these tests on the master seed lot, the organisms used are not more than 5 passages from the master seed lot at the start of the tests.

2-4. *CHOICE OF VACCINE VIRUS*

The vaccine virus shall be shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the birds for which it is intended.

The following tests for intracerebral pathogenicity index (section 2-4-1), amino-acid sequence (section 2-4-2), safety (section 2-4-3), increase in virulence (section 2-4-4) and immunogenicity (section 2-4-5) may be used during the demonstration of safety and immunogenicity.

2-4-1. **Intracerebral pathogenicity index**. Use vaccine virus at the least attenuated passage level that will be present in a batch of the vaccine. Inoculate the vaccine virus into the allantoic cavity of embryonated hens' eggs, 9- to 11- days-old, from an SPF flock (*5.2.2*). Incubate the inoculated eggs for

a suitable period and harvest and pool the allantoic fluids. Use not fewer than ten 1-day-old chickens (i.e. more than 24 h but less than 40 h after hatching), from an SPF flock (*5.2.2*). Administer by the intracerebral route to each chick 0.05 ml of the pooled allantoic fluids containing not less than $10^{8.0}$ EID_{50} or, if this virus quantity cannot be achieved, not less than $10^{7.0}$ EID_{50}. Observe the chickens at least daily for 8 days after administration and score them once every 24 h. A score of 0 is attributed to a chicken if it is clinically normal, 1 if it shows clinical signs of disease and 2 if it is dead. The intracerebral pathogenicity index is the mean of the scores per chicken per observation over the 8 day period.

If an inoculum of not less than $10^{8.0}$ EID_{50} is used, the vaccine virus complies with the test if its intracerebral pathogenicity index is not greater than 0.5; if an inoculum of not less than $10^{7.0}$ EID_{50} but less than $10^{8.0}$ EID_{50} is used, the vaccine virus complies with the test if its intracerebral pathogenicity index is not greater than 0.4.

2-4-2. **Amino-acid sequence**. Determine the sequence of a fragment of RNA from the vaccine virus containing the region encoding for the F0 cleavage site by a suitable method. The encoded amino-acid sequence is shown to be one of the following:

		F2						Cleavage site		F1	
Site		111	112	113	114	115	116	∨	117	118	119
		Gly	Gly	Lys	Gln	Gly	Arg		Leu	Ile	Gly
	or	Gly	Gly	Arg	Gln	Gly	Arg		Leu	Ile	Gly
	or	Gly	Glu	Arg	Gln	Glu	Arg		Leu	Val	Gly

or equivalent with leucine at 117 and no basic amino acids at sites 111, 112, 114 and 115.

2-4-3. **Safety**. Carry out the test for each route and method of administration to be recommended for vaccination and in each avian species for which the vaccine is intended, using in each case birds not older than the youngest age to be recommended for vaccination. Use vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine. For tests in chickens, use not fewer than 20 chickens, from an SPF flock (*5.2.2*). For species other than the chicken, use not fewer than 20 birds that do not have antibodies against Newcastle disease virus. Administer to each bird a quantity of the vaccine virus equivalent to not less than 10 times the maximum virus titre likely to be contained in 1 dose of the vaccine. Observe the birds at least daily for 21 days. The test is not valid if more than 10 per cent of the birds show abnormal clinical signs or die from causes not attributable to the vaccine virus. The vaccine virus complies with the test if no bird shows notable clinical signs of Newcastle disease or dies from causes attributable to the vaccine virus.

2-4-4. **Increase in virulence**. The test for increase in virulence consists of the administration of the vaccine virus at the least attenuated passage level that will be present between the master seed lot and a batch of the vaccine to a group of 5 birds not more than 2 weeks old, sequential passages, 5 times where possible, to further similar groups and testing of the final recovered virus for increase in virulence. If the properties of the vaccine virus allow sequential passage to 5 groups via natural spreading, this method may be used, otherwise passage as described below is carried out and the maximally passaged virus that has been recovered is tested for increase in virulence. Care must be taken to avoid contamination by virus from previous passages. Carry out the test in a target species, using the chicken if it is one of the target species. For the test in chickens, use chickens from an SPF flock (*5.2.2*).

For other species, carry out the test in birds that do not have antibodies against Newcastle disease virus. Administer by eye-drop a quantity of the vaccine virus that will allow recovery of virus for the passages described below. Observe the birds for the period shown to correspond to maximum replication of the vaccine virus, euthanise them and prepare a suspension from the brain of each bird and from a suitable organ depending on the tropism of the strain (for example, mucosa of the entire trachea, intestine, pancreas); pool the samples. Administer 0.05 ml of the pooled samples by eye-drop to each of 5 other birds of the same species, age and origin. Carry out this passage operation not fewer than 5 times; verify the presence of the virus at each passage. If the virus is not found at a passage level, carry out a second series of passages.

A. Carry out the test for intracerebral pathogenicity index (section 2-4-1) using unpassaged vaccine virus and the maximally passaged virus that has been recovered.

B. Carry out the test for amino-acid sequence (section 2-4-2) using unpassaged vaccine virus and the maximally passaged virus that has been recovered.

C. Carry out the test for safety (section 2-4-3) using unpassaged vaccine virus and the maximally passaged virus that has been recovered. Administer the virus by the route to be recommended for vaccination likely to be the least safe and to the avian species for which the vaccine is intended that is likely to be the most susceptible to Newcastle disease.

The vaccine virus complies with the test if, in the tests 2-4-4A, 2-4-4B and 2-4-4C, no indication of increase in virulence of the maximally passaged virus compared with the unpassaged virus is observed. If virus is not recovered at any passage level in the first and second series of passages, the vaccine virus also complies with the test.

2-4-5. **Immunogenicity**. For each avian species for which the vaccine is intended, a test is carried out for each route and method of administration to be recommended using in each case birds not older than the youngest age to be recommended for vaccination. The quantity of the vaccine virus administered to each bird is not greater than the minimum titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of the vaccine.

2-4-5-1. *Vaccines for use in chickens.* Use not fewer than 30 chickens of the same origin and from an SPF flock (*5.2.2*). Vaccinate by a recommended route not fewer than 20 chickens. Maintain not fewer than 10 chickens as controls. Challenge each chicken after 21 days by the intramuscular route with not less than $10^{5.0}$ embryo LD_{50} of the Herts (Weybridge 33/56) strain of Newcastle disease virus. Observe the chickens at least daily for 14 days after challenge. Record the deaths and the number of surviving chickens that show clinical signs of disease. The test is not valid if 6 days after challenge fewer than 100 per cent of the control chickens have died or if during the period between vaccination and challenge more than 10 per cent of the vaccinated or control chickens show abnormal clinical signs or die from causes not attributable to the vaccine. The vaccine virus complies with the test if during the observation period after challenge not fewer than 90 per cent of the vaccinated chickens survive and show no notable clinical signs of Newcastle disease.

2-4-5-2. *Vaccines for use in avian species other than the chicken.* Use not fewer than 30 birds of the species for which the vaccine is intended for Newcastle disease, of the same origin and that do not have antibodies against avian paramyxovirus 1. Vaccinate by a recommended route not fewer than 20 birds. Maintain not fewer than 10 birds

as controls. Challenge each bird after 21 days by the intramuscular route with a sufficient quantity of virulent avian paramyxovirus 1. Observe the birds at least daily for 21 days after challenge. Record the deaths and the surviving birds that show clinical signs of disease. The test is not valid if:

– during the observation period after challenge fewer than 90 per cent of the control birds die or show severe clinical signs of Newcastle disease,
– or if during the period between the vaccination and challenge more than 10 per cent of the vaccinated or control birds show abnormal clinical signs or die from causes not attributable to the vaccine.

The vaccine virus complies with the test if during the observation period after challenge not fewer than 90 per cent of the vaccinated birds survive and show no notable clinical signs of Newcastle disease. For species where there is published evidence that it is not possible to achieve this level of protection, the vaccine complies with the test if there is a significant reduction in morbidity and mortality of the vaccinated birds compared with the control birds.

3. BATCH TESTS

3-1. **Identification**

3-1-1. *Identification of the vaccine virus.* The vaccine, diluted if necessary and mixed with a monospecific Newcastle disease virus antiserum, no longer provokes haemagglutination of chicken red blood cells or infects embryonated hens' eggs from an SPF flock (*5.2.2*) or susceptible cell cultures (*5.2.4*) into which it is inoculated.

3-1-2. *Identification of the virus strain.* The strain of vaccine virus is identified by a suitable method, for example using monoclonal antibodies.

3-2. **Bacteria and fungi**

Vaccines intended for administration by injection comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

Vaccines not intended for administration by injection either comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)* or with the following test: carry out a quantitative test for bacterial and fungal contamination; carry out identification tests for microorganisms detected in the vaccine; the vaccine does not contain pathogenic microorganisms and contains not more than 1 non-pathogenic microorganism per dose.

Any liquid supplied with the vaccine complies with test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas**. The vaccine complies with the test for mycoplasmas (*2.6.7*).

3-4. **Extraneous agents**. The vaccine complies with the tests for extraneous agents in batches of finished product (*2.6.25*).

3-5. **Safety**. For vaccines recommended for use in chickens, use not fewer than 10 chickens from an SPF flock (*5.2.2*) and of the youngest age recommended for vaccination. For vaccines recommended for use only in avian species other than the chicken, use not fewer than 10 birds of the species likely to be most sensitive to Newcastle disease, that do not have antibodies against Newcastle disease virus and of the minimum age recommended for vaccination. Administer to each bird by eye-drop, or parenterally if only parenteral administration is recommended, 10 doses of the vaccine in a volume suitable for the test. Observe the birds at least daily for 21 days. The test is not valid if more than 20 per cent of the birds show abnormal clinical signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no bird shows notable clinical signs of disease or dies from causes attributable to the vaccine.

3-6. **Virus titre**. Titrate the vaccine virus by inoculation into embryonated hens' eggs from an SPF flock (*5.2.2*) or into suitable cell cultures (*5.2.4*). The vaccine complies with the test if 1 dose contains not less than the minimum virus titre stated on the label.

3-7. **Potency**. Depending on the indications, the vaccine complies with 1 or both of the tests prescribed under Immunogenicity (section 2-4-5) when administered according to the recommended schedule by a recommended route and method. If the test in section 2-4-5-2. *Vaccine for use in avian species other than the chicken* is conducted and the vaccine is recommended for use in more than 1 avian species, the test is carried out with birds of that species for which the vaccine is recommended which is likely to be the most susceptible to avian paramyxovirus 1. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

01/2008:2072

PASTEURELLA VACCINE (INACTIVATED) FOR SHEEP

Vaccinum pasteurellae inactivatum ad ovem

1. DEFINITION

Pasteurella vaccine (inactivated) for sheep is a preparation of one or more suitable strains of *Pasteurella trehalosi*, inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for the active immunisation of sheep against disease caused by *P. trehalosi*.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

Production of the vaccine is based on a seed-lot system. The seed material is cultured in a suitable medium; each strain is cultivated separately and identity is verified using a suitable method. During production, various parameters such as growth rate are monitored by suitable methods; the values are within the limits approved for the particular product. Purity and identity of the harvest are verified using suitable methods. After cultivation, the bacterial suspensions are collected separately and inactivated by a suitable method. The vaccine may be adjuvanted.

2-2. *CHOICE OF VACCINE COMPOSITION*

The choice of composition and the strains to be included in the vaccine are based on epidemiological data on the prevalence of the different serovars of *P. trehalosi*.

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the sheep for which it is intended.

The following tests for safety (section 2-2-1) and immunogenicity (section 2-2-2) may be used during the demonstration of safety and efficacy.

2-2-1. **Safety**

2-2-1-1. *Laboratory tests.* Carry out the tests for each route and method of administration to be recommended for vaccination and in sheep of each category for which the vaccine is intended (for example, young sheep, pregnant

ewes). Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine.

2-2-1-1-1. General safety. For each test, use not fewer than 10 sheep that preferably do not have antibodies against the serovars of *P. trehalosi* or against leucotoxin present in the vaccine. Where justified, sheep with a known history of no previous pasteurella vaccination and with low antibody titres (measured in a sensitive test system such as an ELISA) may be used. Administer to each sheep a double dose of the vaccine, then one dose after the interval to be recommended. Observe the sheep at least daily for at least 14 days after the last administration. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 4 days; note the maximum temperature increase for each sheep.

The vaccine complies with the test if no sheep shows abnormal local reactions, notable signs of disease or dies from causes attributable to the vaccine, if the average body temperature increase for all sheep does not exceed 1.5 °C and no sheep shows a rise greater than 2 °C.

2-2-1-1-2. Safety in pregnant ewes. If the vaccine is intended for use or may be used in pregnant ewes, use not fewer than 10 pregnant ewes at the relevant stages of pregnancy. Administer to each ewe a double dose of the vaccine, then one dose after the interval to be recommended. Observe the ewes at least daily until one day after lambing. Record body temperatures the day before each vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 4 days; note the maximum temperature increase for each ewe.

The vaccine complies with the test if:

- no ewe shows abnormal local reactions, notable signs of disease or dies from causes attributable to the vaccine,
- the average body temperature increase for all ewes does not exceed 1.5 °C and no ewe shows a rise greater than 2 °C,
- and no adverse effects on the pregnancy and offspring are noted.

2-2-1-2. *Field studies.* The sheep used for the field trials are also used to evaluate safety. Carry out a test in each category of sheep for which the vaccine is intended. Use not fewer than 3 groups of 20 sheep with corresponding groups of not fewer than 10 controls in 3 different locations. Examine the injection sites for local reactions after vaccination. Record body temperatures the day before vaccination, at vaccination and on the 2 days following vaccination.

The vaccine complies with the test if no sheep shows abnormal local or systemic reactions, notable signs of disease or dies from causes attributable to the vaccine. The average body temperature increase for all sheep does not exceed 1.5 °C and no sheep shows a rise greater than 2 °C. In addition, if the vaccine is intended for use in pregnant ewes, no adverse effects on the pregnancy and offspring are demonstrated.

2-2-2. **Immunogenicity**. Carry out a test for each serovar of *P. trehalosi* for which protection is to be claimed on the label.

A test is carried out for each route and method of administration to be recommended, using in each case lambs of the minimum age to be recommended for vaccination. The vaccine administered to each lamb is of minimum potency.

Use not fewer than 20 lambs that do not have antibodies against *P. trehalosi* and against the leucotoxin of *P. trehalosi*. Vaccinate not fewer than 10 lambs according to the schedule to be recommended. Maintain not fewer than 10 lambs as controls. 21 days after the last vaccination, challenge each lamb by the subcutaneous or another suitable route, with a sufficient quantity of a low-passage, virulent strain of a serovar of *P. trehalosi*. Observe the lambs for a further 7 days; to avoid unnecessary suffering, severely ill lambs are euthanised and are then considered to have died from the disease. During the observation period, examine the lambs for any signs of disease (for example, severe dullness, excess salivation) and record the mortality. Euthanise surviving lambs at the end of the observation period. Carry out post-mortem examination on any lamb that dies and those euthanised at the end of the observation period. Examine the lungs, pleura, liver and spleen for haemorrhages and evaluate the extent of lung consolidation due to pasteurellosis. Collect samples of lung, liver and spleen tissue for re-isolation of the challenge organisms. Score the mortality, clinical observations and the post-mortem lesions and compare the results obtained for these parameters and the bacterial re-isolation results for the 2 groups.

The test is invalid if signs or lesions of *P. trehalosi* infection occur in less than 70 per cent of the control lambs. The vaccine complies with the test if there is a significant difference between the scores obtained for the clinical and post-mortem observations in the vaccinates compared to the controls. For vaccines with a claim for a beneficial effect on the extent of infection against the serovar, the results for the infection rates are also significantly better for the vaccinates compared to the controls.

2-3. *MANUFACTURER'S TESTS*

2-3-1. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-4) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency.

2-3-2. **Bacterial endotoxins**. A test for bacterial endotoxins (*2.6.14*) is carried out on the final lot or, where the nature of the adjuvant prevents performance of a satisfactory test, on the bulk antigen or the mixture of bulk antigens immediately before addition of the adjuvant. The maximum acceptable amount of bacterial endotoxins is that found for a batch of vaccine that has been shown satisfactory in safety tests 2-2-1-1 given under Choice of vaccine composition or in safety test 3-3 described under Batch tests, carried out using 10 sheep. Where the latter test is used, note the maximum temperature increase for each sheep; the vaccine complies with the test if the average body temperature increase for all sheep does not exceed 1.5 °C. The method chosen for determining the amount of bacterial endotoxin present in the vaccine batch used in the safety test for determining the maximum acceptable level of endotoxin is used subsequently for testing of each batch.

3. BATCH TESTS

3-1. **Identification**. When injected into healthy animals that do not have specific antibodies against the serovars of *P. trehalosi* and/or against the leucotoxin present in the vaccine, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 sheep of the minimum age recommended for vaccination or, if not available, of an age as close as possible to the minimum recommended age, and that have not been vaccinated against pasteurella. Administer to each sheep by a recommended route a double dose of the vaccine.

Observe the sheep at least daily for 14 days. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 2 days.

The vaccine complies with the test if no sheep shows notable signs of disease or dies from causes attributable to the vaccine; a transient temperature increase not exceeding 2 °C may occur.

3-4. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-2-2) when administered by a recommended route and method.

01/2008:1360

PORCINE ACTINOBACILLOSIS VACCINE (INACTIVATED)

Vaccinum actinobacillosidis inactivatum ad suem

1. DEFINITION

Porcine actinobacillosis vaccine (inactivated) is a preparation which has one or more of the following components: inactivated *Actinobacillus pleuropneumoniae* of a suitable strain or strains; toxins, proteins or polysaccharides derived from suitable strains of *A. pleuropneumoniae*, and treated to render them harmless while maintaining adequate immunogenic properties; fractions of toxins derived from suitable strains of *A. pleuropneumoniae* and treated if necessary to render them harmless while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for the active immunisation of pigs against actinobacillosis.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The seed material is cultured in a suitable medium; each strain is cultivated separately. During production, various parameters such as growth rate, protein content and quantity of relevant antigens are monitored by suitable methods; the values are within the limits approved for the particular product. Purity and identity are verified on the harvest using suitable methods. After cultivation, the bacterial suspensions are collected separately and inactivated by a suitable method. They may be detoxified, purified and concentrated. The vaccine may be adjuvanted.

2-2. *CHOICE OF VACCINE COMPOSITION*

The choice of strains is based on epidemiological data. The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the pigs for which it is intended.

The following tests for safety (section 2-2-1.) and immunogenicity (section 2-2-2.) may be used during the demonstration of safety and efficacy.

2-2-1. **Safety**

2-2-1-1. *Laboratory tests.* Carry out the test for each route and method of administration to be recommended for vaccination and in each category of pigs for which the vaccine is intended. Use a batch containing not less than the maximum potency that may be expected in a batch of vaccine.

2-2-1-1-1. General safety. For each test, use not fewer than 10 pigs that do not have antibodies against the serotypes of *A. pleuropneumoniae* or its toxins present in the vaccine. Administer to each pig a double dose of the vaccine, then one dose after the interval to be recommended. Observe the pigs at least daily until 14 days after the last administration. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 4 days; note the maximum temperature increase for each pig.

The vaccine complies with the test if no pig shows abnormal, local or systemic reactions or dies from causes attributable to the vaccine and if the average temperature increase for all pigs does not exceed 1.5 °C and no pig shows a rise greater than 2 °C.

2-2-1-1-2. Safety in pregnant sows. If the vaccine is intended for use in pregnant sows, use not fewer than 10 sows at the relevant stages of pregnancy. Administer to each sow a double dose of the vaccine, then one dose after the interval to be recommended. Observe the sows at least daily until farrowing. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 4 days; note the maximum temperature increase for each sow.

The vaccine complies with the test if:

- no sow shows abnormal, local or systemic reactions or dies from causes attributable to the vaccine,
- the average temperature increase for all sows does not exceed 1.5 °C and no sow shows a rise greater than 2 °C,
- and no adverse effects on the pregnancy and offspring are noted.

2-2-1-2. *Field studies.* The pigs used for field trials are also used to evaluate safety. Carry out a test in each category of pigs for which the vaccine is intended. Use not fewer than 3 groups each of not fewer than 20 pigs with corresponding groups of not fewer than 10 controls. Examine the injection site for local reactions after vaccination. Record body temperature the day before vaccination, at vaccination, at the time interval after which a rise in temperature, if any, was seen in test 2-2-1-1. and daily during the 2 days following vaccination; note the maximum temperature increase for each pig.

The vaccine complies with the test if no pig shows abnormal, local or systemic reactions or dies from causes attributable to the vaccine and if the average temperature increase for all pigs does not exceed 1.5 °C and no pig shows a rise greater than 2 °C.

2-2-2. **Immunogenicity**

The challenge strain for the following test is chosen to ensure challenge with each Ap toxin [(1)] produced by the serotypes to be stated on the label; it may be necessary to carry out more than one test using a different challenge strain for each test.

Each test is carried out for each route and method of administration to be recommended. The vaccine administered to each pig is of minimum potency.

For each test, use not fewer than 14 pigs that do not have antibodies against *A. pleuropneumoniae* and Ap toxins. Vaccinate not fewer than 7 pigs according to the schedule to be recommended. Maintain not fewer than 7 pigs as controls. 3 weeks after the last vaccination, challenge all the pigs by the intranasal or intratracheal route or by aerosol with a sufficient quantity of a virulent serotype of *A. pleuropneumoniae*. Observe the pigs at least daily for 7 days; to avoid unnecessary suffering, severely ill control pigs are euthanised and are then considered to have died from the disease. Euthanise all surviving pigs at the end of the observation period. Carry out a post-mortem examination on all pigs. Examine the lungs, the tracheobronchial lymph nodes and the tonsils for the presence of *A. pleuropneumoniae*. Evaluate the extent of lung lesions at post-mortem examination. Each of the 7 lobes

(1) The nomenclature of the toxins of *A. pleuropneumoniae* is described by J. Frey *et al.*, *Journal of General Microbiology*, 1993, 139, 1723-1728.

of the lungs is allotted a maximum possible lesion score [(2)] of 5. The area showing pneumonia and/or pleuritis of each lobe is assessed and expressed on a scale of 0 to 5 to give the pneumonic score per lobe (the maximum total score possible for each complete lung is 35). Calculate separately for the vaccinated and the control pigs the total score (the maximum score per group is 245, if 7 pigs are used per group).

The vaccine complies with the test if the vaccinated pigs, when compared with controls, show lower incidence of: mortality; typical signs (dyspnoea, coughing and vomiting); typical lung lesions; re-isolation of *A. pleuropneumoniae* from the lungs, the tracheobronchial lymph nodes and the tonsils. Where possible, the incidence is analysed statistically and shown to be significantly lower for vaccinates.

2-3. *MANUFACTURER'S TESTS*

2-3-1. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-4) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

Use 5 mice weighing 18-20 g and that do not have antibodies against the serotypes of *A. pleuropneumoniae* or its toxins present in the vaccine. Vaccinate each mouse by the subcutaneous route with a suitable dose. Where the recommended schedule requires a booster injection to be given, a booster vaccination may also be given in this test provided it has been demonstrated that this will still provide a suitably sensitive test system. Before the vaccination and at a given interval within the range of 14-21 days after the last injection, collect blood from each mouse and prepare serum samples. Determine individually for each serum the titre of specific antibodies against each antigenic component stated on the label, using a suitable validated test such as enzyme-linked immunosorbent assay (*2.7.1*). The vaccine complies with the test if the antibody levels are not significantly lower than those obtained for a batch that has given satisfactory results in the test described under Potency.

2-3-2. **Bacterial endotoxins**. A test for bacterial endotoxins (*2.6.14*) is carried out on the final bulk or, where the nature of the adjuvant prevents performance of a satisfactory test, on the bulk antigen or mixture of bulk antigens immediately before addition of the adjuvant. The maximum acceptable amount of bacterial endotoxins is that found for a batch of vaccine that has been shown satisfactory in safety test 2-2-1-1. described under Choice of vaccine composition or the safety test described under Tests, carried out using 10 pigs. Where the latter test is used, note the maximum temperature increase for each animal; the vaccine complies with the test if the average temperature increase for all animals does not exceed 1.5 °C. The method chosen for determining the amount of bacterial endotoxin present in the vaccine batch used in the safety test for determining the maximum acceptable level of endotoxin is used subsequently for batch testing.

3. BATCH TESTS

3-1. **Identification**. When injected into healthy animals that do not have specific antibodies against the antigenic components of *A. pleuropneumoniae* stated on the label, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 pigs of the minimum age recommended for vaccination and that do not have antibodies against the serotypes of *A. pleuropneumoniae* or its toxins present in the vaccine. Administer to each pig by a recommended route a double dose of the vaccine. Observe the pigs at least daily for 14 days. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 2 days.

The vaccine complies with the test if no pig shows notable signs of disease or dies from causes attributable to the vaccine; a transient temperature increase not exceeding 2 °C may occur.

3-4. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-2-2.) when administered by a recommended route and method.

01/2008:0963

PORCINE INFLUENZA VACCINE (INACTIVATED)

Vaccinum influenzae inactivatum ad suem

1. DEFINITION

Porcine influenza vaccine (inactivated) is a preparation of one or more suitable strains of swine or human influenza virus inactivated while maintaining adequate immunogenic properties. Suitable strains contain both haemagglutinin and neuraminidase. This monograph applies to vaccines intended for the active immunisation of pigs against porcine influenza.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in embryonated hens' eggs or in cell cultures. Each virus strain is cultivated separately. After cultivation, the viral suspensions are collected separately and inactivated by a suitable method. If necessary, they may be purified. The vaccine may be adjuvanted.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Embryonated hens' eggs**. If the vaccine virus is grown in embryonated hens' eggs, they are obtained from a healthy flock.

2-2-2. **Cell cultures**. If the vaccine virus is grown in cell cultures, they comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE COMPOSITION*

The choice of strains is based on the antigenic types and sub-types observed in Europe. The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the pigs for which it is intended.

The following tests for safety (section 2-3-1.) and immunogenicity (section 2-3-2.) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**

2-3-1-1. *Laboratory tests.* Carry out the tests for each route and method of administration to be recommended for vaccination and where applicable, in pigs of each category for which the vaccine is intended (sows, fattening pigs). Use

(2) The system of lung scores is described in detail by P.C.T. Hannan, B.S. Bhogal, J.P. Fish, *Research in Veterinary Science*, 1982, 33, 76-88.

a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine.

2-3-1-1-1. General safety. For each test, use not fewer than 10 pigs that do not have antibodies against swine influenza virus. Administer to each pig a double dose of the vaccine, then one dose after 14 days. Observe the pigs at least daily until 14 days after the last administration.

The vaccine complies with the test if no pig shows abnormal local or systemic reactions or dies from causes attributable to the vaccine during the 28 days of the test.

2-3-1-1-2. Safety in the pigs used in test 2-3-2. for immunogenicity. The pigs used in the test for immunogenicity are also used to evaluate safety. Measure the rectal temperature of each vaccinated pig at the time of vaccination and 24 h and 48 h later. Examine the injection site at slaughter for local reactions.

The vaccine complies with the test if no pig shows:

– abnormal body temperature;

– other systemic reactions (for example, anorexia);

– abnormal local reactions attributable to the vaccine.

2-3-1-2. *Field studies*. The pigs used for field trials are also used to evaluate safety. Carry out a test in each category of pigs for which the vaccine is intended (sows, fattening pigs). Use not fewer than 3 groups each of not fewer than 20 pigs in at least 2 locations with corresponding groups of not fewer than 10 controls. Measure the rectal temperature of each vaccinated pig at the time of vaccination and 24 h and 48 h later. Examine the injection site at slaughter for local reactions.

The vaccine complies with the test if no pig shows:

– abnormal body temperature;

– abnormal local reactions attributable to the vaccine.

2-3-2. **Immunogenicity**. The following test carried out using an epidemiologically relevant challenge strain or strains is suitable to demonstrate the immunogenicity of the vaccine. It is carried out for each subtype used in the preparation of the vaccine.

A test is carried out for each route and method of administration to be recommended, using in each case pigs of the minimum age to be recommended for vaccination. The vaccine administered to each pig is of minimum potency.

Use for the test not fewer than 20 pigs that do not have antibodies against swine influenza virus. Vaccinate not fewer than 10 pigs according to the schedule to be recommended. Maintain not fewer than 10 pigs as controls. Take a blood sample from all control pigs immediately before challenge. 3 weeks after the last administration of vaccine, challenge all the pigs by the intratracheal route with a sufficient quantity of a virulent influenza field virus. Euthanise half of the vaccinated and control pigs 24 h after challenge and the other half 72 h after challenge. For each pig, measure the quantity of influenza virus in 2 lung tissue homogenates, one from the left apical, cardiac and diaphragmatic lobes, and the other from the corresponding right lung lobes. Take equivalent samples from each pig.

The test is invalid if antibodies against influenza virus are found in any control pig immediately before challenge. The vaccine complies with the test if, at both times of measurement, the mean virus titre in the pooled lung tissue samples of vaccinated pigs is significantly lower than that for control pigs, when analysed by a suitable statistical method such as the Wilcoxon Mann-Whitney test.

2-4. *MANUFACTURER'S TESTS*

2-4-1. **Residual live virus**. An amplification test for residual live virus is carried out on each batch of antigen immediately after inactivation by passage in the same type of substrate as that used for production (eggs or cell cultures) or a substrate shown to be at least as sensitive. The quantity of inactivated virus harvest used in the test is equivalent to not less than 10 doses of the vaccine. The inactivated viral harvest complies with the test if no live virus is detected.

2-4-2. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-6.) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

Use 5 guinea-pigs, 5-7 weeks old and that do not have antibodies against swine influenza virus. Vaccinate each guinea-pig by the subcutaneous route with a quarter of the recommended dose. Collect blood samples before the vaccination and 21 days after vaccination. Determine for each sample the level of specific antibodies against each virus subtype in the vaccine by haemagglutination-inhibition or another suitable test. The vaccine complies with the test if the level of antibodies is not lower than that found for a batch of vaccine that gave satisfactory results in the potency test in pigs (see Potency).

2-4-3. **Bacterial endotoxins**. For vaccines produced in eggs, the content of bacterial endotoxins is determined on the virus harvest to monitor production.

3. BATCH TESTS

3-1. **Identification**. When injected into healthy animals that do not have specific antibodies against the influenza virus subtypes included in the vaccine, the vaccine stimulates the production of such antibodies. The antibodies may be detected by a suitable immunochemical method (*2.7.1*).

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 pigs, not older than the minimum age recommended for vaccination and that do not have antibodies against swine influenza virus. Administer to each pig by a recommended route a double dose of the vaccine, then one dose after 14 days. Observe the pigs at least daily until 14 days after the last administration.

The vaccine complies with the test if no pig shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual live virus**

3-4-1. *Vaccines prepared in eggs*. If the vaccine has been prepared in eggs, inoculate 0.2 ml into the allantoic cavity of each of 10 fertilised hen eggs, 9-11 days old. Incubate at a suitable temperature for 3 days. The death of any embryo within 24 h of inoculation is considered as non-specific mortality and the egg is discarded. The test is invalid if fewer than 80 per cent of the eggs survive. Collect the allantoic fluid of each egg, pool equal quantities and carry out a second passage on fertilised eggs in the same manner. Incubate for 4 days; the vaccine complies with the test if the allantoic fluid of these eggs shows no haemagglutinating activity.

3-4-2. *Vaccines prepared in cell cultures.* If the vaccine has been prepared in cell cultures, carry out a suitable test for residual live virus using 2 passages in the same type of cell culture as used in the production of vaccine. The vaccine complies with the test if no live virus is detected. If the vaccine contains an oily adjuvant that interferes with this test, where possible separate the aqueous phase from the vaccine by means that do not diminish the capacity to detect residual infectious influenza virus.

3-5. **Extraneous agents**. On the pigs used for the safety test, carry out tests for antibodies. The vaccine complies with the test if it does not stimulate the formation of antibodies other than those against influenza virus. In particular, no antibodies against viruses pathogenic for pigs or against viruses which could interfere with the diagnosis of infectious diseases of pigs (including viruses of the pestivirus group) are detected.

3-6. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-3-2.) when administered by a recommended route and method.

01/2008:0965

PORCINE PARVOVIROSIS VACCINE (INACTIVATED)

Vaccinum parvovirosis inactivatum ad suem

1. DEFINITION

Porcine parvovirosis vaccine (inactivated) is a preparation of a suitable strain of porcine parvovirus, inactivated while maintaining adequate immunogenic properties or of a noninfectious fraction of the virus. This monograph applies to vaccines intended for the active immunisation of sows and gilts for protection of their progeny against transplacental infection.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures. The viral suspension is harvested; the virus is inactivated by a suitable method and may be fragmented (inactivation may be by fragmentation); the virus or viral fragments may be purified and concentrated at a suitable stage of the process. The vaccine may be adjuvanted.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) (including absence of adverse effects on fertility, gestation, farrowing or offspring) and efficacy (*5.2.7*) for the pigs for which it is intended.

The following tests for safety (section 2-3-1.) and immunogenicity (section 2-3-2.) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**

2-3-1-1. *Laboratory tests.* Carry out the tests for each route and method of administration to be recommended for vaccination and where applicable, in pigs of each category for which the vaccine is intended. Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine.

2-3-1-1-1. General safety. For each test, use not fewer than 10 pigs that do not have antibodies against porcine parvovirus or against a fraction of the virus. Administer to each pig a double dose of the vaccine, then one dose after 14 days. Observe the pigs at least daily until 14 days after the last administration.

The vaccine complies with the test if no pig shows notable signs of disease or dies from causes attributable to the vaccine during the 28 days of the test.

2-3-1-1-2. Safety in pregnant sows. If the vaccine is intended for use in pregnant sows, use for the test not fewer than 10 pregnant sows at the stage or at different stages of pregnancy according to the schedule to be recommended. Administer to each sow a double dose of the vaccine, then one dose after 14 days. Observe the sows at least daily until farrowing.

The vaccine complies with the test if no sow shows abnormal local or systemic reactions or dies from causes attributable to the vaccine and if no adverse effects on the pregnancy or the offspring are noted.

2-3-1-1-3. Safety in the pigs used in test 2-3-2. for immunogenicity. The pigs used in the test for immunogenicity are also used to evaluate safety. Measure the rectal temperature of each vaccinated pig at the time of vaccination 24 h and 48 h later. Examine the injection site after vaccination and at slaughter for local reactions.

The vaccine complies with the test if no pig shows:

– abnormal body temperature;
– other systemic reactions (for example, anorexia);
– abnormal local reactions attributable to the vaccine.

2-3-1-2. *Field studies.* The pigs used for field trials are also used to evaluate safety. Carry out a test in each category of pigs for which the vaccine is intended (sows, gilts). Use not fewer than 3 groups each of not fewer than 20 pigs with corresponding groups of not fewer than 10 controls. Measure the rectal temperature of each vaccinated pig at the time of vaccination, 24 h and 48 h later. Examine the injection site after vaccination and at slaughter for local reactions.

The vaccine complies with the test if no pig shows:

– abnormal body temperature;
– abnormal local reactions attributable to the vaccine.

2-3-2. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended, using in each case gilts of 5-6 months old. The vaccine administered to each gilt is of minimum potency.

Use for the test not fewer than 12 gilts that do not have antibodies against porcine parvovirus or against a fraction of the virus. Vaccinate not fewer than 7 gilts according to the schedule to be recommended. Maintain not less than 5 unvaccinated gilts of the same age as controls. The interval between vaccination and service is that to be recommended. Mate all the gilts on 2 consecutive days immediately following signs of oestrus. At about the 40th day of gestation, challenge each gilt with a suitable quantity of a virulent strain of porcine parvovirus. Euthanise the gilts at about the 90th day of gestation and examine their foetuses for infection with porcine parvovirus as demonstrated by the presence of either virus or antibodies.

The test is invalid if:

– fewer than 7 vaccinated gilts and 5 control gilts are challenged;
– fewer than 90 per cent of piglets from the control gilts are infected;

– and the average number of piglets per litter for the vaccinated gilts is fewer than 6.

The vaccine complies with the test if not fewer than 80 per cent of the total number of piglets from vaccinated gilts are protected from infection.

2-4. *MANUFACTURER'S TESTS*

2-4-1. **Residual live virus**. A test for residual live virus is carried out on each batch of antigen immediately after inactivation. The quantity of inactivated viral harvest used in the test is equivalent to not less than 100 doses of the vaccine. The bulk harvest is inoculated into suitable non-confluent cells; after incubation for 7 days, a subculture is made using trypsinised cells. After incubation for a further 7 days, the cultures are examined for residual live parvovirus by an immunfluorescence test. The inactivated viral harvest complies with the test if no live virus is detected.

2-4-2. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-6.) for each batch of the vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

Use not fewer than 5 guinea-pigs, 5-7 weeks old and that do not have antibodies against porcine parvovirus or against a fraction of the virus. Vaccinate each guinea-pig by the subcutaneous route with one-fourth of the prescribed dose volume. Take blood samples after the period corresponding to maximum antibody production and carry out tests on the serum for specific antibodies by a haemagglutination-inhibition test or other suitable test. The vaccine complies with the test if the level of antibodies is not lower than that found for a batch of vaccine that has given satisfactory results in the test described under Potency.

3. BATCH TESTS

3-1. **Identification**. When injected into animals that do not have specific antibodies against porcine parvovirus or the fraction of the virus used in the production of the vaccine, on one or, if necessary, more than one occasion, the vaccine stimulates the formation of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 pigs, 6 weeks to 6 months old and that do not have antibodies against porcine parvovirus or against a fraction of the virus. Administer to each pig by a recommended route a double dose of the vaccine, then one dose after 14 days. Observe the pigs at least daily until 14 days after the last administration.

The vaccine complies with the test if no pig shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Residual live virus**. Use a quantity of vaccine equivalent to 10 doses. If the vaccine contains an oily adjuvant, break the emulsion and separate the phases. If the vaccine contains a mineral adjuvant, carry out an elution to liberate the virus. Concentrate the viral suspension 100 times by ultrafiltration or ultracentrifugation. None of the above procedures must be such as to inactivate or otherwise interfere with detection of live virus. Carry out a test for residual live virus in suitable non-confluent cells; after incubation for 7 days, make a subculture using trypsinised cells. After incubation for a further 7 days, examine the cultures for residual live parvovirus by an immunfluorescence test. The vaccine complies with the test if no live virus is detected.

3-5. **Extraneous agents**. On the pigs used for the safety test carry out tests for antibodies. The vaccine complies with the test if it does not stimulate the formation of antibodies - other than those against porcine parvovirus - against viruses pathogenic for pigs or against viruses which could interfere with the diagnosis of infectious diseases in pigs (including the viruses of the pestivirus group).

3-6. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-3-2.) when administered by a recommended route and method.

01/2008:1361

PORCINE PROGRESSIVE ATROPHIC RHINITIS VACCINE (INACTIVATED)

Vaccinum rhinitidis atrophicantis ingravescentis suillae inactivatum

1. DEFINITION

Porcine progressive atrophic rhinitis vaccine (inactivated) is a preparation containing either the dermonecrotic exotoxin of *Pasteurella multocida*, treated to render it harmless while maintaining adequate immunogenic properties, or a genetically modified form of the exotoxin which has adequate immunogenic properties and which is free from toxic properties; the vaccine may also contain cells and/or antigenic components of one or more suitable strains of *P. multocida* and/or *Bordetella bronchiseptica*. This monograph applies to vaccines intended for the active immunisation of sows and gilts for passive protection of their progeny against porcine progressive atrophic rhinitis.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The bacterial strains used for production are cultured separately in suitable media. The toxins and/or cells are treated to render them safe. The vaccine may be adjuvanted.

2-2. *DETOXIFICATION*

A test for detoxification of the dermonecrotic exotoxin of *P. multocida* is carried out immediately after detoxification. The concentration of detoxified exotoxin used in the test is not less than that in the vaccine. The suspension complies with the test if no toxic dermonecrotic exotoxin is detected. The test for detoxification is not required where the vaccine is prepared using a toxin-like protein free from toxic properties, produced by expression of a modified form of the corresponding gene.

2-3. *ANTIGEN CONTENT*

The content of the dermonecrotic exotoxin of *P. multocida* in the detoxified suspension or the toxin-like protein in the harvest is determined by a suitable immunochemical method (*2.7.1*), such as an enzyme-linked immunosorbent assay and the value found is used in the formulation of the vaccine. The content of other antigens stated on the label is also determined (*2.7.1*).

2-4. *CHOICE OF VACCINE COMPOSITION*

The strains used for the preparation of the vaccine are shown to be satisfactory with respect to the production of the dermonecrotic exotoxin and the other antigens claimed

to be protective. The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the sows and gilts for which it is intended.

The following tests for production of antigens (section 2-2-1.), safety (section 2-2-2.) and immunogenicity (section 2-2-3.) may be used during the demonstration of safety and efficacy.

2-4-1. **Production of antigens**. The production of antigens claimed to be protective is verified by a suitable bioassay or immunochemical method (*2.7.1*), carried out on the antigens obtained from each of the vaccine strains under the conditions to be used for the production of the vaccine.

2-4-2. **Safety**

2-4-2-1. *Laboratory test.* Carry out the test for each route and method of administration to be recommended for vaccination. Use a batch containing not less than the maximum potency that may be expected in a batch of vaccine.

For each test, use not fewer than 10 pregnant sows or gilts that do not have antibodies against the components of the vaccine, from a herd or herds where there are no signs of atrophic rhinitis and that have not been vaccinated against atrophic rhinitis. Administer to each pig a double dose of the vaccine at the stage of pregnancy to be recommended, then one dose after the interval to be recommended. Observe the pigs at least daily until farrowing. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 4 days; note the maximum temperature increase for each pig.

The vaccine complies with the test if no pig shows abnormal local or systemic reactions or dies from causes attributable to the vaccine, if the average temperature increase for all pigs does not exceed 1.5 °C and no pig shows a rise greater than 2 °C and if no adverse effects on the pregnancy and offspring are noted.

2-4-2-2. *Field studies.* The pigs used for field trials are also used to evaluate safety. Use not fewer than 3 groups each of not fewer than 20 pigs with corresponding groups of not fewer than 10 controls. Examine the injection site for local reactions after vaccination. Record body temperature the day before vaccination, at vaccination, at the time interval after which a rise in temperature, if any, was seen in test 2-4-2-1., and daily during the 2 days following vaccination; note the maximum temperature increase for each pig.

The vaccine complies with the test if no pig shows abnormal local or systemic reactions or dies from causes attributable to the vaccine and if the average temperature increase for all pigs does not exceed 1.5 °C and no pig shows a rise greater than 2 °C.

2-4-3. **Immunogenicity**. Each test is carried out for each route and method of administration to be recommended, using in each case pigs that do not have antibodies against the components of the vaccine, that are from a herd or herds where there are no signs of atrophic rhinitis and that have not been vaccinated against atrophic rhinitis. The vaccine administered to each pig is of minimum potency.

2-4-3-1. *Vaccines containing dermonecrotic exotoxin of* P. multocida *(with or without cells of* P. multocida*).* Use not fewer than 12 breeder pigs. Vaccinate not fewer than 6 randomly chosen pigs at the stage of pregnancy or non-pregnancy and according to the schedule to be recommended. Maintain not fewer than 6 pigs as controls. From birth allow all the piglets from the vaccinated and unvaccinated breeder pigs to feed from their own dam. Constitute from the progeny 2 challenge groups each of not fewer than 30 piglets chosen randomly, taking not fewer than 3 piglets from each litter. On the 2 consecutive days preceding challenge, the mucosa of the nasal cavity of the piglets may be treated by instillation of 0.5 ml of a solution of acetic acid (10 g/l $C_2H_4O_2$) in isotonic buffered saline pH 7.2. Challenge each piglet at 10 days of age by the intranasal route with a sufficient quantity of a toxigenic strain of *P. multocida*. At the age of 42 days, euthanise the piglets of the 2 groups and dissect the nose of each of them transversally at premolar-1. Examine the ventral and dorsal turbinates and the nasal septum for evidence of atrophy or distortion and grade the observations on the following scales:

Turbinates

0 no atrophy

1 slight atrophy

2 moderate atrophy

3 severe atrophy

4 very severe atrophy with almost complete disappearance of the turbinate

The maximum score is 4 for each turbinate and 16 for the sum of the 2 dorsal and 2 ventral turbinates.

Nasal septum

0 no deviation

1 very slight deviation

2 deviation of the septum

The maximum total score for the turbinates and the nasal septum is 18.

The test is invalid if fewer than 80 per cent of the progeny of each litter of the unvaccinated breeder pigs have a total score of at least 10. The vaccine complies with the test if a significant reduction in the total score has been demonstrated in the group from the vaccinated breeder pigs compared to that from the unvaccinated breeder pigs.

2-4-3-2. *Vaccines containing* P. multocida *dermonecrotic exotoxin (with or without cells of* P. multocida*) and cells and/or antigenic components of* B. bronchiseptica. Use not fewer than 24 breeder pigs. Vaccinate not fewer than 12 randomly chosen pigs at the stage of pregnancy or non-pregnancy and according to the schedule to be recommended. Maintain not fewer than 12 pigs as controls. From birth allow all the piglets from the vaccinated and unvaccinated breeder pigs to feed from their own dam. Using groups of not fewer than 6 pigs, constitute from their progeny 2 challenge groups from vaccinated pigs and 2 groups from control pigs each group consisting of not fewer than 30 piglets chosen randomly, taking not fewer than 3 piglets from each litter. On the 2 consecutive days preceding challenge, the mucosa of the nasal cavity of the piglets may be treated by instillation of 0.5 ml of a solution of acetic acid (10 g/l $C_2H_4O_2$) in isotonic buffered saline pH 7.2. For a group of piglets from not fewer than 6 vaccinated pigs and a group from not fewer than 6 controls, challenge each piglet by the intranasal route at 10 days of age with a sufficient quantity of a toxigenic strain of *P. multocida*. For the other group of piglets from not fewer than 6 vaccinated pigs and the other group from not fewer than 6 controls, challenge each piglet at 7 days of age by the intranasal route with a sufficient quantity of *B. bronchiseptica*. In addition, challenge each piglet at 10 days of age by the intranasal route with a sufficient quantity of a toxigenic strain of *P. multocida*. At the age of 42 days, euthanise the piglets of the 4 groups and dissect the nose of each of them transversally at premolar-1. Examine the ventral and dorsal turbinates and the nasal septum for evidence of atrophy or distortion and grade the observations on the scale described above.

The test is invalid if fewer than 80 per cent of the progeny of each litter of the unvaccinated breeder pigs have a total score of at least 10. The vaccine complies with the test if a significant reduction in the total score has been demonstrated in the groups from the vaccinated breeder pigs compared to the corresponding group from the unvaccinated breeder pigs.

2-5. *MANUFACTURER'S TESTS*

2-5-1. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-4.) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

Use not fewer than 7 pigs not less than 3 weeks old and that do not have antibodies against the components of the vaccine. Vaccinate not fewer than 5 pigs by a recommended route and according to the recommended schedule. Maintain not fewer than 2 pigs of the same origin as controls under the same conditions. Alternatively, if the nature of the antigens allows reproducible results to be obtained, a test in laboratory animals that do not have antibodies against the components of the vaccine may be carried out. To obtain a valid assay, it may be necessary to carry out a test using several groups of animals, each receiving a different quantity of vaccine. For each quantity of vaccine, carry out the test as follows: vaccinate not fewer than 5 animals with a suitable quantity of vaccine. Maintain not fewer than 2 animals of the same species and origin as controls. Where the recommended schedule requires a booster injection to be given, a booster vaccination may also be given in this test provided it has been demonstrated that this will still provide a suitably sensitive test system. At a given interval within the range of 14-21 days after the last administration, collect blood from each animal and prepare serum samples. Use a validated test such as an enzyme-linked immunosorbent assay to measure the antibody response to each of the antigens stated on the label.

The test is invalid if there is a significant antibody titre in the controls. The vaccine complies with the test if the antibody responses of the vaccinated animals are not significantly less than those obtained with a batch of vaccine that has given satisfactory results in the test or tests (as applicable) described under Potency.

Where animals that do not have antibodies against the antigens stated on the label are not available, seropositive animals may be used in the above test. During the development of a test with seropositive animals, particular care will be required during the validation of the test system to establish that the test is suitably sensitive and to specify acceptable pass, fail and retest criteria. It will be necessary to take into account the range of prevaccination antibody titres and to establish the acceptable minimum antibody titre rise after vaccination in relation to these.

2-5-2. **Bacterial endotoxins**. A test for bacterial endotoxins (*2.6.14*) is carried out on the batch or, where the nature of the adjuvant prevents performance of a satisfactory test, on the bulk antigen or the mixture of bulk antigens immediately before addition of the adjuvant. The maximum acceptable amount of bacterial endotoxins is that found for a batch of vaccine shown satisfactory in safety test 2-4-2-1. given under Choice of vaccine composition or in the safety test described under Tests, carried out using 10 pigs. Where the latter test is used, note the maximum temperature increase for each pig; the vaccine complies with the test if the average temperature increase for all pigs does not exceed 1.5 °C. The method chosen for determining the amount of bacterial endotoxin present in the vaccine batch used in the safety test for determining the maximum acceptable level of endotoxin is used subsequently for testing of each batch.

3. BATCH TESTS

3-1. **Identification**. In animals that do not have specific antibodies against the antigens stated on the label, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use not fewer than 2 pigs that do not have antibodies against *P. multocida* and that preferably do not have antibodies against *B. bronchiseptica*. Administer to each pig by a recommended route a double dose of the vaccine. Observe the pigs at least daily for 14 days. Record body temperature the day before vaccination, at vaccination, 2 h, 4 h and 6 h later and then daily for 2 days.

The vaccine complies with the test if no pig shows notable signs of disease or dies from causes attributable to the vaccine; a transient temperature increase not exceeding 2 °C may occur.

3-4. **Potency**. The vaccine complies with the requirements of the tests mentioned under Immunogenicity (section 2-4-3.) when administered by a recommended route and method.

01/2008:2325

RABBIT HAEMORRHAGIC DISEASE VACCINE (INACTIVATED)

Vaccinum morbi haemorrhagici cuniculi inactivatum

1. DEFINITION

Rabbit haemorrhagic disease vaccine (inactivated) is a preparation of a suitable strain of rabbit haemorrhagic disease virus (RHDV), inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for active immunisation of rabbits.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in rabbits. The rabbits must be healthy, not vaccinated against RHDV, free from antibodies against RHDV, not treated with antibiotics within at least 15 days of their use and from a healthy and monitored breeding unit. A suspension is prepared from a homogenate of suitable internal organs of those rabbits that are euthanised or that succumb to the infection within 120 h of inoculation. The virus in the suspension may be purified and concentrated, and is inactivated by a suitable method.

2-2. *SEED LOTS*

2-2-1. **Extraneous agents**. Each master seed lot complies with the tests for extraneous agents in seed lots prescribed in the monograph *Vaccines for veterinary use (0062)*.

2-3. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the rabbits for which it is intended.

The following tests for safety (section 2-3-1) and immunogenicity (section 2-3-2) may be used during the demonstration of safety and efficacy.

2-3-1. **Safety**

2-3-1-1. *General safety test.* Carry out the test for each route and method of administration to be recommended. Use not fewer than 10 healthy rabbits from the same stock, not older than the minimum age to be recommended for vaccination and free from antibodies against RHDV. Administer to each rabbit by a route and method to be recommended 2 doses of the vaccine. Observe the animals for 21 days. Record the body temperature the day before vaccination, at vaccination, 4 h after vaccination and then daily for 4 days; note the maximum temperature increase for each animal. The vaccine complies with the test if no rabbit shows notable signs of disease or dies from causes attributable to the vaccine, the average body temperature increase for all animals does not exceed 1.5 °C, and no animal shows a temperature rise greater than 2 °C.

2-3-1-2. *Safety in pregnant animals.* If the vaccine is intended for use in pregnant rabbits, administer the vaccine to not fewer than 10 pregnant rabbits according to the schedule to be recommended on the label. Prolong the observation period until 1 day after parturition. The vaccine complies with the test if no rabbit shows notable signs of disease or dies from causes attributable to the vaccine, and no adverse effects on the pregnancy or on the offspring are noted.

2-3-2. **Immunogenicity**. A test is carried out for each route and method of administration to be stated on the label. Use not fewer than 15 healthy, susceptible rabbits not less than 10 weeks old, free from antibodies against RHDV, from the same healthy stock, and reared in suitable isolation conditions to ensure absence of contact with RHDV. Administer 1 dose of vaccine to each of not fewer than 10 of the rabbits according to the instructions for use to be stated on the label. Maintain not fewer than 5 other rabbits as controls. Not less than 7 days after vaccination, challenge each rabbit by a suitable route with a quantity of a virulent strain of RHDV sufficient to cause signs of rabbit haemorrhagic disease (RHD) in a susceptible rabbit. Observe the rabbits for a further 14 days.

The test is invalid if fewer than 80 per cent of control rabbits die with typical signs of RHD within 120 h of challenge.

The vaccine complies with the test if not fewer than 90 per cent of vaccinated rabbits show no signs of RHD.

2-4. *MANUFACTURER'S TESTS*

2-4-1. **Residual live virus**. A test for residual live virus is carried out on the bulk harvest of each batch to confirm inactivation of the RHDV. The test for inactivation is carried out in healthy, susceptible rabbits, not less than 10 weeks old, free from antibodies against RHDV and from the same healthy stock. 5 rabbits are inoculated by a suitable parenteral route (subcutaneous or intramuscular) with at least a 5 ml dose of the suspension. The rabbits are observed for not less than 7 days. At the end of the observation period, the animals are euthanised and liver extracts are tested by a suitable method for freedom from RHDV.

The vaccine complies with the test if no rabbit dies and no RHDV antigen is detected in the livers.

2-4-2. **Batch potency test**. It is not necessary to carry out the potency test (section 3-4) for each batch of the vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency.

The following method is given as an example. Administer 1 dose of vaccine intramuscularly to each of 5 healthy rabbits, 10 weeks old, free from antibodies against RHDV and from the same healthy stock. Maintain 2 rabbits as unvaccinated controls. Collect serum samples from each rabbit just before administration of the vaccine and after the period defined when testing the reference vaccine; determine the antibody titre of each serum by a suitable immunological method, for example, ELISA. The antibody levels are not significantly lower than those obtained with a batch that has given satisfactory results in the test described under Potency.

The test is invalid if the sera collected from the unvaccinated controls and from the rabbits just before the administration of the vaccine show detectable specific antibodies.

3. BATCH TESTS

3-1. **Identification**. When injected into susceptible animals, the vaccine stimulates the production of specific antibodies against RHDV, detectable by a haemagglutination-inhibition test or enzyme immunoassay.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety and residual live virus**. Use not fewer than 2 healthy rabbits, not less than 10 weeks old, free from antibodies against RHDV and from the same healthy stock. Administer by a recommended route to each rabbit 2 doses of vaccine. Observe the rabbits for 14 days.

The vaccine complies with the test if no rabbit shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-3-2), when administered by a recommended route and method.

01/2008:0451

RABIES VACCINE (INACTIVATED) FOR VETERINARY USE

Vaccinum rabiei inactivatum ad usum veterinarium

1. DEFINITION

Rabies vaccine (inactivated) for veterinary use is a preparation of a suitable strain of fixed rabies virus, inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for the active immunisation of animals against rabies.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine is prepared from virus grown either in suitable cell lines or in primary cell cultures from healthy animals (*5.2.4*). The virus suspension is harvested on one or more occasions within 28 days of inoculation. Multiple harvests from a single production cell culture may be pooled and considered as a single harvest.

The virus harvest is inactivated. The vaccine may be adjuvanted.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*).

2-3. *CHOICE OF VACCINE COMPOSITION*

The vaccine virus is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the species for which it is intended.

The following test for Immunogenicity (section 2-3-1) may be used during the demonstration of efficacy in cats and dogs.

The suitability of the vaccine with respect to Immunogenicity (section 2-3-1) for carnivores (cats and dogs) is demonstrated by direct challenge. For other species, if a challenge test has been carried out for the vaccine in cats or dogs, an indirect test is carried out by determining the antibody level following vaccination of not fewer than 20 animals according to the schedule to be recommended; the vaccine is satisfactory if, after the period to be claimed for protection, the mean rabies virus antibody level in the serum of the animals is not less than 0.5 IU/ml and if not more than 10 per cent of the animals have an antibody level less than 0.1 IU/ml.

2-3-1. **Immunogenicity**. Each test is carried out for each route and method of administration to be recommended, using in each case animals of the minimum age to be recommended for vaccination. The vaccine administered to each animal is of minimum potency.

Use for the test not fewer than 35 animals. Take a blood sample from each animal and test individually for antibodies against rabies virus to determine susceptibility. Vaccinate not fewer than 25 animals, according to the schedule to be recommended. Maintain not fewer than 10 animals as controls. Observe all the animals for a period equal to the claimed duration of immunity. No animal shows signs of rabies. On the last day of the claimed period for duration of immunity or later, challenge each animal by intramuscular injection with a sufficient quantity of virulent rabies virus of a strain approved by the competent authority. Observe the animals at least daily for 90 days after challenge. Animals that die from causes not attributable to rabies are eliminated. The test is invalid if the number of such deaths reduces the number of vaccinated animals in the test to fewer than 25 and the test is invalid unless at least 8 control animals (or a statistically equivalent number if more than 10 control animals are challenged) show signs of rabies and the presence of rabies virus in their brain is demonstrated by the fluorescent-antibody test or some other suitable method. The vaccine complies with the test if not more than 2 of the 25 vaccinated animals (or a statistically equivalent number if more than 25 vaccinated animals are challenged) show signs of rabies.

2-4. MANUFACTURER'S TESTS

2-4-1. **Residual live virus**. The test for residual live virus is carried out by inoculation of the inactivated virus into the same type of cell culture as that used in the production of the vaccine or a cell culture shown to be at least as sensitive. The quantity of inactivated virus harvest used is equivalent to not less than 25 doses of the vaccine. After incubation for 4 days, a subculture is made using trypsinised cells; after incubation for a further 4 days, the cultures are examined for residual live rabies virus by an immunofluorescence test. The inactivated virus harvest complies with the test if no live virus is detected.

2-4-2. **Antigen content of the harvest**. The content of rabies virus glycoprotein is determined by a suitable immunochemical method (*2.7.1*). The content is within the limits approved for the particular preparation.

2-4-3. **Batch potency test**. It is not necessary to carry out the potency test (section 3-5) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

Use 5 mice each weighing 18-20 g. Vaccinate each mouse by a subcutaneous or intramuscular route using $1/5^{th}$ of the recommended dose volume. Take blood samples 14 days after the injection and test the sera individually for rabies antibody using the rapid fluorescent focus inhibition test described for *Human rabies immunoglobulin (0723)*.

The vaccine complies with the test if the antibody titre is not less than that obtained with a batch of vaccine that gave satisfactory results in the test described under Potency.

2-4-4. **Antigen content of the batch**. The quantity of rabies virus glycoprotein per dose, determined by a suitable immunochemical method (*2.7.1*), is not significantly lower than that of a batch of vaccine that gave satisfactory results in the test described under Potency.

3. BATCH TESTS

3-1. **Identification**. Administered to animals that do not have antibodies against rabies virus, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it, comply with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

3-3. **Residual live virus**. Carry out the test using a pool of the contents of 5 containers.

For vaccines which do not contain an adjuvant, carry out a suitable amplification test for residual live virus using the same type of cell culture as that used in the production of the vaccine or a cell culture shown to be at least as sensitive. The vaccine complies with the test if no live virus is detected.

For vaccines that contain an adjuvant, inject intracerebrally into each of not fewer than 10 mice each weighing 11-15 g, 0.03 ml of a pool of at least 5 times the smallest stated dose. To avoid interference from any antimicrobial preservative or the adjuvant, the vaccine may be diluted not more than 10 times before injection. In this case or if the vaccine strain is pathogenic only for unweaned mice, carry out the test on mice 1 to 4 days old. Observe the animals for 21 days. If more than 2 animals die during the first 48 h, repeat the test. The vaccine complies with the test if, from the third to the twenty-first days following the injection, the animals show no signs of rabies and immunofluorescence tests carried out on the brains of the animals show no indication of the presence of rabies virus.

3-4. **Safety**. If the vaccine is intended for more than one species including one belonging to the order of Carnivora, carry out the test in dogs. Otherwise use one of the species for which the vaccine is intended. Use 2 animals, that preferably do not have antibodies against rabies virus. Administer to each animal by a recommended route a double dose of the vaccine. Observe the animals at least daily for 14 days.

The vaccine complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine.

3-5. **Potency**.

The potency of rabies vaccine is determined by comparing the dose necessary to protect mice against the clinical effects

of the dose of rabies virus defined below, administered intracerebrally, with the quantity of a reference preparation, calibrated in International Units, necessary to provide the same protection.

The International Unit is the activity of a stated quantity of the International Standard. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Rabies vaccine (inactivated) for veterinary use BRP is calibrated in International Units against the International Standard.

The test described below uses a parallel-line model with at least 3 points for the vaccine to be examined and the reference preparation. Once the analyst has experience with the method for a given vaccine, it is possible to carry out a simplified test using one dilution of the vaccine to be examined. Such a test enables the analyst to determine that the vaccine has a potency significantly higher than the required minimum but will not give full information on the validity of each individual potency determination. It allows a considerable reduction in the number of animals required for the test and should be considered by each laboratory in accordance with the provisions of the European Convention for the Protection of Vertebrate Animals used for Experimental and other Scientific Purposes.

Selection and distribution of the test animals. Use in the test healthy female mice about 4 weeks old and from the same stock. Distribute the mice into at least 10 groups of not fewer than 10 mice.

Preparation of the challenge suspension. Inoculate a group of mice intracerebrally with the CVS strain of rabies virus and when the mice show signs of rabies, but before they die, euthanise the mice and remove the brains and prepare a homogenate of the brain tissue in a suitable diluent. Separate gross particulate matter by centrifugation and use the supernatant liquid as challenge suspension. Distribute the suspension in small volumes in ampoules, seal and store at a temperature below – 60 °C. Thaw one ampoule of the suspension and make serial dilutions in a suitable diluent. Allocate each dilution to a group of mice and inject intracerebrally into each mouse 0.03 ml of the dilution allocated to its group. Observe the animals at least daily for 14 days and record the number in each group that, between the fifth and the fourteenth days, develop signs of rabies. Calculate the ID_{50} of the undiluted suspension.

Determination of potency of the vaccine to be examined. Prepare at least 3 serial dilutions of the vaccine to be examined and 3 similar dilutions of the reference preparation. Prepare the dilutions such that those containing the largest quantity of vaccine may be expected to protect more than 50 per cent of the animals into which they are injected and those containing the smallest quantities of vaccine may be expected to protect less than 50 per cent of the animals into which they are injected. Allocate each dilution to a different group of mice and inject by the intraperitoneal route into each mouse 0.5 ml of the dilution allocated to its group. 14 days after the injection prepare a suspension of the challenge virus such that, on the basis of the preliminary titration, it contains about 50 ID_{50} in each 0.03 ml. Inject intracerebrally into each vaccinated mouse 0.03 ml of this suspension. Prepare 3 suitable serial dilutions of the challenge suspension. Allocate the challenge suspension and the 3 dilutions one to each of 4 groups of 10 unvaccinated mice and inject intracerebrally into each mouse 0.03 ml of the suspension or one of the dilutions allocated to its group. Observe the animals in each group at least daily for 14 days. The test is invalid if more than 2 mice of any group die within the first 4 days after challenge. Record the numbers in each group that show signs of rabies in the period 5 days to 14 days after challenge.

The test is invalid unless:

- for both the vaccine to be examined and the reference preparation the 50 per cent protective dose lies between the smallest and the largest dose given to the mice,
- the titration of the challenge suspension shows that 0.03 ml of the suspension contained at least 10 ID_{50},
- the confidence limits (P = 0.95) are not less than 25 per cent and not more than 400 per cent of the estimated potency,
- the statistical analysis shows a significant slope and no significant deviations from linearity or parallelism of the dose-response lines.

The vaccine complies with the test if the estimated potency is not less than 1 IU in the smallest prescribed dose.

4. LABELLING

The label states:

- the type of cell culture used to prepare the vaccine and the species of origin,
- the minimum number of International Units per dose,
- the minimum period for which the vaccine provides protection.

01/2008:0746

RABIES VACCINE (LIVE, ORAL) FOR FOXES

Vaccinum rabiei perorale vivum ad vulpem

1. DEFINITION

Rabies vaccine (live, oral) for foxes is a preparation of a suitable immunogenic strain of an attenuated rabies virus. The vaccine is incorporated in a bait in such a manner as to enable the tests prescribed below to be performed aseptically. This monograph applies to vaccines intended for the active immunisation of foxes against rabies.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The vaccine virus is grown in cell cultures. The virus suspension is harvested on one or more occasions within 14 days of inoculation. Multiple harvests from a single cell lot may be pooled and considered as a single harvest. It may be mixed with a suitable stabiliser.

2-2. *SUBSTRATE FOR VIRUS PROPAGATION*

2-2-1. **Cell cultures**. The cell cultures comply with the requirements for cell cultures for production of veterinary vaccines (*5.2.4*); if the cell cultures are of mammalian origin, they are shown to be free from rabies virus.

2-3. *CHOICE OF VACCINE VIRUS*

The vaccine virus is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the foxes for which it is intended.

The following characteristics (section 2-3-1) may be used during the demonstration of safety and the following tests for Immunogenicity (2-3-2) may be used during the demonstration of efficacy.

2-3-1. **Virus strain characteristics**. Only a virus strain shown to be satisfactory with respect to the following characteristics may be used in the preparation of the vaccine:

- when administered orally at the dose and by the method to be recommended for use to 40 foxes, it causes no sign of rabies within 180 days of administration,
- when administered orally at 10 times the dose to be recommended to each of 10 foxes, it causes no sign of rabies within 180 days of administration,
- when administered orally at 10 times the dose to be recommended to each of 10 dogs, it causes no sign of rabies within 180 days of administration,
- when administered orally at 10 times the dose to be recommended to each of 10 cats, it causes no sign of rabies within 180 days of administration,
- in natural and experimental conditions, the virus strain does not spread from one animal to another in wild rodents,
- the virus strain has one or more stable genetic markers that may be used to discriminate the vaccine strain from other rabies virus strains.

2-3-2. **Immunogenicity**. A test is carried out for the oral route of administration and with the bait to be stated on the label using foxes. The quantity of vaccine to be administered to each fox is not greater than the minimum virus titre to be stated on the label and the virus is at the most attenuated passage level that will be present in a batch of vaccine.

Use for the test not fewer than 35 foxes at least 3 months old, that do not have antibodies against rabies. Vaccinate not fewer than 25 foxes, according to the schedule to be recommended. Maintain not fewer than 10 foxes as controls. Observe the foxes for 180 days. No fox shows signs of rabies. The test is invalid if fewer than 25 vaccinated foxes survive after this observation period. Challenge each fox 180 days after vaccination by the intramuscular injection of a sufficient quantity of a virulent rabies virus strain approved by the competent authority. Observe the foxes at least daily for 90 days after challenge. Foxes that die from causes not attributable to rabies are eliminated.

The test is invalid if the number of such deaths reduces the number of vaccinated foxes in the test to fewer than 25 and the test is invalid unless at least 9 control animals (or a statistically equivalent number if more than 10 control foxes are challenged) show signs of rabies and the presence of rabies virus in their brain is demonstrated by the fluorescent-antibody test or some other reliable method. The vaccine virus complies with the test if not more than 2 of 25 vaccinated foxes (or a statistically equivalent number if more than 25 vaccinated foxes are challenged) show signs of rabies.

3. BATCH TESTS

3-1. **Identification**

3-1-1. When mixed with a monospecific rabies antiserum, the vaccine is no longer able to infect susceptible cell cultures into which it is inoculated.

3-1-2. A test is carried out to demonstrate the presence of the genetic marker.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Mycoplasmas** (*2.6.7*). The vaccine complies with the test for mycoplasmas.

3-4. **Extraneous agents**

3-4-1. Neutralise the vaccine virus with a suitable monospecific neutralising rabies virus antiserum and inoculate into susceptible cell cultures. The vaccine complies with the test if it no longer provokes cytopathic effects in susceptible cell cultures, and it shows no evidence of haemagglutinating or haemadsorbing agents.

3-4-2. Inoculate 1 in 10 and 1 in 1000 dilutions of the vaccine into susceptible cell cultures. Incubate at 37 °C. After 2, 4 and 6 days, stain the cells with a panel of monoclonal antibodies that do not react with the vaccine strain but that react with other strains of rabies vaccine (for example, street virus, Pasteur strain). The vaccine complies with the test if it shows no evidence of contaminating rabies virus.

3-5. **Virus titre**. Titrate the vaccine virus in suitable cell cultures. The vaccine complies with the test if one dose contains not less than the minimum virus titre stated on the label.

3-6. **Potency**. The vaccine complies with the requirements of the test prescribed under Immunogenicity (section 2-3-2) when administered by a recommended route and method. It is not necessary to carry out the potency test for each batch of the vaccine if it has been carried out on a representative batch using a vaccinating dose containing not more than the minimum virus titre stated on the label.

4. LABELLING

The label states the nature of the genetic marker of the virus strain.

01/2008:1947

SALMONELLA ENTERITIDIS VACCINE (INACTIVATED) FOR CHICKENS

Vaccinum Salmonellae Enteritidis inactivatum ad pullum

1. DEFINITION

Salmonella Enteritidis vaccine (inactivated) for chickens is a preparation of a suitable strain or strains of *Salmonella enterica* Enteritidis, inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for administration to chickens for reducing *S. enterica* Enteritidis colonisation and faecal excretion of *S. enterica* Enteritidis.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The seed material is cultured in a suitable medium; each strain is cultivated separately. During production, various parameters such as growth rate are monitored by suitable methods; the values are within the limits approved for the particular vaccine. Purity of the cultures and identity are verified on the harvest using suitable methods. After cultivation, the bacterial harvests are collected separately, inactivated by a suitable method, and blended. The vaccine may contain adjuvants.

2-2. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the birds for which it is intended. The following tests for safety (section 2-2-1) and immunogenicity (section 2-2-2) may be used during the demonstration of safety and efficacy.

2-2-1. **Safety**. Carry out the test for each route of administration to be recommended for vaccination, using in each case chickens not older than the minimum recommended age. Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine.

Use not fewer than 10 chickens from a flock free from specified pathogens (SPF) (*5.2.2*). Administer by a recommended route and method to each chicken a double dose of vaccine. If the recommended schedule requires a second dose, administer 1 additional dose to each chicken after at least 14 days. Observe the chickens at least daily until at least 21 days after the last administration of the vaccine.

The test is invalid if more than 10 per cent of the chickens show abnormal signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no chicken shows abnormal local or systemic reactions or dies from causes attributable to the vaccine.

2-2-2. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended. The vaccine administered to each animal is of minimum potency.

Use for the test not fewer than 60 SPF chickens (*5.2.2*) not older than the minimum age recommended for vaccination. Vaccinate not fewer than 30 chickens with no more than the minimum recommended number of doses of vaccine. Maintain not fewer than 30 chickens as controls for each group of vaccinates. Challenge both groups, 4 weeks after the last administration of vaccine, by oral administration to each chicken of a sufficient quantity of a strain of *S. enterica* Enteritidis that is able to colonise chickens. Take blood samples from control chickens on the day before challenge. Observe the chickens at least daily for 4 weeks. Take individual fresh faeces samples on day 1 after challenge and at least twice weekly (including day 7) until 14 days after challenge. Test the fresh faeces samples for the presence of *S. enterica* Enteritidis by direct plating. Euthanise all surviving chickens at the end of the observation period, take samples of liver and spleen and test for the presence of *S. enterica* Enteritidis by an appropriate method.

The test is invalid if antibodies against *S. enterica* Enteritidis are found in any control chicken before challenge.

The vaccine complies with the test if:

– the number of *S. enterica* Enteritidis in fresh faeces samples from vaccinated chickens after challenge at the different days of sampling is significantly lower in vaccinates than in controls and remains lower until the end of the test;
– the number of positive samples of liver and spleen is significantly lower in vaccinates than in controls.

2-3. *MANUFACTURER'S TEST*

2-3-1. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-4) for each batch of the vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

Use not fewer than 15 SPF chickens (*5.2.2*). Maintain not fewer than 5 SPF chickens as controls. Administer to each of 10 chickens 1 dose of vaccine by a recommended route. Where the schedule stated on the label requires a booster injection to be given, a booster vaccination may also be given in this test provided it has been demonstrated that this will still provide a suitably sensitive test system. At a given interval after the last injection, collect blood from each vaccinated and control chicken and prepare serum samples. Measure the titre of antibodies against *S. enterica* Enteritidis in each serum sample using a suitable validated serological method. Calculate the titre for the group of vaccinates.

The test is invalid if specific *S. enterica* Enteritidis antibodies are found in 1 or more sera from control chickens at a given interval after the time of administration of the vaccine in the vaccinated group.

The vaccine complies with the test if the antibody titres of the group of vaccinates at a given interval after each vaccination, where applicable, are not significantly lower than the value obtained with a batch that has given satisfactory results in the test described under Potency (section 3-4).

3. BATCH TESTS

3-1. **Identification**. In animals that do not have antibodies against *S. enterica* Enteritidis, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use not fewer than 10 SPF chickens (*5.2.2*), not older than the minimum age recommended for vaccination. Administer a double dose of vaccine by a recommended route to each chicken. Observe the chickens at least daily for 21 days. The test is invalid if more than 20 per cent of the chickens show abnormal signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no chicken shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-2-2) when administered by a recommended route and method.

01/2008:2361

SALMONELLA TYPHIMURIUM VACCINE (INACTIVATED) FOR CHICKENS

Vaccinum Salmonellae Typhimurium inactivatum ad pullum

1. DEFINITION

Salmonella Typhimurium vaccine (inactivated) for chickens is a preparation of a suitable strain or strains of *Salmonella enterica* Typhimurium, inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for administration to chickens for reducing *S. enterica* Typhimurium colonisation and faecal excretion of *S. enterica* Typhimurium.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The seed material is cultured in a suitable medium; each strain is cultivated separately. During production, various parameters such as growth rate are monitored by suitable methods; the values are within the limits approved for the particular vaccine. Purity of the cultures and identity are verified on the harvest using suitable methods. After cultivation, the bacterial harvests are collected separately, inactivated by a suitable method, and blended. The vaccine may contain adjuvants.

2-2. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the birds for which it is intended. The following tests for safety (section 2-2-1) and immunogenicity (section 2-2-2) may be used during the demonstration of safety and efficacy.

2-2-1. **Safety**. Carry out the test for each route of administration to be recommended for vaccination, using in each case chickens not older than the minimum recommended age. Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine.

Use not fewer than 10 chickens from a flock free from specified pathogens (SPF) (*5.2.2*). Administer by a recommended route and method to each chicken a double dose of vaccine. If the recommended schedule requires a second dose, administer 1 additional dose to each chicken after at least 14 days. Observe the chickens at least daily until at least 21 days after the last administration of the vaccine.

The test is invalid if more than 10 per cent of the chickens show abnormal signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no chicken shows abnormal local or systemic reactions or dies from causes attributable to the vaccine.

2-2-2. **Immunogenicity**. A test is carried out for each route and method of administration to be recommended. The vaccine administered to each animal is of minimum potency.

Use for the test not fewer than 60 SPF chickens (*5.2.2*) not older than the minimum age recommended for vaccination. Vaccinate not fewer than 30 chickens with no more than the minimum recommended number of doses of vaccine. Maintain not fewer than 30 chickens as controls for each group of vaccinates. Challenge both groups, 4 weeks after the last administration of vaccine, by oral administration to each chicken of a sufficient quantity of a strain of *S. enterica* Typhimurium that is able to colonise chickens. Take blood samples from control chickens on the day before challenge. Observe the chickens at least daily for 4 weeks. Take individual fresh faeces samples on day 1 after challenge and at least twice weekly (including day 7) until 14 days after challenge. Test the fresh faeces samples for the presence of *S. enterica* Typhimurium by direct plating. Euthanise all surviving chickens at the end of the observation period, take samples of liver and spleen and test for the presence of *S. enterica* Typhimurium by an appropriate method.

The test is invalid if antibodies against *S. enterica* Typhimurium are found in any control chicken before challenge.

The vaccine complies with the test if:

– the number of *S. enterica* Typhimurium in fresh faeces samples from vaccinated chickens after challenge at the different days of sampling is significantly lower in vaccinates than in controls and remains lower until the end of the test;

– the number of positive samples of liver and spleen is significantly lower in vaccinates than in controls.

2-3. *MANUFACTURER'S TEST*

2-3-1. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-4) for each batch of the vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

Use not fewer than 15 SPF chickens (*5.2.2*). Maintain not fewer than 5 SPF chickens as controls. Administer to each of 10 chickens 1 dose of vaccine by a recommended route. Where the schedule stated on the label requires a booster injection to be given, a booster vaccination may also be given in this test provided it has been demonstrated that this will still provide a suitably sensitive test system. At a given interval after the last injection, collect blood from each vaccinated and control chicken and prepare serum samples. Measure the titre of antibodies against *S. enterica* Typhimurium in each serum sample using a suitable validated serological method. Calculate the titre for the group of vaccinates.

The test is invalid if specific *S. enterica* Typhimurium antibodies are found in 1 or more sera from control chickens at a given interval after the time of administration of the vaccine in the vaccinated group.

The vaccine complies with the test if the antibody titres of the group of vaccinates at a given interval after each vaccination, where applicable, are not significantly lower than the value obtained with a batch that has given satisfactory results in the test described under Potency (section 3-4).

3. BATCH TESTS

3-1. **Identification**. In animals that do not have antibodies against *S. enterica* Typhimurium, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use not fewer than 10 SPF chickens (*5.2.2*), not older than the minimum age recommended for vaccination. Administer a double dose of vaccine by a recommended route to each chicken. Observe the chickens at least daily for 21 days. The test is invalid if more than 20 per cent of the chickens show abnormal signs or die from causes not attributable to the vaccine. The vaccine complies with the test if no chicken shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-2-2) when administered by a recommended route and method.

01/2008:0064

SWINE ERYSIPELAS VACCINE (INACTIVATED)

Vaccinum erysipelatis suillae inactivatum

1. DEFINITION

Swine erysipelas vaccine (inactivated) is a preparation of one or more suitable strains of *Erysipelothrix rhusiopathiae*, inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for the active immunisation of pigs against swine erysipelas.

2. PRODUCTION

The vaccine may be adjuvanted.

2-1. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the pigs for which it is intended.

The following test for immunogenicity (section 2-1-1.) may be used during the demonstration of efficacy.

2-1-1. **Immunogenicity**. The test described below is suitable to demonstrate immunogenicity of the vaccine with respect to *E. rhusiopathiae* serotypes 1 and 2. If claims are made concerning another serotype, then a further test to demonstrate immunogenicity against this serotype is necessary.

If the vaccine contains more than 1 serotype, a test for 2 serotypes may be carried out on a single group by injecting each challenge serotype on different flanks of the pigs. Validation and acceptance criteria are applied separately to the respective injection sites. If the vaccine contains more than 1 serotype, the immunogenicity test may also be carried out using a separate group for each serotype.

A test is carried out for each route and method of administration to be recommended, using in each case pigs not less than 12 weeks old and weighing not less than 20 kg. The vaccine administered to each pig is of minimum potency.

For each test, use not fewer than 15 pigs that do not have antibodies against swine erysipelas. Divide the pigs into 2 groups. Vaccinate a group of not fewer than 10 pigs according to the schedule to be recommended. Maintain a group of not fewer than 5 pigs as controls. Challenge each pig 3 weeks after vaccination by the intradermal route by separate injections of 0.1 ml of a virulent strain of each of serotype 1 and serotype 2 of *E. rhusiopathiae*. Observe the pigs at least daily for 7 days.

The test is invalid if fewer than 80 per cent of control pigs show typical signs of disease, i.e. diamond skin lesions at the injection sites. The vaccine complies with the test if not fewer than 90 per cent of the vaccinated pigs remain free from diamond skin lesions at the injection site.

Swine erysipelas bacteria serotype 1 BRP and *swine erysipelas bacteria serotype 2 BRP* are suitable for use as challenge strains.

2-2. *MANUFACTURER'S TESTS*

2-2-1. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-4.) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency. Where the test is not carried out, an alternative validated method is used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

Use 10 mice of a suitable strain (for example, NMRI) weighing 17-20 g, from a uniform stock and that do not have antibodies against swine erysipelas. Vaccinate each mouse by the subcutaneous route with a suitable dose (usually 1/10 of the pig dose). At a given interval (for example, 21-28 days), depending on the vaccine to be examined, bleed the mice under anaesthesia. Pool the sera, using an equal volume from each mouse. Determine the level of antibodies by a suitable immunochemical method (*2.7.1*), for example, enzyme-linked immunosorbent assay with *erysipelas ELISA coating antigen BRP*. The vaccine complies with the test if the antibody level is not significantly less than that obtained with a batch that has given satisfactory results in the test described under Potency.

3. BATCH TESTS

3-1. **Identification**. Injected into animals that do not have antibodies against *E. rhusiopathiae*, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use 2 pigs of the minimum age recommended for vaccination and preferably that have no antibodies against swine erysipelas or, where justified, use pigs with a low level of such antibodies as long as they have not been vaccinated against swine erysipelas and administration of the vaccine does not cause an anamnestic response. Administer to each pig by a recommended route a double dose of the vaccine. Observe the pigs at least daily for 14 days.

The vaccine complies with the test if no pig shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Potency**. The vaccine complies with the requirements of the tests mentioned under Immunogenicity (section 2-1-1.) when administered by a recommended route and method.

01/2008:0065

SWINE-FEVER VACCINE (LIVE), CLASSICAL, FREEZE-DRIED

Vaccinum pestis classicae suillae vivum cryodesiccatum

DEFINITION

Freeze-dried classical swine-fever vaccine (live) is a preparation obtained from a strain of classical swine-fever virus which has lost its pathogenicity for the pig by adaptation either to cell cultures or to the rabbit.

PRODUCTION

For vaccine prepared in rabbits, the seed-lot (or the vaccine) is made from the homog-enised organs and/or blood of rabbits from healthy colonies, euthanised at the peak of the temperature rise following intravenous inoculation of the virus. The vaccine is freeze-dried.

CHOICE OF VACCINE STRAIN

Only a virus strain shown to be satisfactory with respect to the following characteristics may be used in the preparation of the vaccine: safety; non-transmissibility; irreversibility of attenuation; and immunogenic properties. The following tests may be used during demonstration of safety (*5.2.6*) and efficacy (*5.2.7*).

The dose of vaccine used throughout the following tests is determined by the manufacturer on the basis of prior experiments.

Tests in pigs

Selection of animals. The piglets are 6 to 7 weeks old. The sows are primiparae. All animals are healthy and must have had no contact with swine-fever virus and serologically must be free from swine-fever and bovine viral diarrhoea antibodies. They must have a week in which to adapt themselves to the new quarters where the tests are to be carried out.

Safety

(a) Each of five piglets receives intramuscularly as a single injection ten doses of vaccine (group a).

(b) Five piglets are immunodepressed by the daily injection of 2 mg of prednisolone per kilogram of body mass for five consecutive days and on the third day they receive one dose of vaccine (group b).

The animals of groups (a) and (b) are observed for 21 days. They must remain in good health. The temperature curve and the weight curve must not differ significantly from those of control animals.

(c) Ten non-immune pregnant sows each receive two doses of vaccine intramuscularly as a single injection between the twenty-fifth and thirty-fifth days of gestation. Ten non-immune pregnant sows of the same age and of the same origin receive instead of the two doses of vaccine an equal volume of a 9 g/l solution of *sodium chloride R*. The vaccinal virus does not cause abnormalities in the gestation or in the piglets.

Non-transmissibility. Twelve piglets of the same origin are kept together. Six are vaccinated in the normal way and the six others are kept as contact controls. After 40 days, all the pigs are challenged by intramuscular inoculation of a sufficient quantity of the challenge virus (see Potency) to kill an unvaccinated piglet in 7 days. The vaccinated piglets resist challenge whereas the contact piglets must display the typical signs of swine fever.

Irreversibility of attenuation. Each of two piglets receives one dose of vaccine intramuscularly. Seven days later, 5 ml of blood is taken from each of the piglets and the samples are pooled. 5 ml of the pooled blood is injected intramuscularly into each of two other piglets. This operation is repeated six times. The animals must not display any sign of swine fever and must show normal growth.

Immunogenic properties. The immunogenic properties may be demonstrated by the method described for the determination of potency. The quantity of the vaccinal virus corresponding to one dose of vaccine contains at least 100 PD_{50}.

IDENTIFICATION

A. For vaccines prepared in rabbits and lapinised vaccines prepared in cell cultures, inject intravenously 0.5 ml of the vaccine reconstituted as stated on the label into one or more non-immunised rabbits and one or more rabbits immunised either with an identical dose of a vaccine of the same type injected by the same route at least 10 days and at most 2 months beforehand or with a sufficient dose of antiserum administered a few hours before the injection of the vaccine. Measure the temperature of the rabbits in the morning and the evening starting 24 h after the injection and continuing until the fifth day after the injection. The vaccine is identified by its specific pyrogenic character leading to a rise in temperature of at least 1.5 °C in the non-immunised rabbits only.

B. For non-lapinised vaccines prepared in cell cultures, the serum of pigs immunised with the vaccine neutralises the virus used in the preparation of the vaccine.

TESTS

Safety. Use three piglets complying with the requirements prescribed for the selection of animals under Choice of Vaccine Strain. Inject intramuscularly into each piglet ten doses of the reconstituted vaccine as a single injection. Observe the animals for 21 days. The temperature curve remains normal and the animals remain in apparent good health and display normal growth.

Extraneous viruses. Mix the vaccine with a monospecific antiserum and inoculate into susceptible cell cultures. No cytopathic effect is produced.

Carry out a haemagglutination test using chicken red blood cells and the supernatant liquid of the cell cultures. The test is negative. Carry out a haemadsorption test on the cell cultures. The test is negative.

Use ten mice each weighing 11 g to 15 g. Inject intracerebrally into each mouse 0.03 ml of the vaccine reconstituted so that 1 ml contains 1 dose. Observe the animals for 21 days. If more than two mice die within the first 48 h, repeat the test. From the third to the twenty-first day after the injection, the mice show no abnormalities attributable to the vaccine.

Bacterial and fungal contamination. The vaccine to be examined complies with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

Mycoplasmas (*2.6.7*). The vaccine complies with the test for mycoplasmas.

POTENCY

The potency is expressed as the number of 50 per cent protective doses (PD_{50}) for pigs contained in the dose indicated on the label. The vaccine contains at least 100 PD_{50} per dose.

Use piglets complying with the requirements for selection of animals described under Choice of Vaccine Strain. To two groups of five piglets inject intramuscularly:

– 1/40 of a dose of the vaccine to be examined into each piglet of the first group,
– 1/160 of a dose of the vaccine to be examined into each piglet of the second group.

Use two piglets as controls.

Prepare the dilutions using *buffered salt solution pH 7.2 R*. On the fourteenth day after the injection, inoculate intramuscularly into each vaccinated and control animal a sufficient quantity of challenge virus to kill an unvaccinated piglet in 7 days. The challenge virus preparation consists of blood of pigs infected experimentally by virus that has not been submitted to passage in cell cultures. The control animals die within the seven days of inoculation. Observe the vaccinated animals for 14 days. From the number of animals which survive without showing any sign of swine fever, calculate the number of PD_{50} contained in the vaccine using the usual statistical methods.

LABELLING

The label states that the vaccine has been prepared in cell cultures or in rabbits as appropriate.

01/2008:0697

TETANUS VACCINE FOR VETERINARY USE

Vaccinum tetani ad usum veterinarium

1. DEFINITION

Tetanus vaccine for veterinary use is a preparation of the neurotoxin of *Clostridium tetani* inactivated to eliminate its toxicity while maintaining adequate immunogenic properties. The vaccine may be used to induce active and/or passive immunity.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

C. tetani used for production is grown in an appropriate liquid medium. The toxin is purified and then detoxified or it may be detoxified before purification. The antigenic purity is determined in Lf units of tetanus toxoid per milligram of protein and shown to be not less than the value approved for the particular product.

2-2. *CHOICE OF VACCINE COMPOSITION*

The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) for the animals for which it is intended. The following tests for Production of antigens (section 2-2-1), Safety (section 2-2-2) and Immunogenicity (section 2-2-3) may be used during demonstration of safety and efficacy.

The *C. tetani* strain used in the preparation of the vaccine is shown to be satisfactory with respect to the production of the neurotoxin.

2-2-1. **Production of antigens**. The production of the neurotoxin of *C. tetani* is verified by a suitable immunochemical method (*2.7.1*) carried out on the neurotoxin obtained from the vaccine strain under the conditions used for the production of the vaccine.

2-2-2. **Safety**. Carry out the test for each route and method of administration to be recommended and for each species of animal for which the vaccine is intended; use animals of the minimum age recommended for vaccination and of the most sensitive category for the species. Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine.

2-2-2-1. *General safety*

For each test use not fewer than 15 animals, free from antitoxic antibodies. Administer to each animal a double dose of vaccine. Administer to each animal a single dose of vaccine after the interval to be recommended. Observe the animals at least daily until 14 days after the last administration. The vaccine complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine.

2-2-2-2. *Safety in pregnant animals*

If the vaccine is intended for use in pregnant animals, vaccinate the animals at the stage of pregnancy and according to the scheme stated on the label and prolong the observation period required in the general safety test until 1 day after parturition.

The vaccine complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine and if no adverse effects on the pregnancy or the offspring are noted.

2-2-3. **Immunogenicity**

2-2-3-1. *Immunogenicity test in the target species*

It shall be demonstrated for each target species that the vaccine, when administered according to the recommended schedule and by the recommende route, stimulates an immune response (for example, induction of antitoxic antibodies or induction of protective levels of antitoxic antibodies) consistent with the claims made for the product.

2-2-3-2. *Immunogenicity test in guinea-pigs*

Administer to each of at least 5 guinea-pigs that do not have antibodies against the neurotoxin of *C. tetani* by the subcutaneous route 1 dose of vaccine. After 28 days, administer again to each guinea-pig 1 dose by the subcutaneous route. 14 days after the second dose, collect blood from each guinea-pig and prepare serum samples. Determine for each serum the titre of antibodies against the neurotoxin of *C. tetani* using a suitable immunochemical method (*2.7.1*) such as a toxin-binding-inhibition test (ToBI test) and a homologous reference serum. Determine the average antibody titre of the serum samples.

Clostridium tetani guinea-pig antiserum for vaccines for veterinary use BRP is suitable as reference sera.

Tetanus vaccine intended for use in animals other than horses complies with the test if the average antibody titre is not less than 7.5 IU/ml.

Tetanus vaccine intended for use in horses complies with the test if the average antibody titre is not less than 30 IU/ml.

For tetanus vaccine presented as a combined vaccine for use in animals other than horses, the above test may be carried out in susceptible rabbits instead of guinea-pigs. The vaccine complies with the test if the average antibody titre of the sera of the vaccinated rabbits is not less than 2.5 IU/ml.

Clostridia (multicomponent) rabbit antiserum BRP and *Clostridium tetani rabbit antiserum BRP* are suitable as reference serum.

2-3. *MANUFACTURER'S TESTS*

2-3-1. **Absence of toxin and irreversibility of toxoid**. Carry out a test for reversion to toxicity on the detoxified harvest using 2 groups of 5 guinea-pigs, each weighing 350-450 g; if the vaccine is adsorbed, carry out the test with the shortest practical time interval before adsorption. Prepare a dilution of the detoxified harvest so that the guinea-pigs each receive 10 times the amount of toxoid (measured in Lf units) that will be present in a dose of vaccine. Divide the dilution into 2 equal parts. Keep one part at 5 ± 3 °C and the other at 37 °C for 6 weeks. Attribute each dilution to a separate group of guinea-pigs and inject into each guinea-pig the dilution attributed to its group. Observe the animals at least daily for 21 days. The toxoid complies with the test if no guinea-pig shows signs of disease or dies from causes attributable to the neurotoxin of *C. tetani*.

2-3-2. **Batch potency test**. It is not necessary to carry out the Potency test (section 3-4) for each batch of vaccine if it has been carried out using a batch of vaccine with a minimum potency.

Where the test described under Potency is used as the batch potency test, the vaccine complies with the test if the antibody titre in International Units is not less than that found for a batch of vaccine shown to be satisfactory with respect to immunogenicity in the target species.

3. BATCH TESTS

3-1. **Identification**

If the nature of the adjuvant allows it, carry out test A. Otherwise carry out test B.

A. Dissolve in the vaccine sufficient *sodium citrate R* to give a 100 g/l solution. Maintain the solution at 37 °C for about 16 h and centrifuge until a clear supernatant liquid is obtained. The supernatant reacts with a suitable tetanus antitoxin, giving a precipitate.

B. When injected into animals that do not have antibodies against the neurotoxin of *C. tetani*, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph on *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Administer 5 ml of the vaccine by the subcutaneous route as 2 equal divided doses, at separate sites into each of 5 healthy guinea-pigs, each weighing 350-450 g, that have not previously been treated with any material that will interfere with the test. The vaccine

complies with the test if no animal shows notable signs of disease or dies from causes attributable to the vaccine. If within 21 days of the injection any of the animals shows signs of or dies from tetanus, the vaccine does not comply with the test. If more than 1 animal dies from non-specific causes, repeat the test. If any animal dies in the second test, the vaccine does not comply with the test.

3-4. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-2-3-2).

01/2008:1580

VIBRIOSIS (COLD-WATER) VACCINE (INACTIVATED) FOR SALMONIDS

Vaccinum vibriosidis aquae frigidae inactivatum ad salmonidas

1. DEFINITION

Cold-water vibriosis vaccine (inactivated) for salmonids is prepared from cultures of one or more suitable strains of *Vibrio salmonicida*, inactivated while maintaining adequate immunogenic properties. This monograph applies to vaccines intended for the active immunisation of salmonids against cold-water vibriosis.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The strains of *V. salmonicida* are cultured and harvested separately. The harvests are inactivated by a suitable method. They may be purified and concentrated. Whole or disrupted cells may be used and the vaccine may contain extracellular products of the bacterium released into the growth medium.

2-2. *CHOICE OF VACCINE COMPOSITION*

The strain or strains of *V. salmonicida* used are shown to be suitable with respect to production of antigens of assumed immunological importance. The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) in the species of fish for which it is intended.

The following tests for safety (section 2-2-1) and immunogenicity (section 2-2-2) may be used during the demonstration of safety and efficacy.

2-2-1. **Safety**

2-2-1-1. *Laboratory tests.* Safety is tested in three different batches using test 2-2-1-1-1, test 2-2-1-1-2, or both, depending on the recommendations for use.

Carry out the test in each species of fish for which the vaccine is intended, using in each case fish of the minimum body mass to be recommended for vaccination. Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine. The test is carried out in the conditions to be recommended for use of the vaccine with a water temperature not less than 10 °C.

2-2-1-1-1. *Vaccines intended for administration by injection.* Use not fewer than 50 fish from a population that does not have specific antibodies against *V. salmonicida* and has not been vaccinated against nor exposed to cold-water vibriosis. Administer to each fish by the intraperitoneal route a dose corresponding to double that to be recommended, per mass unit. Observe the fish at least daily for 21 days.

The test is invalid if more than 6 per cent of the fish die from causes not attributable to the vaccine. The vaccine complies with the test if no fish shows abnormal local or systemic reactions or dies from causes attributable to the vaccine.

2-2-1-1-2. *Vaccines intended for administration by immersion.* Use not fewer than 50 fish from a population that does not have specific antibodies against *V. salmonicida* and has not been vaccinated against nor exposed to cold-water vibriosis. Prepare an immersion bath at twice the concentration to be recommended. Bathe the fish for twice the time to be recommended. Observe the fish at least daily for 21 days.

The test is invalid if more than 6 per cent of the fish die from causes not attributable to the vaccine. The vaccine complies with the test if no fish shows abnormal local or systemic reactions or dies from causes attributable to the vaccine.

2-2-1-2. *Field studies.* Safety is demonstrated in addition in field trials by administering the dose to be recommended to a sufficient number of fish distributed in not fewer than 2 sets of premises.

The vaccine complies with the test if no fish shows abnormal reactions or dies from causes attributable to the vaccine.

2-2-2. **Immunogenicity**. Carry out the test according to a protocol defining limits of body mass for the fish, water source, water flow and temperature limits, and preparation of a standardised challenge. Each test is carried out for each route and method of administration to be recommended. The vaccine administered to each fish is of minimum potency.

Use for the test not fewer than 200 fish. Vaccinate not fewer than 100 fish according to the instructions for use. Perform mock vaccination on a control group of not fewer than 100 fish; mark vaccinated and control fish for identification. Keep all the fish in the same tank or mix equal numbers of controls and vaccinates in each tank if more than one tank is used. Challenge each fish by injection at a fixed interval after vaccination, defined according to the statement regarding development of immunity, with a sufficient quantity of a culture of *V. salmonicida* whose virulence has been verified. Observe the fish at least daily until at least 60 per cent specific mortality is reached in the control group. Plot for both vaccinates and controls a curve of specific mortality against time from challenge and determine by interpolation the time corresponding to 60 per cent specific mortality in controls.

The test is invalid if the specific mortality is less than 60 per cent in the control group 21 days after the first death in the fish. Read from the curve for vaccinates the mortality (M) at the time corresponding to 60 per cent mortality in controls. Calculate the relative percentage survival (RPS) from the expression:

$$\left(1 - \frac{M}{60}\right) \times 100$$

The vaccine complies with the test if the RPS is not less than 60 per cent for vaccines administered by immersion and 90 per cent for vaccines administered by injection.

2-3. *MANUFACTURER'S TESTS*

2-3-1. **Batch potency test**. The Potency test (section 3-4) may be carried out for each batch of vaccine, using groups of not fewer than 30 fish of one of the species for which the vaccine is intended. Where the test is not carried out, an alternative validated method based on antibody response may be used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

Use not fewer than 35 fish from a population that does not have specific antibodies against *V. salmonicida* and that are within specified limits for body mass. Carry out the test at a defined temperature. Inject into each of not fewer than 25 fish one dose of vaccine, according to the instructions

for use. Perform mock vaccination on a control group of not fewer than 10 fish. Collect blood samples at a defined time after vaccination. Determine for each sample the level of specific antibodies against *V. salmonicida* by a suitable immunochemical method (*2.7.1*). The test is invalid if the control group shows antibodies against *V. salmonicida*. The vaccine complies with the test if the mean level of antibodies in the vaccinates is not significantly lower than that found for a batch that gave satisfactory results in the test described under Potency.

3. BATCH TESTS

3-1. **Identification**. When injected into fish that do not have specific antibodies against *V. salmonicida*, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use not fewer than 10 fish of one of the species for which the vaccine is intended, having, where possible, the minimum body mass recommended for vaccination; if fish of the minimum body mass are not available, use fish not greater than twice this mass. Use fish from a population that does not have specific antibodies against *V. salmonicida* and that has not been vaccinated against nor exposed to cold-water vibriosis. Carry out the test in the conditions recommended for use of the vaccine with a water temperature not less than 10 °C. For vaccines administered by injection or immersion, administer to each fish by the intraperitoneal route a double dose of the vaccine per mass unit. For vaccines administered by immersion only, use a bath with twice the recommended concentration and bathe the fish for twice the recommended immersion time. Observe the fish at least daily for 21 days.

The test is invalid if more than 10 per cent of the fish die from causes not attributable to the vaccine. The vaccine complies with the test if no fish shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-2-2) when administered by a recommended route and method.

4. LABELLING

The label states information on the time needed for development of immunity after vaccination under the range of conditions corresponding to the recommended use.

01/2008:1581

VIBRIOSIS VACCINE (INACTIVATED) FOR SALMONIDS

Vaccinum vibriosidis ad salmonidas inactivatum

1. DEFINITION

Vibriosis vaccine (inactivated) for salmonids is prepared from cultures of one or more suitable strains or serovars of *Vibrio anguillarum*, inactivated while maintaining adequate immunogenic properties; the vaccine may also include *Vibrio ordalii*. This monograph applies to vaccines intended for the active immunisation of salmonids against vibriosis.

2. PRODUCTION

2-1. *PREPARATION OF THE VACCINE*

The strains of *V. anguillarum* and *V. ordalii* are cultured and harvested separately. The harvests are inactivated by a suitable method. They may be purified and concentrated. Whole or disrupted cells may be used and the vaccine may contain extracellular products of the bacterium released into the growth medium.

2-2. *CHOICE OF VACCINE COMPOSITION*

The strains of *V. anguillarum* and *V. ordalii* used are shown to be suitable with respect to production of antigens of assumed immunological importance. The vaccine is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*) in the species of fish for which it is intended.

The following tests for safety (section 2-2-1) and immunogenicity (section 2-2-2) may be used during the demonstration of safety and efficacy.

2-2-1. **Safety**

2-2-1-1. *Laboratory tests.* Safety is tested in 3 different batches using test 2-2-1-1-1, test 2-2-1-1-2 or both, depending on the recommendations for use.

Carry out the test in each species of fish for which the vaccine is intended, using in each case fish of the minimum body mass to be recommended for vaccination. Use a batch of vaccine containing not less than the maximum potency that may be expected in a batch of vaccine. The test is carried out in the conditions to be recommended for use of the vaccine with a water temperature not less than 10 °C.

2-2-1-1-1. Vaccines intended for administration by injection. For each test, use not fewer than 50 fish from a population that does not have antibodies against *V. anguillarum* or where applicable *V. ordalii* and has not been vaccinated against nor exposed to vibriosis. Administer to each fish by the intraperitoneal route a dose corresponding to double that to be recommended, per mass unit. Observe the fish at least daily for 21 days.

The test is invalid if more than 6 per cent of the fish die from causes not attributable to the vaccine. The vaccine complies with the test if no fish shows abnormal local or systemic reactions or dies from causes attributable to the vaccine.

2-2-1-1-2. Vaccines intended for administration by immersion. For each test, use not fewer than 50 fish from a population that does not have antibodies against *V. anguillarum* or where applicable *V. ordalii* and has not been vaccinated against nor exposed to vibriosis. Prepare an immersion bath at twice the concentration to be recommended. Bathe the fish for twice the time to be recommended. Observe the fish at least daily for 21 days.

The test is invalid if more than 6 per cent of the fish die from causes not attributable to the vaccine. The vaccine complies with the test if no fish shows abnormal local or systemic reactions or dies from causes attributable to the vaccine.

2-2-1-2. *Field studies.* Safety is demonstrated in addition in field trials by administering the dose to be recommended to a sufficient number of fish distributed in not fewer than 2 sets of premises.

The vaccine complies with the test if no fish shows abnormal reactions or dies from causes attributable to the vaccine.

2-2-2. **Immunogenicity**. Carry out a separate test for each species and each serovar included in the vaccine, according to a protocol defining limits of body mass for the fish, water source, water flow and temperature limits, and preparation

of a standardised challenge. Each test is carried out for each route and method of administration to be recommended. The vaccine administered to each fish is of minimum potency.

Use for the test not fewer than 200 fish. Vaccinate not fewer than 100 fish, according to the instructions for use. Perform mock vaccination on a control group of not fewer than 100; mark vaccinated and control fish for identification. Keep all the fish in the same tank or mix equal numbers of controls and vaccinates in each tank if more than one tank is used. Challenge each fish by injection at a fixed interval after vaccination, defined according to the statement regarding development of immunity, with a sufficient quantity of cultures of *V. anguillarum* or *V. ordalii* whose virulence has been verified. Observe the fish at least daily until at least 60 per cent specific mortality is reached in the control group. Plot for both vaccinates and controls a curve of specific mortality against time from challenge and determine by interpolation the time corresponding to 60 per cent specific mortality in controls.

The test is invalid if the specific mortality is less than 60 per cent in the control group 21 days after the first death in the fish. Read from the curve for vaccinates the mortality (M) at the time corresponding to 60 per cent mortality in controls. Calculate the relative percentage survival (RPS) from the expression:

$$\left(1 - \frac{M}{60}\right) \times 100$$

The vaccine complies with the test if the RPS is not less than 60 per cent for vaccines administered by immersion and 75 per cent for vaccines administered by injection.

2-3. *MANUFACTURER'S TESTS*

2-3-1. **Batch potency test**. The Potency test (section 3-4) may be carried out for each batch of vaccine, using groups of not fewer than 30 fish of one of the species for which the vaccine is intended. Where the test is not carried out, an alternative validated method based on antibody response may be used, the criteria for acceptance being set with reference to a batch of vaccine that has given satisfactory results in the test described under Potency. The following test may be used.

Use not fewer than 35 fish from a population that does not have specific antibodies against the relevant serovars of *V. anguillarum* and where applicable *V. ordalii* and that are within specified limits for body mass. Carry out the test at a defined temperature. Inject into each of not fewer than 25 fish one dose of vaccine, according to the instructions for use. Perform mock vaccination on a control group of not fewer than 10 fish. Collect blood samples at a defined time after vaccination. Determine for each sample the level of specific antibodies against the different serovars of *V. anguillarum* and against *V. ordalii* included in the vaccine by a suitable immunochemical method (*2.7.1*). The test is invalid if the control group shows antibodies against the relevant serovars of *V. anguillarum* or, where applicable, against *V. ordalii*. The vaccine complies with the test if the mean levels of antibodies in the vaccinates are not significantly lower than those found for a batch that gave satisfactory results in the test described under Potency.

3. BATCH TESTS

3-1. **Identification**. When injected into fish that do not have specific antibodies against *V. anguillarum* and, where applicable, *V. ordalii*, the vaccine stimulates the production of such antibodies.

3-2. **Bacteria and fungi**. The vaccine and, where applicable, the liquid supplied with it comply with the test for sterility prescribed in the monograph *Vaccines for veterinary use (0062)*.

3-3. **Safety**. Use not fewer than 10 fish of one of the species for which the vaccine is intended, having, where possible, the minimum body mass recommended for vaccination; if fish of the minimum body mass are not available, use fish not greater than twice this mass. Use fish from a population that does not have specific antibodies against the relevant serovars of *V. anguillarum* and, where applicable, *V. ordalii* and which has not been vaccinated against nor exposed to vibriosis. Carry out the test in the conditions recommended for the use of the vaccine with a water temperature not less than 10 °C. For vaccines administered by injection or immersion, administer to each fish by the intraperitoneal route a double dose of the vaccine per mass unit. For vaccines administered by immersion only, use a bath with twice the recommended concentration and bathe the fish for twice the recommended immersion time. Observe the fish at least daily for 21 days.

The test is invalid if more than 10 per cent of the fish die from causes not attributable to the vaccine. The vaccine complies with the test if no fish shows notable signs of disease or dies from causes attributable to the vaccine.

3-4. **Potency**. The vaccine complies with the requirements of the test mentioned under Immunogenicity (section 2-2-2) when administered by a recommended route and method.

4. LABELLING

The label states information on the time needed for the development of immunity after vaccination under the range of conditions corresponding to the recommended use.

01/2008:0085

BOTULINUM ANTITOXIN

Immunoserum botulinicum

DEFINITION

Botulinum antitoxin is a preparation containing antitoxic globulins that have the power of specifically neutralising the toxins formed by *Clostridium botulinum* type A, type B or type E, or any mixture of these types.

PRODUCTION

It is obtained by fractionation from the serum of horses, or other mammals, that have been immunised against *Cl. botulinum* type A, type B and type E toxins.

IDENTIFICATION

It specifically neutralises the types of *Cl. botulinum* toxins stated on the label, rendering them harmless to susceptible animals.

POTENCY

Not less than 500 IU of antitoxin per millilitre for each of types A and B and not less than 50 IU of antitoxin per millilitre for type E.

The potency of botulinum antitoxin is determined by comparing the dose necessary to protect mice against the lethal effects of a fixed dose of botulinum toxin with the quantity of the standard preparation of botulinum antitoxin necessary to give the same protection. For this comparison a reference preparation of each type of botulinum antitoxin, calibrated in International Units, and suitable preparations of botulinum toxins, for use as test toxins, are required. The potency of each test toxin is determined in relation to the specific reference preparation; the potency of the botulinum antitoxin to be examined is determined in relation to the potency of the test toxins by the same method.

International Units of the antitoxin are the specific neutralising activity for botulinum toxin type A, type B and type E contained in stated amounts of the International Standards which consist of dried immune horse sera of types A, B and E. The equivalence in International Units of the International Standard is stated from time to time by the World Health Organisation.

Selection of animals. Use mice having body masses such that the difference between the lightest and the heaviest does not exceed 5 g.

Preparation of test toxins. CAUTION: Botulinum toxin is extremely toxic: exceptional care must be taken in any procedure in which it is employed. Prepare type A, B and E toxins from sterile filtrates of approximately 7-day cultures in liquid medium of *Cl. botulinum* types A, B and E. To the filtrates, add 2 volumes of glycerol, concentrate, if necessary, by dialysis against glycerol and store at or slightly below 0 °C.

Selection of test toxins. Select toxins of each type for use as test toxins by determining for mice the L+/10 dose and the LD_{50}, the observation period being 96 h. The test toxins contain at least 1000 LD_{50} in an L+/10 dose.

Determination of test doses of the toxins (L+/10 dose). Prepare solutions of the reference preparations in a suitable liquid such that each contains 0.25 IU of antitoxin per millilitre. Using each solution in turn, determine the test dose of the corresponding test toxin.

Prepare mixtures of the solution of the reference preparation and the test toxin such that each contains 2.0 ml of the solution of the reference preparation, one of a graded series of volumes of the test toxin and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature, protected from light, for 60 min. Using four mice for each mixture, inject a dose of 1.0 ml intraperitoneally into each mouse. Observe the mice for 96 h.

The test dose of toxin is the quantity in 1.0 ml of the mixture made with the smallest amount of toxin capable of causing, despite partial neutralisation by the reference preparation, the death of all four mice injected with the mixture within the observation period.

Determination of potency of the antitoxin. Prepare solutions of each reference preparation in a suitable liquid such that each contains 0.25 IU of antitoxin per millilitre.

Prepare solutions of each test toxin in a suitable liquid such that each contains 2.5 test doses per millilitre.

Using each toxin solution and the corresponding reference preparation in turn, determine the potency of the antitoxin. Prepare mixtures of the solution of the test toxin and the antitoxin to be examined such that each contains 2.0 ml of the solution of the test toxin, one of a graded series of volumes of the antitoxin to be examined, and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Also prepare mixtures of the solution of the test toxin and the solution of the reference preparation such that each contains 2.0 ml of the solution of the test toxin, one of a graded series of volumes of the solution of the reference preparation centred on that volume (2.0 ml) that contains 0.5 IU, and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature, protected from light, for 60 min. Using four mice for each mixture, inject a dose of 1.0 ml intraperitoneally into each mouse. Observe the mice for 96 h.

The mixture that contains the largest volume of antitoxin that fails to protect the mice from death contains 0.5 IU. This quantity is used to calculate the potency of the antitoxin in International Units per millilitre.

The test is not valid unless all the mice injected with mixtures containing 2.0 ml or less of the solution of the reference preparation die and all those injected with mixtures containing more survive.

LABELLING

The label states the types of *Cl. botulinum* toxin neutralised by the preparation.

01/2008:0086

DIPHTHERIA ANTITOXIN

Immunoserum diphthericum

DEFINITION

Diphtheria antitoxin is a preparation containing antitoxic globulins that have the power of specifically neutralising the toxin formed by *Corynebacterium diphtheriae*.

PRODUCTION

It is obtained by fractionation from the serum of horses, or other mammals, that have been immunised against diphtheria toxin.

IDENTIFICATION

It specifically neutralises the toxin formed by *C. diphtheriae*, rendering it harmless to susceptible animals.

ASSAY

Not less than 1000 IU of antitoxin per millilitre for antitoxin obtained from horse serum. Not less than 500 IU of antitoxin per millilitre for antitoxin obtained from the serum of other mammals.

The potency of diphtheria antitoxin is determined by comparing the dose necessary to protect guinea-pigs or rabbits against the erythrogenic effects of a fixed dose of diphtheria toxin with the quantity of the standard preparation of diphtheria antitoxin necessary to give the same protection. For this comparison a reference preparation of diphtheria antitoxin, calibrated in International Units, and a suitable preparation of diphtheria toxin, for use as a test toxin, are required. The potency of the test toxin is determined in relation to the reference preparation; the potency of the diphtheria antitoxin to be examined is determined in relation to the potency of the test toxin by the same method.

The International Unit of antitoxin is the specific neutralising activity for diphtheria toxin contained in a stated amount of the International Standard, which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Preparation of test toxin. Prepare diphtheria toxin from cultures of *C. diphtheriae* in a liquid medium. Filter the culture to obtain a sterile toxic filtrate and store at 4 °C.

Selection of test toxin. Select a toxin for use as a test toxin by determining for guinea-pigs or rabbits the lr/100 dose and the minimal reacting dose, the observation period being 48 h. The test toxin has at least 200 minimal reacting doses in the lr/100 dose.

Minimal reacting dose. This is the smallest quantity of toxin which, when injected intracutaneously into guinea-pigs or rabbits, causes a small, characteristic reaction at the site of injection within 48 h.

The test toxin is allowed to stand for some months before being used for the assay of antitoxin. During this time its toxicity declines and the lr/100 dose may be increased. Determine the minimal reacting dose and the lr/100 dose at frequent intervals. When experiment shows that the lr/100 dose is constant, the test toxin is ready for use and may be used for a long period. Store the test toxin in the dark at 0 °C to 5 °C. Maintain its sterility by the addition of toluene or other antimicrobial preservative that does not cause a rapid decline in specific toxicity.

Determination of test dose of toxin (lr/100 dose). Prepare a solution of the reference preparation in a suitable liquid such that it contains 0.1 IU of antitoxin per millilitre.

Prepare mixtures of the solution of the reference preparation and of the test toxin such that each contains 1.0 ml of the solution of the reference preparation, one of a graded series of volumes of the test toxin and sufficient of a suitable liquid to bring the total volume to 2.0 ml. Allow the mixtures to stand at room temperature, protected from light, for 15 min to 60 min. Using two animals for each mixture, inject a dose of 0.2 ml intracutaneously into the shaven or depilated flanks of each animal. Observe the animals for 48 h.

The test dose of toxin is the quantity in 0.2 ml of the mixture made with the smallest amount of toxin capable of causing, despite partial neutralisation by the reference preparation, a small but characteristic erythematous lesion at the site of injection.

Determination of potency of the antitoxin. Prepare a solution of the reference preparation in a suitable liquid such that it contains 0.125 IU of antitoxin per millilitre.

Prepare a solution of the test toxin in a suitable liquid such that it contains 12.5 test doses per millilitre.

Prepare mixtures of the solution of the test toxin and of the antitoxin to be examined such that each contains 0.8 ml of the solution of the test toxin, one of a graded series of volumes of the antitoxin to be examined and sufficient of a suitable liquid to bring the total volume to 2.0 ml. Also prepare mixtures of the solution of the test toxin and the solution of the reference preparation such that each contains 0.8 ml of the solution of the test toxin, one of a graded series of volumes of the solution of the reference preparation centred on that volume (0.8 ml) that contains 0.1 IU and sufficient of a suitable liquid to bring the total volume to 2.0 ml. Allow the mixtures to stand at room temperature, protected from light, for 15 min to 60 min. Using two animals for each mixture, inject a dose of 0.2 ml intracutaneously into the shaven or depilated flanks of each animal. Observe the animals for 48 h.

The mixture that contains the largest volume of antitoxin that fails to protect the guinea-pigs from the erythematous effects of the toxin contains 0.1 IU. This quantity is used to calculate the potency of the antitoxin in International Units per millilitre.

The test is not valid unless all the sites injected with mixtures containing 0.8 ml or less of the solution of the reference preparation show erythematous lesions and at all those injected with mixtures containing more there are no lesions.

01/2008:0090

GAS-GANGRENE ANTITOXIN, MIXED

Immunoserum gangraenicum mixtum

DEFINITION

Mixed gas-gangrene antitoxin is prepared by mixing gas-gangrene antitoxin (novyi), gas-gangrene antitoxin (perfringens) and gas-gangrene antitoxin (septicum) in appropriate quantities.

IDENTIFICATION

It specifically neutralises the alpha toxins formed by *Clostridium novyi* (former nomenclature: *Clostridium oedematiens*), *Clostridium perfringens* and *Clostridium septicum*, rendering them harmless to susceptible animals.

ASSAY

Gas-gangrene antitoxin (novyi), not less than 1000 IU of antitoxin per millilitre; gas-gangrene antitoxin (perfringens), not less than 1000 IU of antitoxin per millilitre; gas-gangrene antitoxin (septicum) not less than 500 IU of antitoxin per millilitre.

Carry out the assay for each component, as prescribed in the monographs on *Gas-gangrene antitoxin (novyi) (0087)*, *Gas-gangrene antitoxin (perfringens) (0088)* and *Gas-gangrene antitoxin (septicum) (0089)*.

01/2008:0087

GAS-GANGRENE ANTITOXIN (NOVYI)

Immunoserum gangraenicum (Clostridium novyi)

DEFINITION

Gas-gangrene antitoxin (novyi) is a preparation containing antitoxic globulins that have the power of neutralising the alpha toxin formed by *Clostridium novyi* (Former

nomenclature: *Clostridium oedematiens*). It is obtained by fractionation from the serum of horses, or other mammals, that have been immunised against *Cl. novyi* alpha toxin.

IDENTIFICATION

It specifically neutralises the alpha toxin formed by *Cl. novyi*, rendering it harmless to susceptible animals.

ASSAY

Not less than 3750 IU of antitoxin per millilitre.

The potency of gas-gangrene antitoxin (novyi) is determined by comparing the dose necessary to protect mice or other suitable animals against the lethal effects of a fixed dose of *Cl. novyi* toxin with the quantity of the standard preparation of gas-gangrene antitoxin (novyi) necessary to give the same protection. For this comparison a reference preparation of gas-gangrene antitoxin (novyi), calibrated in International Units, and a suitable preparation of *Cl. novyi* toxin for use as a test toxin are required. The potency of the test toxin is determined in relation to the reference preparation; the potency of the gas-gangrene antitoxin (novyi) to be examined is determined in relation to the potency of the test toxin by the same method.

The International Unit of antitoxin is the specific neutralising activity for *Cl. novyi* toxin contained in a stated amount of the International Standard, which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Selection of animals. Use mice having body masses such that the difference between the lightest and the heaviest does not exceed 5 g.

Preparation of test toxin. Prepare the test toxin from a sterile filtrate of an approximately 5-day culture in liquid medium of *Cl. novyi*. Treat the filtrate with *ammonium sulphate R*, collect the precipitate, which contains the toxin, dry *in vacuo* over *diphosphorus pentoxide R*, powder and store dry.

Selection of test toxin. Select a toxin for use as a test toxin by determining for mice the L+ dose and the LD_{50}, the observation period being 72 h. The test toxin has an L+ dose of 0.5 mg or less and contains not less than 25 LD_{50} in each L+ dose.

Determination of test dose of toxin (L+ dose). Prepare a solution of the reference preparation in a suitable liquid such that it contains 12.5 IU of antitoxin per millilitre.

Prepare a solution of the test toxin in a suitable liquid such that 1 ml contains a precisely known amount such as 10 mg.

Prepare mixtures of the solution of the reference preparation and the solution of the test toxin such that each contains 0.8 ml of the solution of the reference preparation, one of a graded series of volumes of the solution of the test toxin and sufficient of a suitable liquid to bring the total volume to 2.0 ml. Allow the mixtures to stand at room temperature, protected from light, for 60 min. Using six mice for each mixture, inject a dose of 0.2 ml intramuscularly into each mouse. Observe the mice for 72 h.

The test dose of toxin is the quantity in 0.2 ml of the mixture made with the smallest amount of toxin capable of causing, despite partial neutralisation by the reference preparation, the death of all six mice injected with the mixture within the observation period.

Determination of potency of the antitoxin. Prepare a solution of the reference preparation in a suitable liquid such that it contains 12.5 IU of antitoxin per millilitre.

Prepare a solution of the test toxin in a suitable liquid such that it contains 12.5 test doses per millilitre.

Prepare mixtures of the solution of the test toxin and the antitoxin to be examined such that each contains 0.8 ml of the solution of the test toxin, one of a graded series of volumes of the antitoxin to be examined and sufficient of a suitable liquid to bring the total volume to 2.0 ml. Also prepare mixtures of the solution of the test toxin and the solution of the reference preparation such that each contains 0.8 ml of the solution of the test toxin, one of a graded series of volumes of the solution of the reference preparation centred on that volume (0.8 ml) that contains 10 IU and sufficient of a suitable liquid to bring the total volume to 2.0 ml. Allow the mixtures to stand at room temperature, protected from light, for 60 min. Using six mice for each mixture, inject a dose of 0.2 ml intramuscularly into each mouse. Observe the mice for 72 h.

The mixture that contains the largest volume of antitoxin that fails to protect the mice from death contains 10 IU. This quantity is used to calculate the potency of the antitoxin in International Units per millilitre.

The test is not valid unless all the mice injected with mixtures containing 0.8 ml or less of the solution of the reference preparation die and all those injected with mixtures containing a larger volume survive.

01/2008:0088

GAS-GANGRENE ANTITOXIN (PERFRINGENS)

Immunoserum gangraenicum (Clostridium perfringens)

DEFINITION

Gas-gangrene antitoxin (perfringens) is a preparation containing antitoxic globulins that have the power of specifically neutralising the alpha toxin formed by *Clostridium perfringens*. It is obtained by fractionation from the serum of horses, or other mammals, that have been immunised against *Cl. perfringens* alpha toxin.

IDENTIFICATION

It specifically neutralises the alpha toxin formed by *Cl. perfringens*, rendering it harmless to susceptible animals.

ASSAY

Not less than 1500 IU of antitoxin per millilitre.

The potency of gas-gangrene antitoxin (perfringens) is determined by comparing the dose necessary to protect mice or other suitable animals against the lethal effects of a fixed dose of *Cl. perfringens* toxin with the quantity of the standard preparation of gas-gangrene antitoxin (perfringens) necessary to give the same protection. For this comparison a reference preparation of gas-gangrene antitoxin (perfringens), calibrated in International Units, and a suitable preparation of *Cl. perfringens* toxin for use as a test toxin are required. The potency of the test toxin is determined in relation to the reference preparation; the potency of the gas-gangrene antitoxin (perfringens) to be examined is determined in relation to the potency of the test toxin by the same method.

The International Unit of antitoxin is the specific neutralising activity for *Cl. perfringens* toxin contained in a stated amount of the International Standard, which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Selection of animals. Use mice having body masses such that the difference between the lightest and the heaviest does not exceed 5 g.

Preparation of test toxin. Prepare the test toxin from a sterile filtrate of an approximately 5-day culture in liquid medium of *Cl. perfringens.* Treat the filtrate with *ammonium sulphate R,* collect the precipitate, which contains the toxin, dry *in vacuo* over *diphosphorus pentoxide R,* powder and store dry.

Selection of test toxin. Select a toxin for use as a test toxin by determining for mice the L+ dose and the LD_{50}, the observation period being 48 h. The test toxin has an L+ dose of 4 mg or less and contains not less than 20 LD_{50} in each L+ dose.

Determination of test dose of toxin (L+ dose). Prepare a solution of the reference preparation in a suitable liquid such that it contains 5 IU of antitoxin per millilitre.

Prepare a solution of the test toxin in a suitable liquid such that 1 ml contains a precisely known amount such as 10 mg.

Prepare mixtures of the solution of the reference preparation and the solution of the test toxin such that each contains 2.0 ml of the solution of the reference preparation, one of a graded series of volumes of the solution of the test toxin and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature, protected from light, for 60 min. Using six mice for each mixture, inject a dose of 0.5 ml intravenously into each mouse. Observe the mice for 48 h.

The test dose of toxin is the quantity in 0.5 ml of the mixture made with the smallest amount of toxin capable of causing, despite partial neutralisation by the reference preparation, the death of all six mice injected with the mixture within the observation period.

Determination of potency of the antitoxin. Prepare a solution of the reference preparation in a suitable liquid such that it contains 5 IU of antitoxin per millilitre.

Prepare a solution of the test toxin in a suitable liquid such that it contains five test doses per millilitre.

Prepare mixtures of the solution of the test toxin and the antitoxin to be examined such that each contains 2.0 ml of the solution of the test toxin, one of a graded series of volumes of the antitoxin to be examined and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Also prepare mixtures of the solution of the test toxin and the solution of the reference preparation such that each contains 2.0 ml of the solution of the test toxin, one of a graded series of volumes of the solution of the reference preparation centred on that volume (2.0 ml) that contains 10 IU and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature, protected from light, for 60 min. Using six mice for each mixture, inject a dose of 0.5 ml intravenously into each mouse. Observe the mice for 48 h.

The mixture that contains the largest volume of antitoxin that fails to protect the mice from death contains 10 IU. This quantity is used to calculate the potency of the antitoxin in International Units per millilitre.

The test is not valid unless all the mice injected with mixtures containing 2.0 ml or less of the solution of the reference preparation die and all those injected with mixtures containing a larger volume survive.

01/2008:0089

GAS-GANGRENE ANTITOXIN (SEPTICUM)

Immunoserum gangraenicum (Clostridium septicum)

DEFINITION

Gas-gangrene antitoxin (septicum) is a preparation containing antitoxic globulins that have the power of specifically neutralising the alpha toxin formed by *Clostridium septicum.* It is obtained by fractionation from the serum of horses, or other mammals, that have been immunised against *Cl. septicum* alpha toxin.

IDENTIFICATION

It specifically neutralises the alpha toxin formed by *Cl. septicum,* rendering it harmless to susceptible animals.

ASSAY

Not less than 1500 IU of antitoxin per millilitre.

The potency of gas-gangrene antitoxin (septicum) is determined by comparing the dose necessary to protect mice or other suitable animals against the lethal effects of a fixed dose of *Cl. septicum* toxin with the quantity of the standard preparation of gas-gangrene antitoxin (septicum) necessary to give the same protection. For this comparison a reference preparation of gas-gangrene antitoxin (septicum), calibrated in International Units, and a suitable preparation of *Cl. septicum* toxin for use as a test toxin are required. The potency of the test toxin is determined in relation to the reference preparation; the potency of the gas-gangrene antitoxin (septicum) to be examined is determined in relation to the potency of the test toxin by the same method.

The International Unit of antitoxin is the specific neutralising activity for *Cl. septicum* toxin contained in a stated amount of the International Standard, which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Selection of animals. Use mice having body masses such that the difference between the lightest and the heaviest does not exceed 5 g.

Preparation of test toxin. Prepare the test toxin from a sterile filtrate of an approximately 5-day culture in liquid medium of *Cl. septicum.* Treat the filtrate with *ammonium sulphate R,* collect the precipitate, which contains the toxin, dry *in vacuo* over *diphosphorus pentoxide R,* powder and store dry.

Selection of test toxin. Select a toxin for use as a test toxin by determining for mice the L+ dose and the LD_{50}, the observation period being 72 h. The test toxin has an L+ dose of 0.5 mg or less and contains not less than 25 LD_{50} in each L+ dose.

Determination of test dose of toxin (L+ dose). Prepare a solution of the reference preparation in a suitable liquid such that it contains 5 IU of antitoxin per millilitre.

Prepare a solution of the test toxin in a suitable liquid such that 1 ml contains a precisely known amount such as 20 mg.

Prepare mixtures of the solution of the reference preparation and the solution of the test toxin such that each contains 2.0 ml of the solution of the reference preparation, one of a graded series of volumes of the solution of the test toxin and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature,

protected from light, for 60 min. Using six mice for each mixture, inject a dose of 0.5 ml intravenously into each mouse. Observe the mice for 72 h.

The test dose of toxin is the quantity in 0.5 ml of the mixture made with the smallest amount of toxin capable of causing, despite partial neutralisation by the reference preparation, the death of all six mice injected with the mixture within the observation period.

Determination of potency of the antitoxin. Prepare a solution of the reference preparation in a suitable liquid such that it contains 5 IU of antitoxin per millilitre.

Prepare a solution of the test toxin in a suitable liquid such that it contains five test doses per millilitre.

Prepare mixtures of the solution of the test toxin and the antitoxin to be examined such that each contains 2.0 ml of the solution of the test toxin, one of a graded series of volumes of the antitoxin to be examined and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Also prepare mixtures of the solution of the test toxin and the solution of the reference preparation such that each contains 2.0 ml of the solution of the test toxin, one of a graded series of volumes of the solution of the reference preparation centred on that volume (2.0 ml) that contains 10 IU and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature, protected from light, for 60 min. Using six mice for each mixture, inject a dose of 0.5 ml intravenously into each mouse. Observe the mice for 72 h.

The mixture that contains the largest volume of antitoxin that fails to protect the mice from death contains 10 IU. This quantity is used to calculate the potency of the antitoxin in International Units per millilitre.

The test is not valid unless all the mice injected with mixtures containing 2.0 ml or less of the solution of the reference preparation die and all those injected with mixtures containing more survive.

01/2008:0091

TETANUS ANTITOXIN FOR HUMAN USE

Immunoserum tetanicum ad usum humanum

DEFINITION

Tetanus antitoxin for human use is a preparation containing antitoxic globulins that have the power of specifically neutralising the toxin formed by *Clostridium tetani*.

PRODUCTION

It is obtained by fractionation from the serum of horses, or other mammals, that have been immunised against tetanus toxin.

IDENTIFICATION

It specifically neutralises the toxin formed by *Cl. tetani*, rendering it harmless to susceptible animals.

POTENCY

Not less than 1000 IU of antitoxin per millilitre when intended for prophylactic use. Not less than 3000 IU of antitoxin per millilitre when intended for therapeutic use.

The potency of tetanus antitoxin is determined by comparing the dose necessary to protect guinea-pigs or mice against the paralytic effects of a fixed dose of tetanus toxin with the quantity of the standard preparation of tetanus antitoxin necessary to give the same protection. In countries where the paralysis method is not obligatory the lethal method may be used. For this method the number of animals and the procedure are identical with those described for the paralysis method but the end-point is the death of the animal rather than the onset of paralysis and the L+/10 dose is used instead of the Lp/10 dose. For this comparison a reference preparation of tetanus antitoxin, calibrated in International Units, and a suitable preparation of tetanus toxin, for use as a test toxin, are required. The potency of the test toxin is determined in relation to the reference preparation; the potency of the tetanus antitoxin to be examined is determined in relation to the potency of the test toxin by the same method.

The International Unit of antitoxin is the specific neutralising activity for tetanus toxin contained in a stated amount of the International Standard which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

Selection of animals. If mice are used, the body masses should be such that the difference between the lightest and the heaviest does not exceed 5 g.

Preparation of test toxin. Prepare the test toxin from a sterile filtrate of an approximately 9-day culture in liquid medium of *Cl. tetani*. To the filtrate add 1 to 2 volumes of glycerol and store slightly below 0 °C. Alternatively, treat the filtrate with *ammonium sulphate R*, collect the precipitate, which contains the toxin, dry *in vacuo* over *diphosphorus pentoxide R*, powder and store dry, either in sealed ampoules or *in vacuo* over *diphosphorus pentoxide R*.

Determination of test dose of toxin (Lp/10 dose). Prepare a solution of the reference preparation in a suitable liquid such that it contains 0.5 IU of antitoxin per millilitre.

If the test toxin is stored dry, reconstitute it using a suitable liquid.

Prepare mixtures of the solution of the reference preparation and the test toxin such that each contains 2.0 ml of the solution of the reference preparation, one of a graded series of volumes of the test toxin and sufficient of a suitable liquid to bring the volume to 5.0 ml. Allow the mixtures to stand at room temperature, protected from light, for 60 min. Using six mice for each mixture, inject a dose of 0.5 ml subcutaneously into each mouse. Observe the mice for 96 h. Mice that become paralysed may be euthanised.

The test dose of toxin is the quantity in 0.5 ml of the mixture made with the smallest amount of toxin capable of causing, despite partial neutralisation by the reference preparation, paralysis in all six mice injected with the mixture within the observation period.

Determination of potency of the antitoxin. Prepare a solution of the reference preparation in a suitable liquid such that it contains 0.5 IU of antitoxin per millilitre.

Prepare a solution of the test toxin in a suitable liquid such that it contains five test doses per millilitre.

Prepare mixtures of the solution of the test toxin and the antitoxin to be examined such that each contains 2.0 ml of the solution of the test toxin, one of a graded series of volumes of the antitoxin to be examined and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Also prepare mixtures of the solution of the test toxin and the solution of the reference preparation such that each contains 2.0 ml of the solution of the test toxin, one of a graded series of volumes of the solution of the reference preparation centred on that volume (2.0 ml) that contains 1 IU and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature,

protected from light, for 60 min. Using six mice for each mixture, inject into each mouse subcutaneously a dose of 0.5 ml. Observe the mice for 96 h. Mice that become paralysed may be euthanised.

The mixture that contains the largest volume of antitoxin that fails to protect the mice from paralysis contains 1 IU. This quantity is used to calculate the potency of the antitoxin in International Units per millilitre.

The test is not valid unless all the mice injected with mixtures containing 2.0 ml or less of the solution of the reference preparation show paralysis and all those injected with mixtures containing more do not.

01/2008:0145

VIPER VENOM ANTISERUM, EUROPEAN

Immunoserum contra venena viperarum europaearum

DEFINITION

European viper venom antiserum is a preparation containing antitoxic globulins that have the power of neutralising the venom of one or more species of viper. The globulins are obtained by fractionation of the serum of animals that have been immunised against the venom or venoms.

IDENTIFICATION

It neutralises the venom of *Vipera ammodytes*, or *Vipera aspis*, or *Vipera berus*, or *Vipera ursinii* or the mixture of these venoms stated on the label, rendering them harmless to susceptible animals.

ASSAY

Each millilitre of the preparation to be examined contains sufficient antitoxic globulins to neutralise not less than 100 mouse LD_{50} of *Vipera ammodytes* venom or *Vipera aspis* venom and not less than 50 mouse LD_{50} of the venoms of other species of viper.

The potency of European viper venom antiserum is determined by estimating the dose necessary to protect mice against the lethal effects of a fixed dose of venom of the relevant species of viper.

Selection of test venoms. Use venoms which have the normal physicochemical, toxicological and immunological characteristics of venoms from the particular species of vipers. They are preferably freeze-dried and stored in the dark at 5 ± 3 °C.

Select a venom for use as a test venom by determining the LD_{50} for mice, the observation period being 48 h.

Determination of the test dose of venom. Prepare graded dilutions of the reconstituted venom in a 9 g/l solution of *sodium chloride R* or other isotonic diluent in such a manner that the middle dilution contains in 0.25 ml the dose expected to be the LD_{50}. Dilute with an equal volume of the same diluent. Using at least four mice, each weighing 18 g to 20 g, for each dilution, inject 0.5 ml intravenously into each mouse. Observe the mice for 48 h and record the number of deaths. Calculate the LD_{50} using the usual statistical methods.

Determination of the potency of the antiserum to be examined. Dilute the reconstituted test venom so that 0.25 ml contains the test dose of 5 LD_{50} (test venom solution).

Prepare serial dilutions of the antiserum to be examined in a 9 g/l solution of *sodium chloride R* or other isotonic diluent, the dilution factor being 1.5 to 2.5. Use a sufficient number and range of dilutions to enable a mortality curve between 20 per cent and 80 per cent mortality to be established and to permit an estimation of the statistical variation.

Prepare mixtures such that 5 ml of each mixture contains 2.5 ml of one of the dilutions of the antiserum to be examined and 2.5 ml of the test venom solution. Allow the mixtures to stand in a water-bath at 37 °C for 30 min. Using not fewer than six mice, each weighing 18 g to 20 g, for each mixture, inject 0.5 ml intravenously into each mouse. Observe the mice for 48 h and record the number of deaths. Calculate the PD_{50}, using the usual statistical methods. At the same time verify the number of LD_{50} in the test dose of venom, using the method described above. Calculate the potency of the antiserum from the expression:

$$\frac{(T_v - 1)}{\mathrm{PD}_{50}}$$

T_v = number of LD_{50} in the test dose of venom.

In each mouse dose of the venom-antiserum mixture at the end point there is one LD_{50} of venom remaining unneutralised by the antiserum and it is this unneutralised venom that is responsible for the deaths of 50 per cent of the mice inoculated with the mixture. The amount of venom neutralised by the antiserum is thus one LD_{50} less than the total amount contained in each mouse dose. Therefore, as the potency of the antiserum is defined in terms of the number of LD_{50} of venom that are neutralised. rather than the number of LD_{50} in each mouse dose, the expression required in the calculation of potency is $T_v - 1$ rather than T_v. Alternatively, the quantity of test venom in milligrams that is neutralised by 1 ml or some other defined volume of the antiserum to be examined may be calculated.

LABELLING

The label states the venom or venoms against which the antiserum is effective.

Warning: Because of the allergenic properties of viper venoms, inhalation of venom dust should be avoided by suitable precautions.

CLOSTRIDIUM NOVYI ALPHA ANTITOXIN FOR VETERINARY USE

Immunoserum Clostridii novyi alpha ad usum veterinarium

DEFINITION

Clostridium novyi alpha antitoxin for veterinary use is a preparation containing the globulins that have the power of specifically neutralising the alpha toxin formed by *Clostridium novyi*. It consists of the serum or a preparation obtained from the serum of animals immunised against *C. novyi* alpha toxin.

PRODUCTION

CHOICE OF COMPOSITION

The antitoxin is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*). For the latter, it shall be demonstrated, for each target species, that the product, when administered at the minimum recommended dose and according to the recommended schedule(s), provides a response or responses consistent with the claims made for the product.

Batch potency test. The test described under Potency is not necessarily carried out for routine testing of batches of antitoxin. It is carried out on 1 or more occasions as decided by or with the agreement of the competent authority. Where the test is not carried out, a suitable validated alternative test is carried out, the criteria for acceptance being set with reference to a batch of antitoxin that has given satisfactory results in the test described under Potency and that has been shown to be satisfactory with respect to immunogenicity in the target species. The following test may be used after a satisfactory correlation with the test described under Potency has been established.

Determine the level of antibodies against *C. novyi* alpha toxin in the batch of antitoxin using a suitable method such as an immunochemical method (*2.7.1*) or neutralisation in cell cultures. Use a homologous reference serum calibrated in International Units of Clostridium novyi alpha antitoxin.

The International Unit is the specific neutralising activity for *C. novyi* alpha toxin contained in a stated amount of the International Standard, which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

The potency of the finished product is expressed in International Units per millilitre and is shown to be not less than the minimum number stated on the label.

IDENTIFICATION

The antitoxin is shown, by a suitable immunochemical method (*2.7.1*), to react specifically with the alpha toxin formed by *C. novyi*.

POTENCY

The potency of Clostridium novyi alpha antitoxin is determined by comparing the dose necessary to protect mice or other suitable animals against the toxic effects of a fixed dose of *C. novyi* alpha toxin with the quantity of a reference preparation of Clostridium novyi alpha antitoxin, calibrated in International Units, necessary to give the same protection. For this comparison, a suitable preparation of *C. novyi* alpha toxin for use as a test toxin is required. The dose of the test toxin is determined in relation to the reference preparation; the potency of the antitoxin to be examined is determined in relation to the reference preparation using the test toxin.

Preparation of test toxin. Prepare the test toxin from a sterile filtrate of an approximately 5-day culture in liquid medium of *C. novyi* type B and dry by a suitable method. Select the test toxin by determining for mice the L+/10 dose and the LD_{50}, the observation period being 72 h. A suitable alpha toxin contains not less than one L+/10 dose in 0.05 mg and not less than 10 LD_{50} in each L+/10 dose.

Determination of test dose of toxin. Prepare a solution of the reference preparation in a suitable liquid so that it contains 1 IU/ml. Prepare a solution of the test toxin in a suitable liquid so that 1 ml contains a precisely known amount such as 1 mg. Prepare mixtures of the solution of the reference preparation and the solution of the test toxin such that each mixture contains 1.0 ml of the solution of the reference preparation (1 IU), one of a series of graded volumes of the solution of the test toxin and sufficient of a suitable liquid to bring the total volume to 2.0 ml. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 mice, each weighing 17-22 g, for each mixture, inject a dose of 0.2 ml intramuscularly or subcutaneously into each mouse. Observe the mice for 72 h. If all the mice die, the amount of toxin present in 0.2 ml of the mixture is in excess of the test dose. If none of the mice die, the amount of toxin present in 0.2 ml of the mixture is less than the test dose. Prepare similar fresh mixtures such that 2.0 ml of each mixture contains 1.0 ml of the solution of the reference preparation (1 IU) and 1 of a series of graded volumes of the solution of the test toxin separated from each other by steps of not more than 20 per cent and covering the expected end-point. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 mice for each mixture, inject a dose of 0.2 ml intramuscularly or subcutaneously into each mouse. Observe the mice for 72 h. Repeat the determination at least once and combine the results of the separate tests that have been carried out with mixtures of the same composition so that a series of totals is obtained, each total representing the mortality due to a mixture of a given composition. The test dose of toxin is the amount present in 0.2 ml of that mixture which causes the death of one half of the total number of mice injected with it.

Determination of the potency of the antitoxin to be examined

Preliminary test. Dissolve a quantity of the test toxin in a suitable liquid so that 1 ml contains 10 times the test dose (solution of the test toxin). Prepare mixtures of the solution of the test toxin and of the antitoxin to be examined such that each mixture contains 1.0 ml of the solution of the test toxin, one of a series of graded volumes of the antitoxin to be examined and sufficient of a suitable liquid to bring the final volume to 2.0 ml. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 mice for each mixture, inject a dose of 0.2 ml intramuscularly or subcutaneously into each mouse. Observe the mice for 72 h. If none of the mice die, 0.2 ml of the mixture contains more than 0.1 IU. If all the mice die, 0.2 ml of the mixture contains less than 0.1 IU.

Final test. Prepare mixtures of the solution of the test toxin and of the antitoxin to be examined such that 2.0 ml of each mixture contains 1.0 ml of the solution of the test toxin and one of a series of graded volumes of the antitoxin to be examined, separated from each other by steps of not more than 20 per cent and covering the expected end-point as determined by the preliminary test. Prepare further mixtures such that 2.0 ml of each mixture contains 1.0 ml of the solution of the test toxin and one of a series of graded

volumes of the solution of the reference preparation, in order to confirm the test dose of the toxin. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 mice for each mixture, proceed as described in the preliminary test. The test mixture which contains 0.1 IU in 0.2 ml is that mixture which kills the same or almost the same number of mice as the reference mixture containing 0.1 IU in 0.2 ml. Repeat the determination at least once and calculate the average of all valid estimates. Estimates are valid only if the reference preparation gives a result within 20 per cent of the expected value.

The confidence limits (P = 0.95) have been estimated to be:

- 85 per cent and 114 per cent when 2 animals per dose are used,
- 91.5 per cent and 109 per cent when 4 animals per dose are used,
- 93 per cent and 108 per cent when 6 animals per dose are used.

The potency of the finished product is expressed in International Units per millilitre and is shown to be not less than the minimum number stated on the label.

CLOSTRIDIUM PERFRINGENS BETA ANTITOXIN FOR VETERINARY USE

Immunoserum Clostridii perfringentis beta ad usum veterinarium

DEFINITION

Clostridium perfringens beta antitoxin for veterinary use is a preparation containing principally the globulins that have the power of specifically neutralising the beta toxin formed by *Clostridium perfringens* (types B and C). It consists of the serum or a preparation obtained from the serum of animals immunised against *C. perfringens* beta toxin.

PRODUCTION

CHOICE OF COMPOSITION

The antitoxin is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*). For the latter, it shall be demonstrated, for each target species, that the product, when administered at the minimum recommended dose and according to the recommended schedule(s), provides a response or responses consistent with the claims made for the product.

Batch potency test. The test described under Potency is not necessarily carried out for routine testing of batches of antitoxin. It is carried out on 1 or more occasions as decided by or with the agreement of the competent authority. Where the test is not carried out, a suitable validated alternative test is carried out, the criteria for acceptance being set with reference to a batch of antitoxin that has given satisfactory results in the test described under Potency and that has been shown to be satisfactory with respect to immunogenicity in the target species. The following test may be used after a satisfactory correlation with the test described under Potency has been established.

Determine the level of antibodies against *C. perfringens* beta toxin in the batch of antitoxin using a suitable method such as an immunochemical method (*2.7.1*) or neutralisation in cell cultures. Use a homologous reference serum calibrated in International Units of Clostridium perfringens beta antitoxin.

The International Unit is the specific neutralising activity for *C. perfringens* beta toxin contained in a stated amount of the International Standard, which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

The potency of the finished product is expressed in International Units per millilitre and is shown to be not less than the minimum number stated on the label.

IDENTIFICATION

The antitoxin is shown, by a suitable immunochemical method (*2.7.1*), to react specifically with the beta toxin formed by *C. perfringens*.

POTENCY

The potency of Clostridium perfringens beta antitoxin is determined by comparing the dose necessary to protect mice or other suitable animals against the toxic effects of a fixed dose of *C. perfringens* beta toxin with the quantity of a reference preparation of Clostridium perfringens beta antitoxin, calibrated in International Units, necessary to give the same protection. For this comparison, a suitable preparation of *C. perfringens* beta toxin for use as a test toxin is required. The dose of the test toxin is determined in relation to the reference preparation; the potency of the antitoxin to be examined is determined in relation to the reference preparation using the test toxin.

Preparation of test toxin. Prepare the test toxin from a sterile filtrate of an early culture in liquid medium of *C. perfringens* type B or type C and dry by a suitable method. Select the test toxin by determining for mice the L+ dose and the LD_{50}, the observation period being 72 h. A suitable beta toxin contains not less than one L+ dose in 0.2 mg and not less than 25 LD_{50} in each L+ dose.

Determination of test dose of toxin. Prepare a solution of the reference preparation in a suitable liquid so that it contains 5 IU/ml. Prepare a solution of the test toxin in a suitable liquid so that 1 ml contains a precisely known amount such as 10 mg. Prepare mixtures of the solution of the reference preparation and the solution of the test toxin such that each mixture contains 2.0 ml of the solution of the reference preparation (10 IU), one of a series of graded volumes of the solution of the test toxin and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than 2 mice, each weighing 17-22 g, for each mixture, inject a dose of 0.5 ml intravenously or intraperitoneally into each mouse. Observe the mice for 72 h. If all the mice die, the amount of toxin present in 0.5 ml of the mixture is in excess of the test dose. If none of the mice die, the amount of toxin present in 0.5 ml of the mixture is less than the test dose. Prepare similar fresh mixtures such that 5.0 ml of each mixture contains 2.0 ml of the solution of the reference preparation (10 IU) and 1 of a series of graded volumes of the solution of the test toxin separated from each other by steps of not more than 20 per cent and covering the expected end-point. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than 2 mice for each mixture, inject a dose of 0.5 ml intravenously or intraperitoneally into each mouse. Observe the mice for 72 h. Repeat the determination at least once and combine the results of the separate tests that have been carried out with mixtures of the same composition so that a series of totals is obtained, each total representing the mortality due to a mixture of

a given composition. The test dose of toxin is the amount present in 0.5 ml of that mixture which causes the death of one half of the total number of mice injected with it.

Determination of the potency of the antitoxin to be examined

Preliminary test. Dissolve a quantity of the test toxin in a suitable liquid so that 2.0 ml contains 10 times the test dose (solution of the test toxin). Prepare mixtures of the solution of the test toxin and of the antitoxin to be examined such that each mixture contains 2.0 ml of the solution of the test toxin, one of a series of graded volumes of the antitoxin to be examined and sufficent of a suitable liquid to bring the final volume to 5.0 ml. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than 2 mice for each mixture, inject a dose of 0.5 ml intravenously or intraperitoneally into each mouse. Observe the mice for 72 h. If none of the mice die, 0.5 ml of the mixture contains more than 1 IU. If all the mice die, 0.5 ml of the mixture contains less than 1 IU.

Final test. Prepare mixtures of the solution of the test toxin and of the antitoxin to be examined such that 5.0 ml of each mixture contains 2.0 ml of the solution of the test toxin and one of a series of graded volumes of the antitoxin to be examined, separated from each other by steps of not more than 20 per cent and covering the expected end-point as determined by the preliminary test. Prepare further mixtures such that 5.0 ml of each mixture contains 2.0 ml of the solution of the test toxin and one of a series of graded volumes of the solution of the reference preparation, in order to confirm the test dose of the toxin. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than 2 mice for each mixture, proceed as described in the preliminary test. The test mixture which contains 1 IU in 0.5 ml is that mixture which kills the same or almost the same number of mice as the reference mixture containing, 1 IU in 0.5 ml. Repeat the determination at least once and calculate the average of all valid estimates. Estimates are valid only if the reference preparation gives a result within 20 per cent of the expected value.

The confidence limits ($P = 0.95$) have been estimated to be:

- 85 per cent and 114 per cent when 2 animals per dose are used,
- 91.5 per cent and 109 per cent when 4 animals per dose are used,
- 93 per cent and 108 per cent when 6 animals per dose are used.

The potency of the finished product is expressed in International Units per millilitre and is shown to be not less than the minimum number stated on the label.

CLOSTRIDIUM PERFRINGENS EPSILON ANTITOXIN FOR VETERINARY USE

Immunoserum Clostridii perfringentis epsilon ad usum veterinarium

DEFINITION

Clostridium perfringens epsilon antitoxin for veterinary use is a preparation containing the globulins that have the power of specifically neutralising the epsilon toxin formed by *Clostridium perfringens* type D. It consists of the serum or a preparation obtained from the serum of animals immunised against *C. perfringens* epsilon toxin.

PRODUCTION

CHOICE OF COMPOSITION

The antitoxin is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*). For the latter, it shall be demonstrated, for each target species, that the product, when administered at the minimum recommended dose and according to the recommended schedule(s), provides a response or responses consistent with the claims made for the product.

Batch potency test. The test described under Potency is not necessarily carried out for routine testing of batches of antitoxin. It is carried out on one or more occasions as decided by or with the agreement of the competent authority. Where the test is not carried out, a suitable validated alternative test is carried out, the criteria for acceptance being set with reference to a batch of antitoxin that has given satisfactory results in the test described under Potency and that has been shown to be satisfactory with respect to immunogenicity in the target species. The following test may be used after a satisfactory correlation with the test described under Potency has been established.

Determine the level of antibodies against *C. perfringens* epsilon toxin in the batch of antitoxin using a suitable method such as an immunochemical method (*2.7.1*) or neutralisation in cell cultures. Use a homologous reference serum calibrated in International Units of Clostridium perfringens epsilon antitoxin.

The International Unit is the specific neutralising activity for *C. perfringens* epsilon toxin contained in a stated amount of the International Standard, which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

The potency of the finished product is expressed in International Units per millilitre and is shown to be not less than the minimum number stated on the label.

IDENTIFICATION

The antitoxin is shown, by a suitable immunochemical method (*2.7.1*), to react specifically with the epsilon toxin formed by *C. perfringens*.

POTENCY

The potency of Clostridium perfringens epsilon antitoxin is determined by comparing the dose necessary to protect mice or other suitable animals against the toxic effects of a fixed dose of *C. perfringens* epsilon toxin with the quantity of a reference preparation of Clostridium perfringens epsilon antitoxin, calibrated in International Units, necessary to give the same protection. For this comparison, a suitable preparation of *C. perfringens* epsilon toxin for use as a test toxin is required. The dose of the test toxin is determined in relation to the reference preparation, the potency of the antitoxin to be examined is determined in relation to the reference preparation using the test toxin.

Preparation of test toxin. Prepare the test toxin from a sterile filtrate of an early culture in liquid medium of *C. perfringens* type D and dry by a suitable method. Select the test toxin by determining for mice the L+/10 dose and the LD_{50}, the observation period being 72 h. A suitable epsilon toxin contains not less than one L+/10 dose in 0.005 mg and not less than 20 LD_{50} in each L+/10 dose.

Determination of test dose of toxin. Prepare a solution of the reference preparation in a suitable liquid so that it contains 0.5 IU/ml. Prepare a solution of the test toxin in a suitable liquid so that 1 ml contains a precisely known amount such as 1 mg. Prepare mixtures of the solution of the reference preparation and the solution of the test toxin such that each mixture contains 2.0 ml of the solution of the reference preparation (1 IU), one of a series of graded volumes of the solution of the test toxin and sufficient of a suitable liquid to bring the total volume to 5.0 ml. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than 2 mice, each weighing 17-22 g, for each mixture, inject a dose of 0.5 ml intravenously or intraperitoneally into each mouse. Observe the mice for 72 h. If all the mice die, the amount of toxin present in 0.5 ml of the mixture is in excess of the test dose. If none of the mice die, the amount of toxin present in 0.5 ml of the mixture is less than the test dose. Prepare similar fresh mixtures such that 5.0 ml of each mixture contains 2.0 ml of the solution of the reference preparation (1 IU) and 1 of a series of graded volumes of the solution of the test toxin, separated from each other by steps of not more than 20 per cent and covering the expected end-point. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than 2 mice for each mixture, inject a dose of 0.5 ml intravenously or intraperitoneally into each mouse. Observe the mice for 72 h. Repeat the determination at least once and combine the results of the separate tests that have been made with mixtures of the same composition so that a series of totals is obtained, each total representing the mortality due to a mixture of a given composition. The test dose of the toxin is the amount present in 0.5 ml of that mixture which causes the death of one half of the total number of mice injected with it.

Determination of the potency of the antitoxin to be examined

Preliminary test. Dissolve a quantity of the test toxin in a suitable liquid so that 2.0 ml contains 10 times the test dose (solution of the test toxin). Prepare mixtures of the solution of the test toxin and of the antitoxin to be examined such that each mixture contains 2.0 ml of the solution of the test toxin, one of a series of graded volumes of the antitoxin to be examined and sufficient of a suitable liquid to bring the final volume to 5.0 ml. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than 2 mice for each mixture, inject a dose of 0.5 ml intravenously or intraperitoneally into each mouse. Observe the mice for 72 h. If none of the mice die, 0.5 ml of the mixture contains more than 0.1 IU. If all the mice die, 0.5 ml of the mixture contains less than 0.1 IU.

Final test. Prepare mixtures of the solution of the test toxin and of the antitoxin to be examined such that 5.0 ml of each mixture contains 2.0 ml of the solution of the test toxin and one of a series of graded volumes of the antitoxin to be examined, separated from each other by steps of not more than 20 per cent and covering the expected end-point as determined by the preliminary test. Prepare further mixtures such that 5.0 ml of each mixture contains 2.0 ml of the solution of the test toxin and one of a series of graded volumes of the solution of the reference preparation to confirm the test dose of the toxin. Allow the mixtures to stand at room temperature for 30 min. Using not fewer than 2 mice for each mixture proceed as described in the preliminary test. The test mixture which contains 0.1 IU in 0.5 ml is that mixture which kills the same or almost the same number of mice as the reference mixture containing 0.1 IU in 0.5 ml. Repeat the determination at least once and calculate the average of all valid estimates. Estimates are valid only if the reference preparation gives a result within 20 per cent of the expected value.

The confidence limits (P = 0.95) have been estimated to be:
- 85 per cent and 114 per cent when 2 animals per dose are used,
- 91.5 per cent and 109 per cent when 4 animals per dose are used,
- 93 per cent and 108 per cent when 6 animals per dose are used.

The potency of the finished product is expressed in International Units per millilitre and is shown to be not less than the minimum number stated on the label.

TETANUS ANTITOXIN FOR VETERINARY USE

Immunoserum tetanicum ad usum veterinarium

DEFINITION

Tetanus antitoxin for veterinary use is a preparation containing principally the globulins that have the power of specifically neutralising the neurotoxin formed by *Clostridium tetani*. It consists of the serum or a preparation obtained from the serum of animals immunised against tetanus toxin.

PRODUCTION

CHOICE OF COMPOSITION

The antitoxin is shown to be satisfactory with respect to safety (*5.2.6*) and efficacy (*5.2.7*). For the latter, it shall be demonstrated, for each target species, that the product, when administered at the minimum recommended dose and according to the recommended schedule(s), provides a response or responses consistent with the claims made for the product. The ability of the product to neutralise the neurotoxin formed by *C. tetani* must also be demonstrated, e.g. by conducting the test in mice as described below.

Demonstration of neurotoxin neutralisation. The ability of tetanus antitoxin to neutralise the neurotoxin of *C. tetani* is determined by establishing the dose necessary to protect mice (or guinea-pigs) against the toxic effects of a fixed dose of tetanus toxin. The test must be conducted in parallel with a test of a reference preparation of tetanus antitoxin, calibrated in International Units, using a quantity expected to give the same protection. The ability of the test antitoxin to neutralise the neurotoxin (potency) can then be expressed in International Units. For this study, a suitable preparation of tetanus toxin for use as a test toxin is required. The dose of the test toxin is determined in relation to the reference preparation; the potency of the antitoxin to be examined is determined in relation to the reference preparation using the test toxin.

Preparation of test toxin. Prepare the test toxin from a sterile filtrate of an 8-10 day culture in liquid medium of *C. tetani*. A test toxin may be prepared by adding this filtrate to *glycerol R* in the proportion of 1 volume of filtrate to 1 to 2 volumes of *glycerol R*. The solution of test toxin may be stored at or slightly below 0 °C. The toxin may also be dried by a suitable method. Select the test toxin by determining for

mice the Lp/10 dose and the paralytic dose 50 per cent. A suitable toxin contains not less than 1000 times the paralytic dose 50 per cent in 1 Lp/10 dose.

Lp/10 dose (Limes paralyticum). This is the smallest quantity of toxin which when mixed with 0.1 IU of antitoxin and injected subcutaneously into mice (or guinea-pigs) causes tetanic paralysis in the animals on or before the 4th day after injection.

Paralytic dose 50 per cent. This is the quantity of toxin which when injected subcutaneously into mice (or guinea-pigs) causes tetanic paralysis in one half of the animals on or before the 4th day after injection.

Determination of test dose of toxin. Reconstitute or dilute the reference preparation with a suitable liquid so that it contains 0.5 IU/ml. Measure or weigh a quantity of the test toxin and dilute with or dissolve in a suitable liquid. Prepare mixtures of the solution of the reference preparation and the solution of the test toxin so that each mixture will contain 0.1 IU of antitoxin in the volume chosen for injection and one of a series of graded volumes of the solution of the test toxin, separated from each other by steps of not more than 20 per cent and covering the expected end-point. Adjust each mixture with a suitable liquid to the same final volume (0.4 ml to 0.6 ml if mice are used for the test or 4.0 ml if guinea-pigs are used). Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 animals for each mixture, inject the chosen volume subcutaneously into each animal. Observe the animals for 96 h and make daily records of the degree of tetanus developing in each group of animals. Repeat the test at least once and calculate the test dose as the mean of the different tests. The test dose of the toxin is the amount present in that mixture which causes tetanic paralysis in one half of the total number of animals injected with it.

Determination of the neutralising ability of the antitoxin to be examined

Preliminary test. Measure or weigh a quantity of the test toxin and dilute with or dissolve in a suitable liquid so that the solution contains 5 test doses per millilitre (solution of the test toxin). Prepare mixtures of the solution of the test toxin and of the antitoxin to be examined so that for each mixture the volume chosen for injection contains the test dose of toxin and one of a series of graded volumes of the antitoxin to be examined. Adjust each mixture to the same final volume with a suitable liquid. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 animals for each mixture, inject the chosen volume subcutaneously into each animal. Observe the animals for 96 h and make daily records of the degree of tetanus developing in each group of animals. Using the results, select suitable mixtures for the final test.

Final test. Prepare mixtures of the solution of the test toxin and of the antitoxin to be examined so that for each mixture the volume chosen for the injection contains the test dose of toxin and one of a series of graded volumes of the antitoxin to be examined, separated from each other by steps of not more than 20 per cent and covering the expected end-point as determined in the preliminary test. Prepare further mixtures with the same amount of test toxin and graded volumes of the reference preparation, centred on 0.1 IU in the volume chosen for injection, to confirm the test dose of the toxin. Adjust each mixture to the same final volume with a suitable liquid. Allow the mixtures to stand at room temperature for 60 min. Using not fewer than 2 animals for each mixture, inject the chosen volume subcutaneously into each animal. Observe the animals for 96 h and make daily records of the degree of tetanus developing in each group of animals. The test mixture which contains 0.1 IU in the volume injected is that mixture which causes tetanic paralysis in the same, or almost the same, number of animals as the reference mixture containing 0.1 IU in the volume injected. Repeat the determination at least once and calculate the mean of all valid estimates. Estimates are valid only if the reference preparation gives a result within 20 per cent of the expected value.

The confidence limits (P = 0.95) have been estimated to be:

- 85 per cent and 114 per cent when 2 animals per dose are used,
- 91.5 per cent and 109 per cent when 3 animals per dose are used,
- 93 per cent and 108 per cent when 6 animals per dose are used.

IDENTIFICATION

The antitoxin is shown, by a suitable immunochemical method (*2.7.1*), to react specifically with the neurotoxin formed by *C. tetani*. The potency test may also serve for identification.

POTENCY

Determine the titre of antibodies against the neurotoxin formed by *C. tetani* using a suitable immunochemical method (*2.7.1*) such as a toxin-binding-inhibition test (ToBI test) and a homologous reference serum, calibrated in International Units per millilitre.

The International Unit is the specific neutralising activity for tetanus toxin contained in a stated amount of the International Standard which consists of a quantity of dried immune horse serum. The equivalence in International Units of the International Standard is stated by the World Health Organisation.

The potency of the finished product is expressed in International Units per millilitre and is shown to be not less than the minimum number stated on the label.

AMMONIA (^{13}N) INJECTION

Ammoniae (^{13}N) solutio iniectabilis

DEFINITION

Ammonia (^{13}N) injection is a sterile solution of [^{13}N]ammonia for diagnostic use. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared nitrogen-13 radioactivity at the date and time stated on the label. Not less than 99 per cent of the total radioactivity corresponds to nitrogen-13 in the form of [^{13}N]ammonia. Not less than 99.0 per cent of the total radioactivity corresponds to nitrogen-13.

PRODUCTION

RADIONUCLIDE PRODUCTION

Nitrogen-13 is a radioactive isotope of nitrogen which may be produced by various nuclear reactions, such as proton irradiation of carbon-13 or oxygen-16, or deuteron irradiation of carbon-12.

RADIOCHEMICAL SYNTHESIS

[^{13}N]Ammonia may be prepared by proton irradiation of water followed by the reduction of the resulting [^{13}N]nitrates/nitrites mixture with a reducing agent. The [^{13}N]ammonia formed is distilled from the reaction mixture and trapped in a slightly acidic solution.

Other methods may produce [^{13}N]ammonia "in-target" by proton irradiation of water containing a small amount of ethanol or acetic acid, or by proton irradiation of a slurry of [^{13}C]carbon powder in water. The resulting solution can be purified, to remove radionuclidic and radiochemical impurities, using anion and cation exchange columns.

CHARACTERS

A clear, colourless solution.

Nitrogen-13 has a half-life of 9.96 min and emits positrons with a maximum energy of 1.198 MeV, followed by annihilation gamma radiation of 0.511 MeV.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The only gamma photons have an energy of 0.511 MeV and, depending on the measurement geometry, a sum peak of 1.022 MeV may be observed.

B. It complies with test (a) for radionuclidic purity (see Tests).

C. Examine the chromatograms obtained in the test for radiochemical purity. The principal peak in the radiochromatogram obtained with the test solution has approximately the same retention time as the principal peak in the radiochromatogram obtained with the reference solution.

TESTS

pH (*2.2.3*). The pH of the injection is 5.5 to 8.5.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

Bacterial endotoxins (*2.6.14*): less than 175/*V* IU/ml, *V* being the maximum recommended dose in millilitres. The injection may be released for use before completion of the test.

CHEMICAL PURITY

Aluminium. In a test-tube about 12 mm in internal diameter, mix 1 ml of *acetate buffer solution pH 4.6 R* and 2 ml of a 1 in 20 dilution of the preparation to be examined in *water R*. Add 0.05 ml of a 10 g/l solution of *chromazurol S R*. After 3 min, the colour of the solution is not more intense than that of a standard prepared at the same time and in the same manner using 2 ml of a 1 in 20 dilution of *aluminium standard solution (2 ppm Al) R* (2 ppm).

The injection may be released for use before completion of the test.

RADIONUCLIDIC PURITY

(a) *Half-life*. The half-life is between 9 min and 11 min.

(b) *Gamma emitting impurities*. Retain a sample of the preparation to be examined for 2 h. Examine the gamma-ray spectrum of the decayed material for the presence of radionuclidic impurities, which should, where possible, be identified and quantified. The total gamma radioactivity due to these impurities does not exceed 1.0 per cent of the total radioactivity.

The injection may be released for use before completion of tests (a) and (b).

RADIOCHEMICAL PURITY

Examine by liquid chromatography (*2.2.29*).

Test solution. The preparation to be examined.

Reference solution. Dilute 1.0 ml of *dilute ammonia R2* to 10.0 ml with *water R*.

The chromatographic procedure may be carried out using:

- a column 0.04 m long and 4.0 mm in internal diameter packed with *cation exchange resin R* (10 µm),
- as mobile phase at a flow rate of 2 ml/min *0.002 M nitric acid*,
- a suitable radioactivity detector,
- a conductivity detector,
- a loop injector,

maintaining the column at a constant temperature between 20 °C and 30 °C.

Inject separately the test solution and the reference solution. The chromatogram obtained with the radioactivity detector and the test solution shows a principal peak with approximately the same retention time as the peak in the chromatogram obtained with the reference solution and the conductivity detector. Not less than 99 per cent of the total radioactivity corresponds to nitrogen-13 in the form of ammonia.

The injection may be released for use before completion of the test.

RADIOACTIVITY

Measure the radioactivity using suitable equipment by comparison with a standardised fluorine-18 solution or by using an instrument calibrated with the aid of such a solution. Standardised fluorine-18 solutions are available from laboratories recognised by the competent authority.

IMPURITIES

A. [^{13}N]O_2^-,

B. [^{13}N]O_3^-,

C. [18F$^-$],

D. H_2[^{15}O].

01/2008:1607

CARBON MONOXIDE (^{15}O)

Carbonei monoxidum (^{15}O)

DEFINITION

Mixture of carbon [^{15}O]monoxide in the gaseous phase and a suitable vehicle such as *Medicinal air (1238)*, for diagnostic use.

Purity:

- minimum 99 per cent of the total radioactivity corresponds to oxygen-15,
- minimum 97 per cent of the total radioactivity corresponds to oxygen-15 in the form of carbon monoxide (CO).

PRODUCTION

RADIONUCLIDE PRODUCTION

Oxygen-15 is a radioactive isotope of oxygen which may be produced by various nuclear reactions such as proton irradiation of nitrogen-15 or deuteron irradiation of nitrogen-14.

RADIOCHEMICAL SYNTHESIS

In order to recover oxygen-15 as molecular oxygen from the nitrogen target gas, carrier oxygen is added at concentrations generally ranging from 0.2 per cent *V/V* to 1.0 per cent *V/V*. After irradiation, the target gas is usually reacted with activated charcoal at a temperature of about 950 °C. The activated charcoal is preconditioned before use by flushing an inert gas at the production flow rate at a temperature of about 950 °C for not less than 1 h. The carbon [^{15}O]monoxide obtained is purified by passage through a carbon dioxide scavenger, such as soda lime, before mixing with the vehicle.

CHARACTERS

Appearance: colourless gas.

Half-life and nature of radiation of oxygen-15: see general chapter *5.7. Table of physical characteristics of radionuclides*.

IDENTIFICATION

A. Gamma spectrometry.

Results: the only gamma photons have an energy of 0.511 MeV and, depending on the measurement geometry, a sum peak of 1.022 MeV may be observed.

B. It complies with the test for radionuclidic purity (see Tests).

C. Examine the chromatograms obtained in the test for radiochemical purity.

Results: the principal peaks in the chromatogram obtained with the test gas using the radioactivity detector are similar in retention times to the principal peaks corresponding to carbon monoxide in the chromatogram obtained with reference gas (a) using the thermal conductivity detector.

TESTS

The following tests are performed on carbon [^{15}O]monoxide as described under radiochemical synthesis before mixing with the vehicle.

Carbon monoxide. Gas chromatography (*2.2.28*) as described in the test for radiochemical purity.

The concentration of carbon monoxide in the test sample is determined before administration and is used to calculate the amount of carbon monoxide to be administered to the patient.

Injection: test sample, reference gas (b).

Examine the chromatogram obtained with the thermal conductivity detector and calculate the content of carbon monoxide.

RADIONUCLIDIC PURITY

Oxygen-15: minimum 99 per cent of the total radioactivity.

A. Gamma spectrometry.

Comparison: standardised fluorine-18 solution, or by using an instrument calibrated with the aid of such a solution. Standardised fluorine-18 solutions and/or standardisation services are available from the competent authority.

Results: the spectrum obtained with the solution to be examined does not differ significantly from that obtained with a standardised fluorine-18 solution.

B. Half-life: 1.9 min to 2.2 min.

The preparation may be released for use before completion of the test.

RADIOCHEMICAL PURITY

Carbon [^{15}O]monoxide. Gas chromatography (*2.2.28*): use the normalisation procedure.

Test sample. Carbon [^{15}O]monoxide as described under radiochemical synthesis.

Reference gas (a). Nitrogen gas mixture R.

Reference gas (b). Nitrogen R, containing 2.0 per cent *V/V* of *carbon monoxide R1*.

Column:

- *size*: *l* = 1.8 m, Ø1 = 6.3 mm and Ø2 = 3.2 mm,
- *stationary phase*: *GC concentrical column R*,

Carrier gas: *helium for chromatography R*.

Flow rate: 65 ml/min.

Temperature:

- *column*: 40 °C,
- *injection port*: 40 °C,
- *thermal conductivity detector*: 70 °C.

Detection: thermal conductivity detector and radioactivity detector connected in series.

Injection: loop injector.

Run time: 10 min.

Retention times: oxygen, nitrogen and carbon monoxide eluting from the inner column = about 0.4 min; carbon dioxide eluting from the inner column = about 0.8 min; oxygen eluting from the outer column = about 2.1 min; nitrogen eluting from the outer column = about 3.1 min; carbon monoxide eluting from the outer column = about 6.2 min.

System suitability: reference gas (a):

- 5 clearly separated principal peaks are observed in the chromatogram obtained using the thermal conductivity detector,
- *resolution*: minimum of 1.5 between the peaks due to carbon dioxide eluting from the inner column and oxygen eluting from the outer column, in the chromatogram obtained using the thermal conductivity detector.

Limits: examine the chromatogram obtained with the radioactivity detector and calculate the percentage content of oxygen-15 substances from the peak areas.

- *carbon [^{15}O]monoxide*: minimum 97 per cent of the total radioactivity.
- *disregard* the first peak corresponding to components co-eluting from the inner column.

RADIOACTIVITY

The radioactive concentration is determined before administration.

Measure the radioactivity using suitable equipment by comparison with a standardised fluorine-18 solution or by measurement in an instrument calibrated with the aid of such a solution.

01/2008:0266

CHROMIUM (^{51}Cr) EDETATE INJECTION

Chromii (^{51}Cr) edetatis solutio iniectabilis

DEFINITION

Chromium (^{51}Cr) edetate injection is a sterile solution containing chromium-51 in the form of a complex of chromium(III) with ethylenediaminetetraacetic acid, the latter being present in excess. It may be made isotonic by the addition of sodium chloride and may contain a suitable antimicrobial preservative such as benzyl alcohol. Chromium-51 is a radioactive isotope of chromium and may be prepared by the neutron irradiation of chromium, either of natural isotopic composition or enriched in chromium-50. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared chromium-51 radioactivity at the date and hour stated on the label. Not less than 95 per cent of the radioactivity corresponds to chromium-51 in the form of chromium edetate. The injection contains a variable quantity of chromium (Cr) not exceeding 1 mg per millilitre.

CHARACTERS

A clear, violet solution.

Chromium-51 has a half-life of 27.7 days and emits gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised chromium-51 solution. Standardised chromium-51 solutions are available from laboratories recognised by the competent authority. The gamma photon has an energy of 0.320 MeV.

B. Examine the electropherogram obtained in the test for radiochemical purity. The distribution of radioactivity contributes to the identification of the preparation.

TESTS

pH (*2.2.3*). The pH of the solution is 3.5 to 6.5.

Chromium. Prepare a reference solution (1 mg per millilitre of Cr) as follows: dissolve 0.96 g of *chromic potassium sulphate R* and 2.87 g of *sodium edetate R* in 50 ml of *water R*, boil for 10 min, cool, adjust to pH 3.5 to 6.5 using *dilute sodium hydroxide solution R* and dilute to 100.0 ml with *water R*. Measure the absorbance (*2.2.25*) of the injection to be examined and the reference solution at the absorption maximum at 560 nm. The absorbance of the injection to be examined is not greater than that of the reference solution.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

RADIONUCLIDIC PURITY

Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised chromium-51 solution.

RADIOCHEMICAL PURITY

Examine by zone electrophoresis (*2.2.31*), using a paper strip as the support and a solution containing 0.2 g/l of *barbital sodium R* and 10 g/l of *sodium nitrate R* as the electrolyte solution. A paper with the following characteristics is suitable: mass per unit area 120 g/m^2; thickness 0.22 mm; capillary rise 105 mm to 115 mm per 30 min.

Apply to the paper 10 µl of the injection as a 3 mm band at a position 10 cm from the cathode. Apply an electric field of about 30 V per centimetre for 30 min using a stabilised current. [^{51}Cr]chromium edetate moves about 5 cm towards the anode. [^{51}Cr]Chromate moves about 10 cm towards the anode and [^{51}Cr]chromic ion moves about 7 cm towards the cathode. Determine the distribution of the radioactivity using a suitable detector. Not less than 95 per cent of the total radioactivity is found in the band corresponding to [^{51}Cr]chromium edetate.

RADIOACTIVITY

Measure the radioactivity using suitable equipment by comparison with a standardised chromium-51 solution or by measurement in an instrument calibrated with the aid of such a solution.

01/2008:0710

CYANOCOBALAMIN (^{57}Co) CAPSULES

Cyanocobalamini (^{57}Co) capsulae

DEFINITION

Cyanocobalamin (^{57}Co) capsules contain [^{57}Co]-α-(5,6-dimethylbenzimidazol-1-yl)cobamide cyanide and may contain suitable auxiliary substances. Cobalt-57 is a radioactive isotope of cobalt and may be produced by proton irradiation of nickel. Cyanocobalamin (^{57}Co) may be prepared by the growth of suitable micro-organisms on a medium containing (^{57}Co) cobaltous ion. Not less than 90 per cent of the cobalt-57 is in the form of cyanocobalamin. The capsules comply with the requirements for hard capsules in the monograph on *Capsules (0016)*, unless otherwise justified and authorised.

CHARACTERS

Hard gelatin capsules.

Cobalt-57 has a half-life of 271 days and emits gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised cobalt-57 solution. Standardised cobalt-57 and cobalt-58 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of cobalt-57 has an energy of 0.122 MeV.

B. Examine the chromatograms obtained in the test for radiochemical purity. The principal peak in the radio-chromatogram obtained with the test solution has a retention time similar to that of the peak in the chromatogram obtained with the reference solution.

TESTS

Disintegration. The capsules comply with the test for disintegration of tablets and capsules (*2.9.1*) except that one capsule is used in the test instead of six.

Uniformity of content. Determine by measurement in a suitable counting assembly and under identical geometrical conditions the radioactivity of each of not less than ten capsules. Calculate the average radioactivity per capsule. The radioactivity of no capsule differs by more than 10 per cent from the average. The relative standard deviation is less than 3.5 per cent.

RADIONUCLIDIC PURITY

Record the gamma-ray spectrum using a suitable instrument calibrated with the aid of standardised cobalt-57 and cobalt-58 solutions. The spectrum does not differ significantly from that of the stan-dardised cobalt-57 solution. Determine the relative amounts of cobalt-57, cobalt-56 and cobalt-58 present. Cobalt-56 has a half-life of 78 days and its presence is shown by gamma photons of energy 0.847 MeV. Cobalt-58 has a half-life of 70.8 days and its presence is shown by gamma photons of energy 0.811 MeV. Not more than 0.1 per cent of the total radioactivity is due to cobalt-56, cobalt-58 and other radionuclidic impurities.

RADIOCHEMICAL PURITY

Examine by liquid chromatography (*2.2.29*).

Test solution. Dissolve the contents of a capsule in 1.0 ml of *water R* and allow to stand for 10 min. Centrifuge at 2000 r/min for 10 min. Use the supernatant.

Reference solution. Dissolve 10 mg of *cyanocobalamin CRS* in the mobile phase and dilute to 100 ml with the mobile phase. Dilute 2 ml of the solution to 100 ml with the mobile phase. Use within 1 h.

The chromatographic procedure may be carried out using:

– a stainless steel column 0.25 m long and 4 mm in internal diameter packed with *octylsilyl silica gel for chromatography R* (5 µm),

– as mobile phase at a flow rate of 1.0 ml/min a mixture prepared as follows: mix 26.5 volumes of *methanol R* and 73.5 volumes of a 10 g/l solution of *disodium hydrogen phosphate R* adjusted to pH 3.5 using *phosphoric acid R* and use within 2 days,

– a radioactivity detector adjusted for cobalt-57,

– as detector a spectrophotometer set at 361 nm,

– a loop injector.

Inject 100 µl of the test solution and record the chromatogram for three times the retention time of cyanocobalamin. Determine the peak areas and calculate the percentage of cobalt-57 present as cyanocobalamin. Inject 100 µl of the reference solution and record the chromatogram for 30 min.

RADIOACTIVITY

The average radioactivity determined in the test for uniformity of content is not less than 90.0 per cent and not more than 110.0 per cent of the declared cobalt-57 radioactivity, at the date stated on the label.

STORAGE

Store in an airtight container, protected from light, at a temperature of 2 °C to 8 °C.

01/2008:0269

CYANOCOBALAMIN (^{57}Co) SOLUTION

Cyanocobalamini (^{57}Co) solutio

DEFINITION

Cyanocobalamin (^{57}Co) solution is a solution of [^{57}Co]-α-(5,6-dimethylbenzimidazol-1-yl)cobamide cyanide and may contain a stabiliser and an antimicrobial preservative. Cobalt-57 is a radioactive isotope of cobalt and may be produced by the irradiation of nickel with protons of suitable energy. Cyanocobalamin (^{57}Co) may be prepared by the growth of suitable micro-organisms on a medium containing (^{57}Co) cobaltous ion. The solution contains not less than 90.0 per cent and not more than 110.0 per cent of the declared cobalt-57 radioactivity at the date stated on the label. Not less than 90 per cent of the cobalt-57 is in the form of cyanocobalamin.

CHARACTERS

A clear, colourless or slightly pink solution. Cobalt-57 has a half-life of 271 days and emits gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised cobalt-57 solution. Standardised cobalt-57 and cobalt-58 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of cobalt-57 has an energy of 0.122 MeV.

B. Examine the chromatograms obtained in the test for radiochemical purity. The principal peak in the radiochromatogram obtained with the solution to be examined has a retention time similar to that of the peak in the chromatogram obtained with the reference solution.

TESTS

pH (*2.2.3*). The pH of the solution is 4.0 to 6.0.

RADIONUCLIDIC PURITY

Record the gamma-ray spectrum using a suitable instrument calibrated with the aid of standardised cobalt-57 and cobalt-58 solutions. The spectrum does not differ significantly from that of the standardised cobalt-57 solution. Determine the relative amounts of cobalt-57, cobalt-56 and cobalt-58 present. Cobalt-56 has a half-life of 78 days and its presence is shown by gamma photons of energy 0.847 MeV. Cobalt-58 has a half-life of 70.8 days and its presence is shown by gamma photons of energy 0.811 MeV. Not more than 0.1 per cent of the total radioactivity is due to cobalt-56, cobalt-58 and other radionuclidic impurities.

RADIOCHEMICAL PURITY

Examine by liquid chromatography (*2.2.29*).

Reference solution. Dissolve 10 mg of *cyanocobalamin CRS* in the mobile phase and dilute to 100 ml with the mobile phase. Dilute 2 ml of the solution to 100 ml with the mobile phase. Use within 1 h.

The chromatographic procedure may be carried out using:

– a stainless steel column 0.25 m long and 4 mm in internal diameter packed with *octylsilyl silica gel for chromatography R* (5 µm),

– as mobile phase at a flow rate of 1.0 ml/min a mixture prepared as follows: mix 26.5 volumes of *methanol R* and 73.5 volumes of a 10 g/l solution of *disodium hydrogen phosphate R* adjusted to pH 3.5 using *phosphoric acid R* and use within 2 days,
– a radioactivity detector adjusted for cobalt-57,
– as detector a spectrophotometer set at 361 nm,
– a loop injector.

Inject 100 µl of the solution to be examined and record the chromatogram for three times the retention time of cyanocobalamin. Determine the peak areas and calculate the percentage of cobalt-57 present as cyanocobalamin. Inject 100 µl of the reference solution and record the chromatogram for 30 min.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised cobalt-57 solution.

STORAGE

Store protected from light at a temperature of 2 °C to 8 °C.

01/2008:1505

CYANOCOBALAMIN (^{58}Co) CAPSULES

Cyanocobalamini (^{58}Co) capsulae

DEFINITION

Cyanocobalamin (^{58}Co) capsules contain [^{58}Co]-α-(5,6-dimethylbenzimidazol-1-yl)cobamide cyanide and may contain suitable auxiliary substances. Cobalt-58 is a radioactive isotope of cobalt and may be produced by neutron irradiation of nickel. Cyanocobalamin (^{58}Co) may be prepared by the growth of suitable micro-organisms on a medium containing (^{58}Co) cobaltous ion. Not less than 84 per cent of the cobalt-58 is in the form of cyanocobalamin. The capsules comply with the requirements for hard capsules in the monograph on *Capsules (0016)*, unless otherwise justified and authorised. The average radioactivity is not less than 90.0 per cent and not more than 110.0 per cent of the declared cobalt-58 radioactivity at the date stated on the label.

CHARACTERS

Hard gelatin capsules.

Cobalt-58 has a half-life of 70.9 days and emits beta (β^+) radiation and gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised cobalt-58 solution. Standardised cobalt-58 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photons of cobalt-58 have energies of 0.511 MeV (annihilation radiation) and 0.811 MeV.
B. Examine the chromatograms obtained in the test for radiochemical purity. The principal peak in the radiochromatogram obtained with the test solution has a retention time similar to that of the peak in the chromatogram obtained with the reference solution.

TESTS

Disintegration. The capsules comply with the test for disintegration of tablets and capsules (*2.9.1*) except that one capsule is used in the test instead of six.

Uniformity of content. Determine by measurement in a suitable counting assembly and under identical geometrical conditions the radioactivity of each of not less than ten capsules. Calculate the average radioactivity per capsule. The radioactivity of no capsule differs by more than 10 per cent from the average. The relative standard deviation is less than 3.5 per cent.

RADIONUCLIDIC PURITY

Record the gamma-ray spectrum using a suitable instrument calibrated with the aid of standardised cobalt-58, cobalt-57 and cobalt-60 solutions. The spectrum does not differ significantly from that of the standardised cobalt-58 solution. Standardised cobalt-58, cobalt-57 and cobalt-60 solutions are available from laboratories recognised by the competent authority. Determine the relative amounts of cobalt-58, cobalt-57 and cobalt-60 present. Cobalt-57 has a half-life of 272 days and its presence is shown by gamma photons of energy 0.122 MeV. Cobalt-60 has a half-life of 5.27 years and its presence is shown by gamma photons of energies 1.173 MeV and 1.333 MeV. Not more than 1 per cent of the total radioactivity is due to cobalt-60 and not more than 2 per cent of the total radioactivity is due to cobalt-57, cobalt-60 and other radionuclidic impurities.

RADIOCHEMICAL PURITY

Examine by liquid chromatography (*2.2.29*).

Test solution. Dissolve the contents of a capsule in 1.0 ml of *water R* and allow to stand for 10 min. Centrifuge at 2000 r/min for 10 min. Use the supernatant.

Reference solution. Dissolve 10 mg of *cyanocobalamin CRS* in the mobile phase and dilute to 100 ml with the mobile phase. Dilute 2 ml of the solution to 100 ml with the mobile phase. Use within 1 h of preparation.

The chromatographic procedure may be carried out using:

– a stainless steel column 0.25 m long and 4 mm in internal diameter packed with *octylsilyl silica gel for chromatography R* (5 µm),
– as mobile phase at a flow rate of 1.0 ml/min a mixture prepared as follows: mix 26.5 volumes of *methanol R* and 73.5 volumes of a 10 g/l solution of *disodium hydrogen phosphate R*, adjusted to pH 3.5 with *phosphoric acid R* and use within 2 days,
– a radioactivity detector adjusted for cobalt-58,
– as detector a spectrophotometer set at 361 nm,
– a loop injector.

Inject 100 µl of the test solution and record the chromatogram for three times the retention time of cyanocobalamin. Determine the peak areas and calculate the percentage of cobalt-58 present as cyanocobalamin. Inject 100 µl of the reference solution and record the chromatogram for 30 min.

RADIOACTIVITY

The average radioactivity determined in the test for uniformity of content is not less than 90.0 per cent and not more than 110.0 per cent of the declared cobalt-58 radioactivity, at the date stated on the label.

STORAGE

Store in an airtight container, protected from light, at a temperature of 2 °C to 8 °C.

01/2008:0270

CYANOCOBALAMIN (^{58}Co) SOLUTION

Cyanocobalamini (^{58}Co) solutio

DEFINITION

Cyanocobalamin (^{58}Co) solution is a solution of [^{58}Co]-α-(5,6-dimethylbenzimidazol-1-yl)cobamide cyanide and may contain a stabiliser and an antimicrobial preservative. Cobalt-58 is a radioactive isotope of cobalt and may be produced by neutron irradiation of nickel. Cyanocobalamin (^{58}Co) may be prepared by the growth of suitable micro-organisms on a medium containing (^{58}Co) cobaltous ion. The solution contains not less than 90.0 per cent and not more than 110.0 per cent of the declared cobalt-58 radioactivity at the date stated on the label. Not less than 90 per cent of the cobalt-58 is in the form of cyanocobalamin.

CHARACTERS

A clear, colourless or slightly pink solution.

Cobalt-58 has a half-life of 70.8 days and emits beta (β+) radiation and gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised cobalt-58 solution. Standardised cobalt-58, cobalt-57 and cobalt-60 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photons of cobalt-58 have energies of 0.511 MeV (annihilation radiation) and 0.811 MeV.

B. Examine the chromatograms obtained in the test for radiochemical purity. The principal peak in the radiochromatogram obtained with the solution to be examined has a retention time similar to that of the peak in the chromatogram obtained with the reference solution.

TESTS

pH (*2.2.3*). The pH of the solution is 4.0 to 6.0.

RADIONUCLIDIC PURITY

Record the gamma-ray spectrum using a suitable instrument having adequate resolution and calibrated with the aid of standardised cobalt-58, cobalt-57 and cobalt-60 solutions. The spectrum does not differ significantly from that of the standardised cobalt-58 solution. Determine the relative amounts of cobalt-58, cobalt-57 and cobalt-60 present. Cobalt-57 has a half-life of 271 days and its presence is shown by gamma photons of energy 0.122 MeV. Cobalt-60 has a half-life of 5.27 years and its presence is shown by gamma photons of energies 1.173 MeV and 1.332 MeV. Not more than 1 per cent of the total radioactivity is due to cobalt-60 and not more than 2 per cent of the total radioactivity is due to cobalt-57, cobalt-60 and other radionuclidic impurities.

RADIOCHEMICAL PURITY

Examine by liquid chromatography (*2.2.29*).

Reference solution. Dissolve 10 mg of *cyanocobalamin CRS* in the mobile phase and dilute to 100 ml with the mobile phase. Dilute 2 ml of the solution to 100 ml with the mobile phase. Use within 1 h.

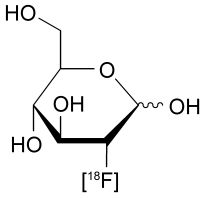
The chromatographic procedure may be carried out using:

- a stainless steel column 0.25 m long and 4 mm in internal diameter packed with *octylsilyl silica gel for chromatography R* (5 μm),
- as mobile phase at a flow rate of 1.0 ml/min a mixture prepared as follows: mix 26.5 volumes of *methanol R* and 73.5 volumes of a 10 g/l solution of *disodium hydrogen phosphate R* adjusted to pH 3.5 using *phosphoric acid R* and use within 2 days,
- a radioactivity detector adjusted for cobalt-58,
- as detector a spectrophotometer set at 361 nm,
- a loop injector.

Inject 100 μl of the solution to be examined and record the chromatogram for three times the retention time of cyanocobalamin. Determine the peak areas and calculate the percentage of cobalt-58 present as cyanocobalamin. Inject 100 μl of the reference solution and record the chromatogram for 30 min.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised cobalt-58 solution or by measurement in an instrument calibrated with the aid of such a solution.



STORAGE

Store protected from light at a temperature of 2 °C to 8 °C.

01/2008:1325

FLUDEOXYGLUCOSE (^{18}F) INJECTION

Fludeoxyglucosi (^{18}F) solutio iniectabilis

DEFINITION

Fludeoxyglucose (^{18}F) injection is a sterile solution of 2-[^{18}F]fluoro-2-deoxy-D-glucopyranose (2-[^{18}F]fluoro-2-deoxy-D-glucose) for diagnostic use. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared fluorine-18 radioactivity at the date and time stated on the label. Not less than 95 per cent of the radioactivity corresponds to fluorine-18 in the form of 2-[^{18}F]fluoro-2-deoxy-D-glucose and 2-[^{18}F]fluoro-2-deoxy-D-mannose, with the 2-[^{18}F]fluoro-2-deoxy-D-mannose fraction not exceeding 10 per cent of the total radioactivity. Not less than 99.0 per cent of the radioactivity corresponds to fluorine-18. The content of 2-fluoro-2-deoxy-D-glucose is not more than 10 mg per maximum recommended dose of injection.

PRODUCTION

RADIONUCLIDE PRODUCTION

Fluorine-18 is a radioactive isotope of fluorine which may be produced by various nuclear reactions induced by proton irradiation of oxygen-18, deuteron irradiation of neon-20, helium-3 or helium-4 irradiation of oxygen-16.

RADIOCHEMICAL SYNTHESIS

2-[^{18}F]Fluoro-2-deoxy-D-glucose may be prepared by various chemical synthetic pathways, which lead to different products in terms of specific radioactivity, by-products and possible impurities.

Most widely used is the method of phase transfer catalysed nucleophilic substitution of 1,3,4,6-tetra-*O*-acetyl-2-*O*-trifluoromethanesulphonyl-β-D-mannopyranose with [^{18}F]fluoride. Generally, [^{18}F]fluoride is adsorbed on an anion-exchange resin and eluted with a solution of potassium carbonate which is then evaporated to dryness. Addition of a phase transfer catalyst such as an aminopolyether in dry acetonitrile may be used to enhance the nucleophilicity of the [^{18}F]fluoride so that it reacts easily with the tetra-acetylated mannosyltriflate at elevated temperature. Hydrolysis under either alkaline or acidic conditions yields 2-[^{18}F]fluoro-2-deoxy-D-glucose. Hydrolysis using hydrochloric acid may lead to the formation of 2-chloro-2-deoxy-D-glucose. Hydrolysis under alkaline conditions may lead to the formation of 2-[^{18}F]fluoro-2-deoxy-D-mannose as a by-product.

Variations of the method substitute the aminopolyether by a tetra-alkyl ammonium salt, or use solid phase catalysed nucleophilic substitution on derivatised anion-exchange resin, e.g. derivatised with 4-(4-methylpiperidino)pyridine.

Electrophilic pathways for production of 2-[^{18}F]fluoro-2-deoxy-D-glucose proceed by the reaction of molecular [^{18}F]fluorine or [^{18}F]acetylhypofluorite with 3,4,6-tri-*O*-acetyl-D-glucal. [^{18}F]Acetylhypofluorite is obtained by conversion of molecular [^{18}F]fluorine on a solid complex of acetic acid and potassium acetate. The production of molecular [^{18}F]fluorine requires the addition of small amounts of fluorine to the neon target gas, usually from 0.1 per cent to 1 per cent, resulting in the reduction of the specific radioactivity of the end-product. Hydrolysis of the *O*-acetyl protected [^{18}F]fluorinated sugar yields 2-[^{18}F]fluoro-2-deoxy-D-glucose and usually small amounts of 2-[^{18}F]fluoro-2-deoxy-D-mannose.

The preparation can be purified by serial chromatography on combinations of ion-retardation resin, ion-exchange resin, alumina and octadecyl derivatised silica gel. Removal of the phase transfer catalyst can be achieved by different methods, all using combinations of separation cartridges.

Production systems and their performance comply with the requirements set by the competent authority.

STARTING MATERIALS

1. Target materials

Each batch of target material must be tested in special production runs before its use in routine fluorine-18 production and manufacture of the preparation, to ensure that under specified conditions, the target yields fluorine-18 in the desired quantity and quality.

2. Precursors for organic synthesis

It is recommended to test the precursors in production runs before their use for the manufacture of the preparation, to ensure that under specified production conditions, the precursors yield the preparation in the desired quantity and quality.

1,3,4,6-Tetra-O-acetyl-2-O-trifluoromethanesulphonyl-β-D-mannopyranose. Examine by infrared absorption spectrophotometry (*2.2.24*), comparing with the *Ph. Eur. reference spectrum of 1,3,4,6-tetra-O-acetyl-2-O-trifluoromethanesulphonyl-β-D-mannopyranose.*

Melting point (*2.2.14*): 119 °C to 122 °C.

3,4,6-Tri-O-acetyl-D-glucal. Examine by infrared absorption spectrophotometry (*2.2.24*), comparing with the *Ph. Eur. reference spectrum of 3,4,6-tri-O-acetyl-D-glucal.*

Melting point (*2.2.14*): 53 °C to 55 °C.

CHARACTERS

A clear, colourless or slightly yellow solution.

Fluorine-18 has a half-life of 109.8 min and emits positrons with a maximum energy of 0.633 MeV, followed by annihilation gamma radiation of 0.511 MeV.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The only gamma photons have an energy of 0.511 MeV; and depending on the measurement geometry, a sum peak of 1.022 MeV may be observed.

B. It complies with the test for radionuclidic purity (see Tests).

C. Examine the chromatograms obtained in test (a) for radiochemical purity. The principal peak in the radiochromatogram obtained with the test solution has approximately the same retention time as the principal peak in the chromatogram obtained with reference solution (b).

TESTS

pH (*2.2.3*). The pH of the injection is 4.5 to 8.5.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

Bacterial endotoxins (*2.6.14*): less than 175/*V* IU/ml, *V* being the maximum recommended dose in millilitres. The injection may be released for use before completion of the test.

CHEMICAL PURITY

Particular tests for chemical purity may be omitted if the substances mentioned are not used or cannot be formed in the production process

(a) 2-Fluoro-2-deoxy-D-glucose and 2-chloro-2-deoxy-D-glucose. Examine by liquid chromatography (*2.2.29*).

Test solution. The preparation to be examined.

Reference solution (a). Dissolve 10 mg of *glucose R* in *water R* and dilute to 100 ml with the same solvent.

Reference solution (b). Dissolve 10 mg of *2-fluoro-2-deoxy-D-glucose R* in *water R* and dilute to *V* with the same solvent, *V* being the maximum recommended dose in millilitres.

Reference solution (c). Dissolve 1.0 mg of *2-chloro-2-deoxy-D-glucose R* in *water R* and dilute to 2.0 ml with the same solvent. Dilute 1 ml of this solution to *V* with the same solvent, *V* being the maximum recommended dose in millilitres.

The chromatographic procedure may be carried out using:

– a column 0.25 m long and 4.0 mm in internal diameter packed with *strongly basic anion-exchange resin for chromatography R* (10 μm),

– as mobile phase at a flow rate of 1 ml/min *0.1 M sodium hydroxide* protected against contamination by carbon dioxide,

– a suitable radioactivity detector for radiochemical purity testing,

– a detector suitable for carbohydrates in the required concentration range,

– a loop injector,

maintaining the column at a constant temperature between 20 °C and 30 °C.

Equilibrate the column with the mobile phase until a stable baseline is achieved.

Inject separately reference solutions (a), (b) and (c). If the validation studies exclude the formation of 2-chloro-2-deoxy-D-glucose inject separately reference solutions (a) and (b). Continue the chromatography for twice the retention time of D-glucose, 2-fluoro-2-deoxy-D-glucose and when required, 2-chloro-2-deoxy-D-glucose respectively.

Inject the test solution. The chromatogram obtained with the detector for carbohydrates shows a principal peak corresponding to D-glucose (test solutions from nucleophilic pathways) or 2-fluoro-2-deoxy-D-glucose (test solutions from electrophilic pathways). When the chromatograms are recorded in the prescribed conditions, 2-chloro-2-deoxy-D-glucose elutes after 2-fluoro-2-deoxy-D-glucose, but their corresponding peaks may not be completely resolved. In the chromatogram obtained with the test solution, the areas of the peaks corresponding to 2-fluoro-2-deoxy-D-glucose and 2-chloro-2-deoxy-D-glucose are not greater than the areas of the peaks in the chromatograms obtained with reference solution (b) and/or reference solution (c) (10 mg of 2-fluoro-2-deoxy-D-glucose per *V* and 0.5 mg of 2-chloro-2-deoxy-D-glucose per *V* respectively).

(b) Aminopolyether. This test is performed only on the bulk solution before addition of sodium chloride by the producer and it is not intended for the final preparation to be injected. Examine by thin-layer chromatography (*2.2.27*), using a *TLC silica gel plate R*.

Test solution. The preparation to be examined.

Reference solution. Dissolve 0.110 g of *aminopolyether R* in *water R* and dilute to 10.0 ml with the same solvent. Dilute 0.2 ml of this solution to *V* with the same solvent, *V* being the maximum recommended dose in millilitres.

Apply separately to the plate 2 µl of the test solution and 2 µl of the reference solution. Develop over a path of about 8 cm using a mixture of 1 volume of *ammonia R* and 9 volumes of *methanol R*. Allow the plate to dry in air for 15 min. Expose the plate to iodine vapour for at least 10 min. In the chromatogram obtained with the test solution the spot corresponding to aminopolyether is not more intense than the spot in the chromatogram obtained with the reference solution (2.2 mg per *V*).

(c) Tetra-alkyl ammonium salts. Examine by liquid chromatography (*2.2.29*).

Test solution. The preparation to be examined.

Reference solution. Dilute 2.1 ml of *0.1 M tetrabutylammonium hydroxide* to 20 ml with *water R*. Dilute 1 ml of this solution to *V* with the same solvent, *V* being the maximum recommended dose in millilitres.

The chromatographic procedure may be carried out using:

- a column 0.125 m long and 4.0 mm in internal diameter packed with *octadecylsilyl silica gel for chromatography R* (5 µm),
- as mobile phase at a flow rate of 0.6 ml/min a mixture of 25 volumes of a 0.95 g/l solution of *toluenesulphonic acid R* and 75 volumes of *acetonitrile R*,
- as detector a spectrophotometer set at 254 nm,
- a loop injector,

maintaining the column at a constant temperature between 20 °C and 30 °C.

Equilibrate the column with the mobile phase until a stable baseline is obtained.

Inject the reference solution. Continue the chromatography for twice the retention time of tetrabutylammonium ions.

Inject the test solution. In the chromatogram obtained with the test solution, the area of the peak corresponding to tetrabutylammonium ions is not greater than the area of the peak in the chromatogram obtained with the reference solution (2.75 mg per *V*).

(d) Solid phase derivatisation agent 4-(4-methylpiperidino)pyridine. Examine by ultraviolet spectrophotometry (*2.2.25*).

Test solution. The preparation to be examined.

Reference solution. Dissolve 20 mg of *4-(4-methylpiperidino)pyridine R* in *water R* and dilute to 100.0 ml with the same solvent. Dilute 0.1 ml of this solution to *V* with the same solvent, *V* being the maximum recommended dose in millilitres.

Measure the absorbance of the test solution and the reference solution at the maximum of 263 nm. The absorbance of the test solution is not greater than that of the reference solution (0.02 mg per *V*).

(e) Residual solvents (*2.4.24*). The concentration of acetonitrile does not exceed 4.1 mg per *V*, *V* being the maximum recommended dose in millilitres. The injection may be released for use before completion of the test.

RADIONUCLIDIC PURITY

Record the gamma-ray spectrum using a suitable instrument. The half-life is between 105 min and 115 min. The injection may be released for use before completion of the test.

RADIOCHEMICAL PURITY

A. Examine by liquid chromatography (*2.2.29*) as described in test (a) for chemical purity.

When the chromatograms obtained with the radioactivity detector are recorded in the prescribed conditions, the principal peak in the chromatogram obtained with the test solution has the same retention time as the peak obtained with reference solution (b) using the carbohydrate detector. The retention times of 2-[^{18}F]fluoro-2-deoxy-D-mannose and [^{18}F]fluoride are approximately 90 per cent and approximately 50 per cent of that of 2-[^{18}F]fluoro-2-deoxy-D-glucose respectively. Other peaks in the chromatogram may be due to partially acetylated 2-[^{18}F]fluoro-2-deoxy-D-glucose derivatives.

Calculate the percentage content of [^{18}F]fluorinated substances from the areas of the peaks in the chromatogram obtained with the test solution. The sum of the percentages of radioactivity corresponding to 2-[^{18}F]fluoro-2-deoxy-D-glucose and 2-[^{18}F]fluoro-2-deoxy-D-mannose is not less than 95 per cent of the total radioactivity with the 2-[^{18}F]fluoro-2-deoxy-D-mannose fraction not exceeding 10 per cent of the total radioactivity.

The method may underestimate or miss unhydrolysed or partially hydrolysed 2-[^{18}F]fluoro-2-deoxytetra-acetyl-D-glucose, since these intermediate reaction products may further hydrolyse to the desired end-product under the chromatographic conditions.

B. Examine by thin-layer chromatography (*2.2.27*) using a *TLC silica gel plate R*.

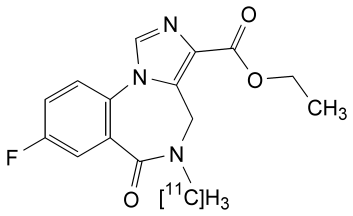
Test solution. The preparation to be examined.

Apply 2 µl to 10 µl to the plate. Develop over a path of 8 cm using a mixture of 5 volumes of *water R* and 95 volumes of *acetonitrile R*. Allow the plate to dry in air for 15 min. Determine the distribution of radioactivity using a suitable detector. Not less than 95 per cent of the total radioactivity is found in the spot corresponding to 2-fluoro-2-deoxy-D-glucose (R_F about 0.45).

Possible contaminants are [^{18}F]fluoride (R_F 0.0); partially acetylated 2-[^{18}F]fluoro-2-deoxy-D-glucose derivatives (R_F about 0.8-0.95).

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised fluorine-18 solution or using an instrument calibrated with the aid of such a solution. Standardised fluorine-18 solutions are available from laboratories recognised by the competent authority.



LABELLING

The accompanying information specifies the particular synthetic pathway of production. The label on the actual container states the maximum recommended dose in millilitres.

01/2008:1917

FLUMAZENIL (*N*-[^{11}C]METHYL) INJECTION

Flumazenili (*N*-[^{11}C]methyl) solutio iniectabilis

DEFINITION

Sterile solution of ethyl 8-fluoro-5-[^{11}C]methyl-6-oxo-5,6-dihydro-4*H*-imidazo[1,5-*a*][1,4]benzodiazepine-3-carboxylate which may contain a stabiliser such as ascorbic acid.

Content: 90 per cent to 110 per cent of the declared carbon-11 radioactivity at the date and time stated on the label.

Content of flumazenil: maximum 50 µg in the maximum recommended dose in millilitres.

PRODUCTION

RADIONUCLIDE PRODUCTION

Carbon-11 is a radioactive isotope of carbon which is most commonly produced by proton irradiation of nitrogen. Depending on the addition of either trace amounts of oxygen or small amounts of hydrogen, the radioactivity is obtained as [^{11}C]carbon dioxide or [^{11}C]methane, respectively.

RADIOCHEMICAL SYNTHESIS

[5-Methyl-^{11}C]flumazenil may be prepared by *N*-alkylation of ethyl 8-fluoro-6-oxo-5,6-dihydro-4*H*-imidazo[1,5-*a*][1,4]benzodiazepine-3-carboxylate (demethylflumazenil) with iodo[^{11}C]methane or [^{11}C]methyl trifluoromethanesulphonate.

Synthesis of iodo[^{11}C]methane

Iodo[^{11}C]methane may be produced from [^{11}C]carbon dioxide or from [^{11}C]methane. The most frequently used method is reduction of [^{11}C]carbon dioxide with lithium aluminium hydride. The [^{11}C]methanolate formed is reacted with hydriodic acid. Alternatively [^{11}C]methane, either obtained directly in the target or by on-line processes from [^{11}C]carbon dioxide, is reacted with iodine.

Synthesis of [^{11}C]methyl trifluoromethanesulphonate

[^{11}C]methyl trifluoromethanesulphonate may be prepared from iodo[^{11}C]methane using a solid support such as graphitised carbon, impregnated with silver trifluoromethanesulphonate.

Synthesis of [5-methyl-^{11}C]flumazenil

The most widely used method to obtain [5-methyl-^{11}C]flumazenil is the *N*-alkylation of demethylflumazenil with iodo[^{11}C]methane in alkaline conditions in a solvent such as dimethylformamide or acetone. The resulting [5-methyl-^{11}C]flumazenil can be purified by semi-preparative liquid chromatography. For example, a column packed with octadecylsilyl silica gel for chromatography eluted with a mixture of ethanol and water is suitable.

PRECURSOR FOR SYNTHESIS

Demethylflumazenil

Melting point (*2.2.14*): 286 °C to 289 °C.

Infrared absorption spectrophotometry (*2.2.24*).

Comparison: *Ph. Eur. reference spectrum of demethylflumazenil.*

CHARACTERS

Appearance: clear, colourless solution.

Half-life and nature of radiation of carbon-11: see general chapter *5.7. Table of physical characteristics of radionuclides.*

IDENTIFICATION

A. Gamma-ray spectrometry.

Results: the only gamma photons have an energy of 0.511 MeV and, depending on the measurement geometry, a sum peak of 1.022 MeV may be observed.

B. It complies with test B for radionuclidic purity (see Tests).

C. Examine the chromatograms obtained in the test for radiochemical purity.

Results: the principal peak in the radiochromatogram obtained with the test solution is similar in retention time to the principal peak in the chromatogram obtained with reference solution (a).

TESTS

pH (*2.2.3*): 6.0 to 8.0.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125).* The injection may be released for use before completion of the test.

Bacterial endotoxins (*2.6.14*): less than 175/*V* IU/ml, *V* being the maximum recommended dose in millilitres. The injection may be released for use before completion of the test.

Flumazenil and impurity A. Liquid chromatography (*2.2.29*).

Test solution. The preparation to be examined.

Reference solution (a). Dissolve 2.5 mg of *flumazenil R* in 5 ml of *methanol R*.

Reference solution (b). Dissolve 2.5 mg of *demethylflumazenil R* in 50 ml of *methanol R*.

Reference solution (c). To 0.1 ml of reference solution (a) add 0.1 ml of reference solution (b) and dilute to *V* with a 0.9 g/l solution of *sodium chloride R*, *V* being the maximum recommended dose in millilitres.

Reference solution (d). Dilute 0.1 ml of reference solution (a) to 50 ml with *methanol R*. Dilute 1.0 ml of this solution to *V* with a 0.9 g/l solution of *sodium chloride R*, *V* being the maximum recommended dose in millilitres.

Column:

– *size*: *l* = 0.15 m, Ø = 3.9 mm,

– *stationary phase*: spherical *octadecylsilyl silica gel for chromatography R* (5 µm) with a specific surface area of 440 m^2/g, a pore size of 100 nm and a carbon loading of 19 per cent,

– *temperature*: maintain at a constant temperature between 20-30 °C.

Mobile phase: *methanol R, water R* (45:55 *V/V*).

Flow rate: 1 ml/min.

Detection: spectrophotometer at 260 nm and radioactivity detector connected in series.

Injection: 100 µl.

Run time: 10 min.

Relative retention with reference to flumazenil: impurity A = about 0.74.

System suitability: reference solution (c):

– *resolution*: minimum 2.5 between the peaks due to flumazenil and impurity A.

Limits: examine the chromatogram obtained with the spectrophotometer:

– *flumazenil*: not more than the area of the corresponding peak in the chromatogram obtained with reference solution (c) (50 µg/*V*),

– *impurity A*: not more than the area of the corresponding peak in the chromatogram obtained with reference solution (c) (5 µg/*V*),

– *any other impurity*: not more than the area of the principal peak in the chromatogram obtained with reference solution (d) (1 µg/*V*).

Residual solvents are limited according to the principles defined in the general chapter (*5.4*), using the general method (*2.4.24*). The preparation may be released for use before completion of the test.

RADIONUCLIDIC PURITY

Carbon-11: minimum 99 per cent of the total radioactivity.

The preparation may be released for use before completion of the test.

A. Gamma-ray spectrometry.

Results: the spectrum obtained with the solution to be examined does not differ significantly from that obtained with a standardised fluorine-18 solution.

B. Half-life: 19.9 min to 20.9 min.

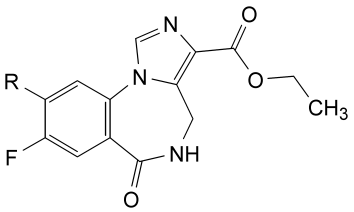
RADIOCHEMICAL PURITY

Liquid chromatography (*2.2.29*) as described in the test for flumazenil and impurity A, with the following modifications.

Injection: test solution and reference solution (a); if necessary, dilute the test solution to a radioactivity concentration suitable for the detector.

Limit: examine the chromatogram obtained with the radioactivity detector:

– *[5-methyl-^{11}C]flumazenil*: minimum 95 per cent of the total radioactivity.



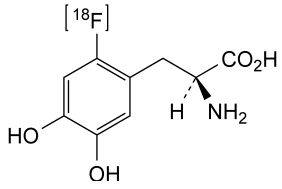
RADIOACTIVITY

Determine the radioactivity using a calibrated instrument.

LABELLING

The label states the maximum recommended dose in millilitres.

IMPURITIES



A. R = H: ethyl 8-fluoro-6-oxo-5,6-dihydro-4*H*-imidazo[1,5-*a*][1,4]benzodiazepine-3-carboxylate (demethylflumazenil),

B. R = CH_2-CO-CH_3: ethyl 8-fluoro-6-oxo-9-(2-oxopropyl)-5,6-dihydro-4*H*-imidazo[1,5-*a*][1,4]benzodiazepine-3-carboxylate (acetone addition compound of demethylflumazenil).

01/2008:1918

FLUORODOPA (^{18}F) (PREPARED BY ELECTROPHILIC SUBSTITUTION) INJECTION

Fluorodopae (^{18}F) ab electrophila substitutione solutio iniectabilis

DEFINITION

Sterile solution of (2*S*)-2-amino-3-(2-([^{18}F]fluoro)-4,5-dihydroxyphenyl)propanoic acid (6-[^{18}F]fluorolevodopa). It may contain stabilisers such as ascorbic acid and edetic acid.

This monograph applies to an injection containing 6-[^{18}F]fluorolevodopa produced by electrophilic substitution.

Content:

– *fluorine-18*: 90 per cent to 110 per cent of the declared fluorine-18 radioactivity at the date and time stated on the label;

– *dopa*: maximum 1 mg per maximum recommended dose in millilitres;

– *6-fluorolevodopa*: maximum 15 mg per maximum recommended dose in millilitres.

PRODUCTION

RADIONUCLIDE PRODUCTION

Fluorine-18 is a radioactive isotope of fluorine that may be produced by various nuclear reactions induced by proton irradiation of oxygen-18, deuteron irradiation of neon-20, or helium-3 or helium-4 irradiation of oxygen-16.

In order to obtain fluorine-18 in a chemical form suitable for electrophilic substitution reactions, such as fluorine gas or gaseous acetylhypofluorite, a small amount of non-radioactive fluorine gas (0.3-0.8 per cent of the target gas volume) must be added as a carrier at some step in the production process.

RADIOCHEMICAL SYNTHESIS

6-[^{18}F]Fluorolevodopa may be prepared by various radiochemical synthetic pathways, which lead to different products in terms of yield, specific radioactivity, by-products and possible impurities. Electrophilic pathways for production of 6-[^{18}F]fluorolevodopa may proceed by fluorodemetallation of a stannylated derivative of levodopa, with molecular [^{18}F]fluorine or [^{18}F]acetylhypofluorite, followed by hydrolysis of protecting groups and final purification by semipreparative liquid chromatography. Pathways using demercuration or dethallation must not be used.

CHARACTERS

Appearance: clear, colourless solution.

Half-life and nature of radiation of fluorine-18: see general chapter *5.7. Table of physical characteristics of radionuclides.*

IDENTIFICATION

A. Test A for radionuclidic purity (see Tests).

B. Determine the approximate half-life by at least 3 measurements of the activity of a sample in the same geometrical conditions over a suitable period of time, for example 30 min.

Results: 105 min to 115 min.

C. Examine the chromatograms obtained in the test for radiochemical purity (see Tests).

Results: the principal peak in the radiochromatogram obtained with the test solution is similar in retention time to the peak due to 6-fluorolevodopa in the chromatogram obtained with reference solution (a).

D. Examine the chromatograms obtained in the test for impurities C and D (see Tests).

Results: the principal peak in the radiochromatogram obtained with the test solution is similar in retardation factor to the peak due to 6-fluorolevodopa in the chromatogram obtained with reference solution (b).

TESTS

pH (*2.2.3*): 4.0 to 5.5.

Sterility. It complies with the test for sterility prescribed in the monograph *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

Bacterial endotoxins (*2.6.14*): less than 175/*V* IU/ml, *V* being the maximum recommended dose in millilitres. The injection may be released for use before completion of the test.

6-Fluorolevodopa, dopa, impurity A and impurity B. Liquid chromatography (*2.2.29*). *Prepare the reference solutions immediately before use.*

Test solution. The preparation to be examined.

Reference solution (a). Dissolve 18.0 mg of *6-fluorolevodopa hydrochloride R* in 5.0 ml of the mobile phase and dilute to *V* with the mobile phase, *V* being the maximum recommended dose in millilitres.

Reference solution (b). Dissolve 1.0 mg of *levodopa R* in 5 ml of the mobile phase and dilute to *V* with the mobile phase, *V* being the maximum recommended dose in millilitres.

Reference solution (c). Dissolve 1.0 mg of *trimethyltin chloride R* (impurity A) in 2.0 ml of the mobile phase. Dilute 1.0 ml of this solution to *V* with the mobile phase, *V* being the maximum recommended dose in millilitres.

Reference solution (d). Mix equal volumes of reference solutions (b) and (c).

Reference solution (e). Dissolve 2.0 mg of *6-hydroxydopa R* (impurity B) in 20.0 ml of the mobile phase. Dilute 0.25 ml of this solution to *V* with the mobile phase, *V* being the maximum recommended dose in millilitres.

Column:

– *size*: *l* = 0.25 m, Ø = 4.0 mm;
– *stationary phase*: spherical *end-capped octadecylsilyl silica gel for chromatography R*;
– *temperature*: maintain at a constant temperature between 20 °C and 30 °C.

Mobile phase: 6.9 g/l solution of *sodium dihydrogen phosphate R* adjusted to pH 2.4 with a 4.8 g/l solution of *phosphoric acid R*.

Flow rate: 1 ml/min.

Detection: spectrophotometer at 200 nm and radioactivity detector connected in series.

Injection: 20 µl.

Run time: 15 min.

Relative retention with reference to 6-fluorolevodopa (retention time = about 6 min): impurity A and impurity B = about 0.7; dopa = about 0.8.

System suitability: reference solution (d):

– *resolution*: minimum 1.5 between the peaks due to dopa and impurity A.

Limits: examine the chromatograms obtained with the spectrophotometer:

– *6-fluorolevodopa*: not more than the area of the corresponding peak in the chromatogram obtained with reference solution (a) (15 mg/*V*);
– *dopa*: not more than the area of the peak due to levodopa in the chromatogram obtained with reference solution (b) (1.0 mg/*V*);
– *sum of impurities A and B*: not more than the area of the principal peak in the chromatogram obtained with reference solution (e) (corresponding to a limit of 0.5 mg/*V* of impurity A or a limit of 0.025 mg/*V* of impurity B, or to lower limits of each if both impurities are present).

Residual solvents: limited according to the principles defined in general chapter *5.4*. The preparation may be released for use before completion of the test.

RADIONUCLIDIC PURITY

Fluorine-18: minimum 99.9 per cent of the total radioactivity. The preparation may be released for use before completion of test B.

A. Gamma-ray spectrometry

Results: the only gamma photons have an energy of 0.511 MeV and, depending on the measurement geometry, a sum peak of 1.022 MeV may be observed.

B. Gamma-ray spectrometry

Determine the amount of fluorine-18 and radionuclidic impurities with a half-life longer than 2 h. For the detection and quantification of impurities, retain the preparation to be examined for a sufficient time to allow the fluorine-18 to decay to a level that permits the detection of impurities.

Results: the spectrum obtained with the preparation to be examined does not differ significantly from a background spectrum.

RADIOCHEMICAL PURITY

Liquid chromatography (*2.2.29*) as described in the test for 6-fluorolevodopa, dopa, impurity A and impurity B.

Examine the chromatogram recorded using the radioactivity detector and locate the peak due to 6-[^{18}F]fluorolevodopa by comparison with the chromatogram obtained with reference solution (a) and the spectrophotometer.

Limit:

– *6-[^{18}F]fluorolevodopa*: minimum 95 per cent of the total radioactivity due to fluorine-18.

Impurities C and D. Thin-layer chromatography (*2.2.27*).

Test solution. The preparation to be examined.

Reference solution (a). Dissolve 2 mg of *DL-6-fluorodopa hydrochloride R* in *water R* and dilute to 10 ml with the same solvent.

Reference solution (b). Dissolve 2 mg of *6-fluorolevodopa hydrochloride R* in *water R* and dilute to 10 ml with the same solvent.

Plate: *octadecylsilyl TLC silica gel plate for chiral separations R*.

Mobile phase: *methanol R, water R* (50:50 *V/V*).

Application: 2 µl.

Development: over a path of 10 cm.

Drying: in air for 5 min.

Detection: spray with a 2 g/l solution of *ninhydrin R* in *anhydrous ethanol R* and heat at 60 °C for 10 min; determine the distribution of radioactivity using a suitable detector.

Retardation factors: impurity D = about 0; 6-[^{18}F]fluorolevodopa = about 0.3; impurity C = about 0.5.

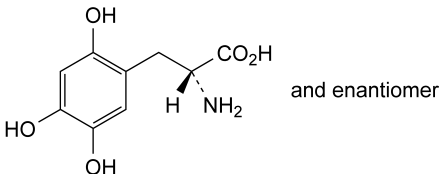
System suitability: reference solution (a):

– the chromatogram shows 2 clearly separated spots.

Limits:

– *impurity C*: maximum 2 per cent of the total radioactivity due to fluorine-18;
– *impurity D*: maximum 4 per cent of the total radioactivity due to fluorine-18.

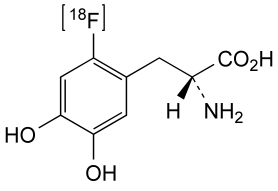
RADIOACTIVITY



Measure the radioactivity using a calibrated instrument.

LABELLING

The label states the maximum recommended dose in millilitres.



IMPURITIES

A. Cl-Sn(CH_3)$_3$: chlorotrimethylstannane (trimethyltin chloride),

and enantiomer

B. (2*RS*)-2-amino-3-(2,4,5-trihydroxyphenyl)propanoic acid (6-hydroxydopa),

C. (2*R*)-2-amino-3-(2-[^{18}F]fluoro-4,5-dihydroxyphenyl)propanoic acid (6-[^{18}F]fluorodextrodopa),

D. [^{18}F]fluoride.

01/2008:0555

GALLIUM (^{67}Ga) CITRATE INJECTION

Gallii (^{67}Ga) citratis solutio iniectabilis

DEFINITION

Gallium (^{67}Ga) citrate injection is a sterile solution of gallium-67 in the form of gallium citrate. It may be made isotonic by the addition of sodium chloride and sodium citrate and may contain a suitable antimicrobial preservative such as benzyl alcohol. Gallium-67 is a radioactive isotope of gallium and may be obtained by the irradiation, with protons of suitable energy, of zinc which may be enriched in zinc-68. Gallium-67 may be separated from zinc by solvent extraction or column chromatography. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared gallium-67 radioactivity at the date and hour stated on the label. Not more than 0.2 per cent of the total radioactivity is due to gallium-66.

CHARACTERS

A clear, colourless solution.

Gallium-67 has a half-life of 3.26 days and emits gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised gallium-67 solution when measured either by direct comparison or by use of an instrument calibrated with the aid of such a solution. Standardised gallium-67 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photons have energies of 0.093 MeV, 0.185 MeV and 0.300 MeV.

B. To 0.2 ml of the injection to be examined add 0.2 ml of a solution containing 1 g/l of *ferric chloride R* and 0.1 per cent *V/V* of *hydrochloric acid R* and mix. Compare the colour with that of a solution containing 9 g/l of *benzyl alcohol R* and 7 g/l of *sodium chloride R* treated in the same manner. A yellow colour develops in the test solution only.

TESTS

pH (*2.2.3*). The pH of the injection is 5.0 to 8.0.

Zinc. To 0.1 ml of the injection to be examined add 0.9 ml of *water R*, 5 ml of *acetate buffer solution pH 4.7 R*, 1 ml of a 250 g/l solution of *sodium thiosulphate R* and 5.0 ml of a dithizone solution prepared as follows: dissolve 10 mg of *dithizone R* in 100 ml of *methyl ethyl ketone R* allow to stand for 5 min, filter and immediately before use dilute the solution to ten times its volume with *methyl ethyl ketone R*. Shake vigorously for 2 min and separate the organic layer. Measure the absorbance (*2.2.25*) of the organic layer at 530 nm, using the organic layer of a blank solution as the compensation liquid. The absorbance is not greater than that of the organic layer obtained with 0.1 ml of *zinc standard solution (5 ppm Zn) R* treated in the same manner.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

RADIONUCLIDIC PURITY

Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised gallium-67 solution, apart from any differences attributable to the presence of gallium-66. Gallium-66 has a

half-life of 9.4 h and its most prominent gamma photon has an energy of 1.039 MeV. Not more than 0.2 per cent of the total radioactivity is due to gallium-66.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised gallium-67 solution or by measurement in an instrument calibrated with the aid of such a solution.

01/2008:1922

HUMAN ALBUMIN INJECTION, IODINATED (^{125}I)

Iodinati (^{125}I) humani albumini solutio iniectabilis

DEFINITION

Sterile, endotoxin-free solution of human albumin labelled with iodine-125. It may contain a suitable buffer and an antimicrobial preservative. The human albumin used complies with the requirements of the monograph on *Human albumin solution (0255)*.

Content: 90 per cent to 110 per cent of the declared iodine-125 radioactivity at the date stated on the label.

Purity:

- minimum of 99.0 per cent of the total radioactivity corresponds to iodine-125,
- minimum of 80 per cent of the total radioactivity is associated with the albumin fractions II to V,
- maximum of 5 per cent of the total radioactivity corresponds to unbound iodide.

Content of albumin: 95 per cent to 105 per cent of the declared albumin content stated on the label.

CHARACTERS

Appearance: clear, colourless to yellowish solution.

Half-life and nature of radiation of iodine-125: see general chapter *5.7. Table of physical characteristics of radionuclides*.

IDENTIFICATION

A. Gamma-ray and X-ray spectrometry.

Comparison: standardised iodine-125 solution, or by using a calibrated instrument. Standardised iodine-125 solutions and/or standardisation services are available from the competent authority.

Results: the spectrum obtained with the preparation to be examined does not differ significantly from that obtained with a standardised iodine-125 solution, apart from any differences attributable to the presence of iodine-126. The most prominent photon has an energy of 0.027 MeV, corresponding to the characteristic X-ray of tellurium, gamma photons of an energy of 0.035 MeV are also present. Iodine-126 has a half-life of 13.11 days and its most prominent gamma photons have energies of 0.388 MeV and 0.666 MeV.

B. Examine by a suitable immunoelectrophoresis technique (*2.7.1*). Using antiserum to normal human serum, compare normal human serum and the preparation to be examined, both diluted if necessary. The main component of the preparation to be examined corresponds to the main component of the normal human serum. The diluted solution may show the presence of small quantities of other plasma proteins.

TESTS

pH (*2.2.3*): 5.0 to 9.0.

Albumin

Reference solution. Dilute *human albumin solution R* with a 9 g/l solution of *sodium chloride R* to a concentration of 5 mg of albumin per millilitre.

To 1.0 ml of the preparation to be examined and to 1.0 ml of the reference solution add 4.0 ml of *biuret reagent R* and mix. After exactly 30 min, measure the absorbance (*2.2.25*) of each solution at 540 nm, using as the compensation liquid a 9 g/l solution of *sodium chloride R* treated in the same manner. From the absorbances measured, calculate the content of albumin in the injection to be examined in milligrams per millilitre.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*.

Bacterial endotoxins (*2.6.14*): less than 175/*V* IU/ml, *V* being the maximum recommended dose in millilitres.

RADIONUCLIDIC PURITY

Iodine-125: minimum 99.0 per cent of the total radioactivity.

Gamma-ray and X-ray spectroscopy.

Comparison: standardised solution of iodine-125.

Determine the relative amounts of iodine-125 and iodine-126 present.

RADIOCHEMICAL PURITY

Iodine-125 in albumin fractions II to V, iodine-125 corresponding to unbound iodide. Size-exclusion chromatography (*2.2.30*).

Test solution. Mix 0.25 ml of the preparation to be examined with 0.25 ml of the mobile phase. Use immediately after mixing.

Reference solution. *Human albumin solution R* or another appropriate human albumin standard diluted with the mobile phase to a suitable albumin concentration.

Column:

- *size*: *l* = 0.6 m, Ø = 7.5 mm,
- *stationary phase*: *silica gel for size-exclusion chromatography R*,
- *temperature*: 25 °C.

Mobile phase: dissolve 11.24 g of *potassium dihydrogen phosphate R*, 42.0 g of *disodium hydrogen phosphate R*, 11.70 g of *sodium chloride R* in 2000 ml of *water R*.

Flow rate: 0.6 ml/min.

Detection: spectrophotometer at 280 nm and radioactivity detector set for iodine-125 connected in series.

Injection: loop injector.

Run time: 85 min.

Retention times:

Peak No.	Fraction	Description of the compound	Retention time (min)
1	I	High molecular mass compound	18 - 20
2	II	Poly III albumin	23 - 24
3	III	Poly II albumin	25 - 26
4	IV	Poly I albumin	28
5	V	Human serum albumin	29 - 31
6	VI	Iodide	43 - 45

The main peak in the chromatogram obtained with the reference solution corresponds to fraction V.

Limits:

– *radioactivity in fractions II to V*: minimum 80 per cent of the total radioactivity applied to the column,
– *iodine-125 in fraction VI*: maximum 5 per cent of the total radioactivity.

RADIOACTIVITY

Measure the radioactivity using suitable equipment by comparison with a standardised iodine-125 solution or by measurement with a calibrated instrument.

LABELLING

The label states:

– the amount of albumin,
– the maximum volume to be injected.

01/2008:1227

INDIUM (^{111}In) CHLORIDE SOLUTION

Indii (^{111}In) chloridi solutio

DEFINITION

Indium (^{111}In) chloride solution is a sterile solution of indium-111 as the chloride in aqueous hydrochloric acid containing no additives. Indium-111 is a radioactive isotope of indium and may be produced by the irradiation of cadmium with protons of suitable energy. The solution contains not less than 90.0 per cent and not more than 110.0 per cent of the declared indium-111 radioactivity at the date and hour stated on the label. Not more than 0.25 per cent of the total radioactivity is due to radionuclides other than indium-111. Not less than 95 per cent of the radioactivity corresponds to indium-111 in the form of ionic indium(III). The method of preparation is such that no carrier is added and the specific radioactivity is not less than 1.85 GBq of indium-111 per microgram of indium.

CHARACTERS

A clear, colourless solution.

Indium-111 has a half-life of 2.8 days and emits gamma radiation and X-rays.

IDENTIFICATION

A. *Carry out the test after allowing sufficient time for short-lived impurities such as indium-110m to decay.* Record the gamma-ray and X-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised indium-111 solution apart from any differences due to the presence of indium-114m, when measured either by direct comparison or by using an instrument calibrated with the aid of such a solution. Standardised indium-111 and indium-114m solutions are available from laboratories recognised by the competent authority. The most prominent gamma photons of indium-111 have energies of 0.171 MeV and 0.245 MeV.

B. To 100 µl of *silver nitrate solution R2* add 50 µl of the solution. A white precipitate is formed.

C. It complies with the test for pH (see Tests).

D. Examine the chromatogram obtained in the test for radiochemical purity. The principal peak has an R_F value of 0.5 to 0.8.

TESTS

pH (*2.2.3*). The pH of the solution is 1.0 to 2.0.

Cadmium. Not more than 0.40 µg/ml, determined by electrothermal atomic absorption spectrometry (*2.2.23, Method I*).

Test solution. Dilute 0.05 ml of the solution to be examined to a suitable volume with a suitable concentration of *hydrochloric acid R*.

Reference solutions. Prepare the reference solutions using *cadmium standard solution (0.1 per cent Cd) R*, diluted as necessary with the same concentration of *hydrochloric acid R* as in the solution to be examined.

Measure the absorbance at 228.8 nm using a cadmium hollow-cathode lamp as source of radiation.

Copper. Not more than 0.15 µg/ml, determined by electrothermal atomic absorption spectrometry (*2.2.23, Method I*).

Test solution. Dilute 0.1 ml the solution to be examined to a suitable volume with a suitable concentration of *hydrochloric acid R*.

Reference solutions. Prepare the reference solutions using *copper standard solution (0.1 per cent) R* diluted as necessary with the same concentration of *hydrochloric acid R* as the solution to be examined.

Measure the absorbance at 324.8 nm using a copper hollow-cathode lamp as source of radiation.

Iron. Not more than 0.60 µg/ml, determined by electrothermal atomic absorption spectrometry (*2.2.23, Method I*).

Test solution. Dilute 0.1 ml of the solution to be examined to a suitable volume with a suitable concentration of *hydrochloric acid R*.

Reference solutions. Prepare the reference solutions using *iron standard solution (0.1 per cent Fe) R* diluted as necessary with the same concentration of *hydrochloric acid R* as the solution to be examined.

Measure the absorbance at 248.3 nm using an iron hollow-cathode lamp as source of radiation.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The solution may be released for use before completion of the test.

RADIONUCLIDIC PURITY

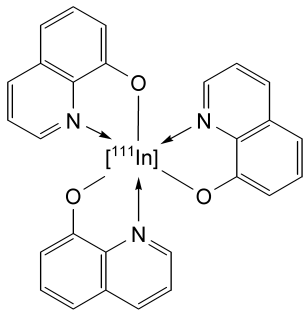
Record the gamma-ray and X-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised solution of indium-111 apart from any differences due to the presence of indium-114m.

Indium-114m. *Carry out the test after allowing sufficient time for short-lived impurities such as indium-110m to decay.* Take a volume equivalent to 30 MBq and record

the gamma-ray spectrum using a suitable detector with a shield of lead, 6 mm thick, placed between the sample and the detector. The response in the region corresponding to the 0.558 MeV photon and the 0.725 MeV photon of indium-114m does not exceed that obtained using 75 kBq of a standardised solution of indium-114m (0.25 per cent) measured under the same conditions, when all measurements are calculated with reference to the date and hour of administration. Standardised indium-111 and indium-114m solutions are available from laboratories recognised by the competent authority.

RADIOCHEMICAL PURITY

Examine by thin-layer chromatography (*2.2.27*) using silica gel as the coating substance on a glass-fibre sheet. Apply to the plate 5 µl of the solution to be examined. Develop immediately over a path of 15 cm using a 9.0 g/l solution of *sodium chloride R* adjusted to pH 2.3 ± 0.05 with *dilute hydrochloric acid R*. Allow the plate to dry in a current of cold air. Determine the distribution of radioactivity using a suitable detector. Indium-111 chloride migrates with an R_F value of 0.5 to 0.8. Not less than 95 per cent of the total radioactivity of the chromatogram corresponds to indium-111 chloride.



RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised indium-111 solution or by measurement in an instrument calibrated with the aid of such a solution.

01/2008:1109

INDIUM (^{111}In) OXINE SOLUTION

Indii (^{111}In) oxini solutio

$C_{27}H_{18}[^{111}In]N_3O_3$ M_r 547.2

DEFINITION

Indium (^{111}In) oxine solution is a sterile solution of indium-111 in the form of a complex with 8-hydroxyquinoline. It may contain suitable surface active agents and may be made iso-tonic by the addition of sodium chloride and a suitable buffer. Indium-111 is a radioactive isotope of indium and may be produced by the irradiation of cadmium with protons of suitable energy. The solution contains not less than 90.0 per cent and not more than 110.0 per cent of the declared indium-111 radioactivity at the date and hour stated on the label. Not more than 0.25 per cent of the total radioactivity is due to radionuclides other than indium-111. Not less than 90 per cent of the radioactivity corresponds to indium-111 complexed with oxine. The method of preparation is such that no carrier is added and the specific radioactivity is not less than 1.85 GBq of indium-111 per microgram of indium.

CHARACTERS

A clear, colourless solution.

Indium-111 has a half-life of 2.8 days and emits gamma radiation and X-rays.

IDENTIFICATION

A. *Carry out the test after allowing sufficient time for short-lived impurities such as indium-110m to decay.* Record the gamma-ray and X-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised indium-111 solution apart from any differences due to the presence of indium-114m, when measured either by direct comparison or by using an instrument calibrated with the aid of such a solution. Standardised indium-111 and indium-114m solutions are available from laboratories recognised by the competent authority. The most prominent gamma photons of indium-111 have energies of 0.171 MeV and 0.245 MeV.

B. Place 5 mg to 10 mg of *magnesium oxide R* in a glass container of approximately 20 mm in internal diameter. Add 20 µl of the solution to be examined. Examine in ultraviolet light at 365 nm. Bright yellow fluorescence is produced.

C. The distribution of radioactivity between the organic and aqueous phases in the test for radiochemical purity contributes to the identification of the preparation.

TESTS

pH (*2.2.3*). The pH of the solution is 6.0 to 7.5.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The solution may be released for use before completion of the test.

RADIONUCLIDIC PURITY

Record the gamma-ray and X-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised solution of indium-111, apart from any differences due to the presence of indium-114m.

Indium-114m. *Carry out the test after allowing sufficient time for short-lived impurities such as indium-110m to decay.* Take a volume equivalent to 30 MBq and record the gamma-ray spectrum using a suitable detector with a shield of lead, 6 mm thick, placed between the sample and the detector. The response in the region corresponding to the 0.558 MeV photon and the 0.725 MeV photon of indium-114m does not exceed that obtained using 75 kBq of a standardised solution of indium-114m (0.25 per cent) measured under the same conditions, when all measurements are calculated with reference to the date and hour of administration. (It should be noted that indium (^{111}In) oxine solution is a precursor used in the *in vitro* labelling of white blood cells or platelets prior to their re-injection into the patient. It is not intended for direct administration). Standardised indium-111 and indium-114m solutions are available from laboratories recognised by the competent authority.

RADIOCHEMICAL PURITY

To a silanised separating funnel containing 3 ml of a 9 g/l solution of *sodium chloride R* add 100 µl of the solution to be examined and mix. Add 6 ml of *octanol R* and shake vigorously. Allow the phases to separate and then run the lower layer into a suitable vial for counting. Allow the upper layer to drain completely into a similar vial. Add 1 ml of *octanol R* to the funnel, shake vigorously and drain into the vial containing the organic fraction. Add 5 ml of *dilute hydrochloric acid R* to the funnel, shake vigorously and drain these rinsings into a third vial. Seal each vial and, using a suitable instrument, measure the radioactivity in each. Calculate the radiochemical purity by expressing the radioactivity of the indium-111 oxine complex, found

in the organic phase, as a percentage of the radioactivity measured in the three solutions. Not less than 90 per cent of the radioactivity corresponds to indium-111 complexed with oxine.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised indium-111 solution or by measurement in an instrument calibrated with the aid of such a solution.

01/2008:0670
corrected 6.0

INDIUM (^{111}In) PENTETATE INJECTION

Indii (^{111}In) pentetatis solutio iniectabilis

DEFINITION

Indium (^{111}In) pentetate injection is a sterile and apyrogenic solution containing indium-111 in the form of indium diethylenetriaminepenta-acetate. It may contain calcium and may be made isotonic by the addition of sodium chloride and a suitable buffer. Indium-111 is a radioactive isotope of indium which may be obtained by proton irradiation, of appropriate energy, of cadmium which may be enriched with cadmium-111 or cadmium-112. The injection contains not less than 90 per cent and not more than 110 per cent of the declared indium-111 radioactivity at the date and hour stated on the label. The radioactivity due to indium-114m is not greater than 0.2 per cent of the total radioactivity at the date and hour of administration. Not less than 95 per cent of the radioactivity corresponds to indium-111 complexed with pentetate.

CHARACTERS

A clear, colourless solution.

Indium-111 has a half-life of 2.8 days and emits gamma radiation and X-rays.

IDENTIFICATION

A. Record the gamma-ray and X-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised indium-111 solution apart from any differences due to the presence of indium-114m, when measured either by direct comparison or by using an instrument calibrated with the aid of such a solution. Standardised indium-111 and indium-114m solutions are available from laboratories recognised by the competent authority. The most prominent gamma photons of indium-111 have energies of 0.171 MeV and 0.245 MeV.

B. Examine the chromatogram obtained in the test for radiochemical purity. The distribution of radioactivity contributes to the identification of the preparation.

TESTS

pH (*2.2.3*). The pH of the injection is 7.0 to 8.0.

Cadmium. Not more than 5.0 µg of Cd per millilitre, determined by atomic absorption spectrometry (*2.2.23, Method II*).

Test solution. Mix 0.1 ml of the injection to be examined with 0.9 ml of a mixture of 1 volume of *hydrochloric acid R* and 99 volumes of *water R*.

Reference solutions. Prepare the reference solutions using *cadmium standard solution (0.1 per cent Cd) R* and diluting with a mixture of 1 volume of *hydrochloric acid R* and 99 volumes of *water R*.

Measure the absorbance at 228.8 nm using a cadmium hollow-cathode lamp as source of radiation and an air-acetylene flame.

Uncomplexed diethylenetriaminepenta-acetic acid. In a micro test-tube, mix 100 µl of the injection to be examined with 100 µl of a freshly prepared 1 g/l solution of *hydroxynaphthol blue, sodium salt R* in *1 M sodium hydroxide*. Add 50 µl of a 0.15 g/l solution of *calcium chloride R*. The solution remains pinkish-violet or changes from blue to pinkish-violet (0.4 mg/ml).

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

Bacterial endotoxins (*2.6.14*): less than 14/*V* IU/ml, *V* being the maximum recommended dose in millilitres.

RADIONUCLIDIC PURITY

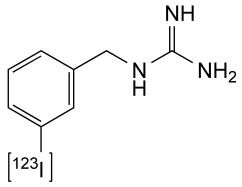
Record the gamma-ray and X-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised solution of indium-111 apart from any differences due to the presence of indium-114m.

Indium-114m. Retain a sample of the injection to be examined for a sufficient time to allow the indium-111 radioactivity to decay to a sufficiently low level to permit the detection of radionuclidic impurities. Record the gamma-ray spectrum of the decayed material in a suitable instrument calibrated with the aid of a standardised indium-114m solution. Indium-114m has a half-life of 49.5 days and its most prominent gamma photon has an energy of 0.190 MeV. The radioactivity due to indium-114m is not greater than 0.2 per cent of the total radioactivity at the date and hour of administration.

RADIOCHEMICAL PURITY

Examine by thin-layer chromatography (*2.2.27*) using silica gel as the coating substance on a glass-fibre sheet. Heat the plate at 110 °C for 10 min. Use a plate such that during development the mobile phase migrates over a distance of 10 cm to 15 cm in about 10 min.

Apply to the plate 5 µl to 10 µl of the injection to be examined and allow to dry. Develop over a path of 10 cm to 15 cm using a 9 g/l solution of *sodium chloride R*. Allow the plate to dry in air. Determine the distribution of radioactivity using a suitable detector. Indium pentetate complex migrates near to the solvent front. The radioactivity of the spot corresponding to indium pentetate complex represents not less than 95 per cent of the total radioactivity of the chromatogram.



RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised indium-111 solution or by measurement in an instrument calibrated with the aid of such a solution.

01/2008:1113

IOBENGUANE (^{123}I) INJECTION

Iobenguani (^{123}I) solutio iniectabilis

$C_8H_{10}[^{123}I]N_3$

DEFINITION

Iobenguane (^{123}I) injection is a sterile, bacterial endotoxin-free solution of 1-(3-[^{123}I]iodobenzyl)guanidine or its salts. It may contain a suitable buffer, a suitable labelling catalyst such as ionic copper, a suitable labelling stabiliser such as ascorbic acid and antimicrobial preservatives. Iodine-123 is a radioactive isotope of iodine and may be obtained by proton irradiation of xenon enriched in xenon-124 (not less than 98 per cent) followed by the decay of caesium-123 formed via xenon-123. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared iodine-123 radioactivity at the date and hour stated on the label. Not less than 95 per cent of the radioactivity corresponds to iodine-123 in the form of iobenguane. The specific radioactivity is not less than 10 GBq of iodine-123 per gram of iobenguane base. Not more than 0.35 per cent of the total radioactivity is due to radionuclides other than iodine-123.

CHARACTERS

A clear, colourless or slightly yellow solution.

Iodine-123 has a half-life of 13.2 h and emits gamma radiation and X-rays.

IDENTIFICATION

A. Record the gamma-ray and X-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised iodine-123 solution apart from any differences attributable to the presence of iodine-125, tellurium-121 and other radionuclidic impurities. The most prominent gamma photon of iodine-123 has an energy of 0.159 MeV. Iodine-125 has a half-life of 59.4 days and emits an X-ray of 0.027 MeV and a photon of 0.035 MeV. Tellurium-121 has a half-life of 19.2 days and the most prominent photons have energies of 0.507 MeV and 0.573 MeV. Standardised iodine-123, iodine-125 and tellurium-121 solutions are available from laboratories recognised by the competent authority.

B. Examine the chromatogram obtained in the test for radiochemical purity. The distribution of the radioactivity contributes to the identification of the preparation.

TESTS

pH (*2.2.3*). The pH of the solution is 3.5 to 8.0.

Specific radioactivity. The specific radioactivity is calculated from the results obtained in the test for radiochemical purity. Determine the content of iobenguane sulphate from the areas of the peaks corresponding to iobenguane in the chromatograms obtained with the test solution and reference solution (b). Calculate the concentration as iobenguane base by multiplying the result obtained in the assay by 0.85.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

Bacterial endotoxins (*2.6.14*): less than 175/*V* IU/ml, *V* being the maximum recommended dose in millilitres.

RADIONUCLIDIC PURITY

Record the gamma-ray spectrum using a suitable instrument. Determine the relative amounts of iodine-125, tellurium-121 and other radionuclidic impurities present. No radionuclides with a longer half-life than iodine-125 are detected. For the determination of iodine-125, tellurium-121 and other radionuclidic impurities, retain the solution to be examined for a sufficient time to allow the radioactivity of iodine-123 to decrease to a level that permits the detection of radionuclidic impurities. Record the gamma-ray spectrum and the X-ray spectrum of the decayed material using a suitable instrument. Not more than 0.35 per cent of the total radioactivity is due to radionuclides other than iodine-123. The injection may be released for use before completion of the test.

RADIOCHEMICAL PURITY

Examine by liquid chromatography (*2.2.29*).

Test solution. The injection to be examined.

Reference solution (a). Dissolve 0.100 g of *sodium iodide R* in the mobile phase and dilute to 100 ml with the mobile phase.

Reference solution (b). Dissolve 10.0 mg of *iobenguane sulphate CRS* in 25 ml of the mobile phase and dilute to 50.0 ml with the mobile phase.

The chromatographic procedure may be carried out using:

- a stainless steel column 0.25 m long and 4.0 mm in internal diameter packed with *silica gel for chromatography R* (5 µm),
- as mobile phase at a flow rate of 1.0 ml/min a mixture of 1 volume of an 80 g/l solution of *ammonium nitrate R*, 2 volumes of *dilute ammonia R2* and 27 volumes of *methanol R*,
- a suitable radioactivity detector,
- a spectrophotometer set at 254 nm and provided with a flow-cell,
- a 10 µl loop injector.

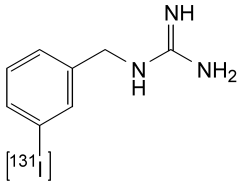
Inject the test solution and the reference solutions. Not less than 95 per cent of the radioactivity of the chromatogram is found in the peak corresponding to iobenguane. Not more than 4 per cent of the radioactivity is found in the peak corresponding to iodide and not more than 1 per cent of the radioactivity is found in other peaks.

RADIOACTIVITY

Measure the radioactivity using a suitable counting apparatus by comparison with a standardised iodine-123 solution or by measurement in an instrument calibrated with the aid of such a solution.

STORAGE

Store protected from light.



LABELLING

The label states the specific radioactivity expressed in GBq of iodine-123 per gram of iobenguane base.

01/2008:1111

IOBENGUANE (^{131}I) INJECTION FOR DIAGNOSTIC USE

Iobenguani (^{131}I) solutio iniectabilis ad usum diagnosticum

$C_8H_{10}[^{131}I]N_3$

DEFINITION

Iobenguane (^{131}I) injection for diagnostic use is a sterile, bacterial endotoxin-free solution of 1-(3-[^{131}I]iodobenzyl)guanidine or its salts. It may contain a suitable buffer. It may also contain a suitable labelling catalyst such as ionic copper and a suitable labelling stabiliser such as ascorbic acid. It may contain antimicrobial preservatives. Iodine-131 is a radioactive isotope of iodine and may be obtained by neutron irradiation of tellurium or by extraction of uranium fission products. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared iodine-131 radioactivity at the date and hour stated on the label. Not less than 94 per cent of the radioactivity corresponds to iodine-131 in the form of iobenguane. The specific radioactivity is not less than 20 GBq of iodine-131 per gram of iobenguane base.

CHARACTERS

A clear, colourless or slightly yellow solution.

Iodine-131 has a half-life of 8.04 days and emits beta and gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised iodine-131 solution by direct comparison with such a solution. Standardised iodine-131 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of iodine-131 has an energy of 0.365 MeV.

B. Examine the chromatogram obtained in the test for radiochemical purity. The distribution of the radioactivity contributes to the identification of the preparation.

TESTS

pH (*2.2.3*). The pH of the solution is 3.5 to 8.0.

Specific radioactivity. The specific radioactivity is calculated from the results obtained in the test for radiochemical purity. Determine the content of iobenguane sulphate from the areas of the peaks corresponding to iobenguane in the chromatograms obtained with the test solution and reference solution (b). Calculate the concentration as iobenguane base by multiplying the result obtained in the assay by 0.85.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

Bacterial endotoxins (*2.6.14*): less than 175/*V* IU/ml, *V* being the maximum recommended dose in millilitres.

RADIONUCLIDIC PURITY

Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised iodine-131 solution. Determine the relative amounts of iodine-131, iod-ine-133, iodine-135 and other radionuclidic impurities present. Iodine-133 has a half-life of 20.8 h and its most prominent gamma photons have energies of 0.530 MeV and 0.875 MeV. Iodine-135 has a half-life of 6.55 h and its most prominent gamma photons have energies of 0.527 MeV, 1.132 MeV and 1.260 MeV. Not less than 99.9 per cent of the total radioactivity is due to iodine-131.

RADIOCHEMICAL PURITY

Examine by liquid chromatography (*2.2.29*).

Test solution. The injection to be examined.

Reference solution (a). Dissolve 0.100 g of *sodium iodide R* in the mobile phase and dilute to 100 ml with the mobile phase.

Reference solution (b). Dissolve 10.0 mg of *iobenguane sulphate CRS* in 25 ml of the mobile phase and dilute to 50.0 ml with the mobile phase.

The chromatographic procedure may be carried out using:

– a stainless steel column 0.25 m long and 4.0 mm in internal diameter packed with *silica gel for chromatography R* (5 µm),

– as mobile phase at a flow rate of 1.0 ml/min a mixture of 1 volume of an 80 g/l solution of *ammonium nitrate R*, 2 volumes of *dilute ammonia R2* and 27 volumes of *methanol R*,

– a suitable radioactivity detector,

– a spectrophotometer set at 254 nm and provided with a flow-cell,

– a 10 µl loop injector.

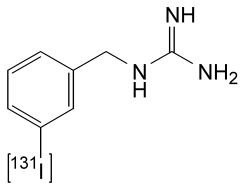
Inject the test solution and the reference solutions. Not less than 94 per cent of the radioactivity of the chromatogram is found in the peak corresponding to iobenguane. Not more than 5 per cent of the radioactivity is found in the peak corresponding to iodide and not more than 1 per cent of the radioactivity is found in other peaks.

RADIOACTIVITY

Measure the radioactivity using a suitable counting apparatus by comparison with a standardised iodine-131 solution or by measurement in an instrument calibrated with the aid of such a solution.

STORAGE

Store protected from light.



LABELLING

The label states the specific radioactivity expressed in gigabecquerels of iodine-131 per gram of iobenguane base.

01/2008:1112

IOBENGUANE (^{131}I) INJECTION FOR THERAPEUTIC USE

Iobenguani (^{131}I) solutio iniectabilis ad usum therapeuticum

$C_8H_{10}[^{131}I]N_3$

DEFINITION

Iobenguane (^{131}I) injection for therapeutic use is a sterile, bacterial endotoxin-free solution of 1-(3-[^{131}I]iodobenzyl)guanidine or its salts. It may contain a suitable buffer, a suitable labelling catalyst such as ionic copper, a suitable labelling stabiliser such as ascorbic acid and antimicrobial preservatives. Iodine-131 is a radioactive isotope of iodine and may be obtained by neutron irradiation of tellurium or by extraction of uranium fission products. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared iodine-131 radioactivity at the date and hour stated on the label. Not less than 92 per cent of the radioactivity corresponds to iodine-131 in the form of iobenguane. The specific radioactivity is not less than 400 GBq of iodine-131 per gram of iobenguane base.

CHARACTERS

A clear, colourless or slightly yellow solution.

Iodine-131 has a half-life of 8.04 days and emits beta and gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised iodine-131 solution by direct comparison with such a solution. Standardised iodine-131 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of iodine-131 has an energy of 0.365 MeV.

B. Examine the chromatogram obtained in the test for radio-chemical purity. The distribution of the radioactivity contributes to the identification of the preparation.

TESTS

pH (*2.2.3*). The pH of the solution is 3.5 to 8.0.

Specific radioactivity. The specific radioactivity is calculated from the results obtained in the test for radiochemical purity. Determine the content of iobenguane sulphate from the areas of the peaks corresponding to iobenguane in the chromatograms obtained with the test solution and reference solution (b). Calculate the concentration as iobenguane base by multiplying the result obtained in the assay by 0.85.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

Bacterial endotoxins (*2.6.14*): less than 175/*V* IU/ml, *V* being the maximum recommended dose in millilitres.

RADIONUCLIDIC PURITY

Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised iodine-131 solution. Determine the relative amounts of iodine-131, iodine-133, iodine-135 and other radionuclidic impurities present. Iodine-133 has a half-life of 20.8 h and its most prominent gamma photons have energies of 0.530 MeV and 0.875 MeV. Iodine-135 has a half-life of 6.55 h and its most prominent gamma photons have energies of 0.527 MeV, 1.132 MeV and 1.260 MeV. Not less than 99.9 per cent of the total radioactivity is due to iodine-131.

RADIOCHEMICAL PURITY

Examine by liquid chromatography (*2.2.29*).

Test solution. The injection to be examined.

Reference solution (a). Dissolve 0.100 g of *sodium iodide R* in the mobile phase and dilute to 100 ml with the mobile phase.

Reference solution (b). Dissolve 10.0 mg of *iobenguane sulphate CRS* in 25 ml of the mobile phase and dilute to 50.0 ml with the mobile phase.

The chromatographic procedure may be carried out using:

– a stainless steel column 0.25 m long and 4.0 mm in internal diameter packed with *silica gel for chromatography R* (5 µm),

IOBENGUANE SULPHATE FOR RADIOPHARMACEUTICAL PREPARATIONS

Iobenguani sulfas ad radiopharmaceutica

$C_{16}H_{22}I_2N_6O_4S$ M_r 648

DEFINITION

Bis[(3-iodobenzyl)guanidine] sulphate.

Content: 98.0 per cent to 102.0 per cent.

CHARACTERS

Appearance: white or almost white crystals.

IDENTIFICATION

A. Infrared absorption spectrophotometry (*2.2.24*).
Comparison: *Ph. Eur. reference spectrum of iobenguane sulphate.*

B. Dissolve about 10 mg in 1 ml of *water R* with gentle heating. The solution gives reaction (a) of sulphates (*2.3.1*).

TESTS

Related substances. Liquid chromatography (*2.2.29*).
Prepare the solutions immediately before use.

Test solution. Dissolve 10.0 mg of the substance to be examined in 1 ml of *anhydrous ethanol R* with gentle heating and dilute to 5.0 ml with the same solvent.

Reference solution (a). Dissolve 10.0 mg of *iobenguane sulphate CRS* in 1 ml of *anhydrous ethanol R* with gentle heating and dilute to 5.0 ml with the same solvent.

Reference solution (b). Dissolve 23.1 mg of *3-iodobenzylammonium chloride R* (salt of impurity A) in 1 ml of *anhydrous ethanol R* with gentle heating and dilute to 10.0 ml with the same solvent.

Reference solution (c). Mix 1 ml of reference solution (a) and 1 ml of reference solution (b).

Reference solution (d). Dilute 0.1 ml of reference solution (b) to 10.0 ml with *anhydrous ethanol R*.

Column:
- *size*: *l* = 0.25 m, Ø = 4.0 mm;
- *stationary phase*: *silica gel for chromatography R* (5 µm);
- *temperature*: maintain at a constant temperature between 20 °C and 30 °C.

Mobile phase: mix 40 ml of an 80 g/l solution of *ammonium nitrate R*, 80 ml of *dilute ammonia R2* and 1080 ml of *methanol R*.

Flow rate: 1 ml/min.

Detection: spectrophotometer at 254 nm.

Injection: 20 µl of the test solution and reference solutions (c) and (d).

Run time: 15 min.

Relative retention with reference to iobenguane (retention time = about 7 min): impurity A = about 0.2.

System suitability: reference solution (c):
- *resolution*: minimum 4.0 between the peaks due to iobenguane and impurity A.

Limit:
- *impurity A*: not more than the area of the corresponding peak in the chromatogram obtained with reference solution (d) (1.0 per cent).

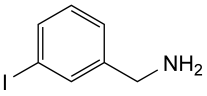
ASSAY

Liquid chromatography (*2.2.29*) as described in the test for related substances with the following modification.

Injection: test solution and reference solution (a).

Calculate the percentage content of $C_{16}H_{22}I_2N_6O_4S$ from the declared content of *iobenguane sulphate CRS*.

STORAGE



Protected from light, at a temperature below 25 °C.

LABELLING

The label recommends testing the substance in a production test before its use for the manufacture of radiopharmaceutical preparations. This ensures that, under specified production conditions, the substance yields the radiopharmaceutical preparation in the desired quantity and quality specified.

IMPURITIES

Specified impurities: A.

A. 1-(3-iodophenyl)methanamine.

01/2008:1533

KRYPTON (^{81m}Kr) INHALATION GAS

Kryptonum (^{81m}Kr) ad inhalationem

DEFINITION

Krypton (^{81m}Kr) inhalation gas is a mixture of krypton-81m and a suitable vehicle such as air.

Krypton-81m is formed by decay of its parent radionuclide rubidium-81. Rubidium-81 has a half-life of 4.58 h.

The krypton-81m formed is separated from the rubidium-81 with a flow of a suitable gas in a rubidium/krypton generator. Rubidium-81 is produced by proton irradiation of krypton isotopes or by helium-3 or helium-4 irradiation of bromine. After separation of rubidium-81 from the target, it is retained by a suitable support.

Krypton-81m is eluted at a suitable flow rate with a vehicle such as air. The level of moisture required in the eluent depends on the type of generator used. The transport tube for administration has a defined length and inner diameter. The radioactivity concentration is determined before administration.

The radioactivity due to radionuclides other than krypton-81m is not greater than 0.1 per cent, expressed as a percentage of the total radioactivity in the preparation and calculated with reference to the date and time of administration.

CHARACTERS

A clear, colourless gas.

Krypton-81m has a half-life of 13.1 s and emits gamma radiation.

IDENTIFICATION

A. Record the gamma-ray and X-ray spectrum using a suitable instrument. The gamma photon of krypton-81m has an energy of 0.190 MeV.

B. The half-life is 11.8 s to 14.4 s.

TESTS

RADIONUCLIDIC PURITY

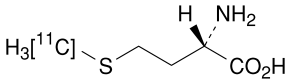
Elute the generator as prescribed. Pass a sufficient amount (2 litres to 10 litres) of eluate at a suitable flow rate through a suitable absorber such as water. Determine the amount of radioactivity eluted. Allow the krypton-81m to decay for 5 min and record the gamma and X-ray spectrum of the residual radioactivity on the absorber using a suitable instrument. Examine the gamma-ray and X-ray spectrum of the absorber for the presence of radioactive impurities, which must be identified and quantified. The absorbed radioactivity is not more than 0.1 per cent of the radioactivity passed through the absorber, calculated with reference to the date and time of administration.

RADIOACTIVITY

Determine the radioactive concentration of the preparation using suitable equipment such as an ionisation chamber or a gamma ray spectrometer. The measurement equipment may be calibrated by reference to a primary calibrated instrument at a laboratory recognised by the competent authority. The radioactivity is measured under defined operating conditions, such as gas flow rate and measurement geometry, that are identical to those used for the calibration of the instrument.

STORAGE

The storage conditions apply to the generator.



LABELLING

The labelling conditions apply to the generator.

01/2008:1617

L-METHIONINE ([11C]METHYL) INJECTION

L-Methionini ([11C]methyl) solutio iniectabilis

DEFINITION

Sterile solution of (2*S*)-2-amino-4-([11C]methylsulphanyl)butanoic acid for diagnostic use.

Content: 90 per cent to 110 per cent of the declared carbon-11 radioactivity at the date and time stated on the label.

Purity:

- minimum of 99 per cent of the total radioactivity corresponds to carbon-11,
- minimum of 95 per cent of the total radioactivity corresponds to carbon-11 in the form of L-[*methyl*-11C]methionine and D-[*methyl*-11C]methionine,
- maximum of 10 per cent of the total radioactivity corresponds to carbon-11 in the form of D-[*methyl*-11C]methionine.

Content of methionine: maximum of 2 mg per maximum recommended dose in millilitres.

PRODUCTION

RADIONUCLIDE PRODUCTION

Carbon-11 is a radioactive isotope of carbon which is most commonly produced by proton irradiation of nitrogen. Depending on the addition of either trace amounts of oxygen or small amounts of hydrogen, the radioactivity is obtained as [11C]carbon dioxide or [11C]methane.

RADIOCHEMICAL SYNTHESIS

L-[*Methyl*-11C]methionine can be prepared by various chemical synthetic pathways. All methods rely on the alkylation of the sulphide anion of L-homocysteine with [11C]methyl iodide or [11C]methyl triflate. Variations in the procedures used to generate the sulphide anion of L-homocysteine and methods to obtain [11C]methyl iodide lead to negligible differences with respect to quality in terms of specific radioactivity, enantiomeric purity and possible chemical and radiochemical impurities.

Synthesis of [11C]methyl iodide

[11C]Methyl iodide can be obtained either starting from [11C]carbon dioxide or from [11C]methane. The most frequently used method is the reduction of [11C]carbon dioxide with lithium aluminium hydride. The formed [11C]methanol is reacted with hydroiodic acid. Alternatively [11C]methane, either obtained directly in the target or by on-line processes from [11C]carbon dioxide, is reacted with iodine.

Synthesis of [11C]methyl triflate

[11C]methyl triflate can be prepared from [11C]methyl iodide using a silver triflate-impregnated solid support such as graphitised carbon.

Synthesis of L-[*methyl*-11C]methionine

The most widely used method to obtain L-[*methyl*-11C]methionine is the alkylation of the sulphide anion, generated from L-homocysteine thiolactone, with [11C]methyl iodide or [11C]methyl triflate in alkaline conditions in a solvent such as acetone. The L-[*methyl*-11C]methionine obtained can be purified by semi-preparative liquid chromatography. For example, a column packed with octadecylsilyl silica gel for chromatography eluted with a 9 g/l solution of sodium chloride is suitable.

L-Homocysteine thiolactone hydrochloride

Specific optical rotation (*2.2.7*): + 20.5 to + 21.5, determined on a 10 g/l solution at 25 °C.

Infrared absorption spectrophotometry (*2.2.24*).

Comparison: *Ph. Eur. reference spectrum of L-homocysteine thiolactone hydrochloride.*

CHARACTERS

Appearance: clear, colourless solution.

Half-life and nature of radiation of carbon-11: see general chapter *5.7. Table of physical characteristics of radionuclides.*

IDENTIFICATION

A. Gamma-ray spectrometry.

Results: the only gamma photons have an energy of 0.511 MeV and, depending on the measurement geometry, a sum peak of 1.022 MeV may be observed.

B. It complies with the test for radionuclidic purity (see Tests).

C. Examine the chromatograms obtained in the test for radiochemical purity.

Results: the principal peak in the radiochromatogram obtained with the test solution is similar in retention time to the principal peak in the chromatogram obtained with reference solution (b).

TESTS

pH (*2.2.3*): 4.5 to 8.5.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

Bacterial endotoxins (*2.6.14*): less than 175/*V* IU/ml, *V* being the maximum recommended dose in millilitres. The injection may be released for use before completion of the test.

CHEMICAL PURITY

Impurity A, impurity B and methionine. Liquid chromatography (*2.2.29*).

Test solution. The preparation to be examined.

Reference solution (a). Dissolve 0.6 mg of *L-homocysteine thiolactone hydrochloride R*, 2 mg of *DL-homocysteine R* and 2 mg of *DL-methionine R* in *water R* and dilute to *V*, *V* being the maximum recommended dose in millilitres.

Reference solution (b). Dissolve 2 mg of *L-methionine R* in the same solvent as used in the test solution and dilute to 10 ml with the same solvent.

Column:

- *size*: *l* = 0.25 m, Ø = 4.6 mm,
- *stationary phase*: spherical *octadecylsilyl silica gel for chromatography R* (5 µm) with a specific surface of 220 m^2/g, a pore size of 8 nm and a carbon loading of 6.2 per cent,
- *temperature*: 25 °C.

Mobile phase: 1.4 g/l solution of *potassium dihydrogen phosphate R*.

Flow rate: 1 ml/min.

Detection: spectrophotometer at 225 nm and radioactivity detector connected in series.

Injection: loop injector.

Run time: 10 min.

Relative retention with reference to methionine (retention time = about 2.6 min): impurity B = about 0.8, impurity A = about 2.7.

System suitability: reference solution (a):

- *resolution*: minimum of 2.5 between the peaks due to methionine and impurity B.

Limits: examine the chromatogram obtained with the spectrophotometer:

- *impurity A*: not more than the area of the corresponding peak in the chromatogram obtained with reference solution (a) (0.6 mg/*V*),
- *impurity B*: not more than the area of the corresponding peak in the chromatogram obtained with reference solution (a) (2 mg/*V*),
- *methionine*: not more than the area of the corresponding peak in the chromatogram obtained with reference solution (a) (2 mg/*V*).

Residual solvents (*2.4.24*): maximum 50 mg/*V* for the concentration of acetone, *V* being the maximum recommended dose in millilitres. The preparation may be released for use before completion of the test.

RADIONUCLIDIC PURITY

Carbon-11: minimum 99 per cent of the total radioactivity.

A. Gamma-ray spectroscopy.

Comparison: standardised fluorine-18 solution, or by using an instrument calibrated with the aid of such a solution. Standardised fluorine-18 solutions and/or standardisation services are available from the competent authority.

Results: the spectrum obtained with the solution to be examined does not differ significantly from that obtained with a standardised fluorine-18 solution.

B. Half-life: 19.9 min to 20.9 min.

The preparation may be released for use before completion of the test.

RADIOCHEMICAL PURITY

L-[Methyl-^{11}C]methionine and impurity E. Liquid chromatography (*2.2.29*) as described in the test for impurity A, impurity B and methionine.

Injection: test solution and reference solution (b).

Limits: examine the chromatogram obtained with the radioactivity detector:

- *total of L-[methyl-^{11}C]methionine and impurity E*: minimum of 95 per cent of the total radioactivity,
- other peaks in the chromatogram may be due to impurity C, impurity D and impurity F.

ENANTIOMERIC PURITY

Impurity E. Thin-layer chromatography (*2.2.27*).

Test solution. The preparation to be examined.

Reference solution (a). Dissolve 2 mg of *L-methionine R* in *water R* and dilute to 10 ml with the same solvent.

Reference solution (b). Dissolve 4 mg of *DL-methionine R* in *water R* and dilute to 10 ml with the same solvent.

Plate: *TLC octadecysilyl silica gel plate for chiral separations R*.

Mobile phase: *methanol R, water R* (50:50 *V/V*).

Application: 2-10 µl.

Development: over a path of 8 cm.

Drying: in air for 5 min.

Detection: spray with a 2 g/l solution of *ninhydrin R* in *ethanol R* and heat at 60 °C for 10 min. Determine the distribution of radioactivity using a suitable detector.

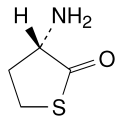
Retardation factors: L-[*methyl*-^{11}C]methionine = about 0.58; impurity E = about 0.51.

System suitability: the chromatogram obtained with reference solution (b) shows 2 clearly separated spots.

Limits:

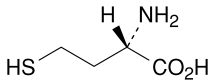
- *total of L-[methyl-^{11}C]methionine and impurity E*: minimum 95 per cent of the total radioactivity,
- *impurity E*: maximum 10 per cent of the total radioactivity.

The preparation may be released for use before completion of the test.



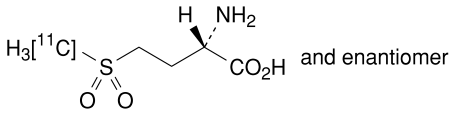
RADIOACTIVITY

Measure the radioactivity using suitable equipment by comparison with a standardised fluorine-18 solution or by measurement in an instrument calibrated with the aid of such a solution.

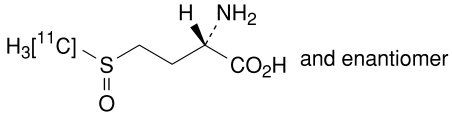


LABELLING

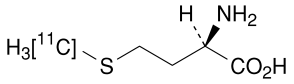
The accompanying information specifies the maximum recommended dose in millilitres.



IMPURITIES



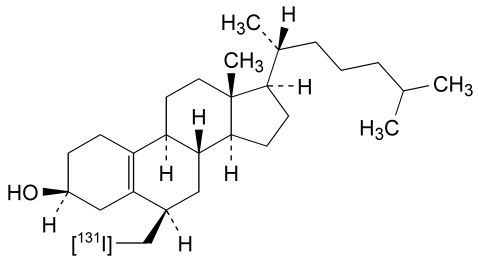
A. (3*S*)-3-aminodihydrothiophen-2(3*H*)-one (L-homocysteine thiolactone),



B. (2*S*)-2-amino-4-sulphanylbutanoic acid (L-homocysteine),

C. (2*RS*)-2-amino-4-([^{11}C]methylsulphonyl)butanoic acid (DL-[*methyl*-^{11}C]methionine *S,S*-dioxide),

D. (2*RS*)-2-amino-4-([^{11}C]methylsulphinyl)butanoic acid (DL-[*methyl*-^{11}C]methionine *S*-oxide),



E. (2*R*)-2-amino-4-([^{11}C]methylsulphanyl)butanoic acid (D-[*methyl*-^{11}C]methionine),

F. [^{11}C]methanol

01/2008:0939

NORCHOLESTEROL INJECTION, IODINATED (^{131}I)

Norcholesteroli iodinati (^{131}I) solutio iniectabilis

DEFINITION

Iodinated (^{131}I) norcholesterol injection is a sterile, bacterial endotoxin-free solution of 6β-[^{131}I]iodomethyl-19-norcholest-5(10)-en-3β-ol. It may contain a suitable emulsifier such as polysorbate 80 and a suitable antimicrobial preservative such as benzyl alcohol. Iodine-131 is a radioactive isotope of iodine and may be obtained by neutron irradiation of tellurium or by extraction from uranium fission products. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared iodine-131 radioactivity at the date and hour stated on the label. Not less than 85 per cent of the radioactivity corresponds to iodine-131 in the form of 6β-[^{131}I]iodomethyl-19-norcholest-5(10)-en-3β-ol. Not more than 5 per cent of the radioactivity corresponds to iodine-131 in the form of iodide. The specific radioactivity is 3.7 GBq to 37 GBq per gram of 6β-iodomethylnorcholesterol.

CHARACTERS

A clear or slightly turbid, colourless or pale yellow solution.

Iodine-131 has a half-life of 8.04 days and emits beta and gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised iodine-131 solution by direct comparison with such a solution. The most prominent photon of iodine-131 has an energy of 0.365 MeV. Standardised iodine-131 solutions are available from laboratories recognised by the competent authority.

B. Examine the chromatogram obtained in test (a) for radiochemical purity. The distribution of radioactivity contributes to the identification of the preparation.

TESTS

pH (*2.2.3*). The pH of the solution is between 3.5 and 8.5.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

Bacterial endotoxins (*2.6.14*): less than 175/*V* IU/ml, *V* being the maximum recommended dose in millilitres.

RADIONUCLIDIC PURITY

Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised iodine-131 solution. Determine the relative amounts of iodine-131, iodine-133, iodine-135 and other radionuclidic impurities present. Iodine-133 has a half-life of 20.8 h and its most prominent gamma photons have energies of 0.530 MeV and 0.875 MeV. Iodine-135 has a half-life of 6.55 h and its most prominent gamma photons have energies of 0.527 MeV, 1.132 MeV and 1.260 MeV. Not less than 99.9 per cent of the total radioactivity is due to iodine-131.

RADIOCHEMICAL PURITY

a) Examine by thin-layer chromatography (*2.2.27*) using *silica gel* GF_{254} *R* as the coating substance.

Test solution. The injection to be examined.

Carrier solution. Dissolve 10 mg of *potassium iodide R*, 20 mg of *potassium iodate R* and 0.1 g of *sodium hydrogen carbonate R* in *distilled water R* and dilute to 10 ml with the same solvent.

Apply to the plate up to 5 µl of the test solution and 10 µl of the carrier solution on the same spot. Develop over a path of 15 cm (about 60 min) using *chloroform R*. Allow the plate to dry in air and examine in ultraviolet light at 254 nm. Determine the distribution of radioactivity using a suitable detector. In the chromatogram obtained, not less than 85 per cent of the total radioactivity is found in the spot corresponding to 6β-iodomethyl-19-norcholest-5(10)-en-3β-ol at an R_F value of about 0.5. Iodide ion remains near the starting-line.

Radiopharmaceutical preparations

b) Examine by thin-layer chromatography (*2.2.27*) using *silica gel GF_{254} R* as the coating substance.

Test solution. The injection to be examined.

Carrier solution. Dissolve 10 mg *potassium iodide R*, 20 mg of *potassium iodate R* and 0.1 g of *sodium hydrogen carbonate R* in *distilled water R* and dilute to 10 ml with the same solvent.

Apply to the plate 10 µl of the carrier solution and then up to 5 µl of the test solution on the same spot. Develop over a path of 15 cm (about 90 min) using a mixture of equal volumes of *chloroform R* and *ethanol R*. Allow the plate to dry in air. Expose the plate to ultraviolet light at 254 nm for 5 min. A yellow spot corresponding to iodide develops at an R_F value of about 0.5. Determine the distribution of radio- activity using a suitable detector. The main peak of radio-activity is near to the solvent front. Other iodocholesterols migrate near the solvent front. In the chromatogram obtained, not more than 5 per cent of the total radioactivity is found in the spot corresponding to iodide.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised iodine-131 solution or by measurement in an instrument calibrated with the aid of such a solution.

STORAGE

Store protected from light at a temperature not exceeding – 18 °C.

01/2008:1620

OXYGEN (^{15}O)

Oxygenium (^{15}O)

DEFINITION

Mixture of [^{15}O]oxygen in the gaseous phase and a suitable vehicle such as *Medicinal air (1238)*, for diagnostic use.

Purity:

- minimum 99 per cent of the total radioactivity corresponds to oxygen-15,
- minimum 97 per cent of the total radioactivity corresponds to oxygen-15 in the form of oxygen (O_2).

PRODUCTION

RADIONUCLIDIC PRODUCTION

Oxygen-15 is a radioactive isotope of oxygen which may be produced by various nuclear reactions such as proton irradiation of nitrogen-15 or deuteron irradiation of nitrogen-14.

RADIOCHEMICAL SYNTHESIS

In order to recover oxygen-15 as molecular oxygen from the nitrogen target gas, carrier oxygen is added at concentrations generally ranging from 0.2 per cent *V/V* to 1.0 per cent *V/V*. After irradiation, the target gas is usually passed through activated charcoal and a carbon dioxide scavenger, such as soda lime, before mixing with the vehicle.

CHARACTERS

Appearance: colourless gas.

Half-life and nature of radiation of oxygen-15: see general chapter *5.7. Table of physical characteristics of radionuclides.*

IDENTIFICATION

A. Gamma spectrometry.

Results: the only gamma photons have an energy of 0.511 MeV and, depending on the measurement geometry, a sum peak of 1.022 MeV may be observed.

B. It complies with the test for radionuclidic purity (see Tests).

C. Examine the chromatograms obtained in the test for radiochemical purity.

Results: the retention times of the principal peaks in the chromatogram obtained with the test gas using the radioactivity detector are similar to those of the principal peaks corresponding to oxygen in the chromatogram obtained with the reference gas using the thermal conductivity detector.

TESTS

The following tests are performed on [^{15}O]oxygen as described under radiochemical synthesis before mixing with the vehicle.

RADIONUCLIDIC PURITY

Oxygen-15: minimum 99 per cent of the total radioactivity.

A. Gamma spectrometry.

Comparison: standardised fluorine-18 solution, or by using an instrument calibrated with the aid of such a solution. Standardised fluorine-18 solutions and/or standardisation services are available from the competent authority.

Results: the spectrum obtained with the solution to be examined does not differ significantly from that obtained with a standardised fluorine-18 solution.

B. Half-life: 1.9 min to 2.2 min.

The preparation may be released for use before completion of the test.

RADIOCHEMICAL PURITY

Oxygen-15 in the form of O_2. Gas chromatography (*2.2.28*): use the normalisation procedure.

Test sample. [^{15}O]oxygen as described under radiochemical synthesis.

Reference gas. Nitrogen gas mixture R.

Column:

- *size*: l = 1.8 m, Ø1 = 6.3 mm and Ø2 = 3.2 mm,
- *stationary phase*: *GC concentrical column R.*

Carrier gas: *helium for chromatography R.*

Flow rate: 65 ml/min.

Temperature:

- *column*: 40 °C,
- *injection port*: 40 °C,
- *thermal conductivity detector*: 70 °C.

Detection: thermal conductivity detector and radioactivity detector connected in series.

Injection: loop injector.

Run time: 10 min.

Retention times: oxygen, nitrogen and carbon monoxide eluting from the inner column = about 0.4 min; carbon dioxide eluting from the inner column = about 0.8 min; oxygen eluting from the outer column = about 2.1 min; nitrogen eluting from the outer column = about 3.1 min; carbon monoxide eluting from the outer column = about 6.2 min.

System suitability: reference gas:

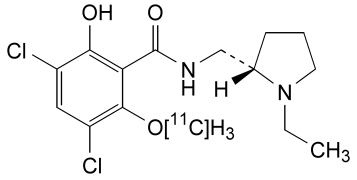
- 5 clearly separated principal peaks are observed in the chromatogram obtained using the thermal conductivity detector,

– *resolution*: minimum of 1.5 between the peaks due to carbon dioxide eluting from the inner column and oxygen eluting from the outer column, in the chromatogram obtained using the thermal conductivity detector.

Limits: examine the chromatogram obtained with the radioactivity detector and calculate the percentage content of oxygen-15 substances from the peak areas.

– *oxygen-15 gas in the form of O_2*: minimum 97 per cent of the total radioactivity,
– disregard the first peak corresponding to components co-eluting from the inner column.

RADIOACTIVITY



The radioactive concentration is determined before administration.

Measure the radioactivity using suitable equipment by comparison with a standardised fluorine-18 solution or by measurement in an instrument calibrated with the aid of such a solution.

01/2008:1924

RACLOPRIDE ([^{11}C]METHOXY) INJECTION

Raclopridi ([^{11}C]methoxy) solutio iniectabilis

DEFINITION

Sterile solution of 3,5-dichloro-*N*-[[(2*S*)-1-ethylpyrrolidin-2-yl]methyl]-2-hydroxy-6-([^{11}C]methoxy)benzamide.

Content: 90 per cent to 110 per cent of the declared carbon-11 radioactivity at the date and time stated on the label.

Purity:

– minimum of 99 per cent of the total radioactivity corresponds to carbon-11,
– minimum of 95 per cent of the total radioactivity corresponds to carbon-11 in the form of [*methoxy*-^{11}C]raclopride.

Content of raclopride: maximum of 10 µg per maximum recommended dose in millilitres.

PRODUCTION

RADIONUCLIDE PRODUCTION

Carbon-11 is a radioactive isotope of carbon most commonly produced by proton irradiation of nitrogen. Depending on the addition of either trace amounts of oxygen or small amounts of hydrogen, the radioactivity is obtained as [^{11}C]carbon dioxide or [^{11}C]methane, respectively.

RADIOCHEMICAL SYNTHESIS

[*Methoxy*-^{11}C]raclopride may be prepared by *O*-alkylation of the corresponding phenolate anion (*S*)-3,5-dichloro-2,6-dihydroxy-*N*-[(1-ethylpyrrolidin-2-yl)methyl]benzamide with iodo[^{11}C]methane or [^{11}C]methyl trifluoromethanesulphonate.

Synthesis of iodo[^{11}C]methane

Iodo[^{11}C]methane may be produced from [^{11}C]carbon dioxide or from [^{11}C]methane. The most frequently used method is reduction of [^{11}C]carbon dioxide with lithium aluminium hydride. The lithium aluminium [^{11}C]methanolate formed is reacted with hydroiodic acid to iodo[^{11}C]methane via [^{11}C]methanol. Alternatively [^{11}C]methane, either obtained directly in the target or by on-line processes from [^{11}C]carbon dioxide, is reacted with iodine.

Synthesis of [^{11}C]methyl trifluoromethanesulphonate

[^{11}C]Methyl trifluoromethanesulphonate may be prepared from iodo[^{11}C]methane using a solid support such as graphitised carbon impregnated with silver trifluoromethanesulphonate.

Synthesis of [*methoxy*-^{11}C]raclopride

Methylation with iodo[^{11}C]methane is performed under alkaline conditions in a solvent such as dimethyl sulphoxide. The methylation with [^{11}C]methyl trifluoromethanesulphonate is performed in a solvent such as dimethylformamide or acetone. The resulting [*methoxy*-^{11}C]raclopride may be purified by semi-preparative liquid chromatography using, for example, a column packed with octadecylsilyl silica gel for chromatography eluted with a mixture of 25 volumes of acetonitrile and 75 volumes of 0.01 M phosphoric acid.

PRECURSOR FOR SYNTHESIS

(*S*)-3,5-Dichloro-2,6-dihydroxy-*N*-[(1-ethylpyrrolidin-2-yl)methyl]benzamide hydrobromide

Melting point (*2.2.14*): 211 °C to 213 °C.

Specific optical rotation (*2.2.7*): + 11.3 to + 11.5, determined on a 15.0 g/l solution in *ethanol R* at 22 °C.

CHARACTERS

Appearance: clear, colourless solution.

Half-life and nature of radiation of carbon-11: see general chapter *5.7. Table of physical characteristics of radionuclides.*

IDENTIFICATION

A. Gamma-ray spectrometry.

Results: the only gamma photons have an energy of 0.511 MeV and, depending on the measurement geometry, a sum peak of 1.022 MeV may be observed.

B. It complies with test B for radionuclidic purity (see Tests).

C. Examine the chromatograms obtained in the test for radiochemical purity.

Results: the principal peak in the radiochromatogram obtained with the test solution is similar in retention time to the principal peak in the chromatogram obtained with reference solution (d).

TESTS

pH (*2.2.3*): 4.5 to 8.5.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

Bacterial endotoxins (*2.6.14*): less than 175/*V* IU/ml, *V* being the maximum recommended dose in millilitres. The injection may be released for use before completion of the test.

CHEMICAL PURITY

Raclopride and impurity A. Liquid chromatography (*2.2.29*).

Test solution. The preparation to be examined.

Reference solution (a). Dissolve 7.2 mg of *raclopride tartrate R* in *water R* and dilute to 50 ml with the same solvent.

Reference solution (b). Dissolve 1.2 mg of *(S)-3,5-dichloro-2,6-dihydroxy-N-[(1-ethylpyrrolidin-2-yl)methyl]benzamide hydrobromide R* in *methanol R* and dilute to 100 ml with the same solvent.

Reference solution (c). To 0.1 ml of reference solution (a) add 0.1 ml of reference solution (b) and dilute to *V* with *water R*, *V* being the maximum recommended dose in millilitres.

Reference solution (d). Dilute 1.0 ml of reference solution (a) to 10.0 ml with *water R*.

Column:

– *size*: *l* = 0.05 m, Ø = 4.6 mm,
– *stationary phase*: spherical *end-capped octadecylsilyl silica gel for chromatography R* (3.5 µm) with a specific surface area of 175 m^2/g, a pore size of 12.5 nm, a pore volume of 0.7 cm^3/g and a carbon loading of 15 per cent,
– *temperature*: 30 °C.

Mobile phase: dissolve 2 g of *sodium heptanesulphonate R* in 700 ml of *water R*, adjust to pH 3.9 with *phosphoric acid R* and dilute to 1000 ml with *acetonitrile R*.

Flow rate: 1 ml/min.

Detection: spectrophotometer at 220 nm and radioactivity detector connected in series.

Injection: loop injector; inject the test solution and reference solutions (b) and (c).

Run time: 10 min.

Relative retention with reference to raclopride: impurity A = about 0.46.

System suitability: reference solution (c):

– *resolution*: minimum of 5 between the peaks due to raclopride and to impurity A.

Limits: examine the chromatogram obtained with the spectrophotometer:

– *raclopride*: not more than the area of the corresponding peak in the chromatogram obtained with reference solution (c) (10 µg/*V*),
– *impurity A*: not more than the area of the corresponding peak in the chromatogram obtained with reference solution (c) (1 µg/*V*).

Residual solvents are limited according to the principles defined in the general chapter (*5.4*), using the general method (*2.4.24*). The preparation may be released for use before completion of the test.

RADIONUCLIDIC PURITY

Carbon-11: minimum 99 per cent of the total radioactivity.

The preparation may be released for use before completion of the test.

A. Gamma-ray spectrometry.

Comparison: standardised fluorine-18 solution, or by using a calibrated instrument. Standardised fluorine-18 solutions and/or standardisation services are available from the competent authority.

Results: the spectrum obtained with the solution to be examined does not differ significantly from that obtained with a standardised fluorine-18 solution.

B. Half-life. 19.9 min to 20.9 min.

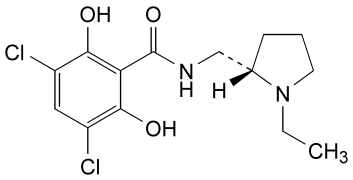
RADIOCHEMICAL PURITY

Liquid chromatography (*2.2.29*) as described in the test for raclopride and impurity A with the following modifications.

Injection: test solution and reference solution (d).

Limits: examine the chromatogram obtained with the radioactivity detector:

– [*Methoxy-^{11}C] raclopride*: minimum of 95 per cent of the total radioactivity.



RADIOACTIVITY

Mesure the radioactivity using suitable equipment by comparison with a standardised fluorine-18 solution or by using a calibrated instrument.

LABELLING

The accompanying information specifies the maximum recommended dose in millilitres.

IMPURITIES

A. 3,5-dichloro-*N*-[[(2*S*)-1-ethylpyrrolidin-2-yl]methyl]-2,6-dihydroxybenzamide.

01/2008:1920

SODIUM ACETATE ([1-^{11}C]) INJECTION

Natrii acetatis ([1-^{11}C]) solutio iniectabilis

$CH_3{}^{11}COONa$

DEFINITION

Sterile solution of sodium [1-^{11}C]acetate, in equilibrium with [1-^{11}C]acetic acid.

Content: 90 per cent to 110 per cent of the declared carbon-11 radioactivity at the date and time stated on the label.

PRODUCTION

RADIONUCLIDE PRODUCTION

Carbon-11 is a radioactive isotope of carbon which is most commonly produced by proton irradiation of nitrogen. By the addition of trace amounts of oxygen, the radioactivity is obtained as [^{11}C]carbon dioxide.

RADIOCHEMICAL SYNTHESIS

[^{11}C]Carbon dioxide may be separated from the target gas mixture by cryogenic trapping or by trapping on a molecular sieve at room temperature. [^{11}C]Carbon dioxide is then released from the trap using an inert gas such as nitrogen at a temperature higher than the trapping temperature. [1-^{11}C]Acetate is usually prepared by reaction of [^{11}C]carbon dioxide with methylmagnesium bromide in organic solvents such as ether or tetrahydrofuran.

Hydrolysis of the product yields [1-^{11}C]acetic acid. It is purified by chromatographic procedures. The eluate is diluted with sodium chloride solution.

PRECURSOR FOR SYNTHESIS

Methylmagnesium bromide. The reactivity of methylmagnesium bromide is tested by decomposition of a defined amount with water. The amount of methane released during this reaction is not less than 90 per cent of the theoretical value.

CHARACTERS

Appearance: clear, colourless solution.

Half-life and nature of radiation of carbon-11: see general chapter *5.7. Table of physical characteristics of radionuclides.*

IDENTIFICATION

A. Gamma-ray spectrometry.

Results: the only gamma photons have an energy of 0.511 MeV and, depending on the measurement geometry, a sum peak of 1.022 MeV may be observed.

B. It complies with test B for radionuclidic purity (see Tests).

C. Examine the chromatograms obtained in the test for radiochemical purity.

Results: the principal peak in the radiochromatogram obtained with the test solution is similar in retention time to the principal peak in the chromatogram obtained with the reference solution.

TESTS

pH (*2.2.3*): 4.5 to 8.5.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

Bacterial endotoxins (*2.6.14*): less than 175/*V* IU/ml, *V* being the maximum recommended dose in millilitres. The injection may be released for use before completion of the test.

CHEMICAL PURITY

Acetate. Liquid chromatography (*2.2.29*).

Test solution. The preparation to be examined.

Reference solution. Dissolve 28 mg of *sodium acetate R* in *water R* and dilute to *V*, *V* being the maximum recommended dose in millilitres.

Column:

– *size*: *l* = 0.25 m, Ø = 4.0 mm;

– *stationary phase*: *strongly basic anion exchange resin for chromatography R* (10 µm);

– *temperature*: 25 °C.

Mobile phase: *0.1 M sodium hydroxide* protected from atmospheric carbon dioxide.

Flow rate: 1 ml/min.

Detection: spectrophotometer at 220 nm and radioactivity detector connected in series.

Injection: loop injector.

Run time: 10 min.

System suitability: reference solution:

– *resolution*: minimum 4.0 between the peaks due to hold-up volume and acetate.

Limit: examine the chromatograms obtained with the spectrophotometer:

– *acetate*: not more than the area of the corresponding peak in the chromatogram obtained with the reference solution (20 mg per *V*).

Residual solvents are limited according to the principles defined in the general chapter (*5.4*), using the general method (*2.4.24*). The preparation may be released for use before completion of the test.

RADIONUCLIDIC PURITY

Carbon-11: minimum 99 per cent of the total radioactivity.

The preparation may be released for use before completion of the tests.

A. Gamma-ray spectrometry.

Comparison: standardised fluorine-18 solution, or by using a calibrated instrument. Standardised fluorine-18 solutions and/or standardisation services are available from laboratories recognised by the competent authority.

Results: the spectrum obtained with the solution to be examined does not differ significantly from that obtained with a standardised fluorine-18 solution.

B. Half-life: 19.9 min to 20.9 min.

RADIOCHEMICAL PURITY

[1-^{11}C]Acetate. Liquid chromatography (*2.2.29*) as described in the test for acetate.

Limit: examine the chromatograms obtained with the spectrophotometer and the radioactivity detector:

– *total of [1-^{11}C]acetate*: minimum 95 per cent of the total radioactivity.

RADIOACTIVITY

Measure the radioactivity using suitable equipment by comparison with a standardised fluorine-18 solution or by measurement with a calibrated instrument.

LABELLING

The accompanying information specifies the maximum recommended dose in millilitres.

01/2008:0279

SODIUM CHROMATE (^{51}Cr) STERILE SOLUTION

Natrii chromatis (^{51}Cr) solutio sterilis

DEFINITION

Sodium chromate (^{51}Cr) sterile solution is a sterile solution of sodium [^{51}Cr]chromate made isotonic by the addition of sodium chloride. Chromium-51 is a radioactive isotope of chromium and may be prepared by neutron irradiation of chromium, either of natural isotopic composition or enriched in chromium-50. The solution contains not less than 90.0 per cent and not more than 110.0 per cent of the declared chromium-51 radioactivity at the date and hour stated on the label. Not less than 90 per cent of the radioactivity corresponds to chromium-51 in the form of chromate. The specific radioactivity is not less than 370 MBq of chromium-51 per milligram of chromate ion.

CHARACTERS

A clear, colourless or slightly yellow solution.

Chromium-51 has a half-life of 27.7 days and emits gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised chromium-51 solution. Standardised chromium-51 solution are available from laboratories recognised by the competent authority. The gamma photon has an energy of 0.320 MeV.

B. Examine the chromatogram obtained in the test for radiochemical purity. The distribution of radioactivity contributes to the identification of the preparation.

TESTS

pH (*2.2.3*). The pH of the solution is 6.0 to 8.5.

Total chromate. Not more than 2.7 µg of chromate ion (CrO_4^{2-}) per megabecquerel. Measure the absorbance of the solution (*2.2.25*) at the absorption maximum at 370 nm. Calculate the content of chromate using the absorbance of a standard consisting of a 1.7 mg/l solution of *potassium chromate R*. If necessary, adjust the solution to be examined and the standard to pH 8.0 by adding *sodium hydrogen carbonate solution R*.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The solution may be released for use before completion of the test.

RADIONUCLIDIC PURITY

Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised chromium-51 solution.

RADIOCHEMICAL PURITY

Examine by ascending paper chromatography (*2.2.26*). Apply to the paper a quantity of the solution sufficient for the detection method. Begin the development immediately and develop for 2.5 h using a mixture of 25 volumes of *ammonia R*, 50 volumes of *alcohol R* and 125 volumes of *water R*. Chromic ions remain on the starting line. Determine the distribution of the radioactivity using a suitable detector. Not less than 90 per cent of the total radioactivity of the chromatogram is found in the spot with an R_F value of about 0.9, corresponding to sodium chromate.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised chromium-51 solution or by measurement in an instrument calibrated with the aid of such a solution.

01/2008:2100

SODIUM FLUORIDE (^{18}F) INJECTION

Natrii fluoridi (^{18}F) solutio iniectabilis

DEFINITION

Sterile solution containing fluorine-18 in the form of sodium fluoride. It may contain carrier fluoride and a suitable buffer.

Content:

– *fluorine-18*: 90 per cent to 110 per cent of the declared fluorine-18 radioactivity at the date and hour stated on the label,
– *fluoride*: maximum 4.52 mg per maximum recommended dose in millilitres.

PRODUCTION

The radionuclide fluorine-18 is most commonly produced by proton irradiation of water enriched in oxygen-18. Fluorine-18 in the form of fluoride is recovered from the target water, generally by adsorption and desorption from anion-exchange resins or electrochemical deposition and redissolution.

CHARACTERS

Appearance: clear, colourless solution.

Half-life and nature of radiation of fluorine-18: see general chapter *5.7. Table of physical characteristics of radionuclides*.

IDENTIFICATION

A. Gamma-ray spectrometry.

Results: the only gamma photons have an energy of 0.511 MeV and, depending on the measurement geometry, a sum peak of 1.022 MeV may be observed.

B. It complies with test B for radionuclidic purity (see Tests).

C. Examine the chromatograms obtained in the test for radiochemical purity (see Tests).

Results: the principal peak in the radiochromatogram obtained with the test solution is similar in retention time to the principal peak in the chromatogram obtained with the reference solution. In the chromatogram obtained with the reference solution, the peak due to fluoride is negative.

TESTS

pH (*2.2.3*): 5.0 to 8.5.

Fluoride. Liquid chromatography (*2.2.29*).

Test solution. The preparation to be examined.

Reference solution. Dissolve 10 mg of *sodium fluoride R* in *water R* and dilute to *V* with the same solvent, *V* being the maximum recommended dose in millilitres.

Column:

– *size*: *l* = 0.25 m, Ø = 4 mm,
– *stationary phase*: *strongly basic anion-exchange resin for chromatography R* (10 µm),
– *temperature*: constant, between 20 °C and 30 °C.

Mobile phase: 4 g/l solution of *sodium hydroxide R*, protected from atmospheric carbon dioxide.

Flow rate: 1 ml/min.

Detection: spectrophotometer at 220 nm and a radioactivity detector connected in series.

Injection: 20 µl.

Run time: 15 min.

System suitability: examine the chromatogram obtained with the reference solution using the spectrophotometer:

– *signal-to-noise ratio*: minimum 10 for the principal peak,
– *retention time of fluoride*: minimum 3 times the hold-up time.

Limit: examine the chromatogram obtained with the spectrophotometer:

– *fluoride*: not more than the area of the corresponding peak in the chromatogram obtained with the reference solution (4.52 mg/*V*).

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

Bacterial endotoxins (*2.6.14*): less than 175/*V* IU/ml, *V* being the maximum recommended dose in millilitres. The injection may be released for use before completion of the test.

RADIONUCLIDIC PURITY

Fluorine-18: minimum 99.9 per cent of the total radioactivity.

The preparation may be released for use before completion of the tests.

A. Gamma-ray spectrometry.

Determine the amount of fluorine-18 and radionuclidic impurities with a half-life longer than 2 h. For the detection and quantification of impurities, retain the preparation to be examined for a sufficient time to allow the fluorine-18 to decay to a level which permits the detection of impurities.

Results: the spectrum obtained with the preparation to be examined does not differ significantly from that of a background spectrum.

B. Half-life: 105 min to 115 min.

RADIOCHEMICAL PURITY

[^{18}F]fluoride. Liquid chromatography (*2.2.29*) as described in the test for fluoride. If necessary, dilute the test solution with *water R* to obtain a radioactivity concentration suitable for the radioactivity detector.

Limit: examine the chromatogram obtained with the radioactivity detector:

– *[^{18}F]fluoride*: minimum 98.5 per cent of the total radioactivity.

RADIOACTIVITY

Determine the radioactivity using a calibrated instrument.

LABELLING

The label states the maximum recommended dose in millilitres.

01/2008:0563

SODIUM IODIDE (^{123}I) INJECTION

Natrii iodidi (^{123}I) solutio iniectabilis

DEFINITION

Sterile solution containing iodine-123 in the form of sodium iodide; it may contain sodium thiosulphate or some other suitable reducing agent and a suitable buffer.

Content: 90 per cent to 110 per cent of the declared iodine-123 radioactivity at the date and hour stated on the label.

PRODUCTION

Iodine-123 is obtained by proton irradiation of xenon enriched in xenon-124 (minimum 98 per cent) followed by the decay of xenon-123 which is formed directly and by the decay of caesium-123. No carrier iodide is added.

CHARACTERS

Appearance: clear, colourless solution.

Half-life and nature of radiation of iodine-123: see general chapter *5.7. Table of physical characteristics of radionuclides.*

IDENTIFICATION

A. Gamma-ray spectrometry.

Results: the spectrum obtained with the preparation to be examined does not differ significantly from that of a standardised iodine-123 solution. The most prominent gamma photon has an energy of 0.159 MeV and is accompanied by the principal X-ray of 0.027 MeV.

B. Examine the chromatograms obtained in the test for radiochemical purity.

Results: the principal peak in the radiochromatogram obtained with the test solution is similar in retention time to the principal peak in the chromatogram obtained with reference solution (a).

TESTS

pH (*2.2.3*): 7.0 to 10.0.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The preparation may be released for use before completion of the test.

RADIONUCLIDIC PURITY

Iodine-123: minimum 99.65 per cent of the total radioactivity.

Gamma-ray spectrometry.

Determine the relative amounts of iodine-123, iodine-125, tellurium-121 and other radionuclidic impurities present. For the detection of tellurium-121 and iodine-125, retain the preparation to be examined for a sufficient time to allow iodine-123 to decay to a level which permits the detection of radionuclidic impurities. No radionuclides with a half-life longer than that of iodine-125 are detected.

The preparation may be released for use before completion of the test.

RADIOCHEMICAL PURITY

[^{123}I]iodide. Liquid chromatography (*2.2.29*).

Test solution. Dilute the preparation to be examined with a 2 g/l solution of *sodium hydroxide R* to a radioactive concentration suitable for the detector. Add an equal volume of a solution containing 1 g/l of *potassium iodide R*, 2 g/l of *potassium iodate R* and 10 g/l of *sodium hydrogen carbonate R* and mix.

Reference solution (a). Dilute 1 ml of a 26.2 mg/l solution of *potassium iodide R* to 10 ml with *water R*.

Reference solution (b). Dilute 1 ml of a 24.5 mg/l solution of *potassium iodate R* to 10 ml with *water R*. Mix equal volumes of this solution and reference solution (a).

Column:

– *size*: *l* = 0.25 m, Ø = 4.0 mm,

– *stationary phase*: *octadecylsilyl silica gel for chromatography R* (5 µm),

– *temperature*: constant between 20 °C and 30 °C.

Mobile phase: dissolve 5.85 g of *sodium chloride R* in 1000 ml of *water R*, add 0.65 ml of *octylamine R* and adjust to pH 7.0 with *dilute phosphoric acid R*; add 50 ml of *acetonitrile R* and mix.

Flow rate: 1.5 ml/min.

Detection: spectrophotometer at 220 nm and a radioactivity detector connected in series.

Injection: 20 µl.

Run time: 12 min.

Relative retention with reference to iodide (retention time = about 5 min): iodate = 0.2 to 0.3.

System suitability: reference solution (b):

– *resolution*: minimum 2 between the peaks due to iodide and iodate in the chromatogram recorded with the spectrophotometer.

Limit: examine the chromatogram obtained with the test solution using the radioactivity detector and locate the peak due to iodide by comparison with the chromatogram obtained with reference solution (a) using the spectrophotometer:

– *[^{123}I]iodide*: minimum 95 per cent of the total radioactivity.

RADIOACTIVITY

Determine the radioactivity using a calibrated instrument.

LABELLING

The label states any substance added.

IMPURITIES

A. [^{123}I]iodate ion.

01/2008:2314

SODIUM IODIDE (^{123}I) SOLUTION FOR RADIOLABELLING

Natrii iodidi (^{123}I) solutio ad radio-signandum

DEFINITION

Strongly alkaline solution containing iodine-123 in the form of sodium iodide.

Content: 90 per cent to 110 per cent of the declared iodine-123 radioactivity at the date and hour stated on the label.

PRODUCTION

Iodine-123 is obtained by proton irradiation of xenon highly enriched in xenon-124 followed by the decay of directly formed xenon-123 and by the decay of caesium-123. No carrier iodide or reducing agents are added.

CHARACTERS

Appearance: clear, colourless solution.

Half-life and nature of radiation of iodine-123: see general chapter *5.7. Table of physical characteristics of radionuclides*.

IDENTIFICATION

A. Gamma-ray spectrometry.

Results: the most prominent gamma photon of iodine-123 has an energy of 0.159 MeV and is accompanied by the principal X-ray of 0.027 MeV.

B. Examine the chromatograms obtained in the test for radiochemical purity (see Tests).

Results: the principal peak in the radiochromatogram obtained with the test solution is similar in retention time to the principal peak in the chromatogram obtained with reference solution (a).

TESTS

Alkalinity (*2.2.4*). The solution is strongly alkaline.

RADIONUCLIDIC PURITY

Iodine-123: minimum 99.7 per cent of the total radioactivity.

Gamma-ray spectrometry.

Determine the relative amounts of iodine-123, iodine-125, tellurium-121 and other radionuclidic impurities present. For the detection of tellurium-121 and iodine-125, retain the solution to be examined for a sufficient time to allow iodine-123 to decay to a level which permits the detection of radionuclidic impurities. No radionuclides with a half-life longer than that of iodine-125 are detected.

The solution may be released for use before completion of the test.

RADIOCHEMICAL PURITY

[^{123}I]iodide. Liquid chromatography (*2.2.29*).

Test solution. Dilute the solution to be examined with an equal volume of a solution containing 1 g/l of *potassium iodide R*, 2 g/l of *potassium iodate R* and 10 g/l of *sodium hydrogen carbonate R* and mix. If necessary, first dilute the solution to be examined with a 2 g/l solution of *sodium hydroxide R* to ensure that the final mixture has a radioactivity concentration suitable for the radioactivity detector.

Reference solution (a). Dissolve 10 mg of *potassium iodide R* in *water R* and dilute to 10 ml with the same solvent.

Reference solution (b). Dissolve 20 mg of *potassium iodate R* in *water R* and dilute to 10 ml with the same solvent. Mix equal volumes of this solution and reference solution (a).

Column:

- *size*: *l* = 0.25 m, Ø = 4.0 mm;
- *stationary phase*: *octadecylsilyl silica gel for chromatography R* (5 µm);
- *temperature*: constant, between 20 °C and 30 °C.

Use stainless steel tubing.

Mobile phase: dissolve 5.85 g of *sodium chloride R* in 1000 ml of *water R*, add 0.65 ml of *octylamine R* and adjust to pH 7.0 with *dilute phosphoric acid R*; add 50 ml of *acetonitrile R* and mix.

Flow rate: 1.5 ml/min.

Detection: spectrophotometer at 220 nm and a radioactivity detector connected in series.

Injection: 20 µl.

Run time: 12 min.

Relative retention with reference to iodide (retention time = about 5 min): iodate = 0.2 to 0.3.

System suitability: reference solution (b):

- *resolution*: minimum 2 between the peaks due to iodide and iodate in the chromatogram recorded with the spectrophotometer.

Examine the chromatogram obtained with the test solution using the radioactivity detector and locate the peak due to iodide by comparison with the chromatogram obtained with reference solution (a) using the spectrophotometer.

Limit:

- *[^{123}I]iodide*: minimum 95 per cent of the total radioactivity.

RADIOACTIVITY

Determine the radioactivity using a calibrated instrument.

LABELLING

The label states:

- the vehicle and any substance added;
- that the solution is not for direct administration to humans.

IMPURITIES

A. iodine-125,

B. tellurium-121,

C. [^{123}I]iodate ion.

01/2008:0938

SODIUM IODIDE (^{131}I) CAPSULES FOR DIAGNOSTIC USE

Natrii iodidi (^{131}I) capsulae ad usum diagnosticum

DEFINITION

Capsules for diagnostic use containing iodine-131 in the form of sodium iodide on a solid support; they may contain sodium thiosulphate or some other suitable reducing agents and a suitable buffering substance. A package contains 1 or more capsules.

Content:

- iodine-131: maximum 37 MBq per capsule; the average radioactivity determined in the test for uniformity of content is 90 per cent to 110 per cent of the declared iodine-131 radioactivity at the date and hour stated on the label;
- iodide: maximum 20 µg per capsule.

PRODUCTION

Iodine-131 is obtained by neutron irradiation of tellurium or by extraction from uranium fission products. No carrier iodide is added.

CHARACTERS

Half-life and nature of radiation of iodine-131: see general chapter *5.7. Table of physical characteristics of radionuclides*.

IDENTIFICATION

A. Gamma-ray spectrometry.

Results: the spectrum obtained with the preparation to be examined does not differ significantly from that of a standardised iodine-131 solution. The most prominent gamma photon has an energy of 0.365 MeV.

B. Examine the chromatograms obtained in the test for radiochemical purity.

Results: the principal peak in the radiochromatogram obtained with test solution (b) is similar in retention time to the principal peak in the chromatogram obtained with reference solution (a).

TESTS

Disintegration: the contents of the capsule dissolve completely within 15 min.

In a water-bath at 37 °C, warm in a small beaker about 20 ml of a 2.0 g/l solution of *potassium iodide R*. Add a capsule to be examined. Stir magnetically at 20 r/min.

Uniformity of content. Determine the radioactivity of each of not fewer than 10 capsules. Calculate the average radioactivity per capsule. The radioactivity of no capsule differs by more than 10 per cent from the average, the relative standard deviation is not greater than 3.5 per cent.

Iodide. Liquid chromatography (*2.2.29*).

Test solution (a). Dissolve a capsule to be examined in 10 ml of *water R*. Filter through a 0.2 µm filter.

Test solution (b). Dissolve a capsule to be examined in *water R*. Filter through a 0.2 µm filter and dilute the filtrate with a 2 g/l solution of *sodium hydroxide R* to a radioactive concentration suitable for the detector. Add an equal volume of a solution containing 1 g/l of *potassium iodide R*, 2 g/l of *potassium iodate R* and 10 g/l of *sodium hydrogen carbonate R* and mix.

Reference solution (a). Dilute 1 ml of a 26.2 mg/l solution of *potassium iodide R* to 10 ml with *water R*.

Reference solution (b). Dilute 1 ml of a 24.5 mg/l solution of *potassium iodate R* to 10 ml with *water R*. Mix equal volumes of this solution and reference solution (a).

Blank solution. Prepare a solution containing 2 mg/ml of each constituent stated on the label, apart from iodide.

Column:

- *size*: *l* = 0.25 m, Ø = 4.0 mm,
- *stationary phase*: *octadecylsilyl silica gel for chromatography R* (5 µm),
- *temperature*: constant between 20 °C and 30 °C.

Mobile phase: dissolve 5.85 g of *sodium chloride R* in 1000 ml of *water R*, add 0.65 ml of *octylamine R* and adjust to pH 7.0 with *dilute phosphoric acid R*; add 50 ml of *acetonitrile R* and mix.

Flow rate: 1.5 ml/min.

Detection: spectrophotometer at 220 nm and radioactivity detector connected in series.

Injection: 20 µl of test solution (a), reference solutions (a) and (b) and the blank solution.

Run time: 12 min.

Relative retention with reference to iodide (retention time = about 5 min): iodate = 0.2 to 0.3.

System suitability:

- in the chromatogram obtained with the blank solution, none of the peaks has a retention time similar to that of the peak due to iodide,
- *resolution*: minimum 2 between the peaks due to iodide and iodate in the chromatogram obtained with reference solution (b) recorded with the spectrophotometer.

Limit: examine the chromatograms obtained with the spectrophotometer:

- *iodide*: not more than the area of the corresponding peak in the chromatogram obtained with reference solution (a) (20 µg/capsule).

RADIONUCLIDIC PURITY

Iodine-131: minimum 99.9 per cent of the total radioactivity.

Gamma-ray spectrometry.

Determine the relative amounts of iodine-131, iodine-133, iodine-135 and other radionuclidic impurities present.

RADIOCHEMICAL PURITY

[^{131}I]iodide. Liquid chromatography (*2.2.29*) as described in the test for iodide with the following modifications.

Injection: 20 µl of test solution (b) and reference solution (a).

Limit: examine the chromatogram obtained with the test solution using the radioactivity detector and locate the peak due to iodide by comparison with the chromatogram obtained with reference solution (a) using the spectrophotometer:

- *[^{131}I]iodide*: minimum 95 per cent of the total radioactivity.

RADIOACTIVITY

Determine the radioactivity of the package using a calibrated instrument.

LABELLING

The label states any substance added and the number of capsules in the package.

IMPURITIES

A. [^{131}I]iodate ion.

01/2008:2116

SODIUM IODIDE (^{131}I) CAPSULES FOR THERAPEUTIC USE

Natrii iodidi (^{131}I) capsulae ad usum therapeuticum

DEFINITION

Capsules for therapeutic use containing iodine-131 in the form of sodium iodide on a solid support; they contain sodium thiosulphate or some other suitable reducing agents and a suitable buffering substance.

Content:

– iodine-131: 90 per cent to 110 per cent of the declared radioactivity at the date and hour stated on the label,
– iodide: maximum 20 µg per capsule.

PRODUCTION

Iodine-131 is obtained by neutron irradiation of tellurium or by extraction from uranium fission products. No carrier iodide is added.

CHARACTERS

Half-life and nature of radiation of iodine-131: see general chapter *5.7. Table of physical characteristics of radionuclides*.

IDENTIFICATION

A. Gamma-ray spectrometry.

Results: the spectrum obtained with the preparation to be examined does not differ significantly from that of a standardised iodine-131 solution. The most prominent gamma photon of iodine-131 has an energy of 0.365 MeV.

B. Examine the chromatograms obtained in the test for radiochemical purity.

Results: the principal peak in the radiochromatogram obtained with test solution (b) is similar in retention time to the principal peak in the chromatogram obtained with reference solution (a).

TESTS

Disintegration: the contents of the capsule dissolve completely within 15 min.

In a water-bath at 37 °C, warm in a small beaker about 20 ml of a 2.0 g/l solution of *potassium iodide R*. Add a capsule to be examined. Stir magnetically at a rotation rate of 20 r/min.

Iodide. Liquid chromatography (*2.2.29*).

Test solution (a). Dissolve a capsule to be examined in 10 ml of *water R*. Filter through a 0.2 µm filter.

Test solution (b). Dissolve a capsule to be examined in *water R*. Filter through a 0.2 µm filter and dilute the filtrate with an equal volume of a solution containing 1 g/l of *potassium iodide R*, 2 g/l of *potassium iodate R* and 10 g/l of *sodium hydrogen carbonate R*. If necessary, first dilute the filtrate with a 2 g/l solution of *sodium hydroxide R* to ensure that the final mixture has a radioactivity concentration suitable for the radioactivity detector.

Reference solution (a). Dilute 1.0 ml of a 26.2 mg/l solution of *potassium iodide R* to 10.0 ml with *water R*.

Reference solution (b). Dilute 1 ml of a 24.5 mg/l solution of *potassium iodate R* to 10 ml with *water R*. Mix equal volumes of this solution with reference solution (a).

Blank solution. Prepare a solution containing 2 mg/ml of each added substance stated on the label, apart from iodide.

Column:

– *size*: *l* = 0.25 m, Ø = 4.0 mm,
– *stationary phase*: *octadecylsilyl silica gel for chromatography R* (5 µm),
– *temperature*: constant, between 20 °C and 30 °C.

Use stainless steel tubing.

Mobile phase: dissolve 5.85 g of *sodium chloride R* in 1000 ml of *water R*, add 0.65 ml of *octylamine R* and adjust to pH 7.0 with *dilute phosphoric acid R*; add 50 ml of *acetonitrile R* and mix.

Flow rate: 1.5 ml/min.

Detection: spectrophotometer at 220 nm and radioactivity detector connected in series.

Injection: 20 µl of test solution (a), reference solutions (a) and (b) and the blank solution.

Run time: 12 min.

Relative retention with reference to iodide (retention time = about 5 min): iodate = 0.2 to 0.3.

System suitability:

– in the chromatogram obtained with the blank solution, none of the peaks has a retention time similar to that of the peak due to iodide;
– *resolution*: minimum 2 between the peaks due to iodide and iodate in the chromatogram obtained with reference solution (b) using the spectrophotometer.

Limits: examine the chromatograms obtained with the spectrophotometer; locate the peak due to iodide by comparison with the chromatogram obtained with reference solution (a):

– *iodide*: not more than the area of the corresponding peak in the chromatogram obtained with reference solution (a) (20 µg/capsule).

RADIONUCLIDIC PURITY

Iodine-131: minimum 99.9 per cent of the total radioactivity.

Gamma-ray spectrometry.

Determine the relative amounts of iodine-130, iodine-131, iodine-133, iodine-135 and other radionuclidic impurities present.

RADIOCHEMICAL PURITY

[^{131}I]iodide. Liquid chromatography (*2.2.29*) as described in the test for iodide with the following modifications.

Injection: 20 µl of test solution (b) and reference solution (a).

Limits: examine the chromatogram obtained with test solution (b) using the radioactivity detector and locate the peak due to iodide by comparison with the chromatogram obtained with reference solution (a) using the spectrophotometer:

B. iodine-130,

C. iodine-133,

D. iodine-135.

01/2008:0281

SODIUM IODIDE (^{131}I) SOLUTION

Natrii iodidi (^{131}I) solutio

DEFINITION

Solution containing iodine-131 in the form of sodium iodide and also sodium thiosulphate or some other suitable reducing agent. It may contain a suitable buffer.

Content:

– *iodine-131*: 90 per cent to 110 per cent of the declared radioactivity at the date and hour stated on the label,
– *iodide*: maximum 20 µg in the maximum recommended dose in millilitres.

PRODUCTION

Iodine-131 is a radioactive isotope of iodine and may be obtained by neutron irradiation of tellurium or by extraction from uranium fission products. No carrier iodide is added.

CHARACTERS

Appearance: clear, colourless solution.

Half-life and nature of radiation of iodine-131: see general chapter *5.7. Table of physical characteristics of radionuclides.*

IDENTIFICATION

A. Gamma-ray spectrometry.

Results: the spectrum obtained with the preparation to be examined does not differ significantly from that of a standardised iodine-131 solution. The most prominent gamma photon has an energy of 0.365 MeV.

B. Examine the chromatograms obtained in the test for iodide.

Results: the principal peak in the radiochromatogram obtained with test solution (a) is similar in retention time to the principal peak in the chromatogram obtained with reference solution (a).

TESTS

pH (*2.2.3*): 7.0 to 10.0.

Sterility. If intended for parenteral use, it complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125).* The solution may be released for use before completion of the test.

Iodide. Liquid chromatography (*2.2.29*).

Test solution (a). The preparation to be examined.

Test solution (b). Dilute the preparation to be examined with *0.05 M sodium hydroxide* until the radioactivity is equivalent to about 74 MBq/ml. Add an equal volume of a solution containing 1 g/l of *potassium iodide R*, 2 g/l of *potassium iodate R* and 10 g/l of *sodium hydrogen carbonate R* and mix.

Reference solution (a). Dilute 1 ml of a 26.2 mg/l solution of *potassium iodide R* to *V* with *water R*, *V* being the maximum recommended dose in millilitres.

Reference solution (b). Dilute 1 ml of a 24.5 mg/l solution of *potassium iodate R* to *V* with *water R*, *V* being the maximum recommended dose in millilitres. Mix equal volumes of this solution and of reference solution (a).

Blank solution. Prepare a solution containing 2 mg/ml of each of the components stated on the label, apart from iodide.

Column:

– *size*: *l* = 0.25 m, Ø = 4.0 mm,
– *stationary phase*: *octadecylsilyl silica gel for chromatography R* (5 µm),
– *temperature*: maintain at a constant temperature between 20 °C and 30 °C.

Use stainless steel tubing.

Mobile phase: dissolve 5.844 g of *sodium chloride R* in 1000 ml of *water R*, add 650 µl of *octylamine R* and adjust to pH 7.0 with *phosphoric acid R*; add 50 ml of *acetonitrile R* and mix.

Flow rate: 1.5 ml/min.

Detection: spectrophotometer at 220 nm and radioactivity detector connected in series.

Injection: 25 µl; inject test solution (a), the blank solution and reference solutions (a) and (b).

Run time: 12 min.

Relative retention with reference to iodide (retention time = about 5 min): iodate = 0.2 to 0.3.

System suitability:

– in the chromatogram obtained with the blank solution, none of the peaks shows a retention time similar to that of the peak due to iodide,
– *resolution*: minimum 2 between the peaks due to iodide and iodate in the chromatogram obtained with reference solution (b) recorded with the spectrophotometer.

Limit: examine the chromatogram obtained with the spectrophotometer; locate the peak due to iodide by comparison with the chromatogram obtained with reference solution (a):

– *iodide*: not more than the area of the corresponding peak in the chromatogram obtained with reference solution (a).

RADIONUCLIDIC PURITY

Iodine-131: minimum 99.9 per cent of the total radioactivity.

Gamma-ray spectrometry.

Determine the relative amounts of iodine-131, iodine-133, iodine-135 and other radionuclidic impurities present.

RADIOCHEMICAL PURITY

[^{131}I]Iodide. Liquid chromatography (*2.2.29*) as described in the test for iodide with the following modification.

Injection: test solution (b).

Limit: examine the chromatogram obtained with the radioactivity detector:

– *[^{131}I]iodide*: minimum 95 per cent of the total radioactivity.

RADIOACTIVITY

Measure the radioactivity using suitable equipment by comparison with a standardised iodine-131 solution or by using a calibrated instrument.

LABELLING

The label states:

– any substance added,
– the maximum recommended dose, in millilitres,
– where applicable, that the preparation is suitable for use in the manufacture of parenteral dosage forms.

IMPURITIES

A. [^{131}I]iodate ion.

01/2008:2121

SODIUM IODIDE (^{131}I) SOLUTION FOR RADIOLABELLING

Natrii iodidi (^{131}I) solutio ad radio-signandum

DEFINITION

Strongly alkaline solution containing iodine-131 in the form of sodium iodide. It does not contain a reducing agent.

Content: 90 per cent to 110 per cent of the declared iodine-131 radioactivity at the date and hour stated on the label.

PRODUCTION

Iodine-131 may be obtained by neutron irradiation of tellurium or by extraction from uranium fission products. No carrier iodide is added.

CHARACTERS

Appearance: clear, colourless solution.

Half-life and nature of radiation of iodine-131: see general chapter *5.7. Table of physical characteristics of radionuclides.*

IDENTIFICATION

A. Gamma-ray spectrometry.

Results: the spectrum obtained with the preparation to be examined does not differ significantly from that of a standardised iodine-131 solution. The most prominent gamma photon of iodine-131 has an energy of 0.365 MeV.

B. Examine the chromatograms obtained in the test for radiochemical purity (see Tests).

Results: the principal peak in the radiochromatogram obtained with the test solution is similar in retention time to the principal peak in the chromatogram obtained with reference solution (a).

TESTS

Alkalinity (*2.2.4*). The preparation is strongly alkaline.

RADIONUCLIDIC PURITY

Iodine-131: minimum 99.9 per cent of the total radioactivity.

Gamma-ray spectrometry.

Determine the relative amounts of iodine-130, iodine-131, iodine-133, iodine-135 and other radionuclidic impurities present.

RADIOCHEMICAL PURITY

[^{131}I]iodide. Liquid chromatography (*2.2.29*).

Test solution. Dilute the preparation to be examined with an equal volume of a solution containing 1 g/l of *potassium iodide R*, 2 g/l of *potassium iodate R* and 10 g/l of *sodium hydrogen carbonate R* and mix. If necessary, first dilute the preparation to be examined with a 2 g/l solution of *sodium hydroxide R* to ensure that the final mixture has a radioactivity concentration suitable for the radioactivity detector.

Reference solution (a). Dissolve 10 mg of *potassium iodide R* in *water R* and dilute to 10 ml with the same solvent.

Reference solution (b). Dissolve 20 mg of *potassium iodate R* in *water R* and dilute to 10 ml with the same solvent. Mix equal volumes of this solution and reference solution (a).

Column:

– *size*: *l* = 0.25 m, Ø = 4.0 mm,
– *stationary phase*: *octadecylsilyl silica gel for chromatography R* (5 µm),
– *temperature*: constant, between 20 °C and 30 °C.

Use stainless steel tubing.

Mobile phase: dissolve 5.85 g of *sodium chloride R* in 1000 ml of *water R*, add 0.65 ml of *octylamine R* and adjust to pH 7.0 with *dilute phosphoric acid R*; add 50 ml of *acetonitrile R* and mix.

Flow rate: 1.5 ml/min.

Detection: spectrophotometer at 220 nm and a radioactivity detector connected in series.

Injection: 20 µl.

Run time: 12 min.

Relative retention with reference to iodide (retention time = about 5 min): iodate = 0.2 to 0.3.

System suitability: reference solution (b):

– *resolution*: minimum 2 between the peaks due to iodide and iodate in the chromatogram recorded with the spectrophotometer.

Limit: examine the chromatogram obtained with the radioactivity detector:

– *[^{131}I]iodide*: minimum 95 per cent of the total radioactivity.

RADIOACTIVITY

Determine the radioactivity using a calibrated instrument.

LABELLING

The label states:

– the method of production of iodine-131,
– the vehicle and any substance added,
– that the preparation is not for direct human use.

IMPURITIES

A. [^{131}I]iodate ion.

01/2008:0564

SODIUM IODOHIPPURATE (^{123}I) INJECTION

Natrii iodohippurati (^{123}I) solutio iniectabilis

DEFINITION

Sodium iodohippurate (^{123}I) injection is a sterile solution of sodium (2-[^{123}I]iodobenzamido)acetate. It may contain a suitable buffer and a suitable antimicrobial preservative such as benzyl alcohol. Iodine-123 is a radioactive isotope of iodine and may be obtained by proton irradiation of xenon enriched in xenon-124 (not less than 98 per cent) followed by the decay of caesium-123 formed via xenon-123. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared iodine-123 radioactivity at the date and hour stated on the label. Not less than 96 per cent of the radioactivity corresponds to iodine-123 in the form of sodium 2-iodohippurate. The specific radioactivity is 0.74 GBq to 10.0 GBq of iodine-123 per gram of sodium 2-iodohippurate. Not more than 0.35 per cent of the total radioactivity is due to radionuclides other than iodine-123.

CHARACTERS

A clear, colourless liquid.

Iodine-123 has a half-life of 13.2 h and emits gamma radiation and X-rays.

IDENTIFICATION

A. Record the gamma-ray and X-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised iodine-123 solution apart from any differences attributable to the presence of iodine-125, tellurium-121 and other radionuclidic impurities. Standardised iodine-123, iodine-125 and tellurium-121 solutions are available from laboratories recognised by the national authorities. The most prominent gamma photon of iodine-123 has an energy of 0.159 MeV and is accompanied by an X-ray of 0.027 MeV. Iodine-125 has a half-life of 59.4 days and emits an X-ray of 0.027 MeV and a photon of 0.035 MeV. Tellurium-121 has a half-life of 19.2 days and the most prominent photons have energies of 0.507 MeV and 0.573 MeV.

B. Examine the chromatograms obtained in the test for radiochemical purity. The spot corresponding to the main peak of radioactivity in the chromatogram obtained with the test solution is similar in position to the spot corresponding to 2-iodohippuric acid in the chromatogram obtained with the reference solution.

TESTS

pH (*2.2.3*). The pH of the solution is 3.5 to 8.5.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

RADIONUCLIDIC PURITY

Record the gamma-ray spectrum using a suitable instrument. Determine the relative amounts of iodine-125, tellurium-121 and other radionuclidic impurities present. No radionuclides with longer half lives than iodine-125 are detected. For the determination of iodine-125, tellurium-121 and other radionuclidic impurities, retain the solution to be examined for a sufficient time to allow the radioactivity of iodine-123 to decrease to a level which permits the detection of radionuclidic impurities. Record the gamma-ray spectrum and X-ray spectrum of the decayed material using a suitable instrument. Not more than 0.35 per cent of the total radioactivity is due to radionuclides other than iodine-123. The injection may be released for use before completion of the test.

RADIOCHEMICAL PURITY

Examine by thin-layer chromatography (*2.2.27*) using *silica gel GF_{254} R* as the coating substance.

Test solution. Dissolve 1 g of *potassium iodide R* in 10 ml of *water R*, add 1 volume of this solution to 10 volumes of the injection to be examined and use within 10 min of mixing. If necessary, dilute with the reference solution (carrier) to give a radioactive concentration sufficient for the detection method, for example 3.7 MBq per millilitre.

Reference solution (*carrier*). Dissolve 40 mg of *2-iodohippuric acid R* and 40 mg of *2-iodobenzoic acid R* in 4 ml of *0.1 M sodium hydroxide*, add 10 mg of *potassium iodide R* and dilute to 10 ml with *water R*.

Apply separately to the plate 10 µl of each solution. Develop over a path of 12 cm (about 75 min) using a mixture of 1 volume of *water R*, 4 volumes of *glacial acetic acid R*, 20 volumes of *butanol R* and 80 volumes of *toluene R*. Allow the plate to dry in air and examine in ultraviolet light at 254 nm. The chromatogram obtained with the reference solution shows a spot corresponding to 2-iodohippuric acid and nearer to the solvent front a spot corresponding to 2-iodobenzoic acid. Iodide ion remains near the starting-line. Determine the distribution of radioactivity using a suitable detector. In the chromatogram obtained with the test solution, not less than 96 per cent of the total radioactivity is found in the spot corresponding to 2-iodohippuric acid and not more than 2 per cent of the total radioactivity is found in either of the spots corresponding to 2-iodobenzoic acid and to iodide ion.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised iodine-123 solution or by measurement in an instrument calibrated with the aid of such a solution.

STORAGE

Store protected from light.

LABELLING

The label states whether or not the preparation is suitable for renal plasma-flow studies.

01/2008:0282

SODIUM IODOHIPPURATE (^{131}I) INJECTION

Natrii iodohippurati (^{131}I) solutio iniectabilis

DEFINITION

Sodium iodohippurate (^{131}I) injection is a sterile solution of sodium 2-(2-[^{131}I]iodobenzamido)acetate. It may contain a suitable buffer and a suitable antimicrobial preservative such as benzyl alcohol. Iodine-131 is a radioactive isotope of iodine and may be obtained by neutron irradiation of tellurium or by extraction from uranium fission products. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared iodine-131 radioactivity at the date and hour stated on the label. Not less than 96 per cent of the iodine-131 is in the form of sodium 2-iodohippurate. The specific radioactivity is 0.74 GBq to 7.4 GBq of iodine-131 per gram of sodium 2-iodohippurate.

CHARACTERS

A clear, colourless liquid.

Iodine-131 has a half-life of 8.04 days and emits beta and gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised iodine-131 solution. Standardised iodine-131 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of iodine-131 has an energy of 0.365 MeV.

B. Examine the chromatograms obtained in the test for radiochemical purity. The main peak of radioactivity in the chromatogram obtained with the test solution is similar in position to the spot corresponding to 2-iodohippuric acid in the chromatogram obtained with the reference solution.

TESTS

pH (*2.2.3*). The pH of the injection is 6.0 to 8.5.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

RADIONUCLIDIC PURITY

Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised iodine-131 solution. Determine the relative amounts of iodine-131, iodine-133, iodine-135 and other radionuclidic impurities present. Iodine-133 has a half-life of 20.8 h and its most prominent gamma photons have energies of 0.530 MeV and 0.875 MeV. Iodine-135 has a half-life of 6.55 h and its most prominent gamma photons have energies of 0.527 MeV, 1.132 MeV and 1.260 MeV. Not less than 99.9 per cent of the total radioactivity is due to iodine-131.

RADIOCHEMICAL PURITY

Examine by thin-layer chromatography (*2.2.27*) using *silica gel GF_{254} R* as the coating substance.

Test solution. Dissolve 1 g of *potassium iodide R* in 10 ml of *water R*, add 1 volume of this solution to 10 volumes of the injection to be examined and use within 10 min of mixing. If necessary dilute with the reference solution (carrier) to give a radioactive concentration sufficient for the detection method, for example 3.7 MBq per millilitre.

Reference solution (carrier). Dissolve 40 mg of *2-iodohippuric acid R* and 40 mg of *2-iodobenzoic acid R* in 4 ml of *0.1 M sodium hydroxide*, add 10 mg of *potassium iodide R* and dilute to 10 ml with *water R*.

Apply separately to the plate 10 µl of each solution. Develop over a path of 12 cm (about 75 min) using a mixture of 1 volume of *water R*, 4 volumes of *glacial acetic acid R*, 20 volumes of *butanol R* and 80 volumes of *toluene R*. Allow the plate to dry in air and examine in ultraviolet light at 254 nm. The chromatogram obtained with the reference solution shows a spot corresponding to 2-iodohippuric acid and nearer to the solvent front a spot corresponding to 2-iodobenzoic acid. Iodide ion remains near the starting-line. Determine the distribution of radioactivity using a suitable detector. In the chromatogram obtained with the test solution, not less than 96 per cent of the total radioactivity is found in the spot corresponding to 2-iodohippuric acid and not more than 2 per cent of the total radioactivity is found in either of the spots corresponding to 2-iodobenzoic acid and to iodide ion.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised iodine-131 solution or by measurement in an instrument calibrated with the aid of such a solution.

STORAGE

Store protected from light.

LABELLING

The label states that the preparation is not necessarily suitable for renal plasma-flow studies.

01/2008:1923

SODIUM MOLYBDATE (^{99}Mo) SOLUTION (FISSION)

Natrii molybdatis (^{99}Mo) fissione formati solutio

DEFINITION

Alkaline solution of sodium [^{99}Mo]molybdate obtained by extraction of fission products of uranium-235. It may contain stabilisers.

Content: 90 per cent to 110 per cent of the declared molybdenum-99 radioactivity at the date and time stated on the label.

PRODUCTION

Molybdenum-99 is usually produced by fission of uranium enriched in uranium-235, which is caused by the absorption of a thermal neutron, resulting in high-specific-activity molybdenum-99. By the fission of uranium after neutron capture, more than 200 different radionuclides are produced. In approximately 6 per cent of the fissions, molybdenum-99 is formed after decay of a number of short-lived parent radionuclides. After dissolution of the target, the molybdenum-99 is separated from the mixture of nuclides and purified by using chromatographic processes in order to obtain molybdenum-99 with a high level of radionuclidic purity.

CHARACTERS

Appearance: clear, colourless or almost colourless solution.

Half-life and nature of radiation of molybdenum-99: see general chapter *5.7. Table of physical characteristics of radionuclides*.

IDENTIFICATION

A. Gamma-ray spectrometry.

Results: the most prominent gamma photon of molybdenum-99 has an energy of 0.740 MeV; a peak with an energy of 0.141 MeV, due to technetium-99-m is also visible.

B. Examine the chromatograms obtained in the test for radiochemical purity (see Tests).

Results: the principal peak in the radiochromatogram obtained with the test solution has a similar retardation factor to the principal spot in the chromatogram obtained with the reference solution.

TESTS

Solution S. Dilute the preparation to be examined to a radioactivity concentration of approximately 370 MBq/ml with a 2.42 g/l solution of *sodium molybdate R*.

Alkalinity. The preparation is alkaline (*2.2.4*).

RADIONUCLIDIC PURITY

Iodine-131, ruthenium-103 and tellurium-132:

– *iodine-131*: maximum 5×10^{-3} per cent of the total radioactivity;

– *ruthenium-103*: maximum 5×10^{-3} per cent of the total radioactivity;

– *tellurium-132*: maximum 5×10^{-3} per cent of the total radioactivity.

The following method has been found to be suitable; other validated methods, approved by the competent authority, may be used.

Gamma-ray spectrometry.

Condition a column with an internal volume of approximately 1.5 ml of *strongly basic anion exchange resin R* with a mixture of equal volumes of *glacial acetic acid R* and *water R*. All elutions of the column are made at a flow rate not exceeding 1 ml/min.

Test solution. In a test-tube, successively add, with mixing, 1 ml of a 24.2 g/l solution of *sodium molybdate R*, 0.5 ml of *strong hydrogen peroxide solution R*, 2.5 ml of *glacial acetic acid R*, 1.0 ml of *iodine-123 and ruthenium-106 spiking solution R* and 1.0 ml of solution S. Allow to stand for 30 min at room temperature.

Reference solution. Mix 1.0 ml of *iodine-123 and ruthenium-106 spiking solution R* and 4.0 ml of *water R*.

Apply the test solution to the column and elute. Just before the disappearance of the liquid from the top of the column, add 6 ml of a mixture of equal volumes of *glacial acetic acid R* and *water R* and elute. Transfer 5.0 ml of the combined eluates to a counting tube. Determine the radioactivity of iodine-123, iodine-131, ruthenium-103, ruthenium-106 and iodine-132 at the gamma-ray energies of 0.159 MeV for iodine-123, 0.365 MeV for iodine-131, 0.497 MeV for ruthenium-103, 0.512 MeV for ruthenium-106 and 0.668 MeV for iodine-132. Determine in the same way the radioactivity of iodine-123 and ruthenium-106 in the reference solution and calculate the recovery of iodine-123 and ruthenium-106 in the combined eluates.

Calculate the radioactivity of iodine-131, iodine-132 and ruthenium-103 in the combined eluates, taking into account the recovery, the fraction of eluate used, the counting efficiency and the radioactive decay. From the radioactivity of iodine-132 (daughter radionuclide of tellurium-132), calculate the radioactivity of tellurium-132, taking into account the time of the test and the time of separation of molybdenum-99.

Total radioactivity due to strontium-89 and strontium-90: maximum 6×10^{-5} per cent of the total radioactivity.

The following method has been found to be suitable; other validated methods, approved by the competent authority, may be used.

Liquid scintillation spectrometry.

Connect 2 columns, each with an internal volume of approximately 1.5 ml of *strongly basic anion exchange resin R*, in series and condition the columns with 10 ml of a 4 g/l solution of *sodium hydroxide R*. All elutions of the columns are made at a flow rate not exceeding 1 ml/min.

Test solution. In a test-tube, successively add, with mixing, 1.0 ml of solution S, 50 µl of *strontium-85 spiking solution R* and 0.05 ml of *strong sodium hypochlorite solution R*. Allow to stand for 10 min at room temperature.

Reference solution. Mix 50 µl of *strontium-85 spiking solution R* with 5.0 ml of a 9.5 g/l solution of *nitric acid R* in a vial for liquid scintillation counting and add 10 ml of *liquid scintillation cocktail R*.

Apply the test solution to the upper of the 2 columns and elute. Just before the disappearance of the liquid from the top of the upper column, add 3 ml of a 4 g/l solution of *sodium hydroxide R* and elute until the columns are dry. Combine the eluates and add 4 ml of a 947 g/l solution of *nitric acid R* (molybdenum-poor eluate). Determine the radioactivity due to molybdenum-99 using gamma-ray spectrometry. If the radioactivity due to molybdenum-99 is higher than 6×10^{-7} per cent of the radioactivity due to molybdenum-99 in 1 ml of solution S, repeat the above procedure using 2 new columns.

Condition a column with an internal volume of approximately 2 ml of *strontium selective extraction resin R* with 5 ml of a 473 g/l solution of *nitric acid R* and dry the column. All elutions of the column are made at a flow rate not exceeding 1 ml/min. Apply to the column the molybdenum-poor eluate and elute. Just before the disappearance of the liquid from the top of the column, add 20 ml of a 473 g/l solution of *nitric acid R* and elute until the column is dry. Rinse the column with 2 ml of a 9.5 g/l solution of *nitric acid R*, dry the column and discard the eluate. Elute the column with 8.0 ml of a 9.5 g/l solution of *nitric acid R* until the column is dry. Transfer 5.0 ml of the eluate into a vial for liquid scintillation counting and add 10 ml of *liquid scintillation cocktail R*.

Determine the total radioactivity due to strontium-89 and strontium-90 in this solution by liquid scintillation spectrometry, and the radioactivity due to strontium-85 by gamma-ray spectrometry. Determine the radioactivity due to strontium-85 in the reference solution by gamma-ray spectrometry. Calculate the recovery of strontium-85 in the eluate. Calculate the measured total radioactivity of strontium-89 and strontium-90 in the eluate, taking into account the recovery of strontium and the fraction of eluate used.

Total radioactivity due to alpha-particle-emitting impurities: maximum 1×10^{-7} per cent of the total radioactivity.

The following method has been found to be suitable; other validated methods, approved by the competent authority, may be used.

Alpha-ray spectrometry.

Test solution. To 0.2 ml of the preparation to be examined add 1.0 ml of *plutonium-242 spiking solution R*, 1.0 ml of *americium-243 spiking solution R* and 9.0 ml of a 927 g/l solution of *hydrochloric acid R*. Evaporate the sample to dryness. Dissolve the residue in 2 ml of a 927 g/l solution of *hydrochloric acid R*. Evaporate again to dryness. Dissolve the residue in 2 ml of a 10.3 g/l solution of *hydrochloric acid R*.

Apply the test solution to a column containing 0.7 g of *anion exchange resin R1*. Collect the eluate and wash the column with 1 ml of a 10.3 g/l solution of *hydrochloric acid R*. Evaporate the combined eluates to dryness and dissolve the residue in 2 ml of a 10.3 g/l solution of *hydrochloric acid R*. Apply this solution to a 2nd column containing 0.7 g of *anion exchange resin R1*. Collect the eluate and wash the column with 1 ml of a 10.3 g/l solution of *hydrochloric acid R*. Evaporate the combined eluates to dryness and dissolve the residue in 1 ml of *nitric acid R*. Evaporate to dryness. Dissolve the residue again in 1 ml of *nitric acid R*.

Add 1 ml of a 42.6 g/l solution of *anhydrous sodium sulphate R* and evaporate to dryness. Add 0.3 ml of *sulphuric acid R*. Warm until the residue is dissolved. Add 4 ml of *distilled water R* and 0.01 ml of *thymol blue solution R*. Add *concentrated ammonia R* dropwise until the colour changes from red to yellow.

Prepare an electrodeposition cell as follows. An electropolished stainless steel planchet is fitted in the cap of a 20 ml polyethylene scintillation vial. The bottom of the vial has been cut off and a hole has been drilled through the centre of the cap for electrical connection to the planchet cathode. The planchet, 20 mm in diameter and 0.5 mm

thick, is rinsed with *acetone R* and *water R* prior to use. The anode, a platinum spiral, is introduced through the bottom of the vial and fitted 5 mm from the cathode.

Pour the solution prepared as described above into the electrodeposition cell and rinse the container with a total of 5 ml of a 10 g/l solution of *sulphuric acid R* (the solution becomes slightly pink). Adjust to pH 2.1-2.4. with *concentrated ammonia R* or with a 200 g/l solution of *sulphuric acid R*. Electrolyse at 1.2 A for 75 min without stirring.

Add 1 ml of *concentrated ammonia R* about 1 min prior to switching off the current. Rinse the planchet with a 57 g/l solution of *ammonia R*. Rinse the planchet with *acetone R* and remove any residual solvent by patting the planchet with absorbent paper. Heat the planchet on a hot plate at 180 °C for 10 min.

Determine the radioactivity of alpha emitters by alpha-ray spectrometry, taking into account the recovery of the alpha-particle-emitting radionuclides (measured using the plutonium-242 and americium-243 spiking solutions).

Total of gamma-ray-emitting radionuclides other than molybdenum-99, technetium-99m, iodine-131, ruthenium-103 and tellurium-132: maximum 1×10^{-2} per cent of the total radioactivity.

The following method has been found to be suitable; other validated methods, approved by the competent authority, may be used.

Gamma-ray spectrometry.

Allow the preparation to decay for 4-6 weeks. Examine the gamma-ray spectrum for the presence of other gamma-ray-emitting impurities. Identify and quantify other gamma-ray-emitting impurities. The preparation may be released for use before completion of the test.

RADIOCHEMICAL PURITY

[^{99}Mo]Molybdate

The following method has been found to be suitable; other validated methods, approved by the competent authority, may be used.

Thin-layer chromatography (*2.2.27*).

Test solution. Dilute the preparation to be examined with a 4.0 g/l solution of *sodium hydroxide R* to a radioactivity concentration suitable for the detector.

Reference solution: 50 g/l solution of *sodium molybdate R* in a 4.0 g/l solution of *sodium hydroxide R*.

Plate: *TLC silica gel plate R*.

Mobile phase: 10.6 g/l solution of *anhydrous sodium carbonate R*.

Application: 5 µl of the test solution and 2 µl of the reference solution.

Development: over 2/3 of the plate.

Drying: in a current of warm air.

Detection: determine the distribution of radioactivity using a suitable detector and spray with a 2 g/l solution of *phenylhydrazine R* in *glacial acetic acid R*; heat at 100-105 °C for 5 min.

Retardation factor: molybdate and pertechnetate = about 0.9.

Limit:

– *sum of [^{99}Mo]molybdate and [^{99m}Tc]pertechnetate*: minimum 95 per cent of the total radioactivity.

RADIOACTIVITY

Determine the radioactivity using a calibrated instrument.

LABELLING

The label states that the preparation is only suitable for the preparation of technetium-99m generators.

IMPURITIES

A. iodine-131,

B. ruthenium-103,

C. tellurium-132,

D. strontium-89,

E. strontium-90.

SODIUM PERTECHNETATE (^{99m}Tc) INJECTION (FISSION)

Natrii pertechnetatis (^{99m}Tc) fissione formati solutio iniectabilis

This monograph applies to sodium pertechnetate (^{99m}Tc) injection obtained from molybdenum-99 extracted from fission products of uranium. Sodium pertechnetate (^{99m}Tc) injection obtained from molybdenum-99 produced by the neutron irradiation of molybdenum is described in the monograph on Sodium pertechnetate (^{99m}Tc) injection (non-fission) (0283).

DEFINITION

Sodium pertechnetate (^{99m}Tc) injection (fission) is a sterile solution containing technetium-99m in the form of pertechnetate ion and made isotonic by the addition of sodium chloride. Technetium-99m is a radionuclide formed by the decay of molybdenum-99. Molybdenum-99 is a radioactive isotope of molybdenum extracted from uranium fission products. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared technetium-99m radioactivity at the date and hour stated on the label. Not less than 95 per cent of the radioactivity corresponds to technetium-99m in the form of pertechnetate ion.

The radioactivity due to radionuclides other than technetium-99m, apart from that due to technetium-99 resulting from the decay of technetium-99m, is not greater than that shown below, expressed as a percentage of the total radioactivity and calculated with reference to the date and hour of administration.

molybdenum-99	0.1 per cent
iodine-131	5×10^{-3} per cent
ruthenium-103	5×10^{-3} per cent
strontium-89	6×10^{-5} per cent
strontium-90	6×10^{-6} per cent
alpha-emitting impurities	1×10^{-7} per cent
other gamma-emitting impurities	0.01 per cent

The injection may be prepared from a sterile preparation of molybdenum-99 under aseptic conditions.

CHARACTERS

A clear, colourless solution.

Technetium-99m has a half-life of 6.02 h and emits gamma radiation.

IDENTIFICATION

Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised technetium-99m solution either by direct comparison or by measurement in an instrument calibrated with the aid of such a solution. Standardised technetium-99m, molybdenum-99, iodine-131, ruthenium-103, strontium-89 and strontium/yttrium-90 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of technetium-99m has an energy of 0.140 MeV.

TESTS

pH (*2.2.3*). The pH of the injection is 4.0 to 8.0.

Aluminium. In a test tube about 12 mm in internal diameter, mix 1 ml of *acetate buffer solution pH 4.6 R* and 2 ml of a 1 in 2.5 dilution of the injection in *water R*. Add 0.05 ml of a 10 g/l solution of *chromazurol S R*. After 3 min, the colour of the solution is not more intense than that of a standard prepared at the same time and in the same manner using 2 ml of *aluminium standard solution (2 ppm Al) R* (5 ppm).

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

RADIONUCLIDIC PURITY

Preliminary test. To obtain an approximate estimate before use of the injection, take a volume equivalent to 37 MBq and determine the gamma-ray spectrum using a sodium iodide detector with a shield of lead, of thickness 6 mm, interposed between the sample and the detector. The response in the region corresponding to the 0.740 MeV photon of molybdenum-99 does not exceed that obtained using 37 kBq of a standardised molybdenum-99 solution measured under the same conditions, when all measurements are expressed with reference to the date and hour of administration.

Definitive test. Retain a sample of the injection for a sufficient time to allow the technetium-99m radioactivity to decay to a sufficiently low level to permit the detection of radionuclidic impurities. All measurements of radioactivity are expressed with reference to the date and hour of administration.

– *Molybdenum-99*. Record the gamma-ray spectrum of the decayed material in a suitable instrument calibrated with the aid of a standardised molybdenum-99 solution. The most prominent photons have energies of 0.181 MeV, 0.740 MeV and 0.778 MeV. Molybdenum-99 has a half-life of 66.0 h. Not more than 0.1 per cent of the total radioactivity is due to molybdenum-99.

– *Iodine-131*. Record the gamma-ray spectrum of the decayed material in a suitable instrument calibrated with the aid of a standardised iodine-131 solution. The most prominent photon has an energy of 0.365 MeV. Iodine-131 has a half-life of 8.04 days. Not more than 5×10^{-3} per cent of the total radioactivity is due to iodine-131.

– *Ruthenium-103*. Record the gamma-ray spectrum of the decayed material in a suitable instrument calibrated using a standardised ruthenium-103 solution. The most prominent photon has an energy of 0.497 MeV. Ruthenium-103 has a half-life of 39.3 days. Not more than 5×10^{-3} per cent of the total radioactivity is due to ruthenium-103.

– *Strontium-89*. Determine the presence of strontium-89 in the decayed material with an instrument suitable for the detection of beta rays, by comparison with a standardised strontium-89 solution. It is usually necessary first to carry out chemical separation of the strontium so that the standard and the sample may be compared in the same physical and chemical form. Strontium-89 decays with a beta emission of 1.492 MeV maximum energy and has a half-life of 50.5 days. Not more than 6×10^{-5} per cent of the total radioactivity is due to strontium-89.

– *Strontium-90*. Determine the presence of strontium-90 in the decayed material with an instrument suitable for the detection of beta rays. To distinguish strontium-90 from strontium-89, compare the radioactivity of yttrium-90, the daughter nuclide of strontium-90, with an yttrium-90 standard after the chemical separation of the yttrium. If prior chemical separation of the strontium is necessary, the conditions of radioactive equilibrium must be ensured. The yttrium-90 standard and the sample must be compared in the same physical and chemical form. Strontium-90 and yttrium-90 decay with respective beta emissions of 0.546 MeV and 2.284 MeV maximum energy and half-lives of 29.1 years and 64.0 h. Not more than 6×10^{-6} per cent of the total radioactivity is due to strontium-90.

– *Other gamma-emitting impurities*. Examine the gamma-ray spectrum of the decayed material for the presence of other radionuclidic impurities, which should, where possible, be identified and quantified. The total gamma radioactivity due to these impurities does not exceed 0.01 per cent of the total radioactivity.

– *Alpha-emitting impurities*. Measure the alpha radioactivity of the decayed material to detect any alpha-emitting radionuclidic impurities, which should, where possible, be identified and quantified. The total alpha radioactivity due to these impurities does not exceed 1×10^{-7} per cent of the total radioactivity.

RADIOCHEMICAL PURITY

Examine by descending paper chromatography (*2.2.26*).

Test solution. Dilute the preparation to be examined with *water R* to a suitable radioactive concentration.

Apply 5 µl of the test solution. Develop for 2 h using a mixture of 20 volumes of *water R* and 80 volumes of *methanol R*. Allow the paper to dry. Determine the distribution of radioactivity using a suitable detector. Not less than 95 per cent of the total radioactivity is in the spot corresponding to pertechnetate ion, which has an R_F value of about 0.6.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised technetium-99m solution or by measurement in an instrument calibrated with the aid of such a solution.

01/2008:0283

SODIUM PERTECHNETATE (^{99m}Tc) INJECTION (NON-FISSION)

Natrii pertechnetatis (^{99m}Tc) sine fissione formati solutio iniectabilis

This monograph applies to sodium pertechnetate (^{99m}Tc) injection obtained from molybdenum-99 produced by neutron irradiation of molybdenum. Sodium pertechnetate (^{99m}Tc) injection obtained from molybdenum-99 extracted from fission products of uranium is described in the monograph on Sodium pertechnetate(^{99m}Tc) injection (fission) (0124).

DEFINITION

Sodium pertechnetate (^{99m}Tc) injection (non-fission) is a sterile solution containing technetium-99m in the form of pertechnetate ion and made isotonic by the addition of sodium chloride. Technetium-99m is a radionuclide formed by the decay of molybdenum-99. Molybdenum-99 is a radioactive isotope of molybdenum produced by neutron irradiation of molybdenum. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared technetium-99m radioactivity at the date and hour stated on the label. Not less than 95 per cent of the radioactivity corresponds to technetium-99m in the form of pertechnetate ion.

The radioactivity due to radionuclides other than technetium-99m, apart from that due to technetium-99 resulting from the decay of technetium-99m is not greater than that shown below, expressed as a percentage of the total radioactivity and calculated with reference to the date and hour of administration.

Molybdenum-99	0.1 per cent
Other radionuclidic impurities	0.01 per cent

The injection may be prepared from a sterile preparation of molybdenum-99 under aseptic conditions.

CHARACTERS

A clear, colourless solution.

Technetium-99m has a half-life of 6.02 h and emits gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised technetium-99m solution either by direct comparison or by using an instrument calibrated with the aid of such a solution. Standardised technetium-99m and molybdenum-99 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of technetium-99m has an energy of 0.140 MeV.

B. Examine the chromatogram obtained in the test for radiochemical purity. The distribution of radioactivity contributes to the identification of the preparation.

TESTS

pH (*2.2.3*). The pH of the injection is 4.0 to 8.0.

Aluminium. In a test tube about 12 mm in internal diameter, mix 1 ml of *acetate buffer solution pH 4.6 R* and 2 ml of a 1 in 2.5 dilution of the injection in *water R*. Add 0.05 ml of a 10 g/l solution of *chromazurol S R*. After 3 min, the colour of the solution is not more intense than that of a standard prepared at the same time in the same manner using 2 ml of *aluminium standard solution (2 ppm Al) R* (5 ppm).

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

RADIONUCLIDIC PURITY

Preliminary test. To obtain an approximate estimate before use of the injection, take a volume equivalent to 37 MBq and record the gamma-ray spectrum using a sodium iodide detector with a shield of lead, of thickness 6 mm, interposed between the sample and the detector. The response in the region corresponding to the 0.740 MeV photon of molybdenum-99 does not exceed that obtained using 37 kBq of a standardised solution of molybdenum-99 measured under the same conditions, when all measurements are expressed with reference to the date and hour of administration.

Definitive test. Retain a sample of the injection for a sufficient time to allow the technetium-99m radioactivity to decay to a sufficiently low level to permit the detection of radionuclidic impurities. All measurements of radioactivity are expressed with reference to the date and hour of administration.

– *Molybdenum-99*. Record the gamma-ray spectrum of the decayed material in a suitable instrument calibrated using a standardised molybdenum-99 solution. The most prominent gamma photons have energies of 0.181 MeV, 0.740 MeV and 0.778 MeV. Molybdenum-99 has a half-life of 66.0 h. Not more than 0.1 per cent of the total radioactivity is due to molybdenum-99.

– *Other gamma-emitting impurities*. Examine the gamma-ray spectrum of the decayed material for the presence of other radionuclidic impurities, which should, where possible, be identified and quantified. The total radioactivity due to other radionuclidic impurities does not exceed 0.01 per cent of the total radioactivity.

RADIOCHEMICAL PURITY

Examine by descending paper chromatography (*2.2.26*). *Test solution*. Dilute the injection with *water R* to a suitable radioactive concentration.

Apply 5 µl of the test solution. Develop for 2 h using a mixture of 20 volumes of *water R* and 80 volumes of *methanol R*. Allow the paper to dry in air. Determine the distribution of radioactivity using a suitable detector. Not less than 95 per cent of the total radioactivity is found in the spot corresponding to pertechnetate ion, which has an R_F value of about 0.6.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised technetium-99m solution or by measurement in an instrument calibrated with the aid of such a solution.

01/2008:0284

SODIUM PHOSPHATE (^{32}P) INJECTION

Natrii phosphatis (^{32}P) solutio iniectabilis

DEFINITION

Sodium phosphate (^{32}P) injection is a sterile solution of disodium and monosodium (^{32}P) orthophosphates made isotonic by the addition of sodium chloride. Phosphorus-32 is a radioactive isotope of phosphorus and may be produced

by neutron irradiation of sulphur. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared phosphorus-32 radioactivity at the date and hour stated on the label. Not less than 95 per cent of the radioactivity corresponds to phosphorus-32 in the form of orthophosphate ion. The specific radioactivity is not less than 11.1 MBq of phosphorus-32 per milligram of orthophosphate ion.

CHARACTERS

A clear, colourless solution.

Phosphorus-32 has a half-life of 14.3 days and emits beta radiation.

IDENTIFICATION

A. Record the beta-ray spectrum or the beta-ray absorption curve using a suitable method. The spectrum or curve does not differ significantly from that of a standardised phosphorus-32 solution obtained under the same conditions. Standardised phosphorus-32 solutions are available from laboratories recognised by the competent authority. The maximum energy of the beta radiation is 1.71 MeV.

B. Examine the chromatogram obtained in the test for radiochemical purity. The distribution of radioactivity contributes to the identification of the preparation.

TESTS

pH (*2.2.3*). The pH of the injection is 6.0 to 8.0.

Phosphates. Dilute the injection with *water R* to give a radioactive concentration of 370 kBq of phosphorus-32 per millilitre. Mix in a volumetric flask, with shaking, 1.0 ml of the solution with a mixture of 0.5 ml of a 2.5 g/l solution of *ammonium vanadate R*, 0.5 ml of *ammonium molybdate solution R* and 1 ml of *perchloric acid R* and dilute to 5.0 ml with *water R*. After 30 min, the solution is not more intensely coloured than a standard prepared at the same time in the same manner using 1.0 ml of a solution containing 33 mg of orthophosphate ion per litre.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

RADIONUCLIDIC PURITY

Record the beta-ray spectrum or the beta-ray absorption curve using a suitable method. The spectrum or curve does not differ significantly from that of a standardised phosphorus-32 solution obtained under the same conditions.

RADIOCHEMICAL PURITY

Examine by ascending paper chromatography (*2.2.26*).

Test solution. Dilute the injection with *water R* until the radioactivity is equivalent to 10 000 to 20 000 counts per minute per 10 µl

Reference solution. Prepare a solution of *phosphoric acid R* containing 2 mg of phosphorus per millilitre.

Using a strip of paper 25 mm wide and about 300 mm long, apply 10 µl of the reference solution. Apply to the same starting-point 10 µl of the test solution. Develop for 16 h using a mixture of 0.3 ml of *ammonia R*, 5 g of *trichloroacetic acid R*, 25 ml of *water R* and 75 ml of *2-propanol R*. Allow the paper to dry in air. Determine the position of the inactive phosphoric acid by spraying with a 50 g/l solution of *perchloric acid R* and then with a 10 g/l solution of *ammonium molybdate R*. Expose the paper to *hydrogen sulphide R*. A blue colour develops. Determine the position of the radioactive spot by autoradiography or by measuring the radioactivity over the whole length of the chromatogram. Not less than 95 per cent of the total radioactivity of the chromatogram is found in the spot corresponding to phosphoric acid.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised phosphorus-32 solution or by measurement in an instrument calibrated with the aid of such a solution.

corrected 6.0

STRONTIUM (^{89}Sr) CHLORIDE INJECTION

Strontii (^{89}Sr) chloridi solutio iniectabilis

DEFINITION

Strontium (^{89}Sr) chloride injection is a sterile solution of [^{89}Sr]strontium chloride. Strontium-89 is a radioactive isotope of strontium and is produced by neutron irradiation of strontium enriched in strontium-88. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared strontium-89 radioactivity at the date stated on the label. Not more than 0.6 per cent of the total radioactivity is due to radionuclides other than strontium-89. The specific radioactivity is not less than 1.8 MBq of strontium-89 per milligram of strontium. The injection contains 6.0 mg/ml to 12.5 mg/ml of strontium.

CHARACTERS

A clear, colourless solution.

Strontium-89 has a half-life of 50.5 days and emits beta radiation with a maximum energy of 1.492 MeV.

IDENTIFICATION

A. Record the gamma-ray and X-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised strontium-89 solution, when measured either by direct comparison or by using an instrument calibrated with the aid of such a solution. Standardised strontium-89 solutions are available from laboratories recognised by the competent authority. The gamma photon detected has an energy of 0.909 MeV and is due to the short-lived daughter product, yttrium-89m (formed in 0.01 per cent of the disintegrations), in equilibrium with the strontium-89.

B. To 0.1 ml of the injection to be examined, add 1 ml of a freshly prepared 1 g/l solution of *sodium rhodizonate R*. Mix and allow to stand for 1 min. A reddish-brown precipitate is formed.

C. To 0.1 ml of *silver nitrate solution R2* add 50 µl of the injection to be examined. A white precipitate is formed.

TESTS

pH (*2.2.3*). The pH of the solution is 4.0 to 7.5.

Note: the following tests for aluminium, iron and lead may be carried out simultaneously with the test for strontium. If this is not the case, the reference solutions are prepared such that they contain strontium at approximately the same concentration as in the test solution.

Aluminium. Not more than 2.0 µg/ml, determined by atomic emission spectrometry (plasma or arc method) (*2.2.22, Method I*).

Test solution. Dilute 0.2 ml of the injection to be examined to a suitable volume with *dilute nitric acid R*.

Reference solutions. Prepare the reference solutions using *aluminium standard solution (10 ppm Al) R* diluted as necessary with *dilute nitric acid R*.

Iron. Not more than 5.0 µg/ml, determined by atomic emission spectrometry (plasma or arc method) (*2.2.22, Method I*).

Test solution. Dilute 0.2 ml of the injection to be examined to a suitable volume with *dilute nitric acid R*.

Reference solutions. Prepare the reference solutions using *iron standard solution (20 ppm Fe) R* diluted as necessary with *dilute nitric acid R*.

Lead. Not more than 5.0 µg/ml, determined by atomic emission spectrometry (plasma or arc method) (*2.2.22, Method I*).

Test solution. Dilute 0.2 ml of the injection to be examined to a suitable volume with *dilute nitric acid R*.

Reference solutions. Prepare the reference solutions using *lead standard solution (10 ppm Pb) R* diluted as necessary with *dilute nitric acid R*.

Strontium. 6.0 mg/ml to 12.5 mg/ml. Examine by atomic emission spectrometry (*2.2.22, Method I*).

Test solution. Dilute 0.2 ml of the injection to be examined to a suitable volume with *dilute nitric acid R*.

Reference solutions. Prepare the reference solutions using *strontium standard solution (1.0 per cent Sr) R* diluted as necessary with *dilute nitric acid R*.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*.

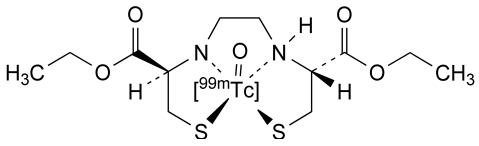
RADIONUCLIDIC PURITY

Gamma emitters. Record the gamma-ray and X-ray spectrum of the injection to be examined using a suitable instrument. Not more than 0.4 per cent of the total radioactivity in the preparation to be examined is due to gamma emitting radionuclides other than yttrium-89m.

Beta emitters. Evaporate to dryness 100 µl of the injection to be examined under a radiant heat source. Dissolve the residue in 2 ml of *47 per cent hydrobromic acid R*, evaporate to dryness under the radiant heat source and dissolve the residue in 2 ml of *dilute hydrobromic acid R1*. Transfer the solution to the top of a column, 5 mm to 6 mm in diameter, packed with approximately 2 ml of *cationic exchange resin R1* (100 µm to 250 µm), previously conditioned with *dilute hydrobromic acid R1* and elute the column with the same solvent until 10 ml of eluate has been collected into a container containing 50 µl of a 15 g/l solution of *anhydrous sodium sulphate R* in *1 M hydrochloric acid*.

To a liquid scintillation vial add an appropriate volume of scintillation liquid followed by 1 ml of *water R*, 0.1 ml of a 15 g/l solution of *anhydrous sodium sulphate R* in *1 M hydrochloric acid* and 100 µl of eluate. Shake to obtain a clear solution. Using suitable counting equipment determine the radioactivity due to sulphur-35 and phosphorus-32 in the sample.

Taking into account the recovery efficiency of the separation, counting efficiency and radioactive decay, determine the radioactive concentration of sulphur-35 and phosphorus-32 in the sample and hence the percentage of total beta emitting impurities in the injection to be examined. Not more than 0.2 per cent of the total radioactivity in the injection to be examined is due to the sum of sulphur-35 and phosphorus-32 radioactivities.



RADIOACTIVITY

Measure the radioactivity using suitable equipment by comparison with a standardised strontium-89 solution or by measurement in an instrument calibrated with the aid of such a solution.

01/2008:2123

TECHNETIUM (^{99m}Tc) BICISATE INJECTION

Technetii (^{99m}Tc) bicisati solutio iniectabilis

DEFINITION

Sterile solution of a complex of technetium-99m with diethyl *N,N'*-ethylenedi-L-cysteinate. It may contain stabilisers and inert additives such as *Mannitol (0559)* and *Disodium edetate (0232)*.

Content: 90 per cent to 110 per cent of the declared technetium-99m radioactivity at the date and hour stated on the label.

PRODUCTION

It is prepared from *N,N'*-(1,2-ethylenediyl)bis[(2*R*)-2-amino-3-sulphanylpropanoic acid] diethyl ester and *Sodium pertechnetate (^{99m}Tc) injection (fission) (0124)* or *Sodium pertechnetate (^{99m}Tc) injection (non-fission) (0283)* in the presence of reducing agents such as a stannous salt.

CHARACTERS

Appearance: clear, colourless solution.

Half-life and nature of radiation of technetium-99m: see general chapter *5.7. Table of physical characteristics of radionuclides*.

IDENTIFICATION

A. Gamma-ray spectrometry.

Results: the most prominent gamma photon of technetium-99m has an energy of 0.141 MeV.

B. Examine the chromatograms obtained in the test for radiochemical purity (see Tests).

Results: the principal peak in the chromatogram obtained with the test solution is similar in retardation factor to the principal peak in the chromatogram obtained with reference solution (a).

TESTS

pH (*2.2.3*): 6.5 to 7.5.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

RADIOCHEMICAL PURITY

Impurities A, B, C, D, E, F. Thin-layer chromatography (*2.2.27*).

Test solution. The preparation to be examined.

Reference solution (a). To vial B of *bicisate labelling kit CRS* in lead shielding add 2 ml of sodium pertechnetate (^{99m}Tc) injection (fission or non-fission) containing 400-800 MBq. Dissolve the contents of vial A of *bicisate labelling kit CRS* in 3 ml of a 9 g/l solution of *sodium chloride R*. Immediately transfer 1.0 ml of the solution contained in vial A to vial B. Mix and allow to stand for 30 min at room temperature.

Reference solution (b). Sodium pertechnetate (^{99m}Tc) injection (fission or non fission).

Plate: *TLC silica gel plate R*.

Mobile phase: *ethyl acetate R*.

Application: 5 µl, allow the spots to dry for 5-10 min.

Development: over 4/5 of the plate.

Drying: in air.

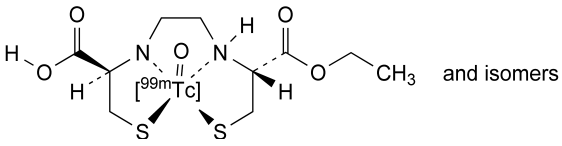
Detection: determine the distribution of radioactivity using a suitable detector.

Retardation factors: technetium-99m bicisate = more than 0.4; impurities A, B, C, D, E and F = less than 0.2.

System suitability: the retardation factor of the principal peak in the chromatogram obtained with reference solution (a) is clearly different from the retardation factor of the peak in the chromatogram obtained with reference solution (b).

Limit:

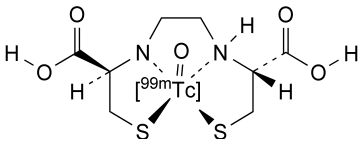
– *sum of impurities A, B, C, D, E and F*: not more than 6 per cent of the total radioactivity.



RADIOACTIVITY

Determine the radioactivity using a calibrated instrument.

IMPURITIES



A. technetium-99m in colloidal form,

B. [^{99m}Tc]pertechnetate ion,

and isomers

C. complex of technetium-99m with ethyl hydrogen *N*,*N*′-ethylenedi-L-cysteinate,

D. complex of technetium-99m with *N*,*N*′-ethylenedi-L-cysteine,

E. complex of technetium-99m with mannitol,

F. complex of technetium-99m with disodium edetate.

01/2008:0126

TECHNETIUM (^{99m}Tc) COLLOIDAL RHENIUM SULPHIDE INJECTION

Rhenii sulfidi colloidalis et technetii (^{99m}Tc) solutio iniectabilis

DEFINITION

Technetium (^{99m}Tc) colloidal rhenium sulphide injection is a sterile, apyrogenic colloidal dispersion of rhenium sulphide the micelles of which are labelled with technetium-99m. It is stabilised with gelatin. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared technetium-99m radioactivity at the date and hour stated on the label. Not less than 92 per cent of the radioactivity corresponds to technetium-99m in colloidal form. The pH of the injection may be adjusted by the addition of a suitable buffer such as a citrate buffer solution. The injection contains a variable amount of colloidal rhenium sulphide, not exceeding 0.22 mg of rhenium (Re) per millilitre, according to the method of preparation.

It is prepared from sodium pertechnetate (^{99m}Tc) injection (fission or non-fission) using suitable sterile, apyrogenic ingredients and calculating the ratio of radionuclidic impurities with reference to the date and hour of administration.

CHARACTERS

A light-brown liquid.

Technetium-99m has a half-life of 6.02 h and emits gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised technetium-99m solution either by direct comparison or by using an instrument calibrated with the aid of such a solution. Standardised technetium-99m and molybdenum-99 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of technetium-99m has an energy of 0.140 MeV.

B. Examine the chromatogram obtained in the test for radiochemical purity. The distribution of radioactivity contributes to the identification of the injection.

C. To 1 ml add 5 ml of *hydrochloric acid R*, 5 ml of a 50 g/l solution of *thiourea R* and 1 ml of a 200 g/l solution of *stannous chloride R* in *hydrochloric acid R*. A yellow colour is produced.

TESTS

pH (*2.2.3*). The pH of the injection is 4.0 to 7.0.

Rhenium

Test solution. Use 1 ml of the injection to be examined.

Reference solutions. Using a solution containing 100 µg of *potassium perrhenate R* (equivalent to 60 ppm of Re) and 240 µg of *sodium thiosulphate R* per millilitre, prepare a suitable range of solutions and dilute to the same final volume with *water R*.

To the test solution and to 1 ml of each of the reference solutions add 5 ml of *hydrochloric acid R*, 5 ml of a 50 g/l solution of *thiourea R* and 1 ml of a 200 g/l solution of *stannous chloride R* in *hydrochloric acid R* and dilute to 25.0 ml with *water R*. Allow to stand for 40 min and measure the absorbance (*2.2.25*) of each solution at 400 nm, using a reagent blank as the compensation liquid. Using the absorbances obtained with the reference solutions, draw a calibration curve and calculate the concentration of rhenium in the injection to be examined.

Physiological distribution. Inject a volume not greater than 0.2 ml into the caudal vein of each of three mice each weighing 20 g to 25 g. Euthanise the mice 20 min after the injection, remove the liver, spleen and lungs and measure the radioactivity in the organs using a suitable instrument.

Measure the radioactivity in the rest of the body after having removed the tail. Determine the percentage of radioactivity in the liver, the spleen and the lungs from the expression:

$$\frac{A}{B} \times 100$$

A = radioactivity of the organ concerned,

B = total radioactivity in the liver, the spleen, the lungs and the rest of the body.

In each of the three mice at least 80 per cent of the radioactivity is found in the liver and spleen and not more than 5 per cent in the lungs. If the distribution of radioactivity in one of the three mice does not correspond to the prescribed proportions, repeat the test on a further three mice. The preparation complies with the test if the prescribed distribution of radioactivity is found in five of the six mice used. The injection may be released for use before completion of the test.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

Pyrogens. It complies with the test for pyrogens prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. Inject not less than 0.1 ml per kilogram of the rabbit's mass. The injection may be released for use before completion of the test.

RADIOCHEMICAL PURITY

Examine by ascending paper chromatography (*2.2.26*). Apply to the paper 10 µl of the injection. Develop immediately over a path of 10 cm to 15 cm using a 9 g/l solution of *sodium chloride R*. Allow the paper to dry. Determine the distribution of radioactivity using a suitable detector. Technetium-99m in colloidal form remains at the starting-point and pertechnetate ion migrates with an R_F of about 0.6. There may be other impurities with an R_F of 0.8 to 0.9. The radioactivity corresponding to technetium-99m in colloidal form represents not less than 92 per cent of the total radioactivity of the chromatogram.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised technetium-99m solution or by measurement in an instrument calibrated with the aid of such a solution.

LABELLING

The label states, in particular, the quantity of rhenium per millilitre.

01/2008:0131

TECHNETIUM (^{99m}Tc) COLLOIDAL SULPHUR INJECTION

Sulfuris colloidalis et technetii (^{99m}Tc) solutio iniectabilis

DEFINITION

Technetium (^{99m}Tc) colloidal sulphur injection is a sterile, apyrogenic colloidal dispersion of sulphur, the micelles of which are labelled with technetium-99m. It may be stabilised with a colloid-protecting substance based on gelatin. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared technetium-99m radioactivity at the date and hour stated on the label. Not less than 92 per cent of the radioactivity corresponds to technetium-99m in colloidal form. The pH of the injection may be adjusted by the addition of a suitable buffer, such as an acetate, citrate or phosphate buffer solution. The injection contains a variable amount of colloidal sulphur, according to the method of preparation.

It is prepared from sodium pertechnetate (^{99m}Tc) injection (fission or non-fission) using suitable sterile, apyrogenic ingredients and calculating the ratio of radionuclidic impurities with reference to the date and hour of administration.

CHARACTERS

A clear to opalescent, colourless to yellowish liquid.

Technetium-99m has a half-life of 6.02 h and emits gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised technetium-99m solution either by direct comparison or by using an instrument calibrated with the aid of such a solution. Standardised technetium-99m and molybdenum-99 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of technetium-99m has an energy of 0.140 MeV.

B. Examine the chromatogram obtained in the test for radiochemical purity. The distribution of radioactivity contributes to the identification of the injection.

C. In a test-tube 100 mm long and 16 mm in internal diameter, evaporate 0.2 ml of the injection to dryness. Dissolve the sulphur by shaking the residue with 0.2 ml of *pyridine R* and add about 20 mg of *benzoin R*. Cover the open end of the tube with a filter paper moistened with *lead acetate solution R*. Heat the test-tube in a bath containing glycerol at 150 °C. The paper slowly becomes brown.

TESTS

pH (*2.2.3*). The pH of the injection is 4.0 to 7.0.

Physiological distribution. Inject a volume not greater than 0.2 ml into the caudal vein of each of 3 mice, each weighing 20 g to 25 g. Euthanise the mice 20 min after the injection, remove the liver, spleen and lungs and measure the radioactivity in the organs using a suitable instrument. Measure the radioactivity in the rest of the body after having removed the tail. Determine the percentage of radioactivity in the liver, the spleen and the lungs from the expression:

$$\frac{A}{B} \times 100$$

A = radioactivity of the organ concerned,

B = total radioactivity in the liver, the spleen, the lungs and the rest of the body.

In each of the 3 mice at least 80 per cent of the radioactivity is found in the liver and spleen and not more than 5 per cent in the lungs. If the distribution of radioactivity in 1 of the 3 mice does not correspond to the prescribed proportions, repeat the test on a further 3 mice. The preparation complies with the test if the prescribed distribution of radioactivity is found in 5 of the 6 mice used. The injection may be released for use before completion of the test.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

Pyrogens. It complies with the test for pyrogens prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. Inject not less than 0.1 ml per kilogram of the rabbit's mass. The injection may be released for use before completion of the test.

RADIOCHEMICAL PURITY

Examine by ascending paper chromatography (*2.2.26*). Apply to the paper 10 µl of the injection. Develop immediately over a path of 10 cm to 15 cm with a 9 g/l solution of *sodium chloride R*. Allow the paper to dry. Determine the distribution of radioactivity using a suitable detector. Technetium-99m in colloidal form remains at the starting-point and pertechnetate ion migrates with an R_F of 0.6. There may be other impurities of R_F 0.8 to 0.9. The radioactivity corresponding to technetium-99m in colloidal form represents not less than 92 per cent of the total radioactivity of the chromatogram.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised technetium-99m solution or by measurement in an instrument calibrated with the aid of such a solution.

01/2008:0689

TECHNETIUM (^{99m}Tc) COLLOIDAL TIN INJECTION

Stanni colloidalis et technetii (^{99m}Tc) solutio iniectabilis

DEFINITION

Technetium (^{99m}Tc) colloidal tin injection is a sterile, colloidal dispersion of tin labelled with technetium-99m. The injection contains a variable quantity of tin not exceeding 1 mg of Sn per millilitre; it contains fluoride ions, it may be stabilised with a suitable, apyrogenic colloid-protecting substance and it may contain a suitable buffer. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared technetium-99m radioactivity at the date and hour stated on the label. Not less than 95 per cent of the radioactivity corresponds to technetium-99m in colloidal form.

It is prepared from sodium pertechnetate (^{99m}Tc) injection (fission or non-fission) using suitable sterile ingredients and calculating the ratio of radionuclidic impurities with reference to the date and hour of administration. Syringes for handling the eluate intended for labelling of the final product, or the final product, should not contain rubber parts.

CHARACTERS

A clear or opalescent, colourless liquid.

Technetium-99m has a half life of 6.02 h and emits gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised technetium-99m solution either by direct comparison or by using an instrument calibrated with the aid of such a solution. Standardised technetium-99m and molybdenum-99 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of technetium-99m has an energy of 0.140 MeV.

B. Mix 0.05 ml of *zirconyl nitrate solution R* with 0.05 ml of *alizarin S solution R*. Add 0.05 ml of the injection to be examined. A yellow colour is produced.

TESTS

pH (*2.2.3*). The pH of the injection to be examined is 4.0 to 7.0.

Tin

Test solution. Dilute 3.0 ml of the injection to be examined to 50.0 ml with *1 M hydrochloric acid*.

Reference solution. Dissolve 0.115 g of *stannous chloride R* in *1 M hydrochloric acid* and dilute to 1000.0 ml with the same acid.

To 1.0 ml of each solution add 0.4 ml of a 20 g/l solution of *sodium laurilsulfate R*, 0.05 ml of *thioglycollic acid R*, 0.1 ml of *dithiol reagent R* and 3.0 ml of *0.2 M hydrochloric acid*. Mix. Measure the absorbance (*2.2.25*) of each solution at 540 nm, using *0.2 M hydrochloric acid* as the compensation liquid. The absorbance of the test solution is not greater than that of the reference solution (1 mg of Sn per millilitre).

Physiological distribution. Inject not more than 0.2 ml into a caudal vein of each of three mice, each weighing 20 g to 25 g. Euthanise the mice 20 min after the injection and remove the liver, spleen and lungs. Measure the radioactivity in the organs using a suitable instrument. Measure the radioactivity in the rest of the body, after having removed the tail. Determine the percentage of radioactivity in the liver, the spleen and the lungs with respect to the total radioactivity of all organs and the rest of the body excluding the tail.

In each of the three mice at least 80 per cent of the radioactivity is found in the liver and spleen and not more than 5 per cent in the lungs. If the distribution of radioactivity in one of the three mice does not correspond to the prescribed proportions, repeat the test on a further three mice. The preparation complies with the test if the prescribed distribution of radioactivity is found in five of the six mice used.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

RADIOCHEMICAL PURITY

Examine by thin-layer chromatography (*2.2.27*) using silica gel as the coating substance on a glass-fibre sheet. Heat the plate at 110 °C for 10 min. Use a plate such that during development the mobile phase migrates over a distance of 10 cm to 15 cm in about 10 min.

Apply to the plate 5 µl to 10 µl of the injection to be examined. Develop immediately over a path of 10 cm to 15 cm using a 9 g/l solution of *sodium chloride R* purged with *nitrogen R*. Allow the plate to dry. Determine the distribution of radioactivity using a suitable detector. Technetium-99m in colloidal form remains at the starting point and pertechnetate ion migrates near to the solvent front. Not less than 95 per cent of the technetium-99m radioactivity corresponds to technetium in colloidal form.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised technetium-99m solution or by measurement in an instrument calibrated with the aid of such a solution.

01/2008:0585

TECHNETIUM (^{99m}Tc) ETIFENIN INJECTION

Technetii (^{99m}Tc) et etifenini solutio iniectabilis

DEFINITION

Technetium (^{99m}Tc) etifenin injection is a sterile solution which may be prepared by mixing sodium pertechnetate (^{99m}Tc) injection (fission or non-fission) with solutions of etifenin [[(2,6-diethylphenyl)carbamoylmethylimino]di-acetic acid; $C_{16}H_{22}N_2O_5$] and stannous chloride. The injection contains a variable quantity of tin (Sn) not exceeding 0.2 mg/ml. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared technetium-99m radioactivity at the date and hour stated on the label. Not less than 95.0 per cent of the radioactivity corresponds to technetium-99m complexed with etifenin.

It is prepared from sodium pertechnetate (^{99m}Tc) injection (fission or non-fission) using suitable, sterile ingredients and calculating the ratio of radionuclidic impurities with reference to the date and hour of administration.

CHARACTERS

A clear, colourless solution.

Technetium-99m has a half-life of 6.02 h and emits gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised technetium-99m solution either by direct comparison or by using an instrument calibrated with the aid of such a solution. Standardised technetium-99m and molybdenum-99 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of technetium-99m has an energy of 0.140 MeV.

B. Examine by liquid chromatography (*2.2.29*).

Test solution. Dilute the injection to be examined with *methanol R* to obtain a solution containing about l mg of etifenin per millilitre.

Reference solution. Dissolve 5.0 mg of *etifenin CRS* in *methanol R* and dilute to 5.0 ml with the same solvent.

The chromatographic procedure may be carried out using:

- a column 0.25 m long and 4.6 mm in internal diameter packed with *octadecylsilyl silica gel for chromatography R* (5 µm to 10 µm),
- as mobile phase at a flow rate of 1 ml/min a mixture of 20 volumes of *methanol R* and 80 volumes of a 14 g/l solution of *potassium dihydrogen phosphate R* adjusted to pH 2.5 by the addition of *phosphoric acid R*,
- a spectrophotometer set at 230 nm.

Inject 20 µl of each solution. The principal peak in the chromatogram obtained with the test solution has a similar retention time to the principal peak in the chromatogram obtained with the reference solution.

TESTS

pH (*2.2.3*). The pH of the injection is 4.0 to 6.0.

Physiological distribution. Inject 0.1 ml (equivalent to about 3.7 MBq) into a caudal vein of each of three mice, each weighing 20 g to 25 g. Euthanise the mice l h after the injection. Remove the liver, gall-bladder, small intestine, large intestine and kidneys, collecting excreted urine. Measure the radioactivity in the organs using a suitable instrument. Measure the radioactivity of the rest of the body, after having removed the tail. Determine the percentage of radioactivity in each organ from the expression:

$$\frac{A}{B} \times 100$$

A = radioactivity of the organ concerned,

B = radioactivity of all organs and the rest of the body, excluding the tail.

In not fewer than two mice the sum of the percentages of radioactivity in the gall-bladder and small and large intestine is not less than 80 per cent. Not more than 3 per cent of the radioactivity is present in the liver, and not more than 2 per cent in the kidneys

Tin

Test solution. Dilute 1.0 ml of the injection to be examined to 5.0 ml with *1 M hydrochloric acid*.

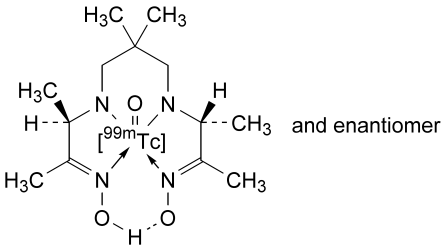
Reference solution. Prepare a reference solution containing 0.075 mg of *stannous chloride R* per millilitre in *1 M hydrochloric acid*.

To 1.0 ml of each solution add 0.4 ml of a 20 g/l solution of *sodium laurilsulfate R*, 0.05 ml of *thioglycollic acid R*, 0.l ml of *dithiol reagent R* and 3.0 ml of *0.2 M hydrochloric acid*. Mix. Measure the absorbance (*2.2.25*) of each solution at 540 nm, using *0.2 M hydrochloric acid* as the compensation liquid. The absorbance of the test solution is not greater than that of the reference solution (0.2 mg of Sn per millilitre).

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

RADIOCHEMICAL PURITY

Examine by thin-layer chromatography (*2.2.27*) using silicic acid as the coating substance on a glass-fibre sheet. Heat the plate at 110 °C for l0 min. The plate used should be such that during development the mobile phase moves over a distance of 10 cm to 15 cm in about 15 min.
Apply to the plate 5 µl to 10 µl of the injection to be examined. Develop immediately over a path of 10 cm to 15 cm using a 9 g/l solution of *sodium chloride R*. Allow the plate to dry. Determine the distribution of radioactivity using a suitable detector. Technetium-99m complexed with etifenin migrates almost to the middle of the chromatogram and pertechnetate ion migrates with the solvent front. Impurities in colloidal form remain at the starting point. The radioactivity corresponding to technetium-99m complexed with etifenin represents not less than 95.0 per cent of the total radioactivity of the chromatogram.



RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised technetium-99m solution or by measurement in an instrument calibrated with the aid of such a solution.

01/2008:1925

TECHNETIUM (^{99m}Tc) EXAMETAZIME INJECTION

Technetii (^{99m}Tc) exametazimi solutio iniectabilis

DEFINITION

Sterile solution of lipophilic technetium-99m exametazime which may be prepared by dissolving a racemic mixture of (3*RS*,9*RS*)-4,8-diaza-3,6,6,9-tetramethylundecane-2,10-dione bisoxime in the presence of a stannous salt in *Sodium pertechnetate (^{99m}Tc) injection (fission) (0124)* or *Sodium pertechnetate (^{99m}Tc) injection (non-fission) (0283)*. It may contain stabilisers and inert additives.

Content: 90 per cent to 110 per cent of the declared technetium-99m radioactivity at the date and time stated on the label.

Purity: minimum of 80 per cent of the total radioactivity corresponds to lipophilic technetium-99m exametazime and its *meso* isomer.

CHARACTERS

Appearance: clear solution.

Half-life and nature of radiation of technetium-99m: see general chapter *5.7. Table of physical characteristics of radionuclides*.

IDENTIFICATION

A. Gamma-ray spectrometry.

Comparison: standardised technetium-99m solution, or by using a calibrated instrument. Standardised technetium-99m solutions and/or standardisation services are available from the competent authority.

Results: the spectrum obtained with the solution to be examined does not differ significantly from that obtained with a standardised technetium-99m solution. The most prominent gamma photon has an energy of 0.141 MeV.

B. Examine the chromatograms obtained in the test Impurity A under Radiochemical purity.

Results: the principal peak in the chromatogram obtained with the test solution is similar in retention time to the peak due to lipophilic technetium-99m exametazime in the chromatogram obtained with the reference solution.

TESTS

pH (*2.2.3*): 5.0 to 10.0.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

RADIOCHEMICAL PURITY

Impurity C. Thin-layer chromatography (*2.2.27*).

Test solution. The preparation to be examined.

Plate: *TLC silica gel plate R*; use a glass-fibre plate.

Mobile phase: 9 g/l solution of *sodium chloride R*.

Application: about 5 µl.

Development: immediate, over 2/3 of the plate.

Drying: in air.

Detection: determine the distribution of radioactivity using a suitable detector.

Retardation factors: impurity C = 0.8 to 1.0; lipophilic technetium-99m exametazime and impurities A, B, D and E do not migrate.

Limits:

– *impurity C*: maximum 10 per cent of the total radioactivity.

Total of lipophilic technetium-99m exametazime and impurity A. Thin-layer chromatography (*2.2.27*).

Test solution. The preparation to be examined.

Plate: *TLC silica gel plate R*; use a glass-fibre plate.

Mobile phase: *methyl ethyl ketone R*.

Application: about 5 µl.

Development: immediate, over 2/3 of the plate.

Drying: in air.

Detection: determine the distribution of radioactivity using a suitable detector.

Retardation factors: lipophilic technetium-99m exametazime = 0.8 to 1.0, impurity A = 0.8 to 1.0, impurity C = 0.8 to 1.0; impurities B, D and E do not migrate.

Limits: calculate the percentage of radioactivity due to impurities B, D and E from test B (*B*) and the percentage of the radioactivity due to impurity C from test A (*A*). Calculate the total percentage of lipophilic technetium-99m exametazime and impurity A from the expression:

$$100 - A - B$$

– *total of lipophilic technetium-99m exametazime and impurity A*: minimum 80 per cent of the total radioactivity.

Impurity A. Liquid chromatography (*2.2.29*).

Test solution. The preparation to be examined.

Reference solution. Dissolve the contents of a vial of *meso-rich exametazime CRS* in 0.5 ml of a 9 g/l solution of *sodium chloride R* and transfer to a lead-shielded, nitrogen-filled vial. Add 6 µl of a freshly prepared 1 g/l solution of *stannous chloride R* in *0.05 M hydrochloric acid* and 2.5 ml of sodium pertechnetate (^{99m}Tc) injection (fission or non-fission) containing 370-740 MBq. Mix carefully and use within 30 min of preparation.

Column:

– *size*: *l* = 0.25 m, Ø = 4.6 mm,

– *stationary phase*: *spherical base-deactivated end-capped octadecylsilyl silica gel for chromatography R* (5 µm) with a pore size of 13 nm and a carbon loading of 11 per cent.

Mobile phase: mix 33 volumes of *acetonitrile R* and 67 volumes of *0.1 M phosphate buffer solution pH 3.0 R*.

Flow rate: 1.5 ml/min.

Detection: radioactivity detector.

Injection: loop injector.

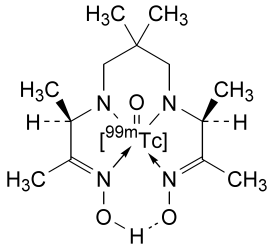
Run time: 20 min.

Relative retention with reference to lipophilic technetium-99m exametazime: impurity A = about 1.2.

System suitability: reference solution:

– chromatogram similar to the chromatogram provided with *meso-rich exametazime CRS*,

– *resolution*: minimum of 2 between the peaks due to lipophilic technetium-99m exametazime and to impurity A.



Limits:

– *impurity A*: maximum 5 per cent of the radioactivity due to lipophilic technetium-99m exametazime and impurity A.

RADIOACTIVITY

Measure the radioactivity using suitable equipment by comparison with a standardised technetium-99m solution or by using a calibrated instrument.

IMPURITIES

A. *meso* isomer of lipophilic technetium-99m exametazime,

B. technetium-99m in colloidal form,

C. [^{99m}Tc]pertechnetate ion,

D. non lipophilic technetium-99m exametazime complex,

E. *meso* isomer of non lipophilic technetium-99m exametazime complex.

01/2008:1047

TECHNETIUM (^{99m}Tc) GLUCONATE INJECTION

Technetii (^{99m}Tc) gluconatis solutio iniectabilis

DEFINITION

Technetium (^{99m}Tc) gluconate injection is a sterile solution, which may be prepared by mixing solutions of calcium gluconate and a stannous salt or other suitable reducing agent with sodium pertechnetate (^{99m}Tc) injection (fission or non-fission). The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared technetium-99m radioactivity at the date and hour stated on the label. Not less than 90 per cent of the radioactivity corresponds to technetium-99m gluconate complex.

It is prepared from sodium pertechnetate (^{99m}Tc) injection (fission or non-fission) using suitable sterile ingredients and calculating the ratio of radionuclidic impurities with reference to the date and hour of administration.

CHARACTERS

A slightly opalescent solution.

Technetium-99m has a half-life of 6.02 h and emits gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised technetium-99m solution either by direct comparison or by using an instrument calibrated with the aid of such a solution. Standardised technetium-99m and molybdenum-99 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of technetium-99m has an energy of 0.140 MeV.

B. 5 µl of the solution complies with identification A prescribed in the monograph on *Calcium gluconate (0172)*.

C. Examine the chromatograms obtained in the test for radiochemical purity. The distribution of the radioactivity contributes to the identification of the preparation.

TESTS

pH (*2.2.3*). The pH of the solution is 6.0 to 8.5.

Physiological distribution. Inject a volume not greater than 0.2 ml into the caudal vein of each of three rats weighing 150 g to 250 g. Measure the radioactivity of the syringe before and after injection. Euthanise the rats 30 min after the injection. Remove at least 1 g of blood by a suitable method and remove the kidneys, the liver, the bladder plus voided urine and the tail. Weigh the sample of blood.

Determine the radioactivity in the organs, the blood sample and the tail using a suitable instrument. Calculate the percentage of radioactivity in each organ and in 1 g of blood with respect to the total radioactivity calculated as the difference between the two measurements made on the syringe minus the activity in the tail. Correct the blood concentration by multiplying by a factor of $m/200$ where m is the body mass of the rat in grams.

In not fewer than two of the three rats used, the radioactivity in the kidneys is not less than 15 per cent, that in the bladder plus voided urine is not less than 20 per cent and that in the liver is not more than 5 per cent. The radioactivity in the blood, after correction, is not more than 0.50 per cent.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

RADIOCHEMICAL PURITY

Examine by thin-layer chromatography (*2.2.27*) using silica gel as the coating substance on a glass-fibre sheet. Heat the plate at 110 °C for 10 min. Use a plate such that during development the mobile phase migrates over a distance of 10 cm to 15 cm in about 10 min.

a) Apply to the plate 5 µl to 10 µl of the solution to be examined. Develop immediately over a path of 10 cm to 15 cm using a 9 g/l solution of *sodium chloride R*. Allow the plate to dry. Determine the distribution of radioactivity using a suitable detector. Impurities in colloidal form remain at the starting point. Technetium gluconate complex and pertechnetate ion migrate near to the solvent front.

b) Apply to the plate 5 µl to 10 µl of the solution to be examined and allow to dry. Develop over a path of 10 cm to 15 cm using *methyl ethyl ketone R*. Dry in a current of warm air. Determine the distribution of radioactivity using a suitable detector. Pertechnetate ion impurity migrates near to the solvent front. Technetium gluconate complex and technetium in colloidal form remain at the starting point.

The sum of the percentages of radioactivity corresponding to impurities in the chromatograms obtained in test (a) and (b) does not exceed 10 per cent.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised technetium-99m solution or by measurement in an instrument calibrated with the aid of such a solution.

01/2008:0640

TECHNETIUM (^{99m}Tc) HUMAN ALBUMIN INJECTION

Technetii (^{99m}Tc) humani albumini solutio iniectabilis

DEFINITION

Technetium (^{99m}Tc) human albumin injection is a sterile, apyrogenic solution of human albumin labelled with technetium-99m. It contains a reducing substance, such as a tin salt in an amount not exceeding 1 mg of Sn per millilitre; it may contain a suitable buffer and an antimicrobial preservative. Although, at present, no definite value for a maximum limit of tin can be fixed, available evidence tends to suggest the importance of keeping the ratio of tin to albumin as low as possible. The human albumin used complies with the requirements of the monograph on *Human albumin solution (0255)*. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared technetium-99m radioactivity at the date and hour stated on the label. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the quantity of albumin stated on the label. Not less than 80 per cent of the radioactivity is associated with the albumin fractions II to V. Not more than 5.0 per cent of the radioactivity due to technetium-99m corresponds to free pertechnetate, as determined by the method described in the test for radiochemical purity.

It is prepared from sodium pertechnetate (^{99m}Tc) injection (fission or non-fission) using suitable sterile and apyrogenic ingredients and calculating the ratio of radionuclidic impurities with reference to the date and hour of administration.

CHARACTERS

A clear, colourless or pale-yellow solution.

Technetium-99m has a half-life of 6.02 h and emits gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised technetium-99m solution either by direct comparison or by using an instrument calibrated with the aid of such a solution. Standardised technetium-99m and molybdenum-99 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of technetium-99m has an energy of 0.140 MeV.

B. Using a suitable range of species-specific antisera, carry out precipitation tests on the preparation to be examined. The test is to be carried out using antisera specific to the plasma proteins of each species of domestic animal currently used in the preparation of materials of biological origin in the country concerned. The injection is shown to contain proteins of human origin and gives negative results with antisera specific to plasma proteins of other species.

C. Examine by a suitable immunoelectrophoresis technique. Using antiserum to normal human serum, compare normal human serum and the injection to be examined, both diluted if necessary. The main component of the injection to be examined corresponds to the main component of the normal human serum. The diluted solution may show the presence of small quantities of other plasma proteins.

TESTS

pH (*2.2.3*). The pH of the injection is 2.0 to 6.5.

Albumin

Reference solution. Dilute *human albumin solution R* with a 9 g/l solution of *sodium chloride R* to a concentration of 5 mg of albumin per millilitre.

To 1.0 ml of the injection to be examined and to 1.0 ml of the reference solution add 4.0 ml of *biuret reagent R* and mix. After exactly 30 min, measure the absorbance (*2.2.25*) of each solution at 540 nm, using as the compensation liquid a 9 g/l solution of *sodium chloride R* treated in the same manner. From the absorbances measured, calculate the content of albumin in the injection to be examined in milligrams per millilitre.

Tin

Test solution. To 1.0 ml of the injection to be examined add 1.0 ml of *2 M hydrochloric acid R*. Heat in a water-bath at 100 °C for 30 min. Cool and centrifuge at 300 *g* for 10 min. Dilute 1.0 ml of the supernatant liquid to 10 ml with *1 M hydrochloric acid*.

Reference solution. Dissolve 95 mg of *stannous chloride R* in *1 M hydrochloric acid* and dilute to 1000.0 ml with the same acid.

To 1.0 ml of each solution add 0.4 ml of a 20 g/l solution of *sodium laurilsulfate R*, 0.05 ml of *thioglycollic acid R*, 0.1 ml of *dithiol reagent R* and 3.0 ml of *0.2 M hydrochloric acid*. Mix. Measure the absorbance (*2.2.25*) of each solution at 540 nm, using *0.2 M hydrochloric acid* as the compensation liquid. The absorbance of the test solution is not greater than that of the reference solution (1 mg of Sn per millilitre).

Physiological distribution. Inject a volume not greater than 0.5 ml and containing not more than 1.0 mg of albumin into a suitable vein such as a caudal vein or a saphenous vein of each of three male rats, each weighing 150 g to 250 g. Measure the radioactivity in the syringe before and after the injection. Euthanise the rats 30 min after the injection. Take one millilitre of blood by a suitable method and remove the liver and, if a caudal vein has been used for the injection, the tail. Using a suitable instrument determine the radioactivity in 1 ml of blood, in the liver and, if a caudal vein has been used for the injection, in the tail. Determine the percentage of radioactivity in the liver and in 1 ml of blood with respect to the total radioactivity calculated as the difference between the measurements made on the syringe minus the activity in the tail (if a caudal vein has been used for the injection). Correct the blood concentration by multiplying by a factor of $m/200$ where m is the body mass of the rat in grams. In not fewer than two of the three rats used, the radioactivity in the liver is not more than 15 per cent and that in blood, after correction, is not less than 3.5 per cent.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

Bacterial endotoxins (*2.6.14*): less than $175/V$ IU/ml, V being the maximum recommended dose in millilitres.

RADIOCHEMICAL PURITY

A. Examine by thin-layer chromatography (*2.2.27*) using silica gel as the coating substance on a glass-fibre sheet. Heat the plate at 110 °C for 10 min. Use a plate such that during development the mobile phase migrates over a distance of 10 cm to 15 cm in about 10 min.

Apply to the plate 5 µl to 10 µl of the injection to be examined and allow to dry. Develop over a path of 10 cm to 15 cm using *methyl ethyl ketone R*. Allow the plate to dry. Determine the distribution of radioactivity using a suitable detector. The technetium-99m human albumin complex remains at the starting-point and pertechnetate ion migrates near to the solvent front. Not more than 5.0 per cent of the technetium-99m radioactivity corresponds to technetium in the form of pertechnetate ion.

B. Examine by size-exclusion chromatography (*2.2.30*).

Mobile phase (concentrated). Dissolve 1.124 g of *potassium dihydrogen phosphate R*, 4.210 g of *disodium hydrogen phosphate R*, 1.17 g of *sodium chloride R* and 0.10 g of *sodium azide R* in 100 ml of *water R*.

Test solution. Mix 0.25 ml of the injection to be examined with 0.25 ml of the mobile phase (concentrated). Use immediately after dilution.

The chromatographic procedure may be carried out using:

- a stainless steel column 0.6 m long and 7.5 mm in internal diameter, packed with *silica gel for size-exclusion chromatography R*,
- as the mobile phase at a flow rate of 0.6 ml/min a mixture of equal volumes of mobile phase (concentrated) and *water R*,
- a radioactivity detector set for technetium-99m,
- a loop injector.

Inject 200 µl of the test solution. Continue the chromatography for at least 10 min after background level is reached.

Peaks are eluted with the following retention times:

I	High molecular mass compound	19-20 min
II	Poly III-albumin	23-24 min
III	Poly II-albumin	25-27 min
IV	Poly I-albumin	28-29 min
V	Human serum albumin	32-33 min
VI	Tin colloid	40-47 min
VII	Pertechnetate	48 min

At least 80 per cent of the radioactivity applied to the column is associated with the albumin fractions II to V.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised technetium-99m solution or by measurement in an instrument calibrated with the aid of such a solution.

LABELLING

The label states:

- the amount of albumin,
- the amount of tin, if any.

01/2008:0296
corrected 6.0

TECHNETIUM (^{99m}Tc) MACROSALB INJECTION

Technetii (^{99m}Tc) macrosalbi suspensio iniectabilis

DEFINITION

Technetium (^{99m}Tc) macrosalb injection is a sterile, apyrogenic suspension of human albumin in the form of irregular insoluble aggregates obtained by denaturing human albumin in aqueous solution; the particles are labelled with technetium-99m. The injection contains reducing substances, such as tin salts in an amount not exceeding 3 mg of Sn per millilitre; it may contain a suitable buffer such as acetate, citrate or phosphate buffer and also non-denatured human albumin and an antimicrobial preservative such as benzyl alcohol. The human albumin employed complies with the requirements prescribed in the monograph on *Human albumin solution (0255)*. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared technetium-99m radioactivity at the date and hour stated on the label. Not less than 90 per cent of the technetium-99m is bound to the particles of the suspension as determined by the test for non-filterable radioactivity. The particles have a typical diameter between 10 µm and 100 µm. The specific radioactivity is not less than 37 MBq of technetium-99m per milligram of aggregated albumin at the date and hour of administration.

It is prepared from sodium pertechnetate (^{99m}Tc) injection (fission or non-fission) using suitable sterile and apyrogenic ingredients and calculating the ratio of radionuclidic impurities with reference to the date and hour of administration.

CHARACTERS

A white or almost white suspension which may separate on standing.

Technetium-99m has a half-life of 6.02 h and emits gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised technetium-99m solution either by direct comparison or by using an instrument calibrated with the aid of such a solution. Standardised technetium-99m and molybdenum-99 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of technetium-99m has an energy of 0.140 MeV.

B. The tests for non-filterable radioactivity and particle size contribute to the identification of the preparation.

C. Transfer 1 ml of the injection to a centrifuge tube and centrifuge at 2500 *g* for 5 min to 10 min. Decant the supernatant liquid. To the residue add 5 ml of *cupri-tartaric solution R2*, mix and allow to stand for 10 min. If necessary, heat to dissolve the particles and allow to cool. Add rapidly 0.5 ml of *dilute phosphomolybdotungstic reagent R*, mixing immediately. A blue colour develops.

TESTS

pH (*2.2.3*). The pH of the injection is 3.8 to 7.5.

Non-filterable radioactivity. Use a polycarbonate membrane filter 13 mm to 25 mm in diameter, 10 µm thick and with circular pores 3 µm in diameter. Fit the membrane into a suitable holder. Place 0.2 ml of the injection on the membrane and filter, adding 20 ml of a 9 g/l solution of *sodium chloride R* during the filtration. The radioactivity remaining on the membrane represents not less than 90 per cent of the total radioactivity of the injection.

Particle size. Examine using a microscope. Dilute the injection if necessary so that the number of particles is just low enough for individual particles to be distinguished. Using a syringe fitted with a needle having a calibre not less than 0.35 mm, place a suitable volume in a suitable counting chamber such as a haemocytometer cell, taking care not to overfill the chamber. Allow the suspension to settle for 1 min and carefully add a cover slide without squeezing the sample. Scan an area corresponding to at least 5000 particles. Not more than 10 particles have a maximum dimension greater than 100 µm. No particle having a maximum dimension greater than 150 µm is present.

Aggregated albumin

Test solution. Transfer a volume of the injection expected to contain about 1 mg of aggregated albumin to a centrifuge tube and centrifuge at about 2500 *g* for 5 min to 10 min. Decant the supernatant liquid. Resuspend the sediment in 2.0 ml of a 9 g/l solution of *sodium chloride R*. Centrifuge at 2500 *g* for 5 min to 10 min. Decant the supernatant liquid. Resuspend the sediment in 5.0 ml of *sodium carbonate solution R1*. Heat in a water-bath at 80 °C to 90 °C to dissolve the aggregated albumin. Allow to cool, transfer to a volumetric flask and dilute to 10.0 ml with *sodium carbonate solution R1*.

Reference solutions. Prepare a range of reference solutions containing 0.05 mg to 0.2 mg of human albumin per millilitre in *sodium carbonate solution R1*.

Introduce 3.0 ml of each solution separately into 25 ml flasks. To each flask add 15.0 ml of *cupri-tartaric solution R2*, mix and allow to stand for 10 min. Add rapidly 1.5 ml of *dilute phosphomolybdotungstic reagent R* and mix immediately. Allow to stand for 30 min and measure the absorbance (*2.2.25*) at 750 nm using *sodium carbonate solution R1* as the compensation liquid. Using the absorbances obtained with the reference solutions, draw a calibration curve and calculate the content of aggregated albumin in the injection.

Tin

Test solution. To 1.0 ml of the injection add 1.0 ml of *2 M hydrochloric acid R*. Heat in a water-bath for 30 min. Cool and centrifuge for 10 min at 300 *g*. Dilute 1.0 ml of the supernatant liquid to 25.0 ml with *1 M hydrochloric acid*.

Reference solution. Dissolve 0.115 g of *stannous chloride R* in *1 M hydrochloric acid* and dilute to 1000.0 ml with the same acid.

To 1.0 ml of each solution add 0.4 ml of a 20 g/l solution of *sodium laurilsulfate R*, 0.05 ml of *thioglycollic acid R*, 0.1 ml of *dithiol reagent R* and 3.0 ml of *0.2 M hydrochloric acid*. Mix. Measure the absorbance (*2.2.25*) of each solution at 540 nm, using *0.2 M hydrochloric acid* as the compensation liquid. The absorbance of the test solution is not greater than that of the reference solution (3 mg of Sn per millilitre).

Physiological distribution. Inject a volume not greater than 0.2 ml into the caudal vein of each of three rats weighing 150 g to 250 g. Euthanise the rats 15 min after the injection, remove the liver, the spleen and the lungs and measure the radioactivity in the organs using a suitable instrument. Measure the radioactivity in the rest of the body, including the blood, after having removed the tail. Determine the percentage of radioactivity in the lungs, the liver and the spleen from the expression:

$$\frac{A}{B} \times 100$$

A = radioactivity of the organ concerned,

B = total radioactivity in the liver, the spleen, the lungs and the rest of the body.

In not fewer than two of the three rats used, at least 80 per cent of the radioactivity is found in the lungs and not more than a total of 5 per cent in the liver and spleen. The injection may be released for use before completion of the test.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

Pyrogens. It complies with the test for pyrogens prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. Inject into the animals not less than 0.1 ml per kilogram of the rabbit's mass. The injection may be released for use before completion of the test.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised technetium-99m solution or by measurement in an instrument calibrated with the aid of such a solution.

LABELLING

The label states:

– that the preparation should be shaken before use,
– the quantity of tin per millilitre, if any,
– that the preparation is not to be used if after shaking, the suspension does not appear homogeneous.

01/2008:0641

TECHNETIUM (^{99m}Tc) MEDRONATE INJECTION

Technetii (^{99m}Tc) medronati solutio iniectabilis

DEFINITION

Technetium (^{99m}Tc) medronate injection is a sterile solution which may be prepared by mixing solutions of sodium methylenediphosphonate and a stannous salt with sodium pertechnetate (^{99m}Tc) injection (fission or non-fission). The injection contains a variable quantity of tin (Sn) not exceeding 3 mg/ml; it may contain antimicrobial preservatives, antioxidants, stabilisers and buffers. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared technetium-99m radioactivity at the date and hour stated on the label. Radioactivity present as chemical forms other than technetium-99m medronate complex is not greater than 5.0 per cent of the total radioactivity.

It is prepared from sodium pertechnetate (^{99m}Tc) injection (fission or non-fission) using suitable sterile ingredients and calculating the ratio of radionuclidic impurities with reference to the date and hour of administration.

CHARACTERS

A clear, colourless solution.

Technetium-99m has a half-life of 6.02 h and emits gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised technetium-99m solution either by direct comparison or by using an instrument calibrated with the aid of such a solution. Standardised technetium-99m and molybdenum-99 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of technetium-99m has an energy of 0.140 MeV.

B. Examine the chromatograms obtained in the test for radiochemical purity. The distribution of the radioactivity contributes to the identification of the preparation.

C. Examine by thin-layer chromatography (*2.2.27*) using cellulose as the coating substance.

Test solution. Dilute the injection to be examined with *water R* to obtain a solution containing about 0.1 mg to 0.5 mg of sodium medronate per millilitre.

Reference solution. Dissolve a suitable quantity (1 mg to 5 mg) of *medronic acid CRS* in a mixture of a 9.0 g/l solution of *sodium chloride R* and *water R* and dilute to 10 ml with the same solvent so as to obtain a solution similar to the test solution with regard to medronate and sodium chloride concentrations.

Apply separately to the plate 10 µl of each solution. Develop over a path of 12 cm to 14 cm (development time about 4 h) using a mixture of 20 volumes of *2-propanol R*, 30 volumes of *1 M hydrochloric acid* and 60 volumes of *methyl ethyl ketone R*. Allow the plate to dry in air and spray with *ammonium molybdate solution R4*. Expose the plate to ultraviolet light at 254 nm for about 10 min. The principal spot in the chromatogram obtained with the test solution is similar in position and colour to the spot in the chromatogram obtained with the reference solution.

TESTS

pH (*2.2.3*). The pH of the solution is 3.5 to 7.5.

Tin

Test solution. Dilute 1.0 ml of the solution to 50.0 ml with *1 M hydrochloric acid*.

Reference solution. Dissolve 0.115 g of *stannous chloride R* in *1 M hydrochloric acid* and dilute to 1000.0 ml with the same acid.

To 1.0 ml of each solution add 0.4 ml of a 20 g/l solution of *sodium laurilsulfate R*, 0.05 ml of *thioglycollic acid R*, 0.1 ml of *dithiol reagent R* and 3.0 ml of *0.2 M hydrochloric acid*. Mix. Measure the absorbance (*2.2.25*) of each solution at 540 nm, using *0.2 M hydrochloric acid* as compensation liquid. The absorbance of the test solution is not greater than that of the reference solution (3 mg of Sn per millilitre).

Physiological distribution. Inject a volume not greater than 0.2 ml, equivalent to not more than 0.05 mg of sodium medronate into a suitable vein such as a caudal vein or the saphenous vein of each of three rats, each weighing 150 g to 250 g. Measure the radioactivity in the syringe before and after injection. Euthanise the rats 2 h after the injection. Remove one femur, the liver, and some blood. Weigh the blood. Remove the tail if a caudal vein has been used for the injection. Using a suitable instrument measure the radioactivity in the femur, liver, and blood, and in the tail if a caudal vein has been used for the injection. Determine the percentage of radioactivity in each sample from the expression:

$$\frac{A}{B} \times 100$$

A = radioactivity of the sample concerned,

B = total radioactivity, which is equal to the difference between the two measurements made on the syringe minus the radioactivity in the tail if a caudal vein has been used for the injection.

Calculate the radioactivity per unit mass in the blood. Correct the blood concentration by multiplying by a factor $m/200$ where m is the body mass of the rat in grams.

In not fewer than two of the three rats: not less than 1.5 per cent of the radioactivity is found in the femur; not more than 1.0 per cent is found in the liver and not more than 0.05 per cent per gram is found in the blood.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

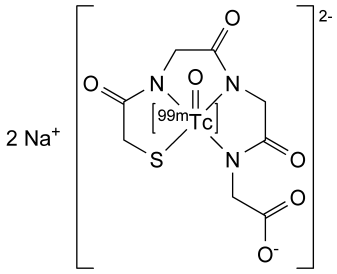
RADIOCHEMICAL PURITY

Examine by thin-layer chromatography (*2.2.27*) using silica gel as the coating substance on a glass-fibre sheet. Use plates such that during development, the mobile phase migrates 10 cm to 15 cm in about 10 min. Determine hydrolysed technetium and technetium in colloidal form by test (a) and pertechnetate ion by test (b).

(a) Apply to the plate 5 µl to 10 µl of the injection. Develop immediately over a path of 10 cm to 15 cm using a 136 g/l solution of *sodium acetate R*. Allow the plate to dry in air. Determine the distribution of radioactivity using a suitable detector. Hydrolysed technetium and technetium in colloidal form remain at the starting point. Technetium medronate complex and pertechnetate ion migrate near to the solvent front.

(b) Apply to the plate 5 µl to 10 µl of the injection and dry quickly. Develop over a path of 10 cm to 15 cm using *methyl ethyl ketone R*. Allow the plate to dry. Determine the distribution of radioactivity using a suitable detector. Pertechnetate ion migrates near to the solvent front. Technetium medronate complex and technetium in colloidal form remain at the starting-point.

The percentage of radioactivity corresponding to pertechnetate ion in the chromatogram obtained in test (b) is not greater than 2.0 per cent and the sum of the percentages of radioactivity corresponding to impurities in the chromatograms obtained in test (a) and test (b) (including pertechnetate ion) is not greater than 5.0 per cent.



RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised technetium-99m solution or by measurement in an instrument calibrated with the aid of such a solution.

01/2008:1372

TECHNETIUM (^{99m}Tc) MERTIATIDE INJECTION

Technetii (^{99m}Tc) mertiatidi solutio iniectabilis

DEFINITION

Technetium (^{99m}Tc) mertiatide injection is a sterile solution which may be prepared by either heating a mixture containing *S*-benzoylmercaptoacetyltriglycine (betiatide), a weak chelating agent such as tartrate, a stannous salt and sodium pertechnetate (^{99m}Tc) injection (fission or non-fission), or by mixing solutions of mercaptoacetyltriglycine (mertiatide), a stannous salt and sodium pertechnetate (^{99m}Tc) injection (fission or non-fission) at alkaline pH. It may contain stabilisers and a buffer. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared technetium-99m radioactivity at the date and time stated on the label. Not less than 94 per cent of the radioactivity corresponds to technetium-99m in the form of [^{99m}Tc]technetium mertiatide.

CHARACTERS

A clear, colourless solution.

Technetium-99m has a half-life of 6.02 h and emits gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised technetium-99m solution either by direct comparison or by using an instrument calibrated with the aid of such a solution. Standardised technetium-99m solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of technetium-99m has an energy of 0.140 MeV.

B. Examine the chromatogram obtained in test (b) for radiochemical purity. The principal peak in the chromatogram obtained with the test solution has approximately the same retention time as the principal peak in the chromatogram obtained with the reference solution.

TESTS

pH (*2.2.3*). The pH of the injection is 5.0 to 7.5.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

RADIOCHEMICAL PURITY

(a) Examine by ascending paper chromatography (*2.2.26*) using a suitable paper as the stationary phase.

Test solution. The solution to be examined.

Apply 2 µl of the test solution to the paper. Develop over a path of 15 cm using a mixture of 40 volumes of *water R* and 60 volumes of *acetonitrile R*. Allow the paper to dry and determine the distribution of the radioactivity using a suitable detector. Not more than 2.0 per cent of the total radioactivity is retained at the origin (R_F value 0.0 to 0.1).

(b) Examine by liquid chromatography (*2.2.29*).

Test solution. The solution to be examined.

Reference solution. Dissolve with heating on a water-bath 5 mg of *S-benzylmercaptoacetyltriglycine CRS* in 5 ml of *water R*. To 1 ml of this solution in a closed vial filled with *nitrogen R*, add 0.5 ml of a 40 g/l solution of *sodium potassium tartrate R*, 25 µl of a 4 g/l solution of *stannous chloride R* in *0.05 M hydrochloric acid R* and 370 MBq to 740 MBq of sodium pertechnetate (^{99m}Tc) injection (fission or non-fission) in a volume not exceeding 3 ml. Heat the mixture on a water-bath for 10 min and allow to cool to room temperature.

The chromatographic procedure may be carried out using:

– a stainless steel column 0.25 m long and 4.0 mm in internal diameter packed with *octadecylsilyl silica gel for chromatography R* (5 µm),

– as mobile phase at a flow rate of 1.0 ml/min:

Mobile phase A. A mixture of 7 volumes of *ethanol R* with 93 volumes of a solution of a 1.36 g/l solution of *potassium dihydrogen phosphate R*, adjusted to pH 6.0 with *0.1 M sodium hydroxide*,

Mobile phase B. A mixture of 10 volumes of *water R* with 90 volumes of *methanol R*,

– a suitable radioactivity detector,

– a 20 µl loop injector.

Equilibrate the column with mobile phase A for 20 min. Inject the test solution and the reference solution. Switch 10 min after each injection to mobile phase B and continue the chromatographic procedure for 15 min.

The test is not valid unless in the chromatogram obtained with the test solution the principal peak has approximately the same retention time as the principal peak in the chromatogram obtained with the reference solution. In the chromatogram obtained with the test solution the sum of the areas preceding the principal peak (corresponding to hydrophilic impurities, including [^{99m}Tc]pertechnetate) is not greater than 3.0 per cent of the sum of the areas of all peaks. The sum of the peaks following the principal peak (corresponding to lipophilic impurities) is not greater than 4.0 percent of the sum of the area of all peaks.

Not less than 94 per cent of the radioactivity corresponds to [^{99m}Tc]technetium mertiatide.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised technetium-99m solution or by measurement in an instrument calibrated with the aid of such a solution.

01/2008:0570

TECHNETIUM (^{99m}Tc) MICROSPHERES INJECTION

Technetii (^{99m}Tc) microsphaerarum suspensio iniectabilis

DEFINITION

Technetium (^{99m}Tc) microspheres injection is a sterile, apyrogenic suspension of human albumin which has been denatured to form spherical insoluble particles; the particles are labelled with technetium-99m. The injection contains reducing substances, such as tin salts in an amount not exceeding 3 mg of Sn per millilitre; it may contain a suitable buffer such as acetate, citrate or phosphate and additives such as wetting agents. The human albumin used complies with the requirements of the monograph on *Human albumin solution (0255)*. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared technetium-99m radioactivity at the date and hour stated on the label. Not less than 95 per cent of the technetium-99m is bound to the particles of the suspension as determined by the test for non-filterable radioactivity. The particles have a typical diameter between 10 µm and 50 µm. The radioactivity is not less than 185 MBq of technetium-99m per million particles at the date and hour of administration.

Technetium (^{99m}Tc) microspheres injection is prepared from sodium pertechnetate (^{99m}Tc) injection (fission or non-fission) using suitable sterile and apyrogenic ingredients and calculating the ratio of radionuclidic impurities with reference to the date and hour of administration.

CHARACTERS

A suspension of white, yellow or artificially coloured particles which may separate on standing.

Technetium-99m has a half-life of 6.02 h and emits gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised technetium-99m solution either by direct comparison or by using an instrument calibrated with the aid of such a solution. Standardised technetium-99m and molybdenum-99 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of technetium-99m has an energy of 0.140 MeV.

B. The tests for non-filterable radioactivity and particle size contribute to the identification of the preparation.

C. Transfer 1 ml of the injection to a centrifuge tube and centrifuge at 2500 *g* for 5 min to 10 min. Decant the supernatant liquid. To the residue add 5 ml of *cupri-tartaric solution R2*, mix and allow to stand for 10 min. If necessary, heat to dissolve the particles and allow to cool. Add rapidly 0.5 ml of *dilute phosphomolybdotungstic reagent R*, mix immediately and allow to stand. A blue colour develops.

TESTS

pH (*2.2.3*). The pH of the injection is 4.0 to 9.0.

Non-filterable radioactivity. Use a polycarbonate membrane filter 13 mm to 25 mm in diameter, 10 µm thick and with circular pores 3 µm in diameter. Fit the membrane into a suitable holder. Place 0.2 ml of the injection on the membrane and filter, adding 20 ml of a 9 g/l solution of *sodium chloride R* during the filtration. The radioactivity remaining on the membrane represents not less than 95 per cent of the total radioactivity of the injection.

Particle size. Examine using a microscope. Dilute the injection if necessary so that the number of particles is just low enough for individual particles to be distinguished. Using a syringe fitted with a needle having a calibre not less than 0.35 mm, place a suitable volume in a suitable counting chamber such as a haemocytometer cell, taking care not to overfill the chamber. Allow the suspension to settle for 1 min and carefully add a cover slide without squeezing the sample. Scan an area corresponding to at least 5000 particles. The particles have a uniform spherical appearance. Not more than 10 particles have a maximum dimension greater than 75 µm. No particle having a maximum dimension greater than 100 µm is present.

Number of particles. Examine using a microscope. Fill a suitable counting chamber such as a haemocytometer cell with a suitable dilution of the injection taking care that particles do not separate during the transfer. Count the number of particles in the chamber. Repeat this procedure twice and calculate the number of particles per millilitre of the injection.

Tin

Test solution. To 1.0 ml of the injection add 0.5 ml of *sulphuric acid R* and 1.5 ml of *nitric acid R*. Heat and evaporate to approximately 1 ml. Add 2 ml of *water R* and evaporate again to approximately 1 ml. Repeat this procedure twice, cool and dilute to 25.0 ml with *1 M hydrochloric acid*.

Reference solution. Dissolve 0.115 g of *stannous chloride R* in *1 M hydrochloric acid* and dilute to 1000.0 ml with the same acid.

To 1.0 ml of each solution add 0.4 ml of a 20 g/l solution of *sodium laurilsulfate R*, 0.05 ml of *thioglycollic acid R*, 0.1 ml of *dithiol reagent R* and 3.0 ml of *0.2 M hydrochloric acid*. Mix. Measure the absorbance (*2.2.25*) of each solution at 540 nm, using *0.2 M hydrochloric acid* as the compensation liquid. The absorbance of the test solution is not greater than that of the reference solution (3 mg of Sn per millilitre).

Physiological distribution. Inject a volume not greater than 0.2 ml into a caudal vein of each of three rats weighing 150 g to 250 g. Euthanise the rats 15 min after the injection, remove the liver, the spleen and the lungs and measure the radioactivity in the organs using a suitable instrument. Measure the radioactivity in the rest of the body, including the blood and voided urine, after having discarded the tail. Determine the percentage of radioactivity in the liver, the spleen and the lungs from the expression:

$$\frac{A}{B} \times 100$$

A = radioactivity of the organ concerned,

B = total radioactivity in the liver, the spleen, the lungs and the rest of the body, including voided urine.

In not fewer than two of the three rats used, not less than 80 per cent of the radioactivity is found in the lungs and not more than a total of 5 per cent in the liver and spleen. The injection may be released for use before completion of the test.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

Pyrogens. It complies with the test for pyrogens prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. Inject not less than 0.1 ml per kilogram of the rabbit's mass. The injection may be released for use before completion of the test.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised technetium-99m solution or by measurement in an instrument calibrated with the aid of such a solution.

LABELLING

The label states:

– the quantity of tin per millilitre, if any,

– that the preparation should be shaken before use.

01/2008:0642

TECHNETIUM (^{99m}Tc) PENTETATE INJECTION

Technetii (^{99m}Tc) pentetatis solutio iniectabilis

DEFINITION

Technetium (^{99m}Tc) pentetate injection is a sterile solution which may be prepared by mixing solutions of sodium diethylenetriaminepenta-acetate or calcium trisodium diethylenetriaminepenta-acetate and a stannous salt with a solution of sodium pertechnetate (^{99m}Tc). It contains a variable quantity of tin (Sn) not exceeding 1 mg/ml; it may contain suitable antimicrobial preservatives, antioxidants, stabilisers and buffers. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared technetium-99m radioactivity at the date and hour stated on the label. Not less than 95.0 per cent of the radioactivity corresponds to technetium-99m complexed with sodium pentetate or calcium trisodium pentetate.

It is prepared from sodium pertechnetate (^{99m}Tc) injection (fission or non-fission) using suitable, sterile ingredients and calculating the ratio of radionuclidic impurities with reference to the date and hour of administration.

CHARACTERS

A clear, colourless or slightly yellow solution.

Technetium-99m has a half life of 6.02 h and emits gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised technetium-99m solution either by direct comparison or by using an instrument calibrated with the aid of such a solution. Standardised technetium-99m and molybdenum-99 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of technetium-99m has an energy of 0.140 MeV.

B. Examine the chromatograms obtained in the test for radiochemical purity. The distribution of radioactivity contributes to the identification of the preparation.

C. Place in a clean, dry 10 ml glass tube a volume of the injection to be examined containing 2 mg of pentetate. Dilute, if necessary, to 1 ml with *water R*. Place in a second tube 1 ml of *water R* (blank). To each tube add 0.1 ml of a 1 g/l solution of *nickel sulphate R*, 0.5 ml of a 50 per cent *V/V* solution of *glacial acetic acid R* and 0.75 ml of a 50 g/l solution of *sodium hydroxide R*. Mix and verify that the pH is not above 5. To each tube add 0.1 ml of a 10 g/l solution of *dimethylglyoxime R* in *alcohol R*. Mix and allow to stand for 2 min. Adjust the pH in each tube to not less than 12 by adding a 100 g/l solution of *sodium hydroxide R*. Mix and check that the pH is not below 12. Allow to stand for 2 min. Heat the tubes gently on a water-bath for 2 min. The solution in the tube containing the injection to be examined remains clear and colourless throughout. The solution in the blank tube becomes red on addition of dimethylglyoxime solution and a red precipitate is formed when the tube is heated on a water-bath.

TESTS

pH (*2.2.3*). The pH of the injection is 4.0 to 7.5.

Tin

Test solution. Dilute 1.5 ml of the injection to 25.0 ml with *1 M hydrochloric acid*.

Reference solution. Dissolve 0.115 g of *stannous chloride R* in *1 M hydrochloric acid* and dilute to 1000.0 ml with the same acid.

To 1.0 ml of each solution add 0.4 ml of a 20 g/l solution of *sodium laurilsulfate R*, 0.05 ml of *thioglycollic acid R*, 0.1 ml of *dithiol reagent R* and 3.0 ml of *0.2 M hydrochloric acid*. Mix. Measure the absorbance (*2.2.25*) of each solution at 540 nm, using *0.2 M hydrochloric acid* as the compensation liquid. The absorbance of the test solution is not greater than that of the reference solution (1 mg of Sn per millilitre).

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

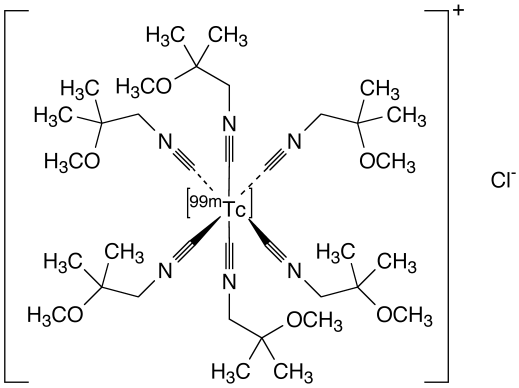
RADIOCHEMICAL PURITY

Examine by thin-layer chromatography (*2.2.27*) using silica gel as the coating substance on a glass-fibre sheet. Heat the plate at 110 °C for 10 min. Use a plate such that during development the mobile phase migrates over a distance of 10 cm to 15 cm in about 10 min.

(a) Apply to the plate 5 µl to 10 µl of the injection to be examined. Develop immediately over a path of 10 cm to 15 cm using a 9 g/l solution of *sodium chloride R*. Allow the plate to dry in air. Determine the distribution of radioactivity using a suitable detector. Impurities in colloidal form remain at the starting point. Technetium pentetate complex and pertechnetate ion migrate near to the solvent front.

(b) Apply to the plate 5 µl to 10 µl of the injection to be examined and allow to dry. Develop over a path of 10 cm to 15 cm using *methyl ethyl ketone R*. Allow the plate to dry. Determine the distribution of radioactivity using a suitable detector. Pertechnetate ion migrates near to the solvent front. Technetium pentetate complex and impurities in colloidal form remain at the starting point.

The sum of the percentages of radioactivity corresponding to impurities in the chromatograms obtained in test (a) and (b) does not exceed 5.0 per cent.



RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised technetium-99m solution or by measurement in an instrument calibrated with the aid of such a solution.

01/2008:1926

TECHNETIUM (^{99m}Tc) SESTAMIBI INJECTION

Technetii (^{99m}Tc) sestamibi solutio iniectabilis

DEFINITION

Sterile solution of (*OC*-6-11)-hexakis[1-(isocyano-κ*C*)-2-methoxy-2-methylpropane][^{99m}Tc]technetium(I) chloride, which may be prepared by heating a mixture containing [tetrakis(2-methoxy-2-methylpropyl-1-isocyanide)copper (1+)] tetrafluoroborate, a weak chelating agent, a stannous salt and *Sodium pertechnetate (^{99m}Tc) injection (fission) (0124)* or *Sodium pertechnetate (^{99m}Tc) injection (non-fission) (0283)*.

Content: 90 per cent to 110 per cent of the declared technetium-99m radioactivity at the date and hour stated on the label.

CHARACTERS

Appearance: clear, colourless solution.

Half-life and nature of radiation of technetium-99m: see general chapter *5.7. Table of physical characteristics of radionuclides.*

IDENTIFICATION

A. Gamma-ray spectrometry.

Results: the spectrum obtained with the solution to be examined does not differ significantly from that of a standardised technetium-99m solution. The most prominent gamma photon has an energy of 0.141 MeV.

B. Examine the chromatograms obtained in the test for impurity C under Radiochemical purity.

Results: the principal peak in the radiochromatogram obtained with the test solution is similar in retention time to the principal peak in the radiochromatogram obtained with the reference solution.

TESTS

pH (*2.2.3*): 5.0 to 6.0.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

RADIOCHEMICAL PURITY

Impurity A and other polar impurities. Thin-layer chromatography (*2.2.27*).

Test solution. The preparation to be examined.

Plate: *TLC octadecylsilyl silica gel plate R.*

Mobile phase: mix 10 volumes of *tetrahydrofuran R*, 20 volumes of a 38.5 g/l solution of *ammonium acetate R*, 30 volumes of *methanol R* and 40 volumes of *acetonitrile R*.

Application: about 5 µl.

Development: immediately over a path of 6 cm.

Drying: in air.

Detection: determine the distribution of radioactivity using a radioactivity detector.

Retardation factors: impurity B and apolar impurities = 0 to 0.1; impurity C and technetium-99m sestamibi = 0.3 to 0.6; impurity A and other polar impurities = 0.9 to 1.0.

Limit: see test for impurity B.

Impurity B. Paper chromatography (*2.2.26*). *If no activity is found at retardation factor 0 to 0.1 in the test for impurity A and other polar impurities, impurity B is absent and the test for impurity B may be omitted.*

Test solution. The preparation to be examined.

Paper: *paper for chromatography R.*

Mobile phase: mix equal volumes of *acetonitrile R, 0.5 M acetic acid* and a 20 g/l solution of *sodium chloride R* .

Application: about 5 µl.

Development: over a path of 10 cm.

Drying: in air.

Detection: determine the distribution of radioactivity using a radioactivity detector.

Retardation factors: impurity B = 0 to 0.1; impurity A, impurity C and technetium-99m sestamibi = 0.8 to 1.0.

Limit:

– *sum of impurity A and other polar impurities, and impurity B*: maximum 5 per cent of the total radioactivity.

Impurity C. Liquid chromatography (*2.2.29*).

Test solution. The preparation to be examined.

Reference solution. To a vial of *sestamibi labelling kit CRS* add 3 ml of a 9 g/l solution of *sodium chloride R* containing 700 MBq to 900 MBq of sodium pertechnetate (^{99m}Tc) injection (fission or non-fission). Heat the mixture in a water-bath for 10 min and allow to cool to room temperature.

Column:

– *size*: *l* = 0.25 m, Ø = 4.6 mm,

– *stationary phase*: spherical *base-deactivated end-capped octadecylsilyl silica gel for chromatography R* (5 µm).

Mobile phase: mix 20 volumes of *acetonitrile R*, 35 volumes of a 6.6 g/l solution of *ammonium sulphate R* and 45 volumes of *methanol R*.

Flow rate: 1.5 ml/min.

Detection: radioactivity detector.

Injection: 25 µl.

Run time: 25 min.

Relative retention with reference to technetium-99m sestamibi: impurity C = about 1.3.

System suitability: reference solution:

– the chromatogram is similar to the chromatogram provided with *sestamibi labelling kit CRS,*

– *relative retention* with reference to technetium-99m sestamibi: impurity C = minimum 1.2.

Limits:

– *impurity C*: not more than 3 per cent of the total radioactivity,

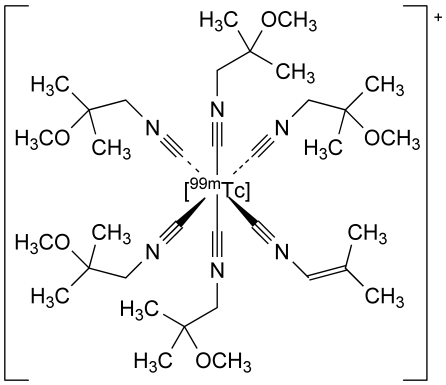
– *technetium-99m sestamibi*: minimum 94 per cent of the total radioactivity.

Calculate the percentage of radioactivity due to technetium-99m sestamibi from the expression:

$$\frac{(100 - B) \times T}{100}$$

B = percentage of radioactivity due to impurity B determined in the test for impurity B under Radiochemical purity,

T = area of the peak due to technetium-99m sestamibi in the chromatogram obtained with the test solution.



RADIOACTIVITY

Determine the radioactivity using a calibrated instrument.

IMPURITIES

A. $[^{99m}Tc]O_4^-$: (^{99m}Tc)pertechnetate ion,

B. technetium-99m in colloidal form,

C. (*OC*-6-22)-pentakis[1-(isocyano-κ*C*)-2-methoxy-2-methylpropane][1-(isocyano-κ*C*)-2-methylprop-1-ene][^{99m}Tc]technetium (1+).

01/2008:0643

TECHNETIUM (^{99m}Tc) SUCCIMER INJECTION

Technetii (^{99m}Tc) succimeri solutio iniectabilis

DEFINITION

Technetium (^{99m}Tc) succimer injection is a sterile solution of *meso*-2,3-dimercaptosuccinic acid labelled with technetium-99m. It contains a reducing substance, such as a tin salt in an amount not exceeding 1 mg of Sn per millilitre, and may contain stabilisers, antioxidants such as ascorbic acid, and inert additives. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared technetium-99m radioactivity at the date and hour stated on the label. Not less than 95.0 per cent of the radioactivity corresponds to technetium-99m succimer complex.

It is prepared from sodium pertechnetate (^{99m}Tc) injection (fission or non-fission) using suitable sterile ingredients and calculating the ratio of radionuclidic impurities with reference to the date and hour of administration. Syringes for handling the eluate intended for labelling of the final product, or for handling the final product should not contain rubber parts.

CHARACTERS

A clear, colourless solution.

Technetium-99m has a half life of 6.02 h and emits gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised technetium-99m solution either by direct comparison or by using an instrument calibrated with the aid of such a solution. Standardised technetium-99m and molybdenum-99 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of technetium-99m has an energy of 0.140 MeV.

B. Examine the chromatogram obtained in the test for radiochemical purity. The distribution of the radioactivity contributes to the identification of the preparation.

C. Place 1 ml of the injection to be examined in a test-tube and add 1 ml of a 20 g/l solution of *sodium nitroprusside R* and 0.1 ml of *glacial acetic acid R*. Mix. Place carefully at the top of the solution a layer of *concentrated ammonia R*. A violet ring develops between the layers.

TESTS

pH (*2.2.3*). The pH of the injection is 2.3 to 3.5.

Tin

Test solution. Dilute 1.5 ml of the injection to be examined to 25.0 ml with *1 M hydrochloric acid*.

Reference solution. Dissolve 0.115 g of *stannous chloride R* in *1 M hydrochloric acid* and dilute to 1000.0 ml with the same acid.

To 1.0 ml of each solution add 0.4 ml of a 20 g/l solution of *sodium laurilsulfate R*, 0.05 ml of *thioglycollic acid R*, 0.1 ml of *dithiol reagent R* and 3.0 ml of *0.2 M hydrochloric acid*. Mix. Allow to stand for 60 min. Measure the absorbance (*2.2.25*) of each solution at 540 nm, using *0.2 M hydrochloric acid* as the compensation liquid. The absorbance of the test solution is not greater than that of the reference solution (1 mg of Sn per millilitre).

Physiological distribution. Inject a volume not greater than 0.2 ml and containing not more than 0.1 mg of dimercaptosuccinic acid into a suitable vein, such as a caudal vein or a saphenous vein, of each of three rats each weighing 150 g to 250 g. Measure the radioactivity in the syringe before and after the injection. Euthanise the rats 1 h after the injection. Remove the kidneys, the liver, the stomach, the lungs and, if a caudal vein has been used for the injection, the tail. Using a suitable instrument determine the radioactivity in the organs and, if a caudal vein has been used for injection, in the tail. Determine the percentage of radioactivity in each organ with respect to the total

radioactivity calculated as the difference between the two measurements made on the syringe minus the activity in the tail (if a caudal vein has been used for the injection).

In not fewer than two of the three rats used, the radioactivity in the kidneys is not less than 40 per cent, that in the liver is not more than 10.0 per cent, that in the stomach is not more than 2.0 per cent and that in the lungs is not more than 5.0 per cent.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

RADIOCHEMICAL PURITY

Examine by thin-layer chromatography (*2.2.27*) using silica gel as the coating substance on a glass-fibre sheet. Heat the plate at 110 °C for 10 min. Use a plate such that during development the mobile phase migrates over a distance of 10 cm to 15 cm in about 10 min.

Apply to the plate 5 µl to 10 µl of the injection to be examined. Develop immediately over a path of 10 cm to 15 cm using *methyl ethyl ketone R*. Allow the plate to dry. Determine the distribution of radioactivity using a suitable detector. Technetium succimer complex remains at the starting point. Pertechnetate ion migrates near to the solvent front. Not less than 95.0 per cent of the total radioactivity is found in the spot corresponding to technetium succimer complex. The radioactivity corresponding to pertechnetate ion represents not more than 2.0 per cent of the total radioactivity.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised technetium-99m solution or by measurement in an instrument calibrated with the aid of such a solution.

STORAGE

Store protected from light.

01/2008:0129

TECHNETIUM (^{99m}Tc) TIN PYROPHOSPHATE INJECTION

Stanni pyrophosphatis et technetii (^{99m}Tc) solutio iniectabilis

DEFINITION

Technetium (^{99m}Tc) tin pyrophosphate injection is a sterile, apyrogenic solution which may be prepared by mixing solutions of sodium pyrophosphate and stannous chloride with sodium pertechnetate (^{99m}Tc) injection (fission or non-fission). The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared technetium-99m radioactivity at the date and hour stated on the label. Not less than 90 per cent of the radioactivity corresponds to technetium-99m complexed with tin pyrophosphate. The injection contains a quantity of sodium pyrophosphate ($Na_4P_2O_7$,$10H_2O$) that may vary from 1 mg to 50 mg per millilitre and a variable quantity of tin (Sn) not exceeding 3.0 mg per millilitre.

It is prepared from sodium pertechnetate (^{99m}Tc) injection (fission or non-fission) using suitable sterile, apyrogenic ingredients and calculating the ratio of radionuclidic impurities with reference to the date and hour of administration.

CHARACTERS

A clear, colourless solution.

Technetium-99m has a half-life of 6.02 h and emits gamma radiation.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised technetium-99m solution either by direct comparison or by using an instrument calibrated with the aid of such a solution. Standardised technetium-99m and molybdenum-99 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photon of technetium-99m has an energy of 0.140 MeV.

B. Examine the chromatograms obtained in the test for radiochemical purity. The distribution of radioactivity contributes to the identification of the injection.

C. To 1 ml add 1 ml of *acetic acid R*. Heat on a water-bath for 1 h. After cooling, add 10 ml of *nitro-vanadomolybdic reagent R* and allow to stand for 30 min. A yellow colour develops.

D. To 1 ml add 2 ml of a 30 per cent *V/V* solution of *sulphuric acid R*, 1 ml of *hydrochloric acid R*, 0.05 ml of *thioglycollic acid R*, 0.4 ml of a 20 g/l solution of *sodium laurilsulfate R* and 0.1 ml of *dithiol reagent R* and allow to stand for 30 min. A pink colour develops.

TESTS

pH (*2.2.3*). The pH of the injection is 6.0 to 7.0.

Sodium pyrophosphate

Test solution. Use 1 ml of the injection to be examined or a suitable dilution of it.

Reference solutions. Using a solution containing *sodium pyrophosphate R* and *stannous chloride R* in the same proportions as in the injection to be examined, prepare a range of solutions and dilute to the same final volume with *water R*.

To the test solution and to 1 ml of each of the reference solutions add successively 10 ml of a 1 g/l solution of *disodium hydrogen phosphate R*, 10 ml of *iron standard solution (8 ppm Fe) R*, 5 ml of *glacial acetic acid R* and 5 ml of a 1 g/l solution of *hydroxylamine hydrochloride R*. Dilute each solution to 40 ml with *water R* and heat in a water-bath at 40 °C for 1 h. To each solution add 4 ml of a 1 g/l solution of *phenanthroline hydrochloride R* and dilute to 50.0 ml with *water R*. Measure the absorbance (*2.2.25*) of each solution at 515 nm using as the compensation liquid a reagent blank containing hydrochloric acid (1.1 g/l HCl) instead of the *iron standard solution (8 ppm Fe) R*. Using the absorbances obtained with the reference solutions, draw a calibration curve and calculate the concentration of sodium pyrophosphate in the injection to be examined.

Tin

Test solution. Use 1 ml of the injection to be examined or a suitable dilution of it.

Reference solutions. Using a solution in hydrochloric acid (6.2 g/l HCl) containing *sodium pyrophosphate R* and *stannous chloride R* in the same proportions as in the injection to be examined, prepare a range of solutions and dilute to the same volume with hydrochloric acid (6.2 g/l HCl).

To the test solution and to 1 ml of each of the reference solutions add 2 ml of a 300 g/l solution of *sulphuric acid R*, 1 ml of *hydrochloric acid R*, 0.05 ml of *thioglycollic acid R*, 0.4 ml of a 20 g/l solution of *sodium laurilsulfate R*

and 0.1 ml of *dithiol reagent R* and dilute to 15 ml with hydrochloric acid (6.2 g/l HCl). Allow the solutions to stand for 30 min and measure the absorbance (*2.2.25*) of each solution at 530 nm, using as the compensation liquid a reagent blank containing the same quantity of *sodium pyrophosphate R* as the injection to be examined. Using the absorbances obtained with the reference solutions, draw a calibration curve and calculate the concentration of tin in the injection to be examined.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

Pyrogens. It complies with the test for pyrogens prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. Inject not less than 0.1 ml per kilogram of the rabbit's mass. The injection may be released for use before completion of the test.

RADIOCHEMICAL PURITY

(a) Examine by thin-layer chromatography (*2.2.27*) using silica gel as the coating substance on a glass-fibre sheet. Heat the plate at 110 °C for 10 min. The plate used should be such that during development the mobile phase migrates over a distance of 10 cm to 15 cm in about 10 min.

Apply to the plate 5 µl to 10 µl of the injection and dry in a stream of nitrogen. Develop over a path of 10 cm to 15 cm using *methyl ethyl ketone R* through which nitrogen has been bubbled in the chromatography tank for 10 min immediately before the chromatography. Allow the plate to dry. Determine the distribution of radioactivity using a suitable detector. The technetium-99m tin pyrophosphate complex remains at the starting-point and pertechnetate ion migrates with an R_F of 0.95 to 1.0.

(b) Examine by thin-layer chromatography (*2.2.27*) using silica gel as the coating substance on a glass-fibre sheet. Heat the plate at 110 °C for 10 min. The plate used should be such that during development the mobile phase migrates over a distance of 10 cm to 15 cm in about 10 min.

Apply to the plate 5 µl to 10 µl of the injection. Develop immediately over a path of 10 cm to 15 cm using a 136 g/l solution of *sodium acetate R*. Allow the plate to dry and measure the distribution of radioactivity using a suitable detector. Impurities in colloidal form remain at the starting-point and technetium-99m tin pyrophosphate complex and pertechnetate ion migrate with an R_F of 0.9 to 1.0.

Add together the percentages of radioactivity corresponding to impurities in the chromatograms obtained in test (a) and test (b). The sum does not exceed 10 per cent.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised technetium-99m solution or by measurement in an instrument calibrated with the aid of such a solution.

LABELLING

The label states, in particular, the quantity of sodium pyrophosphate per millilitre and the quantity of tin per millilitre.

01/2008:0571

THALLOUS (^{201}Tl) CHLORIDE INJECTION

Thallosi (^{201}Tl) chloridi solutio iniectabilis

DEFINITION

Thallous (^{201}Tl) chloride injection is a sterile solution of thallium-201 in the form of thallous chloride. It may be made isotonic by the addition of *Sodium chloride (0193)* and may contain a suitable antimicrobial preservative such as *Benzyl alcohol (0256)*. Thallium-201 is a radioactive isotope of thallium formed by the decay of lead-201. Lead-201 is a radioactive isotope of lead and may be obtained by irradiation, with protons of suitable energy, of thallium which may be enriched in thallium-203. Thallium-201 may be separated from lead-201 by passing through a column of an ion-exchange resin. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared thallium-201 radioactivity at the date and hour stated on the label. Not more than 2.0 per cent of the total radioactivity is due to thallium-202 and not less than 97.0 per cent is due to thallium-201. Not less than 95.0 per cent of the radioactivity is due to thallium in the form of thallous ions. The specific radioactivity is not less than 3.7 GBq per milligram of thallium.

CHARACTERS

A clear, colourless solution.

Thallium-201 has a half-life of 3.05 days and emits gamma radiation and X-rays.

IDENTIFICATION

A. Record the gamma-ray and X-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised thallium-201 solution when measured either by direct comparison or by use of an instrument calibrated with the aid of such a solution. Standardised thallium-201 and thallium-202 solutions are available from laboratories recognised by the competent authority. The most prominent gamma photons have energies of 0.135 MeV, 0.166 MeV and 0.167 MeV. The X-rays have energies of 0.069 MeV to 0.083 MeV.

B. Examine the electropherogram obtained in the test for radiochemical purity. The distribution of radioactivity contributes to the identification of the preparation.

TESTS

pH (*2.2.3*). The pH of the injection is 4.0 to 7.0.

Thallium. To 0.5 ml of the injection add 0.5 ml of hydrochloric acid (220 g/l HCl) and 0.05 ml of *bromine water R* and mix. Add 0.1 ml of a 30 g/l solution of *sulphosalicylic acid R*. After decolorisation add 1.0 ml of a 1 g/l solution of *rhodamine B R*. Add 4 ml of *toluene R* and shake for 60 s. Separate the toluene layer. The toluene layer is not more intensely coloured than the toluene layer of a standard prepared at the same time in the same manner using 0.5 ml of *thallium standard solution (10 ppm Tl) R*.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

RADIONUCLIDIC PURITY

Record the gamma-ray and X-ray spectrum using a suitable instrument calibrated with the aid of standardised thallium-201 and thallium-202 solutions. The spectrum

does not differ significantly from that of the standardised thallium-201 solution. Determine the relative amounts of thallium-201 and thallium-202 and other radionuclidic impurities present. Thallium-202 has a half-life of 12.2 days and its most prominent gamma photon has an energy of 0.440 MeV. Thallium-200 has a half-life of 1.09 days and its most prominent gamma photons have energies of 0.368 MeV, 0.579 MeV, 0.828 MeV and 1.206 MeV. Lead-201 has a half-life of 9.4 h and its most prominent gamma photon has an energy of 0.331 MeV. Lead-203 has a half-life of 2.17 days and its most prominent gamma photon has an energy of 0.279 MeV. Not more than 2.0 per cent of the total radioactivity is due to thallium-202 and not less than 97.0 per cent is due to thallium-201.

RADIOCHEMICAL PURITY

Examine by zone electrophoresis (*2.2.31*), using a suitable strip of cellulose acetate, as the support and a 18.6 g/l solution of *sodium edetate R* as the electrolyte solution. Soak the strip in the electrolyte solution for 45-60 min. Remove the strip with forceps taking care to handle the outer edges only. Place the strip between 2 absorbent pads and blot to remove excess solution.

Test solution. Mix equal volumes of the injection to be examined and the electrolyte solution.

Apply not less than 5 µl of the test solution to the centre of the strip and mark the point of application. Apply an electric field of 17 V/cm for at least 10 min. Allow the strip to dry in air. Determine the distribution of radioactivity using suitable equipment. Not less than 95.0 per cent of the radioactivity migrates towards the cathode.

RADIOACTIVITY

Measure the radioactivity using suitable counting equipment by comparison with a standardised thallium-201 solution or by measurement in an instrument calibrated with the aid of such a solution.

01/2008:0112

TRITIATED (^{3}H) WATER INJECTION

Aquae tritiatae (^{3}H) solutio iniectabilis

DEFINITION

Tritiated (^{3}H) water injection is water for injections in which some of the water molecules contain tritium atoms in place of protium atoms. It may be made isotonic by the addition of sodium chloride. Tritium (^{3}H) may be obtained by the neutron irradiation of lithium. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared tritium activity at the date stated on the label.

CHARACTERS

A clear, colourless liquid.

Tritium has a half-life of 12.3 years and emits beta radiation.

IDENTIFICATION

Record the beta-ray spectrum by the method prescribed in the test for radionuclidic purity. The spectrum does not differ significantly from that of a standardised tritiated (^{3}H) water. Standardised tritiated (^{3}H) water is available from laboratories recognised by the competent authority. The maximum energy of the beta radiation is 0.019 MeV.

TESTS

pH (*2.2.3*). The pH of the injection is 4.5 to 7.0.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*.

RADIONUCLIDIC PURITY

(a) Mix 100 µl of a suitable dilution of the injection with 10 ml of a scintillation liquid consisting of 1000 ml of *dioxan R*, 100 g of *naphthalene R*, 7 g of *diphenyloxazole R* and 0.3 g of *methylphenyloxazolylbenzene R*, the reagents being of an analytical grade suitable for liquid scintillation. Measure the radioactivity of the mixture in a liquid scintillation counter fitted with a discriminator. The count should be about 5000 impulses per second at the lowest setting of the discriminator. Record the count at different discriminator settings. For each measurement count at least 10 000 impulses over a period of at least 1 min. Immediately determine in the same conditions the count for a standardised tritiated (^{3}H) water having approximately the same activity.

Plot the counts at each discriminator setting, correcting for background activity, on semi-logarithmic paper, the discriminator settings being in arbitrary units as the abscissae.The vertical distance between the two curves obtained is constant. They obey the mathematical relationship:

$$\frac{\frac{A_1}{B_1} - \frac{A_2}{B_2}}{\frac{A_1}{B_1}} \times 100 < 20$$

A_1 = radioactivity recorded for the standardised preparation at the lowest discriminator setting,

B_1 = radioactivity recorded for the preparation to be examined at the lowest discriminator setting,

A_2 = radioactivity recorded for the standard at the discriminator setting such that $A_2 \approx A_1 \times 10^{-3}$,

B_2 = radioactivity recorded for the preparation to be examined at the latter discriminator setting.

(b) Record the gamma-ray spectrum. The instrument registers only background activity.

RADIOCHEMICAL PURITY

Place a quantity of the injection equivalent to about 2 µCi (74 kBq), diluted to 50 ml with *water R*, in an all-glass distillation apparatus of the type used for the determination of distillation range (*2.2.11*). Determine the radioactive concentration. Distil until about 25 ml of distillate has been collected. Precautions must be taken to avoid contamination of the air. If the test is carried out in a fume cupboard, the equipment must be protected from draughts. Determine the radioactive concentration of the distillate and of the liquid remaining in the distillation flask. Neither of the radioactive concentrations determined after distillation differs by more than 5 per cent from the value determined before distillation.

RADIOACTIVITY

Determine the radioactivity using a liquid scintillation counter.

01/2008:1582

WATER (^{15}O) INJECTION

Aquae (^{15}O) solutio iniectabilis

DEFINITION

Water (^{15}O) injection is a sterile solution of [^{15}O]water for diagnostic use. The injection contains not less than 90.0 per cent and not more than 110.0 per cent of the declared

oxygen-15 radioactivity at the date and time stated on the label. Not less than 99 per cent of the total radioactivity corresponds to oxygen-15 in the form of water.

PRODUCTION

RADIONUCLIDE PRODUCTION

Oxygen-15 is a radioactive isotope of oxygen which may be produced by various nuclear reactions such as proton irradiation of nitrogen-15 or deuteron irradiation of nitrogen-14.

RADIOCHEMICAL SYNTHESIS

In order to recover oxygen-15 as molecular oxygen from the nitrogen target gas, carrier oxygen is added at concentrations generally ranging from 0.2 per cent *V/V* to 1.0 per cent *V/V*. [^{15}O]Water can be prepared from [^{15}O]oxygen by reaction with hydrogen using a suitable catalyst.

An alternative method is to produce [^{15}O]water "in-target" by adding hydrogen to the irradiated target gas at a concentration generally ranging from 2 per cent *V/V* to 5 per cent *V/V*.

The [^{15}O]water vapour contained in the gas-stream is either bubbled through a reservoir of a sterile 9 g/l solution of sodium chloride, or is exchanged by diffusion into such a solution through a membrane filter for dialysis.

Ammonia is a possible chemical impurity in [^{15}O]water. This may arise either from catalytic conversion of hydrogen and nitrogen on the catalyst or by radiolysis if "in-target" production is used. In addition, there is the possibility of contamination by oxygen-15-labelled oxides of nitrogen. Although these contaminants can be effectively removed from the gas phase by soda lime and charcoal adsorbers, they may break through and be present in the final preparation.

CHARACTERS

A clear, colourless solution.

Oxygen-15 has a half-life of 2.04 min and emits positrons with a maximum energy of 1.732 MeV, followed by annihilation gamma radiation of 0.511 MeV.

IDENTIFICATION

A. Record the gamma-ray spectrum using a suitable instrument. The only gamma photons have an energy of 0.511 MeV and, depending on the measurement geometry, a sum peak of 1.022 MeV may be observed.

B. It complies with the test for radionuclidic purity (see Tests).

C. Examine the chromatogram obtained in the test for radiochemical purity. The retention time of the second peak is due to the radioactivity eluting in the void volume.

TESTS

pH (*2.2.3*). The pH of the injection is 5.5 to 8.5.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

Bacterial endotoxins (*2.6.14*): less than 175/*V* IU/ml, *V* being the maximum administered volume in millilitres. The injection may be released for use before completion of the test.

CHEMICAL PURITY

(a) Ammonium (*2.4.1*). 1 ml complies with the limit test for ammonium (10 ppm).

(b) Nitrates. To 1 ml add 49 ml of *nitrate-free water R*. Place 5 ml of this solution in a test-tube immersed in iced water, add 0.4 ml of a 100 g/l solution of *potassium chloride R*, 0.1 ml of *diphenylamine solution R* and, dropwise with shaking, 5 ml of *sulphuric acid R*. Transfer the tube to a water-bath at 50 °C. After 15 min, any blue colour in the solution is not more intense than that in a standard prepared at the same time in the same manner using a mixture of 4.5 ml of *nitrate-free water R* and 0.5 ml of *nitrate standard solution (2 ppm NO_3) R* (10 ppm).

The injection may be released for use before completion of tests (a) and (b).

RADIONUCLIDIC PURITY

Record the gamma-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised fluorine-18 solution. Standardised fluorine-18 solutions are available from the laboratories recognised by the competent authority.

The half-life is between 1.9 min and 2.2 min. Not less than 99 per cent of total radioactivity corresponds to oxygen-15.

The injection may be released for use before completion of the test.

RADIOCHEMICAL PURITY

Examine by liquid chromatography (*2.2.29*).

Test solution. The preparation to be examined.

The chromatographic procedure may be carried out using:

- a column 0.25 m long and 4.0 mm in internal diameter packed with *aminopropylsilyl silica gel for chromatography R* (10 µm),
- as mobile phase at a flow rate of 1 ml/min a 10 g/l solution of *potassium dihydrogen phosphate R* adjusted to pH 3 with *phosphoric acid R*,
- a suitable radioactivity detector,
- a loop injector,
- an internal recovery detection system, consisting of a loop of the chromatographic tubing between the injector and the column through the radioactivity detector, which has been calibrated for count recovery,

maintaining the column at a constant temperature between 20 °C and 30 °C.

Inject the test solution. Continue the chromatography for 10 min. In the chromatogram obtained, the first peak corresponds to the injected radioactivity of the test solution, the second peak corresponds to the amount of radioactivity as [^{15}O]water. Calculate the percentage content of [^{15}O]water from the areas of the peaks in the chromatogram obtained with the test solution. Not less than 99 per cent of the total radioactivity injected corresponds to oxygen-15 in the form of water.

The injection may be released for use before completion of the test.

RADIOACTIVITY

Measure the radioactivity using suitable equipment by comparison with a standardised fluorine-18 solution or by using an instrument calibrated with the aid of such a solution.

01/2008:0133

XENON (^{133}Xe) INJECTION

Xenoni (^{133}Xe) solutio iniectabilis

DEFINITION

Xenon (^{133}Xe) injection is a sterile solution of xenon-133 that may be made isotonic by the addition of sodium chloride. Xenon-133 is a radioactive isotope of xenon and is obtained by separation from the other products of uranium fission. The injection contains not less than 80 per cent and not more than 130 per cent of the declared xenon-133 radioactivity at the date and hour stated on the label.

The injection is presented in a container that allows the contents to be removed without introducing air bubbles. The container is filled as completely as possible and any gas bubble present does not occupy more than 1 per cent of the volume of the injection as judged by visual comparison with a suitable standard.

CHARACTERS

A clear, colourless solution.

Xenon-133 has a half-life of 5.29 days and emits beta and gamma radiation and X-rays.

IDENTIFICATION

Record the gamma-ray and X-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised xenon-133 solution in a 9 g/l solution of *sodium chloride R*, apart from any differences attributable to the presence of xenon-131m and xenon-133m. If standardised xenon-133 solutions are not readily available, suitable standardised ionisation chambers are obtainable from laboratories recognised by the relevant competent authority. The most prominent gamma photon of xenon-133 has an energy of 0.081 MeV and there is an X-ray (resulting from internal conversion) of 0.030 MeV to 0.035 MeV. Xenon-131m has a half-life of 11.9 days and emits a gamma photon of 0.164 MeV. Xenon-133m has a half-life of 2.19 days and emits a gamma photon of 0.233 MeV.

TESTS

pH (*2.2.3*). The pH of the injection is 5.0 to 8.0.

Sterility. It complies with the test for sterility prescribed in the monograph on *Radiopharmaceutical preparations (0125)*. The injection may be released for use before completion of the test.

RADIONUCLIDIC PURITY

(a) Record the gamma-ray and X-ray spectrum using a suitable instrument. The spectrum does not differ significantly from that of a standardised xenon-133 solution in a 9 g/l solution of *sodium chloride R*, apart from any differences attributable to the presence of xenon-131m and xenon-133m.

(b) Transfer 2 ml of the injection to an open flask and pass a current of air through the solution for 30 min, taking suitable precautions concerning the dispersion of radioactivity. Measure the residual beta and gamma activity of the solution. The activity does not differ significantly from the background activity detected by the instrument.

RADIOACTIVITY

Weigh the container with its contents. Determine its total radioactivity using suitable counting equipment by comparison with a standardised xenon-133 solution or by measurement in an instrument calibrated with the aid of such a solution, operating in strictly identical conditions. If an ionisation chamber is used its inner wall should be such that the radiation is not seriously attenuated. Remove at least half the contents and re-weigh the container. Measure the radioactivity of the container and the remaining contents as described above. From the measurements, calculate the radioactive concentration of xenon-133 in the injection.

CAUTION

Significant amounts of xenon-133 may be present in the closures and on the walls of the container. This must be taken into account in applying the rules concerning the transport and storage of radioactive substances and in disposing of used containers

SUTURES FOR HUMAN USE

Introduction.. 1045
Catgut, sterile..... 1045
Sutures, sterile non-absorbable.. 1046
Sutures, sterile synthetic absorbable braided 1050
Sutures, sterile synthetic absorbable monofilament 1052

01/2008:90004

INTRODUCTION

The following monographs apply to sutures for human use: Catgut, sterile (0317), Sutures, sterile non-absorbable (0324), Sutures, sterile synthetic absorbable braided (0667) and Sutures, sterile synthetic absorbable monofilament (0666). They cover performance characteristics of sutures and may include methods of identification. Sutures are medical devices as defined in Directive 93/42/EEC.

These monographs can be applied to show compliance with essential requirements as defined in Article 3 of Directive 93/42/EEC covering the following:

Physical performance characteristics: diameter, breaking load, needle attachment, packaging, sterility, information supplied by the manufacturer (see Section 13 of Annex 1 of Directive 93/42/EEC), labelling.

To show compliance with other essential requirements, the application of appropriate harmonised standards as defined in Article 5 of Directive 93/42/EEC may be considered.

01/2008:0317

CATGUT, STERILE

Chorda resorbilis sterilis

DEFINITION

Sterile catgut consists of sutures prepared from collagen taken from the intestinal membranes of mammals. After cleaning, the membranes are split longitudinally into strips of varying width, which, when assembled in small numbers, according to the diameter required, are twisted under tension, dried, polished, selected and sterilised. The sutures may be treated with chemical substances such as chromium salts to prolong absorption and glycerol to make them supple, provided such substances do not reduce tissue acceptability.

Appropriate harmonised standards may be considered when assessing compliance with respect to origin and processing of raw materials and with respect to biocompatibility.

Sterile catgut is a surgical wound-closure device. Being an absorbable suture it serves to approximate tissue during the healing period and is subsequently metabolised by proteolytic activity.

PRODUCTION

Production complies with relevant regulations on the use of animal tissues in medical devices notably concerning the risk of transmission of animal spongiform encephalopathy agents.

Appropriate harmonised standards may apply with respect to appropriate validated methods of sterilisation, environmental control during manufacturing, labelling and packaging.

It is essential for the effectiveness and the performance characteristics during use and during the functional lifetime of catgut that the following physical properties are specified: consistent diameter, sufficient initial strength and firm needle attachment.

The requirements outlined below have been established, taking into account stresses which occur during normal conditions of use. These requirements can be used to demonstrate that individual production batches of sterile catgut are suitable for wound closure according to usual surgical techniques.

TESTS

If stored in a preserving liquid, remove the sutures from the sachet and measure promptly and in succession the length, diameter and breaking load. If stored in the dry state, immerse the sutures in alcohol R or a 90 per cent V/V solution of 2-propanol R for 24 h and proceed with the measurements as indicated below.

Length. Measure the length without applying to the suture more tension than is necessary to keep it straight. The length of each suture is not less than 90 per cent of the length stated on the label and does not exceed 350 cm.

Diameter. Carry out the test on 5 sutures. Use a suitable instrument capable of measuring with an accuracy of at least 0.002 mm and having a circular pressor foot 10 mm to 15 mm in diameter. The pressor foot and the moving parts attached to it are weighted so as to apply a total load of 100 ± 10 g to the suture being tested. When making the measurement, lower the pressor foot slowly to avoid crushing the suture. Measure the diameter at intervals of 30 cm over the whole length of the suture. For a suture less than 90 cm in length, measure at 3 points approximately evenly spaced along the suture. The suture is not subjected to more tension than is necessary to keep it straight during measurement. The average of the measurements carried out on the sutures being tested and not less than two-thirds of the measurements taken on each suture are within the limits given in the columns under A in Table 0317.-1 for the gauge number concerned. None of the measurements is outside the limits given in the columns under B in Table 0317.-1 for the gauge number concerned.

Table 0317.-1.– *Diameters and Breaking Loads*

Gauge number	Diameter (millimetres)				Breaking load (newtons)	
	A		B		C	D
	min.	max.	min.	max.

5	0.500	0.599	0.450	0.650	38.0	20.0
6	0.600	0.699	0.550	0.750	45.0	27.5
7	0.700	0.799	0.650	0.850	60.0	38.0
8	0.800	0.899	0.750	0.950	70.0	45.0

Minimum breaking load. The minimum breaking load is determined over a simple knot formed by placing one end of a suture held in the right hand over the other end held in

the left hand, passing one end over the suture and through the loop so formed (see Figure 0317.-1) and pulling the knot tight. Carry out the test on 5 sutures. Submit sutures of length greater than 75 cm to 2 measurements and shorter sutures to one measurement. Determine the breaking load using a suitable tensilometer. The apparatus has 2 clamps for holding the suture, one of which is mobile and is driven at a constant rate of 30 cm/min. The clamps are designed so that the suture being tested can be attached without any possibility of slipping. At the beginning of the test the length of suture between the clamps is 12.5 cm to 20 cm and the knot is midway between the clamps. Set the mobile clamp in motion and note the force required to break the suture. If the suture breaks in a clamp or within 1 cm of it, the result is discarded and the test repeated on another suture. The average of all the results, excluding those legitimately discarded, is equal to or greater than the value given in column C in Table 0317.-1 and no individual result is less than that given in column D for the gauge number concerned.

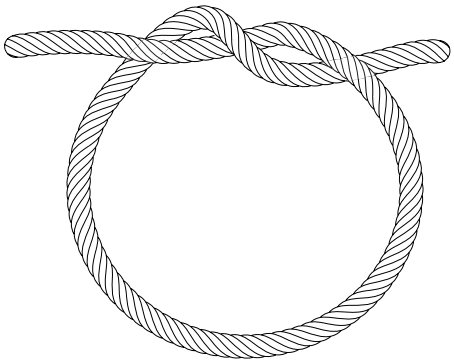

Figure 0317.-1. – *Simple knot*

Soluble chromium compounds. Place 0.25 g in a conical flask containing 1 ml of *water R* per 10 mg of catgut. Stopper the flask, allow to stand at 37 ± 0.5 °C for 24 h, cool and decant the liquid. Transfer 5 ml to a small test tube and add 2 ml of a 10 g/l solution of *diphenylcarbazide R* in *alcohol R* and 2 ml of *dilute sulphuric acid R*. The solution is not more intensely coloured than a standard prepared at the same time using 5 ml of a solution containing 2.83 µg of *potassium dichromate R* per millilitre, 2 ml of *dilute sulphuric acid R* and 2 ml of a 10 g/l solution of *diphenylcarbazide R* in *alcohol R* (1 ppm of Cr).

Needle attachment. If the catgut is supplied with an eyeless needle attached that is not stated to be detachable, it complies with the test for needle attachment. Carry out the test on 5 sutures. Use a suitable tensilometer, such as that described for the determination of the minimum breaking load. Fix the needle and suture (without knot) in the clamps of the apparatus in such a way that the swaged part of the needle is completely free of the clamp and in line with the direction of pull on the suture. Set the mobile clamp in motion and note the force required to break the suture or to detach it from the needle. The average of the 5 determinations and all individual values are not less than the respective values given in Table 0317.-2 for the gauge number concerned. If not more than one individual value fails to meet the individual requirement, repeat the test on an additional 10 sutures. The catgut complies with the test if none of these 10 values is less than the individual value in Table 0317.-2 for the gauge number concerned.

Table 0317.-2. – *Minimum Strengths of Needle Attachment*

Gauge number	Mean value (newtons)	Individual values (newtons)
0.5	0.50	0.25
0.7	0.80	0.40
1	1.7	0.80
1.5	2.3	1.1
2	4.5	2.3
2.5	5.6	2.8
3	6.8	3.4
3.5	11.0	4.5
4	15.0	4.5
5	18.0	6.0

STORAGE (PACKAGING)

Sterile catgut sutures are presented in individual sachets that maintain sterility and allow the withdrawal and use of the sutures in aseptic conditions. Sterile catgut may be stored dry or in a preserving liquid to which an antimicrobial agent but not an antibiotic may be added.

Sutures in their individual sachets (primary packaging) are kept in a protective cover (box) which maintains the physical and mechanical properties until the time of use.

The application of appropriate harmonised standards for packaging of medical devices shall be considered.

LABELLING

Reference may be made to the appropriate harmonised standards for labelling of medical devices.

The details strictly necessary for the user to identify the product properly are indicated on or in each sachet (primary packaging) and on the protective cover (box) and include at least:

- gauge number,
- length in centimetres or metres,
- if appropriate, that the needle is detachable,
- name of the product,
- intended use (surgical suture, absorbable).

01/2008:0324

SUTURES, STERILE NON-ABSORBABLE

Fila non resorbilia sterilia

DEFINITION

Sterile non-absorbable sutures are sutures which, when introduced into a living organism, are not metabolised by that organism. Sterile non-absorbable sutures vary in origin, which may be animal, vegetable, metallic or synthetic. They occur as cylindrical monofilaments or as multifilament sutures consisting of elementary fibres which are assembled by twisting, cabling or braiding; they may be sheathed; they may be treated to render them non-capillary, and they may be coloured.

Appropriate harmonised standards may be considered when assessing compliance with respect to origin and processing of raw materials and with respect to biocompatibility.

Sterile non-absorbable surgical sutures serve to approximate tissue during the healing period and provide continuing wound support.

Commonly used materials include the following:

Silk (Filum bombycis)

Sterile braided silk suture is obtained by braiding a number of threads, according to the diameter required, of degummed silk obtained from the cocoons of the silkworm *Bombyx mori* L.

Linen (Filum lini)

Sterile linen thread consists of the pericyclic fibres of the stem of *Linum usitatissimum* L. The elementary fibres, 2.5 cm to 5 cm long, are assembled in bundles 30 cm to 80 cm long and spun into continuous lengths of suitable diameter.

Poly(ethylene terephthalate) (Filum ethyleni polyterephthalici)

Sterile poly(ethylene terephthalate) suture is obtained by drawing poly(ethylene terephthalate) through a suitable die. The suture is prepared by braiding very fine filaments in suitable numbers, depending on the gauge required.

Polyamide-6 (Filum polyamidicum-6)

Sterile polyamide-6 suture is obtained by drawing through a suitable die a synthetic plastic material formed by the polymerisation of ε-caprolactam. It consists of smooth, cylindrical monofilaments or braided filaments, or lightly twisted sutures sheathed with the same material.

Polyamide-6/6 (Filum polyamidicum-6/6)

Sterile polyamide-6/6 suture is obtained by drawing through a suitable die a synthetic plastic material formed by the polycondensation of hexamethylenediamine and adipic acid. It consists of smooth, cylindrical monofilaments or braided filaments, or lightly twisted sutures sheathed with the same material.

Polypropylene (Filum polypropylenicum)

Polypropylene suture is obtained by drawing polypropylene through a suitable die. It consists of smooth cylindrical mono-filaments.

Monofilament and multifilament stainless steel (Filum aciei irrubiginibilis monofilamentum/multifilamentum)

Sterile stainless steel sutures have a chemical composition as specified in ISO 5832-1 - Metallic Materials for surgical implants - Part 1: Specification for wrought stainless steel and comply with ISO 10334 - Implants for surgery - Malleable wires for use as sutures and other surgical applications.

Stainless steel sutures consist of smooth, cylindrical monofilaments or twisted filaments or braided filaments.

Poly(vinylidene difluoride) (PVDF) (Filum poly(vinylideni difluoridum))

Sterile PVDF suture is obtained by drawing through a suitable die a synthetic plastic material which is formed by polymerisation of 1,1-difluorethylene. It consists of smooth cylindrical monofilaments.

IDENTIFICATION

Non-absorbable sutures may be identified by chemical tests. Materials from natural origin may also be identified by microscopic examination of the morphology of these fibres. For synthetic materials, identification by infrared spectrophotometry (*2.2.24*) or by differential scanning calorimetry may be applied.

Identification of silk

A. Dissect the end of a suture, using a needle or fine tweezers, to isolate a few individual fibres. The fibres are sometimes marked with very fine longitudinal striations parallel to the axis of the suture. Examined under a microscope, a cross-section is more or less triangular to semi-circular, with rounded edges and without a lumen.

B. Impregnate isolated fibres with *iodinated potassium iodide solution R*. The fibres are coloured pale yellow.

Identification of linen

A. Dissect the end of a suture, using a needle or fine tweezers, to isolate a few individual fibres. Examined under a microscope, the fibres are seen to be 12 µm to 31 µm wide and, along the greater part of their length, have thick walls, sometimes marked with fine longitudinal striations, and a narrow lumen. The fibres gradually narrow to a long, fine point. Sometimes there are unilateral swellings with transverse lines.

B. Impregnate isolated fibres with *iodinated zinc chloride solution R*. The fibres are coloured violet-blue.

Identification of poly(ethyleneterephthalate)

It is practically insoluble in most of the usual organic solvents, but is attacked by strong alkaline solutions. It is incompatible with phenols.

A. 50 mg dissolves with difficulty when heated in 50 ml of *dimethylformamide R*.

B. To about 50 mg add 10 ml of *hydrochloric acid R1*. The material remains intact even after immersion for 6 h.

Identification of polyamide-6

It is practically insoluble in the usual organic solvents; it is not attacked by dilute alkaline solutions (for example a 100 g/l solution of *sodium hydroxide R*) but is attacked by dilute mineral acids (for example a 20 g/l solution of *sulphuric acid R*), by hot *glacial acetic acid R* and by a 70 per cent *m/m* solution of *anhydrous formic acid R*.

A. Heat about 50 mg with 0.5 ml of *hydrochloric acid R1* in a sealed glass tube at 110 °C for 18 h and allow to stand for 6 h. No crystals appear.

B. 50 mg dissolves in 20 ml of a 70 per cent *m/m* solution of *anhydrous formic acid R*.

Identification of polyamide-6/6

It is practically insoluble in the usual organic solvents; it is not attacked by dilute alkaline solutions (for example a 100 g/l solution of *sodium hydroxide R*) but is attacked by dilute mineral acids (for example a 20 g/l solution of *sulphuric acid R*), by hot *glacial acetic acid R* and by an 80 per cent *m/m* solution of *anhydrous formic acid R*.

A. In contact with a flame it melts and burns, forming a hard globule of residue and gives off a characteristic odour resembling that of celery.

B. Place about 50 mg in an ignition tube held vertically and heat gently until thick fumes are evolved. When the fumes fill the tube, withdraw it from the flame and insert a strip of *nitrobenzaldehyde paper R*. A violet-brown colour slowly appears on the paper and fades slowly in air; it disappears almost immediately on washing with *dilute sulphuric acid R*.

C. To about 50 mg add 10 ml of *hydrochloride acid R1*. The material disintegrates in the cold and dissolves within a few minutes.

D. 50 mg does not dissolve in 20 ml of a 70 per cent *m/m* solution of *anhydrous formic acid R* but dissolves in 20 ml of an 80 per cent *m/m* solution of *anhydrous formic acid R*.

Identification of polypropylene

Polypropylene is soluble in decahydronaphthalene, 1-chloronaphthalene and trichloroethylene. It is not soluble in alcohol, in ether and in cyclohexanone.

A. It softens at temperatures between 160 °C and 170 °C. It burns with a blue flame giving off an odour of burning paraffin wax and of octyl alcohol.

B. To 0.25 g add 10 ml of *toluene R* and boil under a reflux condenser for about 15 min. Place a few drops of the solution on a disc of *sodium chloride R* slide and evaporate the solvent in an oven at 80 °C. Examine by infrared absorption spectrophotometry (*2.2.24*), comparing with the spectrum obtained with *polypropylene CRS*.

C. To 2 g add 100 ml of *water R* and boil under a reflux condenser for 2 h. Allow to cool. The relative density (*2.2.5*) of the material is 0.89 g/ml to 0.91 g/ml, determined using a hydrostatic balance.

Identification of stainless steel

Stainless steel sutures are identified by confirming that the composition is in accordance with ISO 5832 Part 1.

Identification of poly(vinylidene difluoride)

It is soluble in warm dimethylformamide. It is insoluble in ethanol, hot and cold isopropyl alcohol, ethyl acetate, tetrachlorethylene.

A. The strand melts between 170 °C and 180 °C. It melts in a flame and does not burn after removal of the flame. Place a small piece of suture on an annealed copper wire or sheet. Heat in an oxidising flame. No green colour is produced.

B. Dissolve 0.25 g of the suture in 10 ml of *dimethylformamide R* and boil under a reflux condenser for about 15 min. Place a few drops of the solution on a *sodium chloride R* slide and evaporate the solvent in an oven at 80 °C (1 h). Examine by infrared absorption spectrophotometry (*2.2.24*). The spectrum shows absorption maxima at the following wave-numbers: 838.3 ± 0.5 cm^{-1}, 873.3 ± 1 cm^{-1}, 1070.0 ± 2 cm^{-1}, 1165.0 ± 10 cm^{-1}, 1275 ± 0.5 cm^{-1}, 1399 ± 5 cm^{-1}.

C. To 2 g of suture add 100 ml of *water R* and boil under a reflux condenser for 2 h. Allow to cool. The relative density (*2.2.5*) of the material is 1.71 to 1.78.

PRODUCTION

The appropriate harmonised standards may apply with respect to appropriate validated methods of sterilisation, environmental control during manufacturing, labelling and packaging.

It is essential for the effectiveness and the performance characteristics during use and during the functional lifetime of these sutures that the following physical properties are specified: consistent diameter, sufficient initial strength and firm needle attachment.

The requirements below have been established, taking into account stresses which occur during normal conditions of use. These requirements can be used to demonstrate that individual production batches of these sutures are suitable for wound closure in accordance with usual surgical techniques.

TESTS

Remove the sutures from the sachet and measure promptly and in succession the length, diameter and minimum load.

If linen is tested the sutures are conditioned as follows: if stored in the dry state, expose to an atmosphere with a relative humidity of 65 ± 5 per cent at 20 ± 2 °C for 4 h immediately before measuring the diameter and for the determination of minimum breaking load immerse in *water R* at room temperature for 30 min immediately before carrying out the test.

Length. Measure the length without applying more tension than is necessary to keep them straight. The length of the suture is not less than 95 per cent of the length stated on the label and does not exceed 400 cm.

Diameter. Unless otherwise prescribed, measure the diameter by the following method using 5 sutures. Use a suitable mechanical instrument capable of measuring with an accuracy of at least 0.002 mm and having a circular pressor foot 10-15 mm in diameter. The pressor foot and the moving parts attached to it are weighted so as to apply a total load of 100 ± 10 g to the suture being tested. When making the measurements, lower the pressor foot slowly to avoid crushing the suture. Measure the diameter at intervals of 30 cm over the whole length of the suture. For a suture less than 90 cm in length, measure at 3 points approximately evenly spaced along the suture. During the measurement submit monofilament sutures to a tension not greater than that required to keep them straight. Submit multifilament sutures to a tension not greater than one-fifth of the minimum breaking load shown in column C of Table 0324.-1 appropriate to the gauge number and type of material concerned or 10 N whichever is less. Stainless steel sutures do not require tension to be applied during the measurement of diameter. For multifilament sutures of gauge number above 1.5 make 2 measurements at each point, the second measurement being made after rotating the suture through 90°. The diameter of that point is the average of the 2 measurements. The average of the measurements carried out on the sutures being tested and not less than two-thirds of the measurements taken on each suture are within the limits given in the column under A in Table 0324.-1 for the gauge number concerned. None of the measurements are outside the limits given in the columns under B in Table 0324.-1 for the gauge number concerned.

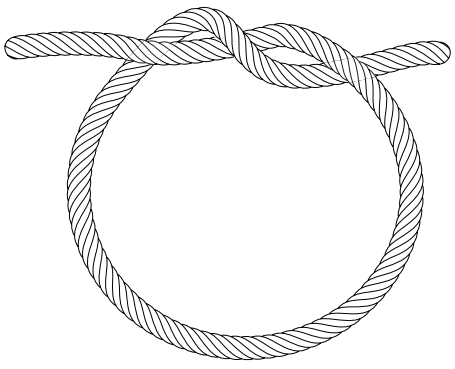

Figure 0324.-1. – *Simple knot*

Minimum breaking load. Unless otherwise prescribed, determine the minimum breaking load by the following method using sutures in the condition in which they are presented. The minimum breaking load is determined over a simple knot formed by placing one end of a suture held in the right hand over the other end held in the left hand, passing one end over the suture and through the loop so formed (see Figure 0324.-1) and pulling the knot tight. For stainless

Table 0324.-1. – *Diameters and minimum breaking loads*

steel sutures gauges 3.5 and above, the minimum breaking load is determined on a straight pull. Carry out the test on 5 sutures. Submit sutures of length greater than 75 cm to 2 measurements and shorter sutures to 1 measurement. Determine the breaking load using a suitable tensilometer. The apparatus has 2 clamps for holding the suture, 1 of which is mobile and is driven at a constant rate of 30 cm/min. The clamps are designed so that the suture being tested can be attached without any possibility of slipping. At the beginning of the test the length of suture between the clamps is 12.5 cm to 20 cm and the knot is midway between the clamps. Set the mobile clamp in motion and note the force required to break the suture. If the suture breaks in a clamp or within 1 cm of it, the result is discarded and the test repeated on another suture. The average of all the results, excluding those legitimately discarded, is equal to or greater than the value given in column C in Table 0324.-1 and no value is less than that given in column D for the gauge number and type of material concerned.

Needle attachment. If the sutures are supplied with an eyeless needle attached that is not stated to be detachable, they comply with the test for needle attachment. Carry out the test on 5 sutures. Use a suitable tensilometer, such as that described for the determination of the minimum breaking load. Fix the needle and suture (without knot) in the clamps of the apparatus in such a way that the swaged part of the needle is completely free of the clamp and in line with the direction of pull on the suture. Set the mobile clamp in motion and note the force required to break the suture or to detach it from the needle. The average of the 5 determinations and all individual values are not less than the respective values given in Table 0324.-2 for the gauge number concerned. If not more than 1 individual value fails to meet the individual requirement, repeat the test on an additional 10 sutures. The attachment complies with the test if none of these 10 values is less than the individual value in Table 0324.-2 for the gauge number concerned.

Table 0324.-2. – *Minimum strengths of needle attachment*

Gauge number	Mean value (newtons)	Individual value (newtons)
0.4	0.50	0.25
0.5	0.80	0.40
0.7	1.7	0.80
1	2.3	1.1
1.5	4.5	2.3
2	6.8	3.4
2.5	9.0	4.5
3	11.0	4.5
3.5	15.0	4.5
4	18.0	6.0
5	18.0	7.0
6	25.0	12.5
7	25.0	12.5
8	50.0	25
9	50.0	25
10	75.0	37.5

Extractable colour. Sutures that are dyed and intended to remain so during use comply with the test for extractable colour. Place 0.25 g of the suture to be examined in a conical flask, add 25.0 ml of *water R* and cover the mouth of the flask with a short-stemmed funnel. Boil for 15 min, cool and adjust to the original volume with *water R*. Depending on the colour of the suture, prepare the appropriate reference solution as described in Table 0324.-3 using the primary colour solutions (*2.2.2*).

The test solution is not more intensely coloured than the appropriate reference solution.

Table 0324.-3. – *Colour reference solutions*

Colour of strand	Composition of reference solution (parts by volume)			
	Red primary solution	Yellow primary solution	Blue primary solution	*Water R*
Yellow-brown	0.2	1.2	-	8.6
Pink-red	1.0	-	-	9.0
Green-blue	-	-	2.0	8.0
Violet	1.6	-	8.4	-

Monomer and oligomers. Polyamide-6 suture additionally complies with the following test for monomer and oligomers. In a continuous-extraction apparatus, treat 1.00 g with 30 ml of *methanol R* at a rate of at least 3 extractions per hour for 7 h. Evaporate the extract to dryness, dry the residue at 110 °C for 10 min, allow to cool in a desiccator and weigh. The residue weighs not more than 20 mg (2 per cent).

STORAGE (PACKAGING)

Sterile non-absorbable sutures are presented in a suitable sachet that maintains sterility and allows the withdrawal and use of a suture in aseptic conditions. They may be stored dry or in a preserving liquid to which an antimicrobial agent but no antibiotic may be added.

Sterile non-absorbable sutures are intended to be used only on the occasion when the sachet is first opened.

Sutures in their individual sachets (primary packaging) are kept in a protective cover (box) which maintains the physical and mechanical properties until the time of use.

The application of appropriate harmonised standards for packaging of medical devices shall be considered in addition.

LABELLING

Reference may be made to the appropriate harmonised standards for the labelling of medical devices.

The details strictly necessary for the user to identify the product properly are indicated on or in each sachet (primary packaging) and on the protective cover (box) and include at least:

- gauge number,
- length, in centimetres or metres,
- if appropriate, that the needle is detachable,
- name of the product,
- intended use (surgical suture, non-absorbable),
- if appropriate, that the suture is coloured,
- if appropriate, the structure (braided, monofilament, sheathed).

01/2008:0667

SUTURES, STERILE SYNTHETIC ABSORBABLE BRAIDED

Fila resorbilia synthetica torta sterilia

DEFINITION

Sterile synthetic absorbable braided sutures consist of sutures prepared from a synthetic polymer, polymers or copolymers which, when introduced into a living organism, are absorbed by that organism and cause no undue tissue irritation. They consist of completely polymerised material. They occur as multifilament sutures consisting of elementary fibres which are assembled by braiding. The sutures may be treated to facilitate handling and they may be coloured.

Appropriate harmonised standards may be considered when assessing compliance with respect to origin and processing of raw materials and with respect to biocompatibility.

Sterile synthetic absorbable braided sutures are wound-closure devices. Being absorbable they serve to approximate tissue during the healing period and subsequently lose tensile strength by hydrolysis.

PRODUCTION

Appropriate harmonised standards may apply with respect to appropriate validated methods of sterilisation, environmental control during manufacturing, labelling and packaging.

It is essential for the effectiveness and the performance characteristics during use and during the functional lifetime of these sutures that the following physical properties are specified: consistent diameter, sufficient initial strength and firm needle attachment.

The requirements below have been established, taking into account stresses which occur during normal conditions of use. These requirements can be used to demonstrate that individual production batches of these sutures are suitable for wound closure according to usual surgical techniques.

TESTS

Carry out the following tests on the sutures in the state in which they are removed from the sachet.

Length. Measure the length of the suture without applying more tension than is necessary to keep it straight. The length of each suture is not less than 95 per cent of the length stated on the label and does not exceed 400 cm.

Diameter. Unless otherwise prescribed, measure the diameter by the following method, using five sutures in the condition in which they are presented. Use a suitable instrument capable of measuring with an accuracy of at least 0.002 mm and having a circular pressor foot 10 mm to 15 mm in diameter. The pressor foot and the moving parts attached to it are weighted so as to apply a total load of 100 ± 10 g to the suture being tested. When making the measurements, lower the pressor foot slowly to avoid crushing the suture. Measure the diameter at intervals of 30 cm over the whole length of the suture. For a suture less than 90 cm in length, measure at three points approximately evenly spaced along the suture. During the measurement, submit the sutures to a tension not greater than one-fifth of the minimum breaking load shown in column C of Table 0667.-1 appropriate to the gauge number and type of material or 10 N whichever is less. For sutures of gauge number above 1.5 make two measurements at each point, the second measurement being made after rotating the suture through 90°. The diameter of that point is the average of the two measurements. The average of the measurements carried out on the

sutures being tested and not less than two-thirds of the measurements taken on each suture are within the limits given in the columns under A in Table 0667.-1 for the gauge number concerned. None of the measurements is outside the limits given in the columns under B in Table 0667.-1 for the gauge number concerned.

Table 0667.-1. – *Diameters and breaking loads*

Gauge number	Diameter (millimetres)				Breaking load (newtons)	
	A		B		C	D
	min.	max.	min.	max.		
0.01	0.001	0.004	0.0008	0.005	-	-
0.05	0.005	0.009	0.003	0.012	-	-

0.3	0.030	0.039	0.025	0.045	0.45	0.23
0.4	0.040	0.049	0.035	0.060	0.70	0.35
0.5	0.050	0.069	0.045	0.085	1.4	0.7
0.7	0.070	0.099	0.060	0.125	2.5	1.3
1	0.100	0.149	0.085	0.175	6.8	3.4
1.5	0.150	0.199	0.125	0.225	9.5	4.8
2	0.200	0.249	0.175	0.275	17.7	8.9
2.5	0.250	0.299	0.225	0.325	21.0	10.5
3	0.300	0.349	0.275	0.375	26.8	13.4
3.5	0.350	0.399	0.325	0.450	39.0	18.5
4	0.400	0.499	0.375	0.550	50.8	25.4
5	0.500	0.599	0.450	0.650	63.5	31.8
6	0.600	0.699	0.550	0.750	-	-
7	0.700	0.799	0.650	0.850	-	-

Minimum breaking load. The minimum breaking load is determined over a simple knot formed by placing one end of a suture held in the right hand over the other end held in the left hand, passing one end over the suture and through the loop so formed (see Figure 0667.-1) and pulling the knot tight.

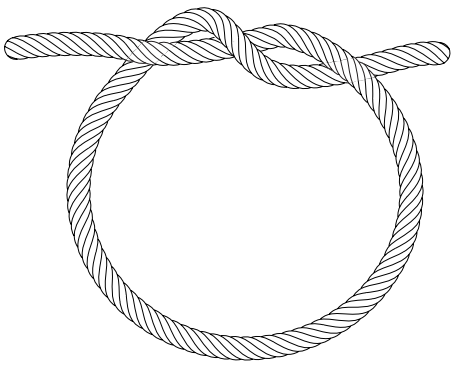

Figure 0667.-1. – *Simple knot*

Carry out the test on five sutures. Submit sutures of length greater than 75 cm to two measurements and shorter sutures to one measurement. Determine the breaking load using a suitable tensilometer. The apparatus has two clamps for holding the suture, one of which is mobile and is driven at a constant rate of 25 cm to 30 cm per minute. The clamps are designed so that the suture being tested can be attached without any possibility of slipping. At the beginning of the test the length of suture between the clamps is 12.5 cm to 20 cm and the knot is midway between the clamps. Set the mobile clamp in motion and note the force required to break the suture. If the suture breaks in a clamp or within 1 cm of it, the result is discarded and the test repeated on another suture. The average of all the results excluding those legitimately discarded is equal to or greater than the value given in column C in Table 0667.-1 and no individual result is less than that given in column D for the gauge number concerned.

Needle attachment. If the suture is supplied with an eyeless needle attached that is not stated to be detachable the attachment, it complies with the test for needle attachment. Carry out the test on five sutures. Use a suitable tensilometer, such as that described for the determination of the minimum breaking load. Fix the needle and suture (without knot) in the clamps of the apparatus in such a way that the swaged part of the needle is completely free of the clamp and in line with the direction of pull on the suture. Set the mobile clamp in motion and note the force required to break the suture or to detach it from the needle. The average of the five deter-minations and all individual values are not less than the respective values given in Table 0667.-2 for the gauge number concerned. If not more than one individual value fails to meet the individual requirement, repeat the test on an additional ten sutures. The attachment complies with the test if none of the ten values is less than the individual value in Table 0667.-2 for the gauge number concerned.

Table 0667.-2. – *Minimum strengths of needle attachment*

Gauge number	Mean value (newtons)	Individual value (newtons)
0.4	0.50	0.25
0.5	0.80	0.40
0.7	1.7	0.80
1	2.3	1.1
1.5	4.5	2.3
2	6.8	3.4
2.5	9.0	4.5
3	11.0	4.5
3.5	15.0	4.5
4	18.0	6.0
5	18.0	7.0

STORAGE (PACKAGING)

Sterile synthetic absorbable braided sutures are presented in a suitable sachet that maintains sterility and allows the withdrawal and use of the sutures in aseptic conditions. The sutures must be stored dry.

They are intended to be used only on the occasion when the sachet is first opened.

Sutures in their individual sachets (primary packaging) are kept in a protective cover (box) which maintains the physical and mechanical properties until the time of use.

The application of appropriate harmonised standards for packaging of medical devices may be considered in addition.

LABELLING

Reference may be made to the appropriate harmonised standards for the labelling of medical devices.

The details strictly necessary for the user to identify the product properly are indicated on or in each sachet (primary packaging) and on the protective cover (box) and include at least:

– gauge number,

– length in centimetres or metres,
– if appropriate, that the needle is detachable,
– name of the product,
– intended use (surgical absorbable suture),
– if appropriate, that the suture is coloured,
– the structure (braided).

01/2008:0666

SUTURES, STERILE SYNTHETIC ABSORBABLE MONOFILAMENT

Fila resorbilia synthetica monofilamenta sterilia

DEFINITION

Sterile synthetic absorbable monofilament sutures consist of sutures prepared from a synthetic polymer, polymers or copolymers which, when introduced into a living organism, are absorbed by that organism and cause no undue tissue irritation. They consist of completely polymerised material. They occur as monofilament sutures. The sutures may be treated to facilitate handling and they may be coloured.

Appropriate harmonised standards may be considered when assessing compliance with respect to origin and processing of raw materials and with respect to biocompatibility.

Sterile synthetic absorbable monofilament sutures are wound- closure devices. Being absorbable they serve to approximate tissue during the healing period and subsequently lose tensile strength by hydrolysis.

PRODUCTION

The appropriate harmonised standards may apply with respect to appropriate validated methods of sterilisation, environmental control during manufacturing, labelling and packaging.

It is essential for the effectiveness and the performance characteristics during use and during the functional lifetime of these sutures that the following physical properties are specified: consistent diameter, sufficient initial strength and firm needle attachment.

The requirements below have been established, taking into account stresses which occur during normal conditions of use. These requirements can be used to demonstrate that individual production batches of these sutures are suitable for wound closure according to usual surgical techniques.

TESTS

Carry out the following tests on the sutures in the state in which they are removed from the sachet.

Length. Measure the length of the suture without applying more tension than is necessary to keep it straight. The length of each suture is not less than 95 per cent of the length stated on the label and does not exceed 400 cm.

Diameter. Unless otherwise prescribed, measure the diameter by the following method, using five sutures in the condition in which they are presented. Use a suitable instrument cap-able of measuring with an accuracy of at least 0.002 mm and having a circular pressor foot 10 mm to 15 mm in diameter. The pressor foot and the moving parts attached to it are weighted so as to apply a total load of 100 ± 10 g to the suture being tested. When making the measurements, lower the pressor foot slowly to avoid crushing the suture. Measure the diameter at intervals of 30 cm over the whole length of the suture. For a suture less than 90 cm in length, measure at three points approximately evenly spaced along the suture. During the measurement, submit the sutures to a tension not greater than that required to keep them straight. The average of the measurements carried out on the sutures being tested and not less than two-thirds of the measurements taken on each suture are within the limits given in the columns under A in Table 0666.-1 for the gauge number concerned. None of the measurements is outside the limits given in the columns under B in Table 0666.-1 for the gauge number concerned.

Table 0666.-1. – *Diameters and breaking loads*

Gauge number	Diameter (millimetres)				Breaking load (newtons)	
	A		B		C	D
	min.	max.	min.	max.		
0.5	0.050	0.094	0.045	0.125	1.4	0.7
0.7	0.095	0.149	0.075	0.175	2.5	1.3
1	0.150	0.199	0.125	0.225	6.8	3.4
1.5	0.200	0.249	0.175	0.275	9.5	4.7
2	0.250	0.339	0.225	0.375	17.5	8.9
3	0.340	0.399	0.325	0.450	26.8	13.4
3.5	0.400	0.499	0.375	0.550	39.0	18.5
4	0.500	0.570	0.450	0.600	50.8	25.4
5	0.571	0.610	0.500	0.700	63.5	31.8

Minimum breaking load. The minimum breaking load is determined over a simple knot formed by placing one end of a suture held in the right hand over the other end held in the left hand, passing one end over the suture and through the loop so formed (see Figure 0666.-1) and pulling the knot tight.

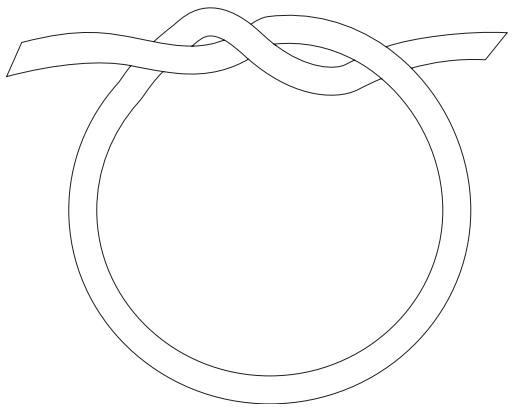

Figure 0666.-1. – *Simple knot*

Carry out the test on five sutures. Submit sutures of length greater than 75 cm to two measurements and shorter sutures to one measurement. Determine the breaking load using a suitable tensilometer. The apparatus has two clamps for holding the suture, one of which is mobile and is driven at a constant rate of 25 cm to 30 cm per minute. The clamps are designed so that the suture being tested can be attached without any possibility of slipping. At the beginning of the test the length of suture between the clamps is 12.5 cm to 20 cm and the knot is midway between the clamps. Set the mobile clamp in motion and note the force required to break the suture. If the suture breaks in a clamp or within 1 cm of it, the result is discarded and the test repeated on another suture. The average of all the results excluding those legitimately discarded is equal to or greater than the value given in column C in Table 0666.-1 and no individual

result is less than that given in column D for the gauge number concerned.

Needle attachment. If the suture is supplied with an eyeless needle attached that is not stated to be detachable, the attachment complies with the test for needle attachment. Carry out the test on five sutures. Use a suitable tensilometer, such as that described for the determination of the minimum breaking load. Fix the needle and suture (without knot) in the clamps of the apparatus in such a way that the swaged part of the needle is completely free of the clamp and in line with the direction of pull on the suture. Set the mobile clamp in motion and note the force required to break the suture or to detach it from the needle. The average of the five determinations and all individual values are not less than the respective values given in Table 0666.-2 for the gauge number concerned. If not more than one individual value fails to meet the individual requirement, repeat the test on an additional ten sutures. The attachment complies with the test if none of the ten values is less than the individual value in Table 0666.-2 for the gauge number concerned.

Table 0666.-2. – *Minimum strengths of needle attachment*

Gauge number	Mean value (newtons)	Individual value (newtons)
0.5	0.80	0.40

CATGUT, STERILE, IN DISTRIBUTOR FOR VETERINARY USE

Chorda resorbilis sterilis in fuso ad usum veterinarium

DEFINITION

Sterile catgut in distributor for veterinary use consists of strands prepared from collagen taken from the intestinal membranes of mammals. After cleaning, the membranes are split longitudinally into strips of varying width, which, when assembled in small numbers, according to the diameter required, are twisted under tension, dried, polished, selected and sterilised. The strands may be treated with chemical substances such as chromium salts to prolong absorption and glycerol to make them supple, provided such substances do not reduce tissue acceptability.

The strand is presented in a distributor that allows the withdrawal and use of all or part of it in aseptic conditions. The design of the distributor is such that with suitable handling the sterility of the content is maintained even when part of the strand has been withdrawn. It may be stored dry or in a preserving liquid to which an antimicrobial preservative but not an antibiotic may be added.

TESTS

If stored in a preserving liquid, remove the strand from the distributor and measure promptly and in succession the length, diameter and breaking load. If stored in the dry state, immerse the strand in alcohol R or a 90 per cent *V/V* solution of *2-propanol R* for 24 h and proceed with the measurements as indicated above.

Length. Measure the length without applying to the strand more tension than is necessary to keep it straight. The length is not less than 95 per cent of the length stated on the label. If the strand consists of several sections joined by knots, the length of each section is not less than 2.5 m.

Diameter. Carry out the test using a suitable instrument capable of measuring with an accuracy of at least 0.002 mm and having a circular pressor foot 10 mm to 15 mm in diameter. The pressor foot and the moving parts attached to it are weighted so as to apply a total load of 100 ± 10 g to the strand being tested. When making the measurements, lower the pressor foot slowly to avoid crushing the strand. Make not fewer than one measurement per 2 m of length. If the strand consists of several sections joined by knots, make not fewer than three measurements per section. In any case make not fewer than twelve measurements. Make the measurements at points evenly spaced along the strand or along each section. The strand is not subjected to more tension than is necessary to keep it straight during measurement. The average of the measurements carried out on the strand being tested and not less than two-thirds of the individual measurements are within the limits given in the column under A in Table 0660.-1 for the gauge number concerned. None of the measurements is outside the limits given in the columns under B in Table 0660.-1 for the gauge number concerned.

Table 0660.-1. – *Diameters and breaking loads*

Gauge number	Diameter (millimetres)				Breaking load (newtons)	
	A		B		C	D
	min.	max.	min.	max.		
1	0.100	0.149	0.085	0.175	1.8	0.4
1.5	0.150	0.199	0.125	0.225	3.8	0.7
2	0.200	0.249	0.175	0.275	7.5	1.8
2.5	0.250	0.299	0.225	0.325	10	3.8
3	0.300	0.349	0.275	0.375	12.5	7.5
3.5	0.350	0.399	0.325	0.450	20	10
4	0.400	0.499	0.375	0.550	27.5	12.5
5	0.500	0.599	0.450	0.650	38.4	20.0
6	0.600	0.699	0.550	0.750	45.0	27.5
7	0.700	0.799	0.650	0.850	60.0	38.0
8	0.800	0.899	0.750	0.950	70.0	45.0

Minimum breaking load. The minimum breaking load is determined over a simple knot formed by placing one end of a strand held in the right hand over the other end held in the left hand, passing one end over the strand and through the loop so formed (see Figure 0660.-1) and pulling the knot tight.

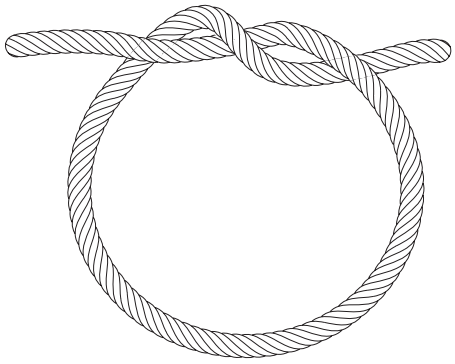

Figure 0660.-1. – *Simple knot*

Make not fewer than one measurement per 2 m of length. If the strand consists of several sections joined by knots, make not fewer than three measurements per section and, in any case, not fewer than one measurement per 2 m of length at points evenly spaced along the strand or along each section. Determine the breaking load using a suitable tensilometer. The apparatus has two clamps for holding the strand, one of which is mobile and is driven at a constant rate of 30 cm per minute. The clamps are designed so that the strand being tested can be attached without any possibility of slipping. At the beginning of the test the length of strand between the clamps is 12.5 cm to 20 cm and the knot is midway between the clamps. Set the mobile clamp in motion and note the force required to break the strand. If the strand breaks in a clamp or within 1 cm of it, the result is discarded and the test repeated on another part of the strand. The average of all the results, excluding those legitimately discarded, is equal to or greater than the value in column C and no value is less than that given in column D in Table 0660.-1 for the gauge number concerned.

Soluble chromium compounds. Place 0.25 g in a conical flask containing 1 ml of *water R* per 10 mg of catgut. Stopper the flask, allow to stand at 37 ± 0.5 °C for 24 h, cool and decant the liquid. Transfer 5 ml to a small test tube and add 2 ml of a 10 g/l solution of *diphenylcarbazide R* in *alcohol R* and 2 ml of *dilute sulphuric acid R*. The solution is not more intensely coloured than a standard prepared at the same time using 5 ml of a solution containing 2.83 µg of *potassium dichromate R* per millilitre, 2 ml of *dilute sulphuric acid R* and 2 ml of a 10 g/l solution of *diphenylcarbazide R* in *alcohol R* (1 ppm of Cr).

Sterility (*2.6.1*). It complies with the test for sterility as applied to catgut and other surgical sutures. Carry out the test on three sections, each 30 cm long, cut off respectively from the beginning, the centre and the end of the strand.

STORAGE

Store protected from light and heat.

LABELLING

The label states:

– the gauge number,

– the length in centimetres or in metres.

01/2008:0608

LINEN THREAD, STERILE, IN DISTRIBUTOR FOR VETERINARY USE

Filum lini sterile in fuso ad usum veterinarium

DEFINITION

Sterile linen thread in distributor for veterinary use consists of the pericyclic fibres of the stem of *Linum usitatissimum* L. The elementary fibres, 2.5 cm to 5 cm long, are assembled in bundles 30 cm to 80 cm long and spun into continuous lengths of suitable diameter. The thread may be creamy-white or may be coloured with colouring matter authorised by the competent authority. The thread is sterilised.

IDENTIFICATION

A. Dissect the end of a thread, using a needle or fine tweezers, to isolate a few individual fibres. Examined under a microscope, the fibres are seen to be 12 µm to 31 µm wide and, along the greater part of their length, have thick walls, sometimes marked with fine longitudinal striations, and a narrow lumen. The fibres gradually narrow to a long, fine point. Sometimes there are unilateral swellings with transverse lines.

B. Impregnate isolated fibres with *iodinated zinc chloride solution R*. The fibres are coloured violet-blue.

TESTS

It complies with the tests prescribed in the monograph on *Strands, sterile non-absorbable, in distributor for veterinary use (0605).*

If stored in a dry state, expose to an atmosphere with a relative humidity of 65 ± 5 per cent at 20 ± 2 °C for 4 h immediately before measuring the diameter and for the determination of minimum breaking load immerse in water R at room temperature for 30 min immediately before carrying out the test.

STORAGE

See the monograph on *Strands, sterile non-absorbable, in distributor for veterinary use (0605).*

LABELLING

See the monograph on *Strands, sterile non-absorbable, in distributor for veterinary use (0605).*

01/2008:0609

POLYAMIDE 6 SUTURE, STERILE, IN DISTRIBUTOR FOR VETERINARY USE

Filum polyamidicum-6 sterile in fuso ad usum veterinarium

DEFINITION

Sterile polyamide 6 suture in distributor for veterinary use is obtained by drawing through a suitable die a synthetic plastic material formed by the polymerisation of ε-caprolactam. It consists of smooth, cylindrical monofilaments or braided filaments, or lightly twisted strands sheathed with the same material. It may be coloured with colouring matter authorised by the competent authority. The suture is sterilised.

CHARACTERS

It is practically insoluble in the usual organic solvents; it is not attacked by dilute alkaline solutions (for example a 100 g/l solution of sodium hydroxide) but is attacked by dilute mineral acids (for example 20 g/l sulphuric acid), by hot glacial acetic acid and by 70 per cent *m/m* formic acid.

IDENTIFICATION

A. Heat about 50 mg with 0.5 ml of *hydrochloric acid R1* in a sealed glass tube at 110 °C for 18 h and allow to stand for 6 h. No crystals appear.

B. To about 50 mg add 10 ml of *hydrochloric acid R1*. The material disintegrates in the cold and dissolves completely within a few minutes.

C. It dissolves in a 70 per cent *m/m* solution of *anhydrous formic acid R*.

TESTS

It complies with the tests prescribed in the monograph on *Strands, sterile non-absorbable, in distributor for veterinary use (0605)* and with the following test:

Monomer and oligomers. In a continuous-extraction apparatus, treat 1.00 g with 30 ml of *methanol R* at a rate of at least three extractions per hour for 7 h. Evaporate the extract to dryness, dry the residue at 110 °C for 10 min, allow to cool in a desiccator and weigh. The residue weighs not more than 20 mg (2 per cent).

STORAGE

See the monograph on *Strands, sterile non-absorbable, in distributor for veterinary use (0605).*

LABELLING

See the monograph on *Strands, sterile non-absorbable, in distributor for veterinary use (0605).*

The label states whether the suture is braided, monofilament or sheathed.

01/2008:0610

POLYAMIDE 6/6 SUTURE, STERILE, IN DISTRIBUTOR FOR VETERINARY USE

Filum polyamidicum-6/6 sterile in fuso ad usum veterinarium

DEFINITION

Sterile polyamide 6/6 suture in distributor for veterinary use is obtained by drawing through a suitable die a synthetic plastic material formed by the polycondensation of hexamethylene-diamine and adipic acid. It consists of smooth, cylindrical monofilaments or braided filaments, or lightly twisted strands sheathed with the same material. It may be coloured with authorised colouring matter or pigments authorised by the competent authority. The suture is sterilised.

CHARACTERS

It is practically insoluble in the usual organic solvents; it is not attacked by dilute alkaline solutions (for example a 100 g/l solution of sodium hydroxide) but is attacked by dilute mineral acids (for example 20 g/l sulphuric acid), by hot glacial acetic acid and by 80 per cent *m/m* formic acid.

IDENTIFICATION

A. In contact with a flame it melts and burns, forming a hard globule of residue and gives off a characteristic odour resembling that of celery.

B. Place about 50 mg in an ignition tube held vertically and heat gently until thick fumes are evolved. When the fumes fill the tube, withdraw it from the flame and insert a strip of *nitrobenzaldehyde paper R*. A violet-brown colour slowly appears on the paper and fades slowly in air; it disappears immediately on washing with *dilute sulphuric acid R*.

C. To about 50 mg add 10 ml of *hydrochloric acid R1*. The material disintegrates in the cold and dissolves within a few minutes.

D. It does not dissolve in a 70 per cent *m/m* solution of *anhydrous formic acid R* but dissolves in an 80 per cent *m/m* solution of *anhydrous formic acid R*.

TESTS

It complies with the tests prescribed in the monograph on *Strands, sterile non-absorbable, in distributor for veterinary use (0605)*.

STORAGE

See the monograph on *Strands, sterile non-absorbable, in distributor for veterinary use (0605)*.

LABELLING

See the monograph on *Strands, sterile non-absorbable, in distributor for veterinary use (0605)*.

The label states whether the suture is braided, monofilament or sheathed.

01/2008:0607

POLY(ETHYLENE TEREPHTHALATE) SUTURE, STERILE, IN DISTRIBUTOR FOR VETERINARY USE

Filum ethyleni polyterephthalici sterile in fuso ad usum veterinarium

DEFINITION

Sterile poly(ethylene terephthalate) suture in distributor for veterinary use is obtained by drawing poly(ethylene terephthalate) through a suitable die. The suture is prepared by braiding very fine filaments in suitable numbers, depending on the gauge required. It may be whitish in colour, or may be coloured with authorised colouring matter or pigments authorised by the competent authority. The suture is sterilised.

CHARACTERS

It is practically insoluble in most of the usual organic solvents, but is attacked by strong alkaline solutions. It is incompatible with phenols.

IDENTIFICATION

A. It dissolves with difficulty when heated in *dimethylformamide R* and in *dichlorobenzene R*.

B. To about 50 mg add 10 ml of *hydrochloric acid R1*. The material remains intact even after immersion for 6 h.

TESTS

It complies with the tests prescribed in the monograph on *Strands, sterile non-absorbable, in distributor for veterinary use (0605)*.

STORAGE

See the monograph on *Strands, sterile non-absorbable, in distributor for veterinary use (0605)*.

LABELLING

SILK SUTURE, STERILE, BRAIDED, IN DISTRIBUTOR FOR VETERINARY USE

Filum bombycis tortum sterile in fuso ad usum veterinarium

DEFINITION

Sterile braided silk suture in distributor for veterinary use is obtained by braiding a variable number of threads, according to the diameter required, of degummed silk obtained from the cocoons of the silkworm *Bombyx mori* L. It may be coloured with colouring matter authorised by the competent authority. The suture is sterilised.

IDENTIFICATION

A. Dissect the end of a strand, using a needle or fine tweezers, to isolate a few individual fibres. The fibres are sometimes marked with very fine longitudinal striations

parallel to the axis of the strand. Examined under a microscope, a cross-section is more or less triangular or semi-circular, with rounded edges and without a lumen.

B. Impregnate isolated fibres with *iodinated potassium iodide solution R*. The fibres are coloured pale yellow.

TESTS

It complies with the tests prescribed in the monograph on *Strands, sterile non-absorbable, in distributor for veterinary use (0605).*

STORAGE

See the monograph on *Strands, sterile non-absorbable, in distributor for veterinary use (0605).*

LABELLING

STRANDS, STERILE NON-ABSORBABLE, IN DISTRIBUTOR FOR VETERINARY USE

Fila non resorbilia sterilia in fuso ad usum veterinarium

DEFINITION

The statements in this monograph are intended to be read in conjunction with the individual monographs on sterile non-absorbable strands in distributor for veterinary use in the Pharmacopoeia. The requirements do not necessarily apply to sterile non-absorbable strands which are not the subject of such monographs.

Sterile non-absorbable strands in distributor for veterinary use are strands which, when introduced into a living organism, are not metabolised by that organism. Sterile non- absorbable strands vary in origin, which may be animal, vegetable or synthetic. They occur as cylindrical monofilaments or as multifilament strands. Multifilament strands consist of elementary fibres which are assembled by twisting, cabling or braiding. Such strands may be sheathed. Sterile non- absorbable strands may be treated to render them non-capillary, and they may be coloured with colouring matter or pigments authorised by the competent authority. The strands are sterilised.

They are presented in a suitable distributor that allows the withdrawal and use of all or part of the strand in aseptic conditions. The design of the distributor is such that with suitable handling the sterility of the content is maintained even when part of the strand has been removed. They may be stored dry or in a preserving liquid to which an antimicrobial preservative but not an antibiotic may be added.

TESTS

Remove the strand from the distributor and measure promptly and in succession the length, diameter and minimum breaking load.

Length. Measure the length in the condition in which the strand is presented and without applying more tension than is necessary to keep it straight. The length of the strand is not less than 95 per cent of the length stated on the label.

Diameter. Unless otherwise prescribed, measure the diameter by the following method using the strand in the condition in which it is presented. Use a suitable instrument capable of measuring with an accuracy of at least 0.002 mm and having a circular pressor foot 10 mm to 15 mm in diameter. The pressor foot and the moving parts attached to it are weighted so as to apply a total load of 100 ± 10 g to the strand being tested. When making the measurements, lower the pressor foot slowly to avoid crushing the strand. Make not fewer than one measurement per 2 m of length and in any case not fewer than 12 measurements at points evenly spaced along the strand. During the measurement submit monofilament strands to a tension not greater than that required to keep them straight. Submit multifilament strands to a tension not greater than one-fifth of the minimum breaking load shown in column C of Table 0605.-1 appropriate to the gauge number and type of material concerned or 10 N whichever is less. For multifilament strands of gauge number above 1.5 make two measurements at each point, the second measurement being made after rotating the strand through 90°. The diameter of that point is the average of the two measurements. The average of the measurements carried out on the strand being tested and not less than two-thirds of the individual measurements are within the limits given in the columns under A in Table 0605.-1 for the gauge number concerned. None of the measurements is outside the limits given in the columns under B in Table 0605.-1 for the gauge number concerned.

Table 0605.-1. – *Diameters and minimum breaking loads*

Gauge number	Diameter (millimetres)				Minimum breaking load (newtons)			
	A		B		Linen thread		All other non-absorbable strands	
	min.	max.	min.	max.	C	D	C	D
0.5	0.050	0.069	0.045	0.085	-	-	1.0	0.35
0.7	0.070	0.099	0.060	0.125	1.0	0.3	1.5	0.60
1	0.100	0.149	0.085	0.175	2.5	0.6	3.0	1.0
1.5	0.150	0.199	0.125	0.225	5.0	1.0	5.0	1.5
2	0.200	0.249	0.175	0.275	8.0	2.5	9.0	3.0
2.5	0.250	0.299	0.225	0.325	9.0	5.0	13.0	5.0
3	0.300	0.349	0.275	0.375	11.0	8.0	15.0	9.0
3.5	0.350	0.399	0.325	0.450	15.0	9.0	22.0	13.0
4	0.400	0.499	0.375	0.550	18.0	11.0	27.0	15.0
5	0.500	0.599	0.450	0.650	26.0	15.0	35.0	22.0
6	0.600	0.699	0.550	0.750	37.0	18.0	50.0	27.0
7	0.700	0.799	0.650	0.850	50.0	26.0	62.0	35.0
8	0.800	0.899	0.750	0.950	65.0	37.0	73.0	50.0

Minimum breaking load. Unless otherwise prescribed, determine the minimum breaking load by the following method using the strand in the condition in which it is presented. The minimum breaking load is determined over a simple knot formed by placing one end of a strand held in the right hand over the other end held in the left hand, passing one end over the strand and through the loop so formed (see Figure 0605.-1) and pulling the knot tight.

Make not fewer than one measurement per 2 m of length at points evenly spaced along the strand. Determine the breaking load using a suitable tensilometer. The apparatus has two clamps for holding the strand, one of which is mobile and is driven at a constant rate of 30 cm per minute. The clamps are designed so that the strand being tested can be attached with-out any possibility of slipping. At the beginning of the test the length of strand between the clamps is 12.5 cm to 20 cm and the knot is midway between the clamps. Set the mobile clamp in motion and note the

force required to break the strand. If the strand breaks in a clamp or within 1 cm of it, the result is discarded and the test repeated on another part of the strand. The average of all the results, excluding those legitimately dis-carded, is equal to or greater than the value in column C and no value is less than that given in column D in Table 0605.-1 for the gauge number and type of material concerned.

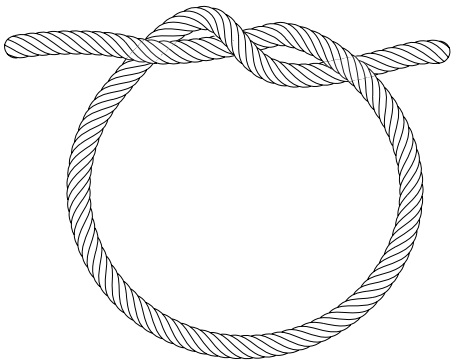

Figure 0605.-1. – *Simple knot*

Sterility (*2.6.1*). They comply with the test for sterility as applied to catgut and other surgical sutures. Carry out the test on three sections each 30 cm long, cut off respectively from the beginning, the centre and the end of the strand.

Extractable colour. Strands that are dyed and intended to remain so during use comply with the test for extractable colour. Place 0.25 g of the strand to be examined in a conical flask, add 25.0 ml of *water R* and cover the mouth of the flask with a short-stemmed funnel. Boil for 15 min, cool and adjust to the original volume with *water R*. Depending on the colour of the strand, prepare the appropriate reference solution as described in Table 0605.-2 using the primary colour solutions (*2.2.2*).

Table 0605.-2. – *Colour reference solutions*

Colour of strand	Composition of reference solution (parts by volume)			
	Red primary solution	Yellow primary solution	Blue primary solution	Water
Yellow - brown	0.2	1.2	–	8.6
Pink - red	1.0	–	–	9.0
Green - blue	–	–	2.0	8.0
Violet	1.6	–	8.4	–

The test solution is not more intensely coloured than the appropriate reference solution.

STORAGE

Store protected from light and heat.

LABELLING

The label states:

- the gauge number,
- the length in centimetres or in metres,
- where appropriate, that the strand is coloured and intended to remain so during use.

INTRODUCTION

All general texts and other monographs of the European Pharmacopoeia that are relevant to homoeopathy are applicable.

The 'Homoeopathy' chapter of the European Pharmacopoeia contains general monographs and individual monographs describing starting materials and preparations used virtually exclusively for homoeopathic medicines. Reference to these monographs for other purposes may be authorised by licensing authorities.

01/2008:2045

HERBAL DRUGS FOR HOMOEOPATHIC PREPARATIONS

Plantae medicinales ad praeparationes homoeopathicas

DEFINITION

Herbal drugs for homoeopathic preparations are mainly whole, fragmented or cut, plants, parts of plants including algae, fungi or lichens in an unprocessed state, usually in fresh form. The state, fresh or dried, in which the drug is used, is defined in the individual monograph of the European Pharmacopoeia or, in the absence, in the individual monograph of a national Pharmacopoeia. In the absence of such a monograph, the state in which the herbal drug is used has to be defined. Certain exudates that have not been subjected to a specific treatment are also considered to be herbal drugs for homoeopathic preparations. Herbal drugs for homoeopathic preparations are precisely defined by the botanical scientific name of the source species according to the binomial system (genus, species, variety and author).

PRODUCTION

Herbal drugs for homoeopathic preparations are obtained from cultivated or wild plants. Suitable cultivation, harvesting, collection, sorting, drying, fragmentation and storage conditions are essential to guarantee the quality of herbal drugs for homoeopathic preparations.

Herbal drugs for homoeopathic preparations are, as far as possible, free from impurities such as soil, dust, dirt and other contaminants such as fungal, insect and other animal contaminants. They do not present signs of decay.

If a decontaminating treatment has been used, it is necessary to demonstrate that the constituents of the plant are not affected and that no harmful residues remain. The use of ethylene oxide is prohibited for the decontamination of herbal drugs for homoeopathic preparations.

Fresh herbal drugs are processed as rapidly as possible after harvesting. Where justified and authorised for transportation or storage purposes, fresh plant material may be deep-frozen; it may also be kept in ethanol (96 per cent *V/V*) or in ethanol of a suitable concentration, provided the whole material including the storage medium is used for processing.

Adequate measures have to be taken in order to ensure that the microbiological quality of homoeopathic preparations containing 1 or more herbal drugs comply with the recommendations given in the text on *Microbiological quality of pharmaceutical preparations* (*5.1.4*).

IDENTIFICATION

Herbal drugs for homoeopathic preparations are identified using their macroscopic and, where necessary, microscopic descriptions and any further tests that may be required (for example, thin-layer chromatography).

TESTS

When a fresh plant is used as a starting material for the manufacture of homoeopathic preparations, the content of foreign matter is as low as possible; if necessary, the maximum content of foreign matter is indicated in the individual monographs. When a dried plant is used as a starting material for the manufacture of homoeopathic preparations, a test for foreign matter (*2.8.2*) is carried out, unless otherwise prescribed in the individual monographs.

A specific appropriate test may apply to herbal drugs for homoeopathic preparations liable to be falsified.

If appropriate, the herbal drugs for homoeopathic preparations comply with other tests, for example, total ash (*2.4.16*) and bitterness value (*2.8.15*).

The test for loss on drying (*2.2.32*) is carried out on dried herbal drugs for homoeopathic preparations. A determination of water (*2.2.13*) is carried out on herbal drugs for homoeopathic preparations with a high essential oil content. The water content of fresh herbal drugs for homoeopathic preparations may be determined by an appropriate method.

Herbal drugs for homoeopathic preparations comply with the requirements for pesticide residues (*2.8.13*). The requirements take into account the nature of the plant, where necessary the preparation in which the plant might be used, and where available the knowledge of the complete record of treatment of the batch of the plant. The content of pesticide residues may be determined by the method described in the annex to the general method.

The risk of contamination of herbal drugs for homoeopathic preparations by heavy metals must be considered. If an individual monograph does not prescribe limits for heavy metals or specific elements, such limits may be required if justified.

Limits for aflatoxins may be required.

In some specific circumstances, the risk of radioactive contamination is to be considered.

ASSAY

Where applicable, herbal drugs for homoeopathic preparations are assayed by an appropriate method.

STORAGE

Store dried herbal drugs protected from light.

01/2008:1038

HOMOEOPATHIC PREPARATIONS

Praeparationes homoeopathicas

DEFINITION

Homoeopathic preparations are prepared from substances, products or preparations called stocks, in accordance with a homoeopathic manufacturing procedure. A homoeopathic preparation is usually designated by the Latin name of the stock, followed by an indication of the degree of dilution.

Raw materials

Raw materials for the production of homoeopathic preparations may be of natural or synthetic origin.

For raw materials of zoological or human origin, adequate measures are taken to minimise the risk of agents of infection, including viruses (*5.1.7*), in the homoeopathic preparations. For this purpose, it is demonstrated that:

- the method of production includes a step or steps that have been shown to remove or inactivate agents of infection;
- where applicable, raw materials of zoological origin comply with the monograph *Products with risk of transmitting agents of animal spongiform encephalopathies (1483)*;
- where applicable, the animals and the tissues used to obtain the raw materials comply with the health requirements of the competent authorities for animals for human consumption;
- for materials of human origin, the donor follows the recommendations applicable to human blood donors and to donated blood (see *Human plasma for fractionation (0853)*), unless otherwise justified and authorised.

A raw material of botanical, zoological or human origin may be used either in the fresh state or in the dried state. Where appropriate, fresh material may be kept deep-frozen. Raw materials of botanical origin comply with the requirements of the monograph *Herbal drugs for homoeopathic preparations (2045)*.

Where justified and authorised for transportation or storage purposes, fresh plant material may be kept in ethanol (96 per cent *V/V*) or in alcohol of a suitable concentration, provided the whole material including the storage medium is used for processing.

Raw materials comply with any requirements of the relevant monographs of the European Pharmacopoeia.

Vehicles

Vehicles are excipients used for the preparation of certain stocks or for the potentisation process. They may include, for example: purified water, alcohol of a suitable concentration, glycerol and lactose.

Vehicles comply with any requirements of the relevant monographs of the European Pharmacopoeia.

Stocks

Stocks are substances, products or preparations used as starting materials for the production of homoeopathic preparations. A stock is usually one of the following: a mother tincture or a glycerol macerate, for raw materials of botanical, zoological or human origin, or the substance itself, for raw materials of chemical or mineral origin.

Mother tinctures comply with the requirements of the monograph *Mother tinctures for homoeopathic preparations (2029)*.

Glycerol macerates are liquid preparations obtained from raw materials of botanical, zoological or human origin by using glycerol or a mixture of glycerol and either alcohol of a suitable concentration or a solution of sodium chloride of a suitable concentration.

Potentisation

Dilutions and triturations are obtained from stocks by a process of potentisation in accordance with a homoeopathic manufacturing procedure: this means successive dilutions and succussions, or successive appropriate triturations, or a combination of the 2 processes.

The potentisation steps are usually one of the following:

- 1 part of the stock plus 9 parts of the vehicle; they may be designated as 'D', 'DH' or 'X' (decimal);
- 1 part of the stock plus 99 parts of the vehicle; they may be designated as 'C' or 'CH' (centesimal).

The number of potentisation steps defines the degree of dilution; for example, 'D3', '3 DH' or '3X' means 3 decimal potentisation steps, and 'C3', '3 CH' or '3C' means 3 centesimal potentisation steps.

'LM-' (or 'Q-') potencies are manufactured according to a specific procedure.

Dosage forms

A dosage form of a homoeopathic preparation complies with any relevant dosage form monograph in the European Pharmacopoeia, and with the following:

- for the purpose of dosage forms for homoeopathic use, 'active substances' are considered to be 'dilutions or triturations of homoeopathic stocks';
- these dosage forms are prepared using appropriate excipients;
- the test for uniformity of content is normally not appropriate; however, in certain circumstances, it is required.

Homoeopathic dosage form 'pillule'

Pillules for homoeopathic use are solid preparations obtained from sucrose, lactose or other suitable excipients. They may be prepared by impregnation of preformed pillules with a dilution or dilutions of homoeopathic stocks or by progressive addition of these excipients and the addition of a dilution or dilutions of homoeopathic stocks. They are intended for oral or sublingual use.

Homoeopathic dosage form 'tablet'

Tablets for homoeopathic use are solid preparations obtained from sucrose, lactose or other suitable excipients according to the monograph *Tablets (0478)*. They may either be prepared by compressing one or more solid active substances with the excipients or by impregnating preformed tablets with a dilution or dilutions of homoeopathic stocks. The preformed tablets for impregnation are obtained from sucrose, lactose or other suitable excipients according to the monograph *Tablets (0478)*. They are intended for oral or sublingual use.

01/2008:2371

METHODS OF PREPARATION OF HOMOEOPATHIC STOCKS AND POTENTISATION

Via praeparandi stirpes homoeopathicas et potentificandi

Homoeopathic stocks are prepared, using suitable methods, from raw materials that comply with the requirements of the monograph *Homoeopathic preparations (1038)*. The methods described below, combined with established methods for potentisation, are examples of methods, but other methods described in an official national pharmacopoeia of a Member State may equally be used.

Where material of animal origin is to be used, particular reference is made to the requirements concerning the use of raw material of zoological or human origin in the monograph *Homoeopathic preparations (1038)*.

In the preparation of liquid dilutions, the ethanol of the concentration prescribed in the method may, if necessary, be replaced by ethanol (30 per cent *m/m*) [ethanol (36 per cent *V/V*)] or ethanol (15 per cent *m/m*) [ethanol (18 per cent *V/V*)].

When the individual monograph allows that the mother tincture be prepared from more than one plant species, the mother tincture can be prepared from the specified parts of an individual plant species or from any mixture thereof.

Unless otherwise stated, mother tinctures are prepared by maceration. Maceration lasts not less than 10 days and not more than 30 days.

Maceration may be replaced by long maceration (maximum 60 days) or very long maceration (maximum 180 days), provided it is demonstrated that the quality of the resulting mother tincture is the same as that of the mother tincture prepared by maceration.

Unless otherwise stated in the individual monograph, the term 'part(s)' denotes 'mass part(s)'. Unless otherwise stated in the method, the maximum temperature for the preparation is 25 °C.

METHOD 1a

Method 1a is used for fresh herbal drugs containing generally more than 70 per cent of expressed juice and no essential oil or resin or mucilage. Mother tinctures prepared according to Method 1a are mixtures of equal parts of expressed juices and ethanol (86 per cent *m/m*) [ethanol (90 per cent *V/V*)].

Express the comminuted herbal drug. Immediately mix the expressed juice with an equal mass of ethanol (86 per cent *m/m*) [ethanol (90 per cent *V/V*)]. Allow to stand in a closed container at a temperature not exceeding 20 °C for not less than 5 days, then filter.

Adjustment to any value specified in the individual monograph

Determine the percentage dry residue (*2.8.16*) or, where prescribed, the percentage assay content of the above-mentioned filtrate. Calculate the amount (A_1), in kilograms, of ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)] required, using the following expression:

$$\frac{m \times (N_x - N_0)}{N_0}$$

m = mass of filtrate, in kilograms;

N_0 = percentage dry residue or percentage assay content as required in the individual monograph;

N_x = percentage dry residue or percentage assay content of the filtrate.

Mix the filtrate with the calculated amount of ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)]. Allow to stand at a temperature not exceeding 20 °C for not less than 5 days, then filter if necessary.

Potentisation

The 1st 'decimal' dilution (D1) is made from:

2 parts of the mother tincture;

8 parts of ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)].

The 2nd decimal dilution (D2) is made from:

1 part of the 1st 'decimal' dilution;

9 parts of ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)].

Subsequent decimal dilutions are produced as stated for D2.

The 1st 'centesimal' dilution (C1) is made from:

2 parts of the mother tincture;

98 parts of ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)].

The 2nd centesimal dilution (C2) is made from:

1 part of the 1st 'centesimal' dilution;

99 parts of ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)].

Subsequent centesimal dilutions are produced as stated for C2.

METHOD 1b

Method 1b is used where the latex of a herbal drug is to be processed.

Mother tinctures prepared according to Method 1b are mixtures of fresh plant latex with ethanol (30 per cent *m/m*) [ethanol (36 per cent *V/V*)]. Mix the fresh latex with 2 parts by mass of ethanol (30 per cent *m/m*) [ethanol (36 per cent *V/V*)] and filter.

Adjustment to any value specified in the individual monograph

Determine the percentage dry residue (*2.8.16*) or, where prescribed, the percentage assay content of the above-mentioned filtrate. Calculate the amount (A_1), in kilograms, of ethanol (30 per cent *m/m*) [ethanol (36 per cent *V/V*)] required, using the following expression:

$$\frac{m \times (N_x - N_0)}{N_0}$$

m = mass of filtrate, in kilograms;

N_0 = percentage dry residue or percentage assay content as required in the individual monograph;

N_x = percentage dry residue or percentage assay content of the filtrate.

Mix the filtrate with the calculated amount of ethanol (30 per cent *m/m*) [ethanol (36 per cent *V/V*)]. Allow to stand at a temperature not exceeding 20 °C for not less than 5 days, then filter if necessary.

Potentisation

The 1st 'decimal' dilution (D1) is made from:

3 parts of the mother tincture;

7 parts of ethanol (30 per cent *m/m*) [ethanol (36 per cent *V/V*)].

The 2nd decimal dilution (D2) is made from:

1 part of the 1st 'decimal' dilution;

9 parts of ethanol (15 per cent *m/m*) [ethanol (18 per cent *V/V*)].

Subsequent decimal dilutions are produced as stated for D2.

METHOD 2a

Method 2a is used for fresh herbal drugs containing generally less than 70 per cent of expressed juice and more than 60 per cent moisture (loss on drying) and no essential oil or resin.

Mother tinctures prepared according to Method 2a (ethanol content approximately 43 per cent *m/m* or 50 per cent *V/V*) are prepared by maceration as described below.

Comminute the herbal drug. Take a sample and determine the loss on drying (*2.2.32*). Unless otherwise prescribed, determine the loss on drying on 2.00-5.00 g of comminuted raw material in a flat-bottomed tared vessel, 45-55 mm in diameter, that has been previously dried as indicated for the raw material. Dry the raw material at 100-105 °C for 2 h then allow to cool in a desiccator.

To the comminuted herbal drug immediately add not less than half the mass of ethanol (86 per cent *m/m*) [ethanol (90 per cent *V/V*)] and store in well-closed containers at a temperature not exceeding 20 °C.

Use the following expression to calculate the amount (A_2), in kilograms, of ethanol (86 per cent *m/m*) [ethanol (90 per cent *V/V*)] required for the mass (*m*) of raw material, then subtract the amount of ethanol (86 per cent *m/m*) [ethanol (90 per cent *V/V*)] already added and add the difference to the mixture.

$$\frac{m \times T}{100}$$

m = mass of raw material, in kilograms;

T = percentage loss on drying of the sample.

Allow to stand at a temperature not exceeding 20 °C for not less than 10 days, swirling from time to time, then express the mixture and filter the resulting liquid.

Adjustment to any value specified in the individual monograph

Determine the percentage dry residue (*2.8.16*) or, where prescribed, the percentage assay content of the above-mentioned filtrate. Calculate the amount (A_1), in kilograms, of ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)] required, using the following expression:

$$\frac{m \times (N_x - N_0)}{N_0}$$

m = mass of filtrate, in kilograms;

N_0 = percentage dry residue or percentage assay content as required in the individual monograph;

N_x = percentage dry residue or percentage assay content of the filtrate.

Mix the filtrate with the calculated amount of ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)]. Allow to stand at a temperature not exceeding 20 °C for not less than 5 days, then filter if necessary.

Potentisation

The 1st 'decimal' dilution (D1) is made from:

2 parts of the mother tincture;

8 parts of ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)].

The 2nd decimal dilution (D2) is made from:

1 part of the 1st 'decimal' dilution;

9 parts of ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)].

Subsequent decimal dilutions are produced as stated for D2.

The 1st 'centesimal' dilution (C1) is made from:

2 parts of the mother tincture;

98 parts of ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)].

The 2nd centesimal dilution (C2) is made from:

1 part of the 1st 'centesimal' dilution;

99 parts of ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)].

Subsequent centesimal dilutions are produced as stated for C2.

METHOD 2b

Method 2b is used for fresh herbal drugs containing generally less than 70 per cent of expressed juice and more than 60 per cent moisture (loss on drying) and no essential oil or resin.

Mother tinctures prepared according to Method 2b (ethanol content approximately 30 per cent *m/m* or 36 per cent *V/V*) are prepared by maceration as described below.

Comminute the herbal drug. Take a sample and determine the loss on drying (*2.2.32*). Unless otherwise prescribed, determine the loss on drying on 2.00-5.00 g of comminuted raw material in a flat-bottomed tared vessel, 45-55 mm in diameter, that has been previously dried as indicated for the raw material. Dry the raw material at 100-105 °C for 2 h then allow to cool in a desiccator.

To the comminuted herbal drug immediately add not less than half the mass of ethanol (62 per cent *m/m*) [ethanol (70 per cent *V/V*)] and store in well-closed containers at a temperature not exceeding 20 °C.

Use the following expression to calculate the amount (A_2), in kilograms, of ethanol (62 per cent *m/m*) [ethanol (70 per cent *V/V*)] required for the mass (*m*) of raw material, then subtract the amount of ethanol (62 per cent *m/m*) [ethanol (70 per cent *V/V*)] already added and add the difference to the mixture.

$$\frac{m \times T}{100}$$

m = mass of raw material, in kilograms;

T = percentage loss on drying of the sample.

Allow to stand at a temperature not exceeding 20 °C for not less than 10 days, swirling from time to time, then express the mixture and filter the resulting liquid.

Adjustment to any value specified in the individual monograph

Determine the percentage dry residue (*2.8.16*) or, where prescribed, the percentage assay content of the above-mentioned filtrate. Calculate the amount (A_1), in kilograms, of ethanol (30 per cent *m/m*) [ethanol (36 per cent *V/V*)] required, using the following expression:

$$\frac{m \times (N_x - N_0)}{N_0}$$

m = mass of filtrate, in kilograms;

N_0 = percentage dry residue or percentage assay content as required in the individual monograph;

N_x = percentage dry residue or percentage assay content of the filtrate.

Mix the filtrate with the calculated amount of ethanol (30 per cent *m/m*) [ethanol (36 per cent *V/V*)]. Allow to stand at a temperature not exceeding 20 °C for not less than 5 days, then filter if necessary.

Potentisation

The 1st 'decimal' dilution (D1) is made from:

2 parts of the mother tincture;

8 parts of ethanol (30 per cent *m/m*) [ethanol (36 per cent *V/V*)].

The 2nd decimal dilution (D2) is made from:

1 part of the 1st 'decimal' dilution;

9 parts of ethanol 15 per cent (*m/m*) [ethanol (18 per cent *V/V*)].

Subsequent decimal dilutions are produced as stated for D2.

METHOD 3a

Method 3a is used for fresh herbal drugs containing essential oil or resin, or generally less than 60 per cent moisture (loss on drying).

Mother tinctures prepared according to Method 3a (ethanol content approximately 60 per cent *m/m* or 68 per cent *V/V*) are prepared by maceration as described below.

Comminute the herbal drug. Take a sample and determine the loss on drying (*2.2.32*). Unless otherwise prescribed, determine the loss on drying on 2.00-5.00 g of comminuted raw material in a flat-bottomed tared vessel, 45-55 mm in diameter, that has been previously dried as indicated for the raw material. Dry the raw material at 100-105 °C for 2 h then allow to cool in a desiccator.

To the comminuted herbal drug immediately add not less than half the mass of ethanol (86 per cent *m/m*) [ethanol (90 per cent *V/V*)] and store in well-closed containers at a temperature not exceeding 20 °C.

Use the following expression to calculate the amount (A_2), in kilograms, of ethanol (86 per cent *m/m*) [ethanol (90 per cent *V/V*)] required for the mass (m) of raw material, then subtract the amount of ethanol (86 per cent *m/m*) [ethanol (90 per cent *V/V*)] already added and add the difference to the mixture.

$$\frac{2 \times m \times T}{100}$$

m = mass of raw material, in kilograms;

T = percentage loss on drying of the sample.

Allow to stand at a temperature not exceeding 20 °C for not less than 10 days, swirling from time to time, then express the mixture and filter the resulting liquid.

Adjustment to any value specified in the individual monograph

Determine the percentage dry residue (*2.8.16*) or, where prescribed, the percentage assay content of the above-mentioned filtrate. Calculate the amount (A_1), in kilograms, of ethanol (62 per cent *m/m*) [ethanol (70 per cent *V/V*)] required, using the following expression:

$$\frac{m \times (N_x - N_0)}{N_0}$$

m = mass of filtrate, in kilograms;

N_0 = percentage dry residue or percentage assay content as required in the individual monograph;

N_x = percentage dry residue or percentage assay content of the filtrate.

Mix the filtrate with the calculated amount of ethanol (62 per cent *m/m*) [ethanol (70 per cent *V/V*)]. Allow to stand at a temperature not exceeding 20 °C for not less than 5 days, then filter if necessary.

Potentisation

The 1st 'decimal' dilution (D1) is made from:

3 parts of the mother tincture;

7 parts of ethanol (62 per cent *m/m*) [ethanol (70 per cent *V/V*)].

The 2nd decimal dilution (D2) is made from:

1 part of the 1st 'decimal' dilution;

9 parts of ethanol (62 per cent *m/m*) [ethanol (70 per cent *V/V*)].

Subsequent dilutions are produced as stated for D2. Use ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)] for dilutions from D4 onwards.

The 1st 'centesimal' dilution (C1) is made from:

3 parts of the mother tincture;

97 parts of ethanol (62 per cent *m/m*) [ethanol (70 per cent *V/V*)].

The 2nd 'centesimal' dilution (C2) is made from:

1 part of the 1st 'centesimal' dilution;

99 parts of ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)].

Subsequent dilutions are produced as stated for C2.

METHOD 3b

Method 3b is used for fresh herbal drugs containing essential oils or resins or generally less than 60 per cent moisture (loss on drying).

Mother tinctures prepared according to Method 3b (ethanol content approximately 43 per cent *m/m* or 50 per cent *V/V*) are prepared by maceration as described below.

Comminute the herbal drug. Take a sample and determine the loss on drying (*2.2.32*). Unless otherwise prescribed, determine the loss on drying on 2.00-5.00 g of comminuted raw material in a flat-bottomed tared vessel, 45-55 mm in diameter, that has been previously dried as indicated for the raw material. Dry the raw material at 100-105 °C for 2 h then allow to cool in a desiccator.

To the comminuted herbal drug immediately add not less than half the mass of ethanol (73 per cent *m/m*) [ethanol (80 per cent *V/V*)] and store in well-closed containers at a temperature not exceeding 20 °C.

Use the following expression to calculate the amount (A_2), in kilograms, of ethanol (73 per cent *m/m*) [ethanol (80 per cent *V/V*)] required for the mass (m) of raw material, then subtract the amount of ethanol (73 per cent *m/m*) [ethanol (80 per cent *V/V*)] already added and add the difference to the mixture.

$$\frac{2 \times m \times T}{100}$$

m = mass of raw material, in kilograms;

T = percentage loss on drying of the sample.

Allow to stand at a temperature not exceeding 20 °C for not less than 10 days, swirling from time to time, then express the mixture and filter the resulting liquid.

Adjustment to any value specified in the individual monograph

Determine the percentage dry residue (*2.8.16*) or, where prescribed, the percentage assay content of the above-mentioned filtrate. Calculate the amount (A_1), in kilograms, of ethanol (43 per cent *m/m*) [ethanol 50 per cent *V/V*)] required, using the following expression:

$$\frac{m \times (N_x - N_0)}{N_0}$$

m = mass of filtrate, in kilograms;

N_0 = percentage dry residue or percentage assay content as required in the individual monograph;

N_x = percentage dry residue or percentage assay content of the filtrate.

Mix the filtrate with the calculated amount of ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)]. Allow to stand at a temperature not exceeding 20 °C for not less than 5 days, then filter if necessary.

Potentisation

The 1st 'decimal' dilution (D1) is made from:

3 parts of the mother tincture;

7 parts of ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)].

The 2nd decimal dilution (D2) is made from:

1 part of the 1st 'decimal' dilution;

9 parts of ethanol (30 per cent *m/m*) [ethanol (36 per cent *V/V*)].

The 3rd decimal dilution (D3) is made from:

1 part of the 2nd decimal dilution;

9 parts of ethanol (15 per cent *m/m*) [ethanol (19 per cent *V/V*)].

Subsequent decimal dilutions are produced as stated for D3.

METHOD 3c

Method 3c is used for fresh herbal drugs containing generally less than 60 per cent moisture (loss on drying).

Mother tinctures prepared according to Method 3c (ethanol content approximately 30 per cent *m/m* or 36 per cent *V/V*) are prepared by maceration as described below.

Comminute the herbal drug. Take a sample and determine the loss on drying (*2.2.32*). Unless otherwise prescribed, determine the loss on drying on 2.00-5.00 g of comminuted raw material in a flat-bottomed tared vessel, 45-55 mm in diameter, that has been previously dried as indicated for the raw material. Dry the raw material at 100-105 °C for 2 h then allow to cool in a desiccator.

To the comminuted herbal drug immediately add not less than half the mass of ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)] and store in well-closed containers at a temperature not exceeding 20 °C.

Use the following expression to calculate the amount (A_2), in kilograms, of ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)] required for the mass (m) of raw material, then subtract the amount of ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)] already added and add the difference to the mixture.

$$\frac{2 \times m \times T}{100}$$

m = mass of raw material, in kilograms;

T = percentage loss on drying of the sample.

Allow to stand at a temperature not exceeding 20 °C for not less than 10 days, swirling from time to time, then express the mixture and filter the resulting liquid.

Adjustment to any value specified in the individual monograph

Determine the percentage dry residue (*2.8.16*) or, where prescribed, the percentage assay content of the above-mentioned filtrate. Calculate the amount (A_1), in kilograms, of ethanol (30 per cent *m/m*) [ethanol (36 per cent *V/V*)] required, using the following expression:

$$\frac{m \times (N_x - N_0)}{N_0}$$

m = mass of filtrate, in kilograms;

N_0 = percentage dry residue or percentage assay content as required in the individual monograph;

N_x = percentage dry residue or percentage assay content of the filtrate.

Mix the filtrate with the calculated amount of ethanol (30 per cent *m/m*) [ethanol (36 per cent *V/V*)]. Allow to stand at a temperature not exceeding 20 °C for not less than 5 days, then filter if necessary.

Potentisation

The 1st 'decimal' dilution (D1) is made from:

3 parts of the mother tincture;

7 parts of ethanol (30 per cent *m/m*) [ethanol (36 per cent *V/V*)].

The 2nd decimal dilution (D2) is made from:

1 part of the 1st 'decimal' dilution;

9 parts of ethanol (15 per cent *m/m*) [ethanol (18 per cent *V/V*)].

Subsequent decimal dilutions are produced as stated for D2.

METHOD 4a

Method 4a is generally used for dried herbal drugs.

Mother tinctures prepared according to Method 4a are prepared by maceration or percolation as described below, using 1 part of dried herbal drug and 10 parts of ethanol of the appropriate concentration (anhydrous, 94 per cent *m/m* - 96 per cent *V/V*, 86 per cent *m/m* - 90 per cent *V/V*, 73 per cent *m/m* - 80 per cent *V/V*, 62 per cent *m/m* - 70 per cent *V/V*, 43 per cent *m/m* - 50 per cent *V/V*, 30 per cent *m/m* - 36 per cent *V/V*, 15 per cent *m/m* - 18 per cent *V/V*), unless otherwise prescribed in the individual monograph.

Production by maceration. Unless otherwise prescribed, comminute the herbal drug, mix thoroughly with ethanol of the appropriate concentration and allow to stand in a closed container for an appropriate time. Separate the residue from the ethanol and, if necessary, press out. In the latter case, combine the 2 liquids obtained.

Production by percolation. If necessary, comminute the herbal drug. Mix thoroughly with a portion of ethanol of the appropriate concentration and allow to stand for an appropriate time. Transfer to a percolator and allow the percolate to flow slowly, at room temperature, making sure that the herbal drug to be extracted is always covered with the remaining ethanol. The residue may be pressed out and the expressed liquid combined with the percolate.

If adjustment to a given concentration is necessary, calculate the amount (A_1), in kilograms, of ethanol of the appropriate concentration required to obtain the concentration specified or used for production, using the following expression:

$$\frac{m \times (N_x - N_0)}{N_0}$$

m = mass of percolate or macerate, in kilograms;

N_0 = percentage dry residue or percentage assay content as required in the individual monograph;

N_x = percentage dry residue or percentage assay content of the percolate or macerate.

Mix the macerate or percolate with the calculated amount of ethanol of the appropriate concentration. Allow to stand at a temperature not exceeding 20 °C for not less than 5 days, then filter if necessary.

Potentisation

The mother tincture corresponds to the 1st decimal solution (Ø = D1).

The 2nd decimal dilution (D2) is made from:

1 part of the mother tincture (D1);

9 parts of ethanol of the same concentration.

The 3rd decimal dilution (D3) is made from:

1 part of the 2nd decimal dilution;

9 parts of ethanol of the same concentration.

Unless a different ethanol concentration is specified, use ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)] for subsequent decimal dilutions from D4 onwards and proceed as stated for D3.

The 1st 'centesimal' dilution (C1) is made from:

10 parts of the mother tincture (D1);

90 parts of ethanol of the same concentration.

The 2nd centesimal dilution (C2) is made from:

1 part of the 1st 'centesimal' dilution;

99 parts of ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)], unless a different ethanol concentration is specified.

Subsequent centesimal dilutions are produced as stated for C2.

METHOD 4b

Method 4b is generally used for animal matter.

Mother tinctures prepared according to Method 4b are prepared by maceration or percolation as described below, using 1 part of animal matter and 10 parts of ethanol of the appropriate concentration (anhydrous, 94 per cent *m/m* - 96 per cent *V/V*, 86 per cent *m/m* - 90 per cent *V/V*, 73 per cent *m/m* - 80 per cent *V/V*, 62 per cent *m/m* - 70 per cent *V/V*, 43 per cent *m/m* - 50 per cent *V/V*, 30 per cent *m/m* - 36 per cent *V/V*, 15 per cent *m/m* - 18 per cent *V/V*), unless otherwise prescribed in the individual monograph.

Production by maceration. Unless otherwise prescribed, comminute the animal matter, mix thoroughly with ethanol of the appropriate concentration and allow to stand in a closed container for an appropriate time. Separate the residue from the ethanol and, if necessary, press out. In the latter case, combine the 2 liquids obtained.

Production by percolation. If necessary, comminute the animal matter. Mix thoroughly with a portion of ethanol of the appropriate concentration and allow to stand for an appropriate time. Transfer to a percolator and allow the percolate to flow slowly at room temperature, making sure that the animal matter to be extracted is always covered with the remaining ethanol. The residue may be pressed out and the expressed liquid combined with the percolate.

If adjustment to a given concentration is necessary, calculate the amount (A_1), in kilograms, of ethanol of the appropriate concentration required to obtain the concentration specified or used for production, using the following expression:

$$\frac{m \times (N_x - N_0)}{N_0}$$

m = mass of percolate or macerate, in kilograms;

N_0 = percentage dry residue or percentage assay content as required in the individual monograph;

N_x = percentage dry residue or percentage assay content of the percolate or macerate.

Mix the macerate or percolate with the calculated amount of ethanol of the appropriate concentration. Allow to stand at a temperature not exceeding 20 °C for not less than 5 days, then filter if necessary.

Potentisation

The mother tincture corresponds to the 1st decimal solution (Ø = D1).

The 2nd decimal dilution (D2) is made from:

1 part of the mother tincture (D1);

9 parts of ethanol of the same concentration.

The 3rd decimal dilution (D3) is made from:

1 part of the 2nd decimal dilution;

9 parts of ethanol of the same concentration.

Unless a different ethanol concentration is specified, use ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)] for subsequent decimal dilutions from D4 onwards and proceed as stated for D3.

The 1st 'centesimal' dilution (C1) is made from:

10 parts of the mother tincture (D1);

90 parts of ethanol of the same concentration.

The 2nd centesimal dilution (C2) is made from:

1 part of the 1st 'centesimal' dilution;

99 parts of ethanol (43 per cent *m/m*) [ethanol (50 per cent *V/V*)], unless a different ethanol concentration is specified.

Subsequent centesimal dilutions are produced as stated for C2.

METHOD 4c

Method 4c is generally used for herbal drugs. The state of the herbal drug, fresh or dried, is specified in the individual monograph.

Mother tinctures prepared according to Method 4c are prepared by maceration.

Comminute appropriately the herbal drug. Take a sample and determine the loss on drying at 100-105 °C for 2 h (*2.2.32*) or the water content (*2.2.13*). Taking this value into account, calculate and add to the herbal drug the quantities of ethanol of the appropriate concentration required to produce, unless otherwise prescribed, a 1 in 10 mother tincture (1:10 mother tincture) with a suitable ethanol content. Allow to macerate for at least 10 days, with sufficient shaking.

Separate the residue from the ethanol and strain at a pressure of about 10^7 Pa. Allow the combined liquids to stand for 48 h and filter. For mother tinctures with a

required assay content, adjustment may be carried out, if necessary, by adding ethanol of the same concentration as used for the preparation of the tincture.

Potentisation

The 1st decimal dilution (D1) is made from:

1 part of the mother tincture;

9 parts of ethanol of the appropriate concentration.

The 2nd decimal dilution (D2) is made from:

1 part of the 1st decimal dilution;

9 parts of ethanol of the appropriate concentration.

Subsequent decimal dilutions are produced as stated for D2, using ethanol of the appropriate concentration.

The 1st centesimal dilution (C1) is made from:

1 part of the mother tincture;

99 parts of ethanol of the appropriate concentration.

The 2nd centesimal dilution (C2) is made from:

1 part of the 1st centesimal dilution;

99 parts of ethanol of the appropriate concentration.

Subsequent centesimal dilutions are produced as stated for C2, using ethanol of the appropriate concentration.

METHOD 4d

Method 4d is generally used for animal matter.

Mother tinctures prepared according to Method 4d are prepared by maceration.

The mass ratio of raw material to mother tincture is usually 1 to 20. To the raw material, appropriately comminuted, add the quantity of ethanol of the appropriate concentration required to produce a 1 in 20 mother tincture. Allow to macerate for at least 10 days, with sufficient shaking. Decant and filter. Allow to stand for 48 h and filter again.

Potentisation

The 1st decimal dilution (D1) is made from:

1 part of the mother tincture;

9 parts of ethanol of the appropriate concentration.

The 2nd decimal dilution (D2) is made from:

1 part of the 1st decimal dilution;

9 parts of ethanol of the appropriate concentration.

Subsequent decimal dilutions are produced as stated for D2, using ethanol of the appropriate concentration.

The 1st centesimal dilution (C1) is made from:

1 part of the mother tincture;

99 parts of ethanol of the appropriate concentration.

The 2nd centesimal dilution (C2) is made from:

1 part of the 1st centesimal dilution;

99 parts of ethanol of the appropriate concentration.

Subsequent centesimal dilutions are produced as stated for C2, using ethanol of the appropriate concentration.

MOTHER TINCTURES FOR HOMOEOPATHIC PREPARATIONS

Tincturae maternae ad praeparationes homoeopathicas

DEFINITION

Mother tinctures for homoeopathic preparations are liquid preparations obtained by the solvent action of a suitable vehicle upon raw materials. The raw materials are usually in the fresh form but may be dried. Mother tinctures for homoeopathic preparations may also be obtained from plant juices, with, or without the addition of a vehicle. For some preparations, the matter to be extracted may undergo a preliminary treatment.

PRODUCTION

Mother tinctures for homoeopathic preparations are prepared by maceration, digestion, infusion, decoction, fermentation or as described in the individual monographs, usually using alcohol of suitable concentration.

Mother tinctures for homoeopathic preparations are obtained using a fixed proportion of raw material to solvent, taking the moisture content of the raw material into account, unless otherwise justified and authorised.

If fresh plants are used, suitable procedures are used to ensure freshness. The competent authorities may require that the freshness is demonstrated by means of a suitable test.

Mother tinctures for homoeopathic preparations are usually clear. A slight sediment may form on standing and that is acceptable as long as the composition of the tincture is not changed significantly.

The manufacturing process is defined so that it is reproducible.

Production by maceration. Unless otherwise prescribed, reduce the matter to be extracted to pieces of suitable size, mix thoroughly and extract according to the prescribed extraction method with the prescribed extraction solvent. Allow to stand in a closed vessel for the prescribed time. The residue is separated from the extraction solvent and, if necessary, pressed out. In the latter case, the 2 liquids obtained are combined.

Adjustment of the contents. Adjustment of the content of constituents may be carried out if necessary, either by adding the extraction solvent of suitable concentration, or by adding another mother tincture for homoeopathic preparations of the vegetable or animal matter used for the preparation.

IDENTIFICATION

Where applicable, at least 1 chromatographic identification test is carried out.

TESTS

The limits in an individual monograph are set to include official methods of production. Specific limits will apply to each defined method of production.

If the test for relative density is carried out, the test for ethanol need not be carried out, and vice versa.

Relative density (*2.2.5*). The mother tincture for homoeopathic preparations complies with the limits prescribed in the monograph.

Ethanol (*2.9.10*). The ethanol content complies with that prescribed in the monograph.

Methanol and 2-propanol (*2.9.11*): maximum 0.05 per cent *V/V* of methanol and maximum 0.05 per cent *V/V* of 2-propanol, unless otherwise prescribed.

Dry residue (*2.8.16*). Where applicable, the mother tincture for homoeopathic preparations complies with the limits prescribed in the monograph.

Pesticides (*2.8.13*). Where applicable, the mother tincture for homoeopathic preparations complies with the test. This requirement is met if the herbal drug has been shown to comply with the test.

ASSAY

Where applicable, an assay with quantitative limits is performed.

STORAGE

Protected from light. A maximum storage temperature may be specified.

LABELLING

The label states:

- that the product is a mother tincture for homoeopathic preparations (designated as "TM" or "Ø"),
- the name of the raw material using the Latin title of the European Pharmacopoeia monograph where one exists,
- the method of preparation,
- the ethanol content or other solvent content, in per cent *V/V*, in the mother tincture,
- the ratio of raw material to mother tincture,
- where applicable, the storage conditions.

ARSENIOUS TRIOXIDE FOR HOMOEOPATHIC PREPARATIONS

Arsenii trioxidum ad praeparationes homoeopathicas

As_2O_3 M_r 197.8
[1327-53-3]

DEFINITION

Content: 99.5 per cent to 100.5 per cent of As_2O_3.

CHARACTERS

Appearance: white or almost white powder.

Solubility: practically insoluble to sparingly soluble in water. It dissolves in solutions of alkali hydroxides and carbonates.

IDENTIFICATION

A. Dissolve 20 mg in 1 ml of *dilute hydrochloric acid R*, add 4 ml of *water R* and 0.1 ml of *sodium sulphide solution R*. The resulting yellow precipitate is soluble in *dilute ammonia R1*.

B. Dissolve 20 mg in 1 ml of *hydrochloric acid R1*, add 5 ml of *hypophosphorous reagent R* and heat for 15 min on a water-bath. A black precipitate develops.

TESTS

Appearance of solution. A 100 g/l solution in *dilute ammonia R1* is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Sulphides. Dissolve 1.0 g in 10.0 ml of *dilute sodium hydroxide solution R*. Add 0.05 ml of *lead acetate solution R*. Any colour in the test solution is not more intense than that in a standard prepared at the same time and in the same manner using a mixture of 10.0 ml of a 0.015 g/l solution of *sodium sulphide R* in *dilute sodium hydroxide solution R* and 0.05 ml of *lead acetate solution R* (20 ppm).

ASSAY

Dissolve 40.0 mg in a mixture of 10 ml of *water R* and 10 ml of *dilute sodium hydroxide solution R*. Add 10 ml of *dilute hydrochloric acid R* and 3 g of *sodium hydrogen carbonate R* and mix. Add 1 ml of *starch solution R* and titrate with *0.05 M iodine*.

1 ml of *0.05 M iodine* is equivalent to 4.946 mg of As_2O_3.

01/2008:2142

BARIUM CHLORIDE DIHYDRATE FOR HOMOEOPATHIC PREPARATIONS

Barii chloridum dihydricum ad praeparationes homoeopathicas

$BaCl_2,2H_2O$ M_r 244.3
[10326-27-9]

DEFINITION

Content: 99.0 per cent to 101.0 per cent of $BaCl_2,2H_2O$.

CHARACTERS

Appearance: white or almost white, crystalline powder or colourless crystals.

Solubility: freely soluble in water, very slightly soluble or practically insoluble in ethanol (96 per cent).

IDENTIFICATION

A. Dissolve 0.1 g in 1 ml of *water R*. Add 0.3 ml of *dilute sulphuric acid R*. A white precipitate is formed; it is insoluble in *dilute hydrochloric acid R* and in *dilute nitric acid R*.

B. It gives reaction (a) of chlorides (*2.3.1*).

TESTS

Solution S. Dissolve 10.0 g in *water R* and dilute to 100 ml with the same solvent.

Appearance of solution. Solution S is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Acidity or alkalinity. To 10 ml of solution S add 0.1 ml of *phenolphthalein solution R*. Not more than 0.2 ml of *0.01 M hydrochloric acid* or *0.01 M sodium hydroxide* is required to change the colour of the indicator.

Heavy metals (*2.4.8*): maximum 10 ppm.

12 ml of solution S complies with limit test A. Prepare the reference solution using *lead standard solution (1 ppm Pb) R*.

ASSAY

Dissolve 0.200 g in 100 ml of *water R*. Add 100 ml of *methanol R*, 10 ml of *concentrated ammonia R* and 2 mg of *phthalein purple R*. Titrate with *0.1 M sodium edetate* until the colour changes from violet to colourless.

1 ml of *0.1 M sodium edetate* is equivalent to 24.43 mg of $BaCl_2,2H_2O$.

01/2008:2143
corrected 6.0

CADMIUM SULPHATE HYDRATE FOR HOMOEOPATHIC PREPARATIONS

Cadmii sulfas hydricus ad praeparationes homoeopathicas

$CdSO_4,8/3H_2O$ M_r 256.5

DEFINITION

Content: 98.0 per cent to 102.0 per cent (anhydrous substance).

CHARACTERS

Appearance: white or almost white, crystalline powder.

Solubility: freely soluble in water, practically insoluble in ethanol (96 per cent).

IDENTIFICATION

A. It gives reaction (a) of sulphates (*2.3.1*).

B. To 2 ml of solution S (see Tests) add 2 ml of *sodium sulphide solution R*. A yellow precipitate is formed.

TESTS

Solution S. Dissolve 5.0 g in *carbon dioxide-free water R* and dilute to 50 ml with the same solvent.

Appearance of solution. Solution S is clear (*2.2.1*) and colourless (*2.2.2, Method II*).

Acidity or alkalinity. To 10 ml of solution S add 0.3 ml of *methyl orange solution R*. Not more than 0.5 ml of *0.01 M hydrochloric acid* or *0.01 M sodium hydroxide* is required to change the colour of the indicator.

Nitrates: maximum 100 ppm.

Dissolve 1.0 g in *water R* and dilute to 20.0 ml with the same solvent. To 1.0 ml of this solution add 0.2 ml of a 10 g/l solution of *sulphanilic acid R* in *acetic acid R* and 0.2 ml of a recently prepared 3 g/l solution of *naphthylamine R* in *acetic acid R*. Add a turning of *zinc R*. A pink colour is produced within 5 min. It is not more intense than that of a mixture of 0.5 ml of *nitrate standard solution (10 ppm NO_3) R* and 0.5 ml of *water R*, prepared at the same time.

Zinc sulphate, alkaline-earth sulphates, rare-earth sulphates. Dissolve 1.0 g in 17 ml of *water R*. Add 0.5 ml of *hydrochloric acid R* and 1 g of *thioacetamide R*. Heat in a water-bath for 10 min. Dilute to 20.0 ml with *water R* and filter. Evaporate 10.0 ml of this solution to dryness in an oven. Ignite the residue at about 800 ± 50 °C to constant mass. The residue weighs a maximum of 2 mg.

Arsenic (*2.4.2, Method A*): maximum 2 ppm, determined on 5 ml of solution S.

Water (*2.5.12*): 16.0 per cent to 20.0 per cent, determined on 80 mg. Shake for 10 min before carrying out the determination.

ASSAY

Dissolve 0.200 g in 50 ml of *water R*. Add 10 ml of *ammonium chloride buffer solution pH 10.0 R* and 50 mg of *mordant black 11 triturate R1*. Titrate with *0.1 M sodium edetate* until the colour changes from red to green.

1 ml of *0.1 M sodium edetate* is equivalent to 20.85 mg of $CdSO_4$.

01/2008:2144

CALCIUM IODIDE TETRAHYDRATE FOR HOMOEOPATHIC PREPARATIONS

Calcii iodidum tetrahydricum ad praeparationes homoeopathicas

$CaI_2,4H_2O$ M_r 366.0
[13640-62-5]

DEFINITION

Content: 97.0 per cent to 102.0 per cent of CaI_2 (anhydrous substance).

CHARACTERS

Appearance: white or almost white powder, very hygroscopic.

Solubility: very soluble to freely soluble in water and in ethanol (96 per cent).

IDENTIFICATION

A. Solution S (see Tests) gives reaction (a) of calcium (*2.3.1*).

B. Solution S (see Tests) gives reaction (b) of iodides (*2.3.1*).

TESTS

Solution S. Dissolve 10.0 g in *distilled water R* and dilute to 100.0 ml with the same solvent.

Appearance of solution. Solution S is clear (*2.2.1*) and not more intensely coloured than reference solution GY_5 (*2.2.2, Method II*).

Free iodine, iodates. To 5 ml of solution S add 2 ml of *methylene chloride R*. Shake and allow to stand. The organic layer is colourless (*2.2.2, Method I*) (free iodine). Add 0.2 ml of *dilute sulphuric acid R*. Shake and allow to stand. The organic layer remains colourless (*2.2.2, Method I*) (iodates).

Sulphates (*2.4.13*): maximum 150 ppm.

Dilute 10 ml of solution S to 15 ml with *distilled water R*.

Iron (*2.4.9*): maximum 10 ppm, determined on 10 ml of solution S.

Heavy metals (*2.4.8*): maximum 10 ppm.

12 ml of solution S complies with limit test A. Prepare the reference solution using *lead standard solution (1 ppm Pb) R*.

Water (*2.5.12*): 18.0 per cent to 22.0 per cent, determined on 0.100 g.

ASSAY

Dissolve 0.300 g in 50 ml of *water R*. Add 5 ml of *dilute nitric acid R* and 25.0 ml of *0.1 M silver nitrate*. Shake. Add 2 ml of *ferric ammonium sulphate solution R2* and titrate with *0.1 M ammonium thiocyanate* until the colour changes to reddish-yellow.

1 ml of *0.1 M silver nitrate* is equivalent to 14.70 mg of CaI_2.

STORAGE

In an airtight container.

01/2008:2030
corrected 6.0

COMMON STINGING NETTLE FOR HOMOEOPATHIC PREPARATIONS

Urtica dioica
ad praeparationes homoeopathicas

DEFINITION

Whole, fresh, flowering plant of *Urtica dioica* L.

CHARACTERS

The plant causes an itching, burning sensation on the skin.

IDENTIFICATION

A. Common stinging nettle is perennial. The taproot sends out creeping subterranean rhizomes, more or less 4-angled in transverse section, from which extend adventious secondary roots and very numerous brownish hairy rootlets. The stipes are erect, generally unbranched, 3-5 mm in diameter and 0.3-1.5 m high, rarely up to 2.5 m high, 4-angled, greyish-green and covered in short hairs and stinging hairs.

The decussate leaves are 30-150 mm long and 20-80 mm wide. The petiole is hispid and usually slightly less than one-third the length of the lamina. The leaf blade is ovate, acuminate, cordate or rounded at the base, and coarsely dentate; the apical tooth is distinctly larger than the lateral teeth. The upper side of the leaves is dark green and usually matt, both sides bear short serried hairs intermingled with long stinging hairs. The 2 stipules are linear-subulate and free. The inflorescences growing from the leaf axils are complex, the flowers unisexual, and, particularly in male plants, generally distinctly longer than the petiole. After shedding their pollen, male inflorescences are erect at an oblique angle or horizontal; female inflorescences are pendent when the fruit is ripe. All flowers have long stalks. The perianth of the male flowers is divided half-way down into equal green lobes, widest at their base, with short bristles and stinging hairs at the margins. The stamens are equal and opposite to the perianth segments, each with a long, whitish filament that curves inwards before pollen is shed and spreads out afterwards. The ovary is rudimentary, button or cup-shaped. The perianth of the female flowers is downy or bristly on the outside and consists of outer, and 2 inner segments; the inner segments are about twice the length of the outer ones. The hypogynous, ovate, unilocular ovary bears a large capitate stigma with a brush-like shock of hair. As the one-seeded fruit grows ripe, the 2 inner segments of the perianth fold around it like wings.

B. It complies with the test for *Urtica urens* (see Tests).

TESTS

Urtica urens. The margin of the lamina is not serrate with teeth twice as long as wide. The clusters of flowers in the axils are longer than the petiole of the leaf. Unisexual, apetalous flowers are not together on the same plant and in the same cluster.

Foreign matter (*2.8.2*): maximum 5 per cent.

Loss on drying (*2.2.32*): minimum 65.0 per cent, determined on 5.0 g of finely cut drug by drying in an oven at 105 °C for 2 h, if performed to demonstrate the freshness of the drug.

Mother tincture

The mother tincture complies with the requirements of the general monograph on *Mother tinctures for homoeopathic preparations (2029)*.

PRODUCTION

The mother tincture of *Urtica dioica* L. is prepared by maceration using alcohol of a suitable concentration.

CHARACTERS

Appearance: greenish-brown or orange-brown liquid.

IDENTIFICATION

Thin-layer chromatography (*2.2.27*).

Test solution. The mother tincture to be examined.

Reference solution. Dissolve 10 mg of *phenylalanine R* and 10 mg of *serine R* in a mixture of equal volumes of *methanol R* and *water R* and dilute to 10 ml with the same mixture of solvents.

Plate: *TLC silica gel plate R*.

Mobile phase: *glacial acetic acid R, water R, acetone R, butanol R* (10:20:35:35 *V/V/V/V*).

Application: 20 µl, as bands.

Development: over a path of 10 cm.

Drying: in air.

Detection: spray with a 1 g/l solution of *ninhydrin R* in *alcohol R*. Heat the plate at 105-110 °C for 5-10 min then examine in daylight within 10 min.

Results: see below the sequence of the zones present in the chromatograms obtained with the reference solution and the test solution.

COPPER ACETATE MONOHYDRATE FOR HOMOEOPATHIC PREPARATIONS

Cupri acetas monohydricus
ad praeparationes homoeopathicas

$Cu(C_2H_3O_2)_2,H_2O$ M_r 199.7
[6046-93-1]

DEFINITION

Content: 99.0 per cent to 101.0 per cent of $Cu(C_2H_3O_2)_2,H_2O$.

Homoeopathic preparations

CHARACTERS

Appearance: greenish-blue crystals or green powder.

Solubility: soluble in water, slightly soluble or very slightly soluble in ethanol (96 per cent).

IDENTIFICATION

A. It gives reaction (a) of acetates (*2.3.1*).

B. Dissolve 0.1 g in 10 ml of *water R* and add *dilute ammonia R1* dropwise. A dark blue colour is produced.

TESTS

Solution S. Dissolve 3.0 g in a mixture of 40 ml of *distilled water R* and 0.6 ml of *glacial acetic acid R*, with heating at 70 °C. Cool and dilute to 45 ml with *distilled water R*.

Appearance of solution. Solution S is clear (*2.2.1*).

Impurities not precipitating with hydrogen sulphide: maximum 0.1 per cent, calculated as sulphates.

To 2.000 g add 92 ml of *water R* and 8.0 ml of *dilute sulphuric acid R*. Heat to 70 °C. Pass a current of *hydrogen sulphide R* until there is no longer precipitation of copper sulphide. Allow to cool and stand, then filter. Evaporate to dryness 50.0 ml of the filtrate in a crucible. Ignite the residue at about 600 ± 50 °C to constant mass.

Chlorides (*2.4.4*): maximum 50 ppm, determined on 15 ml of solution S.

Sulphates (*2.4.13*): maximum 150 ppm, determined on 15 ml of solution S.

Iron (*2.4.9*): maximum 20 ppm.

Dissolve 0.500 g in 10 ml of *water R*. Transfer to a separating funnel. Add 20 ml of *hydrochloric acid R1* and 10 ml of *methyl isobutyl ketone R*. Shake vigorously for 3 min. Allow to stand. Transfer the organic layer to a second separating funnel and add 10 ml of *water R*. Shake vigorously for 3 min. Allow to stand. The aqueous layer complies with the limit test for iron.

Nickel: maximum 10 ppm.

To the residue obtained in the test for impurities not precipitating with hydrogen sulphide, add 2.0 ml of *hydrochloric acid R* and 1.0 ml of *sulphuric acid R*. Evaporate to dryness. Dissolve the residue in a mixture of 3.0 ml of *dilute sulphuric acid R* and 17.0 ml of *water R*. To 4.0 ml of this solution add 4.0 ml of *water R*, 5.0 ml of *bromine water R*, 7.0 ml of *dilute ammonia R1* and 3.0 ml of a 10 g/l solution of *dimethylglyoxime R* in *ethanol (90 per cent V/V) R*. This solution is not more intensely coloured within 1 min than a solution prepared as follows: mix 4.0 ml of a 1 ppm solution of nickel (Ni) prepared from *nickel standard solution (10 ppm Ni) R*, 4.0 ml of *water R* and 5.0 ml of *bromine water R*; carefully add 7.0 ml of *dilute ammonia R1* and 3.0 ml of a 10 g/l solution of *dimethylglyoxime R* in *ethanol (90 per cent V/V) R*.

ASSAY

Dissolve 0.400 g in *water R* and dilute to 50 ml with the same solvent. Add 6.0 ml of *glacial acetic acid R*, 10.0 g of *potassium iodide R* and 1 ml of *starch solution R*. Titrate with *0.1 M sodium thiosulphate*.

1 ml of *0.1 M sodium thiosulphate* is equivalent to 19.97 mg of $Cu(C_2H_3O_2)_2,H_2O$.

01/2008:1610
corrected 6.0

COPPER FOR HOMOEOPATHIC PREPARATIONS

Cuprum ad praeparationes homoeopathicas

Cu A_r 63.5
[7440-50-8]

DEFINITION

Content: 99.0 per cent to 101.0 per cent of Cu.

CHARACTERS

Appearance: reddish-brown powder.

Solubility: practically insoluble in water, soluble in hydrochloric acid and in nitric acid, practically insoluble in alcohol.

IDENTIFICATION

A. To 2 ml of solution S (see Tests) add 0.5 ml of *potassium ferrocyanide solution R*. A reddish-brown precipitate is formed.

B. To 5 ml of solution S add 0.6 ml of *ammonia R*. A blue precipitate is formed. Add 2 ml of *ammonia R*. The precipitate disappears; the solution has an intense blue colour.

TESTS

Solution S. Dissolve 2.0 g in 10 ml of *nitric acid R*. After nitrous fumes are no longer evolved, dilute to 60 ml with *distilled water R*.

Acidity or alkalinity. To 5.0 g add 20 ml of *carbon dioxide-free water R*. Boil for 1 min. Cool. Filter and dilute to 25.0 ml with *carbon dioxide free water R*. To 10 ml of the solution add 0.1 ml of *bromothymol blue solution R1*. Not more than 0.5 ml of *0.01 M hydrochloric acid* or *0.01 M sodium hydroxide* is required to change the colour of the indicator.

Chlorides (*2.4.4*): maximum 100 ppm.

15 ml of solution S complies with the limit test for chlorides.

Sulphates (*2.4.13*): maximum 300 ppm.

15 ml of solution S complies with the limit test for sulphates.

Iron: maximum 50.0 ppm.

Atomic absorption spectrometry (*2.2.23, Method I*).

Test solution. Dissolve 1.00 g in 5 ml of *nitric acid R* and dilute to 50.0 ml with *water R*.

Reference solutions. Prepare the reference solutions using *iron standard solution (20 ppm Fe) R*, diluted as necessary with a 1 per cent *V/V* solution of *nitric acid R*.

Source: iron hollow-cathode lamp.

Wavelength: 248.3 nm.

Flame: air-acetylene.

Lead: maximum 1.00×10^2 ppm.

Atomic absorption spectrometry (*2.2.23, Method I*).

Test solution. Use the test solution prepared for the test for iron.

Reference solutions. Prepare the reference solutions using *lead standard solution (0.1 per cent Pb) R*, diluted as necessary with a 1 per cent *V/V* solution of *nitric acid R*.

Source: lead hollow-cathode lamp.

Wavelength: 283.3 nm.

Flame: air-acetylene.

Zinc: maximum 50.0 ppm.

Atomic absorption spectrometry (*2.2.23, Method I*).

Test solution. Use the test solution prepared for the test for iron.

Reference solutions. Prepare the reference solutions using *zinc standard solution (100 ppm Zn) R*, diluted as necessary with a 1 per cent *V/V* solution of *nitric acid R*.

Source: zinc hollow-cathode lamp.

Wavelength: 213.9 nm.

Flame: air-acetylene.

ASSAY

Dissolve 0.100 g in 5 ml of *nitric acid R*. Heat to expel the nitrous fumes. Add 200 ml of *water R* and neutralise (*2.2.3*) with *dilute ammonia R1*. Add 1 g of *ammonium chloride R* and 3 mg of *murexide R*. Titrate with *0.1 M sodium edetate* until the colour changes from green to violet.

1 ml of *0.1 M sodium edetate* is equivalent to 6.354 mg of Cu.

01/2008:2023

GARLIC FOR HOMOEOPATHIC PREPARATIONS

Allium sativum ad praeparationes homoeopathicas

DEFINITION

Fresh bulb of *Allium sativum* L.

CHARACTERS

It has a characteristic odour after cutting.

IDENTIFICATION

The bulb is generally 3 cm to 5 cm broad and almost spherical; the flat base bears the remnants of numerous short greyish-brown adventitious roots. The bulb consists of about 10 daughter bulbs (cloves) arranged roughly in a circle around a central axis. Individual daughter bulbs are 1 cm to 3 cm long, laterally compressed and convex on the dorsal side. Each daughter bulb has a tough, white or reddish skin around a fleshy tubular leaf, investing a more or less rounded elongated cone of leaf primordia and vegetative apex.

TESTS

Water (*2.2.13*): minimum 55.0 per cent, determined on 10.0 g of the finely cut drug, if performed to demonstrate the freshness of the drug.

Mother tincture

The mother tincture complies with the requirements of the general monograph on *Mother tinctures for homoeopathic preparations (2029)*.

PRODUCTION

The mother tincture of *Allium sativum* L. is prepared by maceration of the cut drug using alcohol of a suitable concentration.

CHARACTERS

Appearance: brownish-yellow liquid.

It has a peculiar and unpleasant aromatic odour.

IDENTIFICATION

A. To 2 ml of the mother tincture to be examined, add 0.2 ml of *dilute sodium hydroxide solution R*. A yellowish-white precipitate develops.

B. Thin-layer chromatography (*2.2.27*).

Test solution. Extract 5 ml of the mother tincture to be examined with 2 quantities, each of 10 ml, of *ether R*. Combine the ether layers and dry over *anhydrous sodium sulphate R*. Filter and evaporate the filtrate in a water-bath at low temperature. Dissolve the residue in 0.4 ml of *methanol R*.

Reference solution. Dissolve 10 mg of *resorcinol R*, 10 mg of *thymol R* and 30 mg of *gallic acid R* in 10 ml of *methanol R*.

Plate: *TLC silica gel F_{254} plate R*.

Mobile phase: *anhydrous formic acid R, toluene R, di-isopropyl ether R* (10:40:50 *V/V/V*).

Application: 40 µl of the test solution and 10 µl of the reference solution.

Development: over a path of 10 cm.

Drying: in air.

Detection: examine in ultraviolet light at 254 nm and identify gallic acid; spray with *anisaldehyde solution R*, heat to 105-110 °C for 5-10 min. Examine in daylight within 10 min.

Results: see below the sequence of the zones present in the chromatograms obtained with the reference solution and the test solution. Other zones may also be visible in the chromatogram obtained with the test solution.

corrected 6.0

HEDERA HELIX FOR HOMOEOPATHIC PREPARATIONS

Hedera helix
ad praeparationes homoeopathicas

DEFINITION

Fresh, young, fully developed but not yet lignified branch of *Hedera helix* L., harvested immediately before or at the beginning of flowering.

IDENTIFICATION

The fresh, young branches of *Hedera helix* L. are thin and flexible, climbing; they cling to their support by stem-roots. The leaves are alternate, simple and petiolate. The petiole shows a cylindrical section. The upper surface of the leaves is glabrous and shiny, darker than the lower surface. The lamina is usually divided into 3 to 5 more or less deeply cut lobes on sterile branches; it is oval, with a pointed apex on fertile branches. The inflorescences are arranged in a simple semi-globular corymb and grouped in terminal clusters. The pedicels of the umbel are covered in whitish hairs. Each flower shows 5 small teeth formed by the upper part of the sepals and 5 petals covered in very small inverted hairs.

TESTS

Foreign matter (*2.8.2*): if required by the competent authority, maximum 5 per cent.

Loss on drying (*2.2.32*): if required by the competent authority, minimum 50 per cent, determined on 5.0 g of the finely cut drug by drying in an oven at 105 °C for 2 h.

Mother tincture

The mother tincture complies with the requirements of the general monograph on *Mother tinctures for homoeopathic preparations (2029)*.

PRODUCTION

The mother tincture of *Hedera helix* L. is prepared by maceration using ethanol of a suitable concentration.

Content: minimum 0.15 per cent *m/m* of hederacoside C ($C_{59}H_{96}O_{26}$; M_r 1221).

CHARACTERS

Appearance: dark greenish-brown liquid.

IDENTIFICATION

Thin-layer chromatography (*2.2.27*).

Test solution. The mother tincture to be examined.

Reference solution. Dissolve 1 mg of *α-hederin R* and 1 mg of *hederacoside C R* in *methanol R* and dilute to 2 ml with the same solvent.

Plate: *TLC silica gel plate R*.

Mobile phase: *glacial acetic acid R, water R, butanol R* (1:1:4 *V/V/V*).

Application: 20 µl, as bands.

Development: over half of the plate.

Drying: in air.

Detection: spray with a 10 per cent *V/V* solution of *sulphuric acid R* in *methanol R* and heat at 100-105 °C for 10 min. Examine in daylight.

Results: see below the sequence of the zones present in the chromatograms obtained with the reference solution and the test solution. Other faint zones may also be present in the chromatogram obtained with the test solution.

Top of the plate	
———	———
α-Hederin: a violet zone	A violet zone (α-hederin)
Hederacoside C: a brown zone	A brown zone (hederacoside C)
———	A greyish-brown zone ———
	A yellow zone
Reference solution	**Test solution**

TESTS

Relative density (*2.2.5*): 0.890 to 0.925.

Ethanol (*2.9.10*): 60 per cent *V/V* to 70 per cent *V/V*.

Dry residue (*2.8.16*): minimum 2.0 per cent.

ASSAY

Liquid chromatography (*2.2.29*).

Test solution. In a 20.0 ml volumetric flask, dilute 3.000 g of the mother tincture to be examined to 20.0 ml with the mobile phase.

Reference solution. In a 50.0 ml volumetric flask, dissolve 20.0 mg of *hederacoside C R* in the mobile phase and dilute to 50.0 ml with the mobile phase.

Column:

– *size*: *l* = 0.25 m, Ø = 4 mm,
– *stationary phase*: *octadecylsilyl silica gel for chromatography R* (5 µm).

Mobile phase: mix 35 volumes of *water R* adjusted to pH 3 with *phosphoric acid R* and 65 volumes of *methanol R*.

Flow rate: 1 ml/min.

Detection: spectrophotometer at 205 nm.

Injection: 20 µl.

Retention time: hederacoside C = about 8 min.

Calculate the percentage content *m/m* of hederacoside C from the following expression:

$$\frac{A_1 \times m_2 \times C \times 40}{A_2 \times m_1}$$

A_1 = area of the peak due to hederacoside C in the chromatogram obtained with the test solution,

A_2 = area of the peak due to hederacoside C in the chromatogram obtained with the reference solution,

m_1 = mass of the mother tincture in the test solution, in grams,

m_2 = mass of *hederacoside C R* in the reference solution, in grams,

C = percentage content of *hederacoside C R*.

Homoeopathic preparations

01/2008:2024

HONEY BEE FOR HOMOEOPATHIC PREPARATIONS

Apis mellifera
ad praeparationes homoeopathicas

DEFINITION

Live worker honey bee (*Apis mellifera* L.).

CHARACTERS

Characters described under Identification.

PRODUCTION

If the bee has been exposed to treatment to prevent or cure diseases, appropriate steps are taken to ensure that the levels of residues are as low as possible.

IDENTIFICATION

The body of a honey bee is about 15 mm long, black, with a silky sheen, and covered with red hairs with a touch of grey. The broad tibiae are without spines. The posterior margins of the segments and legs are brown, with gradual transition to orange-red. The claws are two-membered, the maxillary palps single-membered. On the hind legs are baskets or scoops invested with bristles. The wings have 3 complete cubital cells, with the radial cell twice as long as it is wide; the 3 cells on the lower margin and the 3 middle cells are closed. A duct connects the barbed sting with the poison sac.

Mother tincture

The mother tincture complies with the requirements of the general monograph on *Mother tinctures for homoeopathic preparations (2029)*.

PRODUCTION

The mother tincture of *Apis mellifera* L. is prepared by maceration using alcohol of a suitable concentration.

CHARACTERS

Pale yellow liquid that may darken on storage.

IDENTIFICATION

Thin-layer chromatography (*2.2.27*).

Test solution. The mother tincture to be examined.

Reference solution. Dissolve 12 mg of *4-aminobutanoic acid R*, 12 mg of *leucine R* and 12 mg of *proline R* in 5 ml of *water R* and dilute to 50 ml with *alcohol R*.

Plate: *TLC silica gel plate R*.

Mobile phase: *water R, ethanol R* (17:63 *V/V*).

Application: 20 µl, as bands.

Development: over a path of 10 cm.

Drying: in air.

Detection: spray with *ninhydrin solution R* and heat at 100-105 °C for 10 min; examine in daylight.

Results: see below the sequence of the zones present in the chromatograms obtained with the reference and test solutions. Other zones may also be visible.

HYOSCYAMUS FOR HOMOEOPATHIC PREPARATIONS

Hyoscyamus niger
ad praeparationes homoeopathicas

DEFINITION

Whole, fresh flowering plant of *Hyoscyamus niger* L.

IDENTIFICATION

Hyoscyamus is an annual or biennial plant, with a well developed taproot. The robust, erect stem is hollow and subcylindrical and up to 80 cm long. The soft, viscid, dull dark-green leaves are densely pubescent on both surfaces, especially on the veins. The lower leaves are petiolate and are arranged in a rosette; the lower cauline leaves are semi-amplexicaul and the upper ones are completely amplexicaul. The lamina, up to 25 cm long, is oblong to ovate with 2 to 5 broadly dentate lobes on each side. The midrib is well developed. The secondary veins arise at a wide angle from the midrib and terminate in the apices of the lobes. The flowering tops are densely pubescent and form a short drooping cluster. Each flower arises in the axils of a large bract. The gamosepalous calyx is covered with dense cotton-like hairs and has 5 triangular-ovate lobes, each ending in a short point that becomes spiny. The gamopetalous corolla, with 5 nearly equal lobes, is yellowish and with a delicate, brown to blackish-violet venation. The fruit, sometimes present at the base of the inflorescences, is a pyxis distinctly swollen at the base.

TESTS

Foreign matter (*2.8.2*): if required by the competent authority, maximum 5 per cent.

Loss on drying (*2.2.32*): if required by the competent authority, minimum 50 per cent, determined on 5.0 g of the finely cut drug by drying in an oven at 105 °C for 2 h.

***Hyoscyamus albus* L.** The presence of middle and upper leaves with a petiole and of fruits barely swollen at the base indicates adulteration by *Hyoscyamus albus* L.

Mother tincture

The mother tincture complies with the requirements of the general monograph on *Mother tinctures for homoeopathic preparations (2029)*.

PRODUCTION

The mother tincture of *Hyoscyamus niger* L. is prepared by maceration of the drug, using ethanol of a suitable concentration.

Content: 0.002 per cent *m/m* to 0.01 per cent *m/m* of total alkaloids, expressed as hyoscyamine ($C_{17}H_{23}NO_3$; M_r 289.4).

CHARACTERS

Appearance: dark greenish-brown liquid.

IDENTIFICATION

Thin-layer chromatography (*2.2.27*).

Test solution. Evaporate 10 ml of the mother tincture to be examined in a water-bath at 40 °C, under reduced pressure. Take up the residue with 1 ml of *ammonia R*, and shake with 2 quantities, each of 10 ml, of *ether R*. Combine the ether layers, dry over *anhydrous sodium sulphate R* and filter. Evaporate on a water-bath and dissolve the residue in 0.50 ml of *methanol R*.

Reference solution (a). Dissolve 50 mg of *hyoscyamine sulphate R* in 10 ml of *methanol R* (solution A). Dissolve 15 mg of *hyoscine hydrobromide R* in 10 ml of *methanol R* (solution B). Mix 4 ml of solution A and 2 ml of solution B and dilute to 10 ml with *methanol R*.

Reference solution (b). Dissolve 20 mg of *atropine sulphate R* in *methanol R* and dilute to 10 ml with the same solvent.

Plate: *TLC silica gel plate R*.

Mobile phase: *concentrated ammonia R, water R, acetone R* (3:7:90 *V/V/V*).

Application: 20 µl, as bands.

Development: over a path of 10 cm.

Drying: at 100-105 °C for 15 min.

Detection A: spray with *dilute potassium iodobismuthate solution R* until orange zones become visible. Examine in daylight.

Results A: see below the sequence of the zones present in the chromatograms obtained with the reference solutions and the test solution. Other faint zones may be present in the chromatogram obtained with the test solution.

Top of the plate		
Hyoscine: an orange zone		An orange zone (hyoscine)
Hyoscyamine: an orange zone	Atropine: an orange zone	A orange zone (hyoscyamine/atropine)
		Faint orange zones (starting line)
Reference solution (a)	**Reference solution (b)**	**Test solution**

Detection B: subsequently spray with *sodium nitrite solution R* until the yellow background disappears. Examine in daylight after 15 min.

Results B: see test for atropine.

TESTS

Relative density (*2.2.5*): 0.930 to 0.960.

Atropine. Examine the chromatograms obtained in the test for identification.

Results: the zone due to hyoscyamine in the chromatogram obtained with the test solution changes from orange to reddish-brown but not to greyish-blue (atropine).

Ethanol (*2.9.10*): 40 per cent *V/V* to 50 per cent *V/V*.

Dry residue (*2.8.16*): minimum 1.2 per cent.

ASSAY

Evaporate 100.0 g of the mother tincture to be examined, at a low temperature under reduced pressure, until a residue of about 10 g is obtained. Quantitatively transfer the residue to a separating funnel using a few millilitres of *ethanol (70 per cent V/V) R* . Add 5 ml of *concentrated ammonia R* and 25 ml of *water R*. Extract with successive fractions of a mixture of 1 volume of *chloroform R* and 3 volumes of *peroxide-free ether R* until the alkaloids are completely extracted. Evaporate to dryness a few millilitres of the last organic fraction. Take up the residue in *0.25 M sulphuric acid* and verify the absence of alkaloids using *potassium tetraiodomercurate solution R*. Combine the organic layers and extract several times with *0.25 M sulphuric acid*. Separate the layers by centrifugation if necessary and transfer the acid layers to a second separating funnel. Make the acid layer alkaline with *ammonia R* and shake with at least 3 quantities, each of 30 ml, of *chloroform R*. Combine the chloroform layers, add 4 g of *anhydrous sodium sulphate R* and allow to stand for 30 min with occasional shaking. Decant the chloroform and wash the anhydrous sodium sulphate with 3 quantities, each of 10 ml, of *chloroform R*. Combine the chloroform fractions, evaporate to dryness on a water-bath and dry in an oven at 100-105 °C for 15 min. Dissolve the residue in a few millilitres of *chloroform R*, add 10.0 ml of *0.005 M sulphuric acid* and remove the chloroform by evaporation on a water-bath. Titrate the excess of acid with *0.01 M sodium hydroxide* using *methyl red mixed solution R* as indicator.

Calculate the percentage content *m/m* of total alkaloids, expressed as hyoscyamine, from the expression:

$$\frac{0.2894\,(10 - n)}{m}$$

n = volume of *0.01 M sodium hydroxide* used, in millilitres,

m = mass of the mother tincture used, in grams.

corrected 6.0

HYPERICUM FOR HOMOEOPATHIC PREPARATIONS

Hypericum perforatum ad praeparationes homoeopathicas

DEFINITION

Whole, fresh plant of *Hypericum perforatum* L., at the beginning of the flowering period.

IDENTIFICATION

The perennial plant consists of a spindle-shaped root and a branched rhizome, giving rise to long, decumbent runners. The cylindrical, erect stem is woody at the base, 0.2 m to 1 m long, branched in the upper part, with 2 raised longitudinal lines.

The leaves are opposite, sessile, exstipulate, oblong-oval and 15 mm to 30 mm long. The leaf margins show black glandular dots, and many small translucent oil glands are present on the entire surface and are visible by transmitted light.

The flowers are regular and form corymbose clusters at the apex of the stem. They have 5 green, lanceolate sepals with acuminate apices, and black oil glands near the entire margins; 5 orange-yellow petals, much longer than the sepals, with black oil glands near the terminal margins only; 3 staminal blades, each divided into many orange-yellow stamens and 3 carpels surmounted by red styles. Each petal is asymmetrically linear-ovate in shape, with one of the margin entire and the other dentate.

TESTS

Foreign matter (*2.8.2*): maximum 4 per cent of fruits and maximum 1 per cent of other foreign matter.

Loss on drying (*2.2.32*): if performed to demonstrate the freshness of the drug, minimum 55 per cent, determined on 5.0 g of finely cut drug by drying in an oven at 105 °C.

Mother tincture

The mother tincture complies with the requirements of the general monograph on *Mother tinctures for homoeopathic preparations (2029)*.

PRODUCTION

The mother tincture of *Hypericum perforatum* L. is prepared by maceration using alcohol of a suitable concentration.

CHARACTERS

Dark red to brownish red liquid.

IDENTIFICATION

Thin-layer chromatography (*2.2.27*).

Test solution. The mother tincture to be examined.

Reference solution. Dissolve 5 mg of *rutin R*, 1 mg of *hypericin R* and 5 mg of *hyperoside R* in *methanol R* and dilute to 5 ml with the same solvent.

Plate: *TLC silica gel plate R*.

Mobile phase: *anhydrous formic acid R, water R, ethyl acetate R* (6:9:90 *V/V/V*).

Application: 10 µl of the test solution and 5 µl of the reference solution, as 10 mm bands.

Development: over a path of 10 cm.

Drying: at 100-105 °C for 10 min.

Detection: spray with a 10 g/l solution of *diphenylboric acid aminoethyl ester R* in *methanol R* and then a 50 g/l solution of *macrogol 400 R* in *methanol R*. Examine the plates after 30 min in ultraviolet light at 365 nm.

Results: see below the sequence of the zones present in the chromatograms obtained with the reference solution and the test solution. In the chromatogram obtained with the test solution, the zone due to rutin may be weak or even absent. The chromatogram obtained with the test solution shows a group of zones that may be blue or yellow, with a R_F similar to that of the zone due to hyperoside in the chromatogram obtained with the reference solution. Other weak zones may also be visible.

Top of the plate	
	A yellow to blue zone
Hypericin: a red zone	2 red zones
_____	_____
	Several zones
_____	_____
Hyperoside: a yellow to orange zone	Blue or yellow zones
Rutin: a yellow to orange zone	A yellow to orange zone
Reference solution	**Test solution**

TESTS

Relative density (*2.2.5*): 0.900 to 0.920.

Ethanol (*2.9.10*): 60 per cent *V/V* to 75 per cent *V/V*.

Dry residue (*2.8.16*): minimum 1.3 per cent.

corrected 6.0

IRON FOR HOMOEOPATHIC PREPARATIONS

Ferrum ad praeparationes homoeopathicas

Fe A_r 55.85
[7439-89-6]

DEFINITION

Obtained by reduction or sublimation as a fine blackish-grey powder.

Content: 97.5 per cent to 101.0 per cent.

CHARACTERS

Appearance: fine, blackish-grey powder, without metallic lustre.

Solubility: practically insoluble in water and in alcohol. It dissolves with heating in dilute mineral acids.

IDENTIFICATION

Dissolve 50 mg in 2 ml of *dilute sulphuric acid R* and dilute to 10 ml with *water R*. The solution gives reaction (a) of iron (*2.3.1*).

TESTS

Solution S. To 10.0 g add 40 ml of *water R*. Boil for 1 min. Cool, filter and dilute to 50.0 ml with *water R*.

Alkalinity. To 10 ml of solution S add 0.1 ml of *bromothymol blue solution R1*. Not more than 0.1 ml of *0.01 M hydrochloric acid* is required to change the colour of the indicator to yellow.

Substances insoluble in hydrochloric acid. Dissolve 2.00 g in 40 ml of *hydrochloric acid R*. Heat on a water-bath. As soon as fumes are no longer evolved, filter through a sintered-glass filter (16) (*2.1.2*). Rinse with *water R*. Dry the residue in an oven at 100-105 °C for 1 h. The residue weighs a maximum of 20 mg (1.0 per cent).

Substances soluble in water. Evaporate 10.0 ml of solution S on a water-bath and dry at 100-105 °C for 1 h. The residue weighs a maximum of 2 mg (0.1 per cent).

Chlorides (*2.4.4*): maximum 50 ppm.

Dilute 5 ml of solution S to 15 ml with *water R*. The solution complies with the limit test for chlorides.

Sulphides and phosphides. In a 100 ml conical flask carefully mix 1.0 g with 10 ml of *dilute hydrochloric acid R*. Within 30 s *lead acetate paper R* moistened with *water R* and placed over the mouth of the flask is not coloured more intensely than light brown by the resulting fumes.

Arsenic (*2.4.2*): maximum 5 ppm.

Boil 0.2 g in 25 ml of *dilute hydrochloric acid R* until completely dissolved. The solution complies with limit test A.

Copper: maximum 50.0 ppm.

Atomic absorption spectrometry (*2.2.23, Method I*).

Test solution. Dissolve 1.00 g in a mixture of 60 ml of *dilute hydrochloric acid R* and 10 ml of *dilute hydrogen peroxide solution R*. Reduce to a volume of 5 ml and dilute to 50.0 ml with *water R*.

Reference solutions. Prepare the reference solutions using *copper standard solution (0.1 per cent Cu) R*, diluted as necessary with a 1 per cent *V/V* solution of *hydrochloric acid R*.

Source: copper hollow-cathode lamp.

Wavelength: 324.8 nm.

Flame: air-acetylene.

Lead: maximum 50.0 ppm.

Atomic absorption spectrometry (*2.2.23, Method I*).

Test solution. In a separating funnel, place 20 ml of the test solution prepared for the test for copper. Add 25 ml of *lead-free hydrochloric acid R*. Stir with 3 quantities, each of 25 ml, of *di-isopropyl ether R*. Collect the aqueous layer. Add 0.10 g of *sodium sulphate decahydrate R*. Evaporate to dryness. Take up the residue with 1 ml of *lead-free nitric acid R* and dilute to 20 ml with *water R*.

Reference solutions. Prepare the reference solutions using *lead standard solution (0.1 per cent Pb) R*, diluted as necessary with a 10 per cent *V/V* solution of *nitric acid R* containing 5 g/l of *sodium sulphate decahydrate R*.

Source: lead hollow-cathode lamp.

Wavelength: 217 nm.

Flame: air-acetylene.

ASSAY

Stir for 10 min 0.100 g in a hot solution of 1.25 g of *copper sulphate R* in 20 ml of *water R* in a 100 ml conical flask with a ground-glass stopper. Filter rapidly and wash the filter. Combine the filtrate and the washings, acidify with *dilute sulphuric acid R* and titrate with *0.02 M potassium permanganate* until a pink colour is obtained.

1 ml of *0.02 M potassium permanganate* is equivalent to 5.585 mg of Fe.

LABELLING

The label indicates whether the iron for homoeopathic preparations is obtained by reduction or sublimation.

01/2008:2094
corrected 6.0

ORIENTAL CASHEW FOR HOMOEOPATHIC PREPARATIONS

Semecarpus anacardium ad praeparationes homoeopathicas

DEFINITION

Dried fruit of *Semecarpus anacardium* L. (*Anacardium orientale* L.).

Content: minimum 6.0 per cent *m/m* of total phenol derivatives expressed as eugenol ($C_{10}H_{12}O_2$; M_r 164.2) (dried drug).

IDENTIFICATION

A. The dried fruit is oval and more or less heart-shaped; about 2 cm long, nearly 2 cm wide and 0.5 cm thick. Its surface is smooth, shiny and blackish. A transverse section shows a rather well developed, tough pericarp riddled with rather wide lacunae containing an abundant thick reddish-brown juice. The pericarp covers a white kernel under a reddish skin. The fruit may include the blackish, fleshy, wrinkled, cupuliferous receptacle.

B. Thin-layer chromatography (*2.2.27*).

Test solution. To 1.0 g of suitably cut drug, add 10 ml of *ethanol (90 per cent V/V) R*. Heat under reflux on a water-bath at 60 °C for 15 min. Allow to cool and filter.

Reference solution. Dissolve 5 mg of *gallic acid R* and 5 mg of *caffeic acid R* in *methanol R* and dilute to 10 ml with the same solvent.

Plate: *TLC silica gel plate R*.

Mobile phase: *methanol R, toluene R* (15:85 *V/V*).

Application: 20 µl of the test solution and 10 µl of the reference solution, as bands.

Development: over a path of 15 cm.

Drying: in air.

Detection: spray with a solution containing 10 g/l of *diphenylboric acid aminoethyl ester R* and 50 g/l of *macrogol 400 R* in *methanol R*. Examine in ultraviolet light at 365 nm.

Results: see below the sequence of zones present in the chromatograms obtained with the reference solution and the test solution. Furthermore, other fainter zones may be present in the chromatogram obtained with the test solution.

Top of the plate	
	A greenish-blue fluorescent zone
———	———
	Several violet-blue fluorescent zones
	A yellow fluorescent zone
Caffeic acid: a violet-blue fluorescent zone	
———	———
Gallic acid: a violet-blue fluorescent zone	A violet-blue fluorescent zone (gallic acid)
Reference solution	**Test solution**

Homoeopathic preparations

TESTS

***Anacardium occidentale* L.** Fruits of *Anacardium occidentale* L. are not present. These are up to 35 mm long, 30 mm large, 20 mm thick, light brown and distinctly kidney-shaped. The pericarp is smooth or slightly crinkled with dark marbling in places.

Loss on drying (*2.2.32*): maximum 12.0 per cent, determined on 1.000 g of the finely divided drug by drying in an oven at 105 °C for 2 h.

Total ash (*2.4.16*): maximum 5.0 per cent.

ASSAY

Total phenol derivatives. Absorption spectrophotometry (*2.2.25*).

Stock solution. Place 4.500 g of the crushed drug in a flask. Add 200 ml of *ethanol (90 per cent V/V) R*. Boil in a water-bath under reflux for 4 h. Cool the flask. Quantitatively transfer into a volumetric flask. Dilute to 250.0 ml with *ethanol (90 per cent V/V) R*. Filter the liquid through a paper filter 125 mm in diameter. Discard the first 50 ml of the filtrate. Dilute 5.0 ml of filtrate to 50.0 ml with *ethanol (90 per cent V/V) R* and shake. Dilute 5.0 ml of this solution to 10.0 ml with *ethanol (90 per cent V/V) R* and shake.

Test solution. To 2.0 ml of stock solution add 1.0 ml of *phosphomolybdotungstic reagent R* and 10 ml of *water R*, mix and dilute to 25.0 ml with a 290 g/l solution of *sodium carbonate R*. Wait exactly 3 min then filter the solution through a fibre-glass filter with a 1 µm mesh aperture, discarding the first 5 ml.

Reference solution. Dissolve 80.0 mg of *eugenol R* in *ethanol (90 per cent V/V) R* and dilute to 250.0 ml with the same solvent. Dilute 5.0 ml of the solution to 25.0 ml with *ethanol (90 per cent V/V) R*. To 2.0 ml of this solution add 1.0 ml of *phosphomolybdotungstic reagent R* and 10 ml of *water R*, mix and dilute to 25.0 ml with a 290 g/l solution of *sodium carbonate R*. Wait exactly 3 min then filter the solution through a fibre-glass filter with a 1 µm mesh aperture, discarding the first 5 ml.

Measure the absorbance (*2.2.25*) of the test solution and the reference solution at 755 nm after 30 min using *water R* as compensation liquid.

Calculate the percentage content *m/m* of total phenol derivatives, expressed as eugenol, from the following expression:

$$\frac{A_1 \times m_2 \times 400}{A_2 \times m_1}$$

A_1 = absorbance of the test solution,

A_2 = absorbance of the reference solution,

m_1 = mass of the drug to be examined, in milligrams,

m_2 = mass of eugenol in the reference solution, in milligrams.

Mother tincture

The mother tincture complies with the requirements of the general monograph on *Mother tinctures for homoeopathic preparations (2029)*.

DEFINITION

The mother tincture of oriental cashew is prepared by maceration using ethanol of a suitable concentration from the dried fruit of *Semecarpus anacardium* L. (*Anacardium orientale* L.).

Content: 0.5 per cent *m/m* to 1.0 per cent *m/m* of total phenol derivatives expressed as eugenol.

CHARACTERS

Appearance: yellowish-brown or reddish-brown liquid.

IDENTIFICATION

Thin-layer chromatography (*2.2.27*) as described under Identification B of the drug with the following modification.

Test solution. The tincture to be examined.

Results: see identification B for the drug.

TESTS

Relative density (*2.2.5*): 0.815 to 0.845.

Ethanol (*2.9.10*): 85 per cent *V/V* to 95 per cent *V/V*.

Dry residue (*2.8.16*): minimum 1.50 per cent *m/m*.

ASSAY

Total phenol derivatives. Absorption spectrophotometry (*2.2.25*) as described in the assay of the drug to be examined with the following modifications.

Stock solution. Place 8.000 g of the mother tincture to be examined in a volumetric flask and dilute to 250.0 ml with *ethanol (90 per cent V/V) R*. Dilute 5.0 ml of this solution to 20.0 ml with *ethanol (90 per cent V/V) R*.

Test solution. To 2.0 ml of stock solution add 1.0 ml of *phosphomolybdotungstic reagent R* and 10 ml of *water R*, mix and dilute to 25.0 ml with a 290 g/l solution of *sodium carbonate R*. Wait exactly 3 min then filter the solution through a fibre-glass filter with a 1 µm mesh aperture, discarding the first 5 ml.

Reference solution. Dissolve 80.0 mg of *eugenol R* in *ethanol (90 per cent V/V) R* and dilute to 250.0 ml with the same solvent. Dilute 5.0 ml of the solution to 25.0 ml with *ethanol (90 per cent V/V) R*. To 2.0 ml of this solution add 1.0 ml of *phosphomolybdotungstic reagent R* and 10 ml of *water R*, mix and dilute to 25.0 ml with a 290 g/l solution of *sodium carbonate R*. Wait exactly 3 min then filter the solution through a fibre-glass filter with a 1 µm mesh aperture, discarding the first 5 ml.

Measure the absorbance (*2.2.25*) of the test solution and the reference solution at 755 nm after 30 min, using *water R* as compensation liquid.

Calculate the percentage content *m/m* of total phenol derivatives expressed as eugenol, using the following expression:

$$\frac{A_1 \times m_2 \times 80}{A_2 \times m_1}$$

A_1 = absorbance of the test solution,

A_2 = absorbance of the reference solution,

m_1 = mass of the mother tincture to be examined, in milligrams,

m_2 = mass of eugenol in the reference solution, in milligrams.

01/2008:1624
corrected 6.0

SAFFRON FOR HOMOEOPATHIC PREPARATIONS

Croci stigma
ad praeparationes homoeopathicas

DEFINITION

Dried stigmas of *Crocus sativus* L. usually joined by the base to a short style.

CHARACTERS

Characteristic, aromatic odour.

IDENTIFICATION

A. The dark brick-red stigmas, when dry, are 20 mm to 40 mm long and after soaking with water, about 35 mm to 50 mm long. The tubes, gradually widening at the top, are incised on one side, the upper margin is open and finely crenated. The style connecting the 3 stigmas is pale yellow and not more than 5 mm long.

B. Examine under a microscope using *chloral hydrate solution R*. It shows the following diagnostic characters: elongated epidermal cells, frequently with a short, central papilla; in water they release a yellow colouring matter; the upper border of the stigma has finger-shaped papillae, up to 150 µm long; between them are single, globular pollen grains, about 100 µm wide, with a finely pitted exine, vascular bundles with small spirally thickened vessels and no fibres.

C. Carefully crush pieces of the drug to coarse particles and moisten with 0.2 ml of *phosphomolybdic acid solution R*. The particles turn blue within 1-2 min or they have a blue areole around them.

D. Examine by thin-layer chromatography (*2.2.27*).

Test solution. Carefully crush 0.1 g of the drug with a glass rod and moisten with 0.2 ml of *water R*. After 3 min add 5 ml of *methanol R*, allow to stand for 20 min, protected from light, and filter through a plug of glass wool.

Reference solution. Dissolve 5 mg of *naphthol yellow R* in 5 ml of *methanol R* and add a solution of 5 mg of *Sudan red G R* in 5 ml of *methylene chloride R*.

Plate: *TLC silica gel F_{254} plate R*.

Mobile phase: *water R, 2-propanol R, ethyl acetate R* (10:25:65 *V/V/V*).

Application: 10 µl of the test solution and 5 µl of the reference solution as bands.

Development: over a path of 10 cm.

Drying: in air.

Detection: examine in daylight.

Results: see below the sequence of the zones present in the chromatograms obtained with the reference and test solutions.

Top of the plate	
A red zone A yellow zone	 2 yellow zones An intense yellow zone (crocine)
Reference solution	**Test solution**

Detection: in ultraviolet light at 254 nm.

Results: see below the sequence of the zones present in the chromatograms obtained with the reference and test solutions.

Top of the plate	
A red zone A yellow zone	1 or 2 quenching zones A quenching zone
Reference solution	**Test solution**

Detection: spray with *anisaldehyde solution R* and examine in daylight while heating at 100-105 °C for 5-10 min.

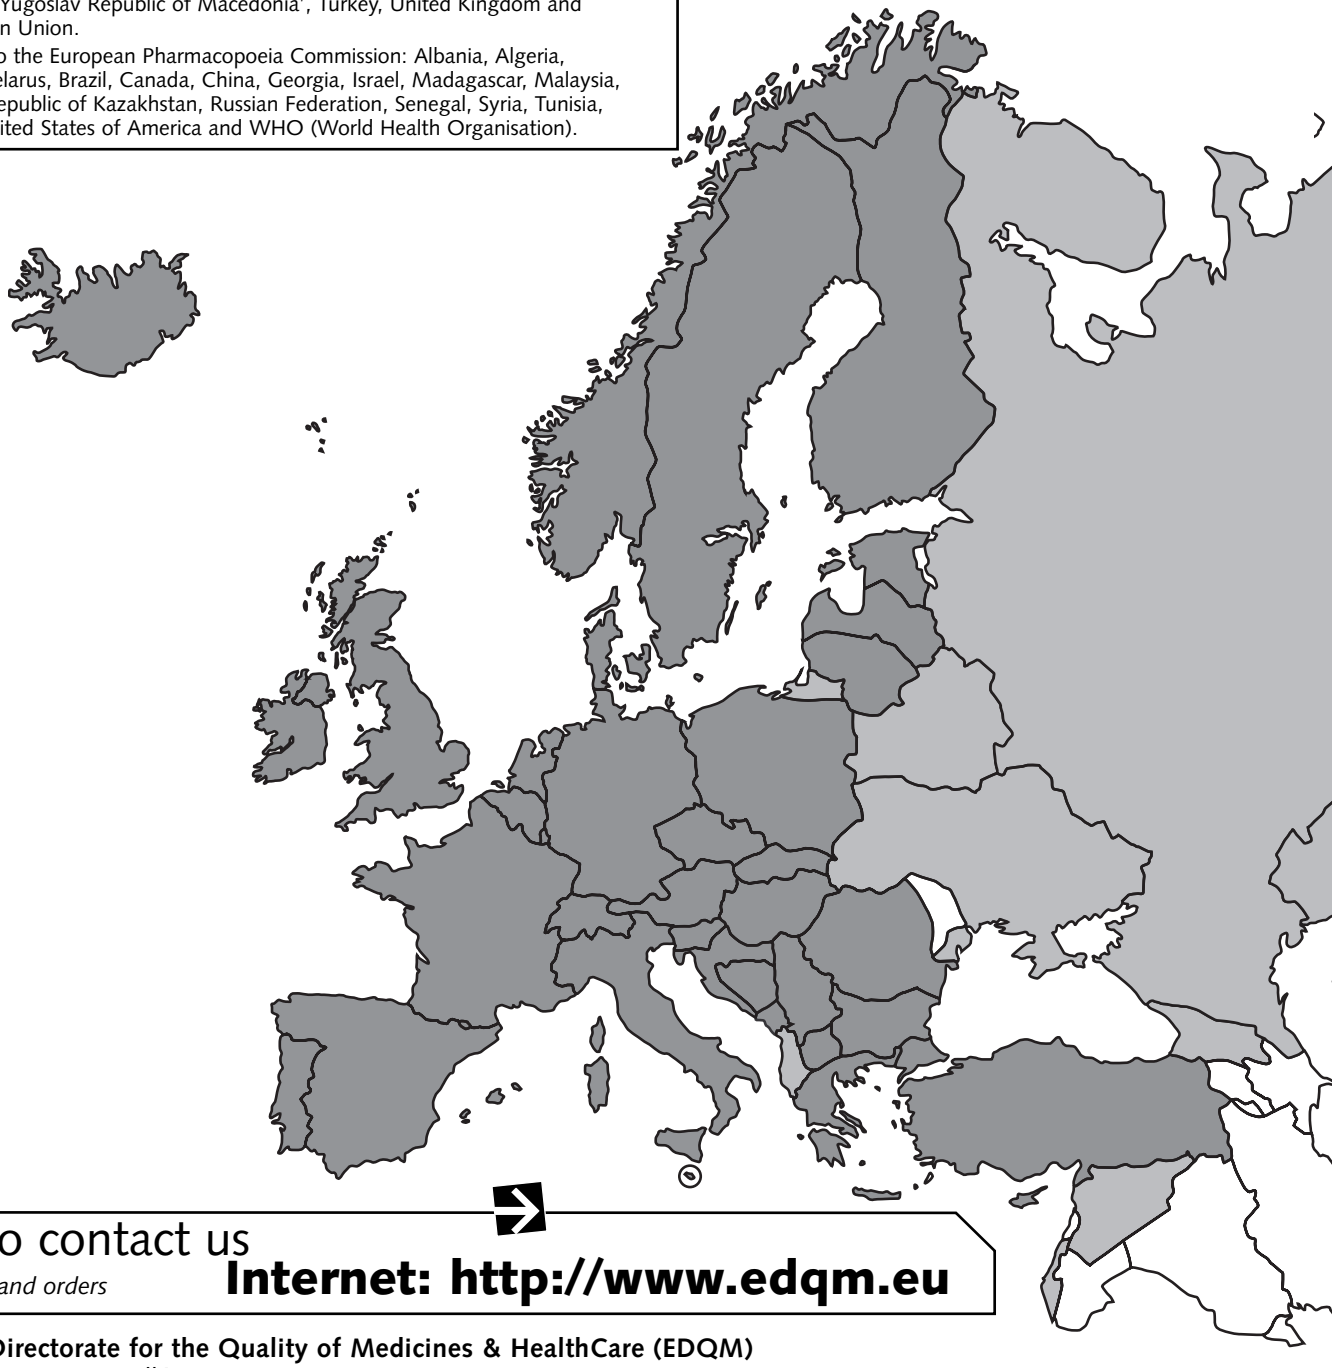
Results: see below the sequence of the zones present in the chromatograms obtained with the reference and test solutions.

Top of the plate	
A red zone A blue to bluish-green zone	1 or 2 red to reddish-violet zones A red to reddish-violet zone 2 blue to bluish-green zones An intense blue to bluish-green zone (crocine)
Reference solution	**Test solution**

E. Dilute 0.1 ml of the test solution (see Identification test D) with 1 ml of *methanol R*. Deposit 0.1 ml of this solution on a filter paper, allow to dry and spray with a 10 g/l solution of *diphenylboric acid aminoethyl ester R* in *methanol R*. Examine in ultraviolet light at 365 nm. The spot shows an intense orange-yellow fluorescence.

TESTS

Colouring intensity. Introduce 0.10 g into a 5 ml volumetric flask and add to 5.0 ml with *distilled water R*. Close the flask and shake every 30 min for 8 h. Then allow to stand for 16 h. Dilute 1.0 ml to 500.0 ml with *distilled water R*. The absorbance (*2.2.25*) measured at 440 nm using *distilled water R* as the compensation liquid, is not less than 0.44.



Foreign matter. Examine the drug microscopically. No parts with rough walls, no crystals and no pollen grains containing 3 germinal pores are present.

Loss on drying (*2.2.32*): maximum 10.0 per cent, determined on 0.200 g by drying in an oven at 105 °C.

Total ash (*2.4.16*): maximum 7.0 per cent, determined on the residue obtained in the test for loss on drying.

Members of the European Pharmacopoeia Commission: Austria, Belgium, Bosnia and Herzegovina, Bulgaria, Croatia, Cyprus, Czech Republic, Denmark, Estonia, Finland, France, Germany, Greece, Hungary, Iceland, Ireland, Italy, Latvia, Lithuania, Luxembourg, Malta, Montenegro, Netherlands, Norway, Poland, Portugal, Romania, Serbia, Slovak Republic, Slovenia, Spain, Sweden, Switzerland, 'the former Yugoslav Republic of Macedonia', Turkey, United Kingdom and the European Union.

Observers to the European Pharmacopoeia Commission: Albania, Algeria, Australia, Belarus, Brazil, Canada, China, Georgia, Israel, Madagascar, Malaysia, Morocco, Republic of Kazakhstan, Russian Federation, Senegal, Syria, Tunisia, Ukraine, United States of America and WHO (World Health Organisation).

EUROPEAN PHARMACOPOEIA 6th EDITION

published 16 July 2007

replaces the 5th Edition on 1 January 2008

Volumes 1 and 2 of this publication 6.0 constitute the 6th Edition of the European Pharmacopoeia. They will be complemented by **non-cumulative supplements** that are to be kept for the duration of the 6th Edition. 2 supplements will be published in 2007 and 3 supplements in each of the years 2008 and 2009. A cumulative list of reagents will be published in supplements 6.4 and 6.7.

If you are using the 6th Edition at any time later than 1 April 2008, make sure that you have all the published supplements and consult the index of the most recent supplement to ensure that you use the latest versions of the monographs and general chapters.

EUROPEAN PHARMACOPOEIA - ELECTRONIC VERSION

The 6th Edition is also available in an electronic format (CD-ROM and online version) containing all of the monographs and general chapters found in the printed version. With the publication of each supplement the electronic version is replaced by a new, fully updated, cumulative version.

In addition to the official English and French online versions, a Spanish online version is also available for the convenience of users.

PHARMEUROPA

Quarterly Forum Publication

Pharmeuropa contains preliminary drafts of all new and revised monographs proposed for inclusion in the European Pharmacopoeia and gives an opportunity for all interested parties to comment on the specifications before they are finalised. Pharmeuropa also contains information on the work programme and on certificates of suitability to monographs of the European Pharmacopoeia issued by the EDQM, and articles of general interest. Pharmeuropa is available on subscription from the EDQM. The subscription also includes Pharmeuropa Bio and Pharmeuropa Scientific Notes (containing scientific articles on pharmacopoeial matters). Pharmeuropa Online is also available as a complementary service for subscribers to the printed version of Pharmeuropa.

INTERNATIONAL HARMONISATION

See the information given in chapter *5.8. Pharmacopoeial Harmonisation*.

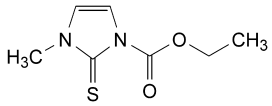
KNOWLEDGE

Consult KNOWLEDGE, the new free database at http://www.edqm.eu to obtain information on the work programme of the European Pharmacopoeia, the volume of Pharmeuropa and of the European Pharmacopoeia in which a text has been published, trade names of the reagents (for example, chromatography columns) that were used at the time of the elaboration of the monographs, the history of the revisions of a text since its publication in the 5th Edition, reference chromatograms, the list of reference standards used, and the list of certificates granted.

COMBISTATS

CombiStats is a computer program for the statistical analysis of data from biological assays in agreement with chapter *5.3* of the 6th Edition of the European Pharmacopoeia. For more information, visit the website (http://www.edqm.eu/combistats).



Version date of the text — **01/2008:0884** corrected 6.0

Text reference number

CARBIMAZOLE

Carbimazolum

Modification to be taken into account from the publication date of volume 6.0

CAS number — $C_7H_{10}N_2O_2S$ [22232-54-8] M_r 186.2

DEFINITION

Chemical name in accordance with IUPAC nomenclature rules — Ethyl 3-methyl-2-thioxo-2,3-dihydro-1*H*-imidazole-1-carboxylate.

Content: 98.0 per cent to 102.0 per cent (dried substance).

CHARACTERS

Appearance: white or yellowish-white, crystalline powder.

Solubility: slightly soluble in water, soluble in acetone and in ethanol (96 per cent).

Application of the first and second identification is defined in the General Notices (chapter 1) — *First identification: B.*

Second identification: A, C.

IDENTIFICATION

A. Melting point (*2.2.14*): 122 °C to 125 °C.

B. Infrared absorption spectrophotometry (*2.2.24*).

Preparation: discs.

Reference standard available from the Secretariat (see www.edqm.eu) — *Comparison*: *carbimazole CRS*.

C. Thin-layer chromatography (*2.2.27*).

Test solution. Dissolve 10 mg of the substance to be examined in *methylene chloride R* and dilute to 10 ml with the same solvent.

Reference solution. Dissolve 10 mg of *carbimazole CRS* in *methylene chloride R* and dilute to 10 ml with the same solvent.

Plate: *TLC silica gel GF_{254} plate R*.

Reagents described in chapter 4 — *Mobile phase*: *acetone R*, *methylene chloride R* (20:80 *V/V*).

Application: 10 µl.

Development: over a path of 15 cm.

Further information available on www.edqm.eu (KNOWLEDGE) — *Drying*: in air for 30 min.

Detection: examine in ultraviolet light at 254 nm.

Results: the principal spot in the chromatogram obtained with the test solution is similar in position and size to the principal spot in the chromatogram obtained with the reference solution.

Reference to a general chapter — TESTS

Related substances. Liquid chromatography (*2.2.29*).

Line in the margin indicating where part of the text has been modified (technical modification) — *Test solution*. Dissolve 5.0 mg of the substance to be examined in 10.0 ml of a mixture of 20 volumes of *acetonitrile R* and 80 volumes of *water R*. Use this solution within 5 min of preparation.

Reference solution (a). Dissolve 5 mg of *thiamazole R* and 0.10 g of *carbimazole CRS* in a mixture of 20 volumes of *acetonitrile R* and 80 volumes of *water R* and dilute to 100.0 ml with the same mixture of solvents. Dilute 1.0 ml of this solution to 10.0 ml with a mixture of 20 volumes of *acetonitrile R* and 80 volumes of *water R*.

Reference solution (b). Dissolve 5.0 mg of *thiamazole R* in a mixture of 20 volumes of *acetonitrile R* and 80 volumes of *water R* and dilute to 10.0 ml with the same mixture of solvents. Dilute 1.0 ml of this solution to 100.0 ml with a mixture of 20 volumes of *acetonitrile R* and 80 volumes of *water R*.

Column:

– *size*: *l* = 0.15 m, Ø = 3.9 mm,

– *stationary phase*: *octadecylsilyl silica gel for chromatography R* (5 µm).

Mobile phase: *acetonitrile R*, *water R* (10:90 *V/V*).

Flow rate: 1 ml/min.

Detection: spectrophotometer at 254 nm.

Injection: 10 µl.

Run time: 1.5 times the retention time of carbimazole.

Retention time: carbimazole = about 6 min.

System suitability: reference solution (a):

– *resolution*: minimum 5.0 between the peaks due to impurity A and carbimazole.

Limits:

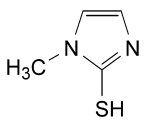
– *impurity A*: not more than 0.5 times the area of the principal peak in the chromatogram obtained with reference solution (b) (0.5 per cent),

– *unspecified impurities*: for each impurity, not more than 0.1 times the area of the principal peak in the chromatogram obtained with reference solution (b) (0.10 per cent).

Loss on drying (*2.2.32*): maximum 0.5 per cent, determined on 1.000 g by drying in a desiccator over *diphosphorus pentoxide R* at a pressure not exceeding 0.7 kPa for 24 h.

Sulphated ash (*2.4.14*): maximum 0.1 per cent, determined on 1.0 g.

ASSAY



Dissolve 50.0 mg in *water R* and dilute to 500.0 ml with the same solvent. To 10.0 ml add 10 ml of *dilute hydrochloric acid R* and dilute to 100.0 ml with *water R*. Measure the absorbance (*2.2.25*) at the absorption maximum at 291 nm.

Calculate the content of $C_7H_{10}N_2O_2S$ taking the specific absorbance to be 557.

IMPURITIES

Specified impurities: A.

Other detectable impurities (the following substances would, if present at a sufficient level, be detected by one or other of the tests in the monograph. They are limited by the general acceptance criterion for other/unspecified impurities and/or by the general monograph *Substances for pharmaceutical use (2034)*. It is therefore not necessary to identify these impurities for demonstration of compliance. See also *5.10. Control of impurities in substances for pharmaceutical use): B.*

A. 1-methyl-1*H*-imidazole-2-thiol (thiamazole),

SPECIMEN

IMPORTANT NOTICE

GENERAL MONOGRAPHS

The European Pharmacopoeia contains a number of general monographs covering classes of products. These general monographs give requirements that are applicable to all products in the given class or, in some cases, to any product in the given class for which there is a specific monograph in the Pharmacopoeia (see *1. General Notices*, General monographs). Where no restriction on scope of a general monograph is given in a preamble, it is applicable to all products in the class defined, irrespective of whether there is an individual monograph for the product in the Pharmacopoeia.

Whenever a monograph is used, it is essential to ascertain whether there is a general monograph applicable to the product in question. The general monographs listed below are published in the section General Monographs (unless otherwise stated). This list is updated where necessary and republished in each Supplement.

Allergen products (1063)

Dosage Forms monographs
(published in the Dosage Forms section)

Essential oils (2098)

Extracts (0765)

Herbal drug preparations (1434)

Herbal drugs (1433)

Herbal drugs for homoeopathic preparations (2045)
(published in the Homoeopathic Preparations section)

Herbal teas (1435)

Homoeopathic preparations (1038)
(published in the Homoeopathic Preparations section)

Immunosera for human use, animal (0084)

Immunosera for veterinary use (0030)

Methods of preparation of homoeopathic stocks and potentisation (2371)
(published in the Homoeopathic Preparations section)

Monoclonal antibodies for human use (2031)

Mother tinctures for homoeopathic preparations (2029)
(published in the Homoeopathic Preparations section)

Products of fermentation (1468)

Products with risk of transmitting agents of animal spongiform encephalopathies (1483)

Radiopharmaceutical preparations (0125)

Recombinant DNA technology, products of (0784)

Substances for pharmaceutical use (2034)

Vaccines for human use (0153)

Vaccines for veterinary use (0062)

Vegetable fatty oils (1579)
